CULM, among botaniſts, a term expreſſing the ſtalk of graminеous plants. See STALK.

CULVERTAIL, in ſhip building, is uſed for a manner of letting one timber into another, ſo that they cannot ſlip aſunder. The faſtening of a ſhip's *carlings* into the beam is ſo performed. See DOVE-TAIL, *Cycl.*

CUMAMUS, in the materia medica, a name given by many of the antients to cubebs. This is plain, from their accounts. Some indeed have ſuppoſed, that they called the *carpeſia* by this name; but this is wholly erroneous, unleſs the word *carpeſia* be underſtood as a name for the cubeb: then indeed *cumamus* and *carpeſia* are the ſame; but when the word *carpeſia* is under its proper ſenſe, as the name of the aromatic twigs of a tree, the word *cumamus* is never uſed as ſynonymous with it.

CUMELE, in botany, the name by which the antient Greek writers have deſcribed the lupulus or hop, with which we make our malt liquors bitter. Their deſcriptions of this plant all agree in giving it the characters and virtues of the hop; yet the tranſlators and commentators on their works, have in general made the *cumene* ſignify a very different plant from our hop: this is the white bryony, a plant that has no one character, except its climbing in common, with the hop, and whoſe virtues are as different as one thing can be from another.

The antients had a way of writing the name of this plant in abbreviation βρύον, bryon, for βρυωνία bryonia; and though the Greeks of ſucceeding ages have called this bryonia at length, yet commentators make it the name of the lupulus.

CAMELOBOTANE, καμηλοβοτανη, in the modern Greek writers, a name given to the lupulus or plant, which produces the hops. This is called *cumele*, by the more antient Greeks, and not *bryon*, as is ſuppoſed by ſome; *bryon*, βρυον, being only an abbreviation of bryonia, white bryony.

CUMINOIDES, in botany, the name of a genus of plants, the characters of which are theſe: The flower is compoſed of ſeveral petals, which are diſpoſed in a circular order, and are uſually fimbriated at the edges; theſe ſtand upon the cup, which afterwards becomes a ſingle oblong ſeed. There is only one known ſpecies of this plant, which is the *cuminum ſylveſtre*, or wild *cummin* of authors. *Tourn.* Inſt. p. 300.

CUMPETES, in the materia medica, a name given by ſome of the Greek writers to the *carpeſia* of Galen and others. This was an aromatic drug, and was the younger ſhoots and tender twigs of an odoriferous tree, growing on ſome mountains in Pamphylia, which were collected in the ſpring, and when dried, were uſed as a ſuccedaneum for the cinnamon. The word *cumpetes* often occurs in Myrepſus; but there is ſome doubt in the orthography, whether it be *cumpetes* or *cumpepes*; there ſeems moſt reaſon to believe the latter is the proper word. Charito mentions this drug in his antidotes, and the commentators uſually explain it by the word *carpeſia* or *carpaſus*, a name by which they underſtood, though improperly, the cubebs. The Greeks of the later ages, and the Latin writers who ſucceeded them, all fell into the ſame error, of calling the *carpeſia* the cubeb; though the accounts of the antient Greeks are againſt it. Nay, Aviſenna ſeems to have given into the ſame error; for he he has tranſcribed into his chapter of cubebs what Galen ſays of the *carpeſia*.

CUN, or CUNNING, at ſea. See COND, *Cycl.*

CUNEIFORM *(Cycl.)* — CUNEIFORM *leaf*, among botaniſts. See the article LEAF.

CUNEIFORMIA *oſſa*. See OSSA *cuneiformia*.

CUNEUS, among the Romans, a term often uſed to ſignify that part of the theatre where the ſpectators ſat, on account of its reſembling the figure of a wedge. *Hoffm.* Lex. in voc.

CUNEUS, the wedge, was alſo a form of battle frequent among the Romans. See BATTLE, *Cycl.* and *Suppl.*

CUNICULUS *americanus*, in zoology, a name given by ſome to the creature called *tapeti*, a ſmall ſpecies of rabbit. See the article TAPETI.

CUNICULUS, in mining, a term uſed by authors, in diſtinction from *puteus*, to expreſs the ſeveral ſorts of paſſages and cuts in theſe ſubterranean works. The *cuniculi*, are thoſe direct paſſages in mines, where they walk on horizontally; but the *putei*, are the perpendicular cuts or deſcents. The miners in Germany call theſe by the names *ſtollen* and *ſchachts*; the firſt word expreſſing the horizontal, and the other the perpendicular cuts. It is an obſervation with our miners, that the damps ſo much dreaded in all mines, happen generally in the horizontal cuts; but Dr. Brown, in his examination of the gold and ſilver mines in Hungary obſerves, that they as often happen there in the *putei* or *ſchachts*, as in the *cuniculi* or *ſtollen*. Another obſervation as to damps with us is, that they are moſt frequent in clayey and ſoft places under ground; but in thoſe mines they are as frequent where the matter is hard ſtone; and one of the moſt miſchievous that had then lately happened, was in a place every way ſurrounded with ſtone ſo hard, that the tools of the miners could ſcarce work through it; and the deſcent had, in the very ſpot where the damp was, been made by means of gunpowder. In ſome of the *cuniculi* in theſe mines, there are damps that regularly return on certain occaſions; as if the lower end of the *cuniculus* be filled up with water; certain parts in going to it are always affected with damps, which will put out a lamp or candle the moment it enters them, and often do great miſchief to the miners in paſſing them. Phil. Tranſ. N° 48.

CUNILA *bubula*, in botany, a name by which Pliny, and ſome other authors, have called the wild marjoram or origanum. *C. Bauhin* Pin. p. 223.

CUNILAGO, in botany, is uſed by ſome authors for the *coryza*. *Ger.* Emac. Ind. 2.

CUNVILLET, in zoology, the name commonly given in Cornwall, and ſome other neighbouring counties, to the *arenaria* or ſanderling. See ARENARIA.

CUOGOLO, in natural hiſtory, the name of a ſtone, much uſed by the Venetians in glaſs-making, and found in the river Feſino. It is a ſmall ſtone, of an impure white, of a ſhattery texture, and is of the ſhape of the pebble.

CUP, among botaniſts, the ſame with what is otherwiſe called *calyx*. See the article CALYX.

CUP-*galls*, in natural hiſtory, a name given by authors to a very ſingular kind of galls found on the leaves of the oak, and ſome other trees. They are of the figure of a cup, or drinking glaſs, without its foot, being regular cones, adhering by their point or apex to the leaf; and the top or broad part is hollowed a little way, ſo that it appears like a drinking-glaſs with a cover, which was made ſo ſmall, as not to cloſe it at the mouth, but to fall a little way into it. This cover is flat, and has in the center a very ſmall protuberance, reſembling the nipple of a woman's breaſt. This is of a pale green, as is alſo the whole gall, excepting only its rim that runs round the top; this is of a ſcarlet colour, and that very beautiful. Beſide this ſpecies of gall, the oak leaves furniſh us with ſeveral others, ſome of which are oblong, ſome round, and others flatted; theſe are of various ſizes, and appear on the leaves at various ſeaſons of the year. They all contain the worm of ſome ſmall fly; and this creature paſſes all its changes in this its habitation, being ſometimes found in the worm, ſometimes in the nymph, and ſometimes in the fly ſtate, in the cavity of it. See Tab. of Inſects, N° 25.

CUPA, among the antients, a kind of boats, uſed in laying bridges over rivers, being broad below, and narrow above. *Hoffm.* Lex. in voc.

CUPPING (*Cycl.*)—See DRY-*cupping*.

CUPRESSUS, the *cypreſs-tree*, in botany, the name of a genus of trees, the characters of which are theſe. The flowers are of the amentaceous kind, being compoſed of a great number of ſcales, or little leaves, and furniſhed with a great number of apices in the alæ of them. Theſe flowers, however, are barren, and the embryo ſeeds firſt appear as ſmall protuberances on different parts of the tree. Theſe finally ripen into a roundiſh fruit, which ſplits into ſeveral parts, and encloſes an angular ſhaped ſeed. See Tab. 1. of Botany, Claſs 19. The ſpecies of *cypreſs* enumerated by Mr. Tournefort, are three. 1. The headed *cypreſs*, or cloſe topped *cypreſs*, called the female ſpecies by authors. 2. The ſpreading or open topped *cypreſs*, commonly called the male kind. 3. The ſpreading Portugal *cypreſs*, with ſmall fruit. *Tourn.* Inſt. p. 586.

CURA *avenacea*, a diet drink of oats, much recommended by ſome authors in various diſtempers. See OATS.

CURCAS, a name given in Egypt to an eſculent root, approaching to the taſte and virtues of the *colocaſia*.

It is alſo a name uſed in Malabar, for a ſmall fruit of the ſhape and ſize of a hazel nut. Both theſe things have the credit of being great provocatives; and it is very probable, that the *curcas* of the Eaſt-Indies may be the fruit called *bel* by Aviſenna, and ſaid to poſſeſs the ſame famous virtues. Garcias has been led into a very great error by this ſimiliarity of names and virtues, and ſuppoſes the *curcas* of Egypt the ſame with the *curcas* of the Eaſt-Indies.

CURCUM, in the materia medica of the Arabians, the name of the large celandine, the roots of which, when dryed, was uſed by the dyers of thoſe times as a yellow colour, and by the phyſicians as deobſtruents.

CURCUMA, *turmeric*. See TURMERIC, *Cycl.* and *Suppl.*

CUREMA, in zoology, the name of a fiſh of the mullet kind, but of a remarkable ſize, growing to two foot long, and having a very large moveable upper lip; the under one being ſmall, triangular in figure, and ſcarce viſible, being ſomething ſhorter than the upper. Its eyes are large, and its fins of a fine ſilvery white; in all other reſpects it reſembles the common mullet. *Marggrave*'s Hiſt. Braſ.

CURIA, in Roman antiquity, was uſed for the ſenate-houſe. See the article SENATE.

There were ſeveral *curiæ* in Rome as the *curia calabra*, ſaid to be built by Romulus; the *curia hoſtilia*, by Tullus Hoſtilius; and the *curia pompeia*, by Pompey the great. *Macr.* Sat. 1. 15. *Liv.* 5. 55. *Suet.* J. Cæſ. 80.

CURIA alſo denoted the places where the *curiæ* uſed to aſſemble. See CURIA, *Cycl.*

Each of the thirty *curiæ* of old Rome had a temple or chapel aſſigned to them, for the common performance of their ſacrifices, and other offices of religion; ſo that they were not unlike our pariſhes. Some remains of which little temples, ſeem to have ſubſiſted many ages after on the palatine hill, where Romulus firſt built the city, and always reſided. *Tacit.* Annal. 12, 24. *Middlet.* of Rom. Senate, p. 25.

CURIASSIERS, in war, horſemen that wear armour. Theſe have ſometimes only breaſt plates.

CURIATA *comitia*. See COMITIA *curiata*.

CURICACA, in zoology, the name of a Braſilian bird, called *maſarino* by the Portugueſe. It is a very large bird, approaching to the ſize of a gooſe, but in ſhape reſembling the curlew. Its beak is ſix fingers breadth long; its head and neck are covered with white and yellow feathers, and its whole body is black, except that on the back, the head, and the lower part of the belly it has a greyiſh caſt. It is much eſteemed at table. There is another ſpecies of it ſmaller than the former, not exceeding the ſize of a pullet, and called *matrictici*. It is common about the rivers. *Marggrave*'s Hiſt. of Braſil.

CURIMATA, in zoology, a name by which ſome authors have called the *lavaretus*, a ſmall fiſh, of a ſort of middle nature, between truttaceous and the herring kind, and caught in the American and German lakes. *Willughby*'s Hiſt. Piſc. p. 183. See LAVARETUS.

CURING, is uſed for the preſerving fiſh, fleſh, and other animal ſubſtances, by means of certain additions of things, to prevent putrefaction. One great method of doing this, is by ſmoaking the bodies; that is, the making them imbibe a great quantity of vegetable fumes; for this is uſually done where wood is burnt. The reaſon of this ſort of preſervation is eaſily ſeen by the curious enquirer, ſince wherever wood, or any vegetable of the acid tribe is burnt, the acid particles go off with the ſmoak, and in this form penetrate into, and lodge themſelves in animal ſubſtances expoſed thereto; by which means this ſmoak acts upon them in the ſame manner that the fumes of ſpirit of nitre would do, and whether it be not a nitrous acid that tinges hams, herrings, &c. to a redneſs in the drying, is a ſubject worthy enquiry. *Shaw*'s Lectures, p. 152.

CURLEW, the Engliſh name of the *arquata* or *numenius*. See ARQUATA.

CURMI, a name given by the antients to a ſort of malt liquor or ale. It was made of barley, and was drank by the people of many nations inſtead of wine, according to Dioſcorides's account; he accuſes it of cauſing pains in the head, generating bad juices, and diſordering the nervous ſyſtem. He alſo ſays, that in the weſtern part of Iberia, and in Britain, ſuch a ſort of liquor was in his time prepared from wheat inſtead of barley. *Dioſcorides* L. 2. c. 110.

CURRANTS (*Cycl.*)—For the botanical characters of *currants*, ſee the article GROSSULARIA.

The ſeveral ſpecies of *currants* are very eaſily propagated, by planting their cuttings any time from September to March, upon a ſpot of freſh earth, which muſt be carefully kept clear from weeds in the ſpring; and in the dry weather, the young plants muſt be frequently watered. When they have ſtood about two years in this place, they will be fit to tranſplant to the places where they are to remain; and this ſhould be done when the leaves are juſt decayed, that they may have time to be rooted before winter. If they are for ſtandards, they ſhould be planted in rows of ten foot diſtance from one another, and the trees in each row four foot from each other; but the much better way is to train them in eſpaliers, in which ſtate they take up much leſs room, and their fruit is much the finer. They ſhould be placed at eight feet diſtant in eſpaliers, and all their branches trained horizontally. They are to be allowed the ſame diſtance when ſet againſt walls or pales. Thoſe againſt a ſouth wall ripen their fruit near three weeks ſooner then thoſe in the open air, and thoſe againſt a north wall, near as much later; ſo that, by a little management of this kind, they may be kept a long time in ſeaſon. *Miller*'s Gardner's Dict.

Currant trees produce their fruit on the former years wood, and alſo on ſmall ſnags that come out of the old wood. This may give a caution as to the manner in which they are to be pruned.

They will thrive in any ſoil, or ſituation; but this fruit is always beſt taſted when they grow in a dry ſpoil, and an open ſpot of ground.

The jelly of *black currants* is ſaid to be very efficacious in cuing inflammations in the throat. See Phil. Tranſ. N° 459. Sect. 27.

CURRE, an Engliſh name for the fiſh called by authors *cuculus*, and by us more frequently named the *red gurnard*. *Willughby*'s Hiſt. Piſc. p. 282. See the article CUCULUS.

CURRENTS (*Cycl.*)—See the Appendix.

CURRUCA, in zoology, the name of a ſmall bird, commonly known in England by the name of the hedge-ſparrow, and called by ſome *maguanina*.

It is of the ſize of the red-breaſt, or of the titlark; its beak is longiſh, ſlender and black. Its back is variegated with black and a duſky rediſh brown; the middle of all the feathers being black, the edges browniſh. The head and neck are ſomewhat greyiſh, but are variegated with duſky ſpots; and the rump is ſomewhat of a greeniſh hue, and not ſpotted at all; its wings are variegated with a rediſh brown, and a little white; its tail is two fingers breadth long, and is all over brown, without any variegation. *Ray*'s Ornithol.

It is in the neſt of this bird that the cuckow hatche her eggs for the moſt part, though not always, the neſts of turtle and wood pidgeons being ſometimes uſed by her for that purpoſe. Hence it was that the antients made the cuckow an emblem of ſuch men as made bold with the marriage bed of others, who, on that account, were called *currucæ*. Thus Juvenal ridicules the ſtupid fondneſs of a huſband, comforting his falſe wife, by calling him *curruca*.

Tu tibi nunc, curruca, *places, fletumque labellis exſorbes, &c.*
Sat. 6. v. 276.

CURTEYN, *curtana*, a name given to king Edward the confeſſor's ſword, which is the firſt ſword that is carried before the

the kings of England at their coronation. *Matt. Paris* in Hen. 3.

It is said, the point of it is broken, as an emblem of mercy.

CURTILAGE, *curtilagium*, in law, a yard, backside, or piece of ground, lying near a dwelling-house.

CURTILLA, in zoology, a name given by some to the *corvus sylvaticus* of Gesner.

CURVATAPINIMA, in zoology, a name by which some authors call the fish more frequently named the *bonito*. *Marggrave*'s Hist. Bras. See the article BONITO.

CURVATOR *coccygis*, in anatomy, a name given by Albinus to a muscle of the coccyx discovered by himself, and not described by any other author. It is an oblong, thin, and small muscle, and for the most part tendinous. It arises with a double head, one from the inner, and the other from the lower and lateral part of the os sacrum, and descending, terminates in three extremities. He calls it the *curvator coccygis*, from its office, which is the bending the coccyx; and says, that he found it in different states, in three subjects; one very perfect and entire; in a second, more imperfect and degenerating; and in the third, resembling a ligament rather than a muscle.

CURVATURE (*Cycl.*) See the Appendix.

CURUCUI, in zoology, the name of an American bird of the wood-pecker kind, and very remarkably beautiful. It is of the size of the magpye; its legs are short, and feathered almost to the toes with black feathers, and under its head it has a sort of beard on each side, made up with black bristles. Its breast and belly are of a very bright and elegant red, and its back and tail are of a deep blue, with a glow of a fiery red shining through the whole. Its tail is broad, and is terminated by a broad black line; the tops of its wings are of a shining green, the middle of the wings are black, made hoary by innumerable white spots, and their long feathers, are all of a blackish brown; the wings are of a hoary white underneath. *Ray*'s Ornithol. p. 96.

CURVE (*Cycl.*) — Modern geometers frequently consider *curves* as composed of an infinite number of infinitely small right lines; and it is often said, that the antients also considered *curves* as polygons of an infinite number of sides. But it is certain, that this principle no where appears in their writings. We never find them resolving any figure into infinitely small elements. On the contrary, they seem to avoid such suppositions, as if they judged them unfit to be received into geometry, though it was sometimes obvious, that their demonstrations might have been abridged, by admitting such notions. They considered curvilinear areas as the limits of circumscribed or inscribed figures of a more simple kind, which approach to these limits; so that the difference between them may become less than any given quantity. The inscribed and circumscribed figures were always conceived to be of a magnitude and number that is assignable; and they demonstrated the mensuration, or the proportions of the curvilinear limits themselves, by arguments *ab absurdo*.

But modern geometers have abandoned the foundations of the antients. It was thought unnecessary to conceive the figures circumscribed or inscribed, in the curvilinear area, or solid, as being always assignable and finite; and the precautions of Archimedes and the antients came to be considered as a check upon geometricians, serving only to retard their progress. Therefore, instead of assignable finite figures, indivisible, or infinitely small elements were substituted; and these being supposed infinite in number, their sum was supposed to coincide with the curvilinear area or solid. See *Maclaur.* Fluxions, in the Introd.

CURVES *of the second order*. See LINES *of the third order*, Appendix.

Logarithmic CURVE. See LOGARITHMIC, in the Appendix.

CURVICAUDA, in natural history, the name of a species of bee fly, very common in England, and very troublesome to horses, commonly known by the name of the wringle tail. See WRINGLETAIL.

CURVIROSTRA *fossilis*, in natural history, the name of a species of fossile shell, found very frequently in the stone quarries of Northamptonshire, and the neighbouring counties. It is a species of cockle, and is distinguished by its beak not standing in the middle, but always inclining to one or the other side. The shell is sometimes found remaining entire, and in its native state and condition, but more frequently there is stony matter deposited in its place. *Hill*'s Hist. of Foss. p. 646.

CURVITY. See CURVATURE.

Radius of CURVITY. See CURVATURE, Appendix.

CURURU, in botany, a name used by Plumier in the same sense with the *feriana* of the same author, in its generical characters, and called by Linnæus *paulinia*. *Plumier*, Gen. 36. See the article PAULINIA.

CURURUCA, in zoology, the name of an American fresh water fish, of an oblong, and not flatted, body. It grows to a foot and half in length; its mouth is very large; it has one long back fin, which is divided as it were into two in the middle, and the anterior rays of this are rigid, and prickly, the hinder ones more flexile and soft. Its scales are moderately large, and of a silvery brightness, with a slight mixture of brown and yellow on the back and sides; its tail, and back-fin, are of a greyish colour; those on the belly are of a brownish yellow. It is eaten in the Brasils. *Marggrave*'s Hist. Brasil.

CUSCASOW, the name of a Mooriſh dish eaten in Egypt. It is made of flower tempered with water, rolled in the hands into small pieces, and then put into a colander, over a boiling pot, stopped close round; so that it is dressed with the steam, and when it is done enough they put butter, to it. *Pocock*'s Egypt, p. 183.

CUSCUTA, *dodder*. In the Linnæan system of botany, this makes a distinct genus of plants, the characters of which are these: the calyx is a one-leaved perianthium, in form of a cup, fleshy at the base, and divided slightly into four obtuse segments at the rim. The flower is composed of only one petal, of an oval figure, a little longer than the cup, and divided slightly into four obtuse segments at the edge. The stamina are four pointed filaments of the length of the cup; the antheræ are roundish; the germen of the pistil is roundish; the styles are two in number, and are erect, and short; the stigmata are simple; the fruit is fleshy, and roundish, and contains two cells splitting open horizontally; the seeds are two from each flower. *Linnæi* Gen. Plant. p. 53. The characters of *dodder*, according to Tournefort, are these: the flower is composed only of one leaf, which is hollowed into the shape of a bell, and is divided into many segments at the edges: the pistil arises from the cup, and is fixed, in the manner of a nail, to the hinder part of the flower; this finally becomes a membranaceous fruit, of a roundish, but somewhat angulated figure, perforated in its hinder part, and standing upon a capsule, which fills the basis of the cup, and containing very small seeds. The species of *dodder*, enumerated by Mr. Tournefort, are these: 1. The common *cuscuta*, or *dodder*. 2. The *epithymum*, small *dodder*, or *dodder* of thyme. *Tourn.* Inst. p. 652. See DODDER.

CUSI, in natural history, a name given by the people of the Philippine islands to a very small and very beautiful species of parrot.

CUSTOS (*Cycl.*) — CUSTOS *placitorum coronæ*, in our antient writers of law, seems to be the same with him we now call *custos rotulorum*, which is mentioned in the writ *de odio & atia*. Reg. of Writs, fol. 133. b. See also *Bracton* lib. 2. c. 5.

CUTT-*water*, the sharp part of the head of a ship below the beak. It is so called because it cuts or divides the water before it comes to the bow, that it may not come too suddenly to the breadth of the ship, which would retard her.

CUTAMBULI, a name given by the old writers on medicine to certain worms bred under the skin, and causing by their creeping a very uneasy sensation. Afterwards the same word was used to express certain uneasy itchings caused by a scorbutic habit, and resembling the crawling of worms.

CUTANEOUS *eruptions*, in infants. See the article INFANT.

CUTHBERT *duck*, in zoology, the name given by authors, as well as by our own people, to a species of duck which breeds in some of our northern islands, and leads its young to sea as soon as they are hatched, whence neither they, nor the old ones, ever return till the breeding time again. It is of the size of the common duck; the male is variegated with black and white; its back being white, and its tail and long wing-feathers black; its beak is shorter than the common ducks, and its legs and feet are black; the female is of one colour, a dull dusky brown. One great singularity in these birds, both male and female, is, that the feathers at the sides of the beak run to an angle under the nostrils. *Ray*'s Ornithol. p. 227.

There seems great reason to suspect that this and the *eider*, or *anas plumis molliſſimis*, are the same species of bird. See EIDER.

CUTTING *teeth*, in anatomy. See DENTES *incisores*.

CUTTLE-*fish bone*. See SEPIUM, *Cycl.*

CUTTOFOE, in botany, a name given by the people of Guinea to a plant which they esteem greatly for its medicinal virtues. They boil it in water, and give the decoction in all cases of the colic, in which it proves a cure. It is a species of the anonis, or rest-harrow, and is common to Africa, and the West-Indies, Sir Hans Sloane having very well figured, and described it, under the name of *anonis non spinosa minor glabra procumbens flore luteo*, the yellow-flowered small, procumbent, smooth *anonis*, without thorns.

It is found in vast abundance on the banks of the Rio Cobre, near the city of St. Jago de la Vega, or Spanish town. Phil. Trans. N° 232.

CUURDO, in botany, is, with some authors, the name of the *cinnamon* tree. *Piso*, Mant. Arom. p. 165.

CYAMEA, in natural history, the name by which the antients called the black, flinty eagle-stone. Pliny describes its blackish colour, and says, that, when broken, there was found within it another stone of the bigness of a horse-bean. This is what rattles in it when shaken.

CYAMOS, in botany, a name used by some authors for the common, garden bean. *Chabræus*, p. 141.

CYANUS, the *blue bottle*, in botany, the name of a genus of plants, the characters of which are these: The flower is of the flosculous kind, being composed of a number of floscules; but these of two different kinds: those which stand in the middle

middle of the flower are ſmall, and divided into a number of equal ſegments; but thoſe placed nearer the edges are much larger and more conſpicuous, and are, as it were, bilabiated: both kinds, however, are placed on the embryos, and all are contained together in a general cup, which is ſcaly, and not prickly. The embryos afterwards become ſeeds winged with down.

The ſpecies of *cyanus* enumerated by Mr. Tournefort are theſe. 1. The broad-leaved perennial mountain *cyanus*. 2. The white flowered broad-leaved mountain *cyanus*. 3. The *cyanus* with longer and narrower leaves. 4. The Alpine *cyanus*, with pennated heads. 5. The mountain *cyanus*, with leafy ſtalks, and oblong heads. 6. The great ſweet-ſcented Turkiſh or oriental *cyanus*, 7. The great ſweet-ſmelling Turkiſh or oriental *cyanus*, with white flowers. 8. The great oriental ſweet *cyanus*, with fleſh coloured flowers. 9. The great oriental ſweet *cyanus*, with yellow flowers. 10. The exotic *cyanus*, called *amberboi*, or *emberboi*. 11. The oriental great *cyanus*, with red fiſtulous flowers. 12. The great oriental *cyanus*, with fiſtulous yellow flowers. 13. The great oriental *cyanus*, with fiſtulous white flowers. 14. The low white-flowered *cyanus*, with hierachium leaves. 15. The purple flowered hierachium leaved low *cyanus*. 16. The hierachium leaved low *cyanus*, with purpliſh olive flowers. 17. The Spaniſh *cyanus*, with pale blue flowers. 18. The long-leaved tree *cyanus*. 19. The common corn *cyanus*, with blue flowers. 20. The common corn-field *cyanus*, with white flowers. 21. The fleſh-coloured flowered *cyanus*. 22. The purple-flowered *cyanus*. 23. The bright red-flowered *cyanus*. 24. The corn-field *cyanus*, with a flower blue in the middle, and white at the edges. 25. The *cyanus* with flowers fleſh-coloured in the middle, and white at the edges. 26. The *cyanus* with flowers purple in the middle, and white at the edges. 27. The *cyanus* with flowers of a violet blue in the middle, and white at the edges. 28. The *cyanus* with flowers pure white in the middle, and fleſh-coloured at the edges. 29. The *cyanus* with flowers purple in the middle, and blue at the edges. 30. The *cyanus* with pale violet-coloured flowers. 31. The *cyanus* with whitiſh blue flowers. 32. The garden *cyanus*, with blackiſh purple flowers. 33. The garden *cyanus*, with double blue flowers. 34. The garden *cyanus*, with double purple flowers. 35. The garden *cyanus*, with double flowers, purple in the middle. *Tourn.* Inſt. p. 445, 446.

The common wild *blue bottle* of our corn-fields, is eſteemed a cardiac and alexipharmic. Conſerves and ſyrups are prepared from it in ſome places, and ſerve very properly for the making other more efficacious medicines of the ſame intention into form. Schroder and ſome others, have greatly extolled the diſtilled water of the flowers in inflammations, and many other diſorders of the eyes; but this ſeems a leſs warranted matter. The flowers of the large garden kind, are ſaid to be particularly good in diſorders of the womb, and the leaves of either in infuſion in dropſies.

There are ſeveral ſpecies of this plant, commonly cultivated in gardens, for the beauty of their flowers. They are almoſt all annuals, periſhing as ſoon as they have ripened their ſeed. In order to have them flower early, their ſeeds ſhould be ſown in July, or the beginning of Auguſt, and when the plants have once got ſtrength, they ſhould be tranſplanted into warm borders, and will endure the cold very well, and will flower very early the next ſummer.

CYANUS, in the natural hiſtory of the antients, is uſed to expreſs two different ſubſtances. The one the *lapis lazuli*, the other the *lapis armenus*, a ſubſtance uſed by the painters in its native ſtate, and very improperly called a ſtone, being a mere earth, and being truly to copper, what yellow ochre is to iron.

The antients having called theſe two ſubſtances by the ſame name, has been the occaſion of a great many errors, and great miſunderſtanding of their works, even among one another, after the ſucceſſion of only a few ages, much more among their commentators in theſe later times. We are apt to think, we go very far back in our reſearches, when we go back to Pliny, in ſearch of the things in uſe among the antients; but this is by no means ſufficient, ſince it will appear to any one who will read, and compare Pliny with the older authors, that while he has taken his accounts of things from thoſe who wrote before him, he has often miſtaken, and miſunderſtood them; and in particular, that his hiſtories of foſſils, are in a great meaſure, taken from the writings of Theophraſtus, and are often very careleſs, and very bad tranſlations of him, Pliny having frequently notoriouſly miſunderſtood him. Of this, the hiſtory he has given us of the ſubſtance now under conſideration, is an evident inſtance; for he has plainly confounded the two ſubſtances, called by the common name *cyanus*, and has told us thoſe things of the *cyanus* gem, or *lapis lazuli*, which Theophraſtus, from whom he tranſlated it, ſays of the paint.

When Theophraſtus, in his hiſtory of ſtones, has gone thro' the gems and ſtone claſs, and is come to the earths, among theſe he names the *cyanus* paint, or *lapis armenus*, having, in another part of the work, treated at large of the *cyanus* gem; of the *cyanus* paint he tells us, that beſide the native kind, which was very valuable, and very ſcarce, there was a fictitious one, which ſerved very well for many kinds of painting, and which was prepared in Egypt, where one of their kings having been the firſt inventor of it, it was recorded to his immortal honour, in the annals of his reign. This was very probable, of a ſubſtance ſo very dear, ſo very ſcarce, and yet ſo much wanted in all fine paintings; but Pliny has tranſlated this paſſage, and unfortunately not minding which of the *cyanus* he attributes it to, has ſaid it all of the *cyanus* gem; a thing never in any great eſteem, and which was never worth the counterfeiting, much leſs of ſo much conſequence, that it ſhould be recorded in the hiſtory of a ſeries of kings, which of them happened to find out the way of imitating it. *Hill's* Theoph. p. 131.

CYATHUS, in antiquity, a liquid meaſure among the Romans, being the twelfth part of the ſextarius. It only held as much as a man could eaſily drink at one draught, and was divided in twelve parts, called *unciæ*. See SEXTARIUS & UNCIA, *Cycl.*

CYBÆA, in antiquity, a kind of ſhip uſed in commerce, of a roundiſh form. *Pitiſc.* Lex. Ant. in voc.

CYBELICUM *marmor*, a name given by the antients, to a ſpecies of marble, dug in a mountain of that name in Phrygia. It was of an extremely bright white, with broad veins of a blueiſh black.

CYBOMANTIA, κυβομαντεια, a ſpecies of divination performed by lots.

CYCEON, a name given by the antient poets and phyſicians, to a mixture of meal and water, and ſometimes of other ingredients. Theſe conſtituted the two kinds of *cyceon*, the coarſer being of the water and meal alone, the richer and more delicate compoſed of wine, honey, flower-water, and cheeſe. Homer, in the eleventh iliad, talks of *cyceon* made with cheeſe and the meal of barley, mixed with wine; but without any mention either of honey or water; and Ovid deſcribing the draught of *cyceon*, given by the old woman of Athens to Ceres, mentions only flower and water. Dioſcorides underſtood the word in both theſe ſenſes; but extolled it moſt in the coarſe and ſimple kind: he ſays, when prepared with water alone, it refrigerates and nouriſhes greatly.

CYCLAMEN, *ſow bread*, in botany, the name of a genus of plants, the characters of which are theſe: The flower conſiſts of one leaf, and is globoſe, and of a rotated form, and uſually divided into five ſegments, which all bend upwards; from the cup there ariſes a piſtil, which is fixed in the manner of a nail, to the hinder part of the flower, and afterwards becomes a roundiſh membranaceous fruit, which contains numerous ſeeds, uſually of a longiſh figure, and angular, and fixed to a placenta.

The ſpecies of *cyclamen* enumerated by authors are theſe. 1. The *cyclamen*, with round leaves, purple on their under ſide. 2. The double flowered *cyclamen*, with round leaves, purple underneath. 3. The *cyclamen*, with a roundiſh leaf, of a pale whitiſh green underneath. 4. The round-leaved autumnal *cyclamen*, with very ſweet fleſh-coloured flowers and leaves, red underneath. 5. The bright red-flowered Syrian, autumnal *cyclamen*, with roundiſh, ſhining, crenated leaves. 6. The Syrian autumnal *cyclamen*, with large ſnow-white flowers, and roundiſh, lucid, ſoft, and crenated leaves. 7. The ſweet-flowered, ſpotted-leaved, ſummer *cyclamen*. 8. The ſummer Roman *cyclamen*, with leaves ſcarce at all ſpotted, and of a longiſh ſhape, and with pale purple flowers. 9. The large round-leaved *cyclamen*, with a pale violet-coloured flower. 10. The autumnal *cyclamen* of mount Libanus. 11. The coan *cyclamen*, or purple-flowered winter *cyclamen*, with roundiſh leaves, purple underneath. 12. The angular-leaved *cyclamen*, flowering both in ſpring and winter, with a large white flower, and purple baſe, called by ſome the Perſian *cyclamen*. 13. The winter and ſpring *cyclamen*, with an angular leaf, and a large fleſh-coloured flower, with a purple baſe. 14. The purple flowered African *cyclamen*, which flowers the whole year. 15. The great African *cyclamen*. 16. The ſpring *cyclamen*, with great white flowers, purple at the baſe, and with angular leaves, variegated with three ſorts of green, called by ſome, the *cyclamen* of Antioch. 17. The autumnal *cyclamen* of Antioch, with double purple flowers. 18. The broad-leaved auriculated *cyclamen*, with bright red flowers. 19. The narroweſt leaved, auriculated *cyclamen*, with white flowers, purple at the baſe, called the Byzantine *cyclamen*. 20. The royal *cyclamen*, with long, angular leaves, reſembling ſerpents tongues. 21. The great white flowered *cyclamen*, with long angular leaves. 22. The great rooted *cyclamen*, with leaves red underneath. 23. The common angular leaved ſpring *cyclamen*. 24. The ivy-leaved *cyclamen*. 25. The many-flowered, ivy-leaved *cyclamen*. 26. The *cyclamen*, with roots of the ſize of a cheſnut. 27. The little rooted *cyclamen*. 28. The long rooted *cyclamen*. 29. The white ſpring *cyclamen*. 30. The red ſpring *cyclamen*. 31. The yellow ſpring *cyclamen*, with heart-faſhioned roots. *Tourn.* Inſt. p. 155.

There are ſeveral ſpecies of this plant cultivated in gardens, for the pretty appearance of its flower: they are propagated by the curious from ſeed, in the manner of the *xiphium*. See XYPHIUM. But they are four or five years before they come to flower, and for the firſt year or two of their flowering,

flowering, their roots are ſo ſmall that the flowers they produce are but few. The roots, however, annually increaſe in bulk, and the number of flowers increaſes in proportion; ſo that they will grow to fourteen inches in diameter, and, when of this ſize, will produce upwards of an hundred flowers in one ſeaſon. The beſt ſeaſon for tranſplanting theſe roots is in June and July, ſoon after the ſeed is perfected; but they ſhould not be kept long out of the ground, for the roots are diſpoſed to ſhoot out freſh fibres, with the firſt moiſt weather after the ſeeds are fallen, and in about ſix weeks produce their flowers, which appear upon long ſingle footſtalks before the leaves appear: theſe ſprout up after the flower is fallen, and remain green all the winter, and being of a fair green, and ſpotted in the middle with white, they make a very pretty appearance, during that dead ſeaſon. The pedicle of the flower afterwards twiſts like a ſcrew, encloſing the embryo of the fruit, which is buried among the leaves, and, by that means, ſcreened from the ſeverity of the winter, and ripens its ſeeds in June. *Miller*'s Gardener's Dict.

CYCLAS, in our old writers, a long garment, cloſe upwards, and open, or large below. Matt. Paris, ſpeaking of the citizens of London, tells us they were *cericis veſtimentis ornati*, cycladibus *auri textis circundati*. Anno 1236.

CYCLOID (*Cycl.*) — The time in which a heavy body deſcribes a *ſemi-cycloid*, by deſcending along it by its gravity, is to the time in which it would fall through the diameter of the generating circle by the ſame gravity as the ſemi-circumference of a circle is to its diameter. *Mac Laurin*'s Fluxions, Art. 407. See the ſame book, Art. 405 — 408, for the properties of the *cycloid*. See alſo his account of Sir Iſaac Newton's diſcoveries, p. 296. for the properties of the *cycloid*, and the motion of a pendulum in that curve. On the ſame ſubject we have a ſhort and elegant treatiſe by Mr. Cotes, Oper. Miſcel. p. 80. not to mention the *horologium oſcillatorium* of Huygens, who firſt applied the *cycloid* to regulate the motions of pendulums.

CYCLOPTERUS, in ichthyology, the name of a genus of the branchioſtegous fiſhes, the characters of which are theſe: the branchioſtege membrane on each ſide contains ſix ſmall and cylindric bones. The body is of an oblong, globoſe figure; the belly-fins unite at their extremities, ſo as to form one circular fin, of the ſhape of a funnel; the fins are ſix in number. We at preſent know only one ſpecies, which is the *lump-fiſh*, or ſea owl. *Artedi* Gen. Piſc. 40. See LUMPUS.

The name is of Greek origin, and is formed of the words κυκλὸς a circle, and πτέρον a fin; and expreſſes that this fiſh has ſomething circular in its fins, thoſe of the belly being concreted into this form. See Tab. of Fiſhes, N° 32.

CYDER (*Cycl.*) — The beſt *cyder* of all the kinds is that made from the redſtreak apple, grafted upon the gennetmoyle ſtock. Theſe two ſorts of apple-trees always agree very well, and the ſtalks ſcarce ever canker, as the crab-ſtalks uſually do, when this apple-tree is grafted upon them. The fruit of the redſtreak, on the ſtock here recommended, is always larger, and milder, and, when ripe, is a very good eating apple, and the *cyder* made from it is mellower, and has not the over-roughneſs and auſterity that has which is made from the ſame apple on the crab-ſtock; the apples alſo need leſs mellowing, in order to their making into *cyder*, the ſtalk, in a great degree, meliorating the fruit; for as an apple grafted on a crab becomes better by obtaining an acrimony and quickneſs from the fruit, ſo a crab, and the redſtreak apple, as it is called, which is in itſelf no other, obtains ſoftneſs, mellowneſs, and bigneſs, by being grafted on a good apple. Phil. Tranſ. N° 70.

It might be a great improvement to many eſtates, to cultivate, on the grounds not fit for corn, the proper ſorts of apples for *cyder*. It is a marketable commodity at all times, and coſts no fuel to brew it; and the labour is but once in the year. The greater quantities of *cyder* are made together, the better it uſually ſucceeds, but the veſſels ſhould alſo be large in which it is kept. In this caſe it will not only keep many years, but will improve all the time. Phil. Tranſ. N° 134.

Pepin CYDER. This is a ſort of *cyder* which, in many places, might be made in great quantities, where the redſtreak *cyder* apple will not thrive: the harſhneſs that is apt to be in this ſort of *cyder*, is the only objection to its value, it being of a good body, and otherwiſe, in all reſpects, commendable. The great reaſon of this harſhneſs is the light foulneſs; or, as the *cyder*-people expreſs it, the flying lee that always is in this ſort. But it is eaſy, by watching a proper time, to draw off the liquor from this into other veſſels, or to ſtrain it through a cloth: in either caſe, much of the lee will be left out, and the *cyder* loſe its harſhneſs. Phil. Tranſ. N° 70.

CYDER *ſpirit*, a ſpirituous liquor drawn from *cyder* by diſtillation, in the ſame manner as brandy from wine. The particular flavour of this ſpirit is not the moſt agreeable, but it may, with care be diveſted wholly of it, and rendered a perfectly pure and inſipid ſpirit, upon rectification. The traders in ſpirituous liquors are well enough acquainted with the value of ſuch a ſpirit as this: they can give it the flavours of ſome other kinds, and ſell it under their names, or mix it in large proportion with the foreign brandy, rum, and arrack, in the ſale, without danger of a diſcovery of the cheat.

CYDONIA, the *quince*, in botany, the name of a genus of trees, the characters of which are theſe: the flower is of the roſaceous kind, being compoſed of ſeveral petals, arranged in a circular form; the cup finally becomes a fleſhy fruit, of a turbinated form, divided into cells within, and containing oblong ſeeds of a callous ſtructure.

The ſpecies of *quince* enumerated by Mr. Tournefort are theſe: 1. The common *quince*, with oblong, ſmooth fruit. 2. The oblong-fruited *quince*, with a ſmooth rind, and ſweet-taſted pulp. 3. The *quince* with a ſmall, oblong, downy, and not eatable fruit. 4. The *quince* with a ſhort, and roundiſh fruit. 5. The common, narrow-leaved *quince*. 6. 6. The broad-leaved, Portugal *quince*. *Tourn.* Inſt. p. 632.

There are three kinds of this tree propagated in the nurſeries about London; the pear-*quince*, the apple-*quince*, and the broad-leaved Portugal *quince*.

The laſt of theſe is moſt eſteemed for the delicate flavour of the fruit: they are all eaſily propagated, either by layers, ſuckers, or cuttings, which muſt be planted in a moiſt ſoil. Thoſe raiſed from ſuckers are ſeldom ſo well rooted as the others, and are ſubject to produce ſuckers again, in a greater abundance, which is not to be wiſhed in fruit-bearing trees.

The cuttings ſhould be planted early in ſpring, and, in dry weather, muſt be often watered, to aſſiſt them in rooting; the ſecond year they ſhould be removed into the nurſery, and ſet in rows, at three feet diſtance, and one foot aſunder in each row. In two or three years more, they will be fit to tranſpant where they are to ſtand, which ſhould always be near a ditch, or river, or in ſome moiſt ſoil; where they will produce twice the quantity of fruit that they will in a dry one, and the fruit will alſo be much larger: but thoſe in a drier ſoil are better taſted, and are earlier ripe.

CYDONITES, (*Cycl.*) in natural hiſtory, the name of a ſtone of the ſhape of a quince. It ſeems to have been a fantaſtic name, given to any common flint, or pebble, that was accidentally found of that ſhape, not appropriated to any peculiar ſpecies of ſtone.

CYEMA, the ſame with embryo. Blancard derives it from κυω, *pario*.

CYGNUS, (*Cycl.*) the *ſwan*, in natural hiſtory, a very well known bird; but, beſide the common tame *ſwan*, there is another ſpecies called the *wild ſwan*, and, in ſome places, the *elk*, and in others, the *hooper*. It is ſomewhat ſmaller than the tame *ſwan*, and is not of ſo clear a white, the middles of the back feathers being greyiſh; the feet are of a yellowiſh brown. *Ray*'s Ornithol. p. 272.

Bartholine has given an accurate account of the anatomy of this bird, and of the ſtructure of its œſophagus, and the windpipe, which is very remarkable. Theſe are ſo framed that they go down together into the ſternum; and, after reaching its bottom, they turn up again, and the windpipe riſing out of the ſtreights of the ſternum, climbs up the intermediate clavicles, on which it leans, as on a baſe, and then bends to the thorax; but before it comes to the thorax and lungs, it forms a ſort of larynx, with an os hyoides, covered with a thick membrane, and reſembling a muſical pipe, wide above, but with a narrow ſlit, and ſtrait, and depreſſed below: under this larynx, before the windpipe enters into the lungs, it is divaricated into two branches like unto bronchia, thicker in the middle, but narrower where they are near the lungs. In this particular it differs from the human aſpera arteria, which, it is true, is divided into branches, but that is not before it has entered into the lungs. *Bartholin*, Diſſert. de Cygni Anatom.

CYGNUS *cucullatus*, the *hooded ſwan*, a name very improperly given by ſome authors to the *dodo*, a very large bird, rather approaching to the caſſowary kind, but not ſo long legg'd, or long neck'd. *Ray*'s Ornithol. p. 107. See DODO.

CYLINDRUS, in conchyliology, the name of a genus of ſhell-fiſh, of which there are many very elegant and precious ſpecies. This genus is more generally, at preſent, called *rhombus*, though this is very improper, the word *cylindrus* very aptly expreſſing the ſhape of the ſhell, which is cylindric and oblong, and the *rhombus*, which ſignifies that figure we call a lozenge, not being at all expreſſive of it.

The characters of this genus are theſe: it is an univalve ſhell, of an oblong cylindric figure, with an oblong mouth, and oftentimes having the clavicle ſeparated from the body by a circle: the columella is, in ſome ſpecies, ſmooth, in others, rough. The moſt obvious character of this genus, without having recourſe to the mouth, is, its having in all the ſpecies, both ends of the ſhell nearly of the ſame ſize, the tail part being always, however, ſomewhat ſmaller than the head. The head is not ſeparated from the body by an elevated rib, as in the volutæ, but have it following the ſhape of the body, though ſometimes it is ſeparated by a dentated furrow; and in ſome, though very few ſpecies, by a rib, or riſing circle. This is a very puzzling circumſtance in the diſtinction of the ſhell, bringing it to a near alliance with the volutæ: but, in this caſe, the point of the ſhell muſt be regarded, which, in the *cylindrus*, is always obtuſe, but, in the voluta always pointed. See Tab. of Foſſils, Claſs 9. and Tab. of Shells, N° 12.

Among

Among the ſpecies of this family of ſhells, there are found two very remarkable diſtinctions; the one is in the ſpecies juſt mentioned, which has a rib near the head; the other is in the olive *cylindrus*, the two extremities of which are nearly equal, but the middle very conſideraby ſwelled.

Some authors, who have not been ſufficiently diſtinct on theſe ſubjects, have called the ſpecies of this genus *volutæ cylindroide*; but it appears very plainly that they deſerve a generical name to themſelves, and there is great advantage in the ſeparating two genera, each of which contains ſo large a number of ſpecies. Rondeletius and Aldrovand, not being able to refer theſe olive-ſhaped *cylindri* to any genus, have placed them by themſelves.

The family of the *cylindri* being very numerous, may be aptly divided into ſeveral ſubordinate ſpecies. 1. The *cylindrus* with the clavicle united to the body. 2. The *cylindrus* with the clavicle ſeparated from the body. 3. The *cylindrus* with a coronated clavicle. 4. The *cylindrus* with a rugoſe columella.

Of the firſt kind, or ſuch as have the clavicle united to the body, we have the following ſpecies. 1. The cloth of gold *cylindrus*. 2. The cloth of ſilver *cylindrus*. 3. The yellow cloth *cylindrus*. 4. The faſciated, cloth of gold, *cylindrus*. 5. The nigella *cylindrus*. 6. The tulip *cylindrus*. 7. The pancake, or amlet *cylindrus*. 8. The reticulated *cylindrus*. 9. The plumoſe *cylindrus*, repreſenting birds feathers. 10. The *cylindrus* variegated with blue ſpots. 11. The granulated *cylindrus*, with various lines, and ſpots. 12. The granulated, yellow *cylindrus*.

Of the ſecond kind, or thoſe which have the clavicle ſeparated from the body of the ſhell, there are the following ſpecies. 1. The decorticated *cylindrus*. 2. The brown, ſpotted, decorticated *cylindrus*. 3. The clouded *cylindrus*. 4. The *cylindrus* with a coronated clavicle. 5. The ſilk, broad *cylindrus*. 6. The ſilver, broad *cylindrus*. 7. The taffeta *cylindrus*. 8. The mohair *cylindrus*. 9. The *cylindrus* of a bright, white-like, poliſhed ſilver.

Of the *cylindri* with a rugoſe columella, we have the following ſpecies: 1. The *olea viridis*, or green olive *cylindrus*. 2. The agate olive *cylindrus*, variegated at the bottom. 3. The cylindric, porphyry *cylindrus*. 4. The black, olive *cylindrus*. 5. The yellow, olive *cylindrus*. 6. The *cylindrus* called by the French the *ſolitaire*. 7. The olive *cylindrus*, faſciated, and variegated in the lower part. 8. The *cylindrus* with marks reſembling letters, or characters. 9. The violet-coloured, or amethyſtine, Panama *cylindrus*. And, 10. The white, olive *cylindrus*, delineated over with yellow lines Hiſt. Nat. Eclair. p. 284, ſeq.

CYLISTICI, Κυλιστικοι, in antiquity, a deſignation given to the *pancratiaſtæ*; becauſe when the weaker found himſelf ſore preſſed by his adverſary, he fell down, and fought, rolling on the ground. *Pott.* Archæol. Græc. l. 2. c. 21. T. 1. p. 444. The word is Greek, formed from κυλιω, to roll, or tumble.

CYLLOSIS., the ſame with *cyllum*. See CYLLUM.

CYLLUM, in medical writers, is uſed to ſignify a leg put out of joint outwardly; alſo one that is lame and crooked.

CYMATITES, in natural hiſtory, a name given by ſome writers to a ſpecies of *aſtroites*, the lineations of which are indented, and repreſent waves. See ASTROITES.

CYMATIUS *ſtorax*. See STORAX.

CYMBARIA, in botany, the name of a genus of plants, the characters of which are theſe: The perianthium is erect, and divided into ſeveral ſegments; two of them, which ſtand oppoſite to one another, are larger and broader than the reſt; the other ten are very narrow: this cup does not fall with the flower. The flower is monopetalous, and its tube is oblong and inflated; the mouth is open; the upper lip is reflex, obtuſe, and divided into two ſegments; the lower one is obtuſe alſo, and is divided into three. The ſtamina are four filaments, of the length of the tube; the antheræ are bifid, and prominent; the germen of the piſtil is oval; the ſtyle is capillary, and of the length of the ſtamina, and the top of it is bent; the ſtigma is obtuſe. The fruit is an oval capſule, compoſed of two valves, and having only one cell; this is ſquare, and contains a number of ſmooth angular ſeeds. *Linnæi* Gen. Plant. p. 282.

CYMBIUM, in natural hiſtory, a name given by many authors to a kind of ſea ſhell, commonly called the *gondola ſhell*. It is of the genus of the *concha globoſa*, or *dolium*, and there are ſeveral ſpecies of it. See GONDOLA.

CYMENE, in botany, a name given by the antient Greeks to a plant with which they uſed to dye woollen things yellow, and with which the women of thoſe times uſed alſo to tinge the hair yellow, that being the favourite colour in thoſe ages. The *cymene* of the Greeks is evidently the ſame plant with the *lutum* or *lutea herba* of the Latins; and this is deſcribed to have leaves like the *linum*, or flax, and flowers like the *geniſta*, or broom. It is plain from this, that the *lutum* of the Romans was the plant we call *geniſtella tinctoria*, or dyer's weed, with which we ſtill uſe to dye yellow, and which anſwers to all the characters of the Roman deſcription. As evident, however, as this is to the judicious botaniſt, it has not prevented errors. Macer, Paulus Ægineta, and many others, have ſuppoſed the *cymene*, or *lutum*, the ſame with *woad*, or *iſatis*, a plant uſed for dying blue, and not at all anſwering to the characters given of the *lutum*.

CYMINALIS, in botany, a name uſed by ſome authors for the *gentian*, the plant whoſe root is the fine bitter drug of that name. *Ger.* Emac. Ind 2.

CYMONIDES, in natural hiſtory, a name given by antient writers to a ſtone which, they ſay, at certain times, became pregnant, and brought forth other ſtones. They called it alſo *cymonites*, *encymonites*, and *encumonis*. It is generally ſuppoſed that they meant the eagle-ſtone by this name; but their deſcriptions of it agree much better with the ſparry incruſtations on the tops of grottos They ſuppoſed this to poſſeſs great virtues in promoting delivery.

CYNAPIUM, in botany, a name uſed by ſome authors for the leſſer *hemlock*, or, as we call it in Engliſh *fool's parſley*. *Rupp. Fl. Jen.* 228.

CYNANCHE, and LYCNANCHE, in medical writers, an inflammation of the inner muſcles of the larynx, accompanied with a difficulty of breathing, and a continual fever, ſo called becauſe it is frequently incident to dogs, and wolves. *Blancard.*

CYNANTHEMIS, in botany, a name given by ſome authors to the *cotula fœtida*, or ſtinking mayweed. *Ger.* Emac. Ind. 2. See COTULA.

CYNANTHROPIA, a term uſed for madneſs given by a dog, wherein the patient flies light, or any thing that is bright, and fears water, and trembles at the ſight and remembrance of it. It proceeds uſually from a poiſonous bite, or the like, of ſome mad creature, as a dog, a wolf, &c. *Blancard.*

CYNARA, in botany, a name generally eſteemed ſynonymous with the word *cinara*, but erroneouſly; the *cinara* being properly the artichoak, and the *cynara* the chardoon, or ſome other thiſtle nearly allied to the artichoak kind, of which the antient Greeks eat the young and blanched ſtalks, as we do the chardoons. Galen has gone a great way, indeed, towards the confounding the two plants together, by accuſing the people of his time for corruptly writing the word *cinara*, when it was originally written *cynara*; but antiquity refuſes to join in this. Sopater Paphius who lived in the time of Alexander the Great, we find writes *cinara*, as Athenæus affirms; and Ptolemy Euergetes, who was a ſcholar of Ariſtarchus, calls it by the ſame name *cinara*, not *cynara*. Many of the ſame authors, who conſtantly write the name of the artichoak *cinara*, alſo write the name *cynara*, as belonging to another plant; and they ſeem to have different etymologies, the word *cinara* being derived from an iſland of the ſame name, where the Greeks found the wild plants of the artichoak grow very plentifully, and the chardoon of the Greeks being called *cynara*, as if dog's thiſtle.

CYNEBOTE, the ſame with *cenegild*. See CENEGILD.

CYNOCEPHALUS, in zoology, the name of one of the genera of monkeys which have a long noſe, and reſemble a dog about the head. Theſe have all tails, ſome longer, ſome ſhorter, and are what we call in Engliſh *baboons*. There are ſeveral ſpecies of theſe, ſome of which are very large.

CYNODES *orexis*, and CYNOREXIS, a canine appetite. *Blancard.* See CANINE *appetite*, and BULIMY, *Cycl.*

CYNOGLOSSUM, in botany. See HOUNDS-TONGUE.

CYNOGLOSSI *radix*, *hound's-tongue root*, in the materia medica, is emollient, anodyne, and narcotic; it is alſo gently aſtringent, and is eſteemed a good medicine in catarrhs, diarrhœas, dyſenteries, and hæmorrhages of all kinds; alſo in the fluor albus, and gonorrhœa.

CYNOGLOSSUS, in zoology, the name of a fiſh common in the Mediterranean ſea, and brought to market at Rome, Venice, and elſewhere. It much reſembles the ſoal-fiſh, but is not of half that bigneſs, and conſiderably ſhorter in proportion to its breadth. It is alſo of a whiter hue; the ſcales are larger; and the anus is ſituated, not in the ſide of the body, but in its under part. Its mouth is very large; its teeth ſharp; and its eyes placed very near each other. It is a much worſe fiſh for the table than the ſoal. *Geſner*, p. 788.

CYNOLUCOS, in natural hiſtory, a name given by the antient writers to a creature which had the ſhape partly of a dog, and partly of a wolf, and was generated, according to their accounts, by a mixture of thoſe two ſpecies of animals in copulation, as the leocrocotta was, between the hyæna and lioneſs. See LEOCROTTA.

CYNOMORIUM, a name given by Micheli, and continued by Linnæus, to a genus of plants, the characters of which are theſe: it produces ſeparate male and female flowers, but they ſtand almoſt cloſe to one another, in the ſame amentum or ear. In the male flowers the general cup is an erect amentum, imbricated on every ſide, and compoſed of oblong, erect, truncated ſquammæ, each containing one flower, and formed narrow at the bottom, and gibbous on one ſide, and hollow on the other; there are no petals, and in the midſt there ariſes, by way of a ſtamen, one firm and ſtrait filament, longer than the cup, and crowned with a double apex. In the female flowers the common amentum is the ſame as in the male, but they have no other cup than is formed by the leaves of the plant. The germen of the piſtil is globoſe; the ſtyle is ſingle, erect, firm, and of the length of the cup; the ſtigma is obtuſe; the ſeed is ſingle and naked. *Linnæi* Gen. Plant. p. 444. *Micheli* Nov. Gen. 12.

CYNOMUIA, the *dog-fly*, in zoology. See DOG-*fly*.

CYNOPHONTIS, Κυνοφονις, in antiquity, a feſtival obſerved in the dog-days at Argos, and ſo called απο της κυνας φονειν, i. e. from killing dogs; becauſe it was uſual on this day to kill all the dogs they met with. *Pott.* l. 2. c. 20.

CYNORRHODON, the *dog-roſe*, the common wild briar, or wild white roſe, the fruit of which is the hip, ſo common in our hedges. *Mont.* 51.

CYNOSBATOS, in botany, a word uſed as the name of different ſhrubs by different authors. It is now generally uſed as the name of the wild, or *dog-roſe*; but ſome authors have applied it to the common bramble; others to the oxycanthus, and others to the caper buſh. *Ger.* Emac. Ind. 2.

The fruit of the *wild roſe* is the *hip*, uſed in conſerve, and ſaid to be good in diſorders of the breaſt, &c. *Quinc.* Pharm.

CYNOSPASTOS, in botany, a name uſed by ſome authors for the *garden piony*. *Ger.* Emac. Ind. 2.

CYNOSURUS, *dog's-tail*, in botany, a kind of graſs called *criſtata* by Scheuchzer, and other authors; but in the Linnæan ſyſtem of botany, under this name, it makes a diſtinct genus of plants, the characters of which are, that the cup is only a partial covering, lying on one ſide, but large, and made of two leaves which are pennated, and remain when the flower is fallen. The glume contains many flowers, and is bivalve, the valves being ſlender, pointed, and equal in ſize; the flower is made of two valves, the exterior one is long, hollow, and bearded; the interior plain, and naked. The ſtamina are three capillary filaments; the antheræ are oblong; the germen of the piſtillum is of a turbinated form; the ſtyles are two in number, hairy and crooked; the ſtigmata are ſingle; the flower does not open, but nicely encloſes the ſeed, which is ſingle, of an oblong ſhape, and pointed at both ends. *Linnæi* Gen. Pl. p. 13.

CYNOZOLOS, in botany, a name given by ſome of the old Greek writers, and, from them, copied by Pliny, and the Latins, to expreſs the black *chamæleon thiſtle*, a poiſonous plant which it was very neceſſary to diſtinguiſh perfectly from the plant called the white chamæleon thiſtle, which was a ſafe and eſculent plant.

CYPERUS. In the Linnæan ſyſtem of botany, this is a genus of plants, the characters of which are, that the cup is an imbricated ſpike, the ſeveral ſcales of which are ſomewhat bent, of an oval figure, and boat-like form; and ſerve to keep the flowers ſeparate. It has no petals; the ſtamina are three extremely ſhort filaments; and the antheræ are oblong and furrowed; the germen of the piſtillum is extremely ſmall; the ſtyle is thread-like, and very long; the ſtigmata are three, and of a capillary form; it has properly no fruit but a ſingle, three-cornered, pointed, and naked ſeed. See Tab. 1. of Botany, Claſs 15. *Linnæi* Gen. Plant. p. 12.

CYPERUS *root*, in the materia medica, the name of a root uſed in medicine, of which there are two kinds, the long and the round; the long *cyperus* is of our own growth; the round, when genuine, we have from the Eaſt-Indies, but what is uſually ſold is the root of a baſtard kind, common about our own ditches, and called by authors, by way of diſtinction from the Indian kind *cyperus rotundus noſtras*.

TheIndian,round *cyperus* is a knobbed root, full of ſmall ſpecks and tubercles, brown on the outſide, and greyiſh within, of a ſlightly ſweet ſmell, and of an acrid taſte. The long *cyperus* is an oblong root, covered with a great number of fibres, not eaſily broke,of a duſky brown without,and a pale bright grey within, of an acrid taſte,and very agreeable ſmell,when freſh and good. The plants which produce them both, grow in watery places, and have leaves and flowers in ſome meaſure reſembling the water graſſes, which from their reſemblance to theſe, are commonly called *cyperus* graſſes. They are both poſſeſſed of the ſame virtues, and cure ill ſcented breaths, and are good in nephritic diſorders, and in colics, and in diſorders of the womb. They are taken either in powder, or decoction. *Pomet*'s Hiſt. of drugs, p 33.

The roots of *cyperus* are attenuants, and deobſtruents, promote urine, and the menſes, are good ſtomachics, and ſerviceable in the firſt ſtages of the dropſy.

CYPHOMA, CYPHOS, and CYPHOSIS, in medical writers, an incurvation of the ſpine, forming a crookedneſs of the back. *Blancard.* in voc.

CYPHON, κυφων, in antiquity, a kind of puniſhment uſed by the Athenians; it was a collar made of wood, ſo called becauſe it conſtrained the criminal who had this puniſhment inflicted on him to bow down his head. *Pott.* Arch. Græc. l. 1. c. 25. T. 1. p. 130.

CYPRESS, (*Cycl.*) *cupreſſus*, in botany. See CUPRESSUS.

Cypreſs nut is a very powerful aſtringent and balſamic. In diarrhœas, and dyſenteries, there is ſcarce any ſimple medicine preferable to it. It is alſo ſaid to be a good febrifuge; but at preſent is little regarded in the ſhops.

The *cypreſs tree*, though found in moſt of our old gardens, is, at preſent, leſs regarded than it really deſerves. It adds a conſiderable beauty to wilderneſſes, or clumps of evergreens. But, beſides this, it ought to be cultivated on account of its valuable wood. See the *Cyclopædia*.

All the ſpecies of *cypreſs* are propagated from ſeeds: theſe ſhould be ſown early in the ſpring, on a bed of warm, dry, ſandy earth, which ſhould be levelled very ſmooth. If the weather prove warm and dry, it will be proper to water the bed, taking care not to waſh the ſeeds out of the ground: in about a month's time, the plants will appear above-ground, which ought to be kept free of weeds. After remaining two years in this bed, they may be tranſplanted into a nurſery: the beſt ſeaſon for removing them is in April, on a cloudy day that ſeems to threaten rain; and, in taking them out of the ſeed-bed, the roots ſhould be preſerved entire, with a ball of earth to each plant. When they have been three or four years in the nurſery, they may be planted out for good; and, if deſigned for timber, the diſtance of eighteen or twenty feet ſhould be allowed every way around them. They muſt be well watered at firſt to ſettle the earth to their roots, which ought to be frequently repeated, if the weather proves dry. *Miller*'s Garden. Dict.

CYPRIANUS, in ichthyology, the name given by Ariſtotle to the *carp*. He has alſo called it *cyprinos*, and Athenæus, Oppian, and many other of the Greek writers uſe indifferently the one, or the other of the words. See CYPRINUS.

CYPRINUS, in the Artedian ichthyology. The name of a very extenſive genus of fiſhes, comprehending what have been before eſteemed many different genera; the characters are theſe: the branchioſtege membrane on each ſide contains three bones; the whole mouth is ſmooth and toothleſs, but low down in the jaws there are two hard and ſerrated bones, which ſerve as teeth, and over againſt theſe, there is one ſoft oval bone to anſwer them. The air bladder is as it were tied with a thread in the middle, and ſo divided into two parts. The fiſh is of the malacopterygious kind, and the two jaws are uſually of the ſame length, but ſometimes the lower one is ſomewhat longer than the upper. *Artedi* Gen. Piſc. 3.

The ſpecies of this comprehenſive genus are theſe: 1. The *cyprinus* with the iris of the eye, and the fins of the belly, and the anus, uſually red. This is the common roach called *mort* by theSwedes. 2. The *cyprinus* with the iris,and all the fins and tail red. This is the fiſh called *ſarfand routag* by the Swedes; the whole back is convex, and the pinna ani has fourteen bones; the vertebræ of this fiſh are thirty-ſeven in number. 3. The five inch *cyprinus*, with twenty-five bones in the pinna ani. This is the fiſh called *biorko*, or *biorkna*, ſometimes the *biork*-fiſh by the Swedes; the iris is of a ſilvery colour, and the fiſh was never deſcribed till Artedi met with it. 4. The *cyprinus* with a yellow iris, and with thirty-ſeven bones in the pinna ani. This is called by the Swedes *faren*; the back is ſomewhat ſharp in the fore-part, and the belly, toward the anus, is alſo ſharp; the fins are all of a hoary appearance, and the number of the vertebræ is forty-four. 5. The broad and thin *cyprinus*, with forty bones in the pinna ani. This is the *ballerus* of authors; the iris is of a ſilvery colour; all the fins are white; the length is ſeldom ſo much as a ſpan. 6. The mucous *cyprinus*, of a black colour all over, having the end of the tail even, not forked. This is the fiſh called by authors the *tinca*, or *tench*; the iris is red, and the linea lateralis is curved. 7. The *cyprinus* with twenty bones in the back fin, and the ſide line ſtrait. This is the fiſh called the *caraſſius* by authors; the back is ſomewhat acute in the anterior part, and the pinna ani has ten bones: the whole body of the fiſh is of a yelloviſh colour, and the upper jaw is longer than the under. 8. The *cyprinus* with four cirri, with little hooks on the third bone of the back fin, and the pinna ani. This is the *carp*, or *cyprinus nobilis* of authors; it is diſtinguiſhed from all the others by the cirri at the mouth, by the ſide lines being ſtrait, and by the back fin having from twenty-three, to twenty-four bones; the vertebræ are thirty-ſeven. 9. The two inch *cyprinus*, with red iris, and nine bones in the pinna ani. This is called by theSwedes the *mud*, *bud*,or *ſkitſpilig*; the body is long and thick, and the back convex. 10. The five inch ſpotted *cyprinus*, with the upper jaw longer than the under, and with two cirri at the mouth. This is the *gudgeon*, or *gobius fluviatis*. 11. The *cyprinus* with the upper jaw longer than the under, with four cirri, and with ſeven bones in the pinna ani. This is the *barbel*. 12. The oblong, large-ſcaled *cyprinus*, with eleven bones in the pinna ani. This is the *chub*, or *chevin*, the *capito*, or *cephalus* of authors; the ſcales are large, and angular, and the upper jaw is longer than the under. 13. The oblong *cyprinus*, with a ſilvery iris, and white fins. This is called *ſlam* by the Swedes; the pinna ani has eleven bones, and the length of the fiſh is ſix or ſeven inches. 14. The *cyprinus* with a yellow iris, with the belly fins and pinna ani, red. This is called *ad* by the Swedes; the pinna ani has thirteen bones; the whole back is convex, and the belly flat; the ſcales are large, and the linea lateralis curved; the length is fifteen, or ſixteen inches; the body is very thick, and the vertebræ are in number forty-one. 15. The *cyprinus* with a naſiform ſnout, very prominent, and with fourteen bones in the pinna ani. This is the *naſus* of authors; its belly is broad, and flat; all the fins of the under part of the body are ſomewhat rediſh; the ſcales are large; the lateral line runs very near the belly; the peritoneum is blackiſh: it is a river fiſh, and breeds in April. 16. The *cyprinus* with a naſiform ſnout, with a ſharp back, and with twenty-four bones in the pinna ani. This fiſh is called *wimber* by the Swedes, and was never deſcribed till Artedi met with it; the ſcales are large; the belly is acute near the anus; the ventral fins are pale-coloured,

coloured, and ſhining; and the peritoneum is of a ſilvery colour. 17. The *cyprinus* with all the fins black, and with twenty-ſeven bones in the pinna ani. This is the common *bream*, the *brama* of authors; the back riſes up in the anterior part, and before the *pinna dorſalis* is acute; the belly alſo is acute near the anus. 18. The five inch *cyprinus*, with twenty bones in the pinna ani. This is the *alburnus* of authors, called by us the *bleak*; the lower jaw in this fiſh is ſomewhat longer than the upper; the fins are all white. 19. The *cyprinus* with the lower jaw longer than the upper, and turned up at the point, with fifteen bones in the pinna ani. This is the fiſh called by the Swedes, the *aſp*; it is two or three foot long; the back is convex all the way, the lateral line crooked, and the belly fins, and pinna ani ſomewhat rediſh. *Artedi* Gen. Piſc. 4.

The *cyprinus nobilis*, or *carp*, is a well known pond-fiſh, of the leather-mouthed kind, and conſequently has no teeth, but, in their place it has a flat, triangular bone in the palate, and, over againſt it, in the lower part of the mouth, two dentated bones bending toward the throat. It has properly no tongue, but nature has, in the place of one, given it a fleſhy palate, which, when taken out, is ſo very like a tongue, that it has deceived not only the vulgar, but even many very good naturaliſts, into the opinion that it was one. The *carp* is almoſt always breeding, and the belly of the female is continually filled with ſpawn; they multiply prodigiouſly, and are found, like eels, in new ponds, and in lakes cauſed by rains, whoſe waters have no communication with thoſe of any other lake, or river, though none were ever put there; hence ſome have pretended to argue from experience, that they were produced without the aſſiſtance of parents of the ſame kind. *Ray*'s Ichthyography, p. 246.

The name *cyprinus* is originally Greek, and is derived from the word Κυπρις, the name of the goddeſs Venus, and was given to this fiſh to expreſs its being very much addicted to venery, and producing a very numerous offspring.

CYPRINUS *latus*, the broad *carp*, in zoology, a name given by many authors to the common *bream*. *Willughby*'s Hiſt. Piſc. p. 248. See BRAMA.

CYPRIUS *lapis*, a kind of adamant brought from *Cyprus*, with which the antients uſed to perforate other gems. *Hofm.* Lex. in voc.

CYPRUS (*Cycl.*) — CYPRUS *bird*, in zoology, a common name for the *atricapilla*, or *black cap*, a very ſmall bird well known in England, and much more plentiful in the iſland of *Cyprus*, where it is eſteemed a very delicate bird at table. *Ray*'s Ornithol. p. 162.

CYPRUS *wood*, in the materia medica, a name given by ſome authors to the *roſe-wood*, becauſe much of it is brought from the iſland of *Cyprus*.

CYRBASIA, Κυρβασια, among the Greeks, a kind of caps with high tops, in form of a cone, which were worn by the prieſts. See *Hofm.* Lex. in voc.

CYROCEPHALUS, in botany, the name given by ſome authors to the *antirrhinum*, the *calves's ſnout*, or *ſnap-dragon*. *Ger.* Emac. Ind. 2.

CYST, (*Cycl.*) in ſurgery, the bag, or membrane, in which an encyſted tumor of the ſteatomatous, atheromatous, or ſarcomatous kind, is included. In the extirpating theſe tumors, if, by neglect, or accident, the *cyſt*, or any conſiderable part of it be left behind, the tumor will not fail to return. Indeed, if the tumor be a ſchirrus, the contents are hard enough to make a clear extirpation of it, notwithſtanding its including coats be wounded: but when the matter of the tumor is ſoft, or fluid, by its eſcaping the tumor will become flaccid; ſo that it will be hardly poſſible to make a clear extirpation of the *cyſt*, without leaving ſome fragments of it behind, which muſt, in that caſe, be brought away afterwards by ſuppuratives, digeſtives, and a proper treatment; and when the ſinus is, by this means, cleared, the wound may be ſafely healed, without any danger of the return of the complaint. *Heiſter*'s Surgery, p. 327.

CYSTIS, (*Cycl.*) in botany, a name by which many of the antient Greek authors have called the *alkekengi*, or *winter cherry*. It had this name *cyſtis* from the remarkable character of its fruit being contained in a ſkinny bladder, or bag. It was generally, however, called *halicaccabum*.

CYTHINON, in botany, a name given by the antient Greeks, to the yellow wood called alſo *thapſum*, and *chryſoxylon*, a wood uſed in dying cloths, and by the ladies, in tinging their hair yellow, the favourite colour of thoſe times. It was called alſo *Scythicum lignum*, Scythian wood, from the country whence it was brought; and from this laſt name it is eaſy to deduce the name *cythinon*. The old Greeks often wrote *cythinon* for *Scythicon*, and the leaving out the initial *ſ*, which was a common practice among them, reduces this word to *Scythinon*, the name before us. Familiar inſtances of this practice occur to us in the words *milax*, for *ſmilax*, *maragdus* for *ſmaragdus*, &c.

CYTISOGENISTA, in botany, *broom-cytiſus*, the name of a genus of plants, the characters of which are theſe: the leaves and flowers agree partly with the broom, and partly with the *cytiſus*, but the leaves are placed on the ſtalks, ſometimes ſingly, ſometimes in a trifoliate order.

The ſpecies of *cytiſo geniſta* enumerated by Mr. Tournefort are theſe: 1. The common, yellow-flowered, beſom *cytiſo-geniſta*, called common *broom*. 2. The white-flowered, common *broom cytiſus*. 3. The Portugal, myrtle-leaved, *broom cytiſus*, with woolly pods. And, 4. The Portugal, *broom cytiſus*, with very large flowers. *Tourn.* Inſt. p. 649.

CYTISUS, *ſhrub trefoil*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the papilionaceous kind; from its cup there ariſes a piſtil, which finally becomes a flat pod, which ſeparates, when ripe, into two parts, and is full of oblong ſeeds. The leaves ſtand three on every ſtalk.

The ſpecies of *cytiſus* enumerated by Mr Tournefort are theſe: 1. The common, hairy *cytiſus*. 2. The hairy *cytiſus*, with longer pods. 3. The hairy *cytiſus*, with purpliſh, yellow flowers. 4. The ſmall-leaved *cytiſus*, with tender, hairy ſtalks. 5. The *cytiſus* with roundiſh, ſmooth leaves, ſtanding on very ſhort pedicles. 6. The green, ſmooth *cytiſus*. 7. The blackiſh, ſmooth *cytiſus*. 8. The hoary *cytiſus*, with narrow and complicated leaves. 9. The broad-leaved, Alpine *cytiſus*, with a pendulous, cluſtery flower. 10. The variegated-leaved, Alpine *cytiſus*, with a pendulous, cluſtery flower. 11. The narrow-leaved, Alpine *cytiſus*, with a long, pendulous, cluſtery flower. 12. The Alpine *cytiſus*, with a ſhort, pendulous, cluſtery flower. 13. The purple-flowered, ſpiked *cytiſus*. 14. The ſilvery, African *cytiſus*, with blackiſh, purple flowers. 15. The prickly *cytiſus*. 16. The dwarf, ſilvery, narrow-leaved *cytiſus*. 17. The very ſmall, viſcous *cytiſus*. 18. The flax-leaved, ſilvery *cytiſus*. 19. The medic-leaved, Montpelier *cytiſus*, with hairy, and very thick-ſet pods. 20. The tall, Spaniſh *cytiſus*, with anagyris leaves, and tufted flowers. 21. The dwarf, Spaniſh *cytiſus*, with glommerated flowers. 22. The medic-leaved, Portugal *cytiſus*, with flowers ſtanding in the alæ of the leaves. 23. The Portugal *cytiſus*, with very ſmall, ſilvery leaves, and ſmall white flowers. 24. The Portugal *cytiſus*, with little leaves, large flowers, and broad, and woolly pods. 25. The narrow-leaved, hairy, African *cytiſus*. 26. The prickly, American *cytiſus*, with yellow flowers ſtanding in the alæ of the leaves. 27. The ſhrubby, American, ſilky-leaved *cytiſus*. *Tourn.* Inſt. p. 648.

We have ſeveral ſpecies of this plant cultivated in the gardens of the curious, where ſome ſpecies make a very agreeable figure, as they grow to be eight or ten feet high, and in May are beautifully loaded with long ſtrings of yellow flowers.

They are all propagated by ſowing their ſeeds, which they afford in great plenty, in March, on a bed of good, freſh, light earth, ſifting over the ſeeds about half an inch of fine mould: in a month's time the plants will come up; they muſt be kept clear from weeds, and watered at times, if the ſeaſon prove dry. They ſhould remain in the ſeed bed, till the March following, when they ſhould be removed into nurſery beds at a foot diſtance, in rows three feet aſunder: here they muſt be watered, and their roots mulched till they are thoroughly rooted, and then the ground kept clear from all weeds. They ſhould remain here three years, and be then removed to the places they are to remain, in October, or elſe in February.

The antient botaniſts evidently were acquainted with two very different ſhrubs, under the name *cytiſus*; and there have been no ſmall errors about the true meaning of ſeveral paſſages in Dioſcorides and Theophraſtus, on occaſion of the miſtaking one of theſe things for another.

Dioſcorides deſcribes the *cytiſus*, as being a ſhrub with leaves white and hoary, both on the upper and under ſide, and of no uſe, or value, to mankind: as to its wood, Pliny tranſlates this account, and adds to it from Hyginus, that it was a very hardy, and ſtrong ſhrub, not being affected by heat, or cold, ſnow, or hail, or any other injuries of the weather, nor of its enemies, as Pliny expreſſes it, (*hoſtium.*) It is not very eaſy to conceive what enemies theſe ſhould be; but the moſt probable conjecture, as to this odd paſſage, is, that Pliny had tranſcribed it in his uſual careleſs way, and that what is called *hoſtium* ſhould be the word *noſtram.*

The ſenſe then is clear enough; the author had juſt before ſaid that the wood was good for no uſe to mankind; and therefore, when he was ſpeaking of the trees ſtanding a long time, and fearing the injuries of no weather, he might very well add, nor of us; for the wood being good for nothing, men would not be at the trouble of cutting it up. It is plain, however, that Theophraſtus means quite a different ſhrub by this name *cytiſus*; for, as Dioſcorides ſays that the wood of his was white throughout, and very light, Theophraſtus obſerves, that it was black at the heart, and as heavy and ſolid as ebony; and, in many places, where he ſpeaks of the hard and elegant woods uſed for inlaying, he mentions the *cytiſus* wood, coupling it with the ebony, heart of oak, and other the hardeſt, and moſt elegant woods known in his time.

Pliny mentions no other *cytiſus* than that of Dioſcorides, which was the common kind cultivated by the Greeks and Romans, as a food for cattle: he ſays, it was raiſed by ſeed, and came to its perfection in three years, and that it was gathered in the ſpring juſt after the time of its flowering; he adds, that this was uſually the office of children, or old women, unfit for other work, and was the cheapeſt of all the offices of huſbandry. It is eaſy to conceive that ſuch a ſhrub as the *cytiſus* of Theophraſtus, with a wood as firm as the heart of oak, and hard as ebony, did not come to perfection in three years from the ſowing; nor could any more be cut up by boys and old women, than eaten by cattle when taken up. There were, therefore, two kinds of *cytiſus* among the antients, the one ſown and cultivated as food for cattle, the other a wild tree, or ſhrub, growing in woods, and being larger than the ſown kind. Dioſcorides, and Pliny, deſcribe the firſt, and Theophraſtus alone the latter, except that Pliny has now and then taken a ſentence from Theophraſtus, when he mentions the *cytiſus* occaſionally among other hard woods, and placed it to the account of his manured *cytiſus*.

Ovid, indeed, where he mentions the *cytiſus* as a wild wood ſhrub, certainly means this kind mentioned by Theophraſtus:

Nec tenuis cytiſus curtave tinus abeſt.

And Columella[a] acknowledges both kinds. It may ſeem a natural objection that culture could never make ſuch a difference in this plant, as that it ſhould be hard and black in the wood, in its wild ſtate, and ſoft and white in the cultivated kind. But we are not to ſuppoſe that the cultivated and wild *cytiſus* were the ſame ſpecies of ſhrub, only altered by theſe two ſtates. The antients were not ſo accurate in their names as later botanical writers have been; and if a wood ſhrub, in ſome reſpects, reſembled their manured *cytiſus*, they would call it by that name, though it had not all the generical characters to make it the ſame.—[a] *Columella*, de R. R. l. 9. c. 4.

CYZICUM *marmor*, a ſpecies of marble ſo called by the antients from the great uſe made of it by a ſtatuary called Cyzicus. It was white, with fine narrow veins of black, and was called alſo *Proconneſium marmor*. See PROCONNESIUM *marmor*.

CZEMER, in medicine, a name given by the people of Hungary, and ſome of the neighbouring nations, to a very troubleſome diſtemperature of the wriſts, and lower part of the arms, to which the people of this part of the world are very ſubject. It conſiſts in a tumor not hard, but very painful to the touch. The general method of cure, is, by giving firſt a ſtrong emetic, and then confining the patient to his bed, and to the uſe of ſudorifics, which in ſome days carry it off. Phil. Tranſ. N° 243.

D.

D, In the Italian muſic, intimates that, in thorough baſſes, the treble or deſcant ought to play alone; as T does the tenor, and B the baſs. *Broſſard.* Dict. Muſ. in Voc.

DC, in the Italian muſic, an abbreviation of *Da Capo*, i. e. from the head or beginning: theſe words or letters are commonly met with at the end of rondeaus, or ſuch airs and tunes as end with the firſt ſtrain, and intimate that the ſong is to be begun again, and ended with the firſt part. *Broſſ.* Dict. Muſ. in Voc.

DAB, in ichthyology, a name given by the Engliſh to a ſmall fiſh of the pleuronectes kind, called by authors the *Paſſer Aſper* and *Limanda*. See PASSER ASPER and PLEURONECTES.

DABUH, a name given by the Arabs to the Hyæna. See HYÆNA. *Hoſm.* Lex. univ.

DACE, in ichthyology, the Engliſh name for the fiſh called by authors the Leuciſcus. According to the new ſyſtem of Artedi, this is a ſpecies of the Cyprinus; and it is called by ſome Albicula and Albicilla. See LEUCISCUS.

This fiſh is extremely common in our rivers, and gives the expert angler great diverſion. The *Dace* will bite at any fly; but he is more than ordinarily fond of the Stone Caddis, or May-fly, which is plentiful in the latter end of April and the whole month of May. Great quantities of theſe may be gathered among the reeds or ſedges by the water-ſide, and on the hawthorn-buſhes near the waters. Theſe are a large and handſome bait; but as they laſt only a ſmall part of the year in ſeaſon, recourſe is to be had to the Ant-fly. Of theſe the black ones, found in large mole-hills or ant-hills, are the beſt. Theſe may be kept alive a long time in a bottle, with a little of the earth of the hill and ſome roots of graſs; and they are in ſeaſon throughout the months of June, July, Auguſt, and September. The beſt ſeaſon of all is when they ſwarm, which is in the end of July, or beginning of Auguſt; and they may be kept many months in a wooden veſſel, waſhed out with a ſolution of honey and water, even longer than with the earth and graſs-roots in the vial; tho' that is the moſt convenient method to be taken with a ſmall parcel, taken for one day's fiſhing. In warm weather this fiſh very ſeldom refuſes a fly at the top of the water; but at other times he muſt have the bait ſunk to within about three inches of the bottom. The winter fiſhing for *Dace* requires a very different bait: This is a white maggot with a rediſh head, which is the produce of the eggs of the Beetle, and is turned up with the plough in great abundance. A parcel of theſe put in any veſſel, with the earth they were taken in, will keep many months, and are an excellent bait.

Small *Dace* may be put into a glaſs-jar with freſh water, and there preſerved alive for a long time, if the water be properly changed. They have been obſerved to eat nothing but the animalcula in the water. They will grow very tame by degrees. Vid. Philoſ. Tranſ. N°. 478. p. 23. ſeq.

DACOLITHUS, in zoology, a name given by many to a ſmall fiſh, a ſpecies of the Loach, and diſtinguiſhed by the name of *Cobitis barbatula aculeata* by Ray and others. It is a very ſmall fiſh, ſeldom exceeding two, or at the utmoſt three inches in length. Its head is broader and flatter than the reſt of its body: Its back is of a duſky brown, ſpotted with black; and its belly yellow. It has two beards on each ſide of the upper jaw; and on the coverings of the gills has, on each ſide, two prickles, or a double-pointed ſharp hook, by means of which it moves itſelf about among the ſtones. This fiſh loves ſhallow waters with a ſtoney bottom, and ſpawns in May and June. *Willughby*'s Hiſt. Piſc. p. 266.

There is another ſpecies of this fiſh, which has ten beards about its mouth, and otherwiſe reſembles this. There is an opinion that they ſwallow little ſtones, and they have hence the German name ſignifying Stone-ſwallowers, or Stone-biters.

DACTYLETHRA, or DACTYLITHRA, δακτυληθρα, δακτυλιθρα, *digitale*, among the antient phyſicians, a medicine uſed to provoke vomiting. It was a ſort of topical application, and is deſcribed at large by Oribaſius.

It ſeems to have begun from the common practice of thruſting the finger down the throat, to provoke the ſtomach to caſt up its contents. The next ſtep to this was, when the finger would not do alone, to rub it over with a preparation of ſcammony, or with the crude juice of the root of the plant: If this had no effect, the next method was to take eight or ten gooſe-feathers, and, rubbing them over with ſome medicinal oil, they thruſt theſe, as far as was neceſſary, down the throat: And when all theſe failed, they uſed the *Dactylethra*, which was made of ſome kind of ſoft leather ſowed together, and of ten or twelve digets in length, and of the ſhape of a finger. This they filled with wool to the length of ſix digets, and left the reſt empty, to be adapted to the finger; then they rubbed it over with one of the medicinal oils, and introduced it as far as was neceſſary into the ſtomach. *Oribaſ.* Collect. Med. l. 8. c. 6.

DACTYLUS, in ichthyology, a name uſed by many authors for the ſolen or razor-fiſh, ſuppoſed to be the *Dactylus* of Pliny, to which he attributes a quality of being luminous in the dark: but Mr. Reaumur has obſerved, that the common ſolen or razor-fiſh has no ſuch quality; but that the *pholas*, or, as the French call it, the *dail* has: and therefore it follows either that the *pholas* is the *Dactylus* of Pliny, or elſe that this author has attributed to one ſpecies of fiſh what is the peculiar property of another. What Pliny has recorded of them is, that they ſhine in the dark; and that they ſhine the more brightly in proportion to their having more water; that their light is ſeen in peoples mouths while they are eating them; and that the drops of water which fall from them upon the hands and the cloaths of perſons who eat them, have the ſame ſhining quality. The ſhell of this creature is not at all luminous, but only its body and juices; and in this it is no way allied to ſome kinds of fiſh, which are known to have the quality of ſhining in the dark, ſince they never ſhine till they are in a ſtate of decay, and in part rotten; whereas theſe have their luminous quality at all times, even when juſt taken out of the ſea. The glow-worm has only a part of its body luminous, but the *pholas* is luminous all over, and is equally ſo in every part: and when the fiſh is taken whole out of the ſhell, and laid in a dark place, every part of its ſurface ſhines with a very bright light: neither is the light peculiar to the external ſurface of the fiſh, but common to the whole body; for if it be wounded tranſverſely, or longitudinally, the cut parts are equally luminous with the other ſurfaces.

The *pholas* is therefore a true natural phoſphorus, and, like the artificial phoſphorus of urine, it renders every thing luminous that it is rubbed againſt. It is ſcarce poſſible for the fingers to touch them without becoming luminous; and, according to Pliny, they muſt, if eaten, make the lips, tongue, teeth, and every other part of the mouth which they touch, luminous in the dark. Mr. Reaumur obſerved of this fiſh, that when freſh caught it abounds with water, and that this water naturally drops away in the handling it; and, according to Pliny's juſt obſervation, theſe very drops of water are luminous.

The light which this fiſh gives to bodies that touch it, is not of any long continuance, but remains only while they are wet. Mr. Reaumur obſerved, that the light upon his fingers grew fainter and fainter by degrees as they dried; and that on dipping them in water to waſh them, it brightened up again. This author was encouraged by this to attempt ſome way of keeping the fiſh, ſo as to make it a phoſphorus ready for uſe at pleaſure; but this did not ſucceed to his wiſhes. His firſt trial was by drying the fiſh, which loſt its luminous property as it loſt its natural moiſture; but after four or five days, on being wetted, became ſomewhat luminous again. This light however was but very faint, in compariſon of the natural one in the vigorous ſtate of the animal; and all his other trials ſucceeded worſe than this.

In the ſummer months, the fiſh may be kept ſeveral days freſh, and with their luminous property; but as they begin to decay, they gradually loſe it. It ſeems alſo, that there being ſome dead ones among the living, would make them loſe their luminous quality, even in that which is their very beſt ſtate. It is well known, that the *pholas* lives in holes within ſtones, from whence it cannot get out; and Mr. Reaumur cauſing ſome of theſe ſtones to be taken up, in which, on breaking, there appeared to be ſome dead ones, and ſome alive, found that the living fiſh from theſe ſtones had not their luminous property, which ſeemed as it were extinguiſhed by the dead and ſtinking ones. Mem. Acad. Par. 1723.

DACTYLUS *Idæus*, in natural hiſtory, a name given by many authors to the Belemnites; ſuppoſed erroneouſly by many, to be the *Lyncurius* of the antients. For other meanings of the word, ſee DACTYLI, *Cycl.*

DÆDALA, δαιδαλα, in antiquity, two feſtivals in Bœotia, one of which was obſerved by the Platæans at Alalcomenus, where was the largeſt grove in all Bœotia. Here they aſſembled, and expoſing to the open air pieces of ſodden fleſh, carefully obſerved whither the crows that came to feed upon them took their flight, and then hewed down all thoſe trees on which any of them alighted, and formed them into ſtatues, which by the antient Greeks were called *Dædala*.

The other ſolemnity was by far the greateſt and moſt remarkable of the two, being celebrated only once in ſixty years. For the ceremonies obſerved in it, ſee *Pott.* Archæol. Græc. l. 2. c. 20.

DÆDIS, Δαιδις, among the Greeks, a ſolemn feſtival that laſted three days, during all which time torches were kept burning, which gave occaſion to the name. *Pott.* Archæol. Græc. l. 2. c. 20.

DÆSION, Δαισιων, in antient chronology, the Macedonian name for the Athenian month *Antheſterion*, which was the ſixth of their year, and anſwered to the latter part of our November and beginning of December. See ANTHESTERION and MONTH.

DAGUS. See DEIS.

DAIE, in zoology, a name under which Nieremberg has described a bird of the size of a pigeon, which, he says, lays forty or fifty eggs, each as large as that of a goose, but having no white: these eggs, he says, as well as the bird itself, are commonly eaten, and are called by the Indians *Tapun*; and that it digs a hole in the sand in a ditch-bottom, and there lays, and leaves the eggs covered with sand to be hatched by the sun. *Ray*'s Ornithol. App. p. 29.

Mr. Ray declares all this to be false and fabulous, and is of opinion that there is no such bird in nature; for though there are some birds which lay eggs very large in proportion to their own size, as the wild swan, and some of the smaller water-fowls, yet these birds lay only one such egg; not to mention the great improbability of any egg being without a white.

DAILE, in a ship, the trough wherein the water runs over the decks.

DAIS. See DEIS.

DAISY, *Great* DAISY. See LEUCANTHEMUM.

DAKER *Hen*, in zoology, the English name for the *ortygometra*, a bird of the gallinaceous kind, somewhat resembling the quail, and called by the Italians the king of the quails, *Re delle quaglie*. It is larger than the quail, and is common in Ireland, and in some of the northern counties of England. *Ray*'s Ornithol. p. 122. See ORTYGOMETRA.

DAKIR, in our statutes, is used for the twentieth part of a last of hides.

According to the statute 51 Hen. 3. *De compositione ponderum & mensurarum*, a *last* of hides consists of twenty *Dakirs*, and every *Dakir* of ten hides. But by 1 Jac. cap. 33. one *last* of hides or skins is twelve dozen. See DICKER.

DALEA, in botany, the name of a genus of plants, the characters of which are these: the cup is small, one leaved, and divided into five segments. The corolla is composed of five petals, which are unequal; four of them being oblong, obtuse, strait, hollow, and equal in size; and the fifth, which stands above, smaller than the others. The stamina are ten diadelphous filaments; the antheræ are roundish; the germen of the pistil is oval, and terminates in a pointed stylus of the length of the stamina; the stigma is simple; the fruit is an oval bivalve pod, consisting of only one cell, and containing only one seed. *Linnæi* Gen. Plant. p. 336.

DAMASONIUM, in botany, the name of a genus of plants, called by most authors by a very improper name, *starry-headed water-plantain*. The characters of the genus are these: the flower is of the rosaceous kind, usually consisting of three leaves, disposed in a sort of circular form. From the flower-cup arises a pistil, which finally becomes a star-fashioned fruit, consisting of several capsules, and containing oblong seeds.

There are only two known species of *Damasonium*: 1. The common *Damasonium*, called *starry-headed water-plantain*: and 2. The great American *Damasonium*, with plantain leaves, yellow flowers, and a globose fruit.

DAMATRIUS, in antient chronology, the Bœotian name of the Athenian month *Pyanepsion*, which was the fifth of their year, and corresponded to the latter part of our October and beginning of November. See PYANEPSION and MONTH.

DAMIER, in conchyliology, the name given by French naturalists to that elegant species of voluta, the spots of which stand in a chequered order, and resemble the marks of a draught or chess-board, that being the common signification of the word *Damier*. See VOLUTA.

DAMPS, (*Cycl.*)—The pernicious damps in mines shew abundantly, that nature affords us inflammable air in some cases; and we have found by experiments that art can do the same, and that very probably on the same principles with the natural. Sir James Lowther having collected the air of some of these damps in bladders, preserved it so well, that, when brought up to London, it would take fire at the flame of a candle, on being let out by the orifice of a piece of tobacco-pipe.

It is well known to all that are versed in chymical experiments, that most metals emit a great quantity of sulphureous vapours during the effervescence they undergo in the time of their solutions in their respective menstruums. On this principle Mr. Maud founded his attempt of producing an inflammable air by art, like the natural one. It is observed that iron, while under solution with oil of vitriol, emits a very great quantity of these vapours, which are very subtile, and not easily condensed. This vapour being received into bladders, in the same manner with the natural air of Sir James Lowther, took fire in the same manner, on being let out in a small stream, and answered all the phænomena of the natural kind.

The exact method of preparing it is this: Take two drams of oil of vitriol, mix it with eight drams of common water; put this into a glass with a flat bottom, about ten inches wide and three deep, with a long neck. To this put in two drams of filings of iron. The solution instantly begins with great heat and ebullition, and vapours are copiously thrown up to the top of the neck of the glass. Lute a bladder empty of air, and, with a tobacco-pipe fastened in its neck: the fumes of the solution will soon fill up the bladder. When it is blown full, tie the neck fast with a string, and then put another in its place; and so on, taking them away as fast as they fill.

The air being afterwards let out at the hole of the tobacco-pipe, will take fire at the approach of the flame of a candle. It usually happens, that in removing the hands to press the bladder in other places, after some of the air is squeezed out, the fire is sucked into the bladder: in this case it fires all the remaining air in the bladder at once, and goes off with a violent explosion, like the report of a gun.

One thing very worthy of notice in the course of this experiment, is, that the air which successively fills several bladders, during the time of the effervescence, must have been either generated *de novo* out of the mixture, or else recovered from being locked up in the body of the metal in an unelastick state. This experiment will easily explain a very probable cause of earthquakes and volcanos, and all other fiery eruptions out of the earth; since by this it appears, that nothing more is necessary to form them than an intervention of iron, with a vitriolick acid, and water. Now iron is generally found accompanied with sulphur, and common sulphur may be analysed into an inflammable oil, and an acid liquor, like oil of vitriol. This acid therefore in the bowels of the earth, by being diluted with a little water, becomes a menstruum capable of acting upon iron, as above described; and an effervescence and intestine heat and tumult must be the consequence. The air which comes from the mixture is rarified; and by how much the more it is compressed by the incumbent earth, by so much the more its impetus will, at length, be increased to an unlimited degree, and like gunpowder it will cause explosions, and make earthquakes and eruptions. Nor does there always need the access of fire to set these vapours to work; for the air in the bladders, if it have been very much heated, will of itself take fire as soon as it is brought into contact with the external air. Philos. Transf. N°. 442. p. 282. and 286.

The German miners think themselves not qualified for their business, if they are not able to make their weather, as they express it; that is, to cure their damps. These are of various kinds in their mines; some so strong that they suffocate the workmen; others less violent, and only making them faint, without doing them any farther hurt, unless they are so imprudent as to continue a long time in the place. The common way of curing the damp is by letting the air in and out, and causing a circulation in it. They sometimes have cured very considerable damps by blowing, for many days together, with large bellows: but the ordinary method of working is by means of long tubes communicating with the air above, by means of which they have continual fresh air, and are able to work on as far as they please. Some of the cuniculi of these mines are five hundred fathoms long; and in the silver trinity-mine by Sebemnitz, there is a passage quite thro' a very large hill, coming out on the opposite side to that where it enters. The tubes always answer very well in the horizontal cuts; but not in the perpendicular ones, when they go to great depths: in these they place a tube all the way down by one side, and they then fit a piece of wood-work to the size of the hole or cut; and several times in a day they are forced to thrust this down, in order to force up all the foul air that is in the pit by the tube, to give room for fresh air in its place. Phil. Transf. N°. 48.

In some of the coal-pits in the neighbourhood of Mendip hills, fire-damps almost continually happen, so that great numbers have been killed, maimed, and burnt by them. The colliers however continue their work notwithstanding, only using the cautions of renewing their air very quick, and using no candles in their work but those of a single wick, and of sixty or seventy to the pound; which notwithstanding will give as good a light there, as others of ten or twelve to the pound in other places. They always have the caution to place even these behind them, and never present them to the breast of the work. When any person is burnt by these damps, they presently betake themselves to a good fire, and, sending for a large quantity of cows milk, they bathe the burnt places with this while warm; and afterwards the places will heal by the common cooling ointments, and healing plaisters.

In regard to the periodical returns of these damps, mentioned by some, we find that by the caution of small candles, used by the colliers of these places, that there is a continual propensity in them to take fire at all times of the year; and though these works seldom do take fire, yet, as the colliers say, they are most subject to it in the violence of winter, and chiefly in a black frost. The danger of firing is alike both in wet and dry grounds. There are no fumes coming out at the mouth of any shaft in these places, which will take fire at lighted torches or candles being held over them. They sometimes take fire of themselves, and set fire to the coal of the mine: they seem to be as frequently on or near the floor of the pits, as about their roofs; and no current of vapours, or wind, is to be met with at the mouths of the shafts by which they go down to these pits. In wet works there are many times bubbles standing on the surface of the water, which will take fire if a candle be held to them; but these, on a close examination, do not appear to be occasioned by subterraneous vapours; but are owing to the dropping of water from the roof of the mine, or the falling in of pieces of coal. These damps are commonly observed in our coal-pits; but the lead-mines on Mendip-hills are also sometimes affected by them. Philos. Collect. p. 8.

DANAE, or DANACE, Δαναη, or Δανάκη, in antiquity, a coin current among the barbarians, being ſomewhat more than the obolus. (See OBOLUS, *Cycl.*) This they put into the mouths of dead people, to pay for their paſſage over the river Acheron. *Pitiſc.*

DANCRETA, in botany, a name given by the people of Guinea to a plant which they uſe in diſorders of the head, boiling it in water, and uſing the decoction in the way of a fomentation. It is a ſpecies of bindweed, and is called by Pettiver *convolvulus quinque foliis Guineenſis foliis non ſerratis*, or the five-leaved Guinea bindweed with leaves not ſerrated. Caſpar Bauhine, in his Prodromus, deſcribes a ſpecies of bindweed growing in Egypt, which exactly agrees with this in all particulars, except that it is finely ſerrated all round the edges of the leaves. Phil. Tranſ. N°. 292.

DANDELION, in botany. See DENS LEONIS.

DANELAGE. See LAW, *Cycl.*

DANGCANGHAC, in natural hiſtory, the name given by the people of the Philippine-iſlands to the heron. The Spaniards call it *gazza*. It is the ſame ſpecies with that ſo common in Europe. See ARDEA.

DAPHNE, Δαφνη, in antiquity, a kind of divination, taken from the crackling of laurel-leaves thrown into the fire. *Pott.* Archæol. Græc. l. 2. c. 18. T. 1. p. 352.

DAPHNEPHORIA, δαφνηφορια, in antiquity, a novennial feſtival, celebrated by the Bæotians in honour of Apollo. For the ceremonies uſed at this ſolemnity, ſee *Pott.* Archæol. Græc. l. 2. c. 20. T. 1. p. 378.

DAPHNIUS *Lapis*, in natural hiſtory, the name of a ſtone the veins of which repreſent the grain of the wood of the bay-tree, and which was probably formed of the wood of that tree, impregnated with ſtony matter, in the manner of the other foſſil woods.

DAPIFERAT, DAPIFERATUS, the office of dapifer. See DAPIFER, *Cycl.*

DAPPLE *Bay*, in the manege, is uſed for a horſe which has marks of a dark bay colour. Such are alſo called *Bays a mirroir*.

DAPPLE *Black*, in the manege, a black horſe, having ſpots or marks blacker and more ſhining than the reſt of his ſkin.

DAPSILES *Coronæ*, among the Romans, a kind of crowns or garlands worn by the women, which covered their faces, and ſerved as a vail. *Hofm.* Lex. in Voc.

DARANI, in the Materia Medica, a word uſed by ſome of the old writers to expreſs the ſal armoniac of thoſe times, which was the ſame with our ſal gemmæ.

DARDANARIUS, in antiquity, is uſed to ſignify an engroſſer, or one that monopolizes any commodity. The name is derived from one Dardanus, famous for this practice. *Hofm.* Lex. in Voc.

DARE, in ichthyology, an Engliſh name for the common dace, or leuciſcus. See DACE and LEUCISCUS.

DARKENED *Room*. See CAMERA, *Cycl.*

DARSINI, in the Materia Medica of the antients, a name given by ſome to cinnamon. It is generally uſed by Aviſenna, Serapion, and the reſt of the Arabian phyſicians. It appears from the name, however, that the cinnamon of thoſe times was collected in the ſame manner as the xylocaſia, or caſſia lignea was; that is, the bark was not ſtripped off from the branches, but the young branches were uſed, bark and all. It is thence it had this name among them, which expreſſes wood of China, not bark of China. *Dar* is a Perſian name for wood, and is borrowed by the Arabians on this occaſion. *Dar Xixgan* is the name of the aſpalathum, or roſe-wood, and ſignifies wood brought from Xixgan; and in the ſame manner *Dar* is often preſixed to words, ſignifying that the ſubſtance meant by them is a wood. Many of the antients have confounded cinnamon and caſſia together; but Aviſenna always keeps them diſtinct. He always tranſlates the caſſia of Dioſcorides, *Salicha*; and the cinnamomum of the ſame author, *Darſini*.

DARSIS, in medical writers, is uſed for an excoriation of the ſkin. *Blancard.*

DARTS *of Gnats*. See the Article GNAT.

DARU, in botany, a name given by Aviſenna and Serapion to a ſpecies of turpentine-tree, which the latter author calls the lentiſk. This grew up to a very large tree, and bore a much larger and more beautiful fruit than the common turpentine-tree. The tree itſelf was alſo more beautiful in the manner of its growth; and it had, in common with the ordinary turpentine-tree, the property of the ends of its leaves becoming red, which gave the whole a very beautiful appearance. Theophraſtus ſeems to have mentioned this tree, tho' without diſtinguiſhing it from the common turpentine-tree by any peculiar name: he ſays, that tho' in Greece the turpentine-tree was but a ſhrub, yet in Syria and ſome other places it grew up into a large tree. And Rawwolf, in his Itinerary, tells us, that beſide the common turpentine-tree known to us, there are two other ſpecies in Arabia; the one called at this time *Bout Quibir*, which, he ſays, bears the ſame ſort of fruit with the Piſtachia, but that it is larger and more round, and ſhort in proportion to its thickneſs. This ſeems to be the *Aldare* of Aviſenna, which he characteriſes by the largeneſs of the fruit. The other Arabian turpentine-tree, mentioned by Rawwolf, is ſmaller, and is called *Bout Saugier*, or *Seguir*: this does not grow to more than the ſize of a common garden-pea; but has the leaves, fruit, and properties of the turpentine-tree. *Rawwolf*'s Itinerary.

DASYMMA, a ſuperficial inequality of the inner part of the eye-lids, accompanied with a redneſs. *Blancard* derives it from δασυς, *hirſutus*.

DATURA, in botany, a name given by many authors to the plant more uſually called *Stramonium*, or the *thorn-apple*. See STRAMONIUM.

DAVACA *terræ*, a portion of land in Scotland ſo called; & *apud priſcos Scotos*, DAWACH of Land, *quod continet quatuor Aratra terræ, quorum unum quodque trahitur octo bobus. Skene.*

DAUCI *Semen*, in the Materia Medica, the name of a ſeed uſed in many of the officinal preparations. The plant which produces it is a ſort of *myrrhis*, or chervill, called *Daucus Creticus*, or candy carrot, by the old authors; but by the moderns *Myrrhis Annua ſemine ſtriato, villoſo, imano*.

The leaves of this plant are finely divided, and hairy; the ſtalks ſlender, and a foot high; and the flowers ſtand in umbells. The ſeeds are of a pale green, hairy and whitiſh, and ſomething like cummin-ſeed; but not ſo long or large, or of ſo ſtrong a ſmell, but of an agreeable flavour, when held ſome time in the mouth. This ſeed being hairy, has very frequently little animalcules and duſt hanging to it; and this fault grows worſe, the longer it is kept, as the animals continue to eat the ſeed, and their excrements become mixed with it in large quantities. It ought therefore to be choſen new, plump and full, and very clean. *Pomet*'s Hiſt. of Drugs, p. 5.

It expels wind, and is good againſt cholics, pains of the womb, and in hyſterical complaints.

DAUCUS, in botany, the name of a large genus of umbelliferous plants, the characters of which are theſe: the flower is of the roſaceous kind, conſiſting of ſeveral heart-faſhioned petals unequal in ſize, and diſpoſed in a circular form. The cup finally becomes a fruit, compoſed of two ſeeds furniſhed with long hairs in the manner of the eye-laſhes of animals. *Tournefort*, Inſt. p. 307.

The ſpecies of *Daucus* enumerated by Mr. Tournefort are theſe: 1. The common yellow-rooted *Daucus*, or yellow carrot. 2. The *Daucus* with yellow roots and yellow-flowers. 3. The orange-coloured-rooted garden *Daucus*, or carrot. 4. The white-rooted carrot. 5. The red-rooted carrot. 6. The common wild carrot, or birdſneſt. 7. The ſea *Daucus*, with ſhining leaves. 8. The viſcid or gummy ſea *Daucus*, with fine ſhining leaves. 9. The American *Daucus*, with ſhining leaves. 10. The Spaniſh *Daucus*, with very large umbells. 11. The narrow-leaved cretic *Daucus*, with very long rays to the umbell. 12. The annual *Daucus*, with flowers at all the knots of the ſtalk, called by authors the knotty Caucalis with rough ſeeds. 13. The little annual *Daucus*, with red flowers, called by ſome the red-flowered Caucalis: and 14. The little annual *Daucus*, with white flowers. *Tournefort*, Inſt. p. 308.

DAUCUS *Sativus*, the carrot. There are two or three ſorts of this plant cultivated for the uſe of the kitchen; and theſe are ſown at ſeveral different ſeaſons of the year, to afford a ſupply of young roots, in all ſeaſons, for the table.

The ſeaſon for ſowing them, for the earlieſt crop, is ſoon after Chriſtmas. They ſhould be ſown in an open ſituation, but near a wall; though if they are ſown cloſe under it, they will be drawn up to ſeed too faſt, and give no good roots: about eight inches diſtant is the propereſt place.

They delight in a warm ſandy ſoil, which ſhould be light, and well dug to a good depth, that the roots may meet with no obſtruction in running down, which makes them grow forked, and ſhoot out lateral branches, eſpecially when the ground has been too much dunged the ſame year that the ſeeds were ſown, which will alſo occaſion their being worm-eaten. The hairyneſs of theſe ſeeds makes them apt to ſtick together in ſmall cluſters, and renders it difficult to ſow them equally: they ſhould therefore be always ſown on a calm day, when there is no wind ſtirring to blow them together, and be well rubbed between the hands to ſeparate them thoroughly: when they are ſown they ſhould be trod in with the feet, and the ground raked level over them.

When they firſt come up, they ſhould be houghed out to four inches diſtance; and a month after this, they muſt be cleared again; and if they are to be drawn while young, they are now to be left at ſix inches diſtance every way: if they are to ſtand to grow large, they muſt be ſeparated to ten inches.

The ſecond ſeaſon for ſowing carrots is in February. This muſt be done under a wall or hedge, and on warm banks; but thoſe which are to be in open large quarters, ſhould not be ſown till the beginning of March. See *Miller*'s Gard. Dict. in Voc.

In July they may be ſown again for an autumnal crop, and finally in the end of Auguſt for thoſe which are to ſtand the winter. Theſe laſt will be fit for uſe in March, before any of the ſpring ones; but they are ſeldom ſo tender or well taſted. In order to preſerve carrots for uſe all winter, they are to be dug up in the beginning of November, and laid in a dry place in ſand; and theſe roots being planted again in February, will ripen ſeeds in Auguſt for ſucceeding crops: the longeſt and ſtraiteſt roots are to be choſen for this purpoſe.

DAUCUS *Sylveſtris*. The ſeeds of this plant are eſteemed

one

one of the moſt powerful diureticks, we are acquainted with, of our own growth. They are alſo given in diſorders of the breaſt and lungs, in pleuriſies, in ſtranguries, and in the ſtone and gravel. They are alſo eſteemed provocatives to venery. An infuſion of them in white wine is excellent in hyſterical comp'aints.

DAUGHTERS, among the antients, were more frequently expoſed than ſons, as requiring greater charges to educate and ſettle them in the world. Potter. Archæol. Græc. l. 4. c. 14. T. 2. p. 332. See EXPOSING *of Children*.

Thoſe who had no legitimate ſons were obliged, by the Athenian laws, to leave their eſtates to their daughters, who were confined to marry their neareſt relations, otherwiſe to forfeit their inheritance; as we find to have been practiſed likewiſe among the Jews, many of whoſe laws ſeem to have been tranſcribed by Solon.

If an heireſs happened to be married before her father's death, this did not hinder the neareſt relation to claim the inheritance, and even to take the woman from her huſband; which is ſaid to have been a common caſe. *Potter* Archæol. Græc. l. 4. c. 15. T. 2. p. 441. ſeq.

DAVIT, a piece of timber in a ſhip, having a notch at one end; in which, by a ſtrap, hangs a block, called the *fiſh-block*: the uſe of this is to hale up the fluke of the anchor, and to faſten it at the ſhip's *bow* or *loof*. This *Davit* may be ſhifted from one ſide of the ſhip to the other, as occaſion ſerves.

There is a ſmall *Davit* in the ſhip's boat, which is ſet over her head with a ſheever, into which is brought the buoy-rope to weigh the anchor: it ſtands in the carlings in the boat's bow.

DAUPHIN, (*Cycl.*)—DAUPHIN, in natural hiſtory, is the name of a ſpecies of ſhell-fiſh. It is one of the round-mouthed ſnails, or *Cochleæ Lunares*, and is ornamented with rows of indented eminences on all the turns of the ſhell.

DAWELL *Coronde*, in the language of the Ceyloneſe, drum-cinnamon. This is called in Low Dutch *Tromm cel Caneel*. The reaſon of the name is, that the wood of the tree which affords this ſpecies, when dried, is light and tough, and is uſed to make drums of. The bark is taken off while the tree is growing, and is of a pale colour. It is a very bad kind of cinnamon, and is very rarely ſold as ſuch; but the natives uſe it in medicine. Philoſ. Tranſ. N°. 409.

DAY, (*Cycl.*)—DAY-COAL, in natural hiſtory, a name given by the miners of England, and the common people who live in coal-countries, to that ſeam or ſtratum of the coal which lies uppermoſt in the earth. The ſame vein or ſtratum of coal uſually runs a great way through the country, and dips and riſes in the earth in different places; ſo that this upper ſtratum, or day-coal, is in the various parts of the ſame ſtratum, ſometimes near the ſurface, and ſometimes at many fathoms deep. The ſubterranean fires found in ſome of our coal-countries principally feed on this coal, and are nearer, or farther from the ſurface as it riſes or ſinks. Phil. Tranſ. N°. 130.

Grand DAYS. See GRAND.

Law DAY. See LAW *Day*.

DAZE, in natural hiſtory, a name given by our miners to a ſort of glittering ſtone, which often occurs in their works; and, as it is an unprofitable ſubſtance, is one of thoſe things which they call weeds. The word *Daze* takes in, with them, every ſtone that is hard and glittering; and therefore it comprehends the whole genus of the *Telangia*, or ſtony Nodules, which have flakes of talc in their ſubſtance: theſe, according to the colour of the ſtony matter they are bedded in, and their own colour, give the names of *black Daze*, *white*, *red*, and *yellow Daze* to theſe ſtones. The *Daze* ſtones in general much reſemble ſome of thoſe nodules with which the ſtreets of London are paved. But in ſome, inſtead of the matter forming regular nodules of a compact ſubſtance, it forms itſelf into a vaſt number of thin plates, which are applied cloſely over one another, and form ſhelves or even ſeries of planes, encompaſſing, ſometimes a roundiſh, ſometimes an oblong maſs of ore.

Theſe *Dazes* are generally of the poorer part of the vein. The ſhoad-ſtones are many of them of this nature, and the ends of the veins degenerate again into them. The beds of rivers in Cornwall afford large quantities of theſe nodules; and as there is alſo granite in that county, and pieces from the ſtrata of that ſtone are ſometimes worn, and rounded into pebble-like ſhapes, and found in the ſame rivers; theſe having alſo flakes of talk in them, are always called by the miners *Daze*. This however leads to no error in the working; for theſe are never found, except in the rivers; and the miners never attempt to trace a vein from any thing found in the bed of a river, becauſe they know how uncertain the original place of that ſtone may be, which has been for ſo many ages ſubject to be toſſed about by the ſtream of a river, perhaps often rendered more rapid by land-floods. Philoſ. Tranſ. N°. 69.

DEAD, (*Cycl.*)—DEAD *Mens-eyes*, in a ſhip, are a kind of blocks, having many holes in them, but no ſheevers; and through them the *lanniers* go, which make faſt the ſhrowds to the chains. Sometimes the main-ſtays of a ſhip are ſet taught in *Dead-Mens-eyes*; but moſt great ſhips uſe double blocks. The *crowfeet* reeve through the *Dead-Mens-eyes*. *Manwayring*.

DEAD *Nettles*, in botany. See SAMIUM.

DEAD-*riſing*, a term in a ſhip for that part of her which lies aft between the keel and her floor-timbers, and next adjoining to the ſtern-poſt under the bread-room, in a man of war. *Guillet*.

DEAD *ropes*, in a ſhip, are ſuch as are not running, *i. e.* which do not run in any block.

DEADING *bed*, among miners. See DEADS.

DEADS, in mining, is uſed to expreſs that part of the ſhelf or faſt ground which contains no ore, but which encloſes the vein or bed of the ore, like a wall on every ſide. The drifts which they ſink for the tin-ore in Cornwall are generally about three feet over, and about ſeven feet high; ſo that a man may conveniently ſtand upright at work, and manage his tools. In caſe the vein itſelf is not broad enough to allow this, as in many places it is not half a foot over, then they pick down the ſtrata that encloſe it, ſo as to make an opening of the ſame breadth. This work they call *breaking up the deads*. Phil. Tranſ. N°. 69.

This word is alſo uſed for ſuch parcels of common looſe mould or earth, lying above the ſhelf, as uſually contain the *ſhoad*, which they find when they are training a load.

In the Mendip lead-mines, when a vein of ore breaks off abruptly in an earth, they call it a *Deading-bed*; and earth without oar they call *Dead earth*.

DEAL. A well-known kind of wood, of great uſe.

A very good method of ſeaſoning planks of *Deal* and fir, is to throw them into ſalt-water as ſoon as they are ſawed, and keep them there three or four days, frequently turning them. In this caſe they will be rendered much harder, by drying afterwards in the air and ſun; but neither this nor any other means yet known, will preſerve them from ſhrinking.

Rods of *Deal* expand laterally, or croſs the grain, in moiſt weather, and contract again in dry; and thence have been found to make an uſeful hygrometer. Phil. Tranſ. N°. 480. p. 184. See HYGROMETER, *Cycl.* & *Suppl.*

DEATH, (*Cycl.*)—It is generally taught, that the life of thoſe animals, which we call perfect, conſiſts in a continued flux and reflux of blood, nervous juice and air, to and from the principal organs; and that a man may be reckoned dead when he no longer breathes, and his heart and arteries have left off all circulation and pulſation. Even Lanciſi, the beſt author on this ſubject, ſays, that without a ſmall degree of reſpiration, and ſome little motion or trembling of the heart, there is no life. In conſequence of this ſyſtem, the general practice is, that as ſoon as theſe ſymptoms of life are gone, all hopes and endeavours to maintain the ſmall remains of life are laid aſide. But Dr. Stevenſon does not admit this doctrine, being of opinion, that after the motion of the heart, arteries, and lungs ceaſes, there often remains a ſmall degree of vital principle, deſerving attention. After a full ſtop of all thoſe organic motions on which life is ſaid to depend, the juices frequently retain ſo much of the animal proceſs as frequently ſerves to keep up warmth for a long time; which, with proper cheriſhing, might perhaps reſtore life entirely. Every age and country affords inſtances of ſurprizing recoveries after lying long for dead. From the number of thoſe preſerved by lucky accidents, we may conclude a far greater number might have been preſerved by timely pains and ſkill. Med. Eſſ. Edinb. Vol. 5. Art. 77.

This ingenious author hopes, from his theory, that one who from all the abovementioned motions ceaſing, may with propriety be called dead, may recover, and be properly ſaid to come to life again.

His theory is, that the cauſe of animal heat, or of the inteſtine motion which had been going on proſperouſly, while the progreſſive motion of the fluids in the veſſels continued, is now checked; yet ſtill proceeds in a lower manner, perhaps like the beginning of fermentation or putrefaction. By this degree of the animal proceſs, the maſs of fluids, particularly in the great reſervoir of venous blood, the heart, rarifying, preſſing every way, and being reſiſted by the valves, ſwells ſo as to fill the flaccid right auricle of the heart, which had been ſome time empty; and thus ſtimulating its fibres, which were at reſt, ſets them a moving again; as we ſee the heart, after being taken out of the body, by being pricked, or having warm water thrown on it, beats afreſh, tho' it has been for ſome time motionleſs. The right auricle being thus filled, and ſtimulated into a contraction, fills the ventricle; which being irritated, likewiſe contracts and empties itſelf into the pulmonary artery; whereby the circulation begins where it left off, and life is reſtored, if the organs and juices are in a fit diſpoſition for it, as they perhaps are much oftner than is imagined.

From hence it ſeems, that death does not inevitably attend an entire organic reſt of what we call the ſolids of the body; nay, that one cannot be called dead till the energy of the blood is ſo far gone, that, though aſſiſted by all poſſible means, it can never be again able to fill, and ſtimulate into contraction, the right ſinus venoſus and auricle of the heart.

See a remarkable caſe, in ſupport of this opinion, in Med. Eſſ. Edinb. Vol. 5. Art. 55.

The learned Winſlow has given us a treatiſe upon the uncertainty of the ſigns of death.

DECACTIS, in natural hiſtory, a name given by ſome to a kind of ſtar-fiſh, of the branched, or aſtrophyte kind, whoſe

rays are ten in number, where they firſt part from the body, and each ſoon branches out into a number more.

DECADARCHUS, Δεκαδαρχος, among the Greeks, a commander of a party of ten men. *Potter*, Archæol. Græc. l. 3. T. 2. p. 56.

DECALITRON, among the antients, a piece of money uſed by the people of Ægina, in value equal to 10$\frac{2}{3}$ Attic oboli. Vid. *Hoſm.* Lex. in voc.

DECAMERIS (*Cycl.*) —In Monſ. Sauveur's ſyſtem the *Decameris* is the tenth part of the heptameris, which he makes the ſeventh part of the meris; and this is the forty-third part of the octave: ſo that the *Decameris* is $\frac{1}{301}$ of an octave. See Mem. Acad. Scienc. 1701, and 1707.

DECAMYRON, in the medicinal writings of the antients, the name of a malagma, conſiſting of ten different kinds of aromatics: theſe were the Indian leaf, maſtick, euphorbium, ſpikenard, adarce, ſtorax, pepper, ointment of nard, opobalſamum, and wax. Vid. *Caſt.* and *James* in voc.

DECANDRIA, in botany, a claſs of plants with hermaphrodite flowers, and ten ſtamina, or male parts in each. See Tab. 1. of botany, Claſs 1.

The word is formed of the Greek δεκα, ten, and ανηρ, male. Of this claſs of plants are the judas tree, baſtard dittany, &c.

DECANUS, in aſtrology, a title given to the god who preſided at any birth, ὁ ωροσκοπος. *Hoſm.* Lex. in voc. See the article ASTROLOGY, *Cycl.*

DECASMUS, δεκασμος, in antiquity, the name of an action or proceſs among the Athenians, which was brought againſt any perſon who offered a bribe. They thought it not enough to puniſh the perſon receiving a bribe, but that the perſon who offered it ought to be puniſhed likewiſe. *Pott.* Archæol. Græc. l. 1. c. 23.

DECEIT, *Deceptio*, or *Dolus*, in law, is uſed for any ſubtile, wily ſhift, or trick; to which may be referred all manner of craft, ſubtilty, guile, fraud, ſleight, cunning, covin, colluſion and practice uſed to deceive another by any means. See *Weſt.* p. 2. ſymbol. tit. indictments. ſect. 68.

DECEIVED, in the manege, is uſed, when a horſe upon a demi-volt of one or two treads, working, for inſtance, to the right, and not having yet furniſhed above half the demi-volt, is preſſed one time or motion forwards with the inner leg, and then is put to a repriſe upon the left, in the ſame cadence with which he began. He thus regains the place where the demi-volt had been begun to the right, and works to the left. A horſe may in this manner be *deceived* on any hand. *Guillet*, Gen. Dict. P. 1. in voc.

DECEMVIRATE, in roman antiquity, the government of the Decemviri. See DECEMVIRI, *Cycl.*

DECENNARY, *Decennaria*, the limits or compaſs of ten *Friburghs*. See DECENNIERS, *Cycl.*

DECEPTIONE, in law, a writ which properly lies for one that receives harm or damage, by him that does any thing deceitfully in the name of another.

This writ is either *original* or *judicial*. Old. Nat. Br. fol. 50. Fitz. Nat. Br. fol. 95. See Reg. of Writs, fol. 112. and Reg. Judicial.

DECIMÆ, *Tithes*, in law. See TITHES, *Cycl.*

DECIMIS *ſolvendis pro poſſeſſionibus alienigenarum*, a writ, yet extant in the regiſter, which lay againſt thoſe that had farmed the Priors Aliens lands of the king, for the rector of the pariſh, to recover his tithe of them. Reg. of Writs, fol. 179.

DECK (*Cycl.*)—*Fluſh*-DECK. See the article FLUSH-*Deck*.

DECOMPOSITE *Leaf*, among botaniſts. See LEAF.

DECTA, in botany, a name uſed by ſome authors for the garden beet. *Ger.* Emac. Ind. 2.

DECUMANNI *Dentes*, a term uſed by the Latin writers on heraldry to expreſs that ſort of line in arms, which we call danſette, or dancetté. See DANCETTE, *Cycl.*

It is a kind of indented line, but is very large, and has very few teeth, commonly no more than three. It is ſuppoſed to have been in its origin no other than the letter M, with its two legs extended from one ſide of the field to the other.

DECUPELATION, the ſame with *Decantation*. *Harris*. See the article DECANTATION, *Cycl.*

DECURRENT *Leaf*, among botaniſts. See LEAF.

DEDUCTOR, in antiquity, a client, who, beſides the ordinary ceremony of ſaluting his patron every morning, was likewiſe obliged to attend him on public occaſions. *Pitiſc.* Lex Antiq. in voc.

DEDUTTIONE, in the Italian muſic, the name which Guido Aretine gave to the riſe of the voice, in pronouncing the ſyllables, *ut*, *re*, *mi*, *fa*, *ſol*, *la*: *quia per has deducitur vox*. On the contrary, when the voice deſcended by *la*, *ſol*, *fa*, *mi*, *re*, *ut*, he called it *Redutione*, *quia per has reducitur vox*. *Broſſ.* Dict. Muſ. in voc.

DEER, *Cervus*, in natural hiſtory, the name of a genus of animals comprehending the common deer, and the elke. The characters of this genus are, that the horns fall off every year, that they are ſolid and branched, and that the animal chews the cud.

The word *Cervus*, uſed alone, is underſtood by authors to mean the Stag, or *red Deer*, the others being all diſtinguiſhed by their ſeveral adjectives; the common *fallow Deer* being called *Cervus platyceros*, or the broad horned *Deer*. *Ray*'s Synopſ. Quad. p. 81.

The *red Deer* differs from the common kind in its ſize, and in the figure of its horns. The *common Deer* is more preſerved in England than in any other part of the world, and carries its diſtinction from the *red Deer* in the falcated figure of its horns.

We keep ſeveral ſpecies of theſe however, and may perhaps increaſe them in ſome ſort to many more, as they are a very ſalacious animal, and will be apt to mingle one ſpecies with another. The principal kinds we know at preſent, are, 1. the *Spaniſh Deer*, which is almoſt as large as the *red Deer*, but has a very ſlender neck, and is of a deep dusky colour; the tail in this ſpecies alſo is longer than in ours, and is black all over, not white next the body. 2. The *mottled Deer*, which are beautifully variegated with black, white, and tawney. 3. The *Virginia Deer*, which are larger and ſtronger than ours, and have thicker necks, and are of a grey or aſh colour rather than tawney, and remarkable for the largeneſs of their penis and ſcrotum. 4. A ſpecies which have their hinder hoofs marked with white on the outſide; the ears and tails of theſe are long, their horns branched, and their forehead a little depreſſed or hollowed between the eyes. Theſe will eat bread, fruits, and any thing that is offered them, and are often beautifully variagated; many of them have black variegations, and a black liſt down their back, with a ſeries of white ſpots on each ſide; others are ſo beautifully marked with white ſpots and other variegations, as to equal the zebra in beauty: theſe they call *menaled Deer*. *Ray*'s Synopſ. Quad. p. 80.

The method of hunting *Deer* in the iſland of Ceylon is very particular. The huntſmen go out in the night, and only two uſually go together; the one of theſe carries upon his head an earthen veſſel, in which there is ſome fire burning and flaming: the ingredients are generally ſmall ſticks cut into pieces, and common roſin; of this the other man carries a ſupply about him to repleniſh the pot when it grows low. The perſon who has the fire upon his head carries in one hand a ſtaff, on which there are fixed eight bells, and the larger theſe are the better. This man goes firſt into the woods, and the other follows cloſe behind with a ſpear in his hand. As ſoon as a *Deer* hears the noiſe of the bells, he turns towards the place whence the ſound comes, and ſeeing the fire he eagerly runs up to it, and ſtands gazing at a ſmall diſtance; the ſecond man has then nothing to do but to kill him with the ſpear, for he ſees neither of them.

Not only *Deer* but elks, and even hares are thus taken, for they gaze at the fire, and never ſee the men. The profits of this ſort of hunting are very large, and the danger nothing; for though there are great numbers of tygers, elephants, and wild boars in theſe woods, the huntſmen are in no danger of them while the fire burns, for they all run away from it. Phil. Tranſ. N° 278. p. 1094.

Mouſe-DEER. See MOUSE-*Deer*.

DEER-*field*, a park, or place where deer are kept.

DEER-*Hays*, engines or great nets, made of cords, to catch deer. *Anno* 19. Hen. 7. cap. 11.

DEER's-*Weed*, in botany, &c. See LUTEOLA.

DE ESSENDO *quietum de tolonio*, a writ that lies for thoſe who are by privilege freed from the payment of toll. See Nat. Br. fol. 226.

DEFECTIVE (*Cycl.*)—DEFECTIVE *third*, in muſic. See the articles DIMINISHED *third*, and DEFICIENT.

DEFEND, *Defendere*, in our antient laws and ſtatutes, ſignifies to prohibit or forbid: as, *uſuarios defendit quoque rex Edwardus ne remanerent in regno*. LL. Edw. Conf. c. 37. & 5 Rich. 2. c. 7. In which ſenſe alſo Chaucer uſes it in the following paſſage:

Where can you ſay in any manner age,
That ever God defended marriage.

In 7 Edw. 1. there is a ſtatute entituled, *Statutum de* Defenſione *portandi arma*, &c. And it is *defended* by law to diſtrain on the highway. *Coke* on Littl. fol. 161.

DEFENDERE *unica manu*, to wage law, by denying the accuſation upon oath. *Et ſi forte forisfactor ille factum negaverit, & foreſtarius ſolus ſit ſine teſte, ille debet ſe* defendere unica manu *ad unicam vocem rationabili die data in curia abbatis, & ſi unicum teſtem vel plures habuerit, debet ſe defendere ſexta manu*, &c. Charta facta inter W. de Bray, mil. & Abb. & Convent. de Oſeney ſine dat. See MANUS.

DEFENDEMUS, (*Cycl.*) a word uſed in feoffments and donations, the deſign of which is to bind the donor and his heirs to defend the donee, if any man go about to lay a ſervitude on the thing given, other than is contained in the donation. *Bract.* lib. 2. c. 16. num. 10. See WARRANTY, *Cycl.*

DEFICIENT (*Cycl.*)—DEFICIENT *Interval*, in muſic, is uſed for an interval leſs than the true by a comma. See INTERVAL, *Cycl.* and *Suppl.*

DEFLAGRATION (*Cycl.*) —This ſhort proceſs has been often recommended to the world as of great uſe in trying the ſtrength of brandies, and other vinous ſpirits, and has been greatly improved in this reſpect by Mr. Geoffroy.

The common way of trying ſpirits by deflagration, is to meaſure out any quantity of it, then to heat it, and ſet it on fire; if after it will no longer burn, the remainder is half as much as the quantity meaſured out for the trial was, then the ſpirit tried is found to conſiſt of half water and half totally inflammable ſpirit; that is, it is exactly what we underſtand by the term perfect proof, and according as the remainder is more or leſs than half the original quantity, it is ſo much below or ſo much above proof, or the due ſtrength of brandy.

This method is much more certain than that by the crown of bubbles, which ariſes upon ſhaking the ſpirit in a vial. Monſ. Geoffroy's method is thus; take a cylindric veſſel two inches high, and as much in diameter, conſiſting of thin plate ſilver, that metal being much leſs liable to ruſt than copper; this veſſel muſt be fitted with a little rectangular gage exactly graduated into lines, half lines, &c. then the veſſel being ſet level upon a copper caſe made to contain it, a parcel of the brandy to be examined is poured in, to the height of ſixteen iines. This height is to be exactly hit by pouring in more than enough at firſt, and then with a ſmall tube ſucking out what is ſuperfluous; then the veſſel being heated a little, ſo as juſt to make the liquor fume, it is to be ſet on fire and left to go out of itſelf; at the inſtant when the flame expires the gage is plunged perpendicularly into the veſſel, and the lines and quarters exactly noted, which the liquor wants of its former height: this difference gives the preciſe quantity of pure ſpirit, or alcohol, originally contained in the liquor: thus, if eight lines of phlegm are found remaining, this being the half of the ſixteen lines of the original filling, it is plain that the liquor contained one half ſpirit, and as ſuch it is found to be of the due ſtrength of brandy; or, as we expreſs it, proof ſpirit. If there remains no more than four lines of the phlegm, the ſpirit was double proof, or of a middle ſtrength, between that of common proof ſpirit and alcohol, and ſo ariſe all the other proportions. Mem. Acad. Par. 1718.

DEFLUVIUM, is uſed to expreſs a diſtemper in trees, whereby they loſe their bark; it is thought to be cauſed by a ſharp humour, that diſſolves the glue whereby the bark is faſtened to the wood, and ſometimes by too much drought. *Harris.*

DEFORCEMENT (*Cycl.*) in the law of Scotland, is uſed for the reſiſting, or offering violence to the officers of the law, while they are actually employed in the exerciſe of their functions, by putting its orders and ſentences in execution; whether they be officers of the ſupreme courts of juſtice, as heralds, purſevants, meſſengers, macers; or of inferior courts, as mayors.

The puniſhment of this crime is confiſcation of moveables, joined with ſome arbitrary puniſhment; as fine, impriſonment, baniſhment, or corporal pains, according to the degrees of violence, and other circumſtances which aggravate the crime: beſides, the party aggrieved may have an action of damages, to be highly taxed out of the firſt and readieſt of the offender's eſcheat, or other eſtate. See *Bayne's* Criminal Law.

Deforcing of officers of the Cuſtom-Houſe is provided againſt by the ſame ſtatutes as in England.

DEFOSSION, *Defoſſio*, the puniſhment of burying alive, inflicted, among the Romans, on veſtal virgins guilty of incontinency. It is alſo a Cuſtom among the Hungarians to inflict this puniſhment on women convicted of adultery. Heretics alſo were puniſhed in this manner. *Hofm.* Lex. in voc. *Defoſſio* and *Hovia.* See BURYING *alive.*

DEGREE (*Cycl.*)—The *degree* of the meridian meaſured by Mr. Picart was in the latitude of 49° 21′, and was found to be equal to 57060 French toiſes. But the French mathematicians who have lately examined Mr. Picart's Operations, aſſure us, that the degree in that latitude is, 57183 toiſes. They meaſured a degree in Lapland in the latitude of 66° 20′, and found it 57438 toiſes. A degree has likewiſe been meaſured at the equator, and found to be conſiderably leſs than in the latitude of Paris. From theſe meaſures it appears that the earth is not a ſphere, but an oblate ſpheroid. See EARTH.

DEGREES *of fire.* See the article FIRE.

Prohibited DEGREES in *Marriage.* See MARRIAGE.

DEGREES *in the civil and canon law.* In computing degrees of conſanguinity, the rule of the civil law is univerſal, either in the direct, or collateral, otherwiſe called the oblique line, *Quot ſunt generationes tot ſunt gradus.* But in the canon law the rule is different for the oblique line. And here a diſtinction is made between the *equal*, and the *unequal* oblique line. In the firſt caſe the rule is, *Quot gradibus perſonæ cognatæ diſtant à communi ſtipite; tot gradibus inter ſe diſtant.* In the other caſe the rule is, *Quot gradibus perſona remotior diſtat à communi ſtipite, tot gradibus perſonæ diſtant inter ſe.* Hence, the ſiſter of a perſon's grandfather, by the civil law is diſtant from that perſon in the fourth degree, whereas by the canon law ſhe is only in the third degree. So that what is ſaid in the Cyclopædia, of two degrees in the civil law making only one in the canon law, is not univerſally true, but holds only in the equal oblique line. Vid. *Heinec.* Inſt. Jur. Civ. §. clv.

DEIS or DAGUS, the chief table in a monaſtery. *Solus in refectorio prandebit ſupremus habens vaſtellum, priore prandente ad magnam menſam quam* Deis *vulgaritur appellamus.*

It is thus called from a cloth called *Dais*, with which the tables of Kings were covered. *Matt. Pariſ.* in vit. Abbat. Sanct. Alb. p. 92.

DELIA, Δηλια, (*Cycl.*) in antiquity, a quinquennial feſtival in the iſland of Delos, inſtituted by Theſeus in honour of Venus. *Pott.* Archæol. Græc. l. 2. c. 20.

There was likewiſe a feſtival celebrated at Athens called *Delia*, for which ſee DELIA, *Cycl.*

DELIAS, Δηλιας, in antiquity, the name of the ſhip in which the Delian proceſſion was annually made by the Athenians. See DELIA, *Cycl.*

DELIBAMENTA, in antiquity, a libation offered to the infernal gods, which was always poured downwards; hence this act was expreſſed by the word *defundare. Pitiſc.* Lex. antiq. in voc.

DELICT, in the law of Scotland, is uſed to expreſs an offence of an inferior degree to a crime, to be puniſhed only by the effect of a civil action, for reparation of private damage.

DELIGATION, *Deligatio*, that part of ſurgery which relates to the binding up of wounds, ulcers, broken bones, &c. *Blancard*, Lex. Med. in voc.

DELIVERANCE. See REPLEGIARE.

DELIVERY (*Cycl.*)—The ſigns of *delivery*, or child birth, juſt coming on, are a frequent emiſſion of the urine, teneſmus of the inteſtinum rectum, or frequent wanting to go to ſtool without any real occaſion; this complaint in this caſe is not continual, but laſts only a little while, and ſoon returns again: and often there comes out of the vagina a bloody and mucous matter, followed by ſome thick and turbid urine, and the uterus ſubſides, and plainly ſinks upon and preſſes againſt the os pubis, in a manner very different from what it does at another time: theſe ſymptoms happening at the natural time of *delivery*, that is, in the fortieth week from the firſt ſuppreſſion of the menſes, or the twentieth or twenty firſt from the fœtus being firſt perceived to move, preſage it with great certainty; and particularly if the ſame face of the moon be preſented at this time that was at the time of the firſt ſuppreſſion of the menſtrual diſcharge. Pains of the back and loins alſo come on at this time, which extend themſelves down to the pubes, and theſe are ſucceeded by ſpaſtick motions of the uterus itſelf, and tremblings of the knees and legs, and finally an opening of the mouth of the uterus; this is ſucceeded by a burſting of the ſecundines, and an effuſion of the water they contain, and after this the opening of the womb becomes larger, and the convexity of the child's head is uſually in ſome manner perceived. Delivery is eaſier with young and healthy perſons than with older, or thoſe who are ſickly; and ſuch who live on coarſe food and are accuſtomed to hard labour, uſually ſucceed better in it than thoſe of idle lives and delicate tables. People who are of an even temper of mind uſually alſo ſucceed better than thoſe addicted much to Paſſions; and it is uſually a good omen if the time of *delivery* be at or near that of the uſual diſcharge of the menſes in a ſtate of health.

Difficult births, or hard and dangerous *deliveries*, are to be preſaged from the following circumſtances: from the mother's being fat and of a plethoric habit, or equally from her being of an over tender and delicate conſtitution, and ſubject to frequent illneſs; ſuch as are troubled with a ſtone in the bladder ſucceed very unhappily in labour, and there is much miſchief often from the perſons being obſtinate and unruly, and not liſtening to the dictates of nature, or the advice of thoſe about her. Perſons who are in years, and are with child for the firſt time, uſually have difficult, and often dangerous labours; the pains continuing longer than they ought; and being languid at times, and not returning at ſuch ſhort intervals as they ſhould, are uſually alſo a bad omen. Spurious pains alſo which do not tend to *delivery* but fly upwards, and affect the breaſt and head, and are attended with faintings and anxieties of the Præcordia, and with head-achs and tooth-ach, are always bad omens; as are alſo an hæmorrhage of the womb, or as our women expreſs it, a flooding before the birth, a too ſoon breaking of the ſecundines and eruption of the water; and, on the other hand, a too great firmneſs and toughneſs of the ſecundines, ſo that they will not break, is not a better omen; convulſions coming on in the time of labour are uſually fatal prognoſtics, and deficiencies in the opening of the uterus from ſchirroſities, excreſcences, or injuries of the vaginæ are alſo very bad preſages. Theſe are the general occaſions of bad and dangerous labours depending on the mother, but there are alſo a not leſs number depending on the child. The firm concretion of the ſecundines, or their excretion before the birth are of this kind, as are alſo the winding of the navel ſtring about the child's neck, a bad conformation of the fœtus, as its being hydrocephalous, or the like, or its being dead in the womb: twins in the womb both offering themſelves to the birth at the ſame time; the bad ſituation of the fœtus, as in the lying of the head upon the os pubis, or the firſt offering of a foot or an arm inſtead of the head; a falſe conception or mole found in the uterus at

the ſame time with the fœtus; and to theſe are to be added the improper efforts of the midwife, and the unlucky accident of the labour happening at the time of the full moon, when it is more than ordinarily difficult.

Symptoms of DELIVERY.—Among the common ones are what are called ſpurious or falſe pains, theſe do nothing toward the promotion of the birth, yet they dreadfully torment the patient, and exhauſt her ſtrength, and that ſometimes at the very time of *delivery*, ſometimes three weeks before it, and in all the intermediate time. Theſe are known from the true labour pains, by their being of a flatulent kind, and running ſometimes tranſverſely acroſs the abdomen, ſometimes upwards from it towards the breaſt; theſe are ſeldom a complaint of nature's cauſing, but are uſually owing to a very improper regimen, or the raſh uſe of medicines.

The method of curing them is by giving internally the emollient medicines and the mild aromatics; and among theſe nothing has more ſucceſs than the chewing of cardamoms; externally, carminative liniments, fomentations, and aromatic ſuffumigations, are often found to be of great uſe and benefit.

In difficult labours, where they are preſaged by the beforementioned ſymptoms, it is proper to uſe emollient fomentations to the parts at night before-hand, and to cauſe the woman to ſit over the ſteam of a decoction of emollient herbs, with linſeed, and the like ingredients: the common people give fat broths for ſome time before, and uſe oily liniments to the abdomen. A laxative diet muſt alſo be uſed, and the bowels kept open by gentle doſes of the mild purgative and lubricating clyſters made of water-gruel and the broths of fat meats with ſugar, oil of olives, and a ſmall quantity of ſalt: and at the full time the patient ſhould be made to walk about, and uſe other gentle motion of the body in a warm room, and to continue this without any fatigue till the labour comes on: after this, if after the waters are diſcharged the mouth of the uterus cloſes again, and the fœtus is drawn back into it, then the forcing medicines are to be given, ſuch as borax, with ſmall doſes of ſaffron in the diſtilled waters of pennyroyal, and other uterine herbs. Some recommend in this caſe the liver of an eel, or the powder of the dry ſecundines of another labour, as ſpecifics; but it ſeems dangerous relying on ſuch helps. While the more powerful medicines are given internally, there may be outwardly laid on the abdomen cataplaſms of aromatic and nervous ingredients.

In caſes of debility of the parent, the moſt powerful analeptics are to be given, and tender perſons who are afraid of pain, and of ſtriving to help themſelves, are to be ſeriouſly and warmly exhorted to do their utmoſt, and bear a greater pain a moment, rather than a leſſer many hours. When the pains are interrupted, vague, or languid, ſmall doſes of borax and ſaffron are to be given, once in four hours; and when they fly upwards to the head and breaſt, and bring on ſtraitneſs of the præcordia, and a difficulty of reſpiration, with pains in the head and teeth, the common antiſpaſmodic powders are to be given, and theſe will be greatly aſſiſted in their operation by a gentle clyſter.

When the patient is fat, and of a plethoric habit, bleeding a little before the time is very neceſſary; and ſometime bleeding in the foot, even in the time of labour. When the patient is in danger of being loſt for want of ſufficient efforts, as is ſometimes the caſe, than ſternutatories and vomits are to be given. When the ſecundines adhere they are to be taken off, either with the finger nails or an inſtrument blunt at the end; and when they are ſo tough as not to break at a proper time they muſt be opened: when the waters have flowed out too ſoon, and the vagina is left dry at the time of the approaching birth of the child, the midwife is to anoint it with oil of almonds, pomatum, or any other lubricating ſubſtance.

Convulſions in the time of labour are to be carefully taken off, if poſſible, by analeptics and cinnabarine medicines: the powder of dried earth-worms is recommended by ſome as a powerful ſpecific: in caſes of a hæmorrhage of the uterus, whether it happen in the time of delivery or of ſome time before, and threaten the life both of the mother and child, it is to be treated in the moſt careful manner by attemperating and aſtringent medicines.

When the fœtus is improperly ſituated, the uſe of forcing medicines, ſo commonly the practice of the ignorant midwives, is extremely dangerous; and the only proper aſſiſtance is the hand of an experienced operator, to bring the fœtus into a proper direction, by carefully turning it while in the uterus. The moſt dangerous of all labours are thoſe in which the fœtus is ill formed, hydrocephalous, monſtrous, complicated, and the like; in theſe caſes nothing can do any good but the hand of an intelligent and experienced practitioner. *Junker*'s Conſpect. Med. p. 719. But quære, whether there be any ground for what this author ſays of the influence of the moon?

DELPHINIUM, *Lark-ſpur*, in Botany, the name of a large genus of plants. The characters of which are theſe: the flower is of the polypetalous anomalous kind, conſiſting of ſeveral irregularly ſized petals, the upper one ending in a ſpur or tail, and receiving into its hollow another of the petals, which has alſo its tail or ſpur: the piſtil which occupies the center of this flower finally becomes a fruit compoſed of ſeveral vaginæ, which open length-wiſe, and contain a number of ſeeds, uſually of an angular form. The ſpecies of *Lark-ſpur* enumerated by Mr. Tournefort are theſe: 1. The hairy aconite leaved perennial mountain *Lark-ſpur*. 2. The ſmooth aconite leaved Portugal *Lark-ſpur*. 3. The blue flowered field *Lark-ſpur*. 4. The white flowered field *Lark-ſpur*. 5. The red flowered field *Lark-ſpur*. 6. The pale fleſh-coloured field *Lark-ſpur*. 7. The deep violet blue field *Lark-ſpur*. 8. The field *Lark-ſpur* with changeable flowers. 9. The field *Lark-ſpur* with white flowers variegated with blue. 10. The tall field *Lark-ſpar* with blue and purple flowers. 11. The tall field *Lark-ſpur* with double flowers. 12. The tall field *Lark-ſpur* with variegated double flowers. 13. The broad leafed field *Lark-ſpur* with ſmall flowers. 14. The garden *Lark-ſpur* with large ſingle blue flowers. 14. The garden *Lark ſpur* with large ſingle bluiſh purple flowers. 15. The tall *Lark-ſpur* with fleſh coloured flowers. 16. The tall *Lark-ſpur* with violet purple flowers. 17. The garden *Lark-ſpur* with large ſingle red flowers. 18. The garden *Lark-ſpur* with large ſingle white flowers. 19. The garden *Lark-ſpur* with large ſingle greyiſh flowers. 20. The garden *Lark ſpur* with ſmall ſingle blue flowers. 21. The garden *Lark-ſpur* with ſmall ſingle red flowers. 22. The garden *Lark-ſpur* with ſmall ſingle white flowers. 23. The garden *Lark-ſpur* with ſmall ſingle fleſh coloured flowers. 24. The garden *Lark-ſpur* with ſmall ſingle greyiſh flowers. 25. The garden *Lark-ſpur* with great double blue flowers. 26. The garden *Lark-ſpur* with great double fleſh coloured flowers. 27. The garden *Lark-ſpur* with great double white flowers. 28. The garden *Lark ſpur* with great double purple flowers. 29. The garden *Lark-ſpur* with great double bright red flowers. 30. The garden *Lark-ſpur* with great double ſilvery white flowers. 31. The great flowered garden *Lark-ſpur* with double purple and white flowers. 32. The double variegated early *Lark-ſpur*. 33. The late flowering *Lark-ſpur* with double white flowers. 34. The late flowering *Lark-ſpur* with double roſe coloured flowers. 35. The *Lark-ſpur* with roſe coloured ſpotted flowers. 36. The *Lark-ſpur* with white flowers variegated with red ſpots. 37. The *Lark-ſpur* with a duſty roſe coloured flower. 38. The platanus leafed *Lark-ſpur*, commonly called *Staves-acre*.

Phyſicians ſeldom preſcribe ſtaves-acre internally, being of a hot burning taſte, and apt to raiſe a great flux of ſpittle. This quality however renders it ſerviceable in ſome caſes. It is ſometimes uſed in maſticatories and gargariſms for the tooth-ach. Its powder, ſprinkled on the head, is ſaid to kill lice; and its ſeeds are bruiſed in oil, and the head anointed therewith, for the ſame purpoſe. Vid. *James*, Dict. Med. in voc. *Delphinium*.

DELPHINUS, *the Dolphin*, (*Cycl.*) in the linnæan ſyſtem of zoology, makes a diſtinct genus of fiſhes of the plagiuri, or tranſverſe tailed order; the characters of which are, that the back has two fins, and there are teeth in both jaws. *Linnæi* ſyſtema naturæ, p. 51.

In the artedian ſyſtem of ichthyology, *Delphinus* is alſo the name of a genus of the plagiuri, or cetaceous fiſhes: the characters of which are theſe; the teeth are placed in both the jaws, the pipe or opening is in the middle of the head, and the back is always pinnated.

The ſpecies of this genus are theſe, 1. The *dolphin*, with a coniform body, with a broad back, and a ſubacute ſnout. This is the *phocæna* or porpeſs. 2. The *dolphin*, with an oblong ſubcylindric body, with a long acute ſnout; this is the *Delphinus* of the generality of authors, and is called the *porpeſſe* alſo by the Engliſh. 3. The *Dolphin* with a back ridg'd upwards, and with broad ſerrated teeth; this is the *orca* of authors, called by us the *grampus* and *north caper*; the body of this fiſh is ſo thick, that its breadth is equal to half its length. *Artedi*. Gen. Piſc. 43. See the article PORPESSE.

The name *Delphinus* is of Greek origin, and is ſuppoſed by ſome to be derived from the word δελφαξ, a pig or hog; and, according to others, from the word δελφυς, *vulva*, this fiſh being of the viviparous kind, and one of thoſe few which have the vulva and penis in the different ſexes, like thoſe of land animals.

The fiſh known by the antients, both Greeks and Latins, under the name of the *dolphin*, has been much miſunderſtood by the generality of people; and except the Greeks now living, no nation has any determinate notion of what fiſh is meant by it: the modern Greeks having preſerved the name to the ſame ſpecies of fiſh, and all other nations having called it by ſome different appellation.

The Greek name δελφις ſeems borrowed from the word δελφαξ, a pig or young hog; and all the nations who have given this fiſh their ſeveral names, have derived them from its reſemblance to the ſame creature, a hog; and this not without reaſon, as there is much analogy between the two animals; the dolphin being as fat as the hog, and having his intrails extreamly like thoſe of that quadruped; but in this there has yet been ſome confuſion, as the common porpeſſe, which

which much reſembles the *Dolphin* in many reſpects, has alſo been indiſcriminately called by the ſame name with that fiſh. The name *Porcus marinus*, a ſea-hog, porco peſce, and as we ſpeak it, *Porpeſſe*, and the *meer ſchwein* of the Dutch, all being, tho' indiſcriminately, names of the phocæna, properly called the *Porpeſſe*, and the *Delphinus* or *Dolphin*. It would be well however if naturaliſts, and indeed all who write or ſpeak on theſe ſubjects, would keep up the proper diſtinctions, always uſing *Delphinus* as the name of the *Dolphin*, and phocæna and the Engliſh name *Porpeſſe* only as the names of that other fiſh diſtinctively from the *Dolphin*.

The difference between the two is, that the *Dolphin* has a much longer ſnout or noſe, ſticking out ſomewhat in form of a gooſe's bill, and is in the whole a longer, ſlenderer, more fleſhy, and leſs fat fiſh, and is the larger of the two. The *Phocæna* or *Porpeſſe* is fatter, ſmaller, broader back'd, and has a more obtuſe and ſhorter ſnout. See the article PHOCÆNA.

The *Dolphin* is a cetaceous fiſh, covered with a ſmooth, but very tough and firm skin; its body is long and rounded, and its back prominent; its noſe long, and rounded at the end; its mouth very large, but ſhutting very nicely and exactly; its teeth ſmall and ſharp, and placed like the teeth of a comb; its tongue broad and ſerrated; its eyes large, but ſo cover'd with the skin that the pupil only appears. Its eyes are placed near the angle of the mouth; and behind theſe are its ears, or auditory paſſages, which are very ſmall. Above the ſnout it has a double pipe, by which it throws out the water neceſſarily taken in with food. It has two ſharp fins join'd like the ſhoulders of a human body to the muſcles, which move them. In the middle of the back it has alſo one fin, which is partly cartilaginous and partly bony, but has no ſpines or prickles. Its back is black, and its belly white, the fleſh is blackiſh, and it has regular lungs in its breaſt of a more tough conſiſtence than thoſe of quadrupeds. Theſe fiſh are ſuppoſed to live a great number of years. The figures of them on ſome antique marbles and coins, which repreſent them crooked, are unnatural; and have been conceived originally by perſons who had ſeen them playing about on the ſurface of the water, in which caſe they ſometimes deceive the eye, and appear crooked: from theſe probably our ſign-painters took their idea of the *Dolphin*. They are an extremely ſwift fiſh in ſwimming, and are able to live a long time out of the water, tho' they can continue but a little while under it without air; hence they are ſometimes taken up dead by fiſhermen in their nets, having been ſuffocated by being forcibly kept under water: they have been known to live three days on dry ground. *Willughby*, Hiſt. Piſc. p. 30.

DELTOIDES (*Cycl.*) —This is a very thick muſcle, covering the upper part of the arm, and forming what is termed the ſtump of the ſhoulder. It is made up of eighteen or twenty ſmall ſingle muſcles in an oppoſite ſituation in reſpect to each other, and united by middle tendons, ſo that taken all together they form ſeveral penniform muſcles. The outer ſurface appears almoſt wholly fleſhy, but on the inner we ſee the ſeveral tendons. All theſe ſmall muſcles are formed and diſpoſed ſo, as to make a conſiderable extent at the upper part; from whence they contract gradually in breadth, till they end in a thick ſtrong tendon, by which the whole muſcle is terminated in a point.

Above, it is fixed in the whole inferior labium of the ſpina ſcapulæ, in the convex or long edge of the acromion, and in the third part of the anterior edge of the clavicle next that apophyſis; it ſurrounds the angle formed by the articulation of theſe two bones by a particular ſlope and fold contrived for that purpoſe: from thence it runs down above one third of the length of the os humeri, where it is inſerted by a thick tendon, in the large muſcular rough impreſſion below the bony ridge, which goes from the great tuberoſity of the head of the bone, and forms the higheſt border of the groove in that part of the bone.

This muſcle may be diſtinguiſhed into three principal portions, one of which is fixed in the ſpine of the ſcapula, one in the acromium, and one in the clavicle: theſe are ſeparated from one another by a ſmall quantity of fat, or a cellular ſubſtance, chiefly near the baſis of the muſcle. The middle or ſtrongeſt portion runs down almoſt directly to its inſertion in the os humeri; the lateral portions ſeem to end ſooner: but that is only becauſe they turn inward toward the bone, and thereby form the biggeſt and thickeſt part of the tendon; the anterior or clavicular portion ſends off ſome fibres to the bone before it reaches the tendon. The portion fixed in the ſpine of the ſcapula ſends backward a thin aponeuroſis, which is ſtrengthened by another tendinous or ligamentary ſeries of fibres. This aponeuroſis is fixed in the baſis of the ſcapula below the ſpine, and from thence is extended toward the inferior angle. The other ſeries begins at the ſpine, and ends near the ſame angle at the beginning of the inferior coſta. Theſe, together with the great tendon, ſeem to contribute to the formation of the tendinous expanſion which covers the muſcles of the arm.

This muſcle at its upper part joins the inſertion of the trapezium, and below that of the brachialis. Anteriorly it joins the pectoralis major, being diſtinguiſhed from it only by a ſmall line of fat, or of a cellular ſubſtance, and a ſmall vein called the cephalica. It covers the head of the os humeri, and adheres to the capſular ligament of the joint, and likewiſe covers the inſertion of the pectoralis major. *Winſlow*'s Anatomy, p. 178.

DELTOIDE *Leaf*, among botaniſts. See LEAF.

DELUBRUM, in roman antiquity, a temple with a large ſpace of conſecrated ground round it. Vid *Pitiſc.* Lex. Ant. in voc. See the article TEMPLE, *Cycl.*

DELUGE (*Cycl.*) —The moſt full and expreſs accounts which we have of the univerſal *Deluge* are in the holy ſcriptures; yet when we conſider theſe carefully, they ſeem to contain only a ſmall part of that amazing ſtory, and for the want of more circumſtances leave us in the dark as to many points, and give us cauſe to wonder at the reception and agreement of the animals in the ark, and at its preſervation in that immenſe ocean; eſpecially at that time when God cauſed the winds to blow to dry up the waters, particularly when it firſt came to the ground. All the objections however that have been, or can be ſtarted in regard to this hiſtory, leave us no room to doubt the reality of the event. We are well aſſured that there once was ſuch an univerſal *Deluge*, which overſpread the whole ſurface of the earth, and the marine bodies found in all parts at land ſufficiently prove that all parts were once covered with water.

Whether we allow that theſe parts of the earth have ariſen out of the ſea, or that the ſea has at ſome time riſen up to them, there are immenſe difficulties in the way of either ſyſtem, and the ſcriptures give us no light into the caſe. The burſting open of the fountains of the great deep, which is given as one of the cauſes of this flood, muſt have been by far the greateſt, for the raining forty days could be of little conſequence toward the drowning of the world; for ſuppoſing it to rain as much in one day as it does with us in a whole year, this is only about forty inches depth, and therefore forty days of ſuch rain could only cover the whole ſurface of the earth with about twenty-two fathom of water; and this would only be ſufficient to drown the low lands next the ſea, but the much greater part of the ſurface of the earth would eſcape.

What is meant by the fountains of the abyſs being broken up, and the opening of the windows of heaven, ſeems not ſo eaſy to be underſtood, but is intended to indicate the waters of the *Deluge*, which was, according to the Moſaic philoſophy, from the letting in of the waters above the firmament, mentioned *Gen.* i. 7. by the windows of heaven; and the riſing up out of the ground of the waters under the earth, ſpoken of in the ſecond commandment; or, as ſome chuſe to underſtand it, by the overflowing of the ſea riſing upon the land, which is expreſſed by the breaking up of the fountains of the great deep, according to their ſenſe of the word.

Upon the whole we may reaſonably conclude, that by one of theſe expreſſions is meant an extraordinary fall of waters from the heavens, not as rain, but in one continued body; as if the firmament ſpoken of by Moſes to ſuſtain the ſupra-aerial ſea had been broken in, and at the ſame time the ocean flowed in upon the land, ſo as to cover all with water.

This cataſtrophe could not have been effected in the common way of underſtanding the accounts of it, but by an increaſe of the waters, and as the withdrawing the flood afterwards muſt in that caſe have been effected only by the again annihilating thoſe waters, the ſyſtem ſeems to labour under more difficulties than any other which has been advanced.

A change of the center of gravity about which the center of the ſea is formed, ſeems not an improbable conjecture, till it appears that this center of gravity was the natural reſult of the materials of which the globe of the earth is compoſed, and by no means alterable while the parts of it remain in their preſent poſition: and beſides, this ſuppoſition could not drown the whole globe, but only that part of it toward which the center of gravity was changed, leaving the other hemiſphere all dry.

Dr. Burnet's hypotheſis is full of inſufficiencies, and contradicts not only the phyſical principles of nature, but alſo the account given of the *Deluge* in the holy ſcriptures more than any other ſyſtem that has been advanced, notwithſtanding the ſeeming agreement he finds between them. And Dr. Hook's opinion of the compreſſion of a ſhell of earth into a prolate ſpheroid, thereby preſſing out the water of an abyſs under the earth, may very well account for drowning two oppoſite zones of the globe; but the middle zone being by much the greater part of the earth's ſurface, muſt by this means be raiſed higher from the center, and conſequently ariſe more out of the water than before.

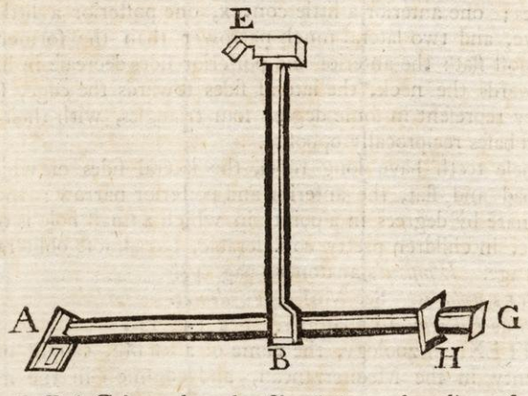
Dr. Halley reſolves it into the ſhock of a comet, or ſome other ſuch tranſient body. The great agitation that muſt have been occaſioned by it in the ſea, he obſerves, would be ſufficient to account for all thoſe ſtrange appearances of heaping vaſt quantities of earth and high cliffs upon beds of ſhells, which once were the bottom of the ſea, and raiſing up mountains where none were before: ſuch a ſhock as this impelling the ſolid parts would occaſion the waters, and all fluid ſubſtances that were unconfined as the ſea is, to run violently with an impetus toward that part of the globe where the blow was received, and

that

that with force ſufficient to take with it the very bottom of the ocean, and to carry it upon land.

In this caſe it is much more difficult to ſay how Noah and his family could be preſerved, than how all other creatures were deſtroyed: ſuch a ſhock would change the length of the day and year, and alter the axis of the globe according to the obliquity of the incidence of the ſtroke, and its direction in relation to the axis. That ſome ſuch thing as this has at ſome time happened, appears very probably from this, that the earth in its preſent ſtate ſeems but the ruins of a former world, in which we every where find ſuch animal bodies as lived before this *Deluge*, either in their own ſtate, or petrified.

It may be objected to this ſyſtem, that ſuch a ſhock as is here ſuppoſed to occaſion the *Deluge*, muſt have brought on that cataſtrophe inſtantaneouſly, and all at once, not gradually as it is ſaid to have happened; and therefore that tho' there are the evident remains of ſuch a ſhock in the petrified animal bodies found in ſtone, *&c.* yet this may have happen'd before the formation of the world into its preſent ſtate long before the time of Noah. It is probable alſo, that ſuch another ſhock may be at ſome time neceſſary, in order to render this earth ſufficiently fruitful in vegetables, which are either immediately or mediately the food of all animals. The parts about the ſurface being ſuppoſed to petrify and harden in time, and that ſuch a concuſſion will in fine be neceſſary in order to bury them, and to bring up a ſofter and more nouriſhing matter to cover the world, which muſt be the caſe in a ſhock and overflowing of this kind; as the ſhock would looſen and ſuſpend in the water all the upper part of the globe, and the heavieſt matter out of this ſubſiding firſt, muſt leave the lighteſt for the laſt ſettling, or that which will make the upper coat of the new formed world, which would then be fit for all vegetable productions. Philoſ. Tranſ. N° 383. p. 120.



DELVIN, in natural hiſtory, a name ſometimes given by the miners in Cornwall to that ſort of talky ſtone or ſlate, which they more generally call killas; but in ſome places, as at Lowancowiggan, they uſe it as the name of a coarſe, but very hard ſtone in which the ore lies. The ore is tin, and is conſiderably rich there, but the hardneſs of this ſtone makes it difficult to be got out.

DEMARCHUS, Δημαρχος, (*Cycl.*) in antiquity, an appellation given to the chief magiſtrate of the city Neapolis. *Pitiſc.* Lex. ant. in voc.

DEMETRIA, Δημητρια, in antiquity, a feſtival in honour of Ceres, called by the Greeks *Demeter*, Δημητηρ. It was uſual on this occaſion for the worſhippers to laſh themſelves with whips made of the bark of trees, and called μυροπλοι. *Pott.* Archæol. Græc. l. 2. c. 20. T. 1. p. 379.

DEMETRIA was likewiſe the name of another feſtival celebrated by the Athenians in honour of Demetrius Poliorcetes, and was the ſame with that afterward called *Dionyſia*. *Pott.* loc. cit.

DEMI-CROSS, an inſtrument uſed by the Dutch to take the ſun's altitude, or that of a ſtar at ſea; but inſtead of which we uſe the croſs-ſtaff or fore-ſtaff. The *Demi-croſs* is of this figure:

The ſtaff A G is graduated eaſily, being only a line of whole tangents, whoſe radius is E B, the length of the croſs piece or tranſum. It hath three vanes; a horizontal vane, as A; a ſight vane, as H; and the ſhade vane, as E.

When the vanes are on the ſtaff and croſs piece, to take the ſun's altitude, hold the inſtrument with the tranſum as upright as you can, and looking through the ſight vane, as H, look for the horizon through the ſlit in the horizon vane, and then ſlide the croſs piece or tranſum to and fro, till you make the ſhade of the vane at E to fall at the ſame time upon the ſlit of the horizon vane, and alſo at A; then are the degrees cut on the ſtaff, by the edge of the croſs piece, the ſun's altitude required.

But to take the height of a ſtar; you muſt remove the horizon vane A, and put it on the end G, and transfer the ſight vane H to A; then holding up the inſtrument as before, looking through the ſight vane, ſee for the horizon through the horizon vane, and for the ſtar by the ſhade vane, ſliding the tranſum to and fro, till the horizon and ſtar are both ſeen by their reſpective vanes, and then the tranſum will cut the degrees of the ſtars Altitude on the ſtaff, allowing about 8 or 10 minutes for your height above the level of the water, as muſt be done in all ſuch caſes.

DEMIDITONE, in muſic, is uſed by ſome for a third minor.

DEMI-HAQUE. See HARQUEBUSS, *Cycl.*

DEMISE (*Cycl.*)—DEMISE *of the King* does not diſcontinue any writ or proceſs. Vid. Stat. 1 Ed. 6. cap. 7. §. 1, 2, 3.

Nor does it determine any commiſſion civil or military, or great office of ſtate, but they ſhall continue in force for ſix months after the ſovereign's *Demiſe*, unleſs made void by the next ſucceſſor. Stat. 7 & 8 Wil. 3. c. 27. ſect. 21. 1 Ann. Stat. 1. cap. 8. 6 Ann. c. 7. ſect. 8.

Neither is a parliament thereby determined till after ſix months. 7 & 8 Will. 3. c. 15.

Nor is a defendant, who hath pleaded to an information, obliged to plead to it again. But he may plead again upon requeſt made to the Court, within five months after the *Demiſe*. 4 & 5 Will. & Mar. c. 18. ſect. 7.

DEMOISELLE, the *Dancing Bird*, a long-leged and long-necked bird of the ſtork kind, a native of Numidia. It is remarkable for its jumping or dancing in its walk. See Tab. of Birds, N° 40.

DEMONIUS *Lapis*, in natural hiſtory, a name given to a ſtone famous among the writers of the middle ages for a number of imaginary virtues, ſuch as rendering people victorious over their enemies, and the like. All the deſcription they have left us of it is, that it was variegated with two colours laid in lines ſo as to repreſent a rainbow. It was probably an agate.

DEMULCENTS, *Demulcentia*, in pharmacy, are medicines which render the acrimonious humours mild. This they do by obtunding or ſheathing their ſharp particles. Vid. *Blancard.* Lex. Med. in voc.

DEN, a ſyllable added to the names of places, and ſhews their ſituation to be in a valley, or near woods, as *Tenterden*, *Biddenden*, &c.

The word is Saxon *Den*, i. e. *Vallis*, or *Locus ſylveſtris*.

DENDRACHATES, in natural hiſtory, the name by which the ancients called that ſpecies of agate we know by the name of the *Mocheа ſtone*. See Tab. of Foſſils, Claſs 5.

This in its natural ſtate is only a whitiſh ſemi-pellucid ſtone, very beautifully vein'd with a fine milky white; but its great beauties are certain accidental delineations in black, which repreſent in a rude and irregular, but a very elegant manner, trees, moſſes, ſea-plants, and a number of other beautiful figures. Many have ſuppoſed theſe to be real moſſes, *&c.* lodg'd in the ſubſtance of the ſtone, but there is no foundation for this opinion; and nothing indeed can be more abſurd, ſince compleat and beautifully tufted oak trees are frequently delineated there of leſs than an inch in height. Theſe figures are in black, and the ſubſtance of the ſtone being white, they are ſeen to a very great advantage. Their true hiſtory is no more than this: the ſtone is ſubject, like our common flints, to imperceptible cracks and flaws, into which the ſteams and effluvia from minerals, and other foſſile bodies, continually pervading the whole ſtructure of the earth, find their way, and perhaps in ſome caſes water itſelf has been at ſome time in them: either water or theſe vapours, we well know, may be naturally enough tinged with black, or capable of leaving a black tinge on the ſurfaces of the bodies they have long remained on; and theſe finding their way into the natural cracks or ſmall crevices of the ſtone, have from the ſides of theſe inſinuated themſelves farther and farther into the maſs, and run into branched figures; or the water where-ever included has, as the maſs of the ſtone ſhrunk and contracted in the drying, ſpread and diffuſed itſelf into the various detach'd figures we ſee; for all the delineations we find in theſe ſtones may be referr'd either to theſe looſe detached figures or cloudy ſpots, or to thoſe which evidently ariſe from the ſides of ſome long cracks or fiſſures.

That water is continually to this day getting into theſe natural crevices of ſtone, and diffuſing itſelf beyond their natural limits in irregular, and often in beautifully branched figures, we ſee in many of our gravel-pits, where many of the larger flints and pebbles being ſtruck eaſily fall to pieces at theſe crevices, the ſides of which are always either wet, or plainly marked with waters having once been there; and if from theſe we trace the leſſer cracks, we ſhall uſually find numbers of figures imperfectly reſembling the delineations in the agates, and the very ſame often alſo on their ſurfaces, merely the effect of mineral effluvia.

On the ſurfaces of the natural creviſes of our ſeptariæ, or ludus Helmontii of the harder kinds, we often alſo meet with what authors call dendritæ, or fuliginous delineations of trees, which are of the very ſame kind with thoſe of this agate, and are ſo far from being inferior to them in beauty, that they even greatly excel them; nay, ſo low and poor a ſubſtance as common chalk is not without them, but is frequently found beautifully marked with branches, trees, ſtars, and a thouſand other figures like thoſe formed by pulling aſunder two levigating ſtones with the fine matter between them, or the ſhooting of ſalts in chemical veſſels, or the figures of hoar-froſt on our windows. *Hill's* Hiſt. Foſſ. p 473.

DENDRANATOMY, a term uſed by Malpighi and others to expreſs the diſſection of the ligneous parts of trees and ſhrubs, in order to the examining their ſtructure and uſes: Galen has uſed the ſame word, and taken ſome pains to diſcover ſome of the ſubjects of theſe reſearches. There is a very remarkable

analogy between the parts of ſome trees, and thoſe of peculiar parts of animal bodies; and Malpighi has, with great juſtice, uſed the comparative anatomy of trees, to explain, by the formation of the galls, and other preternatural tumors on them, the puſtules and other unnatural fleſhy excreſcences on animal bodies.

DENDROPHORI, Δενδροφοροι, in antiquity, perſons whoſe employment it was to cut down trees, and carry them to market. Thoſe were likewiſe called *Dendrophori*, who, in honour of ſome deity, as Bacchus, Sylvanus, &c. carried trees pulled up by the roots through the city. *Pitiſc.* Lex. Ant. in voc.

DENEB, or ALDENEB *Alchail*, in the writings of the Arabian Phyſicians, the name of the equiſetum or horſe-tail: there is, however, no great dependance to be had on what authors ſay of this plant; for the Greek and Roman writers having ſometimes called this plant *polygonum*, from its having many joints; and polygonum being alſo the name of the common knot-graſs; the virtues of theſe two plants, though conſiderably different, are blended together; and the plants themſelves confounded under the ſame name: nay, Pliny has gone ſo far as to take in the *Polygonatum*, or Solomon's ſeal, into the number of *Polygonums*, from the ſimilar ſound of the names; and ſuppoſing all that had been ſaid of polygonum was applicable to the *hippuris*, or horſe-tail; he has told us, that it grows in ſhady woods, and has large ſpreading roots, and a fruit of a round ſhape, and of the ſize of a coriander ſeed.

DENOMINATIVE, in logic. See DENOMINATION, *Cycl.*

DE NON *reſidentia clerici regis*, in law, the name of an antient writ, the form whereof ſee 2 inſt. fol. 624.

DENS *Canis*, *dogs tooth*, in botany, the name of a genus of plants; the characters of which are theſe; the flower is of the lilliaceous kind, and is compoſed of ſix petals, which are pendulous, and bend backward. The middle of the flower is occupied by a piſtill, which finally becomes a roundiſh fruit, or ſeed veſſel, divided into three cells, and containing a number of oblong ſeeds: to this, it is to be added, that the root is fleſhy, and of the ſhape of a dog's tooth. See Tab. 1. of botany, Claſs 9.

The ſpecies of *Dens Canis* enumerated by Mr. Tournefort are theſe. 1. The *dens canis*, with a broad, and ſomewhat roundiſh leaf, and a purpliſh red flower. 2. The broad and roundiſh leaved *dens canis*, with a white flower. 3. The broad, and roundiſh leaved *dens canis*, with a purpliſh white flower. 4. The broad and roundiſh leaved *dens canis*, with an amethyſtine flower. 5. The yellow flowered *dens canis*. 6. The long and narrow leaved *dens canis*, with a milk white flower. 7. The long and narrow leaved *dens canis*, with a purpliſh flower; and 8. The long and narrow leaved *dens canis*, with a reddiſh flower. *Tourn.* Inſt. p. 378.

The powder of the dried root of this plant is ſaid to kill worms in children. Drank in wine, it is an approved remedy for the cholic. It is ſaid to be reſtrictive and reſtorative, and taken in water, cures children of the epilepſy: it is alſo eſteemed a great provocative to venery. Vid. *James*, Dict. Med. in voc.

DENS *Leonis*, *Dandelion*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the ſemi-floſculous kind, and the petals it is compoſed of are placed on the embryo ſeeds, and ſurrounded by the cup. The embryos finally become ſeeds wing'd with down, which are affixed to the thalamus, but expand their downy ends into a globular head, and the ſtalks are uſually hollow and not branched. The ſpecies of *dandelion* enumerated by Mr. Tournefort are theſe: 1. The ſmooth mountain *dandelion*, with very long foliaceous ſtalks. 2. The common broad leaved *dandelion*. 3. The broader leaved *dandelion*. 4. The narrower leaved *dandelion*. 5. The *dandelion* with broad and roundiſh leaves. 6. The *dandelion* with bulbs like the aſphodell. 7. The fineſt leaved *dandelion*, called by ſome the ſtinking hawkweed. 8. The ſmall *dandelion* with rough leaves. 9. The ſmall *dandelion* with radicated leaves. 10. The tuberous rooted *dandelion*. 11. The hoary or hairy leaved *dandelion*. 12. The hoary rough leaved *dandelion*. 13. The rock *dandelion* with hairy and rough leaves. 14. The hairy *dandelion*, with very ſmall and rough leaves. 15. The narrow leaved mountain *dandelion*. 16. The hoary mountain *dandelion*, with ſmall flowers. 17. The ſmall mouſe ear leaved alpine *dandelion*. 18. The leaſt alpine ſmooth *dandelion*. 19. The ſmalleſt rough leav'd *dandelion*. 20. The ſmall Spaniſh *dandelion*. 21. The *dandelion* commonly called mouſe ear. 22. The mouſe ear *dandelion*, with leſs hairy leaves. *Tourn.* Inſt. p. 468.

The common ſpecies of this plant has much the ſame virtues with the common endive, but in a greater degree: the roots eaten in ſpring are eſteemed of great ſervice in obſtructions in the liver and ſpleen.

DENS *Caninus*. See DENTES *Canini*.

DENSHRING, in agriculture. See DEVENSHRING.

DENTALE, in natural hiſtory, the name of a genus of the tubuli marini: the characters of which are, that they are ſhelly tubes, reſembling the tusks of elephants, or the horn of ſome animal which is a little bent. Some authors have called theſe elephants teeth. See Tab. of Foſſils, Claſs 9.

There are two principal kinds of them, the one ſmooth, the other ſtriated. Of the ſmooth kind, ſome are all over white, others are tipped with red at the end: and of the ſtriated ones, ſome are altogether white, others are green, and in ſome the ſtriæ are more prominent, in others fainter, eſpecially in the leſſer ones. See Tab. of Shells, N° 4.

This fiſh is alſo called *dentalium* and *ſyringites*. Taken inwardly, it is uſed as an alkali to ſweeten acids, to ſtop a looſeneſs of the belly, and for ſpitting of blood. It is alſo uſed externally as a drier. Vid. *Lemery*, Dict. des drog. in voc. *Dentalium*.

DENTALE, is a name given by ſome to a fiſh caught in the Mediterranean, and common in the markets of Italy, known more commonly among naturaliſts by the name *Dentex*. *Bellonius*, de Piſc. *Willughby*, Hiſt. Piſc. p. 312. See DENTEX.

DENTARIA, *Toothwort*, in botany, the name of a genus of plants. The characters of which are theſe: the flower conſiſts of four leaves, and is of the cruciform kind; the piſtill ariſes from the cup, and finally becomes a pod, divided by an intermediate membrane into two cells, and containing roundiſh ſeeds. To theſe marks it is to be added, that the pods when ripe burſt open with violence, and throw out the ſeeds to a conſiderable diſtance, and that the roots are fleſhy, ſcaly, and toothed.

The ſpecies of *dentaria* enumerated by Mr. Tournefort are theſe: 1. The ſeven leaved *dentaria*. 2. The ſmooth five leaved *dentaria*. 3. The rough five leaved *dentaria*. 4. The ſeven leaved bulbiferous or bacciferous *dentaria*. 5. The three leaved *dentaria*. 6. The nine leaved *dentaria*. *Tourn.* inſt. p. 225.

The three firſt ſpecies of this plant are uſed internally, for exulcerated lungs, and the wind cholic; the others only externally. Vid. *Lemery*, Dict. des Drog. in voc.

DENTATED *Leaf*. See LEAF.

DENTES CANINI, *Dogs teeth*, are ſo termed, becauſe they are naturally a little pointed, and appear longer than the reſt, almoſt in the ſame manner as in dogs: they might alſo properly enough be called angular, becauſe they make an angle, by which the inciſors are ſeparated from the grinders; the two ſuperior have alſo been named eye-teeth from their ſituation. The bodies of the *Dentes Canini* are thicker, and more prominent than thoſe of the inciſores, they are convex, and a little rounded on the outſide, and end in a ſhort triangular point, one of the ſides of which is a continuation of the convexity of the outſide, and the other two are flatter and turned inwards. Theſe points are often worn out by maſtication: their roots are commonly larger, thicker, longer, and more pointed than thoſe of the inciſores, and ſometimes perforate the bottom of the maxillary ſinus. WINSLOW's anatomy, p. 43.

DENTES *inciſores*, the cutting teeth, have this name from their uſe; and are by ſome authors called *riſorii*, becauſe they appear in laughing: the four upper *inciſores* are larger and broader than the four lower; and of the upper, the two in the middle are larger than the other two: the bodies of theſe teeth reſemble large cutting wedges, and their roots are pointed. Their bodies are ſo diſpoſed that their ſharp ends lie all in a line, making one uniform edge; each body has properly four ſides; one anterior a little convex, one poſterior a little concave, and two lateral much narrower than the former, and almoſt flat: the anterior and poſterior ſides decreaſe in breadth towards the neck, the lateral ſides towards the edge, ſo that they repreſent in ſome degree four triangles, with their apices and baſes reciprocally oppoſite.

Theſe teeth have long roots, the lateral ſides of which are broad and flat, the anterior and poſterior narrow: they terminate by degrees in a point, in which a ſmall hole is obſervable, in children pretty conſiderable, but almoſt obliterated in old age. *Winſlow*'s anatomy, pag. 43.

DENTES *molares*. See MOLARES *dentes*.

DENTES *Piſcium*, in anatomy. See TEETH.

DENTEX, in zoology, the name of a ſea fiſh, caught in great plenty in the Mediterranean, and common in the markets of Italy.

It is a well taſted fiſh, and is caught of five, or ſix, and ſometimes ten pound weight: it is ſomewhat broad and flat in its ſhape, yet conſiderably thick and long. Its head is flatted, its ſnout very long, and its back ridg'd and ſharp; its back and ſides are of a dusky yellowiſh green colour, and ſometimes, in the full grown fiſh, purpliſh, always ſpotted with very bright blue and black ſpots; the back and gill-fins have each a black ſpot near their origin, and the belly fins are yellow.

The teeth are diſpoſed in a ſingle row in each jaw, and there are at diſtances four, which are longer and broader than the reſt, and look like the canine teeth of men, or of quadrupeds: it is from theſe that it has its name, and theſe as well as the reſt of the teeth are in this fiſh covered with lips, as in quadrupeds: its tail is forked, and its ſcales are very large. *Geſner* de Aquat, p. 1119.

DENTICULI *Elephantis*, in the hiſtory of ſhells, a name given by many authors to the *dentales*, a ſmall ſhell of the tubulus marinus kind, which is ſomewhat bent and pointed at one end, and in ſome meaſure repreſents the elephants tusk. See DENTALES.

DENTIFRICE, *Cycl.* The generality of operators for the teeth allow

allow acids, ſuch as ſpirit of vitriol, &c. to be the readieſt of all *dentifrices*, to take off the foulneſs and yellowneſs of the teeth; but though they allow theſe render them white, for the preſent, they diſcountenance a frequent uſe of them, as wearing away too much of the teeth, and injuring the gums.

Tachenius attacks ſpirit of vitriol even in a ſtronger manner, and affirms that it cannot anſwer the firſt purpoſe of making the teeth white: he alledges, that the mixture of ſpirit of vitriol, with any white alkali, produces a yellowiſh colour, not a white one. It is evident, that our ſweat, and all other matter, tranſpiring through the pores is of an alkaline nature, and there continually tranſpires through the gums ſomething of this kind, which lodging itſelf upon the teeth, muſt needs mix with the remains of the ſpirit of vitriol left on them in the cleaning; and, by that means, the whiteneſs at firſt given will gradually go off; and the yellow, which is the natural reſult of an alkali, with ſpirit of vitriol, will appear in its place. *Tachenii* Hippocrat. *Chym.*

DENTIL, in architecture. See DENTICLE, *Cycl.*

DENTILLARIA, in botany, a name, by which ſome authors call the *plumbago*, or leadwort. See PLUMBAGO.

DE ONERANDO *pro rata portionis*, in the law of England, a writ that lies where one is deſtrained for a rent that is to be paid proportionably by others: thus, if a man holds ten oxgangs of land, by fealty and ten ſhillings rent, of the king; and aliens, one oxgang to one, and another to another, in fee; and afterwards the ſheriff diſtrains only one of them for the rent; he that is ſo deſtrained may have this writ for his relief. *Fitz. Herb.* Nat. brev. f. 234.

DEOSCULATION, *Deoſculatio*, in antiquity, one of the moſt antient forms of adoration. See ADORATION, *Cycl.* and *Suppl.*

DEPARTERS *of gold and ſilver*. See the articles FINERS and DEPART, *Cycl.*

DEPERSONATUS. See DISPERSONATUS.

DEPESTA, in antiquity, a wine veſſel, which the Sabines, on any feſtival day ſet on the table of their gods. *Pitſc.* Lex. Ant. in voc.

DEPOPULATORES *agrorum*, in our ſtatutes, ſuch as depopulate or diſ-people lands.

It appears by the ſtatute 4 *Hen.* 4. c. 2. that theſe were great offenders by the antient law, and that the appeal or indictment againſt them ought not to be in a general, but in a ſpecial manner. They got their name of *depopulatores agrorum*, for that by proſtrating or decaying the houſes and habitations of the king's people, they depopulate towns. *Coke*, 3 Inſt. fol. 204.

DEPOSITION, *Depoſitio*, among the antients, a ceremony obſerved immediately upon a perſon's expiring, and was a ſolemn manner of laying the corpſe upon the ground. *Hoſm.* Lex. in voc. See BURIAL.

DEPRESSED *Leaf*. See LEAF.

DEPRESSOR (*Cycl.*) — DEPRESSOR *Alæ naſi*, in anatomy, a name given by Albinus, to a muſcle of the face, called by Cowper *conſtrictor alæ naſi*, and *depreſſor labii ſuperioris*.

DEPRESSOR *angular oris*, in anatomy, a name given by Albinus to the muſcle, called by others *depreſſor labiorum communis*; which ſee.

DEPRIMENS (*Cycl.*) DEPRIMENS *Biventer*, in anatomy, a name given by Spigelius, and others, to one of the muſcles of the lower jaw, called by others *digaſtricus ſive biventer*; and by Albinus *biventer maxillæ inferioris*.

DEPRIMENS *humerum rotundus*, in anatomy, a name given by Spigelius, and others, to a muſcle called by others the *teres major* and *rotundus major*.

DEPRIMENS *occuli*, in anatomy, a name given by Riolanus, and others, to one of the muſcles of the eye, called the *humilis*, and *rectus inferior* by others. It is the *depreſſor occuli* of Cowper, and of Albinus, being one of his four recti.

DEPRIMENS *quintus*, in anatomy, a name given by Spigelius, and ſome others, to the muſcle called the *ceratogloſſus*. See the article CERATOGLOSSUS.

DE QUIBUS *ſur diſſeiſin*, in law, a writ of entry. See *Fitz. Herb.* Nat. brev. fol. 191.

DER, a ſyllable frequently prefixed to the names of places in England. It is ſaid to ſignify that ſuch were formerly places where wild beaſts herded together, ſo called from the Saxon Deop, *fera*, unleſs the ſituation was near ſome river. *Blount.*

DARAIGN, or DEREYN, *diſrationare* vel *dirationare* in our old laws, is generally uſed for the act of proving: thus we find, *dirationabit jus ſuum hæres propinquior. Glanv.*. l. 2. c. 6. And, *dirationavit terram illam in curia mea.* Id. l. 2. c. 20. Bracton uſes it in the ſame ſenſe, *Habeo ſufficientem diſratiocinationem & probationem*, l. 4. tract. 6. c. 16. And ſo he makes uſe of *diſrationare*, l. 4. c. 22. And we find to *dereyn the warranty* in Old Nat. Br. fol. 146. To *deraign* that right, 3 Edw. 1. c. 4. and Weſtmin. t. 2. cap. 5. When the parſon of any church is diſturbed to demand tithes in the next pariſh, by a writ of *indicavit*, the patron ſhall have a writ to demand the advowſon of the tithes, being in demand; and when it is *deraigned*, then ſhall the plea paſs in the court chriſtian, as far forth as it is *deraigned* in the king's court.

DERAINMENT, or DEREINMENT. The ſubſtantive *dereinment* is ſometimes uſed in the ſame ſenſe with the French *deſrayer* or *deſranger*; that is, to diſplace or ſet out of order: thus we find, *deraignment* or departure out of religion, ann. 31. Hen. 8. c. 6. & 5 and 6 Edw. 6. c. 13. Thus alſo we meet with, *dereinment* or diſcharge of their profeſſion, 33 Hen. 8. cap. 29. which is ſaid of thoſe religious men, who forſook their orders or profeſſions. See Kitchin, fol. 152. The leſſee enters into religion, and afterwards is *deraigned*. And *Briton*, c. 21. uſes *ſemonenſe deſrenable*, for a ſummons that may be challenged as defective, or not lawfully made. *Skene* de verb. ſignific. verbo *diſrationare*, makes it ſignify what we call waging and making of law. See LEX *deraiſnia*.

DERBY *marble*. See MARBLE.

DERDER, in the materia medica of the ancients, a name uſed by Aviſenna and Serapio, to expreſs the common elm, whoſe bark they uſed on many occaſions.

DEREFELD, in our old writers, is uſed for a park, q. d. a field of deer.

DERELSIDE, in botany, a name by which ſome authors have called the tamarind tree. *Alpin.* Egypt. p. 328.

DE REVOCATIONE *parliamenti*, the name of a writ for recalling a parliament. Thus in 5 Edw. 3. the parliament being ſummoned, was recalled by ſuch a writ before it met. Vid. *Pryn's* Animad. on the 4 Inſt. f. 44.

DERVIS (*Cycl.*)—Of theſe there are in Egypt two or three kinds; thoſe that are in convents, are in a manner of a religious order, and live retired; though there are of theſe ſome who travel and return again to their convents. Some take this character, and yet live with their families, and exerciſe their trades: of this kind are the dancing *derviſes* at Damaſcus, who go once or twice a week to a little uninhabited convent, and perform their extraordinary exerciſes; theſe alſo ſeem to be a good people: but there is a third ſort of them who travel about the country, and beg, or rather oblige people to give, for whenever they ſound their horn ſomething muſt be given them. The people of theſe orders, in Egypt, wear an octagonal badge, of a greeniſh white alabaſter, at their girdles, and a high ſtiff cap without any thing round it. *Pocock's* Egypt, p. 178.

DESCENDENS *obliquus*, in anatomy, a name given by Fabricius, and others, to the muſcle, called by Albinus *obliquus externus abdominis*.

DESCENT (*Cycl.*)—The ſeparating mercury from its ore by *deſcent*, is performed in the following manner: take two earthen pots, with orifices of equal diameter; adapt an iron plate to the orifice of one of the two pots, in ſuch a manner that it may reſt upon the brink of it, but not jut out too much all round: let this have ſeveral holes bored here and there in it, but not near its bottom; pour into this pure water, to about two inches high, then ſhut it with the iron plate; put upon this plate a ſmaller veſſel, containing the ore of mercury; then cloſe theſe veſſels, with the ſecond pot inverted, ſtopping the joint well with lute; bury the inferior pot in aſhes, and put about the whole a moderate fire, continue it till the upper veſſel is ſlightly red hot, and the mercury will be driven into the lower, in fumes, which will be condenſed by the water into running quickſilver. *Cramer's* art of aſſaying, p. 352.

DESERTERS (*Cycl.*)—For the manner of puniſhing them among the antients, ſee TRANSFUGA.

DESIDERATUM, is uſed to ſignify the deſirable perfections in any art or ſcience: thus, it is a *deſideratum* with the blackſmith, to render iron fuſible, by a gentle heat, and yet preſerve it hard enough for ordinary uſes; with the glaſs-man, and looking-glaſs maker, to render glaſs malleable; with the clock-maker, to bring pendulums to be uſeful where there are irregular motions; with the braſier and copper-ſmith, to make malleable ſolder; with the ſhip-wright, to build veſſels that will ſail under water; with the diver, to procure manageable inſtruments for conveying freſh air to the bottom of the ſea, ſufficient for reſpiration, and the burning of lights; with the aſſay-maſter, to melt or copel ores, or metals, immediately without the uſe of bellows or furnace; and with the carvers and joiners, to faſhion wood in moulds like plaiſter of Paris, or burnt alabaſter, &c. And though, as Mr. Boyle obſerves, the obtaining of theſe *deſiderata* may be thought chimerical, yet it is proper they ſhould be propoſed; for although perfection may not be attainable, yet approaches to it may be made, and arts thereby improved. Vid. *Boyle's* Works abr. Vol. 1. p. 129, 136.

To this we may add, that the making iron malleable with pit-coal, was once perhaps looked upon as chimerical, yet it is now put in practice, to the great advantage of the owners of ſeveral mines in this kingdom.

It is a *deſideratum* in the tin works, to find a method of obtaining the ſilver out of the tin, as it is now got out of the lead, in places where the ores are ſo rich as to make it worth the while.

In the glaſs-works it is a *deſideratum* to ſolder up the cracks and flaws in the pots, while they are detained in the fire, and another to make glaſs without veins.

A taſteleſs and inodorous wine is a *deſideratum* among vintners, and a taſteleſs acid inodorous ſpirit among diſtillers.

The painters want a permanent green, and the callico printers a laſting blue.

In ſhort, all arts have their defects, and it is not at firſt to be gueſſed, for how many of theſe, remedies may be found, by means of chemical reſearches properly directed.

Chemiſtry itſelf is greatly defective in many particulars, as in an experimental hiſtory of general fermentation, ſeparatory and combinatory, in ſubjects of the animal, vegetable, and mineral kingdoms. A hiſtory of putrefaction, rancidneſs, muſtineſs, mouldineſs; and of the making of glues, mucilages, and the like preparations in the moſt perfect manner is alſo wanted.

The ſublimer metallurgy is in particular yet greatly defective. It wants a more eaſy method of extracting the mercuries of metals, than thoſe commonly deſcribed; a cheaper method of meliorations is wanted; and, in general, all the parts of this branch of the art ſeem equally defective.

The ſchemes for new trades will riſe occaſionally in the proſecuting many of the ſubjects; thus, it is natural for the common operations of brewing and ſugar-baking, to ſuggeſt that ſugar may be procured from malt and other vegetables. That nurſeries of peculiar ferments, both native and foreign, may be raiſed on the common principles; and, it is evident, that the introduction of ſuch new trades, would greatly improve the buſineſſes of brewing, ſugar-baking, and the like.

If a proper number of perſons duly qualified for making expements, and improving from them, would ſet about each his particular ſhare of the neceſſary experiments, and communicate the reſult of all their proceſſes to one another, the buſineſs of chemical experiment, would be much better directed in regard to future ſtudents, and many of the deſiderata in the art probably ſupplied. Vid. *Shaw*, Chem. p. 355.

DESION, in chronology, the Macedonian name of the Athenian month *Antheſterion*. See ANTHESTERION.

DE SON TORT *demeſn*, in our law, words of form, uſed in an action of treſpaſs by way of reply to the defendant's plea. Thus, if A. ſues B. in ſuch an action; B. anſwers for himſelf, that he did that which it calls a treſpaſs by the command of C. his maſter. A. replies that B. did it *de ſon tort demeſne, ſans ceo que C. luy command modo et forma*; that is, B. did it of his own wrong, without C.'s commanding him in ſuch manner and form. *Cowel.*

DESPOTIC. See DESPOTISM, *Cycl.*

DETENTS, in a clock, are thoſe ſtops which, by being lifted up or let fall down, lock and unlock the clock in ſtriking.

DETENT-*Wheel*, or HOOP-*Wheel*, in a clock, that wheel which has a hoop almoſt round it, wherein there is a vacancy, at which the clock locks.

DETERRATION, is uſed to ſignify a removal of the earth, ſand, *&c.* from the mountains and higher grounds, down into the valleys and lower parts. This is occaſioned by rains, which waſh the earthy matter down by degrees; but this cannot be very conſiderable, or much raiſe the ſurface of the earth, as ſome have imagined, becauſe a good part of it is ſunk into the clefts and caverns of the rocks and mountains, a great quantity is born down into rivers, and thence into the ſea, and the richer and finer part helps to compoſe the bodies of plants and vegetables. *Harris.*

DETERSOR, in antiquity, a ſervant whoſe buſineſs it was to attend at dinner, and wipe the table. *Pitiſc.*

DETERSORIUM, in antiquity, a name given to the common waſh, which was bean-meal, called *Lomentum*, or the meal of a ſort of pulſe called *Lupines:* this laſt they called *Smegma.*

The antients when they bathed uſed various waſhes for cleanſing the skin; but natrum, and its thin froth, called in Greek *Aphronitron*, were moſt common.

DETRAHENS *Quadratus*, in anatomy, a name given by ſome authors, particularly Spigelius, to a muſcle, called by the generality of anatomiſts the *Platyſma Myodes*; and by Albinus, *latiſſimus Colli.* Douglas calls it alſo *quadratus genæ.*

DEVENSHRING, or DENSHRING, a term uſed by the farmers to expreſs the burning land by way of manure: the method is to cut off the turf about four inches thick, and burn it in heaps, and then ſpread the aſhes upon the land; they probably call it *Devenſhring* from its having been earlieſt practiſed in Devonſhire. See the article BURNING.

DEVEST, *deveſtire*, in feudal writers, is uſed for the oppoſite to inveſting. *Inveſtire* ſignifies *poſſeſſionem Feudi tradere.* On the contrary, *Diveſtire* is *poſſeſſionem auferre.* Feud. lib. 1. c. 7. *Cowel.*

DEVINCTION, *Devinctio*, in antiquity, was uſed to ſignify a love-charm or incantation to gain the affection of a perſon beloved.

It was done by tying knots, and differed little from what was called *Obligatio* or *Catadeſmus.* Virgil in his 8th Eclogue deſcribes it thus:

Nectе tribus nodis ternos Amarylli colores,
Nectе Amarylli modo, & veneris, die, vincula nectо.

Pitiſc. Lex. Ant. in voc.

DEVOIRS *of Calais*, in our old ſtatutes, cuſtoms due to the king for merchandize brought to or carried out of Calais, when our ſtaple was there. 34 Edw. 3. c. 18. & 2 Rich. 2. ſtat. 1. c. 3.

Devoir is French, ſignifying duty.

DEVOTION (*Cycl.*)—Cornelius Nepos uſes the word *Devotion* for a kind of puniſhment conſiſting of direful curſes and marks of infamy. See the article EXECRATION.

DEUS *Myagrus.* See MYAGRUS.

DEUTEROPOTMI, δευτεροποτμοι, among the Athenians, a deſignation given to ſuch who had been thought dead, and, after the celebration of the funeral rites, unexpectedly recover'd. It was unlawful for the *Deuteropotmi* to enter into the temple of the *Eumenides*, or to be admitted to the holy rites, till after they were purified by being let through the lap of a woman's gown, that they might ſeem to be new born. *Pott.* Archæol. Græc. l. 2. c. 4. T. 1. p. 223.

DEUTEROSIS, the Greek name by which the Jews called their *Miſchnah*, or ſecond law. *Deuteroſis* in Greek has the ſame ſignification almoſt as *Miſchnah* in Hebrew; both ſignify an iteration. Euſebius accuſes the Jews with corrupting the true ſenſe of ſcripture with the trifling explanations of their *Deuteroſes.* Epiphanius ſays, that there were four ſorts of theſe quoted, the firſt under the name of Moſes, the ſecond under that of Akiba, the third under that of Adda or Judah, and the fourth under the name of the ſons of the Aſmonæans or Maccabees: It is not eaſy to determine whether the preſent Miſchnah is the ſame with any of theſe, whether it contains them all, or only ſome part, or whether it be different from them all, Jerom ſays, that the Hebrews referred their *Deuteroſes* to Shammai and Hillel. If it were well proved that they were of this antiquity, it would be conſiderable; ſince Joſephus ſpeaks of Sammeas, who is the ſame with Shammai in the beginning of Herod's Reign. Jerom ſpeaks always of the *Deuteroſes* with the utmoſt contempt: he looked upon them as a collection of fables, childiſh ſtuff, and obſcenities. He ſays, the principal authors of theſe fine deciſions, according to the Jews, are Bar-Akiba, Simeon, and Helles. Bar-Akiba is probably the grandfather or father of the famous Akiba. Simeon and Shammai are the ſame perſons, ſo are Helles and Hillel. *Calmet*, Dict. Bibl. in voc.

DEVUIDER, in the manege, is applied to a horſe, that upon working upon *Volts* makes his ſhoulders go too faſt for the croupe to follow; ſo that inſtead of going upon two treads, as he ought, he endeavours to go only upon one. This comes from the reſiſtance he makes in defending againſt the heels; or from the fault of the horſeman, who is too haſty with his hand. *Guil.* Gent. Dict. in voc. See HASTE.

DEW (*Cycl.*)—Thro' the whole courſe of the operations of nature, when there appear two methods by which any thing that we ſee can be effected, we have many reaſons to believe that it is done by that method which is the moſt different from common appearances. As we know there muſt be a revolution, for inſtance, either of the earth round the ſun, or of the ſun round the earth; tho' common appearances ſeem to inform us, that it is the earth which ſtands ſtill, and the ſun which moves round; yet when we come to enquire more deeply into nature, we very plainly find that it is in reality the earth which makes the revolution, while the ſun remains fixed in its place. A thouſand other parallel inſtances might readily be produced; and according to this method of judging, we are to teach ourſelves to judge of the *Dew*, which then becomes one of the number.

The *Dew* which we ſee continually appearing to fall at its ſtated periods, may thus either fall originally from that middle region of the air, whence it ſeems to us to deſcend; or elſe it may be firſt raiſed from the bowels of the earth in form of a vapour, and ſent up into that region, whence it again falls, if it do fall to us, in form of *Dew.* The moſt natural opinion ſeems that of its falling *ab origine* out of the air; and thus the generality of the world look upon it, eſteeming it a gift of heaven for the enriching and fertilizing the earth. But the truth is on the other ſide of the queſtion; and it is indiſputable, that all that we properly call *Dew*, all thoſe drops of water which, tho' imperceptible, as ſuch while ſeparate, eaſily amaſs themſelves into larger drops, and are in that ſtate found on graſs, and on the herbs of the field and garden in the morning, and remain there for a certain time, all this has unqueſtionably been firſt raiſed in vapour out of the earth to which it now again deſcends.

This is no new opinion, tho' not a general one; the old naturaliſts have many of them affirmed it, and there are ſo many familiar proofs of it, that one would think ſcarce any obſerver could be ignorant of it. Every gardener knows that the glaſs bell, which he places over a tender fruit, will be hung over with drops of *Dew* after a certain time, tho' it have no communication with the external air, nor can have received them any other way than in the vapours raiſed from the earth. There have not however been wanting men of great genius and knowledge who have contradicted this opinion, and endeavour'd to account for all that appears in favour of it from other principles. Experiments however are the great guides to truth; and M. Dufay, of the royal academy at Paris, being reſolved to try firſt of all the grand queſtion, whether the matter of *Dew* did firſt aſcend in vapour, or did not, he brought the firſt proof to this ſimple proceſs: if the *Dew* did aſcend, it muſt

muſt wet a body placed lower ſooner than one placed higher, and muſt wet its under ſide ſooner than its upper, and of a number of bodies placed in this manner, the lower muſt be thus gradually wetted all the way before the upper. It appeared certain to him, that the *Dew* aroſe in vapour from the earth after it had been heated by the ſun, and that not leſs of it aroſe in the middle of the day than afterwards, but that then it was diſperſed and evaporated as ſoon as raiſed. On this foundation he determined to make his trials, and for this purpoſe he plac'd two ladders againſt one another, meeting at their tops, ſpreading wide aſunder at their bottoms, and ſo tall as to reach thirty-two foot high. To the ſeveral ſteps of theſe he faſtened large ſquares of glaſs like the panes of a window, and ſet them in ſuch a manner, that they ſhould not ſhade or overhang one another. It was plain that, on the whole, if the *Dew* deſcended without firſt ariſing, the top ſquares muſt be firſt wetted, and that on their upper ſurfaces; but, on the contrary, if the *Dew* firſt aſcended from the earth, the bottom ſurfaces of the lower panes muſt firſt receive it. On the trial it appeared exactly as expected in the latter manner. The lower ſurface of the loweſt piece of glaſs was firſt wetted, then its upper ſurface; then the lower ſurface of the pane next above it, and ſo on gradually till the whole were wetted to the top of the ladders.

It was happy that this Experiment ſucceeded in ſuch perfect regularity; but this is not always to be expected, for a thouſand accidents may prevent it, and the lighteſt wind deſtroy it: thus, ſuppoſing the *Dew* to have aſcended in this exact order up to a certain height, it may there meet with a guſt of wind, which ſhall diſſipate it in ſuch a manner, that it ſhall no more affect the higher planes, till that wind ceaſing, gives it leave, which perhaps may not be till it has riſen to the height of the whole ladder; and then at an inſtant all the upper planes ſhall after this interruption be wetted at once.

This gentleman afterwards tried the ſame experiment with pieces of cloth tied to the ſteps of the ladder inſtead of glaſſes, as he could be able, by weighing theſe, to know of certainty, how, and in what order they received the dew; in this trial ſome accident prevented the ſame perfect regularity from appearing in the aſcent of the *Dew*, but the quantity of moiſture imbibed by the higher pieces, was ſo much leſs than that imbibed by the lower, as abundantly to prove that the moiſture they received was from below not from above. Mr. Muſchenbroek, who is no friend to this opinion, thought he had invalidated all theſe proofs, by trying the ſame experiments, and finding the ſame ſucceſs on a plane covered with ſheet lead, as had before appeared in the garden of the firſt experiments, where the ladders were placed on the ground. Mr. Muſchenbrock, who eaſily ſaw that the vapour could not aſcend, at leaſt not in ſuch quantity through lead, thought he had proved, that however it appeared on the cloaths, it muſt have deſcended from above; but Mr. du Fay very properly overthrew all theſe arguments, by obſerving, that the vapour need not riſe through the lead, nor from that very ſpot, but that as it aroſe from the adjoining open ground, the continual fluctuation of the air, could not but ſpread it abroad, and carry it in its aſcent thither.

The order and manner of the aſcent of *Dew* is thus aſcertained, and its deſcent again cannot appear at all wonderful when we conſider, that at ſuch times, as the heat of the ſun is not ſo great as to diſſipate it, as it riſes, it will, by its natural attraction form itſelf, into drops ſo large, and of ſuch gravity, that the air cannot ſuſtain them. From the ſame ſource and origin, we muſt alſo ſometimes have thick fogs, and theſe, properly ſpeaking, are only *Dew*, in a certain ſtate. Mr. du Fay has proved alſo, that the vapour which is to fall in *Dew*, continues to mount in a direct courſe upwards the whole night. For having hung up a piece of woolen cloth, after he had carefully weighed it, he examined it, at times, through a whole night; and weighing it every time, he found it ſenſibly increaſed in weight; that is, its quantity of moiſture ſenſibly increaſed every time. Theſe are the moſt obvious qualities in regard to the *Dew*, but there are others more nice and curious, which owe their firſt notice to Mr. Muſchenbroek, and have been afterwards verified by Mr. du Fay.

Several different ſubſtances expoſed to the ſame *Dew*, receive and charge themſelves with it in a very different manner, ſome more, others leſs, and ſome even not at all. The drops ſeem to make a ſort of choice of what bodies they ſhall affix themſelves to; glaſs and cryſtals are thoſe which they affix themſelves to, in the moſt ready manner, and in the largeſt quantity; and metals, of all kinds, do not receive them at all, nor do the drops ever affix on them. The two extremes are thus fixed; the intermediate bodies are to be judged of by repeated experiment. The extremes are indeed ſo well aſcertained, that they are eaſily proved; for, if a cryſtal, or glaſs veſſel be ſet out in an evening on a ſilver plate, the glaſs will be found covered all over with *Dew* drops, and the ſilver perfectly dry. China ware is a ſort of glaſs; ſix pounds of mercury being expoſed to the air in a china plate, the *Dew* was found running in ſtreams on the edges of the plate, while not the leaſt trace of a ſingle drop appeared upon the mercury.

The plain way of accounting for this would ſeem, not that *Dew* falls upon ſome bodies without touching others, but that it readily evaporates from the ſurfaces of ſome, while it remains and collects itſelf into drops upon others: and it is hence that we find ſome wet and others dry, which have had the ſame expoſure; but this, though the moſt obvious, and ſeemingly apparent reaſon, is not the true one. Mr. du Fay has obſerved, that if this were the caſe, in thoſe bodies, which we find dry after expoſure, the evaporation muſt be more ſudden than there are powers in nature, to effect; or, in other words, than it is poſſible for it to be; and the truth, in regard to the obſervation, is not this; but that, in reality, the particles of this aſcending *Dew* really do not affix themſelves at all to ſome bodies, while they very readily do it to others; as we ſee in water itſelf, that in a common river, a rough dog, ſhall be miſerably wetted all over, while the feathers of a ſwan ſhall not receive a ſingle drop of moiſture.

There is alſo another ſingle obſervation, which ſhould ſeem to prove that this vapour only aſcends, and does not at all deſcend in form of *Dew* again; but that what we ſee collected into drops on graſs, and plants, collects itſelf in that manner in the beginning of its aſcent. For if a cup of any metal be expoſed a whole night, it will never be found to contain any *Dew*, which if that liquid deſcended muſt have been the caſe; ſince, though it did not naturally ſtick to that metal, it muſt fall into it, and remain there; but this does not happen. What can be collected from the whole, ſeems, that *Dew* is a vapour, which ariſing into the air, and increaſing in quantity, through the courſe of a whole night, expands itſelf every way in it, and moiſtens or wets ſome ſubſtances, and does not moiſten others, and this merely according to the differences of their ſurfaces.

Theſe however are but probable ſyſtems, not abſolutely known facts: ideas of the manner of the actions and operations of bodies, readily flow into the mind, when we have formed a ratio, be it whatever, in our own thoughts for them. Mr. du Fay has many nice opinions in regard to this vapour or liquid, which it were much to be wiſhed were carefully examined by experiments. He ſuppoſes ſome diſtant alliance between the phænomena he has obſerved in *Dew*, and thoſe which appear in electrical bodies, and in thoſe bodies which afford phoſphori. He has obſerved, that all bodies, which are capable of a ſufficient degree of rubbing, become electrical, excepting only the metals; and that all bodies, except only the metals, may alſo be made phoſphori. The metals are the only bodies alſo which wholly refuſe to admit the *Dew*; here are certain properties all appearing in metals, and in metals only; and it ſeems hence there may be ſome affinity in thoſe things, which do, or do not affect the metals only. It is certain, that there are connections in natural bodies, which are too nice for haſty elucidation, yet are not unworthy all the care that can diſcover them. Mem. acad. Scien. 1736.

It is very certain that ſubſtances of a very different kind from the uſual and natural matter of the *Dew*, have ſometimes fallen in that form. Our Philoſophical Tranſactions give an account, that in the year 1695, there fell in Ireland, in ſeveral parts of the provinces of Leinſter and Munſter, for a conſiderable part of the winter and ſpring, a fatty ſubſtance, reſembling butter inſtead of the common *Dew*; it was of a clammy texture and dark yellow colour; and was, from its great reſemblance, generally called *Dew-butter* by the country people. It always fell in the night, and chiefly in the mooriſh low grounds, and was found hanging on the tops of the graſs, and on the thatch of the houſes of the poor people. It was ſeldom obſerved to fall twice in the ſame place, and uſually wherever it fell it lay a fortnight upon the ground before it changed colour, but after that it gradually dried up, and became black. The cattle fed in the fields where it lay, as well as in others, and received no hurt from it: it fell in pieces of the bigneſs of ones finger end, but they were diſperſed ſcatteringly about, and it had an offenſive ſmell, like that of a churchyard. There were in the ſame places very ſtinking fogs during the winter, and ſome people ſuppoſed this no other than a ſediment or connection of the heavier matter of thoſe fogs. It would not keep very long, but it never bred worms. The country people willing to have ſome good of it, tried it on their childrens fore-heads, and it always cured them. Philoſ. Tranſ. n° 220. p. 222.

Cryſtalline DEWS, a term uſed by ſome modern writers, to expreſs certain *Dews*, or ſteams; which, in their fall upon the earth, become, as they ſay, cryſtal. This greatly favours the opinion of the antients, that all cryſtal was only water frozen into a kind of ice harder than ordinary, but it is erroneous. Mr. Beaumont gives an account in the Philoſophical Tranſactions of theſe cryſtal *Dews* on Mendip hills; in which he tells us, that the miners of that place find ſometimes in the roads where the earth is bare, triangular cryſtals, about two inches in length, and an inch over, not with ſharp angles, but roundiſh and blunted ones, and carried up round at the ends like a cocoa nut; and that none of theſe are ever found under ground in digging, but only lying on the ſurface. He tells us alſo, that he had ſeen ſome taken up in Glouceſter-

ſhire, and confirms the opinion of theſe *cryſtalline Dews*, producing real cryſtals, by the account given of ſome places in Italy, where cryſtals are, as it is ſaid, frequently produced in clear evenings by a coagulation of the *Dews* falling on nitrous ſteams. Whatever the cryſtals are, which authors ſeem to ſuppoſe to have been generated in this manner, it is very certain, that they have in reality another origin; and theſe are only the accounts of ignorant and inconſiderate people, to give credit to the ſtrange and unnatural method here given for their formation. Philoſ. Tranſ. n° 129.

May-DEW. See Ros-*mayalis*.

Orange-DEW. See ORANGE.

Sun-DEW. See Ros-*ſolis*.

Earth of DEW. See the article EARTH.

DEX, a name uſed by many Greek writers, for a worm or maggot, hatched of the egg of a beetle, and remarkable for its eroding wood. It is alſo called thrips and enxylon. The old Greeks uſed the pieces of wood eroded by it in various directions as ſeals. See the article THRIPS.

DIABATHRA, in antiquity, a kind of ſhoe worn by the Grecian women. *Pitiſc.* Lex. Ant. in voc.

DIABE, in zoology, the name of a prickly ſea fiſh of the orbis or globe fiſh kind, and in all things reſembling the hiſtrix or porcupine fiſh, except that its ſpines or prickles are all fixed into its skin by three inſertions. *Marcgrave*'s Hiſt. Braſ. l. 4. c. 14.

DIABETES (*Cycl.*)—In this diſeaſe the urine is thin and pellucid, and has no ſediment, and is of a ſweetiſh taſte; the quantity voided is always very great; and if the patients endeavour to retain it, they are afflicted with ſwellings about the loins, and a ſenſation of weight and preſſure in the hypochondria.

Perſons ſubject to the Diabetes. — It is a very rare diſeaſe, and ſeems to have been ſo in other ages as well as the late ones. Galen expreſsly ſays, that he never met with more than two perſons who had it; the people affected with it are uſually ſuch as have diſorders of the viſcera in general; and it is often but a ſymptomatick affection, ariſing from an improper treatment of perſons in fevers.

Prognoſticks in it. It is always a very terrible diſeaſe, but the longer ſtanding it is of, the more difficult it is to be cured; it is not, however, ſuddenly of fatal conſequence, but the people uſually live ſome time with it, though they in the end generally die tabid, after having been afflicted with it a length of time.

Method of cure. The infarctions of the viſcera, which are the occaſion of this, are firſt to be regarded, and are to be attacked with ſuch aperients as are not ſtrongly diuretick; of this kind are decoctions of the roots of dandelion, ſuccory, polypody, and the like; and of the capillary herbs. Pills alſo are to be taken, made of ammoniacum, and the other reſolvent gumms, with the bitter extracts; and interchangeably with theſe the digeſtive neutral ſalts, ſuch as tartarum vitriolatum, and the like: during this courſe, the febrile heat, which always attends this diſtemper, is to be taken off by the vegetable acids, ſuch as ſorrel and purſelain, and tincture of roſes made in the uſual way. Some recommend the teſtaceous powders in general; and others are peculiarly laviſh in the praiſes of crawfiſh reduced to powder whole, after baking them in an oven. The great diſcharge of urine is to be leſſened, in the mean time, by gentle laxatives now and then given, ſuch as infuſions of ſenna, rhubarb, and the like; and finally, if the diſeaſe goes off, or but remits conſiderably of its violence, the chalybeates, and other reſtoratives, are to be given, to reſtore the parts to their due ſtate.

It is a common error to give aſtringents in a *Diabetes*; for, if they take effect, they too violently conſtringe the viſcera, and bring on pains and ſwellings in the loins, and not rarely an aſcites and death itſelf in the end.

Perſons ſubject to this diſeaſe ſhould be extreamly careful of themſelves in their regimen; they ſhould avoid all hot things, and beware of themſelves that they do not fall into violent paſſions; they ſhould feed principally on emulſive and gelatinous diets, to make up for the waſte of fleſh that always attends this diſeaſe. *Junker*'s Conſp. Med. p. 540.

Dr. Morgan thinks the tincture of cantharides may almoſt be abſolutely depended on for ſtopping the immediate flow of urine in the *Diabetes*. The way he prepares his tincture is, by infuſing half an ounce of cantharides upon a pound of the elixir vitrioli; of which tincture, from fifteen to thirty or forty drops, may be given twice or thrice a day in Briſtol hot well water. Mecan. pract. of Phyſ. p. 114.

Dr. Jurin found the chalybeate waters acidulated with the oil of ſulphur, very ſucceſsful in this diſtemper. Med. Eſſ. Edinb. Abr. Vol. 2. p. 469.

Allum poſſet-drink is alſo ſaid to be an effectual cure for a *Diabetes*. Ibid.

DIABOLUS *Marinus*, *the ſea devil*, in zoology, the name of an ugly and ſtrangely ill-ſhaped fiſh, of the ray kind. Its noſe or ſnout is bifid, and runs out into two horns, and its ſides are both terminated by thin fins: its skin toward the head is variegated with dusky ſpots. It grows to a very conſiderable ſize, being ſometimes caught of ſix or ſeven feet long. *Ray*'s Ichthiogr. append. p. 5. See Tab. of Fiſhes, N° 65.

DIACAUSTIC. See *Cauſtic by* REFRACTION.

DIACELTATESSON, in chemiſtry, a name given by Van Helmont, to a purging preparation, procured from the fixed flowers of antimony, in the following manner: take eighteen grains of the fixed diaphoretick flowers of antimony, ſixteen grains of roſin of ſcammony, and ſeven grains of cream of tartar, make all together into a powder. Or take nine grains of the fixed antimony, nine grains of roſin of ſcammony, and three grains of cream of tartar, make them into a fine powder. The former is the largeſt doſe for a grown perſon, and the latter the leaſt; they are to be taken without any acid; and if they operate too violently, the violence may be ſtopped by taking any thing acid: it is to be given in intermittents, ſo as to finiſh its operation immediately before the coming on of the fit: it is ſaid by the author always to cure quartans before the fourth doſe, and all intermittent and continued fevers.

Boerhaave obſerves, that he had often given it with good effects, but never with that great ſucceſs which the author aſcribes to it; who ſays, that it radically cures the gout and fevers, heals ulcers of the larynx, œſophagus and bladder, and purges the body when in perfect health, but not otherwiſe. This candid writer obſerves, that Helmont ſeems always to have carried the virtues of his medicines by a ſubtilty of reaſoning, beyond what will be found warrantable of them from experience. Boerh. chem. part 2. p. 338.

DIACENTROS, is uſed by Kepler, to ſignify the ſhorteſt diameter of the elliptical orbit of any planet.

DIACHALASIS, in the medicinal works of the antients, a term uſed to expreſs a ſolution of continuity in the bones of the cranium at the ſutures; that is, when the bones recede from their mutual indentations, an accident that frequently happens from large wounds of the head.

DIACHRISTA, a name given by the antient writers in medicine to certain compoſitions, whoſe uſe was to be applied to the fauces, uvula, palate, and tongue, for the abſterſion of phlegm.

DIACODUS, in natural hiſtory, a name given by ſome to the diadochos, a kind of beryll or ſapphire, of which many fabulous things are aſſerted.

DIACOPE, Διακοπη, in Grammar, the ſame with what is otherwiſe called *Tmeſis*. See TMESIS, *Cycl.*

DIADELPHIA, in botany, a claſs of plants with hermaphrodite flowers, whoſe ſtamina, by the conjunction of their filaments, are formed into two bodies.

The word is formed of the Greek δις twice, and αδελφα communities. Among the plants of this claſs are the fumitory, milk-wort, broom, &c.

The characters of the Diadelphia are theſe: the perianthium conſiſts of one leaf, and is of a bell-like ſhape, and gibbous at the baſe: this always falls with the flower. It ſtands on a pedicle, is obtuſe at the top, and carries a drop of honey-like juice at the baſe. Its mouth or rim is divided into five ſegments, which are ſometimes erect, ſometimes oblique, and always irregular, and acute. The bottom ſegment, which has no fellow, is longer than all the reſt; and the top pair are ſhorteſt of all, and ſtand fartheſt aſunder. The receptacle of the fructification is incloſed in the bottom, where it is wetted with the drop of honey. The flower is of an irregular ſhape, and is of that kind called by authors papilionaceous, from its ſomewhat reſembling the wings of a butterfly. The ſeveral parts of theſe flowers have their ſeparate names; a right underſtanding of which is neceſſary, in order to the comprehending the meaning of the deſcriptions authors give of them. Theſe names are vexillum, alæ, and carina. See Tab. 1. of Botany, Claſs 1. *Linnæi* Gen. Plant. p. 335.

The vexillum is a large incumbent petal, which covers the others, and ſtands in a plane horizontal direction, and has its upper unguis inſerted into the margin of the receptacle or cup; in that part of it which is out of the cup it approaches to a roundiſh figure, and is uſually undivided, or very lightly ſo, and has eſpecially near the apex, a line or ſtreak in the center, which ſtands up above the level of the reſt of the petal, and the petal looks as if depreſſed downwards: that part of this petal which is neareſt the baſe, approaches to a ſemi-cylindric figure, and is then affixed within the cup. The diſk of this petal is depreſſed on each ſide, but the two ſides are turned a little upwards near the edges.

In that part where the tubular part of this petal ends, to give place to its expanſion into the body; there are two concave impreſſions toward the back, which appear ſomewhat prominent at their lower extremity, and ſerve to compreſs the alæ that ſtand under them.

The alæ, in theſe flowers, are two equal petals, a regular pair, and placed under the vexillum, one on each ſide of the flower: theſe are incumbent at the edges, and placed perpendicularly at the ſides, and are of a roundiſh, but ſomewhat oblong figure, broader in the outer part than in the inner; their upper rim is ſtrait and thin, their lower ſomewhat inclined toward a circular figure: the baſe of each is bifid, and the lower ſegment is carried on into an unguis much longer than the other, and is inſerted into the ſide of the receptacle.

It

It is in the whole of much the ſame length with the cup, and is ſhorter, and bent above.

The carina is the lower petal, and is often divided into two ſegments: this is placed under the vexillum, and between the alæ; it is of the ſhape of a boat, being hollow and compreſſed at the ſides: it repreſents, in its poſture, as well as ſhape, a boat on the water, but it is mutilated at the baſe, and is extended in its lower part into an unguis, which is of the length of the cup, and is inſerted into the receptacle. The lateral and upper part being jagged, is received among the like part of the alæ: the ſides of the carina are of a ſhape, reſembling the wings; and their ſituation, in the flower, is much the ſame, but they ſtand ſomewhat more inward and lower. The carina or line of this petal is carried ſtrait along half the petal; after this it ariſes into a ſegment of a circle, but the marginal line runs ſtrait quite to the apex, where it forms an obtuſe angle, with the extremity of the carina, or line. The ſtamina, in theſe flowers, which are called Diadelphia, are two filaments of different ſhape, one of them ſtands below the piſtil, and in a manner involves it; and the other ſtands above, and is depreſſed upon it. The lower filament, which involves the germa of the piſtil, is, in its lower half, membranaceous, of a cylindric figure, and ſplit open. In its upper part, where it divides itſelf into nine parts of a ſubulated figure, which in their length and flexure reſemble the ſhape of the carina; the intermediate or lower ſegiments among theſe are longer alternately in pairs. The upper filament is of a ſubulated and ſetoſe make, it covers the ſlit in the middle of the lower filament before deſcribed; it lies upon this, and is placed in the ſame direction, and is ſhorter; it ſeparates itſelf from the other at the baſe, and gives paſſage to a honey-like liquor.

The antheræ of the whole flower are ten in number; there are nine of them placed on the ſegments of the lower filament, and one on the ſummit of the upper one which has no diviſion; they are ſmall, but are all of equal ſize in the ſame flower.

The piſtil, in theſe flowers, is ſingle, and grows from the receptacle within the cup. Its germen is of an oblong figure, ſomewhat cylindric, but compreſſed in a ſlight manner; it is ſtrait, and is of the length of the cylindric part of the lower filament, by which it is involved and incloſed.

The ſtile is of a ſubulated capillary form and aſcendant, its length and ſituation in the flower are the ſame with thoſe of the radii or ſegments of the upper part of the lower filament, among which it is placed; this ſtile is not permanent, but withers with the ſtamina.

The ſtigma is hoary, it is of the length of the ſtile, it turns upward, and is placed immediately under the ſtamina and antheræ.

The fruit, in all the plants of this claſs, is an oblong cylindric and ſomewhat flatted pod; this is obtuſe, bivalve, and marked with two ſutures, the one above and the other below, each running the whole length of the pod, and the upper one deſcending a little at the baſe, otherwiſe they are all the way ſtrait; the pod always naturally opens at the upper ſuture.

The ſeeds are contained ſeveral in every pod, and are of a roundiſh figure, ſmooth, fleſhy, and pendulous, and have a mark of an embryo, prominent near that part where they are inſerted to the ſides of the pod. The proper receptacles of the ſeeds are very ſmall, ſhort, and attenuated at the baſe, obtuſe in the disk, of an oblong figure, and are inſerted longitudinally into the upper ſuture of the pod; and this, in ſuch an order, that when a pod is carefully opened, onehalf of the ſeeds are always found in one of the valves, and the other half on the other.

This is a perfect natural claſs of plants, and is the moſt remarkable of all others in the ſtructure of the flower. The common ſituation of the flower is in an obliquely pendulous direction, it inclines toward an acute angle from a perpendicular line. The former ſyſtematiſts, in botany, as Linnæus obſerves, took great notice of the pod in this claſs of plants, and thought it the principal ſubject of diſtinction; but he very judiciouſly makes it but of very little conſequence, and will not allow it ſufficient to diſtinguiſh the genera one from another: but the cup, which had always before his time been diſregarded, he eſteems a very eſſential part of the plant, and ſufficiently certain to erect the different genera upon in many caſes. Some of the old writers had been uſed to take the leaves into their marks, by which to diſtinguiſh genera of this claſs; but Linnæus wholly excludes this part of a plant from this office. Magnol has obſerved, that the carinæ of the diadelphia or papilionaceous flowers is dipetalous, and is compoſed of two diſtinct oblong petals; the lower edges of which join ſo nicely and cloſely together, that they ſeem only one; and are not joined in their ſubſtance, but only in their ſituation. Linnæus has ſtrictly examined this, and finds that the author is ſo far right, that this is really the caſe in many of the papilionaceous flowers, but not in all: ſome not only appearing to have, but really and certainly having a carina compoſed of only one petal.

The conſideration of the ſtigma, is of more conſequence in this than in moſt other flowers, and even more than that of any other part of the fructification in this. The ſeeds of all the plants of this claſs are eatable, excepting in a very few particulars; their leaves alſo are a grateful food to cattle. *Linn.* Gen. Plant. p. 337.

DIADOCHUS, in natural hiſtory, the name given by the antients to a gemm, approaching to the nature of the beryl or aqua marine, probably a pale ſapphire; for they had no peculiar generical name for that gemm, but call'd the beautiful deep coloured ones only sky blue beryls, berylli acroides. The writers of the middle ages have given ſtrange accounts of the magical virtues of this ſtone, ſuch as its calling up ſpirits, and many other the like things, on being thrown into water: they ſaid, however, that if it happened by any accident to touch a dead body it loſt all its virtue.

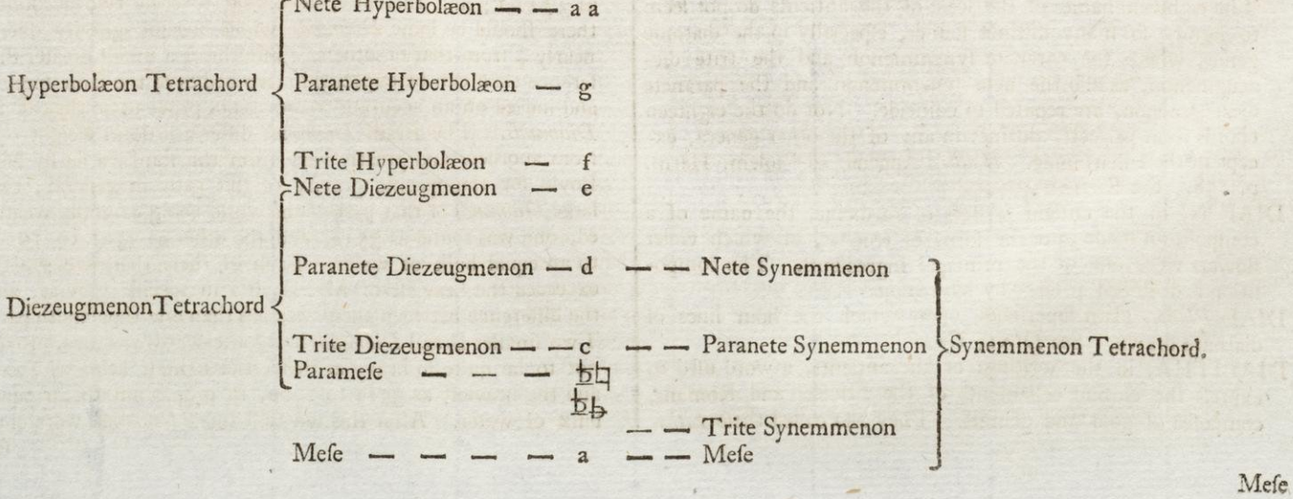
DIADROME, is ſometimes uſed for the vibration, motion, or ſwing of a pendulum.

DIÆRESIS, Διαιρεσις, a figure in Grammar, otherwiſe called *Tmeſis*. See TMESIS, *Cycl.*

DIÆTETÆ, Διαιτηται, among the Athenians, were of two ſorts, the cleroti and diallacterii. The former were a kind of public arbitrators, choſen by lot, to determine all cauſes exceeding ten drachms within their own tribe. Their office was annual, at the expiration of which they were obliged to give up their accounts; and if it was proved, that they refuſed to give judgment, or to have been corrupted, they were puniſhed with infamy. Their ſentence, however, was not final, an appeal lying from it to the ſuperior courts.

The *Diallacterii*, on the contrary, were private arbitrators, from whoſe ſentence there lay no appeal; and accordingly they always took an oath, to adminiſter juſtice without partiality, which the *Cleroti* did not. *Potter*'s Archæol. Græc. l. 1. c. 22. T. 1. p. 122. ſeq.

DIAGLAUCIUM, a name given by the old writers on medicine to a ſort of collyrium, in which the juice of the glaucium, or yellow poppy, was a principal ingredient. It was uſed for beginning lippitudes and ophthalmies.



DIAGONAL *Scale*. See SCALE, *Cycl.*

DIAGRAM (*Cycl.*)—The muſical ſcale or *Diagram* of the antients, was of the compaſs of two octaves, and contained eighteen ſounds, whoſe uſual Greek names are mentioned in the Cyclopædia from Malcolm's Treat. of Muſic, p. 519.

Martianus Capella mentions them by the following names, which he thus tranſlates into Latin:

Προσλαμβανομενη, Adquiſitus: ὑπατη ὑπατων, principalis principalium: παρυπατη ὑπατων, ſub-principalis principalium: ὑπατων διατονη, principalium extenta: ὑπατη μεσων, principalis mediarum: παρυπατη μεσων, ſub-principalis mediarum: μεσων διατονη, mediarum extenta: μεση, media: τριτη συνημμενων, tertia conjunctarum: συνημμενων διατονη, conjunctarum extenta: ὑπατη συνημμενων, ultima conjunctarum: παρα μεσην, prope media: τριτη διεζευγμενων, tertia diviſarum: διεζευγμενων διατονη, diviſarum extenta: ὑπατη διεζευγμενων, ultima diviſarum. τριτη ὑπερβολαιων, tertia excellentium: ὑπερβολαιων διατονη, excellentium extenta: ὑπατη ὑπερβολαιων, ultima excellentium. *Wallis*'s Append. ad Ptolem. Harm. p. 156.

We ſhall here inſert the whole *Diagram*, or Greek Scale, with the correſponding letters of our modern notation.

Meſon Tetrachord	Meſe — — —	a
	Lichanos Meſon — —	G
	Parypate Meſon — —	F
	Hypate Meſon — — —	E
Hypaton Tetrachord	Lichanos Hypaton — —	D
	Parypate Hypaton — —	C
	Hypate Hypaton — — —	B♮
	Proſlambanomenos — —	A

It is to be obſerved, that this *Diagram* only repreſents the diatonic genus; and therefore, after the names *Lychanos Hypaton*, and *Lychanos Meſon*, ſome add *Diatonos*, to diſtinguiſh them from the Lichanoi of the Chromatic or harmonic genera. *Wallis*, Append. ad Ptolem. Harm. p. 157. See LICHANUS.

The Tetrachords in this Diagram are conjunct or disjunct. The conjunct have a common note, chord, or ſound. Thus the Hypate Meſon, which is the laſt of the Hypaton Tetrachord, is the firſt of the meſon. The meſe alſo is the laſt chord of the meſon, and the firſt of the ſynemmenon tetrachord. So likewiſe the nete diezeugmenon is the laſt chord of the diezeugmenon, and the firſt of the hyperbolæon tetrachord. The disjunct tetrachords are thoſe which are ſeparated by a tone. Thus the meſon and diezeugmenon tetrachords are ſeparated by the tone between the meſe and parameſe: ſo likewiſe the ſynemmenon and hyperbolæon tetrachords are ſeparated by the tone between the nete ſynemmenon, and the nete diezeugmenon.

Some of the names of the chords in this *Diagram* being placed nearer to each other than the reſt, ſignify that there is only a ſemi-tone between them. Thus, between the hypate hypaton and the parypate hypaton, or between the meſe and the trite ſynemmenon, or between the parameſe and trite diezeugmenon, the interval is no more than a ſemi-tone.

It has been obſerved by Dr. Pepuſch [a], that the antients conſidered a deſcending as well as an aſcending ſcale; the former proceeding from acute to grave preciſely by the ſame intervals, as the latter did from grave to acute, and the ſame names ſerved for both. But the proſlambanomenos, and the reſt of the names correſponded to different notes of our ſcale. An example of one octave will explain the learned Author's meaning.

Aſcending		Deſcending
A — Proſlambanomenos		g
B — Hypate hypaton	— —	f
C — Parypate hypaton	— —	e
D — Lychanos hypaton	— —	d
E — Hypate meſon	— —	c
F — Parypate meſon	— —	b
G — Lychanos meſon	— —	a
a — Meſe	— —	G

The intervals here, both aſcending and deſcending, are the ſame, and in the ſame order, viz. tone, ſemi-tone, tone, tone, ſemi-tone, tone, tone. So that the one ſcale is preciſely the reverſe of the other. This diſtinction of an aſcending and a deſcending ſcale, is ſaid to be conducive to the variety and perfection of melody, though little underſtood by modern compoſers.[b] [[a] Phil. Tranſ. N° 481. p. 369. [b] Phil. Tranſ. ibid.]

The eighteen names of the ſcale of the antients do not ſeem to ſignify ſo many diſtinct ſounds, eſpecially in the diatonic genus, where the paranete ſynemmenon and the trite diezeugmenon, as alſo the nete ſynemmenon and the paranete diezeugmenon, are reputed to coincide. Nor do the eighteen chords ſeem perfectly diſtinct in any of the other genera, except in the enharmonic. *Wallis*'s Append. ad Ptolem. Harm. p. 158. See ENHARMONIC.

DIAION, in the antient writers of medicine, the name of a compoſition made into the form of troches, of which violet flowers were one of the principal ingredients. The compoſition is deſcribed at large by Myrepſuus.

DIAL-*Planes*, plain ſuperficies, upon which the hour lines of dials are drawn. See DIAL, *Cycl.*

DIALITHA, in the writings of the antients, a word uſed to expreſs the elegant ornaments of the Greeks and Romans, compoſed of gold and gemms. They alſo called theſe *Lithocolla*, cemented ſtones or gemms: the gold being, in this caſe, as a cement, to hold the ſtones together. They wore bracelets and other ornamental things about their habits thus made; and their cups and table-furniture for magnificient treats were of this kind. The green ſtones were found to ſucceed beſt of all in theſe things; and the emerald and greeniſh topaz, or, as we call it, chryſolite, were moſt in eſteem for this purpoſe. This uſe of the ſtones explains what Pliny very often ſays of them in his deſcription: *Nihil jucundius aurum decet*; nothing becomes gold better: this, he ſays, of the green topaz or chryſolite; and this, and many other like paſſages, have greatly perplexed the critics who did not hit upon this explication. The Latins called theſe *Dialitha* and *Lithocolla aurum gemmatum*; and thus Martial, where he ſays *miratur ſcythicas virentis auri flammas Jupiter*, alludes to cups of Gold, ornamented with Scythian gemms, that is, emeralds. Some of the Latins have expreſſed theſe cups by the word *Gemmium*; but erroneouſly: for *Gemmium* is properly the name of a roſe or cup, formed out of ſome one ſtone, as an agate, or the like; but the *Gemmatum Pocculum* is not a cup made of a gemm, but beſet with gemms: this therefore is properly the Dialithum of the Greeks.

DIALLACTERII, among the Athenians. See DIÆTETÆ.

DIALLELOS, Διαλληλος, in rhetoric, a figure, wherein the words and meaning of a ſentence are inverted, as *doctis diſertior, diſertis doctior*. *Voſſ.* Rhet. l. 5. p. 405.

DIALLING (*Cycl.*)—The general theory of *Dialling* is eaſily deduced from the principles of the ſphere, and thoſe of perſpective. The moſt ſimple kind of *Dial* is the equinoctial, where the ſhadow is received upon a plane parallel to the circles of the ſun's diurnal motion, or to the equator; and is projected by a ſtile, or right line perpendicular to thoſe planes. As the ſun moves over equal arcs on its parallel in equal times; the motion of the ſhadow in this *Dial* muſt likewiſe be uniform, ſo that the intervals between the hours muſt be equal, which is done by dividing a circle into twenty-four equal parts. The conſtruction of other *Dials* may be deduced from this, by the rules of perſpective. For one *Dial* may be conſidered as the projection of another, on a propoſed plane.

Practical Rules for the conſtruction of *Dials*, are given in the Cyclopædia under *Dial*. Thoſe who deſire farther inſtructions may conſult the authors there mentioned in the article DIALLING.

A horizontal *Dial* being given, others may be deſcribed from it, in the manner ſhewn by s'Graveſande, in his eſſay on perſpective, chap. 9.

DIALOGISM, Διαλογισμος, in rhetoric, is uſed for the ſoliloquy of perſons deliberating with themſelves. We have an inſtance of it in Virgil, where Dido ſays,

En quid agam? rurſuſne procos irriſa priores
Experiar? &c.

In which ſenſe it is diſtinguiſhed from dialogue. *Voſſ.* Rhet. l. 5. p. 355. See DIALOGUE, *Cycl.*

DIALOGISM is alſo taken in a more extenſive ſenſe for diſcourſe in general, whether held by a perſon alone, or in company. *Voſſ.* loc. cit.

DIAMARTYRIA, Διαμαρτυρια, in antiquity, a proteſtation that the deceaſed perſon had left an heir; and made to hinder the relations from entering upon the eſtate. *Pott.* Archæol. Græc. l. 1. c. 24. T. 1. p. 128.

DIAMNES, a word uſed by Johannes Anglicus, and ſome other authors, for an involuntary diſcharge of urine.

DIAMOND (*Cycl.*)—*Specific gravity of* DIAMONDS. Mr. Boyle has given us the obſervation of a perſon much converſant in *Diamonds*, that ſome of thoſe gemms in their rough ſtate were much heavier than others of the ſame bigneſs, eſpecially if they were cloudy or foul; and Mr. Boyle mentions one that weighed 8 grains and $\frac{8}{16}$, which being carefully weigh'd in water, according to the rules of hydroſtatics, proved to an equal bulk of that liquor, as $2\frac{2}{3}$ to 1. So that as far as could be judged by that experiment, a *Diamond* weighs not thrice ſo much as water; and yet in his table of ſpecific gravities, that of a *Diamond* is ſaid to be to water as 3400 to 1000, that is, as $3\frac{1}{3}$ to 1; and therefore, according to theſe two accounts, there ſhould be ſome *Diamonds* whoſe ſpecific gravity differs nearly $\frac{1}{8}$ from that of others. But this is a much greater difference than can be expected in two bodies of the ſame ſpecies, and indeed on an accurate trial does not prove to be the caſe in *Diamonds*. The Braſil *Diamonds* differ a little in weight one from another, and greatly vary from the ſtandard ſet by Mr. Boyle for the ſpecific gravity of this gem in general; two large *Diamonds* of that part of the world being carefully weighed, one was found as 3518, and the other as 3521 to 1000, to an equal bulk of water. Each of theſe therefore greatly exceeded the heavieſt of Mr. Boyle's in ſpecific gravity, and the difference between them was leſs than one thouſandth part. Two ſmaller Brazil *Diamonds* being afterwards weighed, proved not to be quite ſo heavy as theſe, the lighteſt being as 3501, and the heavieſt as 3511 to 1000, in proportion to an equal bulk of water. After this ten Eaſt India *Diamonds* were choſen

ſen out of a large parcel, each as different from the other as could be, in ſhape, colour, and whatever other reſpects might make a change; theſe being weighed in the ſame ſcales and water as the former, the lighteſt proved to be as 3512, and the heavieſt as 3525 to 1000, in proportion to water. The very near agreement of theſe laſt with one another, and with the former two, weighed at a diſtance of time, makes it highly improbable there ſhould be ſo great a difference as that expreſſed in Mr. Boyle's tables, in any *Diamonds* whatever, much leſs ſo great a difference as appears between the lighteſt of his, and the heavieſt of theſe, being above one ſeventh of the whole. It is very certain that there may be ſome difference in theſe trials from the nature and temper of the water uſed in the experiments; ſome waters, as that of pumps or wells, being heavier than rain or diſtilled water, and the heat or coldneſs of the water may alſo make ſome variation: this, however, is much leſs than might be expected; careful experiments having proved, that the ſpecific gravity of any body will not differ above $\frac{1}{200}$ at moſt, on account of the difference of the water in quality and temper taken together; whereas the heavieſt and lighteſt of the *Diamonds* in Mr. Boyle's and theſe experiments differ about one thirty-fifth part, which is about ſix times as much as $\frac{1}{200}$.

Mr. Ellicot, who made theſe experiments, has drawn out a table of their ſeveral differences, which is done with great care and accuracy, and taking in all the common varieties in *Diamonds*, may ſerve as a general rule of their mean gravity and differences.

	In air.	In water.	Specific gravity.
	Grains.	Grains.	
Water — — — — — —			1000
N° 1. A Brazil *Diamond*, fine water, and rough coat —	92,425	66,16	3518
2. Ditto, fine water, rough coat	88,21	63,16	3521
3. Ditto, fine bright coat — —	10,025	7,170	3511
4. Ditto, fine bright coat — —	9,560	6,830	3501
5. An Eaſt-India *Diamond*, pale blue — — —	26,485	18,945	3512
6 Ditto, bright yellow — —	23,33	16,71	3524
7 Ditto, very fine water, bright coat — — —	20,66	14,8	3525
8 Ditto, very bad water, honeycomb coat — — —	20,38	14,59	3519
9 Ditto, very hard, blueiſh caſt	22,5	16,1	3515
10 Ditto, very ſoft, good water	22,615	16,2	3525
11 Ditto, a large red foulneſs in it	25,48	18,23	3514
12 Ditto, ſoft, bad water — —	29,525	21,140	3521
13 Ditto, ſoft, brown coat ——	26,535	18,99	3516
14 Ditto, very deep green coat —	25,25	18,08	3521
The mean ſpecific gravity of the Brazil *Diamonds* appears to be —— —— —— ——			3513
The mean of the Eaſt-India Diamonds —— ——			3519
The mean of both —— —— —			3517

Therefore, if any thing determinate is to be ſaid, as to the ſpecific gravity of the *Diamond* it is, that it is to water as 3517 to 1000. Philoſ. Tranſ. N° 476. p. 472.

Valuation of DIAMONDS—Mr. Jeffries lays down the following rule for the valuation of *Diamonds* of all weights. He firſt ſuppoſes the value of a rough *Diamond* to be ſettled at 2 l. per carrat, at a medium; then to find the value of *Diamonds* of greater weights, multiply the ſquare of their weight by 2, and the product is the value required. E. G. to find the value of a rough *Diamond* of two carrats, $2 \times 2 = 4$, the ſquare of the weight, which multiplied by 2, gives 8 l. the true value of a rough *Diamond* of two carrats. For finding the value of manufactured *Diamonds*, he ſuppoſes half their weight to be loſt in the manufacturing them; and therefore to find their value, we muſt multiply the ſquare of double their weight by 2, which will give their true value in pounds: thus, to find the value of a wrought *Diamond* weighing two carrats; we firſt find the ſquare of double the weight, viz. $4 \times 4 = 16$, then $16 \times 2 = 32$. So that the true value of a manufactured *Diamond* of two carrats is 32 l.

By this rule Mr. Jeffries has conſtructed tables of the price of *Diamonds* from 1 to 100 carrats. *Jeffries* on *Diamonds*, p. 8, 9. & p. 11. ſeq. of his tables.

Rough *Diamonds* are more commonly found of a ſix pointed figure than of any other; and theſe are called *ſix pointed rough* Diamonds, the figure of which is compoſed of two ſquare pyramids, joined at their baſes. Hence the whole figure is compoſed of eight triangular faces, or planes, four of which meet in a point above the baſe, and four below it, in another point.

The diſtance of theſe two points is the axis of the figure.

Dimenſions of a ſquare brilliant DIAMOND.—To make a complete *ſquare Brilliant*, if the rough *Diamond* be not found to be of the figure here deſcribed, it muſt be made ſo. And if the work be perfectly executed, the length of the axis will be equal to the ſide of the ſquare baſe of the pyramid.

Jewelers then form the table and collet, by dividing the block or length of the axis into 18 parts. They take $\frac{1}{18}$ from the upper part, and $\frac{1}{18}$ from the lower. This gives a plane at $\frac{4}{18}$ diſtance from the girdle for the table; and a ſmaller plane at $\frac{8}{18}$ diſtance, for the collet; the breadth of which will be $\frac{1}{2}$ of the breadth of the table. In this ſtate the ſtone is ſaid to be, *a complete ſquare table* Diamond. *Jeffries* on Diamonds, p. 13.

The Brilliant is an improvement on the table *Diamond*, and was introduced within the laſt century, according to Mr. Jeffries.

To render a Brilliant perfect, each corner of the above deſcribed table *Diamond*, muſt be ſhortened by $\frac{1}{25}$ of its diagonal. The corner ribs of the upper ſides muſt be flattened, or run towards the center of the table $\frac{1}{9}$ leſs than the ſides. The lower part which terminates in the girdle, muſt be $\frac{1}{8}$ of one ſide of the girdle; and each corner rib of the under ſides muſt be flattened at the top, to anſwer the above flattening at the girdle, and at bottom muſt be $\frac{1}{4}$ of each ſide of the collet.

The parts of the ſmall work which completes the brilliant, or the ſtar and ſkill facets, are of a triangular figure. Both of theſe partake equally of the depth of the upper ſides from the table to the girdle, and meet in the middle of each ſide of the table and girdle, as alſo at the corners. Thus they produce regular lozenges on the four upper ſides and corners of the ſtone. The triangular facets, on the under ſides, joining to the girdle, muſt be half as deep again as the above facets to anſwer to the collet part.

The ſtone here deſcribed is ſaid to be a *full ſubſtanced Brilliant*. If the ſtone be thicker than in the proportion here mentioned, it is ſaid to be an *over-weighted Brilliant*.

If the thickneſs be leſs than in this due proportion, it is called a *ſpread Brilliant*.

The beauty of *Brilliants* is diminiſhed by their being either over-weighted or ſpread. The true proportion of the axis or depth of the ſtone to its ſide, is as 2 to 3.

Brilliants are diſtinguiſhed into ſquare, round, oval, and drops, from the figure of their reſpective girdles.

Dimenſions of a roſe DIAMOND—In *roſe Diamonds* the depth of the ſtone from the baſe to the point, muſt be half the breadth of the diameter of the baſe of the ſtone. The diameter of the crown muſt be $\frac{3}{5}$ of the diameter of the baſe. The perpendicular from the baſe to the crown muſt be $\frac{3}{4}$ of the depth of the ſtone. The lozenges, which appear in all circular roſe *Diamonds*, will be equally divided, by the ribs that form the crown; and the upper angles, or facets, will terminate in the extreme point of the ſtone, and the lower in the baſe or girdle.

The taſte which now prevails of converting roſe *Diamonds* into *Brilliants*, is condemned by Mr. *Jeffries*; unleſs the roſe *Diamonds* be over-weighted. He thinks, that the diſplay of beauty, in roſe *Diamonds*, is often preferable to that of *Brilliants*. See his treatiſe on *Diamonds*, p. 32, 35.

Mr. Jeffreys's table of the value of *Diamonds* differs conſiderably from that in the Cyclopædia. This not following the rule laid down by him, of the values increaſing in the duplicate proportion of the weights.

Complexions of DIAMONDS—The fineſt *Diamonds* are thoſe of a complexion like that of a drop of the cleareſt rock water: and if ſuch ſtones be of a regular form, and truly made; as alſo free from ſtains, fouls, ſpots, ſpecks, flaws, and croſs veins, they will have the higheſt luſtre of any, and be eſteemed the moſt perfect.

If *Diamonds* be tinctured yellow, blue, green, or red, in a high degree, they are next in eſteem. But if they partake of theſe colours only in a low degree, it greatly ſinks their value. There are other complexions of *Diamonds*, ſuch as the brown, and thoſe of a dark hue; the firſt ſometimes reſemble the browneſt ſugar-candy, and the latter dusky-iron.

The *firſt water* in *Diamonds* means the greateſt purity and perfection of their complexion, which ought to be that of the cleareſt drop of water.

When *Diamonds* fall ſhort of this perfection, they are ſaid to be of the *ſecond* or *third water*, &c. till the ſtone may be properly called a coloured one: for it would be an impropriety to ſpeak of a *Diamond* imperfectly coloured, or having other defects, as a ſtone of a *bad water* only.

Magnitude of DIAMONDS—The moſt remarkable *Diamonds* for ſize now known, are, Governor Pitt's Diamond, purchaſed by the late Duke of Orleans for Louis the XVth King of France, weighing 136 $\frac{3}{4}$ carrats: the *Diamond* of the Great Duke of Tuſcany, which weighs 139 $\frac{1}{2}$ carrats: that of the Great Mogul, weighing 279 $\frac{9}{16}$ carrats: and one, mentioned by Mr. Jeffries, in a merchant's hands, weighing 242 $\frac{5}{16}$ carrats.

According to Mr. Jeffries's Rule, that the value of *Diamonds* is in the duplicate ratio of their weights, and that a manufactured *Diamond* of 1 carrat is worth at a medium 8 l. the Great Mogul's *Diamond* muſt be valued at above 624962 l. this being the value of a *Diamond* of 279 $\frac{1}{2}$ carrats.

Corniſh DIAMONDS, in natural hiſtory, a name given in England to all the ſpecies of cryſtals, which are compoſed of a column, terminated at each end by a pyramid. The name takes in two genera of cryſtal, of each of which there are ſeveral ſpecies. Dr. Hill has determined this to be the true figure of perfect cryſtal, and accounts all thoſe which are affixed by one end to ſome ſolid body, and terminated at the other by a pyramid, to be mutilated or imperfect cryſtals. The ſame author, according to the length or thickneſs of the intermediate column, has divided theſe bodies into two genera, the firſt the macroteloſtyla, the other the brachyteloſtyla. *Hill*'s hiſt. of foſ. p. 160 to 165. See the articles MACROTELOSTYLA and BRACHYTELOSTYLA.

DIAMOND *Powder* is of great uſe for grinding hard ſubſtances. And Mr. Boyle obſerves, that though it be much dearer than emery, yet it makes ſo great diſpatch, and the tools employed laſt ſo much longer, as greatly to over-balance the cheapneſs of the emery. *Boyle*, Phil. Works abr. vol. 1. p. 135.

DIANÆ *Arbor*.—Lewenhoeck, in one of his papers of the Philoſophical Tranſactions, deſcribes a microſcopic kind of *Arbor Dianæ*; which muſt afford the curious in thoſe obſervations, a very pleaſing ſpectacle. Having diſſolved ſome pure ſilver in aqua fortis, and weakened this ſolution, by adding ſome common water to it; after this, putting this diluted ſolution into a glaſs, and dropping into it a few filings of copper, one particle at a time; there will be found on ſome of theſe, extempore ſilver trees; the ſilver leaving the liquor, and affixing itſelf in very ſmall particles to the copper, which, as they grow more and more numerous, link themſelves to one another, and form the ſame ramoſe maſſes that are called the ſilver trees. A ſtem, or main trunk, is, in this caſe firſt form'd, and after this a number of fine and elegant branches growing from it every way, till at laſt there is a whole tree reſembling thoſe low and headed oaks, which are common on heaths and in other barren places. This is ſo ſudden an effect of the putting in the copper, that a few ſeconds are ſufficient to form ſeveral trees. If a few more particles of copper are thrown into this liquor, the whole quantity of ſilver that was held in a ſtate of ſolution in it will be precipitated from it, and fixed in the form of theſe ſmall trees and ſhrubs on the ſeveral pieces of copper. The formation and arrangement of theſe ſmall particles of ſilver into trees, is not more natural in this ſtate of their ſeparation from the particles of a fluid, in which they were ſuſpended, than in their natural concretions within the bowels of the earth, where they fix themſelves to the ſurfaces, and within the cracks and crevices of hard ſtones, in the ſame arboreſcent forms; and the moſt common ſilver ores afford us an infinite number of what may be called natural *Arbores Dianæ*, or trees of native ſilver. On comparing theſe natural ſilver trees in the ores, with thoſe formed upon the particles of copper, from a water in which they were ſuſpended in a ſtate of ſolution, it appears, highly probable, that in the time of the origin of theſe ores, the ſtone which makes the bed, or matrix, in which the rich metal now lies in branches and flakes, was ſoft and fluid; and that, at that time, the particles of ſilver were as cloſely combined among, and as perfectly ſuſpended in its matter as thoſe of the ſolution in this experiment are in the liquor; and that when the matter of the ſtone came to coaleſce, and harden its particles, uniting together, formed hard concretions; from which the fluid was excluded, or driven out, and with it the ſilver ſtill ſuſpended in it: but, as this fluid, ſo much altered, by the ſeparation of the ſtony matter from it, was now no longer equal to the office of holding the ſilver ſuſpended in ſolution, it became juſt like this diluted ſolution of ſilver in the acid, ready to part with, and depoſite it in the form of trees and ſhrubs, on any ſubſtance proper to receive it; and that the ſtony particles, now ſeparated, and coagulated into hard maſſes, were ſuch proper ſubſtances; and did exactly, in this natural precipitation, what the filings of copper do in the artificial one. There is yet the more analogy in this caſe, becauſe, both the ſilver and the copper added afterwards, are ſubſtances ſoluble in the ſame menſtruum that is employed; and ſo it appears evident, that the ſtony matter of the matrix, or bed of the ſilver ore, and the ſilver itſelf were both equally ſoluble in that menſtruum, whatever it was, which before held them both ſuſpended: and that as ſoon as the one of theſe two ſoluble ſubſtances was added to the liquor in its ſolid ſtate, the other was precipitated upon it in this branched form. Philoſ. Tranſ. N° 286. p. 1496. See ARBOR *Dianæ*, *Cycl.*

DIANDRIA, in botany, a claſs of plants, which have hermaphrodite flowers, with two ſtamina or male parts in each.

The word is formed of the Greek Δις twice, and Ανηρ male. Of this claſs of plants are the jeſſamine, phillerea, olive, roſemary, &c. See Tab. 1. of botany, Claſs 1.

DIAPASON (*Cycl.*)—The antients had ſeven variations, ſchemes, figures, or ſpecies of the *Diapaſon*, ariſing from the various poſitions of the tones and ſemi-tones in the ſcale.

The firſt ſpecies of the *Diapaſon* was from the hypate hypaton to the parameſe; or from B♮ to b♮ of our notation. It was called *Myxolydian*.

The ſecond, called *Lydian*, from the parypate hypaton, to the trite diezeugmenon, or from C to c.

The third, called *Phrygian*, from the Lichanos Hypaton to the Paranete Diezeugmenon; or from D to d.

The fourth, called *Dorian*, from the Hypate meſon to the Nete Diezeugmenon; or from E to e.

The fifth, named *Hypolydian*, from the parypate meſon to the trite Hyperbolæon; or from F to f.

The ſixth, called *Hypophrygian*, from the lichanos meſon to the paranate Hyperbolæon; or from G to g.

The ſeventh, named *Hypodorian*, *Common* and *Locrian*, from the meſe to the nete Hyperbolæon, or from the Proſlambanomenos to the meſe, that is, from our a to a a, or from A to a. *Euclid.* Introd. Harm. p. 15, ſeq. *Bacchius*, p. 18. Edit. Meibom. See DIAGRAM.

DIAPASON *Diateſſaron*. The Pythagoreans did not admit this interval as a conſonance or concord; for this reaſon, that its ratio 8 : 3 was neither multiple nor ſuper-particular. But Ptolemy contends for its being a good concord for this reaſon, that the *Diapaſon* added to any concord, produces a concord. Ariſtoxenus herein agrees with him. Vid. *Wallis*'s Append. ad Ptolem. Harm. p. 155.

DIAPERD, in Heraldry, ſee DIAPRE, *Cycl.*

DIAPHRAGM (*Cycl.*)—The *Diaphragm* is looked upon as a double digaſtrick muſcle, made up of two different portions, one large and ſuperior, the other ſmall and inferior; the firſt is called the great muſcle of the *Diaphragm*; the ſecond, the ſmall one.

The great or principal muſcle is fleſhy in its circumference, and tendinous or aponeurotic in the middle. This centre is of conſiderable breadth, and repreſents in ſome degree a treſoil leaf. The fleſhy circumference is radiated, the fibres of which it is compoſed being fixed by one extremity to the edge of the middle aponeuroſis, and by the other to all the baſis of the cavity of the thorax, being inſerted by digitations in the lower parts of the appendix to the ſternum, of the loweſt true ribs, of all the falſe ribs, and in the neighbouring vertebræ. There are therefore twelve coſtal inſertions, two vertebral, and one ſternal. The fibres inſerted in the appendix enſiformis run from behind directly forward, and from a ſmall parallel plane; The firſt coſtal inſertion runs a little obliquely toward the cartilage of the ſeventh true rib; the ſecond is into the whole cartilage of the firſt falſe rib; the third partly in the bone, and partly in the cartilage of the ſecond falſe rib; the fourth in the bone, and ſometimes a little in the cartilage of the third falſe rib; the fifth in the bone, and a little in the cartilage of the fourth falſe rib, being broader than the reſt; the ſixth is in the cartilage of the laſt falſe rib, and almoſt through the whole length of the bone. At the head of this rib it joins the vertebral inſertion, which runs from the lateral part of the laſt vertebra of the back to the firſt vertebra of the loins. The lateral inſertions of the great muſcle of the *Diaphragm* on the right ſide appear to be lower than thoſe on the left, and the right lateral portion appears to be larger than the left, as being more arched. The ſmall muſcle of the *Diaphragm* is thicker than the other, but of much leſs extent; it is ſituated along the foreſide of the bodies of the laſt vertebræ of the back, and ſeveral of thoſe of the loins, being turned a little to the left hand; it is of an oblong form, repreſenting in ſome meaſure a fleſhy collar, the two lateral portions of which croſs each other, and afterwards become tendinous towards the lower part. The upper part of the body of this muſcle is fixed in the ſlope of the middle aponeuroſis of the great muſcle. The outer edges of the alæ, or lateral portions, join the poſterior plane of the great muſcle, and adhere to the body of the laſt vertebræ of the back. The extremities, called alſo pillars or crura, are inſerted by ſeveral tendinous digitations in the vertebræ of the loins; the upper part of the fleſhy body is formed by a particular intertexture of fibres belonging to the alæ; the fibres that come from the left, croſs over thoſe from the right; and this again ſends a ſmall faſciculus of fibres over thoſe of the left. The right croſs is larger and longer, the left ſmaller and ſhorter. An oval opening in this muſcle gives paſſage to the œſophagus, and the aorta lies in the interſtice between the two crura. There are in all three openings in the *Diaphragm*, one round and tendinous for the paſſage of the vena cava; one oval and fleſhy for the extremity of the œſophagus; and one forked, partly fleſhy and partly tendinous, for the aorta. *Winſlow*'s anatomy, p. 226.

The *Diaphragm* is the chief organ of reſpiration. Dr. Martin thinks the enlargement of the cavity of the breaſt in inſpiration more owing to the depreſſion of the *Diaphragm*, than to any remarkable change in the poſture of the ſternum and ribs. See RESPIRATION.

Mr. Senac has given us a new deſcription of the ſtructure of the *Diaphragm*, with remarks on the action of this muſcle. See Mem. Acad. Scienc. 1729.

DIAPORESIS, Διαπορησις, in rhetoric, is uſed to expreſs the heſitation or uncertainty of the ſpeaker.

We have an example in Homer, where Ulyſſes going to relate his ſufferings to Alcinous, begins thus:

Τί πρῶτον, τί δ' ἔπειτα, τί δ' ὑστάτιον κατάλεξω?
Quid primum, quid deinde, quid poſtremo aloquar?

This

This figure is moſt naturally placed in the exordium or introduction to a diſcourſe. *Voſſ.* Rhet. l. 5. p. 384. See DOUBTING, *Cycl.*

DIARRHOEA (*Cycl.*)—The *Diarrhœa*, looſeneſs or purging of the bowels, as it is uſually called by us, is properly an increas'd periſtaltick motion of the guts, by means of which nature attempts to throw off a mucous or bilious matter lodged in too great a quantity in the primæ viæ, and diſturbing her regular operations.

Phyſicians diſtinguiſh *Diarrhœas* into ſeveral kinds: 1. The ſimple *Diarrhœa*. This is when a ſerous and mucous matter is voided by ſtool. 2. The choleric *Diarrhœa*, in which a bilious foulneſs is thrown off. 3. The Lienteric *Diarrhœa*, in which caſe the food is thrown off ſo ſpeedily, that it appears in its natural ſtate, and to have ſuffered no concoction. 4. The cœliac *Diarrhœa*; in this the excrements are a little different from the food when taken in, and are of a chylous appearance. 5. The dyſenterick and hepatic *Diarrhœa*, ſee DYSENTERY and HEPATIC flux. 6. The critical *Diarrhœa*, which happens in fevers on the day of the criſis. This uſually is the caſe in quotidians of the continual kind, and ſometimes in tertians in the time of the fit. 7. The ſemicritic. Theſe are *Diarrhœas* which appear at irregular times in catarrhal and petechial fevers. 8. The ſymptomatic *Diarrhœas*. Theſe appear in the ſmall-pox, meaſles, and purple fever. 9. The icteric *Diarrhœa*. In this the ſtools are whitiſh as in the jaundice. 10. The periodic *Diarrhœas*. Theſe are ſuch as return upon the patient at certain regular times of the year, particularly at the ſpring and autumn. And finally, 11. The colliquative *Diarrhœa*. This is that kind that appears toward the laſt ſtage of hectics and conſumptions, and uſually carries off the patient. *Junker*'s Conſp. Med. p. 551.

Signs of a DIARRHOEA.—The ſigns which precede a *Diarrhœa* of any kind are uſually a tenſive pain and rumbling, and noiſe in the abdomen, and pungent acute pains, particularly about the region of the navel. The appetite is uſually very bad in the beginning of a *Diarrhœa*, and in its future ſtages the ſtrength fails; and the longer it continues, the worſe ſymptoms it brings on: a teneſmus is one common complaint, and the head is weaken'd and aches at times; and, finally, an internal heat is felt, which is a very bad ſymptom, and threatens miſchiefs of various kinds.

Perſons moſt ſubject to DIARRHOEAS.—The ſimple *Diarrhœa*, in which a mucous and ſerous matter is voided, is principally a diſeaſe incident to people of phlegmatic habits, whoſe ſtools are generally watery. When this kind of *Diarrhœa* obſerves any regular period, it is a ſign of a ſanguine temperament in the perſon. The bilious *Diarrhœas* are moſt frequent with perſons of choleric habits; and the critical *Diarrhœas* in fevers uſually happen to perſons of a ſanguine one. Men of tender and delicate conſtitutions, if they walk about a room when hot with their feet naked, are uſually affected afterwards with a ſimple *Diarrhœa*.

Cauſes of DIARRHOEAS.—Among the principal Cauſes of *Diarrhœas* may be reckoned the ſudden repreſſion of ſweats in a morning while the perſon is in bed.

Crude foods, and ſuch as are difficult of digeſtion, often throw people into *Diarrhœas*, as alſo over fat meats, eſpecially if perſons drink much after them; and nothing ſo frequently as the free eating of ſummer fruits, eſpecially if the perſon chance to ſwallow a quantity of any thing liquid ſoon after them.

Feculent or fermenting liquors will alſo do it, and ſometimes the drinking cold liquors in a large quantity, or even the external cold; but in this caſe the tender habit of the patient is as much to be accuſed as any thing.

The cauſe of a lienteric *Diarrhœa* is principally the cicatrizing of the bowels after their eroſion in a dyſentery, in which the lacteal veſſels have been alſo injured. The cœliac *Diarrhœa* is uſually laid upon a fault in the ſtomach; but it is as often owing to an obſtruction of the lacteal veſſels, as to a weakneſs of that organ. The choleric *Diarrhœa* is uſually occaſioned by an effuſion of a larger portion than uſual of bile into the inteſtines, and this is often occaſioned by a violent fit of paſſion in the perſon. *Junker*'s Conſp. Med p. 553.

Prognoſtics in DIARRHOEAS.—All *Diarrhœas* are diſeaſes of the greateſt conſequence when improperly treated, or raſhly and ſuddenly ſtopped by opiates and aſtringents. On the contrary, the whole courſe of a ſimple *Diarrhœa*, if nature be left to herſelf, is attended with no danger. When the moſt ſimple and, in itſelf, innocent *Diarrhœa* is treated in that manner, the conſequences are violent and pungent pains in the abdomen; and, in old people eſpecially, a tranſlation of the matter, which nature would have carried off by that ſoft way, to the head and breaſt; whence vertigos and ſuffocative catarrhs are often brought on, and the perſons die ſuddenly, and as it is ſuppoſed of apoplexies. The danger of ſtopping a bilious *Diarrhœa* is ſtill greater, for the frequent conſequence of this is a cauſus, or other violent fever of that kind; but the greateſt danger of all attends the ſtopping of a critical *Diarrhœa*. The ſymptomatick *Diarrhœas* in the ſmall-pox, meaſles, and purple fevers are often of fatal conſequence. Periodic *Diarrhœas*, if nature be left to herſelf, are always ſalutary. The ſimple lienteric and cœliac *Diarrhœas* uſually give way eaſily to medicines, and the choleric are of no dangerous conſequence, unleſs they are attended with a fever. Finally, it is to be obſerved, that any *Diarrhœa* continuing an immoderate time will by degrees waſte the ſtrength, and throw the patient into a ſlow fever and an atrophy.

Method of curing DIARRHOEAS.—In a ſimple *Diarrhœa* the firſt intention is to incide and attenuate the mucous matter, and then to abſterge it by digeſtive, reſolvent, and colliquating medicines; ſuch are the bitters and aromaticks, with ſome of the acrid ones, as the roots of gentian, arum and zedoary, together with ginger, galingals, and the aromatic ſeeds. Theſe may be aſſiſted by the digeſtive ſalts, as cream of tartar, arcanum duplicatum, and vitriolated tartar, with the fixed ſalts of wormwood, and the like. To theſe may be added occaſionally the digeſtive and attenuating gums, as ammoniacum, and the like; and in ſome caſes it is proper to reduce the vicious matter into a ſort of pulpy conſiſtence. This is to be done by the abſorbents, as crabs-eyes, and the like. When there is a quantity of a bilious matter mixed with this, the admixture of ſmall doſes of nitre with the other medicines is of great effect; and when the peccant matter is by this means prepared for evacuation, nature is to be aſſiſted in her attempt to throw it off by this proper paſſage by ſmall doſes of gently laxative medicines, ſuch as rhubarb, and the like. After this, if the motion of the bowels do not abate and come to its uſual ſtandard on their being thus eaſed of their load, theſe ſymptoms are to be taken off by gentle aſtringents. For though theſe motions were no way to be impeded, when nature meant them for the throwing off what offended her, and were ſalutary in that ſtate; yet when they remain after the end is obtained, they are to be conſider'd as a diſeaſe. The medicines proper on this occaſion are dried quinces, the abſorbent powders, ſuch as red coral, and the like, gentle opiates, and the aſtringent ſyrups of cinnamon, and the like; and finally, the cure is to be compleated by reſtoring the bowels to their due tone by gentle chalybeates.

The lienterick and cœliac *Diarrhœas* require the ſame method of treatment with theſe, except that in the lienterick a vomit in the beginning is uſually very proper: but in the cœliac, when there is an obſtruction of the lacteal veſſels, a vomit has no uſe; but the reſolvents, aperients, and laxatives alone are to be depended upon.

Periodic *Diarrhœas* are to be treated in this manner like the ſimple ones, and nature is to be aſſiſted, not checked, in her operations in them. In theſe caſes a medicated wine prepared with rhubarb, gentian, zedoary, and black hellebore, is a very valuable medicine. When worms are ſuſpected to be in the caſe, as they very frequently are, the uſual anthelminthics are to be joined to the medicines before directed.

The critical and ſemicritical, as well as ſymptomatic *Diarrhœas* in fevers, are to be treated as directed under the fevers to which they belong; and the icteric *Diarrhœa*, in which the ſtools are white as in the jaundice, is to be treated as the jaundice. *Junker*'s Conſp. Med. p. 557. See the articles WORMS, FEVER, *&c.*

DIARRHOEA *of Infants*, ſee INFANT.

DIARTHROSIS (*Cycl.*)—In the *Diarthroſis*, or moveable articulations of the bones, the pieces are really ſeparated, and the parts in which they touch are each of them covered by a ſmooth cartilage, by means of which they eaſily ſlide over one another; whereas in the ſynarthroſis, or immoveable articulation, the pieces are joined together in ſuch a manner, that the parts in which they touch have nothing particular in their ſurface, and cannot ſlide upon one another.

The *Diarthroſis* is either manifeſt with large motion, or obſcure with ſmall motion. Each of theſe is alſo again of two kinds, one indeterminate, with motion many different ways, as that of the os humeri upon the ſcapula of the os fremoris on the os innominatum. The other alternative, or with motion, confined to the two oppoſite ſides only, as that of the ulna on the os humeri, and that of the two laſt phalanges on the firſt and ſecond. A bone is ſaid to be moveable many different ways, when it can be turned upwards and downwards, forwards and backwards, to the right and to the left, or quite round. The motion quite round is made either on a pivot, that is, about an axis, or in manner of a ſling, when the bone deſcribes a ſort of cone, or the figure of a funnel, one end of it moving in a very ſmall ſpace, the other in a large circle. The firſt of theſe round motions is termed rotation by anatomiſts; the other is only the reſult of a combination of ſeveral different motions upwards, downwards, *&c.* and it is to be remarked, that rotation is not to be met with in all the articulations for motion many different ways; as the articulation of the firſt phalanges with the metacarpal bones, *&c.* does not admit of it.

Moreover, this indeterminate *Diarthroſis* is of two kinds, the one orbicular or globular; the other flat, or planiform. The orbicular *Diarthroſis* is when the round end of one bone moves in the cavity of another more or leſs proportionable to it. As the head of the os ſemoris in the acetabulum of os innominatum,

tum, or when the cavity in one bone moves upon an eminence in another, as the baſes of the firſt phalanges on the heads of the metacarpal bones. The planiform *Diarthroſis* is when the articulated bones ſlip upon one another, much in the ſame manner as when we rub the palm of one hand upon the palm of the other. This articulation is found in the bones of the carpus and tarſus, and in the oblique proceſſes of the vertebræ. The antients called the firſt of theſe two kinds of articulation enarthroſis, the other arthrodia; and ſome modern French writers ſeem to comprehend both under the word genou, a term borrowed from workmen, who probably firſt ignorantly took it from the human body to apply it to their inſtruments. This term indeed, as they uſe and explain it, agrees well enough with all the degrees of the orbicular *Diarthroſis*; but there are undoubtedly many articulations of the other kind ſo very flat, that a skilful workman would not apply the term genou to ſuch.

The alternative or reciprocal *Diarthroſis* bears ſome reſemblance to a hinge, and for that reaſon the antient Greeks called it ginglymus. This has been divided into ſeveral kinds, but properly ſpeaking there are only two. The firſt is that which is confined to flexion and extenſion, and as in one of theſe motions, the two bones always make an angle, it may be not improperly termed the angular ginglymus: this is exactly the ſame with the motion of a hinge. The ſecond kind is adapted only to ſmall turns toward each ſide, or to ſmall lateral rotations, in the language of anatomiſts: this therefore may be termed a lateral ginglymus. In each kind ſeveral differences are to be taken notice of. In the angular ginglymus, either each bone partly receives, and partly is received by the other, there being reciprocal eminences and cavities in each, as in the articulation of the os humeri with the ulna. Or there are only a number of eminences in one bone received into a like number of cavities in the other, as in the articulation of the os femoris with the tibia. The lateral ginglymus is either ſingle, as in the articulation of the firſt vertebra of the neck with the apophyſis dentiformis of the ſecond; or double, that is, in two different parts of the bone, as in the articulation of the ulna with the radius. It muſt in general be obſerved concerning theſe kinds of articulations, that ſome of them are more perfect and cloſe than others, and that they are not all confined to flexion and extenſion, or to the reciprocal turns already explained.

The obſcure *Diarthroſis*, or that which admits only of ſmall motions, is alſo of different kinds, examples of which are found in the articulations of the bones of the carpus and metacarpus, and of the fibula with the tibia. This articulation has by ſome been called doubtful or neutral, and by others amphiarthroſis, while others have reduced it to a ſynarthroſis. The firſt of theſe names might paſs, but the reſt are improper. *Winſlow*'s Anatomy, p. 152.

DIASCHISM, *Diaſchiſma*, in muſic, the difference between the comma and enharmonic dieſis. This is expreſſed by the ratio $\frac{2048}{2025}$, for $\frac{128}{125} : \frac{81}{80} = \frac{2048}{2025}$. Mr. Euler [a] has taken this term in the ſenſe here mentioned. Others call it the leſſer comma [b]. The octave contains 61 *Diaſchiſms* nearly. [[a] Tentam. Nov. Theor. Muſic. p. 107 and 112. [b] Ibid. p. 107.] See COMMA, *Cycl.*

DIASIA, Διασια, in antiquity, a feſtival at Athens in honour of Jupiter, ſurnamed Μειλιχιος, i. e. the *Propitious*. *Pott.* Archæol. l. 2. c. 20.

DIASTASIS, a word uſed by the writers in medicine in many different ſenſes. It is frequently uſed as a name for that ſeparation of the bones, when they naturally recede from one another. Sometimes it is uſed as the term for an interſtice, as that between the ulna and radius, or between the tibia and fibula. Sometimes it is put for a diſtenſion of the muſcles in convulſions; and, when applied to the ſtomach, it is made to ſignify an inclination to vomit.

DIASTEM, Διαστημα, in the antient muſic, was the difference of tenſions [a]. It anſwers to what we call an interval.

Ariſtoxenus [b] enumerates many differences of intervals: ſuch as greater, or leſs; conſonant, or diſſonant; compounded, or uncompounded; related to one genus, or to another; laſtly, rational or irrational. [[a] *Ariſtox.* ap. *Wallis.* Append. ad Ptolem. Harmon. p. 154. [b] Id. ibid. p. 16. Edit. *Meibom. Wallis*, ibid.]

DIASTOLE (*Cycl.*)—Authors, who have treated of the heart, have all contented themſelves with accounting for its ſyſtole on rational principles, and have been ſatisfied with referring its *Diaſtole* to no other principle than a motion of reſtitution. But Dr. Drake has thought more deeply on this ſubject, and has found that reſpiration has an effect upon the heart in this ſenſe which had not been underſtood before. The ſyſtole being the proper motion of the heart, a ſtate of contraction by means of that ſyſtole muſt needs be its natural ſtate, and conſequently no motion of reſtitution natural, and without external violence it could have no *Diaſtole* at all.

This will appear more plain, if we conſider the circumſtances of the heart, and its motion as a muſcle, with reſpect to other muſcles. That contraction is the proper action and natural ſtate of all muſcles, is evident from experience as well as from reaſon: for, if any muſcle be freed from the power of its antagoniſt, it is immediately contracted; and is not by any action of the will or ſpirits, to be reduced to a ſtate of dilatation: thus, if the muſculi flexores of any joint be divided, the extenſores of that joint, the oppoſite muſcles to the flexores, being freed from the contrary action of their antagoniſts, will exert themſelves; the joint will be extended without the conſent of the will, and it will continue in that poſture: and, on the other hand, if the extenſors are divided, the contractors will of themſelves exert their force, and the limb will be contracted without the conſent of the will, and it will continue in this poſture. It is very evident from all this, that the muſcles of the human body have no reſtitutionary power of their own, but that all power of this kind in them is derived from the action of their antagoniſts by which they are balanced: thus likewiſe the ſphincters of the gula, anus, and veſica, having no proper antagoniſts, are always in a ſtate of contraction, and ſuffer nothing to paſs through them, but what is forced on by the action of other ſtronger muſcles; which, though not properly antagoniſts to theſe, yet, on all neceſſary occaſions, perform the office of ſuch.

That the heart is a muſcle furniſhed and provided for motion, like other muſcles, has been demonſtrated, beyond all contradiction, long ago, by Lower, and many others, who have written of it, and it is a ſolitary muſcle: it has no antagoniſt, and is not under the direction of the will: as it performs alſo no voluntary motion, it in all things approaches more to the nature of the ſphincter muſcles, than to any kind beſide; but, in its conſtant actions of contraction and dilatation, it differs exceedingly from all the muſcles of the body. This reciprocal motion of the heart has given the learned abundance of trouble, who finding nothing peculiar in the ſtructure which ſhould occaſion it, nor any antagoniſt whoſe relation ſhould produce it, have been extremely perplexed to find out the cauſe of it. Lower having proved the heart a muſcle, and eſtabliſhed the manner of its muſcular motion, takes notice of no farther aſſiſtance that it receives for the performing this, than what it has from the brain, by means of the eighth pair of nerves. Borelli, in his *Animal Oeconomy*, computes the motive power of the heart, to be equal to, at leaſt, that of a weight of three thouſand pounds. The obſtacles to the motion of the blood, through the arteries, he eſteems equivalent to one hundred and eighty thouſand pounds, which is ſix times as much as he rates the force of the heart at; then deducting forty five thouſand pounds, for the adventitious help of the muſcular elaſtic coat of the arteries, he leaves the heart, with the full force of three thouſand pounds to overcome the reſiſtance of a hundred and thirty-five thouſand pounds; that is, with one, to remove forty-five. This ſtupendous effect, he ſatisfies himſelf with aſcribing to the energy of percuſſion; but, had he proceeded, in his calculation, to the veins; which, he allows to contain conſtantly a quantity of blood, quadruple to the contents of the arteries, and to which this energy of percuſſion does not either reach at all, or but very languidly; he might probably have ſeen a neceſſity of ſome other expedient, to remove ſo inſuperable a difficulty.

But not to inſiſt regularly on the exactneſs of this computation, we may allow a much greater deduction than would be juſtifiable, without leſſening the difficulty. Dr. Lower, notſtanding the care and ſagacity with which he examined this ſubject, ſeems to have overlooked ſomething of very great moment, in the explication of the action of the heart; for, though it ſhould be granted, that the muſcular fibres of the heart, acted by the nerves, are the immediate inſtruments of its ſyſtole or contraction, yet it muſt not be denied that the intercoſtal muſcles and diaphragm are of great ſervice, to aid and facilitate this contraction, by opening a paſſage for the blood through the lungs, which denied, would be an invincible obſtacle: neither do the lungs promote the motions of the heart in that way only, but the manner in which they aſſiſt the heart in its contraction, will appear manifeſtly, if we conſider the different poſture, ſituation, and capacity of the blood veſſels of the lungs, in the ſeveral times of elevation and depreſſion of the coſtæ.

The pulmonary artery ariſes from the right ventricle of the heart, and runs in one trunk, till it comes to the aſpera arteria, where it is divided, and ſends a branch along with each diviſion of the aſpera arteria; according to all the minuteſt ſubdiviſions of which, it is alſo ſubdivided, accompanying all the bronchi in their paſſage through the lungs.

The pulmonary vein, which empties itſelf into the left ventricle of the heart, ſpreads itſelf on the aſpera arteria and bronchi, and continues its progreſs in the ſame manner, in which the artery does. The neceſſary conſequence of this diſpoſition is, that this artery and vein, being co-extended with, and faſtened to the bronchi, muſt needs ſuffer ſuch alteration of ſuperficial dimenſions, as the bronchi do in the elevation and depreſſion of the coſtæ; while the ribs are in a ſtate of depreſſion, whether before commerce with the external air, or after the annular cartilages of the bronchi, ſink into one another, and by that means their dimenſions are exceedingly contracted; in conformity to this condition of the bronchi, the pulmonary artery and vein muſt likewiſe either

by

by means of their muſcular coats, contract themſelves to the ſame dimenſions, or lie in folds or corrugations, which is much leſs probable.

On the other hand, when the ribs are elevated, and the diaphragm bears downward, the air ruſhing into the lungs, ſhoots out the cartilaginous rings, and divaricates the branches of the tracheæ, and by them extends and divaricates the ſeveral diviſions of the pulmonary artery and veins, and thereby lengthens and enlarges their cavities. This enlargement of their cavities is very conſiderable, not only upon the ſcore of the addition, which they receive in length thereby, but alſo on account of their divarication; for whereas, when the ribs are depreſſed, and the lungs ſubſide, the blood veſſels are not only contracted, but their branches, which are exceeding numerous approach one another, and lie in juxta poſition, by which their cavities are very much compreſſed and ſtreightned: when the ribs are elevated and the lungs turgid with air, not only the fibres, by which their coats in the oppoſite ſtate were contracted, are extended; but thoſe innumerable veſſels, which lying before in lines almoſt contiguous to one another, compreſſed each other, making an acute angle at their junctures, are divaricated and ſeparated from each other, and make an obtuſe one, whereby their channels are widened.

Thus a paſſage is opened for the blood from the right ventricle of the heart to the left, through the lungs, to which it could not otherwiſe paſs; and the oppoſition, which the blood contained in that ventricle muſt otherwiſe have had made to its conſtriction is taken off, and the ſyſtole thereby facilitated; nor is this all, for the diaſtole being cauſed, as is certainly and demonſtrably the caſe, by the force of the blood ruſhing into the ventricles; this ampliation and extenſion of the pulmonary artery is a ſort of check or counterpoiſe to it, and prevents an endeavour towards two contrary actions at once, which would neceſſarily fruſtrate both: for the heart being a ſpringy and compreſſible body, whoſe proper action, which is contraction, depends upon the influx of certain fluids into its fibres and ſubſtance; and containing beſide a fluid in its ventricles, or great cavities, in one of which is the mouth of this artery, the action of this veſſel muſt in a great meaſure reſemble that of a ſyringe, whoſe extremity is immerſed in water. The enlargement or expanſion of the channels of the artery, anſwering the drawing of the embolus, as the conſtrictive motion of the muſcle of the heart, does the preſſure of the atmoſphere on the ſurface of the water; the one making way for the fluid, and the other forcing it, to flow where the reſiſtance is leaſt. In this ſenſe we may allow a ſort of attraction to the pulmonary artery, depending wholly upon the action of the intercoſtal muſcles, and diaphragm, which we muſt therefore confeſs to be very ſerviceable and inſtrumental in promoting the ſyſtole of the heart. Phil. Tranſ. N° 281. p. 1222.

DIATONIC (*Cycl.*)—The *Diatonic* genus was by the antients divided into two ſpecies: the *molle*, and the *intenſum*. The laſt is in daily practice. It is commonly ſaid to conſiſt of two tones and a ſemi-tone: but, to ſpeak exactly, it conſiſts of a ſemi-tone major, a tone minor, and a tone major. Phil. Tranſ. N° 481. p. 212.

We find it accurately defined by Didymus, in Ptolemy's harmonics publiſhed by Dr. Wallis. Vid. Wallis Oper. vol. 3. p. 92. The numbers by which Didymus expreſſes its intervals, are, $\frac{9}{8} \times \frac{10}{9} \times \frac{16}{15} = \frac{4}{3}$. Ptolemy, indeed, makes the *Diatonicum* intenſum, to be expreſſed by $\frac{10}{9} \times \frac{9}{8} \times \frac{16}{15} = \frac{4}{3}$; but, it is plain, this is only tranſpoſing the tones major and minor, which makes no eſſential difference, nor is it ſufficient to conſtitute a new ſpecies. But the firſt of the before-mentioned ſpecies, the *Diatonicum molle*, has not, till lately, been accurately defined by any author. Its component intervals, according to Dr. Pepuſch, are, the ſemi-tone major, an interval compoſed of two ſemitones minor, and the complement of theſe two to the fourth; which complement is equal to a tone major, and an enharmonic Dieſis. Phil. Tranſ. N° 481. p. 271, 272.

Beſides, the two ſpecies of the *Diatonic* mentioned by Ariſtoxenus and Euclid; Ptolemy, and other antient muſicians, have left us ſeveral different *Diaontic* diviſions of the tetrachord; ſuch are the *Dianotic* of Archytas, of Eratoſthenes, and of Didymus, which laſt agrees perfectly with the truth of muſical proportions. Ptolemy himſelf gives us no leſs than five different *Diatonics*, by the names of *molle*, *tonicum*, *ditonicum*, *intenſum*, *æquabile*. Phil. Tranſ. N° 481. p. 271. See GENUS.

But, except one (the *intenſum*) they are all inconſiſtent with the true theory of muſic; which admits of no numbers, or proportions, but 2, 3, and 5, and ſuch as ariſe from theſe primes. Indeed Ptolemy's tetrachords are ſo miſ-tuned, that Salinas has charged him with having had no ear. Vid. Phil. Tranſ. ibid. p. 267.

DIATONUM, Διατονον, in the the antient muſic, is uſed for the Diatonic genus. See DIATONIC.

DIATRÆTA, a word uſed by Pliny, and other of the antient Romans, to expreſs a ſort of cups and vaſes, which were of great value, and only ſeen at the tables of the great. They were pellucid and colourleſs, and cut into various forms, and were often engraved upon with figures expreſſive of the deeds of honour of the family who poſſeſſed them. The firſt *Diatretæ* were made of pure cryſtal of the rock, and the working of theſe rendered them very expenſive; but afterwards they were made of common white glaſs, and ſunk greatly in their price and value. The antients were very nice in their diſtinctions of the ſeveral kinds of cryſtal. They termed the pureſt and fineſt of all *acentatum*, and the others, which were ſubject to blemiſhes and foulneſſes of ſeveral kinds, they called by names expreſſive of them. There was nothing they ſo much feared in the pieces they ſelected for this work, as what they called an over hardneſs, that is, a brittleneſs, which made the veſſel often fly under the engraver's tool, after it had been formed into ſhape at a great expence: for this reaſon they were cautious of uſing the very brighteſt and cleareſt maſſes; for they often found thoſe ſucceed beſt, which had ſome of thoſe flaws which we call hairs in them. Theſe they thought the tougheſt pieces of cryſtal, and theſe flaws they eaſily concealed among the ſtrokes of their work. See the articles SAL and NUBES.

DIATYPOSIS, Διατυπωσις, in rhetoric, the lively deſcription of a thing, ſetting it, as it were, before the eyes of the audience. Thus Cicero, VII. in Verr. *Ipſe inflammatus ſcelere & furore, in forum venit; ardebant oculi; toto ex ore crudelitas eminebat, &c.*

DIAULION, in antiquity, a deſignation given to a performance on the antient ſtage with the flute alone.

DIAULODROMI, Διαυλοδρομοι, in antiquity, thoſe racers who turned round the meta, or goal, and finiſhed their courſe at the carcer, or place of ſtarting. The *Diaulodromi* always took a ſhort breathing or reſt, when they arrived at the meta, before they ſet out again for the carcer. *Pitiſc.* Lex. Ant. in voc. See CARCER.

DIAULOS, in antiquity, the name of a particular kind of race, wherein the racers always returned to the place from whence they ſtarted, and were called *Diaulodromi*. *Pitiſc.* Lex. Ant. in voc. See DIAULODROMI.

DIAULOS is alſo uſed to ſignify a diſtance of two ſtadia. Id. ibid.

DICE *Marle*, in husbandry. See the article MARLE.

DICERATON, in the writers of medicine, a name given to a collyrium mentioned by Celſus, and thus named from κερας, a horn, burnt hartſhorn being a principal ingredient in it.

DICHORÆUS, in poetry, the foot of a Latin verſe conſiſting of four ſyllables; of which the firſt is long, the next ſhort, the third long, and the laſt ſhort. It is a double *Choræus*, as *cōmprĕbārĕ*.

DICHOTOPHYLLUM, in botany, the name by which Dillenius, and ſeveral others, call the hydroceratophyllum of Vaillant; and ſome other writers, a genus of plants charactered by Linnæus in his genera plantarum under the name of *Ceratophyllon*. *Dillen.* Gen. 3. See CERATOPHYLLON.

DICKER, or DICRE, *Dicra*, in our old writers, a quantity of leather conſiſting of ten hides. *Blount.*

Some derive the word from the Greek δεκα, ten.

We find the word *Dicra* applied to other things beſides leather; thus, *Civitas Glouceſtriæ reddebat* XXXVI Dicras *ferri*, which is interpreted 36 *Dickers* of iron, ten bars to the *Dicre*. *Gale*'s Hiſt. Brit. 766. ap. *Blount.*

DICROTUS, in natural hiſtory, a word uſed by the antients to expreſs the deer or ſtag when in its third year's growth. It was called *Nebus* by the antient Greeks in the firſt year, *Puttolea* in the ſecond, *Dicrota* in the third and in the fourth, and all its life afterwards *Ceraſtes*.

DICROTUS, in the medicinal writings of the antients, the epithet given to a peculiar ſort of pulſe, which Dr. Nihill calls very properly in Engliſh the rebounding pulſe. In this kind of pulſe the artery beats as it were double; and it is eſteemed a certain ſign of a future critical hæmorrhage by the noſe. When the rebounding pulſe is perceived at about every thirtieth pulſation, the hæmorrhage uſually follows in about four days after; when it recurs at every ſixteenth pulſation, the hæmorrhage generally follows in three days; when every eighth pulſation, it is to be expected in two days and a half; and, finally, when it recurs at every fourth, third, or ſecond pulſation, or is continual in every one, the hæmorrage is to be expected within four and twenty hours. Sometimes nature runs regularly through all the before-mentioned progreſſions of this critical pulſe from its firſt appearance at every thirtieth ſtroke, to the ſingle pulſation; and in this caſe the hæmorrhage is ſeen gradually approaching, and happens regularly as expected: but ſometimes ſhe haſtens or delays it; and then the pulſe ſhifting in its indications, it cannot be judged of with any certainty; when the artery rebounds upon the finger with great celerity, and very briskly follows the firſt ſtroke, the hæmorrhage is juſt at hand, and will appear on the patient's blowing his noſe.

The quantity of the hæmorrhage may be gueſſed from the ſtrength of the rebound in the pulſe, and as the blood diſcharges itſelf, this ſymptom in the pulſe gradually goes off; and if after the hæmorrhage it ſhould be perceived again, it is a ſign of another criſis of the ſame kind. Finally, when the rebounding of the artery is more evident in one

wriſt than in the other, the blood uſually flows in the greateſt violence from that ſide of the noſe, or that noſtril which is on the ſame ſide with the hand in the artery of which the rebounding has been moſt violent.

DICTORES, in our old writers, is uſed for an arbitrator. *Blount*.

DICTUM, in our old writers, is uſed for an arbitrament or award. *Blount*, in *Dictores*.

DICTUM *de Kenelworth*, an edict or award between king Henry the IIId, and thoſe barons who had been in arms againſt him. It was ſo called becauſe made at Kenelworth caſtle in Warwickſhire, anno 51. Hen. 3. It contained a compoſition of five years rent for the Lands of thoſe who had forfeited them in that rebellion. Id. ibid.

DIDAPPER, a common Engliſh name for the ſmall ſpecies of colymbus or diver, very common in our rivers, and more commonly called the *Dob-chick*. See DOB-CHICK.

DIDAR, among the Arabian authors, the name of the elm. *Ger*. Emac. Ind. 2.

DIDELPHIS, the name by which Linnæus calls the animal called philander by other writers. This creature, in that author's ſyſtem of zoology, is alſo a diſtinct genus of animals, the character of which is their having eight paps placed between the duplicature of the abdomen. *Linnæi* ſyſtema naturæ, p. 36.

DIDYNAMIA, in botany, a claſs of plants, whoſe flowers have two of their male parts or ſtamina of greater efficacy in the action of impregnation of the ſeeds than the others: they are known by the two efficacious ſtamina being always much longer than the others.

The word is formed of the Greek Δις, twice, and Δυναμις, power or efficacy. Of this claſs of plants are thyme, lavender, baſil, &c.

This claſs comprehends the plants called by Rivinus *monopetali irregulares*, or plants with flowers of an irregular ſhape, but formed of one leaf; and the plants with labiated or perſonated flowers, according to Tournefort. There are certain general characters which are found in all of this claſs. The perianthium is one leaved, erect, and tubular; it is divided at the end into five ſegments, which are uſually unequal in ſize, and it remains after the flower is fallen. The flower conſiſts of one petal, and ſtands erect: its baſe always contains honey, and ſerves in the place of the nectaria of other flowers. The verge or limb of the flower is uſually ringent or gaping, the upper lip is ſtrait, and the under one broader than the upper, and divided into three ſegments, of which the middle one is the largeſt. The ſtamina are four filaments of a ſubulated ſhape; they are fixed to the tube of the flower, and placed near its back. Two of theſe are uſually longer than the other four. Theſe ſtand near one another, and are placed in the middle: they are all placed in a parallel direction, and rarely exceed the length of the flower. The antheræ are uſually laid under the upper lip of the flowers, and are placed in pairs, joining together near their tops. The germen of the piſtil uſually ſtands above the receptacle or cup; the ſtyle is ſingle and capillary, and is bent in the ſame direction with the ſtamina; it uſually ſtands among them, and a little exceeds them in length; its top alſo is a little crooked, and the ſtigma is commonly emarginated. Many of the genera of this claſs have no fruit, but the ſeeds are contained naked in the cup; and when there is a fruit, it uſually contains two cells. When there is no ſeed-veſſel, the ſeeds are contained in the bottom of the cup, and are four in number; and in ſuch plants as have a ſeed-veſſel, they are uſually more than four, and are always affixed to a ſort of placenta within the capſule.

The flowers of the far greater part of theſe plants ſtand erect, or nearly ſo, making only a ſmall angle with the ſtalk; by this means the antheræ are much better defended from injuries than they otherwiſe would be; and, by means of this poſition, the farina, when diſcharged from the antheræ, naturally falls upon the ſtigma of the piſtil, and is in little danger of being loſt. The characters of this claſs of plants are delivered as general, not particular: moſt of them are found regularly in all the plants of it, but ſome vary in one or other of the particulars, and to this is owing the diſtinction of the ſeveral genera. This is a remarkably natural claſs of plants, not one ſpecies of it deviating from the characters of the reſt; though there are ſome of thoſe plants which have only two ſtamina, which ſeem otherwiſe entitled to a place in it. Such are the pinguicula gratiola, verbena lycopus, and the like. Theſe however cannot be received into it, becauſe the eſſential character of it is that the ſtamina are four in number, two longer and two ſhorter. *Linnæi* Gen. Plant. p. 261.

Linnæus divides this claſs of plants into two general ſeries. The firſt the *gymnoſpermia*, and the ſecond the *angioſpermia*. The firſt of theſe comprehends the labiated plants of Tournefort, and the verticillate plant of Mr. Ray's method, and the other the perſonated plants of Tournefort.

The gymnoſpermia, or verticellate plants, are diſtinguiſhed from the reſt, by having the ſeeds four in number, and ſtanding naked in the cup; and the ſtigma divided into two ſedgments, the lower of which is crooked.

The angioſpermia, or perſonated plants, are diſtinguiſhed from the others, by always having a ſeed veſſel of ſome form, though very various; and, by the ſtigma being obtuſe and various.

Of the firſt kind, or gymnoſpermia, are the galeopſis and ballota, with the like; and, of the ſecond kind, or angioſpermia, are the antirrhinum, &c.

DIEBEL, in ichthyology, a name given by Kentman and others to the chubb or capito. It is properly a ſpecies of the cyprinus. See CAPITO and CYPRINUS.

DIELCYSTINDA, among the antients, a kind of exerciſe performed by boys, who being divided into two parties or ſides, each endeavoured to draw the other over to their ſide, and the party which prevailed gained the victory. *Hofm*. Lex. in voc.

DIEMERES, in the antient muſic, a word uſed ſometimes alone, and ſometimes joined with the word phorbeia. It expreſſed a ſort of bandage, uſed by the antients, to tie up the lower lip in playing on the pipe. The other kind of phorbeia conſiſted only of one perpendicular piece, which went down the cheek, and one tranſverſe one which covered the whole mouth, but had a hole cut into it, to admit the mouth-piece of the pipe. See PHORBEIA.

DIESIS *(Cycl.)*—Ariſtoxenus, and other antient muſicians, often mention the tone as divided into four parts, and the ſemitone into two; thereby making ten diviſions or *dieſes* in the fourth. And this is true, if we conſider theſe ſounds in one tenſion; that is either aſcending or deſcending: but accurately ſpeaking, when we conſider all the *dieſes* or diviſions of a fourth, both aſcending and deſcending we ſhall find thirteen; five to each tone, and three to the ſemi-tone major. But then it is to be obſerved, that ſome of theſe diviſions will be leſs than the enharmonic *Dieſis*: for, if we divide the ſemitone major, into the ſemi-tone minor, and enharmonic *Dieſis*, aſcending; for inſtance, E, ♮ E, F, and then divide in like manner deſcending F, b F, E, we ſhall have the ſemi-tone major divided into three parts: thus, E, b F, ♮ E, F; where the interval between b F and ♮ E, is leſs than the enharmonic *Dieſis* between E & b F, or between ♮ E & F. Phil. Tranſ. N° 481. p. 273.

But if we ſuppoſe theſe ſmall intervals equal, by increaſing the leaſt diviſion, and diminiſhing the true enharmonic *Dieſis*, we ſhall then have a fourth divided into thirteen equal parts; and this naturally leads us to divide the octave into thirty-one equal parts, which gives us the celebrated temperament of Huygens. See TEMPERAMENT.

The logarithm or meaſure of the octave $\frac{2}{1}$ being 1. 000,000, the meaſure of the *Dieſis* $\frac{128}{125}$ will be 0. 034215. Hence 29 *Dieſes* will be nearly equal to the octave. *Euler*. Tentam. Nov. Theor. Muſc. p. 106. See INTERVAL.

DIEXAHAEDRIA, in natural hiſtory, the name of a genus of ſpars. The word is derived from the Greek δις, twice εξ ſix and εδρα ſide. The bodies of this genus are ſpars, compoſed of twice ſix planes, being formed of two hexædral pyramids, joined baſe to baſe, without any intermediate column. Of this genus there are only two known ſpecies. 1. One with long, narrow, and ſharp pointed pyramids, found in lamb's cave on mendip hills: and 2. one with long, broad, and obtuſe pyramids: this is found in the mine of Goſſelar in Saxony, and in many of the mines of the hart's foreſt. *Hill*'s hiſt. of Foſſils, p. 213.

DIEXODUS, Διεξοδος, in rhetoric, is uſed for digreſſion.

DIFFARREATION, *Diffarreatio*, in antiquity, a religious ceremony, uſed upon occaſion of obtaining a divorce. It was directly oppoſed to the ceremony of contracting marriage, called *Confarreation*. *Pitiſc*. Lex. Ant. in voc. See CONFARREATION, *Cycl*.

DIFFERENCE *(Cycl.)* — It was a fundamental principle among the antient geometers that the *difference* of any two unequal quantities, by which the greater exceeds the leſſer, may be added to itſelf, till it ſhall exceed any propoſed finite quantity of the ſame kind. This principle ſeems inconſiſtent with the ſuppoſition of an infinitely ſmall quantity or difference, which added to itſelf any number of times, is never to be ſuppoſed to become equal to any finite quantity whatſoever; which is the foundation of the modern method of infiniteſimals. However, this laſt may, with proper caution, be made uſeful and accurate. Vid. *Maclaurin*'s fluxions Introd. p. 4. and art. 495. ſeq.

DIGASTRICUS *(Cycl.)* — The *Digaſtric* muſcle, according to Winſlow, is a ſmall long muſcle ſituated laterally between the whole baſis of the jaw and the throat. It is fleſhy at both the extremities and tendinous in the middle, as if it conſiſted of two ſmall muſcles joined endwiſe by a tendon. It is fixed by one fleſhy extremity in the ſulcus of the maſtoide apophyſis, and from thence runs forward inclining to the os hyoides, where the firſt fleſhy body ends in a round tendon, which is connected to the lateral part and root of the cornua of that bone by a kind of aponeurotic ligament, and not by a pulley, as appears at firſt ſight, becauſe of its paſſage by the extremity of the muſculus ſtylogloſſus. Here the

the tendon is incurvated, and preſently ends in the other fleſhy body, which is fixed immediately above the internal labium of the baſis of the chin, near the ſymphyſis, in a ſmall unequal depreſſion. *Winſlow*'s anatomy, p. 254.

The *Digaſtric* muſcles, according to Mr. Monro, do not ſolely pull the lower jaw down, but ſerve to draw up the os hyoides, and parts annexed to it, in deglutition. We have an account of the ſituation and uſes of theſe muſcles, by this learned profeſſor, in the Med. Eſſ. Edinb. vol. 1. art. 11.

DIGESTION (*Cycl.*)—Some ſuppoſe *Digeſtion* owing to gentle heat and motion. By this heat and motion the texture of the nouriſhment is changed in the bodies of animals; and then, the conſtituent ſolid parts are endued with peculiar attractive powers of certain magnitudes, by which they draw out of the fluids moving through them, like parts in certain quantities, and thereby preſerve their forms and juſt magnitudes. See Dr. *Bryan Robinſon* of the anim. œcon.

Others think *digeſtion* performed by a violent trituration of the ſtomach; but ſeveral obſervations ſeem to contradict this opinion. See TRITURATION.

DIGESTION, in chemiſtry—The chemiſts of late years have too much given into the more elaborate and forced proceſſes, and neglected the more natural and eaſy ones. Among theſe latter is *Digeſtion*; a proceſs ſo eaſy, that it requires ſcarce any quality in the operator but patience, and yet will do ſuch things as all the elaborate proceſſes of that art can never arrive at without it. There is ſcarce a proceſs that has more puzzled the chemiſts of an age or two ago, than the volatilizing ſalt of tartar; yet Langelot aſſures us, that after uſing all the caution in the common proceſſes that an earneſt deſire of ſucceſs could inſpire him with, he failed in them all; till trying the effect of a long *Digeſtion*, he ſucceeded ſo well in the firſt attempt, that he converted almoſt the whole ſalt into a pure white volatile ſubſtance, leaving only a few inſipid earthy fæces behind.

Another great uſe of *Digeſtion* is the duly preparing the eſſences of mineral ſulphurs; the ſtony ſea plants, which greatly reſemble the nature of foſſils, are alſo better treated by this proceſs than by any other. Tartariſed ſpirit of wine, receiving a very high tincture from red coral, after a long *Digeſtion*, in any diſtilled vegetable oil, though it will not in the common way be at all coloured by it. Phil. Tranſ. N° 87. See CORAL,

DIGGING, in mineralogy, a term appropriated by the miners to expreſs that penetrating into the earth, where they have the ore before them, and every ſtroke of the tools turns to account. They appropriated the word to this ſenſe, expreſſing the random openings, which they make in ſearch of mines, by the word *hatching*, or *eſſay-hatching*. See the article TRACING *of mines*.

When the eſſay hatches have been opened ſo long, that the orifice of the mine or load is found, the opening which has led to it, loſes its name of eſſay-hatch, and is called a ſhaft or metal-hatch; this is to be ſunk down about a fathom, and then they leave a ſquare ſpace, called a *ſhamble*, and ſo continue ſinking from caſt to caſt; that is, as high as a man can conveniently throw up the ore with a ſhovel, till the load is found to grow ſmall, or elſe to degenerate into ſome unprofitable ſubſtance, or weed, as they metaphorically expreſs it. The degeneracy of the ore is ſoon perceived, by the finding mundick or marchaſite growing more plentiful among it. This is a ſulphureous mineral, of a yellow, whitiſh, or greeniſh colour, and is very troubleſome to the Corniſh miners. The other unprofitable ſubſtances found in the place of the ore, or mixed in large quantities with it, where it degenerates, are daze, which is white, black, or yellowiſh; *iron mould*, which is black or ruſty; *caul*, which is red; *gliſter*, which is blood-red, or black, is alſo another degeneracy of the ore. Theſe are the common names given by the miners to various foſſils, explained under their ſeveral heads, and theſe are the marks by which they know the vein is almoſt exhauſted in that part, and will not long be worth digging.

In this caſe, they begin to drive either eaſt or weſt, as the goodneſs of the land, or the convenience of the hill, unite. The drift or opening, on this occaſion, is three foot over, and ſeven foot high, ſo that a man may conveniently ſtand and work: but in caſe the land is not broad enough of itſelf, as ſome ſcarce are half a foot; then they break down the deads firſt on the north ſide of the land, for the greater conveniency of the right arm in working, and then they begin to rip the load itſelf; by the term deads, they mean that part of the ſhelf, which contains no metal, but encloſes the load or vein as a wall between two rocks.

The inſtruments commonly uſed in mines with us, and that ſerve for ripping the lands are the *beele*, or as it is called in Cornwall the *tubber*. This is a weapon of eight or ten pounds weight, well ſteeled and ſharpened at each end, ending in a point each way, and having a hole in the middle: this will laſt half a year, but muſt be new ſharpened every fortnight. The ſecond inſtrument is a *ſledge*; this is uſually made from ten to twenty pounds weight; and will laſt ſeven years, if new ordered once in three or four months. Beſide theſe, they have *gadds*, or wedges; theſe are of about two pounds weight; they are made four ſquare, and well ſteeled at the point, and they muſt have ladders and wheel-barrows to carry the deads, and the ore out of the adits to the ſhambles. The general proportion of the workmen in Cornwall is this, two ſhovel-men and three beele-men in a drift; theſe are as many as the drift will contain without ſtanding in one another's way. The beele-men rip the deads and the ore, and the ſhovel-men carry it off and land it, by caſting it up from one of the ſhambles to another all the way up; in ſome places they ſave the trouble of this caſting it to the ſhambles by a winder and two buckets; theſe are ſo contrived, that one goes up as the other comes down, and they are filled and emptied with great eaſe. Philoſ. Tranſ. N° 69.

DIGITALIS, *Fox-glove*, in botany, the name of a genus of plants, the characters of which are theſe: the flower conſiſts of one leaf, of a tubular form, very wide, open at the mouth, and ſeeming bilabiated. The piſtil ariſes from the cup, and is fixed in the manner of a nail into the hinder-part of the flower; this afterwards ripens into a fruit, or capſule, of an oval, pointed figure, divided into two cells, and uſually containing very ſmall ſeeds. The ſpecies of *Fox-glove* enumerated by Mr. Tournefort are theſe. 1. The purple *Fox-glove*. 2. The pale red *Fox-glove*. 3. The white *Fox-glove*, with large flowers. 4. The ſmall purple Spaniſh *Fox-glove*. 5. The oriental *Fox-glove*, called by authors ſeſamum. 6. The dusky ſeeded oriental *Fox-glove*. 7. The trifid leaved oriental *Fox-glove*, with ſnow white flowers. 8. The ſmalleſt *Fox-glove*, called by many authors *Gratiola*. 9. The flax leaved Portugal marſh *Fox-glove*. 10. The large flowered yellow *Fox-glove*. 11. The great *Fox-glove*, with ſmall pale yellow flowers. 12. The leſſer *Fox-glove* with ſmall yellow flowers. 13. The ſmall narrow leaved yellow *Fox-glove*. 14. The broad leaved *Fox-glove*, with a ferrugineous flower. 15. The broad leaved *Fox-glove*, with a ſmall ferruginous flower. 16. The middle *Fox-glove*, with a yellowiſh flower. 17. The narrow leaved *Fox-glove*, with a ferruginous flower. 18. The narrow leaved purple *Fox-glove*. 19. The narrow leaved yellow Spaniſh *Fox-glove*. 20. The narrow leaved black flowered Spaniſh *Fox-glove*. See FOX-*glove*.

DIGITATED *Leaf*, among botaniſts. See LEAF.

DIGITUS *Veneris*, *Venus Finger*, in botany, a name by which ſome authors have called the nymphæa, or water lilly. *Ger.* Emac. Ind. 2.

DIJAMBUS, in poetry, the foot of a latin verſe of four ſyllables; it is compounded of two *iambics*, as fĕvĕrĭtās.

DIIPOLIA, Διιπολεια, in antiquity, an Athenian feſtival, celebrated in honour of *Jupiter Polieus*, or protector of the city. For the ceremonies obſerved at this ſolemnity, ſee *Potter*'s Archæol. Græc. l. 2. c. 20. t. 1. p. 381.

DILATATOR *Poſticus Urethræ*, in anatomy, a name given by Heiſter, and ſome others, to what is ſuppoſed to be a peculiar muſcle by many, and called alſo *levator ſextus ani*, and by ſome other names, though it is really only a proceſs of the ſphincter ani running into the perinæum. See SPHINCTER.

DILE, in Botany, a name by which ſome authors have called the iſatis or woad. *Ger.* Emac. Ind. 2.

DILIGENZA, in the Italian muſic, is uſed for a ſoft or ſweet manner of ſinging or playing.

DILL, in botany, &c. See ANETHUM.

DILLENIA, in Botany, the name of a genus of plants, the characters of which are theſe: the perianthium is compoſed of five leaves, which are large, roundiſh, hollow, and of a coriaceous texture, and remain when the flower is fallen: the flower is compoſed of five roundiſh hollow petals; theſe alſo are large and of a coriaceous texture. The ſtamina are numerous filaments forming a ſort of globe, the antheræ are oblong and erect. The germina are about twenty in number, they are of an oval oblong figure, and pointed, they are ſomewhat compreſſed, and adhere together by their inner ſurfaces: there are no ſtyles. The ſtigmata are large and pointed, and are diſpoſed in form of a ſtar; the fruit is roundiſh, and is covered with a number of capſules, divided by ſo many furrows. The ſeeds are numerous and ſmall. *Linnæi* Gen. Plant. N° 253. Hort. Mal. vol. 3. 38, 39.

DILICTUM, a term uſed by Agricola, to expreſs a brine, made by pouring water upon ſand, ſtones, earth, &c. that had been before ſtrongly impregnated with Sea ſalt; from this brine, a ſalt, for the uſe of the table, was made by evaporation in his time, and is ſo ſtill in many parts of the world. At Junthall in Germany they have a ſalt work of this kind, where they make at the rate of eight hundred loaves of ſalt in a week, each loaf weighing four hundred weight. Here, and at ſeveral other places in the Upper Auſtria, there are deep mines, in which they dig mud and earth ſtrongly impregnated with common ſalt. This ſaline earth they break into lumps, of a proper ſize, and caſt them into pits in the bottom of the mines, where they cover them with water; and this, in a few weeks ſtanding, becomes a brine ſaturated to the higheſt degree, every pound of it containing ſix ounces of ſalt. This brine is conveyed thence by pipes into ciſterns, and is boiled in iron pans into a white ſalt. In other places, as at Roche, the

water is directed to pass among earths thus impregnated, and from thence becomes saturated with salt in the same manner, and is afterwards boiled in the common way. *Hoffman* de Salin. Hallens, c. 2. and 4. Obs. Phys. Chym. l. 2. obs. 16. The sand of the sea is also in some places used as a substance to make salt from. There are works of this kind on the coast of Normandy, where a brine is made from the sand, and evaporated at so small an expence, that it is worth their while to export it to England and other countries. We had formerly some works of this kind in England, as at Wirewater, and some other places in Lancashire and Westmoreland, where pit-coal being scarce, they boiled it with turf fires; but since the works of the brine salt, and purified rock salt, have succeeded so happily with us: these are all laid aside, except some inconsiderable ones in Lancashire. These are near Ulverstone, and the sand from which they make their brine there, is extracted from the flat sandy shores, which are only covered with water in the highest tides, which flow two or three days before, and three or four days after the new and full moon; for those parts of the sand which are overflowed by the neap tides are seldom sufficiently dried, and are at too great a distance from the salterns.

This sand they collect in flats and washes, or in parts of the sands, which are perfectly plain, and in little hollows, where the sea water is left, and either sinks into the sand, or is dried up by the heat of the sun, and leaves the salt behind. This is only collected in dry weather, and at such times when the sea water has been exhaled from it by the sun, and there have been no rains afterwards to wash the salt out of it. They dig a pit adjoining to the saltern eighteen foot long, three broad, and one deep; the bottom of this they cover with straw, or rushes, and then fill it up with sand collected in this manner; they pour upon this sea water, and this imbibing the salt from the sand is filtered through the straw or rushes, and runs clear through a pipe at the bottom. *Brownrig* of Salt, N° 136.

DIMACHÆ, in antiquity, a kind of horsemen, first instituted by Alexander. Their armour was lighter than that of the infantry, and at the same time heavier than that used by horsemen, so that they could act as horse or foot as occasion required. *Pitisc.* Lex. Ant. in voc.

DIMACHÆRUS, Διμαχαιρος, in antiquity, a gladiator who fought with two swords. Vid. Hist. Acad. Inscript. T. 2. p. 374. seq.

DIMETIENT, in geometry, is sometimes used for *Diameter*. *Harris*, in voc.

DIMINISHED *interval*, in music, is applied to such as are lessened by a semi-tone minor. Thus from C ♮ to E being a third minor, if E be lowered by a semi-tone minor, we shall have E b, and then from C ♮ to E b is called a *diminished* third, in the language of practical musicians, and occurs frequently in their works. But strictly speaking, in this case, the note E must be lowered more than a semi-tone minor, as shall be shewn farther on.

DIMINISHED *Second* is a semi-tone major, lessened by a semi-tone minor. See the articles INTERVAL and SECOND.

DIMINISHED *Third*, by some called *defective third*, is properly a third minor lessened by a semi-tone minor. But among practical musicians, it commonly signifies an interval equal to two semi-tones major. And this they confound with the former; but there is a difference between them, equal to the difference between a tone-major and minor, that is, a comma. The first mentioned of these *diminished* thirds, will be expressed by $\frac{144}{125} = \frac{6}{5} : \frac{25}{24}$, and is equal to the tone major and enharmonic diesis; for $\frac{144}{125} = \frac{9}{8} \times \frac{128}{125}$. The second *diminished* third will be expressed by, $\frac{256}{225} = \frac{16}{15} \times \frac{16}{15}$, which is a comma less than the former. See the table in the article INTERVAL.

DIMINISHED *Fourth*. See the table in the article INTERVAL.

The *diminished* fourth often occurs in practice, as from C to G ♮ descending; and sometimes, though more rarely from G ♮ to C ascending.

DIMINISHED *Fifth*, in music, is less than the true fifth by a semi-tone minor, and is therefore equal to two lesser thirds.

Practitioners often confound the *diminished* fifth, with the semi-diapente, or false fifth, which is a comma less. See INTERVAL.

DIMINISHED *Sixth*.—This interval, according to Ozanam, contains two tones and three semi-tones major; or a fourth and diminished third; or a *diminished* fourth and third minor. Thus from C ♮ to A b is a *diminished* sixth.

But, as there are two *diminished* thirds, so there may be as many *diminished* sixths; these being the complements of the former to the octave. One of these *diminished* sixths will be expressed by $\frac{1024}{675} = \frac{4}{3} \times \frac{256}{225}$, and this is a semi-tone major more than the semi-diapente: the other *diminished* sixth will be $\frac{192}{125} = \frac{4}{3} \times \frac{144}{125}$, which is a semi-tone minor less than the flat sixth. Practitioners confound these two; and, in effect, in temperate scales they coincide, as do all other intervals, differing only by a comma. See TEMPERAMENT.

DIMINISHED *Seventh*, is of two kinds, differing by a comma. See the table in the article INTERVAL.

That *diminished* seventh, which is the complement of the superfluous second to the octave, is the only one in use. It is a semi-tone major more than the sixth minor, as from C ♮ to B b.

DIMINISHED *Octave*, is a semi-tone minor less than the octave, as from C to *c* b. It occurs sometimes in the basses of instrumental pieces of music. See INTERVAL.

DIMORPHOTHECA, in Botany, a name given by Vaillant to a genus of plants, which Linnæus makes the same with the calendula. The characters are these: the common cup is simple, erect, and divided into several parts. The flower is of the compound radiated kind, its disk is composed of a great number of hermaphrodite floscules, and its radius of a vast number of female flowers: these are very long, and are of the same number with the segments of the cup. The hermaphrodite floscules are tubular, and lightly divided into five segments at the edge, and are of the length of the cup. The female flowers in the radius are of a ligulated form, and divided into three denticulations at the end; they are also hairy at the base, and have no ribs. The stamina in the hermaphrodite flowers are five filaments, very short and slender, and the antheræ are cylindric, tubular, and of the length of the flower. The pistill in the hermaphrodite flowers has its germen standing below the flower. The style is capillary, and is scarcely of the length of the stamina; and the stigma is obtuse, bifid, and erect. In the female flowers, the germen of the pistill is oblong and of a triangular form; the style is capillary, and of the length of the stamina; and the stigmata are two, and are oblong, pointed, and reflex. There is no capsule for the seeds but the cup becomes roundish and depressed, and closes at the summit. There are no seeds from the central flowers of the disk; but those near the margin, have each a single seed after them which is membranaceous, and surrounded with a cordated compressed substance; they are of an oblong figure, broader at the top than elsewhere, and probably are steril.

The seeds which follow the female flowers are single, larger, and of an oblong figure; they are crooked, and approach to a somewhat triangular form, and are externally marked with a sort of figure of a plant in a longitudinal direction. The receptacle is naked and flat. *Linnæi* Gen. Plant. p. 419.

DINUS, in medicine, according to some, is the name of a disease, called more usually *Vertigo*. See VERTIGO.

DIOCALLIA, in Botany, a name by which Apuleius and some other authors have called the common sweet chamomile. *Ger.* Emac. Ind. 2.

DIOCLEIA, Διοκλεια, in antiquity, a solemnity kept in the spring at Megara, in memory of the Athenian hero Diocles, who died in the defence of the youth he loved. *Pott.* Archæol. Græc. l. 2. c. 20.

DIOCTAHÆDRIA, in natural history the name of a genus of spars. The word is derived from the Greek δις twice, οκτω eight, and εδρα a side. The bodies of this genus are spars composed of twice eight planes, or two octangular pyramids joined base to base, without any intermediate column. Of this genus there are three known species. 1. One with long pyramids, which is found in the mines of Rammelsberg in the Hartz forest in Germany, and no where else, so far as is yet known. 2. One with short and sharp pointed pyramids found in many of the mines of the Hartz forest, and sometimes tinged with the colours of the gemms. And 3. One with short and obtuse pyramids, which is found in the mines of Cornwall, and lodged in the cetton stone of Rutland. *Hill*'s Hist. of of Foss. p. 211.

DIODIA, in Botany, the name of a genus of plants. The characters of which are these: the perianthium consists of two leaves, of an oval figure, equal in size, and placed upon the germen, these remain when the flower is fallen. The flower is of the one-leaved labiated kind; its tube is slender and longer than the cup; its upper lip is erect and bifid, and the lower lip is expanded, and divided into two pointed segments. The stamina are four filaments of the thickness of a bristle; and two of these, which are opposite to one another, are somewhat shorter than the others. The antheræ are oblong, and versatile. The germen of the pistil is roundish, but in some degree four cornered, this stands under the cup of the flower. The style is capillary, and of the length of the stamina, and the stigma is bifid. The fruit is a capsule, of an oval figure, with four corners, so as to appear square, and is crowned with the cup grown larger; this is composed of two valves, and contains two cells; the seeds are single, of an oval oblong figure, and convex on one side, and plain on the other. *Linnæi*, Gen. Plant. p. 291.

DIOECESIS, Διοικησις, among the Romans, a præfecture of several provinces joined together, under the same governor, called *Præfectus*. *Hoffm.* Lex. in voc. See PRÆFECT and DIOCESE, *Cycl.*

DIONYSIACA, (*Cycl.*) in antiquity, was also a designation given to plays and all manner of sports acted on the stage; because playhouses were dedicated to Dionysius, i. e. Bacchus and Venus, as being the deities of sports and pleasure. *Potter*, Archæol. Græc. l. 1. c. 8. t. 1. p. 41.

DIONYSIAS *Lapis*, in natural history, the name of a stone described by Pliny, and some other of the antients, as a black

stone

ſtone variagated with red ſpots. There are ſome fabulous accounts recorded of its virtues, ſuch as its preventing drunkenneſs, and giving water the taſte of wine. Some of the writers of the middle age have attributed many other virtues to the ſtone of this name; but they ſomewhat deviate from Pliny's account in their deſcription of it: they ſay it is of a ferrugineous colour variegated with white, and that it is found only in the Eaſt-Indies; theſe are too ſhort deſcriptions to be certain what ſtone they were intended for. *Plin.* l. 37. c. 10. *Hofm.* Lex. in voc.

DIOECIA, in Botany, a claſs of plants which have the male and female parts, not in the ſame, but in different flowers, and thoſe not on the ſame individual, but on different plants of the ſame ſpecies; either of which, though they are called the male and female plants, from their thus carrying the ſeparate male and female flowers, might have ariſen from the ſame ſeed.

The word is formed of the Greek δὶς twice, and οἶκος habitation. Among the plants of this claſs are the willow, miſletoe, hemp, ſpinach, &c.

All the plants of this claſs are in the different individuals, diſtinctly males and females; and thence in every ſpecies of this claſs. There is a male and female plant, which in the time of flowering appear very different from one another. The male plants, as well as the others, growing from the ſeeds of the ſame individual female plant: and it is found, that the female plants of this claſs never produce perfect ſeeds, or ſuch as can yield plants from ſowing, unleſs there be a male plant of the ſame ſpecies near them at the time of their flowering. It is obſerved in ſome of the ſpecies of this claſs, that though in general the plants raiſed from the ſeeds are ſome male and others female ſeparately; yet there are ſome which are hermaphrodites, or have the two ſexes conjoined. It is a curious obſervation, that there are no ſeparate male and female plants in the claſſes of the aſperifoliate or ſtellate plants, nor in the umbelliferous claſs, or that of the didynamia, tetradynamia, monadelphia, diadelphia, or ſyngeneſia. The reaſon of which appears very evidently, from an obſervation of the conduct of the fructification in thoſe claſſes. *Linnæi* Gen. Plant. p. 470.

DIOMEDIS *Avis*, in Zoology, the name of a bird of the web footed kind, with a ſlender beak, hooked at the end, and with its hinder toe not connected by the membrane that joins the reſt. It is of the ſize of a common hen, but its neck and legs are much longer: its colour is a dusky, and ſomewhat greyiſh brown, and under the belly there is more or leſs white: its beak is of a fine red, or in ſome of a yellowiſh colour, with a black end. It is found in the Inſula Diomedea, now called Tremiti, in the Adriatic Sea, and is ſaid to be peculiar to that place.

DIOPTRA, among the antients, an inſtrument invented by Hipparchus, which ſerved for ſeveral uſes, as to level water; to take the height of towers, or places at a diſtance; to determine the places, magnitudes, and diſtances of the ſtars. *Hofm.* Lex. in voc.

DIORTHOSIS, in ſurgery, an operation, by which crooked or diſtorted members, are made even, and reſtored to their primitive and regular ſhape.

DIOSCOREA, in Botany, the name of a genus of plants, the characters of which are theſe: it produces ſeparate male and female flowers; the cup is a one leaved perianthium, of a bell like ſhape, divided into ſix lanceolated ſegments, which expand at the top; there is no other flower but this cup. The ſtamina are ſix very ſhort capillary filaments, with ſimple antheræ. In the female flowers, the cup is the ſame as in the male, and there are no petals. The piſtil has a ſmall trigonal germen, from which ariſe three ſtyles of a ſimple ſtructure, terminated by ſimple ſtigmata. The fruit is a large triangular capſule, which has three cells, and is compoſed of three valves. The ſeeds are two in each cell, and they are compreſſed, and have a membranaceous ring. Linnæus obſerves, that he could never trace out the cup, as Plumier deſcribes it in the dried ſpecimens. *Linnæi* Gen. Pl. p. 479. *Plumier* Gen. 26.

DIOSCURIA, Διοσκουρια, in antiquity, a feſtival in honour of the Διοσκουροι, or Caſtor and Pollux, who were reputed to be the ſons of Jupiter. It was obſerved by the Cyrenæans, but more eſpecially by the Spartans, whoſe country was honoured by the birth of theſe heroes. The ſolemnity was full of mirth, being a time wherein they ſhared plentifully of the gifts of Bacchus, and diverted themſelves with ſports, of which wreſtling matches always made a part. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 384.

DIOSPIROS, in Botany, a name given by Pliny, and ſome other authors, to the plant called *Lacryma Jobi*, or Job's tears. *Ger.* Emac. Ind. 2.

DIOSPOROS, in Botany, a name given alſo by ſome of the antients to the lithoſpernum or gromwell; ſome chuſe to write it *Dioſpyros*, but this ſeems erroneous. The plain derivation of the word, being from the Greek διὸς σπορος, the ſeed of Jupiter. It ſeems to have obtained this name from its beauty and hardneſs. *Pliny*, l. 26.

DIOSPYROS, in Botany, the name by which Linnæus calls the Guiacana, of Tournefort and others. *Linnæi* Gen. Pl. p. 166. See GUIACANA.

DIOSPYRUM, in Botany, a name by which ſome authors have called the milium ſolis or gromwell. *Ger.* Emac. Ind. 2.

DIOTA, among chymiſts, a term uſed for a circulating or double veſſel.

DIPHRIS, a ſtone mentioned by the antient writers; and ſaid, by Pliny, to be of two kinds, the one black, the other white; and that theſe carried each of them the mark of one of the ſexes, deſcribed by a line of the oppoſite colours: they were therefore called the male and female: the white was called the male, and had the character of the male ſex figured in a black line, the other the female; and had the marks of that ſex deſcribed by a white one: we know no ſuch ſtones at this time.

DIPHTHERA, Διφθερα, among the antients, a garment made of ſkins, and worn only by ſhepherds and country labourers. *Hofm.* Lex. in voc.

DIPHYES, in natural hiſtory, a name given by ſome authors, to a kind of ſtone, which repreſents both the male and female parts of generation of the human ſpecies. We have ſtones which repreſent the figures of ſhells, becauſe they have been formed in them: and nothing can be more proper than the calling them by the name of the ſhell, from which they borrow their figure; but this is not to be ſuppoſed the caſe in regard to this ſtone, which has nothing to do with thoſe parts in its formation, but owes its figures merely to the accidental conformation of the hinge and protuberances of a ſhell, in which it has been formed. We have a ſpecies of chama, whoſe external form at the mouth repreſents the female pudenda; but the figure of this ſtone is owing to the internal ſhape of the ſhell, in which it has been caſt. This is an unknown ſpecies of concha anomia, which has ſuch ridges on one ſhell, and ſuch cavities in the other, that the ſtone caſt or moulded in it, has on one ſide the figure of the female pudenda, and on the other of the male: it is uſually of a dusky brown colour, and of a ferrugineous ſubſtance; as the ſame ſhell may, however, have received in different places different ſubſtances into its cavity, all which would neceſſarily be of this form, we hear, among authors, of ſome black, and ſome white ſtones of this kind. Authors have treated of this ſtone in a very idle and fabulous manner, but this is its true hiſtory.

DIPLASIASMUS, in medicine, a reduplication of diſeaſes.

Diplaſiaſmus is alſo uſed for two muſcles of the arm, which ſerve to turn it about. *Blancard.*

DIPLOIS, Διπλοις, in antiquity, a double *pallium*, or cloak, worn chiefly by the *Cynics*. *Hofm.* Lex. in voc.

DIPONDIUS, in the ſcripture language, is uſed by St. Luke [a], to ſignify a certain coin, which was of very little value. Our tranſlation of the paſſage is, *are not two ſparrows ſold for two farthings?* In St. *Matthew* [b], who relates the ſame thing, we read, *Are not two ſparrows ſold for a farthing?* The Greek reads *Aſſarion* inſtead of *As*. Now *Aſſarion*, as ſome ſay, was worth half an *As*, that is to ſay, four French deniers and $\frac{1}{8}$: and, according to others, two deniers and $\frac{5}{12}$. *Dipondius* ſeems rather to ſignify half an *As*. *Calmet*, Diction. Bibl.

[a *Luke* xii. 6. b *Matt.* x. 29.]

Dr. Arbuthnot differs in opinion from the author laſt quoted. He ſays, that this coin was at firſt *libralis*, or of a pound weight, and even when diminiſhed it retained the name of *libella*. So that *Dipondius* denoted two Aſſes. *Arbuth.* tables of antient coins, &c. c. 3.

DIPPING, (*Cycl.*) in mineralogy, a term uſed to expreſs the deviation of the veins of ore, from that regular and ſtrait line, in which they uſually run. A great deal of the skill of the miners conſiſts in the underſtanding this dipping of the veins, and knowing how to manage in it. In Cornwall they have this general rule to guide them in this reſpect: moſt of their tin loads, which run from eaſt to weſt, conſtantly dip towards the north. Sometimes they underlie; that is, they ſlope down toward the north three foot in eight perpendicular. This muſt carefully be obſerved by the miners, that they may exactly know where to make their air ſhafts when occaſion requires; yet, in the higher mountains of Dartmaer there are ſome conſiderable loads, which run north and ſouth: theſe always underlie toward the eaſt.

Four or five loads may run nearly parallel to each other in the ſame hill; and yet, which is rare, they may meet all together in one hatch, as it were a knot, which well tins the place, and ſo ſeparate again, and keep their former diſtances. Phil. Tranſ. N° 69.

DIPSACUS, *Teaſell*, in the Linnæan ſyſtem of Botany, makes a diſtinct genus of plants; the characters of which are theſe: the calyx is a common perianthium, containing many flowers, and compoſed of ſeveral ſlender little leaves, placed round the receptacle, and longer than the flowers. The flower is formed of one leaf, or petal, the whole making a ſtrait tube, divided into four ſegments; at the extremity all placed erect, and the outer one larger and more pointed than the reſt. The ſtamina are four capillary filaments longer than the flower. The antheræ are laid cloſely on them. The germen of the piſtil is placed below the proper receptacle of the flower; the ſtyle is ſlender, and of the length of the flower, and the ſtigma is ſingle. The fruit is one large and common receptacle, of a conic form, made up of the leaves of the cups longer than

thoſe of the flowers, and ſeparating the flowers one from another. The ſeeds are ſingle, oblong, and ſomewhat cubic in figure, and are crowned with a marginaceous rim. *Linnæi* Gen. Plant. p. 22.

The DIPSACUS, according to Tournefort, is characterized thus: the flower is of the floſculous kind, being compoſed of ſeveral ſmall floſcules, collected into a kind of a honey-comb-like ſtructure; the head is compoſed of ſeveral imbricated leaves, and theſe are fixed to an axis, and laid like ſcales over one another. The floſcules ariſe from the alæ of theſe, and are divided into many ſegments at their ends; theſe are placed on the coronated end of an embryo, which afterwards becomes a ſtriated ſeed.

The ſpecies of *Dipſacus* enumerated by Mr. Tournefort are theſe. 1. The cultivated great *Dipſacus*. 2. The great wild *Dipſacus*. 3. The jagged leaved *Dipſacus*. 4. The four leaved giant *Dipſacus*, with ſmooth ſcabious like leaves, and a pear faſhioned head: and 5. The Indian great *Dipſacus*, with numerous heads. *Tourn.* Inſt. p. 466.

The leaves of the common wild *Teaſell* dried, and given in powder, or infuſion, are a very powerful remedy againſt flatus's and crudities of the ſtomach. There is alſo another, though ſomewhat whimſical uſe, for which this plant is become famous among the country people. If the heads are opened longitudinally about September or October, there is generally found a ſmall worm in them: one of theſe only is found in each head, whence naturaliſts have named it the *vermis ſolitarius dipſaci*. They collect three, five, or ſeven of theſe, always obſerving to make it an odd number, and ſealing them up in a quill, give them to be worn as an amulet for the cure of agues. Faith has wrought ſo many cures for them, that they are in many parts of the kingdom of much higher reputation than the bark.

DIPSACUS, in medicine, according to ſome, is the ſame with a Diabetes. *Caſt.* Lex. Med. in voc. *Diabetes*. See DIABETES.

DIPSAS, a ſort of ſerpent, the biting whereof produces ſuch a thirſt as proves mortal; whence it is called *Dipſas*, which in Greek ſignifies thirſty. In Latin it is called ſitula, a pail. Moſes ſpeaks of it in Deut. viii. 15.

The Hebrew word *tzimaon* anſwers very well to the Greek *Dipſas*, and expreſſes the thirſt occaſioned by the biting of this ſerpent. Some by the Hebrew *tzimaon* underſtand a deſart or dry place. *Calmet*, Diction. Bibl.

DIPYRENON, in ſurgery, the name of a probe, with a double button at the end, reſembling two ſmall berries growing together.

DIRECTION (*Cycl.*)—*Quantity of* DIRECTION, in mechanics, is uſed for the product of the velocity of the common center of gravity of a ſyſtem of bodies, by the ſum of their maſſes.

In the colliſion of bodies, the quantity of *Direction* is the ſame before and after the impulſe. *Bernoulli*, Diſcours ſur le movement. Oper. tom. 3. p. 32 & 56.

DIRECTOR, (*Cycl.*) in ſurgery, a grooved probe, to direct the edge of the knife or ſciſſars in opening ſinus's or fiſtulas, that, by this means, the ſubjacent veſſels, nerves, and tendons, may remain unhurt. Sometimes one end is made in form of a ſpoon, to contain powders to ſprinkle upon wounds or ulcers. Sometimes alſo it is forked at the end to divide the frænum of the tongue. *Heiſter*'s Surg. Introd. Sec. 36.

DIRECTRIX, in geometry, the line of motion, along which the deſcribing line, or ſurface, is carried in the Geneſis of any plane or ſolid figure. It is otherwiſe called *Dirigent*. See DIRIGENT, *Cycl.*

DIRIBITORES, among the Romans, officers appointed to diſtribute tablets to the people at the *Comitia*. See COMITIA, *Cycl.*

DIRITTA, in the Italian muſic, a term intimating that the piece is to be played or ſung in conjoint degrees. Thus, *Contrapunto alla Diritta*, according to Angelo Berardi, is when one is obliged to raiſe or fall the voice by the ſame degrees, i. e. by an equal number aſcending or deſcending, without making a leap, even of the interval of a third. *Broſſ.* Dict. Muſ. in voc.

DISARM, in the manege—To *diſarm* the lips of a horſe, is to keep them ſubject, and out from above the bars, when they are ſo large as to cover them, and prevent the true preſſure or *appui* of the mouth, by bearing up the bit, and ſo hindering the horſe to feel the effects of it upon the bars. *Guil.* Gent. Dict. in voc.

DISBOSCATION, *Diſboſcatio*, a turning wood-ground into arable or paſture, an aſſarting. See ASSART, *Cycl.*

DISCEIT, in our old writers. See DECEIT and DECEPTIONE.

DISCOBOLI, Δισκοβολοι, among the antients, an appellation given to thoſe who gained the victory at the *Diſcus*. *Hofm.* Lex. in voc. See DISCUS, *Cycl.*

DISCOIDES *Fibula*, in natural hiſtory, the name of a genus of the echinodermata, or ſea hedge-hogs; the periphery of the baſe of theſe is exactly round, and the body of a convexo-concave figure. The principal ſpecies of this genus is the ſubuculus, which has ſometimes a roſeaceous top, the lines being very neat and elegant, ſometimes a plain and ſmooth top, ſometimes is all over covered with extreamly minute and fine ſtriæ, and ſometimes it is much flatter than at others. *Klein's* Echinoderm.

DISCRETIONE, in the Italian muſic, is uſed to direct the ſinger or player to execute his part with care diligently.

DISDIACLASTIC *Cryſtal*, in natural hiſtory, a name given by Bartholine, and ſome others, to the pellucid foſſile ſubſtance, more uſually called from the place whence it was firſt brought, *Iſland cryſtal*; though properly it is no cryſtal at all, but a fine pellucid ſpar, called by Dr. Hill from its ſhape parallellopipedum. See ISLAND-*Cryſtal*.

This cryſtal is met with in other places beſide Iſland, but not ſo plentifully. It is there found in great abundance all over the country, but is particularly plentiful in a mountain, not far from the bay of Roezfiord, where the fineſt and moſt pellucid pieces are found on digging. The mountain lies in 65 degrees latitude, and has its whole outſide made up of it; but, though this makes a very bright and glittering appearance, it is not ſo fine as that which lies at a little depth, and is met with on opening the ſurface. This is generally taken up out of the earth in maſſes of a foot long, and its corners very frequently are terminated in theſe large maſſes, by a ſort of cryſtals, very different in figure and qualities from the reſt of the maſs. The ſtone itſelf is of a parallellopiped figure; but theſe excreſcences are either ſingle pyramids affixed to columns, like common cryſtal or double pyramids, with or without columns between. The ſtone itſelf is ſoft; theſe are hard, and cut glaſs; the ſtone calcines to lime in the fire, theſe run into glaſs; in ſhort, the ſtone itſelf is true ſpar, and theſe are true cryſtal: beſide theſe, there ſometimes grows out of the ends of the larger maſſes a pure and fine abeſtus. This likewiſe is the caſe ſometimes in the ſpar, found about Barege in France, and ſhews how nearly together the formation of bodies wholly different from one another, may happen. The general figure of the ſtone is parallellopiped; or, as ſome expreſs it, rhomboide; and it retains this not only while whole, but alſo when broken to pieces. Every fragment it naturally falls into, though ever ſo ſmall, being truly of that ſhape. But it is remarkable, that in ſome places of this mountain, the ſame ſort of matter is found in form of triangular pyramids, all which have the ſame property of the double refraction with the parallellopipeds of the ſame ſubſtance; ſo that the original error of ſuppoſing its qualities owing to its ſhape, is refuted by this, as well as by the trials made with other pellucid bodies of the ſame figure, which do not ſhew this remarkable property. *Bartholine* de Cryſtal-Iſland. Phil. Tranſ. N° 67.

The iſland cryſtal is electrical, and when rubbed will draw up ſtraws, feathers, and other light ſubſtances, in the ſame manner that amber does. It is not ſo hard as to endure poliſhing. The ſides, however, are of an extreamly fine natural poliſh, which is moſt perfectly ſeen on breaking a thinner piece nimbly between the fingers: for where a larger maſs is ſtruck with a hammer, the percuſſion has not the ſame effect upon every part, nor is reſiſted equally every where; and therefore the broken ſurfaces have often ſome of the plates, or thin laminæ, of which they conſiſt, raiſed up, and become ſcabrous and rough by that means. The whole body is rather clear than bright: it is of the colour of limpid water; but that colour, when it has been wetted, and dried again, becomes very much duller; and hence, it is, that the outer ſurfaces of the pieces, which lie on the outſide of the mountain, are uſually very dark and dull in compariſon of the others that it ſhews when broken; the rains and ſnows often wetting and drying again upon it. When the ſurface is bright, there often appears the figure of a rainbow, with all the colours on it. The angles of the regular pieces are not pointed alike; all the flat ſides being obliquely inclined to one another. The oppoſite plains are always parallel in this cryſtaline priſm. Two of the plain angles are always acute, and the other two are always obtuſe, and never any of them is equal to the collateral angles of the inclinations. The objects ſeen through it appear ſometimes, and in certain poſitions of the priſm, double; and, the diſtance between the two images of the object, is always greater or leſs according to the largeneſs or ſmallneſs of the priſm, inſomuch, that in thin pieces of it, the difference of the double image almoſt vaniſhes; and it has been hence ſaid, by ſome, that only thick maſſes of this ſtone had the property. The object appearing double, both images appear with a fainter colour, and ſometimes one part of the ſame ſpecies is obſcurer than another; and, to an attentive eye, one of theſe images will always appear higher than the other.

In a certain poſition of the ſtone the image of the object ſeen through it appears only ſingle, as through any other tranſparent body; and there is, on the contrary, a particular poſition, in which it appears ſix-fold. If any of the obtuſe angles of this priſm be divided by a line into two parts, and the viſual rays paſs from the eye to the object through that line or its parallel; both images of the object will meet in one, either in that line, or in one parallel to it.

Whereas objects ſeen through diaphanous bodies, are wont to remain in the ſame place, in whatever manner the tranſparent body is moved, nor does the image on the ſurface move, unleſs the object itſelf be moved; in this particular pellucid body,

one

one of these images is moveable, but the other is all the while fixed. This is the natural and obvious method in the examining the properties of the stone: but there is a way to render the moveable object fixed, and the fixed one moveable; or to render both the one and the other moveable at the same time. The moveable image, in the common way of observing, does not move about at random, but always in a regular manner about the fixed object, and while it turns about this, it never describes a perfect circle, but only in one case. The common laws of dioptricks, teach us, that a diaphanous body having only one surface, sends from one object but one image refracted to the eye, and having more surfaces than one, it represents one image of the object in each; and, as in this island crystal, when we look only upon one surface we have two images, it is evident, that there must be something peculiar in the nature and internal structure of the body itself to occasion it. The whole masses of this stone are wonderfully composed of plates, or laminæ, extreamly thin, laid evenly and regularly on one another; and forming, in a manner, scarce conceivable, both the horizontal and the perpendicular surfaces. Each of these plates is composed of a vast number of small parallellopiped figures, arranged in a neat and orderly manner together; and each of these minute parallellopipeds is again composed of plates composed of other parallellopipeds, and so on as far as microscopes can trace them. There is therefore something singular in the structure of this body, which may very well give it the property of refracting differently from the other pellucid stones; and, it is observable, that all the spars of this massy kind, as well as some of the pyramidal ones, have the same property; and that, in the same degree, in proportion to their bigness, whenever they are sufficiently pellucid. The vast masses of white spar which are found in the lead mines of Derbyshire, though they are not externally of the parallellopiped figure of the island crystal, nor have any thing of its brightness or transparence in the general lump; yet, when they are broken, they separate into rhomboidal fragments, and some of these are found to be tolerably pellucid: all those which are so have the property of the island crystal; and being laid upon paper, where a black line is drawn, they all shew that line double in the same manner as the real island crystal does. Bartholine has two hypotheses for the explication of the various refractions of this stone, not so much founded on reasonings as on experience: the one is, that there are some lines, by which the rays pass through the body of the stone unrefracted, which lines, though they have been held to be perpendicular in the diaphanous bodies, commonly known, yet it does not appear necessary, that they should always be supposed such; since they may, perhaps, in some cases, be much otherwise: the other is, that it may be supposed, that half the light or appearance diffused from the object, is refracted, according to the usual laws of refraction; but the other half, according to the unusual refraction; or which is all one, that the usual and unusual refraction, have the same power to refract the rays of the object. *Barthol.* de Crystal Island. See the article PARALLELLOPIPEDIUM.

DISEASE (*Cycl.*)—The colder the country, in general, the fewer and the less violent are the *Diseases*. Scheffer tells us, that the Laplanders know no such thing as the plague or fevers of the burning kind, nor are subject to half the *distempers* we are. They are robust and strong, and live to eighty, ninety, and many of them to more than a hundred years; and, at this great age, they are not feeble and decrepid, as with us; but a man of ninety is able to work or travel as well as a man of sixty with us. They are subject, however, to some diseases more than other nations: thus they have often *distempers* of the eyes, which is owing to their living in smoak, or being blinded by the snow. Pleurisies and inflammations of the lungs are also very frequent among them; and the small-pox often rages with great violence. They have one general remedy against these, and all other internal diseases: this is the root of that sort of moss, as Scheffer expresses it, which they call jerth. They make a decoction of this root in the whey of rain-deer milk, and drink very large doses of it warm, to keep up a breathing sweat; if they cannot get this, they use the stalks of angelica boiled in the same manner; they have not so great an opinion of this as of the other remedy; but the keeping in a sweat, and drinking plentifully of diluting liquors, may go a great way in the cure of their diseases, whether either the one, or the other of the drugs, have any virtue or not. They cure pleurisies, by this method, in a very few days; and get so well through the small-pox with it, that very few die of it.

It has been always observed, that people of particular places were peculiarly subject to particular *Diseases*, which are owing to their manner of living, or to the air, and effluvia of the earth and waters. Hoffman has made some curious observations on diseases of this kind. He observes, that swellings of the throat have always been common to the inhabitants of mountainous countries: and the old Roman authors say, Who wonders at a swelled throat in the Alps? The people of Switzerland, Carinthia, Styria, the Hartz-forest, Transylvania, and the inhabitants of Cronstradt, he observes are all subject to this disease from the same cause; and, it seems, that these strumous swellings are owing to the water which they drink, and which in mountainous places is usually very highly impregnated with sparry or stony particles. The French are peculiarly troubled with fevers, with worms, and with hydroceles and sarcoceles; and all these disorders seem to be owing originally to their eating very large quantities of chesnuts. The people of our own nation are peculiarly afflicted with hoarsenesses, catarrhs, coughs, dysenteries, consumptions; and the women with the fluor albus, or whites; and children, with a *Disease* scarce known elsewhere, which we call the rickets. In different parts of Italy different *Diseases* reign. At Naples the venereal *Disease* is more common than in any other part of the world. At Venice people are peculiarly subject to the bleeding piles. At Rome tertian agues and lethargic distempers are most common. In Tuscany, the epilepsy, or falling sickness. And in Apulia they are most subject to burning fevers, pleurisies, and to that sort of madness which is attributed to the bite of the tarantula, and which, it is said, is only to be cured by music.

In Spain apoplexies are common, as also melancholy hypocondriacal complaints and bleeding piles. The Dutch are peculiarly subject to the scurvy, and to the stone in the kidneys. Denmark, Norway, Sweden, Pomerania, and Livonia, are all terribly afflicted with the scurvy; and, it is remarkable, that in Denmark, Sweden, and Norway, fevers are very common; but in Island, Lapland and Finland, there is scarce ever such a *Disease* met with; tho' peripneumonies be very common in these places, as also diseases of the eyes and violent pains of the head. The Russians and Tartars are afflicted with ulcers, made by the cold, of the nature of what we call chilblains, but greatly worse; and in Poland and Lithuania there reigns a peculiar *Disease*, called the plica polonica; so terribly painful, and offensive, that scarce any thing can be thought of worse.

The people of Hungary are very subject to the gout and rheumatism: they are more infested also with lice and fleas than any other people in the world, and they have a peculiar *Disease* which they call cremor.

The Germans, in different parts of the Empire, are subject to different reigning *Diseases*. In Westphalia they are peculiarly troubled with peripneumonies and the itch. In Silesia, Franconia, Austria, and other places thereabout, they are very liable to fevers of the burning kind, to bleedings at the nose, and other hæmorrhages; and to the gout, inflammations, and consumptions. In Misnia they have purple fevers; and the children are peculiarly infested with worms. In Greece, Macedonia, and Thrace, there are very few *Diseases*; but what they have, are principally burning fevers and phrensies. At Constantinople the plague always rages; and, in the West-Indian islands, malignant fevers, and the most terrible colics.

DISEASES *feigned*—The cheat of feigning *Diseases*, for idleness, or profit sake, or for other occasional purposes, has been too common in all ages, and is too difficult to be discovered in all cases; though, in many, there are ways of coming at the truth. We have had a very late instance of a young lady, who puzzled several of our best physicians, to account for the nature of a *Disease*, which showed itself in a singular kind of excoriations; and the secret perhaps had never been discovered, had not a bottle of aquafortis been accidentally found in her chamber; the touching the arms, &c. with which had occasioned all the appearances, which some strange fault in the juices had been before accused of.

Dissimulation, in regard to *Diseases*, may be reduced to three kinds: in the first, the sickness is pretended by words only, and really is not; of this nature are the pretended head-ach, colic, and the like; which, as the patient can only know of, the physician may always be deceived by his words. In the second, there are not only words for testimonies of the sickness, but there appear signs and marks of it on the body, which yet are only counterfeited to serve certain purposes. Scabbyness, leprosy, and even the exulceration of the lungs may be thus counterfeited; the last by a pretended spitting of blood. Gravidation is often pretended also. Our beggars often contrive the means of these to excite compassion. In the third kind of dissimulation of *Diseases*, we are to include the concealing a *Disease*, which really exists, instead of the owning one which does not.

The great occasion of this kind of dissimulation is the pox, and the concealing of this often proves the ruin of the patient's constitution, or his reason; a miserable death or madness being too often the consequences.

In the discovery of these deceits, on which the credit of the physician often depends, it is not mere medical knowledge that will succeed, but there must be added to it a sagacity in exploring all circumstances and outward accidents, and especially those things which relate to the genius, temper and state of the person suspected. The Dæmoniacs, of former ages, exorcised by the priests, who wanted to propagate the credit of their religion, or their own sanctity, have generally been cheats of this kind, and might have been discovered by any

who

who had talents and opportunities for the proper examinations. Sylvaticus, an Italian author, has given an excellent ſet of rules for the diſcovery of theſe frauds, and all others of pretended ſickneſſes, to which we refer the curious reader.

DISEASES *of infants*. See INFANTS.

Peſtilential DISEASES. See PESTILENTIAL.

Soporous DISEASES. See SOPOROUS.

DISEASES *of Trees*. See DISTEMPERATURE.

DIS-ERGOT, in the manege. See ERGOT.

DISGORGE, in the manege, is uſed for diſcuſſing or diſperſing an inflammation or ſwelling: thus if a horſe's legs are gorged or ſwelled, we ſay he muſt be walked out to *diſgorge* them.

DISGUISE.—Perſons doing unlawful acts in *diſguiſe* are by our ſtatutes ſometimes ſubjected to great penalties, and even declared felons. Thus perſons convicted of hunting in *diſguiſe* in foreſts, parks, or warrens, or of unlawful hunting in the night, are to ſuffer as felons [a]. But the principal act of parliament in this reſpect is that commonly called the Black-Act, which makes appearing *diſguiſed* and armed in a foreſt, or grounds incloſed, or hunting deer, or robbing a warren, or taking away fiſh, felony [b]. The concealers of ſuch offenders are alſo made guilty of felony [c]. There are alſo rewards of 50 *l.* appointed for thoſe who ſhall be wounded in apprehending the offenders; and if a man be killed in ſo doing, the reward goes to his executors or adminiſtrators [d]. Proſecutions on this act may be commenced within three years, and the trial may be in any county [e]. [[a] Stat. 1 Hen. 7. c. 7. [b] See the Stat. 9 Geo. 1. c. 22. §. 1. [c] Ib. §. 5. [d] Ib. §. 12. [e] Ib. §. 13, 14.]

DISH, (*Cycl.*) in mining, is a trough made of wood, about 28 inches long, 4 inches deep, and 6 inches wide; by which all miners meaſure their ore. If any be taken ſelling their ore, not firſt meaſuring it by the bar-maſter's *Diſh*, and paying the king's duties, the ſeller forfeits his ore, and the buyer forfeits for every ſuch offence forty ſhillings to the lord of the field, or farmer. *Houghton*'s compl. miner, p. 15, and in the explan. of the terms.

DISLOCATION (*Cycl.*) — We have an inſtrument of Mr. Freke's invention for the reduction of *diſlocated* ſhoulders, deſcribed in the Philoſophical Tranſactions, N° 470.

DISPART, in gunnery, is uſed for the ſetting a mark on the muzzle-ring of a piece of ordnance, or thereabouts; ſo that a ſight-line taken upon the top of the baſe-ring againſt the touch-hole, by the mark ſet on or near the muzzle, may be parallel to the axis of the concave cylinder. The common way of doing which, is, to take the two diameters of the baſe-ring, and of the place where the *Diſpart* is to ſtand, and divide the difference between them into two equal parts, one of which will be the length of the *Diſpart*, which is ſet on the gun with wax or pitch, or faſtened there with a piece of twine or marlin: but an inſtrument may be made to do it to all poſſible nicety.

DISPERSION (*Cycl.*)—DISPERSION *of Inflammations*, in medicine. The grand intention in the treatment of all inflammations ſhould be to open ſuch ſmall veſſels as are obſtructed, and to reſtore the blood to its natural conſiſtence and free circulation; and this is commonly term'd in ſurgery the reſolution or *diſperſion* of tumors. When in caſes of this kind the inflammatory ſigns are but gentle, it is always beſt immediately to ſet about the diſperſing the tumor. If the cauſe of the inflammation is external and obvious, as thorns, ſplinters, bullets, or any other foreign body ſtuck in the part, this is to be immediately removed, if that can be done with ſafety. So when the inflammation proceeds from too tight a bandage in wounds, *&c.* or from a luxation or fracture, the firſt thing to be done is to looſen the bandage, to ſet the fracture, or to reduce the luxation. It is after this very proper to open a vein in the arm, and after that to give a brisk but not heating purge; and if the ſymptoms do not abate, this method is to be repeated at proper intervals. Internal medicines which are watery, diluting, cooling, and attenuating, do great ſervice on theſe occaſions.

A proper regimen is alſo to be obſerved in regard to diet: all aliments that are of difficult digeſtion, all pickled or ſalted meats, and all ſpices and fermented liquors, with every thing elſe that may tend to heat and inflame the blood, are to be carefully avoided. The moſt proper aliments are broths, and drinks made of pearl barley, oats, or flower. Decoctions of all the cooling plants, as ſorrel, endive, *&c.* mixed with ſmall quantities of lemon juice, or any other of the vegetable acids; and when the inflammation is great, a little nitre ſhould be added to theſe drinks. Nor is there leſs care required about the external applications; for though ſome to appeaſe inflammations uſe only heating medicines, and others only cooling ones, yet either ſort if applied at random, and in all caſes, may prove pernicious, for one medicine can never in theſe caſes ſerve for all conſtitutions. To perſons of a hot temperament the cooling external remedies are in theſe caſes to be applied. Of this kind are the litharge vinegar applied warm on linnen rags folded together, or hot vinegar mixed with red lead, or with bole armoniac, and applied in the ſame manner; or oxycrate, or vinegar and water mixed in equal quantities; or of any of theſe liquors may be taken ſix ounces, and to this an ounce of common ſalt, and two ounces of either nitre or ſal armoniac being added, and with this mixture linnen rags many times doubled, and applied wet to the part, will be of great ſervice. In the night time alſo, when theſe applications cannot ſo conveniently be renewed, a plaſter of the red lead, or other cooling one, may be of no ſmall uſe. This is the proper method in hot conſtitutions; but, on the contrary, in cold and phlegmatic ones, ſpirit of wine alone, or camphorated ſpirit, or either of theſe with an admixture of a ſmall quantity of Venice treacle, are very ſucceſsful remedies for the *Diſperſion* of inflammations, being applied on linnen cloths doubled in the ſame manner; ſo alſo is ſpirit of wine mixed with lime-water, or even lime-water alone, or Hungary-water with lapis calaminaris, ceruſs, ſal armoniac, or bole armenic, or a mixture of a pint of rectified ſpirit of wine with two ounces of Caſtile ſoap. This laſt applied warm is hardly ſecond to any medicine in theſe intentions. Decoctions of wormwood, mint, ſavin, ſouthernwood, and other ſuch herbs made with ſalt-water or lime-water, are alſo very good external applications; and to theſe may be added when neceſſary, either camphorated ſpirit of wine, or Caſtile ſoap: and not only the decoction of theſe herbs, but the herbs themſelves when boiled may be applied as a cataplaſm, with great ſucceſs. *Heiſter*'s Surgery, p. 181.

DISPROVING, in rhetoric. See REFUTATION.

DISSIPATION (*Cycl.*) — *Circle of* DISSIPATION, in optics, is uſed for that circular ſpace upon the retina, which is taken up by one of the extreme pencils of rays iſſuing from an object.

To underſtand which, it is to be obſerved, that when the diſtance of an object from the eye is too ſmall, or too great, for perfect or diſtinct viſion, the rays of each pencil iſſuing from the object cannot be united at a point on the retina, but beyond it, or before they arrive at the retina; conſequently the rays of each pencil will occupy a circular ſpace upon the retina; and this circle is called the circle of *Diſſipation*, becauſe the rays of a pencil, inſtead of being collected into a central point, are diſſipated all over this circle.

The conſideration of the circles of *Diſſipation* formed by the rays coming from the extremities of objects, is of uſe to account for ſeveral curious phænomena of viſion. See the article MOON, and Dr. Jurin's *Eſſay on diſtinct and indiſtinct viſion*, at the end of Dr. Smith's Optics.

Radius of DISSIPATION, the radius of the circle of *Diſſipation*.

DISTANCE (*Cycl.*)—*Diſtance*, according to an ingenious author, cannot of itſelf and immediately be ſeen. For *Diſtance* being a line directed endwiſe to the eye, it projects only one point in the fund of the eye, which point remains invariably the ſame, whether the *Diſtance* be longer or ſhorter. Dr. *Berkeley*, Eſſay on Viſion.

A late eminent mathematician [a] obſerves, that the *Diſtance* here ſpoken of, is *Diſtance* from the eye; and that what is ſaid of it muſt not be applied to *Diſtance* in general. The apparent *Diſtance* of two ſtars is capable of the ſame variations as any other quantity or magnitude. Viſible magnitudes conſiſt of parts into which they may be reſolved as well as tangible magnitudes, and the proportions of the former may be aſſigned as well as thoſe of the latter; ſo that it is going too far to tell us, that viſible magnitudes are no more to be accounted the object of geometry than words; and that the ideas of ſpace, outneſs, and things placed at a diſtance, are not, ſtrictly ſpeaking, the object of ſight; and are not otherwiſe perceived by the eye than by the ear. [a] Mr. *Maclaurin* in his account of Sir Iſaac Newton's diſcoveries, p. 225.

Apparent DISTANCE. See the article APPARENT.

DISTEMPER, among phyſicians. See DISEASE.

DISTEMPERATURES *of Trees*.—Some of theſe are in the tree itſelf, and others in the ſoil and other things about it. Of the laſt kind are weeds, which are of the utmoſt ill conſequence to all ſorts of trees while young, and ſhould be pulled up by hand after rain: if they are too ſtrong rooted for this, they muſt be dug up; and this will have a double advantage, as the ſtirring the earth about their roots will do the trees very great good. When the trees are grown to any tolerable height, they require no care about weeds, for they kill them with their own dropings. Suckers are another *Diſtemperature* of trees ariſing from the tree itſelf: they muſt be pulled off, or cut up cloſe to the place where they come out, opening the earth to come at them there. Over-much wet often is a very great prejudice to trees, and eſpecially to thoſe kinds which naturally love a dry ſoil. This is to be remedied by cutting drains: and if a drip fret the body of the tree by the head (which will certainly decay it) the place muſt be firſt cut ſmooth, and then ſome loam or clay, mixed well with horſe-dung, is to be applied to the place, which will defend it from miſchief till a new bark is formed over it. All wounds made in trees in winter are much harder to cure than thoſe made in ſummer; and for theſe it is proper to add ſome tallow to the mixture of loam and dung.

When trees are bark-bound, which is eaſily ſeen by the unnatural tightneſs and ſtraining of the bark over them, it is to be remedied by cutting through the bark with a knife from the top to the bottom of the tree. This may ſeem a dangerous remedy

remedy to thoſe who have not experienced it, but it never was found to do any injury to trees. It is to be done in February or March; and if the wound gape very much, it may be filled up with cow-dung, which will defend the tree from injury till it heals. The digging about the root of the tree is a very good practice alſo on this occaſion, and the cutting off the dead or withered branches.

The grubs of beetles, called teredines and coſſi, which get between the bark and the tree, do great miſchief: if the places can be found out where they lie, it is proper to pierce into the bark with a pointed inſtrument upon them, and then to open a ſmall hole below to let out whatever moiſture may be there. When trees of the fruit kind are burnt up and bliſter'd on the bark with hot and dry ſeaſons, and this is followed by a vaſt number of the pucerons or tree-lice, which feed on the juices, ſome recommend the boring a large hole in the main root, and pouring in ſome brandy, then ſtopping up the hole with a pin of the ſame wood. The tree ſuffers nothing by this, but the juices are ſo much altered for the preſent by it, that theſe animals do not like them, and conſequently quit their habitation. *Mortimer*'s Husbandry, *&c.* p. 70. See the article PUCERON.

If a tree is by any accident barked or ſtripped all round, ſo that it cannot grow any longer, the proper method is to cut it off juſt above ſome principal branch; the ſtump muſt be cut off ſlanting and covered with clay, and the branch will ſoon become the body of a tree in the place of the other: the place where the ſtump is cut off being covered with a bark in the manner of a tree that is graſted.

Deer and hares, as alſo rabbits, are apt to bark trees, and do them great miſchief. The defences againſt deer are by paling them round, or painting the lower part of the tree, but the firſt is much the better method. The hares and rabbits may be kept off by tying bands of ſtraw round the foot of every tree as far as they can reach. Evelyn recommends the rubbing them over with human dung made into a ſoft paſte with urine, ſo that it may be laid on with a bruſh; but this is attended with great trouble, as it muſt be renewed after every hard rain. Some uſe tar and lime mixed together, but this always damages the tree more than theſe creatures would have done; and in general ſtraw-bands, where any thing is neceſſary, do beſt. Id. ibid. See DISEASES *of Plants*, *Cycl.*

DISTENSION (*Cycl.*)—DISTENSIO, Διαταϛις, in the antient muſic, was uſed for the differences of ſounds with relation to acute and grave. *Wallis* Append. ad Ptolem. Harm. p. 154. Nature in this reſpect, ſtrictly ſpeaking, aſſigns no limits. But, with regard to our uſe, the antient muſicians held, that the nature of what ſounded, and alſo of what was to judge, that is, the human ear, was to be conſidered: for, neither the human voice, nor even any inſtrument, can give intervals or *diſtenſions* immenſely great or ſmall, nor could the ear judge of ſuch. Ariſtoxenes fixes the leaſt interval or *diſtenſion* in practice, to the dieſis enharmonica. As to the greateſt, he thinks it does not exceed two octaves, and a fourth, or a fifth, if we conſider any human voice; or three octaves, if we conſider one and the ſame inſtrument. He does not deny that the extent of the voice, conſidered in differenr ſubjects, as in men and children, may go even beyond four octaves. *Ariſtoxen.* p. 21. edit. Meibom.

DISTICHOUS *Stalk*, among botaniſts. See the article STALK.

DISTILLATION (*Cycl.*)—*Combinatory* DISTILLATION, a term introduced into uſe by Dr. Shaw, in his Eſſay on *Diſtillation*, to expreſs that ſort of rectification of diſtilled ſpirits which is done with additions, and which he otherwiſe calls improper rectification, by way of diſtinction from that proper rectification, which is only the method of reducing a ſpirit to its utmoſt degree of purity and perfection.

In the *Combinatory Diſtillation* many ingredients are added in order to rectify the ſpirit, as the diſtillers expreſs it; and ſome parts of theſe actually come over and mix themſelves along with the ſpirit ſo intimately, as not to be ſeparable again without great difficulty. This is done with a deſign to alter, improve, or aboliſh the natural flavour of the ſpirit, but inſtead of rectifying it, they only obſcure and pervert its true qualities. In the buſineſs of rectification, properly ſo called, of the malt ſpirit, all that is neceſſary is the rediſtilling the low wines procured from the waſh; the again diſtilling over the ſpirit thus obtained, and called proof ſpirit, into a totally inflammable liquor called alcohol. This is done by the common proceſſes, only taking care not to increaſe the fire by ſudden ſpurts, ſo as to raiſe the oil with the ſpirit, which if once mixed will not be eaſily ſeparated again, and ſcarce ever perfectly, whatever care is uſed. *Shaw*'s Eſſay on Diſtillery.

The methods of combinatory rectification, on the other hand, are very numerous, every diſtiller having his peculiar noſtrum about it. Malt ſpirit is the general ſubject of this proceſs, and the means uſed to rectify it on this plan may be reduced to three heads: 1. That by fixed alkaline ſalts alone. 2. That by fixed alkaline ſalts and acid ſpirits. And, 3. That by ſaline bodies and flavouring additions. The general method is that by fixed alcaline ſalts alone; but it is ſurpriſing to ſee in how careleſs and ſlovenly a manner this is done by the generality of our diſtillers, though we are allowed to excel all other nations in it. The effect of this operation, when carefully performed, is to attenuate and thin the ſpirit, and to keep back a part of its groſs and fœtid oil, and ſo far to alter the part of the oil which comes over, as ſcarce to leave the ſpirit diſtinguiſhable for a malt ſpirit.

This end is greatly promoted by a prudent and ſteady management of the fire, and by leaving out the faints; but this is a thing our diſtillers never attend to, they hurry over the operation, working the ſtill in its full force, and by this means raiſe and carry over the oil; though the whole buſineſs of the proceſs is to keep it back; and they even ſuffer the fulſome bitter oil, made into a kind of liquid ſoap with the ſalt in this proceſs, to run among the ſpirit with the faints; by this the whole intent of the proceſs is fruſtrated, and the ſpirit rendered much harder to clean than it was before.

This operation is uſually performed upon proof ſpirit, and the quantity allowed is from eight to fourteen pounds of ſalt of tartar, fixed nitre, pot-aſh, or more commonly calcined tartar to the piece. The tartar being only roaſted to a blackneſs in this laſt proceſs, is ſold under the abſurd notion of a vinous ſalt, and the dealers will often praiſe the vinoſity of their ſpirit, becauſe diſtilled from this ſalt; but the truth is, that this ſalt never fails to give, inſtead of a vinoſity, a ſaponaceous, urinous, or lixivial taſte and ſmell. This is the great misfortune that attends the method of rectifying by means of fixed ſalt, for they all of them become volatile in part during the operation; and this volatile portion paſſes over the helm with the ſpirit, and impregnates it, uniting itſelf alſo with that portion of oil yet retained in the ſpirit, and much more firmly combining it and the ſpirit together than they were before; ſo that in reality the ſpirit thus rectified is no other than an alkaline or tartariſed ſpirit, as the chemiſts call it; a thing extremely different from a true vinous ſpirit.

This method therefore, though it were practiſed to the utmoſt perfection, would never do what was intended by it, but would alter inſtead of rectifying the ſpirit. Hence there appears the neceſſity of ſome acid to deaden the force of the alkali thus uſed in the rectification. The neceſſity of this gave occaſion to the method of mixing acids and alkalies together for theſe purpoſes. The acids uſed by our diſtillers on this occaſion are thoſe of the mineral kingdom by reaſon of their cheapneſs, and the moſt common in uſe among them are oil of vitriol, ſpirit of nitre, oil of ſulphur, and the like. The moſt celebrated rectifiers in the malt way have got their reputation by the uſe of theſe acids. There is ſome choice however to be made of the ſpirits according to the greater or leſſer foulneſs and need of rectification, and they muſt not only be well proportioned, but carefully introduced, and regularly mixed; and indeed without ſome skill and judgment in the management of theſe corroſives, no diſtiller ought to attempt to meddle with them.

Theſe ſtrong and violent acids at beſt are not ſo well adapted to the work as the milder ones, particularly the ſulphureous ſpirit of vitriol, which comes over in the rectification of the oil; to this may be added the common ſpiritus nitri dulcis, and Mr. Boyle's acid ſpirit of wine well prepared.

Some of our rectifiers inſtead of the fixed ſalts uſe quick-lime, which cleanſes and dephlegmates conſiderably: but this method requires the aſſiſtance of acids alſo afterwards, to take off not only the alkaline diſpoſition, but alſo the ſtinking flavour it leaves behind it. Some alſo uſe chalk, virgin earth calcined, and burnt animals bones. Theſe are of conſiderable uſe in the rectifying brandy without rendering the ſpirit any more unfit for the purpoſe of the compounders than before, or requiring much acid afterwards.

The great art of uſing the flavouring ingredients in rectification is the proper admixture of ſalts in the operation, for without theſe the flavours added by this means do very little. The ſalts uſed on this occaſion are either the fixed alkalies, as pot-aſh and calcined tartar, or decrepitated common ſalt, or calcined vitriol, alum, or ſandiver. The flavouring ingredient is to be applied afterwards, and the whole quantity of the ſpirit either drawn over again, or not, as the occaſion and nature of the addition requires. But theſe ſaline bodies perform ſo very little, that the ſpirit is uſually left impregnated with a flavour from its own oil, which is but badly hidden, or overpowered by the other ingredients. The moſt common flavourers, as they call them, are theſe, mace, orrice root, parſnip, artichoak, rhodium, raiſin ſtalks, damask roſes, wine lees, rape or grape husks, and the oil of wine. The laſt of theſe is infinitely preferable to all the others, but is not ſo well known. Theſe and the like ingredients judiciouſly mixed, will, when the ſpirit is very well purified firſt, give the flavour of foreign brandies with ſome tolerable exactneſs; but if this is not attained, their flavour will be loſt in the original one, and the general taſte reſulting from the whole will be like nothing at all. The ultimate perfection aimed at in all the proceſſes of *combinatory Diſtillation*, is the depurating the Engliſh malt ſpirit at one operation, ſo as to render it taſteleſs and inodorous, and yet vinous; or elſe to make it reſemble the French brandy, arrack, or ſome other low-flavoured vinous ſpirits.

This is certainly practicable, though not usually practised to the perfection that it might be: the principal thing to be endeavoured after, is the obtaining a tasteless spirit, capable of receiving any impression, and then the business of flavouring is easy. The method of rectifying, by fixed alkaline salts, is capable of great improvement, as by steeping the spirit first brought near to the state of alcohol, upon a well dried salt of tartar, or any other cheaper, but pure fixed alkali; by this means it will be almost totally freed of its oil without volatilizing much of the salt, as it does in the way of distillation; by this means a weak tincture of salt of tartar may be procured, and an acid added to this, to take off the effects of the alkali in the spirit, the whole is then to be distilled; and the fire being well managed, a very clean spirit will be thus procured at one operation, such as can no way else be obtained at once.

The use of the compound neutral salts in rectification seems not yet to be sufficiently known; what is meant by these salts is a fixed alkaline salt saturated with an acid one. Such a salt has indeed been expected from the caput mortuum, or white saline cake, remaining upon the *Distillation* of the spirit of nitre with oil of vitriol, but it proves too hard, stony, and insoluble, to be of any great use on this occasion: a much better effect may be expected from soluble tartar, carefully prepared, and properly used; though even this is apt to render the spirit a little saponaceous. Some compound neutral salts have been made however upon this foundation, that would rectify common malt spirit from proof at a single operation, much better than all the other more perplexed and tedious methods in use. A prudent use of fine dry sugar may also be of some service, as it readily unites with the essential oil, and detains and fixes it, without imparting any urinous or other nauseous flavour to the spirit rectified upon it; another hint to this purpose, which may be made to turn to very good account, is that given by the ingenious method invented by Dr. Cox, of taking all the oil out of the volatile salts, by first bringing them to a neutral state with spirit of salt, and then subliming them with salt of tartar, which does the business to perfection. In the case of spirits the acid may be varied, and virgin earth, chalk, calcined flints, or the like absorbents used in the stead of salt of tartar, and yet the general effect will be the same. *Shaw*'s Essay on Distillery.

Brewing for DISTILLATION. *See* BREWING.

DISTILLED *juice of Tar.* See TAR-*water*.

DISTILLED *waters.* The waters *distilled* from plants and other medicinal things, may receive something from the vessels in which they are *distilled*, which may in some degree alter their properties. Even water alone *distilled* in glass vessels, and in those of metal, differs so much, that these two distillations being mixed, will render one another turbid. The florentine academicians have taken this change of waters under their consideration among the many other minutiæ, of natural and experimental philosophy omitted by others. They found that common water *distilled* in leaden vessels would render all other waters turbid, on mixing with it; whether it were spring, fountain, river, or well water, except alone the water of the conduit at Pisa: an experiment that proved a quality in that water, different from all others, though never before suspected in it. The experiment being repeated at various seasons afterwards, the water of this conduit was sometimes found to grow turbid also, but this was at such times as other waters, from rain, &c. had blended themselves with the genuine water of the spring. Waters *distilled* in glass vessels, and mixed with waters *distilled* in lead vessels, were supposed by the Florentines indeed not to render one another turbid; but, by the observations often made by the curious Redi, it proved that they did. This author assures us, that having *distilled* the parietaria in a glass cucurbit, and shifted the receiver fourteen times, and mixed all these shifted waters with rose water *distilled* in lead, they always became turbid, though he repeated it after several months: but after distilling in balneo, the remainder of these fourteen shiftings, in a silver vessel, with a glass head, changing the receiver eight times; he found, indeed, the water that was gathered in the eighth or last receiver untroubled: though he mixed with it several shiftings of water *distilled* in lead, but all the other seven shiftings grew still turbid when thus mixed. *Redi*'s Observat.

Common water *distilled* in gold, silver or glass, with a glass head, and kept in glass, remains always clear; but, in crystal of Pisa, it grows turbid in a few hours; then milky, and in a few days yellow, and after all this bitter; whereas in crystal of Rome or Venice, the same water does not grow turbid till after two or three days, and never becomes yellow or bitter in it; and in crystal of Paris it will scarce grow turbid, but after a very considerable time. The various materials used in the making these several kinds of crystal, at the glass-houses of these different places, and the various manner of working them are the occasion of this great difference in them; and on these principles we may find a new and more than ordinary way of judging of the goodness of glasses which seem equal to one another.

DISTILLED *waters* of laurel leaves. See LAUROCERASUS.

DISTILLERY. The business of fermentation is one of the great preparations to the *Distillery*. What we usually call vinous fermentation in particular, is the kind it is concerned principally in. By this we usually understand that physical action, or intestine commotion of the parts of a vegetable juice tincture, or solution, which renders them fit to yield an inflammable spirit on distillation.

This fermentation in the hands of the distiller differs from the common one, that is used in the making of potable vinous liquors, as being much more violent, tumultuary, active, and combinatory than that. A large quantity of yeast, or other ferment, is added to the distiller's fermentation: the free air is admitted, and every thing is contrived to quicken the operation, so that it is sometimes finished in two or three days. This great dispatch, however necessary to the large dealer, has its inconveniencies attending it; for the spirit is by this means always fouler, more gross, and really terrestrial, than it would have been if the liquor had undergone a proper fermentation in a slower manner. It also suffers a diminution in its quantity, from the violent and tumultuary admission, conflict, and agitation of the free air, both in the body and upon the surface of the liquor, especially if the liquor be not immediately committed to the still as soon as the fermentation is fairly slacked or fully ended. It is a very difficult task to render the business of fermentation at once perfect and advantageous. To ferment, in perfection, necessarily requires length of time, and careful attendance, and close vessels, beside several other articles of nice management, which cannot be expected to be received and practised in the large way, on account of the trouble and expence, unless it could be proved to the distillers, as possibly it some time may, that the quantity of spirit would be so much greater from the same quantity of materials managed thus, than by the common way, that it will more than pay its own expence; to which may be added, the very well known advantage of the spirit thus procured by perfect fermentation, being much finer than that obtained in the common way: till this shall be made out, it may not be amiss to try how much of the more perfect art of vinous fermentation, is profitably practicable by the distiller in the present circumstances of things. The improvements to be made in this affair will principally regard, 1. The preparation or previous disposition of the fermentable liquor. 2. The additions tending to the general, or some particular end. 3. The admission or exclusion of the air. 4. The regulation of the external heat or cold; and 5. A suitable degree of rest at last. When proper regard is had to these particulars, the liquor will have its due course of fermentation, and it will thence become fit to yield a pure and copious inflammable spirit by distillation. The tincture, solution, or liquor intended for fermentation, for the still, should be considerably thin and aqueous. That sort of richness that there is in the ten shilling small beer, is the utmost that ought to be allowed to it. This property not only fits it to ferment readily, but also to yield a larger quantity in proportion of a pure vinous spirit, than it would do if it were more rich and clammy: the gross, foul, viscid, and earthy particles of such glutinous liquors, being after fermentation apt to rise up with the boiling heat which must necessarily be employed to raise the spirit; and the spirit thus of course comes over foul and fetid. There is also another advantage attending the thinness of this liquor, which is, that it will sooner become fine by standing before fermentation; whence it may be commodiously drawn off from its fæces or bottom, which must always in case of corn, malt, or any other mealy substance, be kept out where the purity of the spirit is consulted. A certain degree of warmth seems necessary in all the northern climates, to all sorts of artificial liquors, intended for immediate fermentation, especially in winter; but the natural juices of vegetables, which have never been inspissated, as that of grapes, and other fruits, when fully ripened, will usually ferment, as soon as they are expressed without any external assistance. But, as a certain degree of inspissation, prevents all tendency to fermentation in all vegetable juices, though otherwise strongly disposed to ferment; so a long continuance, or an increase of the inspissating heat, especially if it acts immediately through a metalline or solid body upon the juice, will destroy its fermenting property; and it will do this the more effectually, as the heat employed approaches to that of scorching, or the degree capable of giving an empyreuma. After the same manner, several experiments make it appear that there is a certain degree of heat; the continuance, or least increase of which, proves detrimental or destructive to fermentation; as there is another, which in a wonderful manner encourages and promotes it. These two degrees of heat ought to be carefully noted and settled by the thermometer, or other certain methods, for philosophical and chymical uses; but for common, or all oeconomical occasions, they may be limited to what we call a tepid and fervid heat: a fervid heat is the bane of all vinous fermentation, as a tepid one, or rather an imperceptible warmth is the great promoter of them. In this neutral state therefore, with proper contrivances to preserve and continue it, the liquor is to be put into a suitable vessel for fermentation; at which time if it works not of itself, it must be quickened by addi-

additions; and, in general, by ſuch things are generally called ferments. *Shaw*'s Eſſay on Diſtillery. See the articles FERMENT, SPIRITS, MAKING *up*, LOWERING, *&c.*

Malt DISTILLERY. See MALT *Diſtillery.*

DISTORTION (*Cycl.*)—A terrible malady to the human ſhape, has been very often the mere effect of careleſsneſs and ill habits. Mr. Winſlow, in the memoirs of the academy of ſciences of Paris, gives a very remarkable account, to this purpoſe, of a lady of quality, whom he had known to be perfectly ſtrait for ſeveral years; but who taking afterwards to a ſedentary courſe of life, got a cuſtom of dreſſing herſelf very careleſsly, and of leaning as ſhe ſat, either forwards, or to one or the other ſide. It was not many months before ſhe found it troubleſome and painful to ſtand or ſit upright, and ſoon afterwards ſhe found an inequality in the lower part of the back bone: alarmed at this, ſhe conſulted the gentleman who gave the account. Who, to prevent the increaſe of the malady, ordered the wearing a particular ſort of jumps inſtead of her ſtays, and had a pad applied of proper ſize: but this was ſoon neglected; and the conſequence was, that the back bone, in a little time became more and more crooked, and at length bent itſelf ſideways, in two contrary directions, ſo as to repreſent the figure of the Roman S; and the lady refuſing to take the proper meaſures, loſt a fourth part of her height, and continued for the remainder of her life, not only crooked both from right to left, and from left to right; but ſo oddly folded together, that the firſt of the falſe ribs on one ſide approached very near the creſt of the os ilium on that ſide, and the viſcera of the lower belly became ſtrangely puſhed out of their regular places to the oppoſite ſide; and the ſtomach itſelf was ſo compreſſed, that whatever ſhe ſwallowed, ſeemed to her to fall into two ſeparate cavities. Mem. Acad. Scienc. 1740.

DISTRIBUTION (*Cycl.*)—The ſurplus of an eſtate, or *pur autre vie*, is diſtributable by adminiſtrators. See ADMINISTRATORS, *Cycl.*

DISUNITE, in the manege, is uſed for a horſe that drags his haunches, that gallops falſe, or upon an ill foot. See GALLOP.

DITCH (*Cycl.*)—In marſhes, and other wet land, where there are no hedges, the common fence or incloſure for land is a *Ditch*. They allow theſe *Ditches* ſix foot wide againſt highways that are broad, and againſt commons five foot. But the common *Ditches* about incloſures, dug at the bottom of the bank, on which the quick is raiſed, are three foot wide at the top, one at the bottom, and two foot deep; by this means each ſide has a ſlope, which is of great advantage; for where they neglect this, and dig them perpendicular, they are always waſhing down; beſide, in a narrow bottomed *Ditch*, if cattle get down into it, they cannot ſtand to turn themſelves to crop the quick; but where the *Ditch* is four foot wide, it ſhould be two and a half deep; and where it is five wide, it ſhould be three deep, and ſo in proportion.

DITCH *water* is often uſed as an object for the microſcope, and ſeldom fails to afford a great variety of animalcules.

This water very often appears of a greeniſh, reddiſh, or yellowiſh colour; and this is wholly owing to the multitudes of animals of theſe colours which inhabit it. Theſe animals are uſually of the ſhrimp kind: and Swammerdam, who very accurately examined them, has called them from the branched figures of their horns *pulex aquaticus arboreſcens*. They copulate in May and June; and are often ſo numerous at that ſeaſon, that the whole body of the water they are found in, is ſeen to be of a red, green, or yellow colour, according to the colours of their bodies. The green thin ſcum alſo, ſo frequently ſeen on the ſurface of ſtanding waters in ſummer is no other than a multitude of ſmall animalcules of this or ſome of the other kinds. Dunghill water is not leſs full of animals than that of *Ditches*; but is often found ſo thronged with animalcules, that it ſeems altogether alive; this is ſo very much crowded with theſe creatures, that it is proper to dilute it before they can be diſtinctly viewed, by adding clear water to it. There are uſually in this fluid a ſort of eels, which are extremely active; and beſide theſe, and many other of the common inhabitants of fluids, there is one ſpecies found in this which ſeems peculiar to it; the middle part of theſe is dark, and beſet with hairs, but both ends are tranſparent; their tails are tapering, with a long ſprig at the extremity, and their motion is ſlow and wadling. *Baker*'s microſcope, 87. See PEPPER-*water*.

DITONICUM *Diatonum*. See GENUS.

DITRIHÆDRIA, in natural hiſtory, the name of a genus of ſpars. The word is derived from the Greek δις twice, τρις three, and ἑδρα, a ſide, or plane. The bodies of this genus are ſpars compoſed of twice three planes, being formed of two trigonal pyramids joined baſe to baſe, without the intervention of any intermediate column. Of this genus there are five known ſpecies. 1. One with long and pointed pyramids, found in the mines of Cornwall, and ſome other parts of England. 2. One with long and broad pyramids found looſe in the fiſſures of the alabaſter quarries of Blanckenberg in Germany. 3. One with ſhort and broad pyramids found in the mines of Rammelsberg. 4. One with extreamly broad depreſſed pyramids, found in the alabaſter quarries at Blankenberg, and ſometimes in the mines of Goſſelaer in Saxony. 5. One with ſhort but ſharp pointed pyramids, found very frequently in the mines of the Hartz-foreſt, and ſometimes on Mendip Hills with us. *Hill*'s Hiſt. of Foſſ. p. 218.

DITTANY, in Botany, *&c.* See FRAXINELLA.

DITTANY *of Crete*, *dictamnum creticum*, in medicine, was highly extolled by the antients, as a vulnerary, and antidote againſt venomous bites. They alſo gave it to promote the menſes and aſſiſt delivery. With us it is diſuſed, except in ſome officinal compoſitions.

DIVALE, an Engliſh name uſed by ſome writers, and in ſome counties of England in common expreſſion, for the deadly nightſhade, or ſolanum lethale, a plant with poiſonous berries, looking like black cherries. *Ger.* Emac. Ind. 4.

DIVER, in zoology, the Engliſh name of the *Colymbus*, a genus of water birds; the characters of which are, they have narrow, ſtrait, and ſharp bills, their heads are ſmall, their wings ſhort, their feet placed far backward on the body, and near the tail, and their legs broad and flatted, their claws broad like the nails of ones fingers. They are called *Colymbi*, and in Engliſh *Divers*, from their great expertneſs in diving, and long continuance under water.

There are properly two ſubordinate genera of theſe birds. The one having the feet not webbed, but the toes looſe, yet all widened by a membrane, and having no tail. Thoſe of the other genus have webbed feet like the duck, and have tails. Of each of theſe genera there are ſeveral ſpecies; thoſe of the firſt, or ſuch as have no tails are, 1. The *Colymbus major*, or greater loon, called by the Venetians *Fiſſanelle*. 2. The *Colymbus major criſtatus*, or creſted great loon. This is called alſo the *lepus marinus*, or ſea hare, and is common both in Europe and America; the baſe of its beak is covered with a deep yellow membrane; the head is black on the crown and grey on the ſides, the back part of the head is ornamented with a black creſt, the top of the neck is black, and the reſt of the neck is of a mixed colour of red and a ferrugineous brown; the back and wings are black, and the breaſt and belly of a greyiſh white; it has no tail, and its toes are ſeparate. 3. The *Colymbus cinereus*, or grey *Diver*. This is a very rare ſpecies, but is found in ſome parts of England; it is all over of a pale grey, and has a creſt behind its head. 4. The *Colymbus major criſtatus & cornutus*, the greater creſted and horned *Diver*; this has a long and ſtrong beak, and the feathers on the top of its head, and on the upper part of its neck, ſtand prominent, and are part black and part yellow; the neck is ſhort, and is all over partly reddiſh, partly black; the breaſt and belly are of a whitiſh red, and the back is mottled with grey, browniſh red, and black. It is common in ſome parts of Yorkſhire; the laſt ſpecies is the common *Dedapper*, or *Dobchick*. See Tab. of Birds, N° 47.

Of the ſecond genus there are only three known ſpecies. 1. The *Colymbus maximus caudatus*, or great tailed *Diver*, which is a very remarkable bird, and ſeems of a middle nature between thoſe web footed fowls, which have their hinder toe joined and brought forward with the reſt, and thoſe which have not. It is of a middle ſize, between the duck and gooſe; its head is ſmall, and its tail rounded at the end; and the upper part of its neck is ſo thick ſet with feathers, that it appears even larger than the head; its colours differ ſomething in the different birds; ſometimes it is ſeen in the back, neck, and head, of a fine black, variegated with white ſpots and lines, and with a ring of white about the neck; and ſometimes without the ring, and with the back of a greyiſh colour, variegated only with ſpots without any lines: poſſibly this may be the difference of the ſexes. It is ſuppoſed, that this bird cannot fly, by reaſon of the ſhortneſs of its wings, but this is erroneous. It is common in Italy, and ſometimes is ſeen with us. The other two ſpecies of the tailed *Divers* are the *Colymbus arcticus Lumme dictus*. The northern *Diver* called the *Lumme*, and the *Colymbus maximus* of Geſner, called the *Fluder*, or ſea fludder. *Ray*'s Mythol. p. 258 to 260. See LUMME and FLUDDER.

DIVERGENCY—For the *Point* of divergency or divergence in optics, ſee VIRTUAL *Focus*, *Cycl.*

DIVERSIFYING, in rhetoric, is of infinite ſervice to the orator; it is an accompliſhment eſſential to his character, and may fitly be called the ſubject of all his tropes and figures. Voſſius lays down ſix ways of *diverſifying* a ſubject. 1. By enlarging on what was briefly mentioned before. 2. By a conciſe enumeration of what had been inſiſted on at length. 3. By adding ſomething new to what is repeated. 4. By repeating only the principal heads of what had been ſaid. 5. By tranſpoſing the words and periods. 6. By imitating them. *Voſſ.* Rhet. l. 5. p. 281. *ſeq.*

DIVIDEND (*Cycl.*) —Stealing of any *dividend* warrants of the Bank, South-Sea Company, Eaſt-India Company, or of any other corporation, is made felony, with or without benefit of clergy, in the ſame manner as if the offender had ſtolen, or taken by robbery, goods to the value of the money due on ſuch *dividend* warrants. Stat. 2 Geo. 2. c. 25. Sec. 3.

DIVIDUAL, in arithmetic, is uſed for that part of the dividend

dend, distinguished by a point, in working by the rule of division.

DIVING (*Cycl.*)—Diving *Bladder*, a term used by Borelli for a machine, which he contrived for *Diving* under the water to great depths, with great facility, and prefers to the common *diving* bell. The vesica, or bladder, as it is usually called, is to be of brass or copper, and about two foot in diameter. This is to contain the *Diver*'s head, and is to be fixed to a goat's skin habit, exactly fitted to the shape of the body of the person. Within this vesica there are pipes, by means of which a circulation of air is contrived; and the person carries an air pump by his side, by means of which he may make himself heavier or lighter, as the fishes do, by contracting or dilating their air bladder: by this means, the objections all other *diving* machines are liable to are obviated, and particularly that of the air; the moisture by which it is clogged in respiration, and by which it is rendered unfit for the same use again, being here taken from it by its circulation through the pipes, to the sides of which it adheres, and leaves the air as free as before. *Borelli* Opera Pusthuma.

DIUIOHU, in Botany, a name given by the people of Guinea to a species of plant, with which they use to ripen and break boils, beating the leaves and laying them on.

DIVISIBILITY (*Cycl.*)--Divisibility *of magnitude*.—All that is supposed, in strict geometry, concerning the *Divisibility* of magnitude, amounts to no more, than that a given magnitude may be conceived to be divided into a number of parts, equal to any given or proposed number. It is true, that the number of parts, into which a given magnitude may be conceived to be divided, is not to be fixed or limited, because no given number is so great but a greater may be conceived and assigned: but there is not, therefore, any necessity of supposing the number of parts actually infinite; and if some have drawn very abstruse consequences from such a supposition, yet geometry ought not to be loaded with them. *Mac Laurin*'s Fluxions, art. 290. See Extension.

DIVISION (*Cycl.*)—The sign of *Division* made use of in algebra, is sometimes a line drawn between the dividend or divisor, thus: $\frac{a}{b}$; sometimes the sign $\div$ is placed between the two quantities thus, $a \div b$. Others, particularly the Germans, after Leibnitz, make use of two points only; thus, $a : b$. All which equally signify a divided by b.

Division, in rhetoric, the arrangement of a discourse under several heads, to be spoken to separately. *Voss.* Rhet. l. 3. p. 366. See Disposition, *Cycl.*

Divisiones, in antiquity, certain presents of money, oil, bread, wine, or the like, appointed by will to be distributed annually among certain persons or companies, and sometimes to the people in general. *Pitisc.* Lex. Ant. in voc.

DIUTURNITY, the long continuance or duration of any being.

DIZOSTOS, in Botany, a name given by some of the old Greek writers to the *apios* or knobby rooted spurge: it is so called, because of its having usually two or three slender, and rush like stalks, growing up from the roots, which seem as if they were fit to be used as cords or bandages. See the article Apios.

DO, In the Italian music, is a syllable used instead of *ut*, being supposed more resonant and musical than *ut*. *Bross.* Dict. Mus. in voc.

Do *Law*. To *do law*, *facere legem*, is the same as to *make law*, anno 23 Hen. 6. c. 14. See Make.

DOBCHICK, in zoology, the common English name of a small water fowl, the least of all the *Diver* kind, and known among authors by the name of *Colymbus minor*. It seldom exceeds six ounces in weight, and has a short beak not more than a finger's breadth long, large at the base, but tapering to a point at the end; its eyes are large, and it is covered with a very thick downy plumage; it is of a very deep blackish brown on the back, and very white on the belly; its wings are very small, and it has no tail.

DOBULA, in ichthyology, a name given by Gesner, and other writers to the chubb. It has been called *capito* and *cephalus* by the moderns, and *squalus* by the antients; but it requires no generical name, being properly only a species of the cyprinus. See the articles Cephalus and Cyprinus.

Dobula is also used for a fresh water fish, of the leuciscus, or dace kind, but is of a larger and thinner shape, and a much better tasted fish. It is caught in the fresh waters of Germany about Hamburgh, and in many other places. *Schonefeldt* Hist. pisc.

DOCIMASIA, Δοκιμασια, in antiquity, a custom among the Athenians, by which every man, before he was admitted to a public employment, was obliged to give an account of himself, and his past life, before certain judges in the forum; for if any man had lived a vicious and scandalous life, he was thought unworthy of the meanest office. Nor was this thought enough: for the first ordinary assembly after their election, they were a second time brought to the test; when, if any thing scandalous was found against them, they were deprived of their honours. *Pott.* Archæol. Græc. l. 1. c. 11. T. 1. p. 73.

DOCIMASTICAL *Experiments*. See Assaying.

DOCIMENUM *marmor*, a name given by the antients to a species of marble, of a bright and clear white, much used in the large sumptuous buildings, as temples and the like. It had its name from Docimenos, a city of Phrygia, afterwards called Synaia, near which it was dug, and from whence it was sent to Rome. It was accounted little inferior to the Parian in colour, but not capable of so elegant a polish; whence it was less used by the statuaries, or in other smaller works. The Emperor Adrian is said to have used this marble in building the temple of Jupiter, and many other of the great works of the Romans are of it.

DOCK (*Cycl.*)—Dock-*root*, in the materia medica. See the article Lapathi *radix*.

Dock, in the manege, is used for a large case of leather, as long as the *Dock* of a horse's tail, which serves it for a cover. The French call the *Dock*, *trousse-queue*. It is made fast by straps to the crupper; and has leathern thongs that pass between his thighs, and along the flanks to the saddle straps, in order to keep the tail tight, and to hinder it to whisk about.

Dock-*Yards*, in ship-building, are magazines of all sorts of naval stores; the principal ones in England, are those at Chatham, Portsmouth, Plymouth, Woolwich, Deptford, and Sheerness. In time of peace, ships of war are laid up in these *Docks*, those of the first rates mostly at Chatham, where, and at other yards, they receive, from time to time, such repairs as are necessary.

These yards are generally supplied from the northern crowns, with hemp, pitch, tar, rosin, and several other species. But as for masts, particularly those of the largest size, they are brought from New England.

How much it imports the good of the public, to keep those magazines constantly replenished, every one is able to judge: and it were much to be wished, the improving the fore-mentioned commodities in our English plantations, might meet with all possible encouragement; lest one time or other, it may prove difficult to get them elsewhere. It is reasonable to think such an undertaking will put the nation to some considerable charge, ere it be brought to perfection; but when so, many are the advantages that will arise from it.

DOCTOR (*Cycl.*)—A *Doctor* of the civil law may exercise ecclesiastical jurisdiction, though a layman. Stat. 37 Hen. 8. c. 17. Sect. 4.

DODDER, *Cuscuta* and *Epithymum*, in medicine, is an attenuant and aperient; and as such prescribed in obstructions of the viscera, in dropsies, jaundies, and other chronic diseases. See Cuscuta and Epithymum.

DODECACTIS, in natural history, a name by which Linkius, and some other authors, have called a kind of astrophyte, or branched star-fish, which has twelve rays, first parting from the body, and each of these finally divided into many others.

DODECADACTYLON, in anatomy, a name given by some of the old authors, to the gut called the *duodenum*, from its being usually about twelve fingers breadth long.

It is the first part of the small guts, beginning from the pylorus of the stomach, and ending where the gut *jejunum* begins: it is so called, as if it were the length of twelve fingers, which yet is never observed in any men amongst us; perhaps the antients mistook, from inspecting the guts of some brutes. It is most usually called *Duodenum*. *Blancard*.

DODECANDRIA, in Botany, a class of plants which have hermaphrodite flowers, with twelve stamina or male parts in each. See Tab. 1. of Botany, Class 1.

The word is formed of the Greek δωδεκα twelve, and ανηρ male. Of this class of plants are the asarabacca, agrimony, &c.

DODO, in zoology, the name of a bird, called also by some *cygnus cucullatus*, by others *gallus gallinaceus perigrinus*, and by Bontius *dronte*. It is a very singular bird, somewhat larger than a swan, but wholly different from the swan in shape, though by some esteemed a kind of that bird. Its head is large, and is covered with a membrane resembling a hood; its beak is of an oblong figure, and is yellow at its origin and black at the point, and is somewhat crooked: it is very naked, having only a few feathers scattered over its body, and the rudiments of wings made up of a few naked quills; the hinder part of its body is very bulky and fat, and has a tail made of four or five curled greyish feathers, resembling those of the ostrich. Its legs very thick and strong. See Tab. of Birds, N° 22. *Ray*'s Ornithol. p. 107.

DODONÆA, in botany, the name of a genus of plants about which authors were very unsettled in their opinions, till Linnæus characterized it under this name. Burman has made it a species of the carpinus, and Plumier of the staphylodendron. The characters are these: The perianthium is divided into three oval, erect, and equal segments. There are no petals. The stamina are eight in number, and are extremely short. The antheræ are of an oblong figure, they stand very low, and

and ſcarce exceed the length of the cup. The germen of the piſtil is of a three-corner'd ſhape, the ſtyle is ſubulated and very long, and the ſtigma is ſimple. The fruit is a roundiſh capſule, having three inflated cells with prominent angles. The ſeeds are contained one in each cell. The cup has ſometimes four ſegments, and the fruit four cells. *Linnæi*, Gen. Pl. p. 159.

DODRA, in Roman antiquity, a drink prepared from nine different ingredients; which are enumerated by the epigrammatiſt in the following line,

Jus, aqua, mel, vinum, panis, piper, herba, oleum, ſal.

Vid. *Auſon.* Epigram. 86. *Pitiſc.* Lex. Ant. in voc.

DOG (*Cycl.*)— The manner of chuſing a *Dog* and bitch for breeding of good whelps is this. The bitch muſt be of a good kind, and well proportioned, with large ribs and flanks. The *Dog* muſt be of a good kind, and young. The beſt rule is, that a young *Dog* and an old bitch breed excellent whelps. The months of January, February, and March are the beſt for theſe creatures to couple in. The bitch ſhould be uſed to a good kennel, that ſhe may like it after her whelping, and ſhe ought to be kept warm at the time. The whelps ſhould be weaned at two months old, and the firſt or ſecond never choſen. Among the reſt it is hard to chuſe which is beſt: but many prefer that which was pupped laſt againſt all other appearances.

Another method of chuſing is the taking the cunning of the bitch into the aſſiſtance, by removing the whole litter out of the kennel, and watching to ſee which ſhe takes up firſt to carry back: this is eſteemed the beſt and ſtrongeſt puppy. Others chuſe by weight, eſteeming the lighteſt puppy likely to make the beſt *Dog*. As ſoon as the choice is made, which ſhould be ſoon after the creature has littered, all thoſe are to be drowned which are not pitched upon, that thoſe which are to be bred up may have the more care and the better nouriſhment. Hounds for the chace are to be choſen by their colours: the white with black ears and a black ſpot at the ſetting on of the tail, are generally eſteemed the beſt to compoſe a kennel of, and are of the beſt ſcent and condition. The black hound, the black tanned, or the all liver-colour'd, or all white, the true Talbots, are beſt for the ſtring or line; and the grizzled, whether mixed or unmixed, if their hairs are ſhagged, are uſually the beſt runners. There ſhould always be a couple of theſe in the pack.

The general marks of a good hound are, that the head be in a good proportion, neither too long, nor too round, but rather inclining to the former than the latter; the noſtrils ſhould be even, the ears large, the back broad, the fillet great, the haunches large, the thighs well truſſed, the hams ſtrait, tall, and big near the reins, the reſt ſlender, the leg ſhould be big, and the ſole of the foot dry, and in the form of that of a fox, with long and large claws.

DOG-*Fly*, *Cynomyia*, in natural hiſtory, the name of a ſpecies of fly common in woods and among buſhes, and particularly troubleſome to dogs. It uſually ſeizes upon the ears, and 'tis in vain to beat it off, for it returns in a moment, and cannot be prevented but by being killed. It ſtings very ſeverely, and always raiſes a bliſter in the part. It ſomewhat reſembles the flat black fly ſo troubleſome to cattle. It has no trunk, but has two teeth much reſembling thoſe of the waſp. Its wings are always placed ſo cloſe upon its body that they are not ſeen. There are two kinds of it, one larger and found in woods, and the other common in hedges.

DOG-*Roſe*, a name for the common bryar or hip-tree. It is obſervable of ſome kinds of this ſhrub, that the flowers ſmell extremely ſweet in the night, or very early in the morning, but not at all ſo in the day-time. The reaſon of which ſeems to be the ſame as in all the noctuolent plants, of which there are ſeveral kinds, as ſome of the geraniums, and of the jaſmines, *&c.* that is, that the ſun exhales and diſſipates their odorous effluvia in the day-time as ſoon as they are expanded from the flower, but that in theſe cold times the vapours are condenſated, and reach our noſe in an agreeable manner. Phil. Tranſ. N° 114.

Mad DOG. See MAD.

Water DOG. See WATER.

DOGA, in antiquity, a large veſſel into which the wine was put when newly brought from the vintage. *Pitiſc.* Lex. Ant. in voc.

DOGGERS, in the Engliſh alum works, a name given by the workmen to a ſort of ſtone found in the ſame mines with the true alum rock, and containing ſome alum, though not nearly ſo much as the right kind. The county of York, which abounds greatly with the true alum rock, affords alſo a very conſiderable quantity of theſe *Doggers*; and in ſome places they approach ſo nearly to the nature of the true rock, that they are wrought to advantage.

Whether the finer of theſe *Doggers*, or the right alum rock be uſed, they always add urine and a ſea-weed in the making the alum. Moſt of the hills between Scarborough and the river Tees abound in both kinds of ſtone, and there is alſo a great abundance of it about Preſton in Lancaſhire. It is of a bluiſh colour. Thoſe mines which lie deep in the earth, and are tolerably well moiſtened with ſprings, are the beſt. Thoſe mines that are abſolutely dry are not good, and the ſtone they contain is often of the *Dogger* kind inſtead of the true rock. On the other hand, where there is too much water the ſtone is apt to be rotted and corrupted, and a great quantity of the alum is loſt.

The mine often lies ſeventy yards or more under the ſurface of the earth; and for the more convenient working of it, they generally begin to dig on the declining of a hill, where they may have water at command. They dig down the mine by ſtages to ſave carriage, and to throw down the ſtone ore near the place where they calcine it.

The true alum rock, while it remains in the earth, is a hard ſtone; but on being expoſed to the air, it moulders in pieces, and yields a liquor of which vitriol or copperas is made; but being calcined, it yields no vitriol, but is fit for the making of the alum. The *Doggers* are of the ſame hardneſs with the true rock while in the earth, but they do not break and moulder ſo eaſily in the air where the mine is all of the true rock. There will often iſſue out at its ſides a brackiſh water, which is a ſort of liquid alum, and with the ſun's heat will be evaporated, and leave pure alum behind it. The general way of calcining the rock is with cinders of Newcaſtle coal, wood, and furze-buſhes. The fire place is made about two foot and a half thick, two yards wide, and ten yards long; and betwixt every two fires of this kind there are ſtops made of wet rubbiſh, ſo that any one or more of them may be kindled without damage to the reſt. They lay on every heap of this fewel eight or ten yards thickneſs of the alum rock broken to pieces, and then kindling the fire, as it burns up toward the top, they lay on more and more of the rock. The ſulphur remaining in the ſtones aſſiſts the burning; and if the heap be finally carried to twenty yards high, it will burn as fiercely at the top as at the bottom. When the ſtones are properly calcined they become whitiſh; but in windy weather the fire is apt to be irregular, and where it is carried moſt by the wind it over calcines the ſtones, and makes them red; and where it has leaſt force, they are left black and half calcined; ſo that to the proprietor of a work of this kind, it is of great conſequence to attend a fair day for the burning. The alum rock when thus calcined is thrown into pits of water, where there is a communication with other pits to the number of four; and it is ſo contrived, that every parcel of the alum rock is waſhed with four waters, and every quantity of the liquor, before it comes to the boiling, has waſhed four parcels of the rock; every quantity of the rock is left four and twenty hours ſteeping in the water, and conſequently every parcel of the liquor is four days in preparing before it comes to the boiling-houſe.

When the works are firſt begun in any place, they uſually boil the liquor into alum alone without the mixture of any other ingredient; but after a time they generally add the ſea-weed and urine to ſave expence by procuring the more alum from an equal quantity of the liquor. The things they add are the urine of healthful people, and the ſalt extracted from the ſea-weed, which is a ſort of pot-aſh. The urine of poor labouring people, who drink little ſtrong drink, is beſt. The kelp or pot-aſh is put into the liquor while boiling, but the urine is put into veſſels of wood cover'd with clay, and the liquor after boiling is put to it. The redder the liquor looks, the more urine is required in proportion to it. The liquor remains four days in theſe veſſels; the alum begins to ſhoot on the ſecond day, and continues ſhooting till the end of the fourth. The maſters of the works not being willing to loſe time, never ſuffer the liquor to remain more than four days in the coolers: they tell the workmen that if it ſtood longer the ſalt would turn to copperas or green vitriol, which ſtory, however abſurd, is firmly believed by them.

Temperate weather is greatly the moſt eligible for alum making; if the weather be too hot, the liquor is longer in cooling, and the alum in gathering, than it ſhould be, and is always obtained in leſs quantity, though purer, than otherwiſe. In very cold and froſty weather, on the other hand, the alum ſhoots too ſoon, and the nitrous matter and ſlime not having time to ſubſide, are mixed with the alum. This produces ſometimes a double quantity of alum, but ſo foul, that it is afterwards in great part conſumed in the waſhing. This waſhing is done with water already impregnated very ſtrongly with alum, ſo that the ſalt when tolerably pure loſes little or nothing by it. Being waſhed, it is put into another pan with a quantity of water, where it melts and boils a little; and thence it is ſcraped into a great cask, where it commonly ſtands ten days, and is then fit for the market. The *Doggers* treated in the ſame manner as the alum rock yield the ſame ſalt, but in leſs quantity, and are often not worth the expence of working; as ſome of them are however much richer in alum than the others, it is always worth while to try them, where they are found in large quantities, and in ſufficiently convenient places for working. Philoſoph. Tranſact. N° 142.

DOGGER-*fish*, in our ſtatutes, ſeem to be fiſh brought in the fiſhing veſſels, called *Doggers*, to Blackneſs Haven, *&c.* anno 31 Edw. 3. Stat. 3. c. 2.

DOGGER-*men*, fiſhermen belonging to *Dogger* ſhips. 25 Hen. 8. c. 4.

DOGGET. See DOCKET.

DOGS-BANE, *Apocynum*, in Botany, the name of a plant, which conſtitutes a large genus, the characters of which are theſe: the flower conſiſts of one leaf and is made in the faſhion of a bell, but not regularly figured in all the ſpecies.

In ſome the flower is bell faſhioned, and divided into ſeveral ſegments; and from its cup there ariſes a piſtil, which perforates the bottom of the flower, and is fixed to its hinder part like a nail; this changes into a fruit, compoſed of two vaginæ, and opening from the baſe to the apex, and filled with large quantities of ſeeds, winged with down, and fixed to a rough placenta. *Tournefort's* Inſt. p. 91.

In others the flower is bell faſhioned, and is multifid and inverted; and its middle is filled by a very elegant head, compoſed of five little horns expanded into a circle; to the lower part of this head there is affixed a piſtil, which is joined to it in the manner of a nail; this ariſes from the cup, and finally ripens into a fruit, compoſed of two vaginæ, which open from the baſe to the apex, and contain numerous ſeeds, winged with down, and placed in the manner of ſcales, and affixed to a foliacious placenta. To this, it is to be added, that the *Apocynums* all abound with a milky juice.

The ſpecies of *Apocynum* enumerated by Mr. Tournefort are theſe. 1. The upright, hoary, broad leaved Egyptian kind, called by many authors *Beidelſar*. 2. The hoary broad leaved erect kind of malabar, with purpliſh white flowers. 3. The hoary broad leaved erect American kind, with pale bluiſh red flowers. 4. The hoary broad leaved erect Syrian kind, with ſmall dusky purple flowers. 5. The great erect Syrian kind, with green ſtalks and whitiſh flowers. 6. The narrow leaved erect Syrian kind. 7. The ſmall erect American kind, with very long and narrow leaves. 8. The Virginian kind, with a green flower, and very long pod. 9. The Indian *Apocynum*, with leaves like thoſe of the tutſan, and flowers like thoſe of the lilly of the valley, and of a beautiful reddiſh colour. 10. The roundiſh leaved *Apocynum*. 11. The Venetian, willow leaved ſea *Dogsbane* with purple flowers. This has been called very improperly by ſome a *tithymal*, *eſula*, and *alypum*. 12. The hairy *Apocynum* of New England, with a tuberous root and yellow flowers. 13. The *Dogsbane* of Curaſſo, with long leaves, like thoſe of oleander, and with a fibroſe root, and orange coloured flowers. 14. The broader leaved orange coloured flowered *Dogsbane* of Curaſſo. 15. The erect African *Dogsbane*, with a broad, ſmooth, and willow like leaf, and a hairy pod. 16. The green climbing *Apocynum*, with periwinkle leaves, and a hairy fruit. 17. The hoary climbing *Dogsbane*, with periwinkle leaves. 18. The climbing African *Dogsbane*, with a tuberoſe root, like that of aſphodell, and very narrow leaves. 19. The American *Apocynum*, with leaves like thoſe of the agnus caſtus. 20. The climbing American *Dogsbane*, with a large hairy yellow flower, and very long and ſlender pods. 21. The long almond leaved American *Dogsbane*. 22. The climbing American *Dogsbane*, with almond like leaves, and pods like thoſe of the emerus. 23. The climbing American *Dogsbane*, with pods rough at the end, and ſticking to peoples cloaths. 24. The citron leaved, climbing American *Dogsbane*, with ſpotted pods. 25. The bay-leav'd and climbing American *Dogsbane*, with white umbellated flowers. 26. The Tree *Dogsbane* of the Canaries, looking like æleagnus. And 27. The ſhrub by the Spaniſh *Dogsbane*, with leaves like thoſe of toad's flax. Moſt of the ſpecies are poiſonous. *Tourn.* Inſt. p. 92.

DOG's-*tail*, in Botany. See CYNOSURUS.

DOG's-*teeth*, in anatomy. See DENTES *Canini*.

DOG's-*tooth*. in Botany. See DENS *Canis*.

DOG-*wood*—This wood, when put into water, is ſaid to ſtupify fiſh there, ſo that they are eaſily taken with the hand. It is uſed in America for this purpoſe, and the method is to tie it to the ſtem of the fiſhing boat. See *Boyle's* Works abr. vol. 1. p. 137. It is the wood of a ſpecies of cornus.

DOITKIN, a kind of baſe coin of ſmall value, prohibited by the ſtatute 3 Hen. 5. c. 1. Hence came the phraſe, *Not worth a Doitkin*.

DOLABRUM, among the Romans, a kind of knife uſed in ſacrifices among that people. Vid. Hiſt. Acad. Inſcript. T. 2. p. 345.

DOLE, (*Cycl.*) in the law of Scotland, is uſed for a malevolent intention. The word is taken from the civil law term *Dolus*.

Dole, in the law of Scotland, as well as in the civil law, is an eſſential ingredient to conſtitute an action criminal. In crimes wherein the will, not the event muſt be regarded, no negligence can equal *Dole*; unleſs the negligence be ſo extremely ſupine, as not to be conceivable without implying *Dole*.

Under *Dole* are comprehended the vices and errors of the will, which are immediately productive of the criminal fact, though not premeditated, but the effect of ſudden paſſion. In this reſpect *Dole* differs from what the Engliſh law calls malice. However both laws agree in this, that the bare intention never brought forth into act, is no crime; yet giving counſel to perpetrate, and the fact following, is.

DOLE-*fish*, in our ſtatutes, ſeems to be that fiſh, which the fiſhermen, yearly employed in the north ſeas, do of cuſtom receive for their allowance or ſhares. V. ſtat. 35 Hen. 8. c. 7.

DOLET, in natural hiſtory, a word uſed by ſome writers, in medicine, for red vitriol, or colcothar of vitriol.

DOLG-BOTE, in the Saxon laws, a recompence, amends, or ſatisfaction, made for a ſcar or wound. Sax. Dict. LL. Aluredi Regis, c. 23.

DOLICHODROMUS, in the antient exerciſes, one who ran the length of a *Dolichos*. See DOLICHOS.

DOLICHOLITHOS, in natural hiſtory, a name given by ſome authors to a ſpecies of ſtone, of a blackiſh colour, and of the ſhape of a kidney bean, found in great abundance about Tyrol, and yielding a ſmell on rubbing.

DOLICHOS, in Botany, the name of a genus of plants of the papilionaceous kind; the characters of which are theſe: the perianthium is compoſed of one leaf; it is very ſhort, and is divided into four ſegments at the end; the upper ſegment is emarginated. The flower is of the papilionaceous kind; the vexillum is roundiſh, large, and emarginated, and is wholly bent backward; and there are two callous oblong bodies running parallel to one another, and growing in the tender part of the vexillum toward its baſe. Theſe compreſs the alæ together: the alæ are of an obtuſe oval figure, and are of the length of the carina: the carina is compreſſed, the filaments are diadelphous, and the antheræ are ſimple. The germen of the piſtil is ſlender and compreſſed, the ſtyle points upward, the ſtigma is bearded, and runs from the middle of the inner part of the ſtyle to its apex, which is callous and obtuſe. The fruit is a large pod of a pointed oblong figure, it is bivalve, and is divided into two cells; the ſeeds are of an elliptic figure, and uſually are compreſſed. This plant approaches greatly to the phaſeoli, but is diſtinguiſhed at firſt ſight by the carina of the flower, which is not ſpiral, as in that genus. *Linnæi* Gen. Pl. p. 350.

DOLICHOS, in antiquity, a word uſed by different writers in different ſenſes. The antient phyſicians underſtood by it long or prolix, and uſed it in this ſenſe in their deſcriptions of diſeaſes. Others uſed it for the fruit or pod of the kidney bean. Suidas makes it ſignify a race, or courſe, of twelve ſtadia, or of twenty-four.

DOLIUM, in natural hiſtory, the name of a genus of ſhells, called by ſome *conchæ globoſæ*, and by the French, *tonnes*. The characters are theſe: it is an univalve ſhell, with a globoſe, or round belly, with a lax aperture, ſometimes ſmooth and ſometimes dentated. The clavicle is either moderately umbonated or depreſſed; and the columella is, in ſome ſpecies ſmooth, in others wrinkled. Some authors have called theſe *conchæ ampullaceæ*; and they have had, at times, many other names, but all tending to the ſame ſenſe, and expreſſing the globular figure of the body, which is the great character by which theſe are diſtinguiſhed from all other ſhells. See Tab. of ſhells, N^o^ 15.

The Perſian ſhell, ſo much eſteemed in cabinets, is a very ſingular one; but the globoſe figure of its body evidently refers it to this genus, though it differ in many other particulars from all the ſpecies of it. Aldrovandus could not tell what to make of the ſhells of this genus; but has thrown them together at the end of his book, obſerving, that they would ſeem of the turbinated kind, but that they want the turbo. Hiſt. Naturel. Eclairc. p. 300.

The author of the Armarium Balfourianum, calls the Perſian ſhell the *turbo cochlea*; and ſays, that many range it among the porcelains. The Ethiopian crown is another very remarkable ſpecies of the *Dolium*; it is always of a fine yellow, and is ſurrounded with a crown of regular eminences. The lyra, or harp ſhell, called alſo the caſſandra, is another very elegant ſhell of this genus, often finely variegated with the moſt brilliant colours. That peculiar ſpecies, known by the name of lyra nobilis, is variegated in an extreamly elegant manner, with a dark brown. The fig and the radiſh ſhells are alſo of this genus, and are very particular in their long ſhape, their crooked tail, and their colours. *Fabius Column.* de Purpura. p. 28. c. 18.

Rumphius is very much to be blamed for confounding theſe ſhells with the helmet ſhell kind, which he calls *Caſſides*. But nothing can be more erroneous than this, as the helmets are a genuine kind of murex, and theſe a genus wholly diſtinct from thoſe, and from all other ſhells. The ſhell which Rondeletius has figured under the name of the echinophora, is alſo one of theſe globoſe ſhells, or dolia, and is covered all over with ſmall and ſhort ſpines, or buttons: he has placed it among the buccinums. Armarium Balfour. p. 144.

Fabius Columna has deſcribed the little gondola ſhell, which is a ſpecies of this genus, much at large; and ſays, that it ſails at pleaſure in the manner of the nerites; he calls it conchæ natatilis, or neritodes minima. This genus of ſhells, comprehending a great number of ſpecies; and there appearing

ing among them ſeveral marks and characters peculiar to certain ſpecies, and not to others; it may be proper to arrange them under ſeveral ſeries denoted by theſe marks.

I. Of the round umbilicated *Dolia* we find the following ſpecies. 1. The white, thin, and ſtriated *Dolium*. 2. The furrowed *Dolium*, with yellow circular ridges. 3. The furrowed *Dolium*, ſurrounded with ſpotted ridges. 4. The partridge ſhell, or regularly ſpotted and ſtriated *Dolium*. 5. The white thick *Dolium* furrowed all over, and with dentated edges. 6. The ſtriated and ſpotted *Dolium*, with a wrinkled columella.

II. Of the oblong and ſmooth *Dolia*, we have the following ſpecies. 1. The yellow *Dolium*, without an umbo. 2. The white *Dolium*, with an umbo. 3. The Ethiopian crown, or the brown coronated *Dolium*, with an umbo. 4. The oblong *Dolium*, with no umbo. 5. The contabulated and variegated *Dolium*, with an exerted clavicle.

III. Of the oblong coſtated and umbonated *Dolia* we have the following ſpecies. 1. The *Lyra* or *Harp-ſhell*, pennated and adorned with thicker roſe coloured ribs. 2. The *Harp-ſhell*, with eleven ribs. 3. The noble *Harp-ſhell*; this is of a very elegant figure, and is of a brown colour variegated with white. 4. The reddiſh *Harp-ſhell*, with fourteen red ribs. 5. The umbonated *Perſian ſhell*, otherwiſe called the *Perſian Purpura*, or *Panama ſhell*. When this is poliſhed, it appears of a very different kind, and has ſeveral white lines on it, and is ſmooth. 6. The *Mullberry-ſhell*. 7. The ſtriated *Dolium*, with brown and white ſpots.

IV. Of the *Dolia* of the fourth ſeries, which have long and arched tails, there are the following ſpecies. 1. The *Fig-ſhell*, with a depreſſed clavicle. 2. The violet coloured, or ametleyſtine rediſh *Dolium*. 3. The ſtriated pale yellow *Dolium*. 4. The thick yellow *Dolium*, with ſtreaks and protuberances regularly placed. 5. The white *Dolium*, with ſtreaks and protuberances placed regularly.

V. Of the *Dolia* of the fifth ſeries, which from their ſhape are called bullæ, we have the following ſpecies. 1. The great and thick *Gondola ſhell*; this is of a grey colour, and is called by ſome the *ſea nut*. 2. The oblong greeniſh *Gondola ſhell*. 3. The oblong reddiſh *Gondola ſhell*. 4. The thin white papyraceous *gondola ſhell*. 5. The yellow *Gondola ſhell*, with four brown faſciæ. 6. The yellow *Gondola ſhell*, with brown capillary ſtreaks. 7. The great white *Gondola ſhell*, umbilicated on each ſide.

VI. To theſe is to be added a very rare ſpecies of *Dolium*, which is faſciated, of a blue colour on the outſide and white within, this is called by ſome the *Vitta Cerulea*; and there is an olive coloured ſhell of the ſame kind. Hiſt. Nat. Eclairc. N° 303.

DOLPHIN, (*Cycl.*) in ichthyology, the Engliſh name of a fiſh of the cetaceous kind, called alſo ſometimes the *Porpeſſe*, but improperly. The word *Porpeſſe* is properly the name of the conick bodied *Dolphin*, with a broad back and ſubacute ſnout; but the *Dolphin*, properly ſo called, and to which the name *Porpeſſe* is erroneouſly given, is the *Delphinus* of Artedi, with an oblong and ſubcylindric body, and a long and acute ſnout. This is the *Delphis* of Ariſtotle and the other Greek writers, and the other properly called the *Porpeſſe* is their *Phocæna*. Ælian, Appian, and Athæneus, all join in calling this *Dolphin*, properly ſo named, the *Delphis* and *Delphin*, and the ſame name is preſerved by all the more accurate of the Latin writers. See DELPHINUS.

DOLPHIN, is alſo a name given by the Engliſh to the fiſh called *Hippurus*, by the generality of authors; but by ſome *Hippoſele* and *Equiſele*, and by others *Dorado*. According to the new ſyſtem of Artedi, this fiſh is a ſpecies of the *Coryphæna*, and is diſtinguiſhed from all the other kinds, by its having a forked tail. See HIPPURUS and CORYPHÆNA.

DOM *and* SOM, words uſed in antient charters, ſignifying a power of judging, and ſecurity in poſſeſſing.

DOMENGER, in middle age writers, is ſometimes uſed for damſel. See DAMSEL, *Cycl.*

DOMICELLUS. See DAMSEL, *Cycl.*

DOMINARUM AQUA, a name given by Mynſicht to a diſtilled water, which he recommends to the ladies to facilitate delivery.

DOMNICELLUS. See DAMSEL, *Cycl.*

DOMO *Reparanda*, a writ that lies for one againſt his neighbour, by the fall of whoſe houſe he fears damage to his own. Reg. of writs, fol. 153. In which caſe the *Civilians* have the action *de damno infecto*.

DONARIA, among the antients, in its primary ſignification, was taken for the places where the oblations offered to the gods were kept; but afterwards was uſed to denote the offerings themſelves; and ſometimes, though improperly, the temples. *Hofm.* Lex. in voc.

DONAX, in zoology, a name by which ſeveral of the old authors have called the ſolen or razor fiſh. See SOLEN.

DONAX, in botany, the name by which ſome authors call the great reed, the arundo maxima, or arundo cypria of others. *Tourn.* Inſt. p. 256. See ARUNDO.

DONGON, in natural hiſtory, a name given by the people of the Philippine Iſlands to a peculiar ſpecies of crane, which has a large body like a gooſe, and a ſhorter neck than the common kind: it has a long and very broad beak, and is of a grey colour; they have, beſides this, another ſpecies of crane, which they call tipul or tihol; as remarkable for the length of its neck and legs, as this for the breadth of its beak. This tipul can ſtand erect, and look over a tall man's head. See TIPUL.

DONNA, or *La* DONNA, in ichthyology, a name given by Zuchelli, and ſome other authors, to the manati or ſea cow. See the article MANATI.

DONZELLINA, in zoology, a name by which ſome called the *julis* a very beautifully painted fiſh, of the Mediterranean, approaching to the nature of the turdus or wroſſe. *Willughby*, Hiſt. piſc. p. 324. See the article JULIS.

DOR, the Engliſh name for the common black beetle. Some alſo apply it to the duſty beetle, that flies about hedges in the evening. See SCARABÆUS.

DORADO, in zoology, the name of a large ſea fiſh, called by the Braſilians guaracapema; and ſo much reſembling the hippuris, as by many to be ſuppoſed to be the ſame fiſh; it grows to ſix or ſeven feet in length, and is of a ſomewhat broad and flatted form, being a foot and a half broad near the head; the head ends in a ſquare, and is thinned away to an edge, for the advantage of the creatures ſwimming the more ſwiftly. Its mouth is but ſmall for its ſize, and is furniſhed with very ſharp teeth; its eyes are large and round, and placed but a little above its mouth; its gills are large. It has one long fin running the whole length of the back, and another anſwering it on the belly, reaching from the anus to the tail; the tail is long, large, and forked; its ſcales are very ſmooth, and ſcarce ſenſible to the touch; its head, back and ſides are of a ſilver green, its belly white; its back and ſides are ſpotted with blue; it is a very ſwift fiſh in ſwimming, and is a very delicate and well taſted one. *Willughby*, Hiſt. piſc. p. 214.

DOREAS *Lybica*, in natural hiſtory, the name by which Ælian and ſome other authors have called the common antelope. See GAZELLA.

DOREE, or *John* DOREE, in ichthyology, a name given by us to a fiſh, called by authors, the faber and gallus marinus. We have borrowed the name *Doree* from the French; and, as to the word *John*, by ſome writers prefixed to it, it ſeems only a corruption of the French word *jaune*, yellow. They expreſſing the colour of the ſides of this fiſh, which is a gold yellow, by the phraſe *jaune doreé*: this has given us the words *John Doreé*, or by thoſe who ſpell yet worſe, *John Dory*; as we ſee it in ſome authors. See FABER.

According to the new Artedian ſyſtem, this is a ſpecies of the Zeus, and is diſtinguiſhed by that author from the others of that genus, by the name of the Zeus, with a prickly belly, and with a tail, not forked at the end, but rounded. *Willughby*, Hiſt. piſc. p. 295. See Tab. of fiſhes, N° 50, and ZEUS.

DORIALTIDES, in natural hiſtory, the name of a ſtone, to which great virtues, medicinal and magical, were attributed by the writers of the middle ages. It was ſaid to be found in the head of a cock, or of ſome other animal; and that it was made lucid by being laid on an ant-hill, the account ſeems altogether idle and imaginary.

DORIAN, in antient muſic, the fourth ſpecies of the diapaſon. See DIAPASON.

DORING, or DARING, among the ſportſmen, a term uſed to expreſs a method of taking larks, by means of a clap-net and a looking-glaſs. For this ſport there muſt be provided four ſticks, very ſtrait and light, about the bigneſs of a pike; two of theſe are to be four foot nine inches long, and all notched at the edges, or the ends. At one end of each of theſe ſticks there is to be faſtened another of about a foot long on one ſide; and on the other ſide a ſmall wooden peg, about three inches long. Then four more ſticks are to be prepared, each of one foot length; and each of theſe muſt have a cord of nine foot long faſtened to it at the end. Every one ſhould have a buckle for the commodious faſtening on to the reſpective ſticks when the net is to be ſpread.

A cord muſt alſo be provided, which muſt have two branches. The one muſt be nine foot and a half, and the other ten foot long, with a buckle at the end of each: the reſt, or body of the cord muſt be twenty-four yards long. All theſe cords, as well the long ones, as thoſe about the ſticks, muſt be well twiſted, and of the bigneſs of ones little finger. The next thing to be provided is a ſtaff of four foot long, pointed at one end, and with a ball of wood on the other, for the carrying theſe conveniencies in a ſack or wallet.

There ſhould alſo be carried, on this occaſion, a ſpade to level the ground where there may be any little irregularities; and two ſmall rods, each eighteen inches long, and having a ſmall rod, fixed with a packthread at the larger end of the other. To theſe are to be tied ſome packthread loops, which are to faſten in the legs of ſome larks; and there are to be reels to theſe, that theſe birds may fly a little way up and down.

When all this is done, the looking-glaſs is to be prepared in the following manner. Take a piece of wood, about an inch and half thick, and cut it in form of a bow, ſo that there may be

about

about nine inches ſpace between the two ends; and let it have its full thickneſs at the bottom, that it may receive into it a falſe piece; in the five corners of which, there are to be let in five pieces of looking-glaſs. Theſe are to be ſo fixed, that they may dart their light upwards, and the whole machine is to be ſupported on a moveable pin, with the end of a long line fixed to it; and made in the manner of the childrens play-thing of an apple and a plum-ſtone; ſo that the other end of the cord being carried through a hedge, the barely pulling it may ſet the whole machine of the glaſſes a turning. This and the other contrivances are to be placed in the middle between the two nets. The larks fixed to the place, and termed calls, and the glittering of the looking-glaſſes, as they twirl round in the ſun, invite the other larks down; and the cord that communicates with the nets, and goes through the hedge, gives the perſon behind an opportunity of pulling up the nets, ſo as to meet over the whole, and take every thing that is between them. The places where this ſort of ſporting ſucceeds beſt are open fields remote from any trees or hedges, except one by way of ſhelter for the ſportſman, and the wind ſhould always be either in the front or back; for if it blows ſideways, it prevents the playing of the nets.

DORONICUM, *Leopard's Bane*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the radiated kind; its disk is compoſed of floſcules, and its outer edge of ſemifloſcules, all ſtanding upon embryo's, and incloſed in a funnel-like, or baſon-like cup. The embryo's finally become ſeeds winged with down, and affixed to the thalamus of the flower.

The ſpecies of *Doronicum* enumerated by Mr. Tourneſort are theſe: 1. The ſweet rooted *Doronicum*. 2. The branched or ſcorpion-rooted *Doronicum*. 3. The broad leaved ſcorpion-rooted *Doronicum*. 4. The plantain leaved *Doronicum*. 5. The German plantain leaved *Doronicum*. 6. The long leaved rough and hairy *Doronicum*. 7. The broad leaved large flowered *Doronicum*. 8. The largeſt *Doronicum* with leaves ſurrounding the ſtalks. 9. The black rooted *Doronicum*. 10. The Portugal plantain leaved *Doronicum*. The *Doronica* are all eſteemed poiſonous. *Tourn.* Inſt. p. 487.

DORONICI *Radix*, in the materia medica, the name of a root kept in the ſhops in ſome places, but at preſent little uſed. It is a ſmall yellow root, appearing white when broken, of a ſweet aſtringent taſte, and viſcous in the mouth. The faireſt and plumpeſt roots ſhould be choſen, and ſuch as are freſh dried, or at leaſt not worm eaten. The root is brought from the mountains of Swiſſerland, and ſome other places. The plant which produces it is the *Doronicum Officinarum* of Gerrard, and is kept with us in the gardens of the curious. The leaves are broad, and the flower is yellow, and of the ſize of a marygold.

It is ſaid to be an alexipharmic, but is not uſed in the preſent practice. Authors are indeed not at all agreed about its nature; ſome accounting it a very valuable medicine, and others a poiſon. *Pomet*'s Hiſt. of Drugs, p. 40.

DORSCH, in ichthyography, the common name of ſmall fiſh of the cod kind, frequent in the Baltick, but more rare in other ſeas, and called by authors the aſellus varius, or ſtriatus. It is remarkable for having the ſmootheſt and ſofteſt skin of all the cod kind; nevertheleſs it has ſmall ſcales. It is uſually caught of a foot, or a little more, in length. Its head is proportionably ſmaller than the haddocks, and ends in a ſharper point; the jaws being both alſo furniſhed with teeth, its mouth opens very wide, its back and the upper part of its ſides are black, or of a dusky brown, and ſometimes, eſpecially in winter, is of a paler greyiſh colour, and ſpotted with black ſtreaks. The lines running from the gills to the tail are one on each ſide, and are whitiſh. Its belly is of a greyiſh or yellowiſh white. It approaches neareſt to the ſpecies called the whiting pollack, but differs from it in having a beard. It is a fine fiſh for the table. *Willoughby*, Hiſt. Piſc. p. 172.

DORSI (*Cycl.*)—DORSI *primus*, in anatomy, a name given by Fallopius, and many other authors, to a muſcle, now generally known by the name of *Quadratus Lumborum*, or the external lumbal muſcle. See QUADRATUS.

DORSTENIA, in botany, is uſed by Plumier, and ſome other authors, for the plant of which the contrayerva uſed in medicine is the root. *Plum.* Nov. Gen. 29. T. 8.

DORSTENIA, in the Linnæan ſyſtem, is uſed for a genus of plants, the characters of which are theſe: the cup is a common involucrum, large, of a fat figure, and angular, covered with the common receptacle of the flowers, and with numerous very ſmall flowers in it. Each ſingle perianthium is quadrangular, hollow, buried in the common involucrum, and growing to it. There are no petals. The ſtamina are four ſlender and very ſhort filaments. The antheræ are roundiſh. The germen of the piſtillum is roundiſh, the ſtyle ſimple, and the ſtigma obtuſe. The common receptacle becomes thick and fleſhy, and contains the ſeeds which are numerous and ſmall. *Linnæi* Gen. Plant. p. 50.

DORSUM *Piſcium*. The back in fiſhes is a part from which authors take the characters of ſeveral of their diſtinctions. Its principal differences taken notice of by Artedi are theſe: conſidered in regard to its length, it is either ſtrait, as in the pike, &c. or gibboſe, riſing up into a prominence in the middle, as in the pearch, bream, and many other fiſh. Then conſidered tranſverſly, it is either flat, as in the pike; or convex, as in moſt other fiſhes; or finally, it is formed into a ſubacute angle, as in the pagrus and ſome others. From the conſideration of the back, the ichthyologiſts generally deſcend to the ſides: theſe alſo are the ſubject of ſeveral characters and diſtinctions, as they are in the different fiſh more or leſs flat, or more or leſs convex. The breaſt and belly follow theſe in deſcription, and their principal differences are their being convex, as in the petromyzon, the eel, &c. or flat, as in the pike, the bream, and many others; or finally, raiſed or pointed, with a ridge or acute angle, as in the clupeæ. There is alſo another ſingularity, which is, that in ſome the belly and breaſt are flat, but the lower part of the belly, between the ventral fins and the anus, is contracted into a ſort of ſharp angle: this is ſeen in ſome of the cyprini. *Artedi* Ichthyolog.

DORYCNIUM, in botany, a name given by ſome to the upright umbellated ſilvery bindweed, called by others *Cneorum*. See the article CONVOLVULUS.

DORYDREPANON. See the article DREPANON.

DORYPHORI, an appellation given to the life-guard-men of the Roman emperors. They were held in ſuch high eſtimation, as frequently to have the command of armies conferred on them.

It was uſual alſo for chief commanders to have their *Doryphori*, or life-guard, to attend them. *Pitiſc.* Lex. Ant. in voc.

DOSENS, ſtreight cloths made in Devonſhire, and ſo called in Rot. Parl. 2 Hen. 5. See DOWSEINES.

DOSSER, a ſort of basket to be carried on the ſhoulders of men. It is uſed in carrying the overplus earth from one part of a fortification to another, where it is wanted. There are likewiſe ſmall carts and wheel-barrows for the ſame uſe. *Guillet.* Gent. Dict. in voc.

DOSSIL, in ſurgery, is lint made into a cylindric form, or reſembling the ſhape of dates or olive-ſtones. *Doſſils* are ſometimes ſecured by a thread tied round their middle. *Heiſt.* Surgery, Introd. §. 53.

DOTE (*Cycl.*)—DOTE *Aſſignanda*, in law, a writ that lay for a widow, where it was found by office, that the king's tenant was ſeized of tenements in fee, or fee-tail, at the day of his death; and that he held of the king in chief, &c. in which caſe, the widow came into the Chancery, and there made oath, that ſhe would not marry without the king's leave. Anno 15. Edw. 3. c. 4. And hereupon ſhe had this writ to the eſcheator; for which ſee Reg. of writs, fol. 297. and Fitz. Nat. Br. fol. 263.

Theſe widows are called the king's widows.

DOTE *unde nihil habet*, in law, a writ of dower that lies for the widow againſt the tenant, who bought land of her husband in his lifetime, whereof he was ſolely ſeized in Fee-ſimple or Fee-tail, in ſuch ſort, as the iſſue of them both might have inherited. *Fitz.* Nat. Br. fol. 147.

DOTIS *Admenſuratione*. See ADMEASUREMENT, *Cycl.* and Reg. of Writs, fol. 171.

DOTTERELL, in zoology, the name by which the mainellus is commonly known in moſt parts of England. See MAINELLUS.

DOTTO, in natural hiſtory, a name given by ſome authors to a ſpecies of the emerald, which was of a good green, but not clear or fine.

DOUBLE (*Cycl.*)—DOUBLE, in the manege. A horſe is ſaid to *double* his reins, when he leaps ſeveral times together to throw the rider. Thus we ſay, this *Ramingue doubles* his reins, and makes *Pontlevis*. See RAMINGUE and PONTLEVIS.

DOUBLE *Caſt*, in husbandry, a term uſed by the farmers for that method of ſowing that does not diſpenſe the neceſſary quantity of ſeed for a piece of land at one bout, but requires the going over it every where twice in a place. *Plot.* Oxf. p. 251.

DOUBLE *Horizontal Dial*, one with a *double* gnomon, whereof one points out the hour on the outward circle, and the other ſhews the hour on the ſtereographic projection drawn upon it. This dial finds the meridian, hour, the ſun's place, riſing, ſetting, &c. and many other propoſitions of the globe. See DIAL, *Cycl.*

DOUBLE *Dancette*, in heraldry. See DANCETTE, *Cycl.*

DOUBLES, in our ſtatutes, ſignify as much as letters patent, being a French word made of the Latin diploma. Anno 14 Hen. 6. c. 6.

DOVE, in zoology. See COLUMBA.

Ring-DOVE. See the article RING-*Dove*.

DOVELLA, in ichthyology, a name given by the Maſſilians to the fiſh called the donzellina: by the Italians, it is the julia or julis of authors; and, according to the Artedian ſyſtem, it is a ſpecies of the labrus. That author diſtinguiſhes it by the name of the labrus of variegated colours, with two large teeth in the upper jaw. See LABRUS.

DOULEIA, Δουλεια, among the Athenians, a kind of puniſhment by which the criminal was reduced into the condition of a ſlave. It was never inflicted upon any but the Ατιμοι, ſojourners

journers and freed ſervants. *Pott.* Archæol. Græc. l. 1. c. 25. T. 1. p. 130.

DOWLE and DEAL, in our old writers, are uſed to ſignify a diviſion. The word comes from the Saxon *dal*, i. e. *diviſio*, and that from *dælan*, *dividere*; whence our Engliſh word *dealing* is formed.

In this ſenſe it is that the ſtones laid to the boundaries of lands are called *Dowleſtones*.

DOWSEINES, a ſort of kerſeys made in Devonſhire, in length twelve yards; whence alſo their name, which is otherwiſe writ *doſens*, *dozens*, or *dozeins*.

DOZEIN, *Decenna*. In the ſtatute for view of frank-pledge, made 18 Edw. 2, one of the articles for ſtewards in their leets to enquire of, is, if all the *Dozeins* be in the aſſize of our Lord the king, and which not, and who received them. Art. 3. See DECINERS.

DOZEIN is alſo uſed for a ſort of Devonſhire kerſeys. Anno 5 and 6 Edw. 6. c. 6. See DOWSEINES.

DOZELLINA, in zoology, a name by which ſome authors have called the muſtela of the common ſpecies, which we in Engliſh term the *Sea Loche*, and *Whiſtle-fiſh*. *Willoughby*'s Hiſt. Piſc. p. 121.

DRABLER, in the ſea language, a ſmall ſail in a ſhip, which is the ſame to a bonnet, that a bonnet is to a courſe, and is only uſed when the courſe and bonnet are too ſhoal to cloath the maſt. See BONNET and COURSE.

DRABS, in the Engliſh ſalt works, a name given to a ſort of wooden caſes into which the ſalt is put, as ſoon as it is taken out of the boiling pan. Theſe are partitions like ſtalls made for horſes, they are lined on three ſides and at the bottom with boards, and at the front have a ſliding board to put in or take out occaſionally. Their bottoms are made ſhelving, being higheſt at the backſide, and gradually inclining forwards; by which means the ſaline liquor that remains mixed with the ſalt eaſily drains out from it, and the ſalt in three or four days becomes ſufficiently dry, and is then taken out and laid up in large heaps for ſale. In ſome places they uſe cribs inſtead of the *Drabs*. See CRIBS.

DRACO *Marinus*, in zoology, the name of a fiſh of the cuculus kind, known in England by the name of the weaver. It is a very long bodied fiſh, ſomewhat flat, with a crooked belly and ſtrait back. The ſides are variegated with browniſh and yellow lines running obliquely from the back to the belly, and leaning toward the tail. The coverings of the gills are yellow, and the belly is white. Its ſcales are very ſmall and thin, and its head is of a moderate ſize, ſomewhat flatted, and ſinking into a hollow between the eyes. The eyes are placed very near one another, and ſtand nearer the end of the ſnout than in any other fiſh of the ſcaly kind. The mouth is very large, and the lower jaw is longer than the upper; both the jaws are furniſhed with teeth, and the head is full of tubercles. It has two fins on the back: the foremoſt of theſe is very ſhort, and the other very long. The foremoſt of theſe fins have ſeveral prickly points, and theſe are ſaid to inflict a ſort of poiſonous wound. Its tail is but ſlightly forked, and is bluiſh in colour. Its fleſh is delicate, and it grows in ſome ſeas to twelve, or even eighteen inches in length. The fiſhermen are much afraid of its pricking them, and always as ſoon as they have caught it, cut off the back fin. *Geſner* de aquat. p. 89.

DRACO *Volans*, in natural hiſtory, a name given by ſome people to one of the flying lizards. Others have applied the ſame term to a very different ſubject, expreſſing by it a ſort of ignis fatuus very common in this iſland, and others of the more northern countries, which is much redder, larger, and more terrible than our common lambent fires, or will in the wiſps, as our country people expreſs them. This ſort of exhalation is principally ſeen on the borders of rivers, and in marſhy places, and ſeldom riſes very high from the ground, but plays and dances about the ſurface in an agreeable manner; and if people go up to it, will ſtick to their hands or cloaths without burning, or doing them any injury. They are more common in the ſummer months than in the winter, and are more frequently ſeen in thick weather than in clear.

DRACOCEPHALON, *Dragon's Head*, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of one leaf, and is of the labiated kind, and the upper lip which is galeated, and the lower which is divided into three ſegments, reſemble in ſome ſort the head of a ſerpent. The piſtil ariſes from the cup of the flower, and is fixed in the manner of a nail to the hinder part of it; the four embryos which ſurround this, ripen into ſo many ſeeds, which the cup ſerves as a receptacle for. See Tab. 1. of Botany, Claſs 4.

The only known ſpecies of this is the American *Dracocephalon* of Breynius, which has been called by others a ſpecies of digitalis or foxglove. *Tourn.* Inſt. p. 181.

DRACONTEAS, a name given by Neophytus, and ſome others of the later Greek writers, to two plants diſtinguiſhed by the epithets of the great and the little kinds. The great *Draconteas* is the plant we call dragons[a], and the ſmall *Draconteas* is the arum. Neophytus ſays that the roots of ſome ſpecies of the ſmall *Draconteas* were eatable, which we alſo know to be true at this time; for though with us the juice of this plant is fiery and corroſive, yet we know that there are eſculent arums in other parts of the world. The Greek writers, from the earlieſt times we have accounts of, were not ignorant of this; and Theophraſtus in particular has deſcribed an eſculent rooted arum under the name of arum edodimum.

[a] See DRACUNCULUS.

DRACONTHEMA, a name uſed by ſome of the old writers in medicine for what we call *ſanguis draconis*, or dragon's blood, a red vegetable reſin.

DRACONTIA, or DRACONTIA *Lapis*, in natural hiſtory, a name given by authors to a roundiſh or oval pellucid ſtone, which ſeems no other than a cryſtal cut into that form, and poliſhed by the ſavage inhabitants of ſeveral nations before the Roman conqueſts, and intended to be worn as ornaments. Authors tell a number of idle and fabulous ſtories about this ſtone, imagining it to be naturally of this figure and poliſh, and to be found in the head of a dragon. Pliny, Solinus, and many other authors, give us ridiculous and idle accounts of the manner of taking this ſtone out of the creature's head, which, they ſay, muſt be done while it is yet not quite dead; and ſuppoſe it to have great virtues againſt the bites of ſerpents and other venomous beaſts. They are not indeed all agreed about the ſpecies of the ſtone; Ficinus deſcribing an aſtroites under this name, and others ſome other coloured ſtone; but the generality of writers, eſpecially the old ones, make it colourleſs and pellucid.

DRACONTIUM. The Greeks, from whom the botanical writers have taken this name, never uſed it ſingly as the denomination of a plant, but only as an adjective expreſſing ſome peculiarity in which that plant differed from ſome others of the ſame ſpecies. Thus the plant which we now call ſimply *Dracontium*, was called by the Greeks *Arum Dracontium*, that is, the arum with ſtalks ſpotted like dragons or ſnakes skins; and the plant we call dracunculus or tarragon had the ſame epithet from its fiery heat.

DRACUNCULI, (*Cycl.*) a name uſed by authors for a ſort of long and ſlender worms, which breed in the muſcular fleſh of the arms, legs, &c. and from their being more frequent in ſome parts of Guinea than elſewhere, are called by many Guinea worms. They have been long known in the world; and Plutarch quotes Agathercidas for an account of theſe animals, which, he ſays, the people about the red ſea were at a certain time very much afflicted with. Plutarch tells us that they thruſt out their heads through the skin, and on being hurt draw them in again, and cauſe an intolerable pain and inflammation. Theſe worms principally affect children, and their origin is not unlike that of the worms in the inteſtines. While they move about, they create no trouble; but when they fix their reſidence, the place about them ſuppurates, and then being uneaſy they thruſt out their heads; and if they are broken in attempting to draw them out, the conſequence is very bad. They may ſometimes be manifeſtly ſeen to move. They are no where ſo frequent as on the gold coaſt in Guinea about Anamaboe and Cormantyn. The worm is white, round, long, and uniform, very much reſembling a piece of white round tape or bobbin. It is lodged between the inteſtines of the membranes and muſcles, where it inſinuates itſelf to a prodigious length, ſometimes exceeding five ells. It occaſions no great pain in the beginning; but when it is about to ſhow its head, a ſwelling and inflammation appear on the part, which is uſually the ankle, or ſome part of the leg or thigh.

The countries where this creature is thus produced are very hot, and ſubject to great droughts, and the inhabitants make uſe of ſtagnating and corrupted water, in which it is probable the ova of theſe animals lie: the white people and negroes who drink this water are equally ſubject to theſe worms.

The ſurgeons ſeldom attempt to extract this worm by inciſion, but when the tumor appears, they endeavour to bring it to a ſuppuration as ſoon as they can; and when they have broke the ſwelling, and the head of the worm appears, they faſten it to a ſtick, and continue gradually winding it round at the rate of an inch or two in a day, till they by this means have wound it all out. If it be wound too haſtily, it is apt to break in the operation; and if it does, the end is not eaſily recovered again; and if not, there are abſceſſes formed, not only at the place where it breaks, but all along the whole winding of the muſcles where the dead worm remains; ſo that often from one worm thus broken, there are produced a number of obſtinate ulcers in different parts. When the worm has not been broken, the ulcer out of which it was extracted heals eaſily, and there is no farther trouble about it. *Town*'s Diſeaſes of the Weſt Indies, p. 561.

DRACUNCULUS, in zoology, the name of a ſea-fiſh, called by Bellonius and Geſner, a kind of the exocætus. It is a ſmall fiſh, of about a hand's breadth long, and ſometimes a little larger. It is of a long and rounded body, and of a dead greeniſh or olive colour on the back, and white on the belly, and is marked on the ſides with a great number of bluiſh, white, and very light ſmall ſpots. On the upper part of its head below the eyes, it has alſo a purpliſh triangular ſpot. The eyes are large, and ſtand very cloſe together, and the mouth

very wide; the upper jaw is a little longer than the under, and both are furniſhed with very ſmall teeth. The apertures of the gills are only two ſmall holes near the upper part of the head. It has two pair of fins on the belly, and two fins on the back, the one placed toward the head, and the other a little lower. Both are ſituated in a kind of furrow, and the hinder is very high, and beautifully ſpotted with black and white, and has its ribs running to a vaſt length beyond its edge. The tail is very long, and not forked. It is common in the Mediterranean and other ſeas, and is brought to market among other ſmall fiſh at Rome, and in other places. See Tab. of Fiſhes, N° 17. *Ray*'s Ichthyograph. p. 136.

DRACUNCULUS, *Dragons*, in botany, the name of a genus of plants, the flower and fruit of which wholly agree with thoſe of arum; but the leaves are divided into ſeveral deep ſegments. The ſpecies of *Dragons* enumerated by Mr. Tournefort are theſe:

1. The common *Dragons*. 2. The common *Dragons* with leaves variegated with yellow. 3. The common *Dragons* with leaves variegated with white. 4. The great Indian late flowering *Dragons* with ſtalks not ſpotted. 5. The leſſer Indian *Dragons* with plain ſtalks. 6. The great Ceyloneſe *Dragons* with rough ſtalks variegated with green and yellow. 7. The great Ceyloneſe *Dragons* with rough ſtalks, green variegated with white. 8. The great purple ſtalked American *Dragons*, with roots like thoſe of the cyclamen. 9. The polypody-leaved prickly *Dragons* of Ceylon, with a creeping root. 10. The ſmooth Ceyloneſe *Dragons* with green and white ſtalks. 11. The great Ceyloneſe *Dragons* with a trifid ſtalk. 12. The climbing American *Dragons*. 13. The climbing American *Dragons*, with trifoliate and auriculated leaves. 14. The dwarf American trifoliate *Dragons*. 15. The colocaſia-like American *Dragons* with jagged leaves. 16. The low American *Dragons* with a white flower and white fruit. 17. The American *Dragons* with an extremely long, green piſtil. 18. The five-leaved Indian *Dragons*. 19. The Indian *Dragons* with trifid leaves. *Tourn.* Inſt. p. 160. See the the article SERPENTARIA, *Cycl.*

All the ſpecies are propagated by parting their knobby roots, which when they have ſtood undiſturbed for three years will afford a great number of off-ſets. Theſe are to be taken off and planted in autumn ſoon after the green leaves decay; for if they are removed after they have taken freſh root and began to ſhoot, they ſeldom produce flowers the ſucceeding ſummer; or if they do, they are very weak: they will thrive in almoſt any ſoil and ſituation.

DRACUNCULUS, *Dragons* or *Tarragon*, an eſculent garden herb. The latter name has moſt univerſally obtained for this plant in England, the other being the uſual Engliſh name of the great dracontium. Some of the antients have ſhewn their great ignorance in natural philoſophy, by ſuppoſing the *Dracunculus* not to be an original ſpecies of plant, but to be raiſed at pleaſure out of two other plants, by ſowing the ſeeds of the common flax in the roots of an onion.

DRAGMA, in pharmacy, a name uſed by the antients for a handful of any herb or other medicine.

DRAGMIS, in pharmacy, a word uſed by the antients to ſignify a pugil, or as much of any thing as can be taken up at a pinch, between the thumb and two fingers.

DRAGON-*Beams*, in architecture, are two ſtrong braces or ſtruts, which ſtand under a breaſt ſummer, and meet in an angle on the ſhoulder of the king-piece.

DRAGON-*Fly*. See LIBELLA.

DRAGON-*Shell*, in natural hiſtory, a name given by people curious in ſhells to a ſpecies of concamerated patella or limpet. This has its top very much bent, and is of an aſh-colour on the outſide, but of an elegant and bright fleſh-colour within. This has been found ſticking on the back of a tortoiſe, as the common limpets do on the ſides of rocks: and ſome have been found affixed to large ſhells of the pinna marina brought from the Eaſt Indies at different times. Hiſt. Nat. Eclacic. part 2. p. 243.

DRAGONS, in botany, *&c.* ſee DRACUNCULUS.

DRAGOON, (*Cycl.*) in ornithology, the name of a ſmall kind of carrier-pidgeon, called *columba tabellaria minima* by Moore. It is a baſtard breed between the two ſpecies of pidgeons called the *horſeman* and the *tumbler*. They are very good breeders, and as they are lighter than the horſeman, they are ſuppoſed more expeditious in flight for a few miles, but the horſeman outdoes them at greater lengths. *Moore*'s Columb. p. 32.

DRAGS, in the ſea language, is uſed for whatever hangs over the ſhip in the ſea, as ſhirts, coats, or the like: and boats when towed, or whatever elſe that, after this manner, may hinder the ſhip's way when ſhe ſails.

DRAINS, a name given in the fen countries to certain large cuts or ditches, of twenty, thirty, nay ſometimes forty foot wide, carried through the marſhy ground to ſome river, or other place capable of diſcharging the water they carry out of the fen lands. Moſt of theſe drains are made in our fen countries by a body of men called *The Undertakers*, whoſe reward is one third of the ground they *drain*. They erect ſluices alſo at a great expence, often not leſs than two thouſand pounds each. Yet theſe, with all the care they employ in erecting them, are ſubject to be blown up by the vaſt weight of water that lies upon them when the lands are overflown. Some of theſe ſluices have two or more pair of doors, of ſix, eight, or ten foot high, which ſhut when the water in the river is higher than in the *Drains*, by the weight and force of it; and ſo, *è contra*, throw out a body of eight foot ſquare of water for about ſix or ſeven hours during the ebb. The real uſe of theſe *Drains* is very evident from the preſent ſtate of the land where they are cut, and that of it before. In Cambden's time all this was bog, and now it is all firm land. The country about Crowland was in that author's time ſo ſoft, that it was not paſſable by carriages; and thus grew a witticiſm upon it, that all the carts that entered this town were caſed on the wheels with ſilver: but this is now ſo firm ground, that carriages of any kind paſs over it. The duck ponds uſed to be called the fen corn fields, and they now are ſuch in reality, their bottoms being dry, and producing oats, and rape ſeed or cole ſeed with great increaſe. Philoſ. Tranſ. N° 223.

DRANK, a name given by our farmers to the great wild oats. Theſe are often very troubleſome to the plowed lands, eſpecially after wet ſeaſons and much froſt. Many to deſtroy this weed ſow the land with black oats, which being ripe much ſooner than the ſeeds of this plant, are cut down before it can ſow itſelf for another year; eſpecially if they are cut a little the earlier, which will do them no harm, if they be ſuffered to lie a while upon the ground afterwards for the grain to ſwell before they are carried in. But, in general, when plowed lands begin to run to theſe weeds and thiſtles, it is a token to the farmer that it is time to fallow them, or elſe to ſow them with hay-ſeed, and make paſtures of them. The ſowing beans upon a land ſubject to theſe weeds is alſo a good method, becauſe the farmer may ſend in his ſheep when they are about three inches high, which will eat up the *Drank*, and all the other weeds, and will not hurt the beans. The general method is to put twenty ſheep to an acre; but they muſt be put in only in dry weather, and not left too long. *Mortimer*'s Husband. p. 318.

DRAPERY *Painter*. See PAINTER.

DRAUGHT (*Cycl.*) — DRAUGHT *Compaſſes*, thoſe provided with ſeveral moveable points, to draw fine *Draughts* in architecture, *&c.* See the article COMPASS, *Cycl.*

DRAUGHT-*Hooks*, are large hooks of iron fixed on the cheeks of a cannon carriage, two on each ſide, one near the trunnion-hole, and the other at the train, and are called the fore and hind *Draught-hooks*. Large guns have *Draught-hooks* near the middle tranſum, to which are fixed the chains, which ſerve to eaſe the ſhafts of the limbers on a march. The fore and hind hooks are uſed for drawing a gun backwards or forwards by men with ſtrong ropes, called *Draught-ropes*, fixed to theſe hooks. *Guillet*.

DRAUGHT-*Horſe*, in farming, a ſort of coarſe made horſe deſtined for the ſervice of the cart or plough. In the choice of theſe horſes for what is called the ſlow *Draught*, they are to be choſen of an ordinary height, for otherwiſe when put into the cart one draws unequally with the other, and the tall ones hang upon the low ones. The *Draught-horſe* ſhould be large bodied and ſtrong loined, and of ſuch a diſpoſition, as rather to be too dull than too brisk, and rather to crave the whip than to draw more than is needful. Mares are the fitteſt for this uſe for the farmer, as they will be kept cheap, and not only do the work, but be kept breeding, and give a yearly increaſe of a foal, of the ſame kind, and fit to be bred to the ſame purpoſes. They ſhould have a good head, neck, breaſt, and ſhoulders; for the reſt of the ſhape, it is not of much conſequence. Only for breeding the mare ſhould have a large belly, for the more room a foal has in the dam, the better proportioned it will be. *Draught-horſes* ſhould be always kept to that employ. Some put them to the ſaddle on occaſion, but it does them great harm, alters their pace, and ſpoils them for labour. The *Draught-horſe* ought to have a large broad head, becauſe horſes of this ſhaped head are leſs ſubject than others to diſeaſes of the eyes. The ears ſhould be ſmall, ſtrait and upright; the noſtrils large and open, that he may breathe with the more freedom. A horſe with a full and bold eye always promiſes well. On the other hand, a ſunk eye and an elevated brow are very bad ſigns. The horſe is eſteemed fitteſt for this purpoſe alſo, that has a large and round buttock, which neither ſinks down nor cuts. He muſt have a firm and ſtrong tail, and the dock muſt be thick and well furniſhed with hair, and placed neither very high nor very low. The legs ſhould be rather flat and broad than round. The roundneſs of the leg being a fault in a horſe deſtined to labour that will ſoon ruin him. As to the hinder legs, the thighs ſhould be fleſhy and long, and the whole muſcle which ſhews itſelf on the outſide of the thigh ſhould be large and very thick. Nothing is ſo eſſential to the health of theſe ſerviceable creatures as cleanlineſs: if they are fed ever ſo well, and not kept clean, they will be ſubject to numerous diſeaſes.

The ſervant who has the care of them ought to be up very early, and to clean the racks and mangers from all filth. The currying

currying of them ought to be carefully performed every morning, but not in the ſtable, for the duſt to fall upon the other horſes, as it is too often done. After the horſes are duſted, they ſhould daily twiſt a whiſp of ſtraw hard up, and weting it in water, rub the legs, ſhoulders and body with it. Many of the diſeaſes of *Draught-Horſes*, which are not owing to naſtineſs, are owing to bad water; ſuch as are too raw, too muddy, or too cold, being all improper. If there be any running ſtream in the neighbourhood, they ſhould always be had to that to water, every day in ſummer, but in winter, well-water is warmiſh, and is better for them. If there be a neceſſity of giving them well-water in ſummer, it muſt be drawn up ſome hours before the time, and expoſed to the ſun-beams in tubs or troughs; marſh-water or that of lowland ditches is worſt of all. When the labouring horſe has drank his water, he ſhould have his oats given him, and theſe ſhould be carefully ſifted, and the manger duſted firſt. It is a common practice as ſoon as a horſe is come in from his work, to rub down the legs with a hard whiſp of hay, but the beſt judges of horſes, abſolutely condemn this, and obſerve, that this rubbing of the legs after hard labour, brings down humours into them, and makes them ſtiff.

The rubbing itſelf is wholeſome, but the doing it when the creature is hot is the miſchief; while a horſe is in a ſweat it is a great relief and refreſhment to him to have his body rubbed down, but when he is cool is the proper time to rub his legs. The racks are to be well ſupplied with hay, and the horſes ſhould be left to reſt and eat, about two hours, and then led to water; after this their oats ſhould be given them, and they ſhould then go to work again.

In the evening when the labour of the day is over, the firſt thing to be done, is to examine the feet, and ſee if any thing is amiſs about the ſhoes, and what earth or gravel is lodged in the foot, between the ſhoe and the ſole, is to be picked out with a knife, and ſome freſh cow-dung put in its place, which will cool and refreſh the part.

A very material thing for the preſervation of all ſorts of cattle, but of none ſo much as *Draught-Horſes*, is freſh and clean litter; this is a thing too often neglected in the care of theſe creatures, and many even neglect the cleaning away the old litter on purpoſe, leaving it there to imbibe more moiſture, that it may be the better manure for the land. It is true, that by this the dung is enriched and will go farther, but the benefit they reap from this, is nothing in compariſon of the miſchief they do the horſe in the mean time; for the heat this gives his feet, is alone enough to ruin him. The owner often finds the effect of this, without knowing the cauſe; the horſe becomes tender footed and weakly, and is unable to do his buſineſs, though fed in the beſt manner that can be; the dung in this caſe is left under him that there may be ſome advantage from his feeding, and the diſtemper is increaſed inſtead of being relieved, till in the end the horſe is generally rendered uſeleſs.

DRAWING *a caſt*, among bowlers. See BOWLING.

DREAMS—According to *Wolfius* every *dream* takes its riſe from ſome ſenſation, and is continued by the ſucceſſion of phantaſms in the mind. His reaſons are, that when we *dream* we imagine ſomething, or the mind produces phantaſms; but no phantaſm can ariſe in the mind, without a previous ſenſation: hence neither can a *dream* ariſe without ſome previous ſenſation. He obſerves farther, that tho' it be certain *a priori*, from the nature of the imagination, that *dreams* muſt begin by ſome ſenſation, yet that it is not eaſy to confirm this by experience; it being often difficult to diſtinguiſh thoſe ſlight ſenſations, which give riſe to *dreams* from phantaſms or objects of imagination. Yet this is not impoſſible in ſome caſes, as when the weak ſenſation ſufficient to give riſe to a *dream* gradually becomes ſtronger, ſo as to put an end to it, as it often happens in uneaſy and painful ſenſations. *Wolf.* Phychol. empir. §. 123.

The ſeries of phantaſms, or objects of imagination which conſtitute a *Dream*, ſeem to be ſufficiently accounted for, from the law of imagination, or of aſſociation; tho' it may be extremely difficult to aſſign the cauſe of every minute difference, not only in different ſubjects, but in the ſame, at different times and in different circumſtances. We have an eſſay on this ſubject by M. Formey, in the Mem. de L'Acad. de Berlin. Tom. 2. p. 316. He expreſsly adopts Wolfius's propoſition abovementioned [a] that every dream begins by a ſenſation, and is continued by a ſeries of acts of imagination, or of phantaſms; and that the cauſe of this ſeries is to be found in the law of the imagination [b]. [a Pſychol. empir. §. 123, 321, 327. b Si naturale ſomnium eſt, initium capere debet per legem ſenſationis, & continuari per legem imaginationis. *Wolf.* Pſychol. rational. § 327.]

Hence he concludes thoſe *Dreams* to be ſupernatural, which either do not begin by ſenſation, or are not continued by the law of the imagination. ibid. §. 328, 329.

A learned author has lately aſſerted, that *our dreams are prompted by ſeparate immaterial beings*. He contends, that the phantaſm, or what is properly called the viſion, is not the work of the ſoul itſelf, and that it cannot be the effect of mechanical cauſes; and therefore ſeems to conclude, they muſt be the work of ſeparate ſpirits acting on our minds, and giving us ideas while we ſleep. We muſt refer to the Author of this extraordinary hypotheſis, for a farther account of it. See Eſſay on the phænomenon of dreaming, in the 2d vol. of the Enquiry into the nature of the human ſoul, 3d edit. Lond. 1745.

DREAMS, in medicine.—The phyſicians who have accurately examined the ſtate of their patients in every particular circumſtance, have not omitted at times, to enquire into their *dreams* in thoſe hours of ſleep which their ill ſtate allows them, and partly from experience, partly from reaſon and analogy have found, that there are many preſages of diſeaſes to come, and many indications of ſuch as are preſent, but unperceived, at leaſt not ſeen in their full extent, to be had from what the ſenſes ſuffer in *Dreams*. Indeed if *Dreams* are different from what might be expected from the buſineſs of the day, or the turn of thought before, they may always be looked upon as ſigns of a more or leſs diſtempered ſtate of the body, and the true condition of that ſtate, may often be better learned from them, than from any other means. What has been obſerved by phyſicians in regard to the prognoſticks from *Dreams*, may be ſumm'd up in the following manner; to *dream* of fire indicates a redundance of yellow bile; to *dream* of fogs or ſmoak indicates a predominancy of black bile; to *dream* of ſeeing a fall of rain or ſnow, or a great quantity of ice, ſhews that there is a redundance of phlegm in the body; he who fancies himſelf converſant among ſtinks may be aſſured, that he harbours ſome putrid matter in his body; to have red things repreſented before you in ſleep, denotes a redundance of blood; if the patient *dreams* of ſeeing the ſun, moon and ſtars, hurry on with prodigious ſwiftneſs, it indicates an approaching delirium; to *dream* of a turbid ſea, indicates diſorders of the belly; and to *dream* of ſeeing the earth overflowed with water, or of being immerged in a pond or river, indicates a redundance of watery humours in the body; to *dream* of ſeeing the earth burnt or parched up, is a ſign of great heat and dryneſs; the appearance of monſters and frightful enemies, indicates deliriums in diſeaſes; and to *dream* often of being thrown down from ſome very high place, threatens an approaching vertigo, or ſome other diſorder of the head, as an epilepſy, apoplexy, or the like. Theſe and a great many others are the obſervations of Hippocrates on the *dreams* of his patients. From thoſe and from ſome farther aſſiſtances, Lomnius has carried the ſubject to a very great length, and given many rules of judging from them. *Lomnii* Med. Obſ. But quære, how true.

DREGS *of Oil*, a name given by the people who trade in oil, to that coarſe and thick part of it, which ſubſides to the bottom of the veſſels in which great quantities of it are kept. This is not fit for the common uſes of the clear oil at the top, but there are ſeveral purpoſes to which it ſerves very well. Great quantities of theſe lees or *Dregs* of common oil are uſed by the ſoapboilers, principally in making the common ſoft ſoap. The leather-dreſſers alſo uſe it in conſiderable quantities to ſoften the hides they are employed to prepare for the ſeveral artificers who uſe them. Some of theſe *Dregs* are alſo uſed in the making of flambeaux, which inſtead of being made of yellow wax as pretended, are uſually compoſed of pitch, roſin and this oil, mixed in ſuch a proportion as to make a maſs of a proper hardneſs and conſiſtence. People who uſe preſſes, and other works in which there are many ſcrews, ſometimes buy this to greaſe their ſcrews, inſtead of ſoap or ſuet. Theſe are the uſes mentioned by Savary; but beſide theſe we have in England another manufacture, which conſumes a greater quantity, then all theſe put together. This is the making ſperma ceti, ſome perſons among us have found the art of making this out of the fæces of oil, and will give an oilman at any time as much clear oil in exchange for theſe dregs, as they are in quantity. All the other uſes of theſe dregs leave the trader at a great loſs; and as Savary obſerves, the more fæces the oil contains, the greater is the loſs to the buyer; but with us, this is rendered equal, and there is no loſs in it.

All ſorts of oil produce more or leſs fæces and *Dregs*, but of all others, the whale oil is obſerved to produce the largeſt quantity, and the nut oil the leaſt. *Savary's* Dict. Comm.

DREIT DREIT, in our old writers, ſignifies a double right, that is, *jus poſſeſſionis & jus dominii*. Bracton lib. 4. c. 27. and lib. 4. tract. 4. c. 4. and lib. 5. tract. 3. c. 5. *Coke* on *Littl.* fol. 266.

DRENGAGE, *Drengagium*, vel *ſervitium Drengagii*, in our old writers, the tenure by which the *Drenches* held their lands; concerning which, ſee Term. Trin. 21 Edw. 3. Ebor. and Northum. Rot. 191. *Notandum eſt, eos omnes eorumve anteceſſores, qui e* Drengorum *claſſe erant, vel per* Drengagium *tenuere, ſua incoluiſſe patrimonia ante adventum Normannorum. Spelm.* Gloſſ. *Du Cange*, Gloſſ. Lat. in voc. *Drenches.*

DREPANON, Δρέπανον, among the Greeks, an engine of iron crooked like a ſickle and fixed to the top of a long pole. It was uſed in cutting aſunder the cords of the ſail yards, in order to diſable the ſhip by letting fall the ſails, and was otherwiſe called *Dorydrepanon*. *Potter* Archæol. T. 2. p. 141.

DRESSING *of ores*; the preparing them as they come rough from the mine, for the working by fire. This is done ſeveral ways in different countries, and in reſpect to the different ores of the metals; in Devonſhire we have a very eaſy method, which is ſo expeditious, and ſo good for all the purpoſes, that it is worthy copying in other places. After the ore is dug, it is toſſed up by hand from ſhamble to ſhamble by the ſhovelmen in the mine, and drawn up in buckets by a wynch at the top of the ſhaft. As ſoon as the whole quantity for one dreſſing is brought up, the large ſtones are broken, and the whole is then carried to the mills, where one horſe turns a wheel that moves the machines for poudering a great quantity of it; theſe are called the ſtamping or knocking mills. The ore is unloaded at the head of the paſs or entrance into theſe mills; this paſs is made of two or three bottom boards and two ſide boards, in form of a hollow trough, and ſtands in a ſlanting direction. The ore by its own weight is carried down this trough, and lodges itſelf in the coffer. The coffer is a long ſquare box made of the firmeſt timber, and of three feet long, and a foot and half broad; the ore is not ſuffered to fall into this all at once, but is ſtopped over the mouth of the trough by a croſs board, where a cock turns in a quantity of water at the ſame time, which waſhes down juſt as much of the ore with it into the trough, as there ought to be. In this coffer there are three lifters placed between two ſtrong board leaves, having two braces or thwart pieces on each ſide to keep them ſteady, as a frame with ſtamp heads. Theſe heads are of iron, and weigh about thirty or ſorty pounds a-piece, and ſerve to the breaking the lumps of ore in the coffer.

The lifters are always made of heart of oak, and have as many intimbers or guiders between them; they are lifted up in order, by a double number of toppits, which are faſtened to as many arms paſſing diametrically thro' the great beam, which is either turned by the wheel and horſe, or where there is conveniency of water, by an overſhot water-wheel on two boulſters. The tappets exactly but eaſily meet with the tongues, which are ſo placed in the lifters, as that they eaſily ſlide from each other, and ſuffer the lifters to fall with great force on the ore in the trough. The frequent pounding of theſe ſoon reduces the large maſſes into a ſort of ſand, which is waſhed out of the trough by the continual current of the water from the cock thro' a braſs grate, which is placed at one end of the coffer between two iron bars.

The powdered ore is conveyed out of the trough into the *launder*, which is a trench cut in the floor of eight foot long, and ten foot over, this is ſtopped at the lower end with turf, ſo that the water is all ſuffered to paſs away, and the powder of the ore is ſtopped. Thus the launder by degrees fills up with the dreſſed ore, and this is removed out with ſhovels as occaſion requires. The launder is divided into three parts, the forehead, the middle, and the tail; that ore which lies in the forehead, that is, within a foot and half of the grate, is always the richeſt and beſt, and is laid up in a heap by itſelf; the middle and tail afford a poorer ore, and theſe are ſometimes laid up in ſeparate heaps; ſometimes thrown into one heap together.

DRIFT (*Cycl.*) — DRIFT, in mining, a paſſage cut out under the earth betwixt ſhaft and ſhaft, or turn and turn, or a paſſage or way wrought under the earth to the end of a meer of ground, or part of a meer. See *Houghton*'s Compl. Miner. in the Explan. of the Terms.

DRILL, or DRILL-*Box*, a name given to an inſtrument uſed in the new method of horſehoing husbandry for ſowing the land. The *Drill* is the engine that plants the corn and other ſeeds in rows; it makes the channels and ſows the ſeeds in them, and covers them with earth when ſown, and all this at the ſame time, and with great expedition. The principal Parts of the *Drill* are the ſeed-box, the hopper, the plow and its harrow. The ſeed-box is the chief of theſe, it meaſures or rather numbers out the the ſeeds which it receives from the hopper, and is for this purpoſe as an artificial hand, but it delivers out the ſeed much more equally, than that can be done by a natural hand. The plow and hopper are drawn by a horſe, and by theſe the ground is opened, and the ſeed is depoſited in it; the harrow follows, and lightly rakes in the earth over them. When the ground is fine, and the ſeeds ſmall, a hurdle with ſome prickly buſhes faſtened to its under part, will ſerve better than the harrow. The whole apparatus for this method of ſowing, is finely deſcribed and illuſtrated with figures by *Tull* in his Horſehoing Husbandry, to which we refer.

DRILL, in mechanics, a ſmall inſtrument for making ſuch holes as *punches* will not conveniently ſerve for. *Drills* are of various ſizes, and are chiefly uſed by ſmiths and turners. Vid. *Moxon.* Mech. Exerc. p. 6. 234.

It is a very well known fact, that a *Drill* made of iron, has frequently not only a polarity, but ſo ſtrong an attractive virtue of the magnetick kind, that it will ſuſpend a common needle from its point. It is uſually ſuppoſed that a *Drill* acquires this polarity by boring iron. But it is not only by boring of iron, that this power is obtained, but in the very making. As ſoon as one of them is finiſhed and hardened, its point becomes a north pole before it has ever been worked either in iron or any other materials, ſo that of the great numbers of theſe inſtruments found in a ſhop, endued with this power, it is to be ſuppoſed that more of them owe it to their original make, than to any after uſe. All pieces of wrought iron which in ſhape reſemble *Drills*, that is, which are of a long and ſlender form, will not only have this polarity, but they will change it on being placed for ſome time in an inverted poſture, and that which was the oppoſite to the north pole, by ſtanding downwards will be the north pole. This has been an old obſervation, but on a fair experiment, it does not prove to be true in all things without exception, tho' it be ſo in moſt particulars. The larger pieces of iron ſeem to be moſt eaſily influenced in their polarity, by changing their poſition, but the ſmall ones will ſometimes be found to have fixed poles, which no change of poſture will alter. Philoſ. Tranſ. N°. 246. See MAGNET.

DRILLING, is popularly uſed for exerciſing of ſoldiers.

The word is derived from the French *Drille*, which ſignifies a raw ſoldier: *Calo, miles exigui pretii*, ſays Le Clerc [a], who derives *Drille* from the Hebrew *chol*, ſignifying *all*, or a *whole*. As this derivation ſeems no ſmall paradox, we ſhall here inſert this learned Author's deduction. 1°. From *chol* is formed the Greek ὁλος *totus*. 2°. From ὁλος is formed the Latin *ſolus*. 3°. From *ſolus*, comes *ſolidus*. 4°. From *ſolidus* is derived *ſolidum*, a piece of money. 5°. From *ſolidum* comes *ſolidarius*, or a ſoldier receiving a *ſolidum*. 6°. From *ſolidarius*, *ſoldarius* is eaſily derived, and hence the French *ſoudar*. 7°. From *ſoudar* comes the diminutive *ſoudrille*. 8°. From *ſoudrille*, the tranſition *per aphæreſin* to *Drille* is eaſy. This etymology is applauded by Menage; but he, as Le Clerc [b] obſerves, does not aſcend to the Hebrew ſpring; in which the reader may perhaps think him judicious. [a *Le Clerc*, Diſſert. Etymol. ad Math. Martinii Lexicon. Philolog. b Id. ibid.]

DRINK (*Cycl.*)—The firſt *Drinks* of mankind were certainly water and milk; but the love of luxury and debauchery ſoon introduced the art of preparing intoxicating and inebriating *Drinks* out of vegetables. The vine gave the firſt of theſe liquors; after this, wheat, barley, millet, oats, rice, apples, pears, and pomegranates; and after theſe the juices drained from the pine, ſycamore and maple were brought to this uſe; in latter times, roots, berries, and the pith of the ſugar cane, have been employed for the ſame purpoſes: honey alſo is at preſent in ſome repute, but before the uſe of the other things here mentioned, the vinous liquor made of honey and water was in the very higheſt eſtimation. The bees were natural purveyors, and their ſtores were one of the firſt delicacies probably of the human race. It was very natural to attempt the meliorating ſo raw a drink as water, by an addition of this ſweet ſubſtance; and ſuch a mixture needing only time for fermentation to become vinous, accident might ſoon lead to this diſcovery. Mead therefore may naturally be ſuppoſed to have been one of the firſt ſtrong liquors in uſe in the world, and among the very oldeſt writers among the Greeks we find it named as a thing well known. Homer, Heſiod and Ariſtophanes all give plain proofs of their having been acquainted with it; and Orpheus repreſents night counſelling Jupiter to make Saturn drunk with mead, and then to dethrone and caſtrate him. The people who have ſtudied the human frame to moſt purpoſe, all agree, that amongſt the ſtrong *Drinks*, wine is the moſt pernicious; and that good water, milk, beer and cyder are greatly preferable to it, none of them bringing on the variety of diſorders, to which immoderate wine drinkers are ſubject, ſuch as decay of ſight, trembling of the limbs, &c.

Mr. Boyle mentions an acquaintance of his who uſed to *drink* but once in ſeveral days, and that in no great quantity, yet ſweat freely, and had his urine in juſt quantity. See Works Abr. Vol. 1. p. 306.

DRINKLEAN, in our old writers, a ſcot-ale or contribution of the tenants towards a potation, *i. e.* ale provided to entertain the lord or his ſteward. In ſome records it is written, *Potura Drinklean.*

DRIVE-*Bolts*, in ſhip building. See BOLTS, *Cycl.*

DRIVER, the name given by our ſportſmen to an inſtrument uſed in the taking pheaſant powts, in the method called driving. This inſtrument conſiſts only of a parcel of ozier wands ſuch as are uſed by the basket-makers, which are made up into a bundle, or ſort of great whisk, and faſtened in a handle; and to prevent their ſpreading too much at the points are tied round in one or two places in the length; with this inſtrument the ſportſman having fixed his nets, drives the young birds into them. See DRIVING.

DRIVING, amongſt ſportſmen, a term applied to the taking of young pheaſants, and ſome other birds in nets of an open ſtructure. The method of doing this, is, when an eye of pheaſants are found, the ground all about is to be ſearched, for the finding of their principal haunts. The induſtrious ſearcher

er will soon be able to make out some one of their paths, which are beaten in the manner of sheep-tracks, only more slightly. When one of these is found, the place is to be marked by seting up a stick with another tied to its top like the hand of a road post, marking out the place where the path seems to run to. On examining the rest of the ground thereabouts, having regard to the same direction, it is highly probable, that several more of the same sort of tracks will be found all running the same way. By one or other of these probably the sportsman will be led to their haunt, which he will not miss knowing by the nakedness and barrenness of the ground, and its being covered with the dung and feathers of the young birds. When this is found, the nets are to be placed near this spot loose and circularly, in such a manner, that the under part being fastned down to the ground, the upper may be a hollow, and give a passage to the young birds in, and entangle them when there. When the nets are fixed, the person must go to the haunts and call them together by the artificial noise of the pheasant-call, which is so like the real note of the pheasant, that the powts or young ones, will seldom fail being deceived by it. When they hear this and begin to answer it with their chucking and piping; the call is to be stopped, and a person is to get behind them taking the wind with himself, as they always run with the wind. He is to have in his hand the instrument called by the sportsmen a driver; which is no more than a parcel of those long white ozier wands used by our basket makers, fixed in a handle, so that they may be conveniently managed, and tied round in two or three places with ozier bands or packthread to keep them from spreading too much.

When the person who carries this instrument perceives that he is come pretty near some of the powts, he must softly beat the bushes with the driver, or only lightly draw it over them; the little noise this makes will terrify these timorous creatures, and they will gather together in the track and run a little way forward, and then all stop and turn about; on this the person is to make the same noise again, upon which they will run farther, and when they stop again, the same noise will again send them forward. Whatever other powts are in the way will join the main body in this fright, and the whole will be driven in this manner, like a flock of sheep, and by a little address of the sportsman be sent into the nets; so that out of a whole eye, it often happens that not one is missed.

If in the fright the birds happen to run out of their track, and take a wrong way, then the driver is to make a raking noise with his instrument dragged along the ground, on that side on which they are running; this will amaze and terrify them so, that they will immediately start back, and come into the beaten track that leads directly to the haunt. There are but two cautions necessary to the succeeding perfectly in this method of taking them: these are secresy and patience. Whatever stops they make, or however tediously they move, the sportsman who would make sure of them, must bear with it; for over rashness and hurrying will spoil all, and he must content himself with terrifying them by the noise alone, keeping himself carefully out of their sight, for if they espy him, all the plan is disconcerted, and they will no more move forwards, but will every one run a different way, and hide under the roots of trees, and thick bushes, and all the art in the world, will never bring them out again till night, when it will be too dark to watch them.

DRIVING *of wild fowl*, is only practicable in the moulting time, which is in July and August; and is to be done by means of a spaniel, well trained to the purpose. The nets are to be set in creeks and narrow places, or at their usual night retreats, and the dog is to put them up, and *driving* them forward, they will be sent immediately into the nets, not being able to fly away from the dog, from the want of their wing feathers. The people who live in the fenns, find great account in this practice, taking very great numbers of wild-ducks by it. They are usually indeed poor and out of flesh at this time, but as they are always taken alive, and without any hurt, the people find it easy to fatten them with beasts livers, barley, paste, scalded bran, and the like; and they will on this become in a very little time, fat and well tasted, excelling in flavour both the tame ducks commonly kept in the yards, and the wild ducks in their natural state. When the sportsman takes the dog into places where they are not so frequent, he may hunt them singly, and the dog alone will take them.

DRIVING, in metallurgy, is used by the refiners of silver, to express the rising up of copper from its surface in red fiery bubbles. When the lead that was added for the refining the silver is burnt away, before the copper is gone from it, these bubbles appear very fiercely on the surface. They say on this occasion, that the metal *drives*, and then add more lead till the remainder of the copper is consumed. Phil. Trans. N°. 142.

DROCK, in husbandry, a name given by our farmers to a part of the common plow. It is an upright piece of timber, running nearly parallel with the hinder part of the plow, but belonging to the right side of the tail, as that does to the left. The ground wrist of the plow is fastened to this, as also is the earth board. *Tull's* Husbandry. See the articles WRIST, EARTH-BOARD, and PLOW.

DROFFAND or DRYFFAND, in our old writers, was a quit rent, or yearly payment made by some tenants to the king or their landlords, for driving their cattle through the mannor to fairs or markets. The word comes from the Saxon *Dryfene*, driven.

DROMEDARY, in zoology, the name of a species of camel which has only one bunch on its back. Its hairs are soft to the touch, and are shorter than those of our oxen, except that there are some longer on the head, the throat and the top of the neck; and on the middle of the back, there are hairs of a foot long, and these tho' very soft and flexile, yet naturally standing in an erect posture, they make the most visible part of the bunch. For when these are removed by the hand, the flesh scarce appears more prominent, than that of the back of a hog, and there is not the least fleshy or callous excrescence there.

The head is small in proportion to the body; the upper lip is divided as in the hare; the feet are not hoofed, but each terminated by two small claws; the sole of the foot is broad and very fleshy, and seems soft to the touch, tho' the skin is very hard and callous; the feet are indeed cloathed as it were with living shoes, which are of very great service to it in traveling over the sandy countries. It has six callous hardnesses on the knees and shoulders of the forelegs, and one on each of the hinder ones. And beside these there is another much larger, which adheres to the breast, on an eminence which is there, as if made to support it; this is usually eight inches long, six inches broad, and about two thick. The use of these is to sustain the weight of the creatures body on occasion of his stooping to rest, or to be loaded.

Its stomach is very large, and divided into four parts as in other of the ruminating animals, but of a singular structure; in that at the upper part of the second ventricle, there are several square holes, which are the orifices of a great number of a sort of bags placed between the membranes which compose the stomach, and these seem to be the receptacles of water kept for the time of necessity, for the creature always drinks a vast quantity at once, and will then live a great while without drinking again. It is yet a question to be decided, whether this creature is of the retromingent kind, and whether it copulates backwards? this has been affirmed by some, but it is greatly doubted by others. *Ray's* Syn. Quad. p. 143. See Tab. of Quadrupeds, N° 16. and the article CAMEL.

DROMONARII, in antiquity, rowers belonging to the ships called *Dromones*.

DROMONES, in antiquity, a kind of yatchts or expeditious ships used in carrying provisions, or other necessaries. *Pitisc.* Lex. Ant. in. voc.

DROMONES, DROMOS, or DROMUNDA, in middle age writers signified any large ships; but afterwards it was used chiefly for men of war; and in this sense 'tis used in Walsingham, Anno 1292, and in Knighton, lib. 3. c. 14, &c.

DROMEUS, in natural history, a word used by the antients, as the name of two very different animals, the stag and the dromedary. The meaning of the word is swift in running; and the stag had this name as being swifter than any other animals, and the dromedary as being swifter than any of the camel kind beside. The not remarking this double meaning of the word *dromeus*, has made some people in their expositions of the antient Greeks, run into very great absurdities, attributing to the stag. what could only belong to the dromedary; and to this animal, what could only belong to the stag.

DRONE, in natural history, a sort of bee of a larger size than the common working bee, and of a lazy disposition, never going out to work to collect either wax or honey, but living on the honey collected by the rest. These are the males of the swarm; the common working bees are of no sex at all, and the female is usually only one in a hive. See QUEEN BEE.

The dissection of the *Drone*-bee gives as great proof of its being the male, as that of the queen does of her being female. In this creature there is no appearance of ovaries or eggs, nor any thing of the structure of the common working bees, but the whole abdomen is filled with transparent vessels, winding about in various sinuosities, and containing a white or milky fluid. This is plainly analogous to that fluid in the males of other animals, which is destined to render the eggs of the female prolific; and this whole apparatus of vessels which much resembles the turnings and windings of the seminal vessels in other animals, is plainly intended only for the preparation and retention of this matter, till the destined time of its being emitted on the eggs. At the extremity of the last ring of the body is placed the aperture of the anus in the female, and in the working bees; and it is at this aperture, that the sting is also thrust forth; but the case is quite otherwise in the drone

or male bee; for the extremity of that ring is not open, but abſolutely cloſed; and the aperture of the anus is in the under part of that ring about its middle. On preſſing the body of this bee, there is alſo forced out at this part, the penis; this is a ſmall and ſlender fleſhy body, contained between two horns of a ſomewhat harder ſubſtance, which join at their baſe, but gradually part aſunder as they are continued in length. When the preſſure is continued, there are finally thruſt out at the ſame aperture, a part of the internal apparatus of the ſeminal veſſels, and in fine, there is uſually ſome of the milky liquor extravaſated; but this ſeems rather to be let out by the burſting of a veſſel, than by any natural paſſage. Theſe parts found in all the drones, and none of them in any other bees except theſe, ſeem to prove very evidently, the difference of ſex; but there is one thing extremely remarkable in regard to them, which is, that tho' they appear ſo evidently on being forced out of the body by preſſure, yet it is very difficult to find them in it on diſſection. The cauſe ſeems to be their ſwelling when expoſed to the air; and Swammerdam ſuppoſes, that to this purpoſe they are furniſhed with a great number of tracheæ, which readily admit the air as ſoon as ever they are expoſed to it.

It is no uncommon thing for a hive to afford only one female bee, with five or ſix hundred, or even a thouſand *Drones*. The queen ſeems in this caſe, to have a very numorous ſeraglio; yet ſo it is, that in the midſt of ſo many males, and tho' ſhe is loaded with ſuch an immenſe number of eggs, all which muſt be impregnated by the male, no one ever ſaw, or at leaſt no author who has treated on this ſubject, has mentioned his having ſeen the queen and any of her ſeraglio in copulation.

This however is no ſort of proof that the thing is not done, for without giving the female a ſenſe of modeſty or ſhame to govern her actions, we may obſerve, that ſhe always loves the inner receſſes of her habitation; and that as her uſual reſidence is among the center of the combs, there is no reaſon to ſuppoſe, that ſhe would leave that place, and crawl to the edge on purpoſe to ſhew herſelf to the ſpectator in that act. We are acquainted with no other method of animal generation, but by the copulation of male and female in any of the fly kinds; and as analogy is the beſt of all methods of arguing in caſes of this kind, it is to be obſerved, that there are other inſects of the nature of the bees, which we are well aſſured uſe copulation in the common way. Thus the waſps and the common great humble bees are in their ſwarms compoſed of males, females, and labouring creatures, which are of no ſex at all; and both the drones among the waſps, and thoſe among the humble bees, have been ſeen in copulation with the females of their kinds.

The great number of males in proportion to the females in the ſwarms of waſps, takes off the argument againſt the male bees copulating with the female, from the ſuppoſed inequality of their numbers; and it is to be added, that we are not to wonder at our not ſeeing the bees in this action, when we conſider that beſides the obſtruction which the combs give our ſight, the female bee is uſually ſo covered with a cluſter of the working bees, that ſhe is uſually hid from our inſpection in her travels about the edges of the combs by this croud of attendants.

Many of the antients as well as moderns, have ſuppoſed that the eggs of the female bee, are not impregnated with the male ſperm, while in the body of the creature; but that they are depoſited unimpregnated, in the cells, and that the male afterwards ejects the male ſperm on them, as they lie in the cells; in the ſame manner as the generation of fiſhes is ſuppoſed to be performed by the males impregnating the ſpawn after it is caſt out by the female. But this is evidently proved erroneous in the caſe of the bees, as it uſually happens, that during the whole time of the eggs lying in the cells, there is not one male bee alive in the place.

Swammerdam whoſe obſervation of the hives was too accurate to let him fall into this miſtake, and who knew very well, that this ſort of impregnation, was only the erroneous gueſs of perſons little skilled in nature, had recourſe even to a more ſtrange and ridiculous ſource of impregnation, than this: he ſuppoſes, that the female never copulates with the male, but that the effluvia of his body in paſſing by her, renders the eggs within her capable of producing yonng ones, and ſuppoſes according to this doctrine, that nature ſends the vaſt numbers of males to every female, that in the paſſage of the latter thro' the hive, theſe meetings on occaſions of impregnation, might be more frequent. What has been obſerved by Mr. Reaumur in regard to the copulation of the *Drones* with the female bee, ſeems to give all the part of the invitations and careſſes to the female, the males being very indolent and inactive; and this indeed is very neceſſary; for ſhould the males be the aggreſſors, in a place where there are a thouſand of them to one female; that creature could have no reſpite, and could neither feed nor lay her eggs; but on the other hand, as they are indolent and inactive, ſhe lives as quiet a life as ſhe pleaſes among them, and only ſingles out ſuch as ſhe likes occaſionally for her purpoſes.

M. Reaumur contrived to get a female into a box, and putting a male to her, found that all the careſſes and blandiſhments, which the common bees pay'd to her, ſhe returned abundantly to the male; ſhe ſtroaked him with her trunk, and offered him honey to feed on out of her mouth; and this kindneſs for a long time had no effect upon him; at length however, he grew more active and brisk, and the female then got upon his back and bending downward, the hinder part of the body ſeemed to receive into it the male part; the ſtructure of which renders it indeed neceſſary, that the creatures ſhould be in this poſture; for it is bent into the ſhape of a hook, and the point turned upwards, ſo that it would be impoſſible for the male ever to introduce it into her body, if he got upon her in the ordinary way. The time that the bees remained in copulation, if this junction could be ſo called, was but very ſhort, and the female often repeating it, the male uſually died at laſt in the operation.

The common hen will often lay eggs daily for a long time together, and in the ſame manner the female bee lays every day for many months. But there is this great difference, that the hen in order to be thus fecundated, muſt live with a cock all the time, and be often in copulation with him. Whereas the female bee continues laying almoſt the whole year round by only having had the males with her during a few weeks. When the ſhort time in which the male bees are neceſſary in the hive is over, the labourers all fall upon them, and produce a cruel ſlaughter among them. They leave not ſo much as one alive, and every morning carry out of their habitation, the carcaſſes of the ſlaughter of the former day's butchery. Nay they do not ſpare even the young ones in the worm or nymph ſtate, but ſearch out all the large cells which they had before made for their reception, and finding they will not hereafter be neceſſary to them, deſtroy them in this defenceleſs ſtate. Theſe ſlaughters happen at different ſeaſons of the year according to the different accidents of the ſwarm; They are always eaſily known by the numbers of dead carcaſes found about the hives, and happen uſually in June or July, tho' ſometimes later; for a ſwarm not received into the hive till May, will let the males live till Auguſt. *Reaumur*, Hiſt. Inſect. T. 10. p. 128, 149, 157.

DRONE-*fly*, or BEE-*fly*, a two wing'd fly, ſo extremely like the common bee as to be at firſt ſight not eaſily diſtinguiſhable from it. The diſtinction between the two inſects however, beſide the different number of their wings, is that the bee has a ſomewhat longer and leſs thick body, and the head is proportionably much ſmaller, than that of the fly which ſo much reſembles them. The bee fly alſo ever carries its wings parallel in their poſition, but without its body; whereas the bee itſelf uſually carries its wings croſſed on the back, and covers its body with them; this is not however an invariable poſture with the wings of the bee, tho' it is the moſt frequent one. The bee fly is found among the flowers, as is the bee, and tho' it gathers no wax, it has a trunk by means of which it ſucks the honey.

The trunk, by means of which the *fly* is enabled to do this, has no teeth, and conſequently the *fly* belongs to Mr. Reaumur's firſt general claſs of the two-winged *flies*; and the form of its body, which is ſhort and flat, determines it to be of his firſt ſubordinate genus of that claſs. This is properly a ſeparate genus of *flies*, of which there are many ſpecies. Mr. Ray has deſcribed ſix, and a cloſe obſervation will enable us to add much to that number. The different ſpecies vary extremely from one another in ſize. The ſmaller of them are not ſo large as the common blue fleſh-*fly*, the others equal or exceed this *fly* in ſize. They differ alſo in colour in their different ſhades of brown; and ſome of them have ſpots of a fine deep black, and others of a fine gloſſy yellow, which make them very diſtinguiſhable from bees.

The moſt ſingular and obſervable part of the life of this inſect is that which it paſſes without wings, and in form of a *fly*-worm and nymph. The general exterior form of the *fly*-worms of this genus has been well enough known to the generality of naturaliſts; and Goedart, Merian, and Albinus were well acquainted with them ſo far; but they did not give themſelves the trouble of a farther examination, and were not ſenſible that theſe worms had many obſervable things to offer to our conſideration.

The matter among which they are found is that of all others the moſt offenſive and diſagreeable. They are of the claſs of thoſe with variable heads; but their great diſtinction from all others is their having a long ſlender tail. This at different times the worm makes of very different lengths, but in its ſhorteſt it is longer than the body of the creature. It is round, ſmooth, and at times extremely ſmall at the extremity, and ſometimes much reſembles the tail of a rat; whence the whole claſs of theſe worms are well diſtinguiſhed by the name of rat-tail'd worms.

Nothing is more vague than our manner of gueſſing at the uſe of the parts of animals at firſt ſight. Nature, we know, gives them no organ in vain, and therefore we are to find the uſe for which they were given. Goedart gueſſed theſe long tails were given to this claſs of worms to enable them to crawl

along

along without rolling about, to which their round figure would without theſe naturally have ſubjected them. But this cannot be agreed to on a general examination, when we find that there are a vaſt number of other worms of as round bodies as theſe, which have no power of flattening themſelves, no viſcous matter exſudated from their skin, nor either feet or tail, which yet are able to move along without rolling.

Notwithſtanding that Goedart did not perceive it, this ſpecies of worms have legs alſo, and thoſe in a ſufficient number. They have ſeven pair of theſe placed at pretty regular diſtances, and the firſt pair not far from the head of the creature, the laſt but at a ſmall diſtance from the tail. Theſe are all ſhort and membranaceous, but they are well contrived for laying hold of things; for they are round and large at the bottom, and are ſurrounded there with fine and ſharp hooks. The creature has a power not only of retracting theſe hooks into the ſubſtance of its feet, but can even retract its feet into its body, and render them inviſible, till it has occaſion to thruſt them out again to walk with.

To know the uſe of the tail of this worm, it is however neceſſary firſt to know the nature of the worm itſelf. Theſe authors took it for a terreſtrial worm; but it is in reality an aquatic, as Swammerdam and Valliſneri rightly judged. 'Tis in the water that it acquires its growth, and it never leaves that element till the time that it is in a ſtate to undergo its firſt metamorphoſis, in order to its change into the *fly* ſtate. Theſe worms being uſually found on dry land, aud only picked up now and then ſparingly, gave the world for a great while no room to believe that they were ſo numerous as they really are, nor had people any idea that they were to look for them in the water. In examining veſſels of corrupted and ſtinking water however, they have been found in very great multitudes together lying among the mud at the bottom. Theſe taken out of this filth, and put into veſſels of clean water, will ſoon ſhew the curious obſerver the uſe of their long tails. Notwithſtanding that theſe worms are to live under water and in mud, there is no doubt to be made but that, like other of water *fly* worms, they have a neceſſity of breathing freſh air; and 'tis to this great purpoſe that their long tail ſerves them; for while they lie buried in the mud, this is extended up to the top of the water, and being open at the extremity lets in the air into the body of the creature. It is a pleaſing ſight to obſerve, that theſe animals, after having been put into a veſſel of freſh water, all get quickly to the bottom, and each thruſts up the extremity of its tail to the ſurface.

It is very eaſy, from ſeeing that at whatever depths the worms lie their tails ſtill reach the ſurface, to conclude, that they have a power of lengthening them at pleaſure. The ready way to be aſſured of this is to add depth to the water by pouring more into the veſſel; for as the worms love the bottom, they muſt, if they will remain there, lengthen their tails proportionably in order to breathe from the ſurface. The repeating ſeveral of theſe additions ſhews, that the worm is able to extend its tail to the length of five inches; an extremely remarkable length for a creature, whoſe body is not much more than half an inch, and whoſe tail in its more common ſtate is not much longer than that. Five inches is however the ſtint, beyond which they cannot go in this action; and when the water in the veſſel is made of a greater depth, the worms leave the bottom, and either crawl up the ſides of the veſſel to a proper height, or elſe ſwim in the water at the depth of five inches, which is the depth at which they carry their tails up to the ſurface.

The organization of ſo remarkable a part as the tail of this animal, cannot but appear to the curious greatly worth the enquiring into; and the tranſparence both of it, and of the body of the creature, is ſuch as to favour very greatly this examination. And indeed in many of the younger of theſe worms, and ſuch as have not yet come to the ſtate at which they quit the water, one may diſtinguiſh the parts within the body as plainly almoſt as if placed for examination in a glaſs tube. It is eaſy in all ſtates of the worm to diſtinguiſh that its tail is compoſed of two hollow tubes, the one of which nicely fits, and is eaſily retracted within the other, or thruſt out of it again, as the creature's occaſions require. The outter and larger tube ſeems an elongation of the fleſhy matter that forms the rings of the body. It is white like the body, and is compoſed of a vaſt number of rings, as the body is. Within this is lodged a leſſer pipe, a great part of which is of a blackiſh brown; and by means of this colour, the inner tube may be diſtinguiſhed even when it is wholly within the other. This inner one may be called the tube of reſpiration. It is eaſy to ſee now that the tail of the worm may be made more and more long, as his inner tube is thruſt out of the other, which ſerves it as a caſe or ſheath. But this is not all; it is eaſily known that theſe pipes are in themſelves capable of extenſion, by obſerving, that when the whole inner tube is lodged within the caſe, or outer one, yet this is of no determinate length, but is ſometimes longer, ſometimes ſhorter.

Both the inner and outer tube are indeed compoſed of annular fibres, and are capable of extenſion in length by the leſſening their diameters. Thus when the tail is extended to its whole length, the upper part of the tube of reſpiration appears no thicker than a large thread, or a horſe-hair.

The tube of reſpiration is terminated by a ſmall brown prominence, in which there may be diſtinguiſhed two apertures deſigned to give a paſſage to the air; and around this there may be diſcovered five ſmall pencils of hairs, which, when the end of the tail is on the ſurface of the water, ſpread on it like the rays of a ſtar. The mechaniſm by which the inner tube is extended out of its caſe, and is again retracted into it, when ſuch extenſion is no longer neceſſary, is extremely plain and ſimple, and the eye is very well able to diſcern the whole operation. There are in the body of the worm two large trachea laid in a parallel direction to one another, and extended the whole length of the body from head to tail. They have their origin very near the head, the one on the right hand, and the other on the left, and their diameter in this place is very ſmall; they inſenſibly grow larger as they approach the hinder part of the body, and when arrived at this ſize they keep it to the extremity of the body. They are here two large veſſels, whoſe brightneſs and whiteneſs reſemble white ſattin. Near the origin of the tail theſe tracheæ ſuddenly become narrower; and for the reſt of their extent, each is no more than an extremely thin tube, but that ſo long, that it has not room to be lodged in it without making ſeveral folds and convolutions in a very ſmall ſpace; and this the more, as the ſmaller tube, or tube of reſpiration, is the more retracted within its caſe.

The long and ſlender portions of theſe reſervoirs of air are two hollow threads as it were, the ends of which are faſtened to the tube of reſpiration. When this tube is thruſt in part out of its caſe, and the tail is by that means become longer, theſe threads follow it out; they unfold themſelves in proportion to the length it is thruſt out to, and are drawn out of the body into the caſe, or larger outer tube of the tail. In this caſe the folds and convolutions they make in the body are few, and diſtinct; and when the tail is yet much farther lengthened, and the tube of reſpiration is carried out to its utmoſt length, and leaves the outer tube an empty caſe, theſe hollow threads are extended into two parallel ſtrait lines, their folds and convolutions are all loſt, and they are brought into the now empty caſe in form of two parallel tubes: and when this tube of reſpiration is again retracted into its caſe, theſe hollow threads recede into their old places, and make their former folds and convolutions at the end of the great tracheæ, or the great reſervoirs of air, of which they are properly no other than elongations.

It is moſt probable, that to the unfolding and expanding of theſe two veſſels, the whole action of the thruſting out of the tube of reſpiration from its caſe, when the depth of water requires it, is owing; and that the retracting of it in again is, in like manner, the effect of the returning of theſe veſſels into their original folds and convolutions: ſince if we allow this veſſel but a little ſtrength, as they muſt have if of a cartilaginous ſtructure, that will be enough on its expanding to throw out the eaſily moveable tube of reſpiration from its caſe; and as they are faſtened to the end of this tube, it is a moſt neceſſary conſequence, that their contracting themſelves into their old convolutions muſt pull it in again.

Beſide this, there muſt alſo be a power in the animal of extending and retracting the parts of each of theſe pipes or tubes by means of their annular ſtructure. But this depends on the ſame principle as muſcular motion in general, and is a ſubject of too abſtruſe enquiry to be entered into here. This tube of reſpiration is however not only capable of being retracted wholly into its caſe, but it is ſometimes drawn into the body of the creature between the two principal tracheæ, and carried up almoſt to the head, and is even ſometimes bent and folded.

The worm has the power of changing the figure of its head like the reſt of this claſs. It ſhews at times two fleſhy horns, the inſertions of which are in the under part of the body, and near theſe is the mouth. This is ſurrounded by a ſort of arch of a brown cartilaginous ſubſtance; and within this is a little fleſhy protuberance, which may be taken for the tongue. Its anus is a tranſverſe ſlit, placed between the inſertion of the laſt pair of legs, and the origin of the tail. This is ſurrounded by a number of fleſhy bodies forming a kind of fringe, which the creature either ſhews or hides at pleaſure. Theſe may not improperly be taken for a part of the inteſtines, which the creature is obliged to puſh out of its body when it is to void its excrements; and when that is done, it retracts them in again. The microſcope ſhews them to be all hollow.

Many of the water *fly* worms do not quit that element till in the *fly* ſtate; but this ſpecies, as ſoon as they have acquired their full growth, leave the water, and crawl upon the earth. Their bodies in this new element become dirty and greyiſh; and when they have found a proper ſpot of ground where the earth is ſoft and moiſt, they bury themſelves, and after a neceſſary time for their change come out in the form of *flies*.

Their changes are all made under a ſhell of their own skin, which

which in a few hours is found beginning to harden, and by degrees becomes very firm, of a yellowiſh colour, and is remarkable for having four horns, two larger and two ſmaller, placed in different directions near the head: and theſe are the organs of reſpiration to the incloſed nymph.

Theſe are the changes of the *flies* of this claſs. They are of ſeveral ſpecies, and differ in ſize not leſs than the worms from which they are produced. Of theſe the largeſt are found in vaults and privies; and in winter, multitudes of them may be met with in the hollows of willows and other trees where there is water. *Reaumur*, lib. cit. T. 4. p. 441—459.

DRONTE, in zoology, the name given by Bontius, and ſome other authors, to the bird more uſually called *Dedo*; a very large and ill ſhaped fowl, ſomewhat approaching to the nature of the caſſowary, but not ſo tall. *Ray*'s Ornithology, p. 107. See the article DODO.

DROPS (*Cycl.*)—*Engliſh* DROPS, a name given, in the time of king Charles the ſecond, to a chemical preparation eſteemed of great virtue againſt vapours and lethargick affections, and ſaid to be purchaſed for a large price by that monarch from the inventor. The medicine appeared to be only a ſpirit drawn by the retort from raw ſilk, and afterwards rectified with oil of cinnamon, or any other eſſential oil; and was in reality no better than the common ſal volatile oleoſum, or any of the volatile ſpirits, as thoſe of hartſhorn, ſal armoniac, or the reſt, impregnated with an eſſential oil, except that it was leſs diſagreeable than any of them to the taſte, and therefore fit for perſons of nice palates. Mem. Acad. Par. 1700.

Rupert's DROPS. See RUPERT.

DROPSY (*Cycl.*)—Some think that the anaſarca, leucophlegmatia, hydrops aſcites, tympanites, hydrocele, *&c.* differ ſo exceeding little, that it is ſcarce worth while to retain ſo many pompous Greek names. Medic. Eſſ. Edinb. vol. 1. p. 226.

The oil of juniper, or an infuſion of juniper-berries roaſted, and made into a liquor like coffee, is ſaid to be good for the *Dropſy*.

Exerciſe is alſo recommended to hydropic people immediately before tapping, that the groſſer particles in the water of their belly may be mixed with the thinner, and ſo run out with them. And if there is reaſon to ſuſpect any ſuch groſs parts remaining after the operation, ſome adviſe the injection of barley-water to dilute and bring them away.

We have lately had accounts, in the philoſophical tranſactions, of *Dropſies* cured by tapping, and afterwards injecting Cahor wine, mixed with Briſtol water.

There is alſo an account of an uncommon *Dropſy*, from the want of a kidney, in the Philoſophical Tranſactions. The ſubject was a young woman; the water evacuated from the abdomen on diſſection, meaſured near half a hogſhead, and was contained in a large ſack, which almoſt occupied the whole cavity of the abdomen above ſix feet in circumference, and extended upwards of four feet from the xyphoid cartilage, to the os pubis. The figure and deſcription of this ſack and the adjacent parts, may be ſeen in Phil. Tranſ. N°. 482. Sect. 2.

We read of an hydropic body becoming ſo infectious, that the ſurgeon who tapped the corpſe, was thrown into a peſtilential fever. Phil. Tranſ. N°. 454. Sect. 4.

DROPSY *of the lungs*. See HYDROPS *pulmonum*.

DROSOLITHUS, in natural hiſtory, the name of a ſtone to which many great virtues are attributed, by the writers of the middle ages; but the accounts they have left us of it, are too imperfect to give us any juſt idea of what ſtone it was. They ſay it was variegated with many colours, and that when laid upon the fire, it ſweat or oozed out large drops of clear water, all over its ſurface.

DROUGHTS—Great *Droughts* are very prejudicial to the farmer and his paſture, and ſuch years afford but very little reward for the labour and expence of keeping it in order. The only remedies are high incloſures, and plenty of water at hand. The firſt of theſe is always in the farmer's power, and ſhould be carefully provided by planting hedges in a proper manner, in counties moſt ſubject to ſuffer by this diſadvantage. The other is not always ſo eaſy, but may be managed ſeveral ways, as by ſinking wells; but theſe, when deep, are very expenſive; or by bringing the water in pipes, gutters, or other conveyances: and this is eaſily done where there is a ſpring or brook in the neighbourhood higher than the lands. Pumps, wheels, and ſuch other engines are alſo uſed in ſome places to bring on the water; and in others, ponds, ciſterns, and receptacles are made to take in the rains and winter floods, and retain the water till ſummer, when it is wanted.

The farmers of England are very deficient in this laſt method, which they might uſe to their great benefit in many places. In Spain they have no water in many parts but what they preſerve in this manner. And at Amſterdam and Venice they have whole cellars made into ciſterns, which receive the water that falls in rains, and preſerve it all the year. Want of water for the cattle in ſummer in many places might be eaſily remedied by ſome care of this kind, and many thouſand acres of land made uſeful, which are now left as waſte, by this means alone. It is very evident that this is feaſible, becauſe it is done in places where there falls much leſs rain annually than with us; and yet by this the inhabitants have always freſh water enough for the uſe of their houſes, cattle and gardens, none of which ever fail. *Mortimer*'s Huſbandry, p. 296. See CISTERN.

DROWNING (*Cycl.*) was formerly the capital puniſhment for a woman, as hanging was for men. *Hoſm.* Lex. in voc. See FOSSA and FURCA, *Cycl.*

DRUM (*Cycl.*) is uſed to ſignify a kind of fiſh in Virginia. The oil of this fiſh is ſaid to cure pains in the limbs frequent in the country. See Phil. Tranſ. N° 454. §. 1.

DRUNKENNESS (*Cycl.*) is puniſhable by the law of England [a]. The penalty is five ſhillings fine, or the ſtocks in caſe of non-payment. For a ſecond offence the guilty perſon may be bound to his good behaviour [b]. [[a] See Stat. 4. Jac. 1. c. 5. 21 Jac. 1. c. 7. [b] 21 Jac. 1. ibid.]

Hobbes [a] makes voluntary *Drunkenneſs* a breach of the law of nature, which directs us to preſerve the uſe of our reaſon. The law of England alſo does not allow it to be an excuſe in any caſe whatſoever. [[a] *Hob.* de cive.]

DRUPE, among botaniſts, a ſpecies of pericarpium, conſiſting of a ſoft, fleſhy, and ſucculent pulp, in the center of which there is a nucleus. See PERICARPIUM.

DRUSA, in natural hiſtory, a name given by ſome of the Saxon miners to the common pyrites, and by others to ſome peculiar kinds of it. But in general it is underſtood to ſignify both the pyrites and the marcaſite.

DRY (*Cycl.*)—A *dry* air, cæteris paribus, leſſens the weight of the human body, and the contrary quality increaſes it. See MOISTURE *of the air*.

DRY *Cupping*, in ſurgery, the application of cupping-glaſſes to various parts of the body, and raiſing the common tumors under them without opening them with the ſcarificator.

The uſe of *Dry cupping* is twofold, either to make a revulſion of the blood from ſome particular part affected, or elſe to cauſe a derivation of it into the affected part upon which the glaſs is applied. It is in the firſt ſenſe that Hippocrates orders a large cupping-glaſs to be applied under the breaſts of women, who have a too profuſe diſcharge of the menſes, intending thereby to cauſe a revulſion of the blood upwards from the uterus. And upon the ſame principle have hæmorrhages at the noſe been ſtopped by applying cupping-glaſſes to the legs and feet, particularly about the ankles and knees. Spitting of blood from the lungs has alſo been cured by the ſame method; and Scultetus gives a remarkable inſtance of a woman, who by the repeated application of ſix cupping-glaſſes, without ſcarification, to her thighs, was not only relieved of the troubleſome ſymptoms ariſing from an obſtruction of the menſes, but was alſo freed from the obſtruction itſelf.

Dry-cupping is alſo uſed with ſucceſs to make a revulſion by applying the glaſſes to the temples, behind the ears, or to the neck and ſhoulders, for the removal of pains, vertigos and other diſorders of the head; they are alſo applied to the upper and lower limbs, to drive blood and ſpirits into them when they are paralytick, and laſtly to remove the ſciatica, or other pains in the joints: the operation in theſe caſes is to be repeated till the part looks red and becomes painful. *Heiſter*'s Surgery, p. 308.

DRY-*meat*, in the manege, is uſed for corn and hay. After taking the horſe from graſs, or houſing him, he is frequently put to *dry-meat*.

DRYAS, in botany, the name of a genus of plants called alſo by ſome *Dryadæa*, and by Tournefort and others, made a ſpecies of the caryophyllata. The characters are theſe: The perianthium is compoſed of one leaf divided into eight ſtrait obtuſe equal ſegments, ſomewhat ſhorter than the petals of the flower. The flower conſiſts of eight oblong expanded emarginated petals inſerted into the cup. The ſtamina are numerous, very ſhort capillary filaments inſerted into the cup. The antheræ are ſimple and ſmall. The germina are numerous, ſmall and ſet cloſe together; the ſtyles are capillary, and are inſerted into the ſides of the germina, and the ſtigmata are ſimple. There is no fruit, but the ſeeds ſtand naked together, and are numerous, and of a roundiſh compreſſed figure, and ſuſtain a number of hairy ſtyles. *Linnæi* Gen. p. 223. Tourn. 151.

DRYINUS, *Oak-ſnake*, a ſpecies of ſerpent, ſo called from its being uſually found about hollow oaks. Bellonius, who has mentioned it, ſays, that ſcarce any ſerpent grows to a larger ſize, or makes a more terrible hiſſing. Authors in general ſeem however ſo little agreed about its deſcription, that it is not eaſy to aſcertain the name to any peculiar ſpecies of ſnake. *Ray*'s Syn. Anim. p. 290.

DRYITES *Lapis*, in natural hiſtory, a name given by authors to a ſubſtance but ill deſerving the name of a ſtone; it being only foſſil wood, found in detached maſſes, not in whole trees or compleat branches; which when taken up is found to retain ſo much of its vegetable nature, as to burn, tho' it appears plainly to have imbibed ſome ſtony matter. There is much of this foſſil wood found in Italy, in the banks and on the ſhores of rivers. We know alſo by what we ſee of the foſ-

ſil wood of England, that it may be found in all degrees of petrifaction, from that of almoſt unaltered wood, to abſolute ſtone or mineral matter, with only the ſuperficial grain of wood. Of the firſt kind is all our bog wood, or the trees or parts of trees found in bogs, which burn at leaſt as well as the *Dryites* of the antients; and of the latter, is the wood found in our ſtone quarries or gravel pits, converted as it were into a mere ſtone; and in our clay pits, ſo filled with the matter of the common vitriolic pyrites, as only to ſhew the external appearance of wood, the inſide being merely a maſs of that mineral matter. The famous petrifactions of the lake called Lough Neagh in Ireland, afford us alſo an inſtance of wood being partly petrified, partly left unaltered, except as to its natural decay; ſome of the maſſes found there, being in one part hard ſtone, and in the other wood, yet capable of burning and only decaying thro' moiſture without the leaſt particle of ſtony matter among them. See FOSSIL *Wood*.

DRYOPEIA, Δρυοπεια, in antiquity, an anniverſary day obſerved in memory of Dryops, one of Apollo's ſons. *Potter* Archæol. Græc. l. 2. c. 20. T. 1. p. 385.

DS JERENANG, a name by which ſome authors have called a kind of ſpecies of palm-tree from the fruit of which is procured a dragons blood. *Kempfer*, Amœn. exot. p. 552.

DUCENTESIMA, in antiquity, a tax of the two hundredth penny, exacted by the Roman emperors. Vid. *Pitiſc.* Lex. Ant. in voc.

DUCK, *anas*, in zoology, the name of a very large genus of birds, the characters of which are theſe. The beak is ſhorter in proportion, than that of the gooſe, and the feet proportionably larger. The legs are ſhorter and are placed farther backward, and the back is flatter, and the body more compreſſed. Some of theſe love the freſh waters, others are found only at ſea, and of both theſe there are very numerous ſpecies. *Ray*'s Ornitholog. p. 276.

This fowl is furniſhed with a peculiar ſtructure of veſſels about the heart, which enable it to live without reſpiration a conſiderable time under water, as is neceſſary for it in diving. This made Mr. Boyle think it a properer object for experiments by the air pump, than any of the other birds. A full grown duck being put into the receiver of the air pump, of which ſhe filled one third part, and the air exhauſted, the creature ſeemed to bear it better for the firſt moments, than a hen or other ſuch fowl; but after about a minute, ſhe gave great ſigns of diſcompoſure, and in leſs than two minutes her head fell down, and ſhe appeared dying, till revived by the leting in the air. Thus whatever facility of diving, this and other water fowl may have, it does not appear, that they can ſubſiſt without air for reſpiration, any longer than other animals. A young callow *Duck* was afterwards tried in the ſame manner, and with the ſame ſucceſs, being reduced very near death in leſs than two minutes. But it is obſervable, that both birds ſwelled extremely on the pumping out of the air, ſo as to appear much larger to the ſpectators, eſpecially about the crop. It not being intended that any water fowl ſhould live in an exceedingly rarify'd air, but only be able to continue on occaſion ſome time under water. Nature tho' ſhe has provided them with the means of this, has done nothing for them in regard to the other.

The ſtrongeſt inſtance of this creatures being calculated to live any where, we have in the accounts of the blind *Ducks* of the Zirchintzer lake in Carniola. It is now well known, that this lake communicates with another lake underground in the mountain Savornick, and fills or empties itſelf according to the fulneſs or emptineſs of that lake; the waters of the upper lake running off at the time of its emptying by large holes in the bottom, and that in vaſt quantities. The *Ducks* which are very plentiful in the water, are often carried down with it, and forced into the ſubterraneous lake the waters retire to. In this unnatural habitation, many of them doubtleſs periſh, but ſome remain alive; theſe become blind and loſe all their feathers, and in the next filling of the lake, both they and vaſt numbers of fiſh are thrown up with the water. They are fat at this time, but make a ſtrange appearance in their naked ſtate, and are eaſily caught, for want of ſight to avoid the danger. In about a fortnight they recover their ſight and their feathers, and are then of the ſize of a common wild duck, but of a black colour, having a white ſpot upon their forehead. When opened on being taken on their firſt coming up in their blind ſtate, their ſtomachs are found full of ſmall fiſhes, and ſomewhat reſembling weeds. It ſeems from this, that they cannot be abſolutely blind, but that the degree of light to which they have been accuſtomed in their dark habitation, had formed their eyes to ſee by that ſmall quantity, ſo well as to get their food by it; and their blindneſs on coming into broad day light again, is no other than that of a man who has been long in the dark, on having in an inſtant a large blaze of candles ſet juſt under his eyes. The eye in neither caſe can bear the ſudden change, and muſt be habituated to it, before it can ſee objects by it. Theſe blind *Ducks* are not only caſt up in this lake, but after great rains they are frequently thrown up at a hole in the mountain Storſeg near the town of Laas. The water guſhing out at this hole with great force on theſe occaſions, brings away with it theſe blind and bald ducks; and their frequency on theſe occaſions in theſe places, makes them eſteemed no rarity; but the common people underſtand that there are underground lakes, which they inhabit, and out of which they are thus thrown. Phil. Tranſ. N°. 191.

Northern DUCK, *Anas arctica*, a name given by Cluſius to a water fowl well known on our coaſts, and called by ſeveral other names both by authors and our own common people. Aldrovand calls it *Pica Marina*, and Fratercula from Geſner, and Wormius and Hoier, the *Lunda*. We call it in ſome places the *Puffin*, and in others the *Golden-head*, *Bottlenoſe*, *Helegug*, *Coulta-neb* or *Counterneb* and the *Mullett* and *Pope*. It is ſmaller than the common *Duck*; its beak is flatted ſideways, and is broad and ſhort, ſomewhat of a triangular figure, and ending in a point; it has a callous ſubſtance at its baſe, like that over the beak of the parrot. It is partly grey, partly red and has three remarkable furrows on it. Its legs are placed very backward, and are yellow when the bird is young, they afterwards are red, and have no hinder toe. Its head, neck and back are black, its breaſt, throat and belly white; but there is a remarkable black ring which ſurrounds the throat. The ſides of the head are alſo whitiſh, or of a very pale grey. Its wings are extremely ſhort, and furniſhed with very ſmall feathers; yet by the help of theſe it flies very nimbly along the ſurface of the water, but it cannot fly at all except its wings continually touch the water. It builds no neſt, but lays its eggs on the naked earth, or in the deſerted rabbit-holes; and what is very remarkable, each lays only one egg. This is very large, and of a reddiſh colour. They breed with us, but are birds of paſſage, leaving us in autumn, and returning about March in ſmall numbers, as if to examine the place; after which they again depart, and in May return with the whole numbers; and if it happens to be a ſtormy ſeaſon, multitudes of them are thrown dead upon the ſhores. For they are neither able to travel, nor to get food, except in calm weather. *Ray*'s Ornitholog. p. 244.

Braſilian DUCK, *Anas Braſilienſis*, the name of an American bird of the *Duck*-kind, but of the ſize of the gooſe. Its beak, legs, and feet are brown, and its body is all over black, except that the upper part of the wings is white. It is not however, of a dead or dusky black, but has a very ſtrong gloſs of green among it. It has a creſt compoſed of black feathers on its head, and over the origin of the bill a large red fleſhy tubercle, and a naked red membrane round its eyes. They fly up to the tops of the higheſt trees, and are a very fleſhy and delicately taſted bird. *Margrave*'s Hiſt. Braſ.

The ſharp-tailed DUCK, *Anas Caudacuta*, in zoology, the name of a peculiar ſpecies of *Duck*, having a long tail like a pheaſant. It is called in ſome places the ſea pheaſant, but more generally is known with us, by the name of the *Cracker*. See the article CRACKER.

Horn-DUCK, *Anas Cornicenſis*, the name of an American *Duck*, deſcribed by Nieremberg, and having its name from its imitating with its note, the ſound of the huntſman's horn. It is a very bold tho' a weak bird, and is very difficultly tamed. This is one of the many birds mentioned by this author, which from his imperfect account, it is impoſſible to know whether a new ſpecies, or ſome of thoſe deſcribed by Margrave or others. *Ray*'s Ornithol. p. 100.

Indian DUCK, *Anas Indica*, the name of a bird of the *Duck* kind deſcribed by Geſner and others, as a diſtinct ſpecies, but ſeeming by the deſcription to be the ſame, with what we call the Muſcovy *Duck*.

Lybian DUCK, *Anas Lybia*, a name given by Aldrovand, Bellonius, and ſome authors to a ſpecies of *Duck*, brought from that part of the world, but which appears to be the ſame with what we commonly know, by the name of the *Muſcovy Duck*. *Ray*'s Ornitholog. p. 295.

Muſcovy DUCK, *Anas Moſcata*, the name of a ſpecies of *Duck*, the largeſt of all the *Duck* kind. The general colour both in the male and female is a purpliſh black, though the female is ſometimes quite white. It has red fleſhy protuberances about its beak and its eyes, and its voice is hoarſe, very ſoft, and ſcarce to be heard, unleſs when it is angry. The eggs of this bird are of a remarkably round figure. *Ray*'s Ornitholog. p. 294.

The fly-catching DUCK, *Anas Muſcaria*, a name given by ſeveral authors to a ſpecies of *Duck*, from its catching flies that play on the ſurface of the water. It is deſcribed as a diſtinct ſpecies, but Mr. Ray ſuppoſes it the ſame with our wild *Duck*.

The black DUCK, *Anas niger*, a ſpecies of *Duck* larger than the common kind. The head and neck in this, are of a greeniſh black, the legs and feet red on the anterior part, and yellow below, and behind; the webs of the feet very black; all the body is black except a ſtreak of white of an inch long on the wings, and a white ſpot on each ſide of the head behind the eyes. All the feathers are ſo gloſſy and ſhining, that the bird looks as if coated with the fineſt ſattin. It never

never appears with us, except in very hard winters. On the coaſts of Norway, there are large flocks, of it. *Ray*'s Ornitholog. p. 278.

Hook-bill'd DUCK, *Anas roſtro adunco*, it is of the ſhape and ſize of the common *Duck*, but differs from it in the ſhape of the bill, which is ſomewhat longer and hooked downwards; and in the head, which is ſmaller and ſlenderer. See *Ray*'s Ornitholog. p. 294.

St. Cuthbert's DUCK, *Anas St. Cuthberti*, the name of a ſpecies of *Duck*, ſeeming to be the ſame with the *Eider* of Wormius, and other authors. The male is black and white, the female all brown. See CUTHBERT and EIDER.

Tufted DUCK, a ſpecies of *Duck* with a black head; otherwiſe called *Capo Negro*. See CAPO *Negro*.

There are four other ſpecies of *Duck*, under the following denominations, *viz.*

ANAS *Clypeata*, a ſpecies of *Duck*, called in Engliſh the *Shoveler*. It has both theſe names from the remarkable ſhape of its beak, which is broad, and rounded and hallowed at the extremity. See the article SHOVELER.

ANAS *fiſtularis*, a name given by many to the common wigeon, more generally known by the name *Penelope*. See PENELOPE.

ANAS *Strepera*, in zoology, a name by which ſome authors have called the *Gadwall* or grey, a ſmall ſpecies of wild *Duck*. See GADWALL.

ANAS *Platyrinchos*, a name given by Aldrovand and ſeveral other authors, to a ſpecies of ſea *Duck*, more commonly known by the name of *Clangula*, and called in Engliſh the *Golden Eye*. *Aldrovand.* Hiſt. p. 225. See CLANGULA.

DUCKUP, a word uſed at ſea by the ſteerſman, or he that is at the helm, when either main-ſail, fore-ſail, or ſprit-ſail hinder his ſight ſo, that he cannot ſee to ſteer by a land-mark, or the like; for then his word is, *Duckup* the clew lines of thoſe ſails: and as to the ſprit-ſail, when a ſhot is to be made by a chaſe-piece, and the clew of that ſail hinders the ſight, they ſay, *Duckup* the clew lines of the ſprit-ſail, that is, hale the ſail out of the way.

DUCTUS (*Cycl.*)—DUCTUS *pneumaticus*, in ichthyology, the name of a certain duct or canal, found in all thoſe fiſh, which have an air-bladder, reaching from that bladder to the orifice of the ſtomach, or ſome other part of it. This *Duct* is variouſly ſituated in the different kinds. In ſome, as in the ſimple bladders, it ariſes from their top or ſummit, and enters the orifice of the ſtomach. This is the caſe in the coregones, ſalmons, &c. In ſome others, as the clupeæ, it ariſes from the middle of the ſimple bladder, and is inſerted in the lower part or fundus of the ſtomach. In the double bladders, it generally ariſes from the beginning of the loweſt lobe, and enters the ſtomach at the diaphragm, this is the caſe in all the cyprini. The uſe of this pneumatic duct or canal, is evidently to admit the air from the ſtomach into the bladder, deſtined to receive it, in which it is retained, and which ſerves by its greater lightneſs than water, ſo far to balance the over-weight of the bones and muſcular fleſh of the fiſh, that it can remain ſuſpended by means of it at any depth. The pleuronecti and ſuch other fiſhes as have no air bladder, have no trace of this duct, and they always remain at the bottom of the water; and even thoſe which have it may be reduced to the ſame ſtate, by piercing it through with a needle, in which caſe the fiſh can no more riſe to the top of the water, but creeps as it were about the bottom continually. *Artedi* Ichthyolog.

DUCTUS *Roriferus*, in anatomy, the ſame with *Ductus Chyliferus*. See THORACIC *Duct*, *Cycl.*

DUKE (*Cycl.*) — DUKE, among Hebrew grammarians, is an appellation given to a ſpecies of accents anſwering to our comma. See ACCENT, *Cycl.*

DULCICHNIUM, in botany, a name given by ſome authors to the *cyperus dulcis*, or ſweet cyperus. *Ger. Emac.* Ind. 2.

DULCINO, in the Italian muſic, a wind inſtrument, otherwiſe called *Quart-fagotto*. It ſerves for tenor to the hautboy, and is no more than a little baſſoon. *Broſſ.* Dict. Muſ. in voc.

DULEDGE, in gunnery, a peg of wood which joins the ends of the ſix fellows, which form the round of the wheel of a gun-carriage; and the joint is ſtrengthened on the outſide of the wheel by a ſtrong plate of iron, called the *Duledge plate*.

DULKAK, among Arabian writers, a fabulous ſea monſter in form of a man riding on an oſtrich, which attacks ſhips, and fights with the men on board. *Hofm.* Lex. in voc.

DULL, in the manege. The common marks of a *dull*, ſtupid horſe, are white ſpots round the eye, and on the tip of the noſe, upon any general colour whatever. Though the vulgar take theſe ſpots for ſigns of ſtupidity, yet it is certain they are marks of the goodneſs of a horſe; and ſuch horſes as have them, are very ſenſible and quick upon the ſpur. The French call theſe ſpots *Marques de Ladre*. *Guillet.*

DULMA, a Turkiſh diſh made of any vegetable, as cucumbers, onions, cabbage leaves, *&c.* ſtuffed with forced meat. *Pocock*'s Egypt. p. 183.

DULNESS *of hearing*. See the article HEARING.

DULWICH *Water*, a well known mineral water near London. It contains a kind of cathartic bitter ſalt. It ſeems not to have any iron in it. Phil. Tranſ. N° 461. §. 22.

DUM *non fuit compos mentis*, in law, a writ that lies for one, who aliens any lands or tenements while not of ſound memory or judgment, in order to recover the ſame from the *Alienee*, againſt whom the writ is taken.

DUM *fuit infra ætatem*, in law, a writ which lies for him, who, before he came to full age, made a feoffment of his land, to recover it again of the *Vendee*. *Fitz.* Nat. Br. fol. 192.

DUNDIVER, in zoology, the name of a water fowl, eſteemed a diſtinct ſpecies of bird, not only by the vulgar, but by the generality of authors, but being in reality no other than the female merganſer or gooſander. It is very different from the male in colour, its head being of a dusky reddiſh brown. It has a fine creſt behind its head, and is ſo large as uſually to weigh four pounds and a half. Its back is all over of a pale grey; its breaſt and belly are of a pale aſh colour. The wings both in this and in the male are very ſhort in proportion to the ſize of the body, yet they fly along the ſurface of the water very ſwiftly. *Ray*'s Ornitheol. p. 253.

DUNG, in agriculture, &c. All kinds of *Dung* contain ſome matter, which when mixed with the ſoil ferments therein, and by that fermentation, diſſolves the texture of the earth, and divides and crumbles its particles very much. This is the real uſe of *Dung* in agriculture, for as to the pure earthy part of it, the quantity is ſo very ſmall, that after a perfect putrefaction, it bears an extremely inconſiderable proportion to that of the earth it is intended to manure. *Tull*'s Husbandry.

The fermenting quality of *Dung* is principally owing to the ſalts it contains, and yet thoſe or any other ſalts applied immediately to the roots of plants always deſtroy them. This proves that the buſineſs of the *Dung* is not to nouriſh but to divide and ſeparate that terreſtrial matter, which is to afford the nouriſhment to vegetables, through the mouths of their roots. And the acrimony of the ſalts of *Dung* is ſo great, that the niceſt managers of vegetables we have, the (floriſts) have wholly baniſhed the uſe of it from their gardens. The uſe of *Dung* ſhould be alſo forbid in kitchen-gardens, for it is poſſible to ſucceed full as well without it; and it gives an ill taſte to all the excellent roots and plants, that are to ſtand in the earth in which it is an ingredient. The water of a cabbage raiſed in a garden, manured with *Dung*, if boiled is of an intolerable ſtink; but this is not ſo much owing to the nature of the plant, as of the manure uſed to it; for a field-cabbage being boiled, the water has ſcarce any ſmell, and what it has, is not diſagreeable.

It is alſo a well known fact in the country, that a carrot rais'd in a garden, has nothing of that ſweet flavour, that ſuch as grow in the fields have, but in the place of this natural reliſh, the garden one has a compound taſte, in which the matter of the manure has no ſmall ſhare. And there is the ſame ſort of difference in the taſte of all roots, nouriſhed with ſuch different diet. *Dung* not only ſpoils the flavour of the eſculent vegetables, but it ſpoils the drinkables into the original compoſition of which it enters: they are obliged to uſe *Dung* to the poor vineyards in Languedoc, and the conſequence is, that the wine is nauſeous. The poor who only raiſe a few vines for the wine they drink themſelves, and cannot be at the expence of this manure, have the leſs of it, but then it is better by many degrees than the other: and it is a general obſervation which the French expreſs in theſe words, that the poor people's wine in Languedoc, is the beſt, becauſe they carry no *Dung* into their vineyards. *Tull*'s Horſehoing Husbandry, p. 20.

Another diſadvantage attending the uſe of *Dung* is, that it gives riſe to worms. It is for this reaſon, that garden carrots are generally worm eaten, and field carrots ſound; and the ſame obſervation will hold good in other vegetables, in the field and in the garden. Vegetable and animal *Dung* are in fact only the putrefaction of earth, after it has been altered by paſſing through vegetable or animal veſſels. Vegetable *Dung*, unleſs the vegetable be buried alive in the ſoil, makes a much leſs ferment in it, than animal *Dung* does: but the *Dung* or putrid matter of vegetables is much more eligible and wholeſome for the eſculent roots and plants, than that of animals is. Venomous animals are found to be very fond of *Dung*, and are brought into gardens by the ſmell of the *Dung* uſed in them as manure. The ſnakes uſually frequent *Dung*-hills, and lay their eggs in them; and gardens where *Dung* is much uſed, are always frequented by toads; whereas the fields where roots are planted, are much leſs infeſted by them.

However unneceſſary and prejudicial *Dung* is in gardens, it is however very neceſſary in the corn fields, and little can be done without it in the old method of husbandry. *Dung* is not ſo injurious in fields as in gardens, becauſe it is uſed in much ſmaller quantities in proportion to the quantity of ſoil, and cabbages, turnips, potatoes and other things growing in fields, and intended only for the food of cattle, will not be injured by *Dung*, tillage, and hoeing all together; for the crops will by this means be the greater, and the cattle will like the food never the worſe. *Dung* is very beneficial in giving large crops of wheat; and it is found by experience, that the country farmers at a diſtance from a large town, can never have ſo good crops by all his tillage, as thoſe who live in the neighbourhood of cities, where *Dung* is produced in great plenty,

and eaſily had. The *Dung* uſed in fields, beſides its diſſolving and dividing virtue is of great uſe in the warmth its fermenting gives to the young plants of the corn in their weakeſt ſtate, and in the moſt ſevere ſeaſons; the laſting of this ferment is not eaſily determined, becauſe the degrees of heat, are very difficult to be judged of when they become ſmall.

The farmers uſually underſtand by the term *Dung*, not only the excrements of animals, with the litter, but every thing that will ferment with the earth; ſuch as the green ſtalks and leaves of plants buried underground and the like. And every thing they add to it except fire.

The uſes of the *Dungs* of ſeveral animals are ſufficiently proved every day. They are uſed to repair the decays of exhauſted and worn-out land, and to cure the ſeveral defects in different naturally bad ſoils; the faults of which are as different, as the nature of the different *Dungs* uſed to improve them. Some land is too cold, moiſt and heavy, and the other too light and dry: and to improve and meliorate theſe, we have ſome *Dung* hot and light, as ſheep's, horſes's, pidgeons, &c. and others fat and cooling, as that of oxen, hogs, &c.

There are two remarkable qualities in *Dung*; the one is to produce a certain ſenſible heat capable of bringing about great effects. The other is to fatten the ſoil, and render it more fertile. The firſt of theſe is ſeldom found in any other *Dung*, but that of horſes and mules, while newly made and a little moiſt. The great effects of this, are ſeen in the kitchen garden, where it invigorates and gives a new life to every thing, ſupplying the place of the ſun; and to this we owe in a manner, all the vegetable delicacies of the ſpring.

Beſide this, horſe *dung* is the richeſt of all improvements that can be had in any quantity for poor hungry lands; yet when either too new, or when uſed alone, it is very prejudicial to ſome lands; and if ſpread too thin on dry lands in ſummer, it becomes of very little ſervice, the ſun ſoon exhaling all its richneſs, and leaving it little more than a heap of ſtubble or dry thatch. And though too much of it can hardly be uſed in the kitchen garden among colliflowers, cabbages, and the like, yet it is eaſy to over *dung* land intended for corn, and gives riſe by that means to a very fatal quantity of weeds.

Horſe *dung* is always beſt for cold lands, and cow *dung* for hot ones; but being mixed together, they make a very good manure for moſt ſorts of ſoils, and for ſome they are very properly mixed with mud.

Sheep's *dung* and deer's *dung* differ very little in their quality, and are eſteemed by ſome, the beſt of all *dung* for cold clays; for this purpoſe ſome recommend the beating them to powder, and ſpreading them thin over the autumn or ſpring crops, at about four or five loads to an acre, after the ſame manner, as aſhes, malt-duſt, &c. are ſtrewed. And in Flanders and ſome other places, they houſe their ſheeps at nights in places ſpread with clean ſand, laid about five or ſix inches thick, which being laid on freſh every night, is cleared out once a week, and with the *dung* and urine of the ſheep, is a very rich manure, and ſells at a very conſiderable price. It is principally uſed for ſtubborn lands; but Mr. Quinteney is of opinion, that it is the beſt of all manure for land in general.

Hog's *dung* is by many recommended as the fatteſt and richeſt of all *dung*, and is found on experience, to be better than any other kind for fruit trees, apples, pears and the like; it is alſo a very rich *Dung* for graſs, and is ſaid to do as much good in one load, as any other *Dung* whatever in two.

The *Dungs* of pidgeons, hens and geeſe are great improvers of meadow and corn land. That of pidgeons is unqueſtionably the richeſt that can be laid on corn land; but before it is uſed, it ought to be expoſed for ſome time out of the dove-houſe to the open air, to take off its fiery heat. It is in general very proper for cold clay lands, but then it always ſhould be well dried before it is laid on, becauſe it is apt to clod in the wet. It is beſt alſo to mix it with ſome dry earth to break its parts, that it may be ſpread the more regularly; and it is in itſelf ſo very rich and hot, as to bear ſuch an admixture, without any great impoveriſhing it. This *Dung* is alſo by ſome recommended as better than any other for aſparagus, and ſtrawberries, and for the propagation and culture of the tenderer garden flowers.

The *Dung* of pidgeons is alſo particularly recommended by Mr. Gentil for thoſe trees, whoſe leaves are apt to turn yellow, if they grow in cold ſoils; but for this uſe it ſhould firſt lie three years in a dunghil, and then be applied ſparingly in autumn, laying about an inch thickneſs of it at the root of the tree, and ſuffering it to remain there till the March following.

The *Dung* of poultry being hot and full of ſalts, tends much to facilitate vegetation, and is abundantly quicker in its operation than the *Dung* of animals, which feed on the leaves of plants. It is an obſervation of Sir Hugh Plat, that one load of grains will enrich ground, more than ten loads of common *Dung*; and it is eaſy to infer from hence, that the ſame grain muſt needs be of greatly more virtue, when it has paſſed through an animal body. Human *Dung* is alſo a great improver of all cold and ſour lands, but ſucceeds beſt when mixt with other *Dungs* or earths to give it a fermentation.

But for all ſtubborn clayey ſoils, there is no manure ſo good as the cleanſing of London ſtreets; the parts of tough land will be more expeditiouſly ſeparated by this, than by any other compoſt, and where it is to be had, it is of the greateſt value both for field and garden land. *Miller*'s Gard. Dict.

Gooſe-DUNG. This is a very valuable manure, and as uſeful to the farmer as pidgeon's *Dung*, or that of any other fowl. The antients thought otherwiſe, and condemned it as prejudicial both to corn and graſs, and many are of the ſame opinion ſtill; but without any foundation in fact. Indeed where corn is high, and when graſs is ready to mow, theſe birds if they get among it will do great damage by treading it down with their broad feet, but their *Dung* inſtead of being hurtful to the land, does it great ſervice. Near Sutton in Notinghamſhire, there is a barren piece of land given by the town, for a gooſe-paſture; the geeſe have been kept in it many years, and their *Dung* has ſo enriched it, that it is one of the fruitfulleſt pieces of ground, in the whole country. There has been an opinion alſo, that cattle feeding on graſs, where theſe creatures had much dunged the ground, would ſuffer by it; but it appears from trial, that cattle are moſt fond of all of thoſe parts of paſtures, where the geeſe have dunged moſt; and that they ſuffer no alteration by it, except the growing fat upon it.

The *Dung* of fowls in general is very enriching to land. Fig-trees, aſparagus-beds, and ſtrawberries, and many curious flowers ſucceed better in earth manured with pidgeon's *dung* than in any other; and Fowley Iſland in Lancaſhire, a place ſo called from the abundance of wild fowl continually found on it, is ſo enriched with their *Dung*, that it fattens ſheep in a ſurpriſing manner. *Mortim*'s Husbandry.

DUNG-WORMS, a ſpecies of fly-worms of a ſhort and ſomewhat flat body found in great plenty among cow-dung in the months of September and October. Theſe have all their metamorphoſes into the fly ſtate, performed within a ſhell of their own skin.

The worm in its firſt transformation, and when it is become only a caſe to the encloſed nymph, is not diſtinguiſhable by the eye from another that is living, but by its wanting motion, and on feeling, it always appears ſtiff and rigid in this ſtate.

The fly produced from this worm, is one of Reaumur's firſt claſs of the two winged flies; it has a trunk with lips, and has no teeth; it is of the claſs of thoſe with the ellipſoid bodies, but its body is remarkably long for one of thoſe, and is compoſed of ſix rings: its head is very round, and nearly of a ſpherical form, and is large in proportion to its body; it has antennæ of the lenticular or battledore form; its reticular eyes are of a deep cheſnut brown, and its three ſmall eyes are placed in the common manner: its corcelet is of a fine gilded green, and its back is not eaſily to be deſcribed as to colour, for it is changeable and ſeems compoſed of a violet colour, and of a deeper and a paler copper colour. The under part or belly, is of a pale yellow, and the legs and balancers of a yet paler yellow. *Reaumur*'s Hiſt. Inſect. v. 4. p. 350.

DUNLIN, in zoology, an Engliſh name of a bird of the ſnipe-kind, not diſtinguiſhed by the Latin authors by any particular name. It is of the ſize of the ſmaller ſnipe, its beak is furrowed, its breaſt is white, as is alſo its throat, and both are variegated with black ſpots; the middle of the belly is black, variegated with white, and all the back and other upper parts of a rediſh hue, variegated with ſpots of black, and with a little white; its wings are of a bluiſh brown, its legs long and black, and the hinder toe very ſhort; the tail is variegated with brown reddiſh and white. It is common in watery places in the northern counties of England, and picks up its food out of the mud. *Ray*'s Ornitholog. p. 226.

DUNTER-*Gooſe*, a ſpecies of the wild gooſe found in Zetland. Phil. Tranſ. N° 473. §. 8.

DUODENUM (*Cycl.*) — The deſcription and draughts of the *Duodenum*, as given by moſt anatomiſts, appearing faulty, Mr. Monro has endeavoured to rectify their omiſſions and miſtakes in the Med. Eſſ. Edinb. vol. 4. art. 11.

This inteſtine is ſometimes found ſo large, as to be called *ventriculus ſuccenturiatus*. Id. ibid.

Authors ſeldom take notice of the *Duodenum* as the ſeat or cauſe of any particular diſeaſe; but its diſtenſion and preſſure on the many veſſels to which it is contiguous, may diſturb the functions of the animal œconomy.

DUPLICATE *Root*, among botaniſts, one compoſed of two coats. See ROOT.

DUPLODES. See GAMBEZON, *Cycl.*

DURALE, or DURO, in the Italian muſic, ſignifies hard, harſh, or more properly ſharp. This name is given to B natural, by reaſon its ſound is ſharp, when compared with B mol, or flat. *Broſſ.* Dict. Muſ. in voc.

DURANTA, in botany, the name of a genus of plants firſt deſcribed by *Plumier* under the name caſtorea. The characters of the genus are theſe. The cup is a one leaved erect perianthium divided into five acute ſegments, containing the germen of the piſtil, and remaining after the flower is fallen. The flower is monopetalous, and of the gaping kind. The tube is long and cylindric. The limb is divided into two lips; the

the upper one is oval, erect, and concave; the lower is divided into three principal ſegments. The two ſide ones roundiſh and expanded, and the middle one divided again into two roundiſh ſegments. The fruit is a round berry covered with the cup, containing four angular ſeeds in one cell. *Plumier*, p. 17. *Linnæi* Gen. Plant. p. 521.

DURION, in natural hiſtory, the name of a fruit common in China and the Eaſt Indies, and eſteemed by the Indians the fineſt of all fruits; but the Europeans do not allow it this, becauſe of its diſagreeable ſmell. The tree which bears it is large and much branched, and its wood is like that of the hazel. The leaves are of a very ſingular figure, being about ſix inches long, and ſixteen or eighteen inches broad: they terminate in a long and ſlender point. The upper ſide of the leaves is of a dusky green, the under ſide is whitiſh with ſome yellow ſpecks. The leaves grow on ſhort pedicles, which are joined to the ſtalks by a protuberance or oblong knot. The fruit grows to the large branches, adhering to their middles by a ſtrong wood ſtalk. It is of the ſize of an ordinary melon, and of a conic ſhape, pointed at the extremity, and is all over beſet with prickles reſembling thoſe of a hedge-hog: they are green, and very large and thick. When thoroughly ripe, the fruit opens at the extremity into five parts, and the cracks or openings running by degrees up to the top, the inner ſubſtance or pulp is diſcovered. This is of a whitiſh colour, and of a very agreeable flavour, which may not unaptly be compared to that of cream and ſugar; but it is of a more firm conſiſtence. This fruit contains in every compartment five large ſeeds perfectly reſembling the common cheſnut, but that they have no other covering than their own skin.

The courſe of vegetation is elegantly ſeen in diſſecting the pedicle which ſupports this fruit; for in this are ſeen the three different juices which ſerve to the nouriſhment of the three different parts of the fruit. In cutting this pedicle tranſverſly, we firſt find between the bark and the woody fibres, a yelloviſh, thick, and glutinous juice: this ſerves for the nutriment of the thorns. A ſecond juice diſcovers itſelf within the firſt woody fibres, which is white and more ſolid, and leſs glutinous. This gives nouriſhment to a thick skin of a ſilvery white, which lines the pulpy part of the fruit. And, finally, in the center of the pedicle there runs a third, much whiter and ſofter than the former, which ſerves to the nouriſhment of the pulp, or ſoft and ſweet-taſted part of the fruit.

The fruit itſelf, were its ſmell as agreeable as its taſte, would vye with any fruit in the world; but its very diſagreeable ſcent requires time and cuſtom to enable any one to bear it; but uſe makes the natives wholly diſregard it. The ſmell is very like that of onions, that have lain in heaps till they are very rotten. The fruit is not only agreeable to the taſte, but of a very cordial virtue; but it will intoxicate and get into the head, if eaten in a large quantity, eſpecially ſuch of the fruits as are of a yelloviſh colour. The natives make debauches with it, as our poorer people do with ſpirituous liquors. But it is not ſo eaſily come at as thoſe, and therefore is very fatal to many families among them, who will ſell their liberties for a time to purchaſe enough of it for a debauch.

The *Durion* tree flowers in January. The flowers are of a dusky colour, and of the ſize of a nut. As ſoon as theſe fall, the fruit begins to appear. It afterwards increaſes ſlowly in ſize till the month of June, in which it begins to ripen. Others continually ſucceed theſe early ones during the whole ſummer, ſo that there is a ſucceſſion of them during that ſeaſon, and they do not begin to grow ſcarce till about the middle of October. Mem. Acad. Scienc. Par. 1699.

DURUNEGI, in the materia medica, a name given by the Arabian writers to the root of the doronicum, which is ſo well deſcribed by Aviſenna, that we are very well informed of its nature, and find it to be the root of the ſame plant, which we at this time know by that name. He ſays it came to them in pieces, looking like the ſhort joints of a woody root; and that it was either yellow or white on the inſide, and of a greyiſh colour on the ſurface, and that it was conſiderably hard and ponderous.

The doronicum we know at this time has a root that very well anſwers theſe characters; and tho' yellow, when freſh, is very apt to become whitiſh in decaying. The interpreter of Aviſenna, whoſe comments are moſt generally received, adds, that the pieces of *Durunegi* in the ſhops were about the length and ſize of the laſt joint of the thumb. But it is not eaſy to make out this from the text without making very free with the words; and indeed the pieces of the doronicum we now receive from Germany are generally longer and thinner than this deſcription ſeems to make them, though they very well anſwer to the account of Aviſenna of their coming off in a ſort of joints. The root being naturally jointed, or compoſed of a great number of pieces.

The name *Durunegi* is a very plain copy of the Greek name of the ſame plant, which is not doronicon, as might be ſuppoſed from the Latin doronicum, but *durunizi*, or δωρωνιζι. The change of the ζ into a *g*, or the *g* into a ζ, is very common in the turning Greek into Arabick, or Arabick into Greek names. Thus the zedoar of the Greeks is the geduar of the Arabians, and ſo in a thouſand other inſtances.

The word *Durunegi*, or, as it is ſometimes written, *Duronegi*, is however ſometimes made to expreſs another plant, whoſe ſhape, as well as virtues, are very different from that abovementioned.

The ſecond kind of *Durunegi* was a root not jointed, but formed all of one piece, and very much reſembled our zedoary in ſhape. It was always white on the inſide, and grey on the ſurface, 'twas of an agreeable taſte, and was preſcribed as an aromatic and cardiac in many compoſitions. In the viaticum Conſtantini we find it preſcribed along with ſpikenard, cinnamon, and zedoary; and in another part of the ſame piece, nutmeg, caſtor, duronegi and zedoary are preſcribed together. It is very evident from this, that the *Durunegi* here meant, could not be the poiſonous doronicum; and it is much to be lamented, that we do not find different names for ſo very different plants. We have at this time two plants of the doronicum kind, the one called thora, and the other antithora; the one allowed to be a poiſon, the other by many eſteemed an alexipharmic. The thora, or poiſonous kind, is yellow within, and the antithora is white. Theſe may probably be the two kinds of *Durunegi* mentioned by the Arabians: and if ſo, the poiſonous qualities of the one, and the virtues of the other, ſtand on a higher record than many have ſuppoſed. Theſe two roots were lately ſent over into England among four parcels of gentian, and did much miſchief, many people ſuffering greatly by the bitter infuſions in which they made a part. This was probably owing wholly to the thora, or yellow root, which has a poiſonous ſmell; not to the other, which has all the appearances of being innocent.

DUST *Moſs*, in botany. See BYSSUS.

DWARFS (*Cycl.*)—*Dwarfs* were called *Nani* and *Nanæ* amongſt the Romans; and were held in ſuch requeſt, that artificial methods were uſed in order to prevent the growth of boys deſigned for *Dwarfs*, by incloſing them in a box, or binding them with bandages. Auguſtus's niece Julia, was mighty fond of one of theſe *Dwarfs* called Sonopas, who was only two feet and a hand-breadth high. *Pitiſc.* See DWARFING.

DWARF-*Trees*, were formerly very much in requeſt in gardens, but ſince the introducing of Eſpaliers, they are much neglected. The manner however of propagating *dwarf* pears, which have been found to ſucceed the beſt of any *Dwarfs*, is this: they are to be grafted on a quince ſtock, and that at about ſix inches above the ground, and when the bud has ſhot ſo far as to have four eyes, it is to be ſtopped, to give riſe to lateral branches. Two years after the budding, the trees will be fit to tranſplant to where they muſt remain. They ſhould be ſet at five and twenty feet ſquare diſtance, and the ground between may be ſown or planted for kitchen uſe, while the trees are young, only obſerving not to plant too near their roots. There ſhould be ſtakes driven down all round the tree, to which the branches muſt be nailed with liſt, while they are young, training them into an horizontal direction, and no branches are to be ſuffered afterwards to croſs one another, and in the ſhortening the ſhoots, the uppermoſt eye muſt always be left outwards. The ſummer and autumn pears are thoſe which do beſt in *dwarfs*, for the winter ones never ſucceed well on them.

Apples are alſo ſometimes planted as *Dwarfs*, and are for this purpoſe moſt commonly grafted on paradiſe ſtocks. Theſe ſpread much leſs than the pears, and therefore need only be ſet at about eight feet diſtance. Some alſo plant apricocks and plumbs for *Dwarfs*, but theſe being of a more tender conſtitution ſeldom ſucceed well. *Miller*'s Gard. Dict.

DWARF *Fern*, in botany. See FILICULA.

DWARFING, a term uſed by ſome authors for the ſtopping the natural growth of animals, and rendering them ſmaller than they would naturally be. In Bononia they are very fond of ſmall dogs; and inſtead of ſtopping their growth by the way in uſe here, of giving them milk wherein daiſy-roots are boiled, they do it by waſhing their feet and their back-bone every day, from the time they are pupped, with either cold water alone, or water with aſtringent ingredients, ſuch as biſtort and oak-bark boiled in it. This prevents the extenſion of the parts by hardening and corrugating them. They preſcribe alſo a method of *dwarfing* of men by anointing their back-bones in their infancy with the greaſe of moles, bats, and dormice. But this ſeems merely imaginary. The other operating by natural cauſes may poſſibly have ſome effect; and perhaps the addition of alum to the water, and making them take ſpirituous liquors internally, might be of great uſe. Act. Erud. Lipſ. 1670.

DYES *Yellow*. See the article YELLOW.

DYERS's Weed. See LUTEOLA.

DYEING (*Cycl.*) — The art of *dyeing* is indebted for many of its valuable colours to the vegetable kingdom; and may be much more ſo, if the world will be at the pains of enquiring into the properties of the plants that grow about the fields. Mr. Juſſieu obſerved in the drying plants between ſheets of paper, in order to the making a hortus ſiccus in the common way, that

ſome

ſome plants tinged the paper with colours the ſame with thoſe they naturally poſſeſs, and others with different ones; and that many plants in drying aſſumed a colour which was not natural to them. Alkanet, woad, the ſeveral ſorts of gallium, and ſome of the ſpecies anonis, tinge the papers between which they are dried to a yellowiſh or reddiſh colour, becauſe their ſtalks, or ſome other part of them, are of that colour. The common ros ſolis, or ſun dew, whoſe leaves are red, tinges the paper red alſo; and the ros ſolis of Portugal diffuſes this tinge through three or four ſheets of paper. The alpine veronica, though green in itſelf, leaves its mark in red upon the paper; and many of the common leguminous plants always become black in the drying. The common mercury, which is green while growing, becomes blue in the drying; and turneſol has the ſame change, though it is white in its natural ſtate.

One great reaſon of theſe changes of colour is, that all paper is impregnated with alum; and this ſalt may very eaſily extract, or even alter the colours of plants, whoſe juices it receives; and in ſuch caſes, where the alum is not in ſufficient quantity to do this, it is no wonder that it ſhould however ſo far affect the leaves as to turn them black.

On this principle Mr. Juſſieu attempted, by means of alum, to ſeparate colours from ſeveral plants, not known or uſed at preſent among the dyers, which might prove ſerviceable to them. The firſt experiments made on this occaſion proved, that there were many plants not uſed at preſent, which afford colours not at all inferior to thoſe in common uſe. The experiments the ſame gentleman tried on the drugs uſed for *dyeing* in the Indies, proved very plainly that they were no way ſuperior in many caſes to vegetables of our own growth; and that in order to have the moſt lively colours from ſuch ſubſtances, it is always neceſſary to have recourſe to ſome ſalt.

Among the other drugs uſed abroad in *dyeing*, there were ſent over to France, on this occaſion, certain yellow flowers of the radiated kind, which afforded on trial a very beautiful yellow dye; and Mr. Juſſieu found, on trying parallel experiments, that there were alſo yellow flowers in Europe of a like radiated kind, which were capable of affording a like beautiful yellow *dye*.

The flower which Mr. Juſſieu tried theſe experiments upon, was the common yellow corn marygold, the chryſanthemum ſegetum of Lobell. This plant flowers in the middle of July, and Mr. Juſſieu drying its flowers between papers at that time of the year, found that they did not loſe their colour, as moſt others do in the operation, but became of a deeper yellow than before. Hence it was eaſy to judge, that this flower contained a matter proper for colouring; and decoctions being made of it of different ſtrength, cloths of different kinds dipped into them became tinged to a light pale yellow, and kept this colour after being boiled in fair water. A little alum was after this added to the decoctions, and cloths dipped in theſe became much more finely *dy'd*, the colour being greatly ſtronger and more lively. They alſo imbibed the colour much more ſpeedily from theſe decoctions; and on boiling afterwards in water, they loſt no part of it, but remained as ſtrongly and as lively tinged as before. This experiment was afterwards tried by a *dyer*, under whoſe hands it ſucceeded much better than before with Juſſieu, who was unacquainted with the regular methods of the trade. The decoction of the flowers gave a ſort of ſulphur colour; but linnen, woolen, and ſilken things, which had been the day before ſteeped in alum water, received from this decoction a very beautiful and ſufficiently ſtrong yellow. Another decoction of the flowers made ſtronger than the firſt, tinged a woollen cloth to a greeniſh lemon colour; and the ſame decoction gave a bright gold yellow to ſilk: and a piece of woollen cloth, before *dyed* blue with indigo, on dipping it in this decoction became of a beautiful deep green. A ſmall quantity of chimney-ſoot added to the decoction made it tinge cloth to a yellowiſh brown; and a ſmall quantity of roucou added to the ſimple decoction produced an olive yellow.

The mixture of ſeveral other drugs uſed to be added to the decoctions of the common luteola or dyer's weed to vary its tinge, produced the ſame changes with the decoction of this flower, and abundantly teſtify'd its value and uſe in the *dyeing* trade. Mem. Acad. Par. 1724.

There is great reaſon to believe, that the art of *dyeing* might be carry'd to much greater perfection than it is at preſent, if the attempts to improve it were in proper hands, and the perſons employ'd in it could be enabled to ſet out with all the knowledge there is at preſent in regard to its ſeveral materials, and their manner of uſe, as a fund of real facts on which to ground future diſcoveries. This however ſeems difficult to be brought about, for the people who exerciſe the art generally are acquainted only with a certain ſet of rules, which though they know not why they follow, yet they will not depart from them, and eſteem every thing loſs of time that can be propoſed to them as improvements. They keep their knowledge alſo a cloſe ſecret from thoſe who might be expected to improve upon it; and uſually one man trades only in ſome one part of it without any knowledge of the reſt. Hence the difficulties attending the acquiring a knowledge of the firſt principles of the art are very diſcouraging, but they are not unſurmountable. The idea which preſents itſelf moſt naturally to us, as to the manner in which ſtuffs are *dy'd*, is, that the colouring particles which ſwim in the liquor, immediately attach themſelves to the ſurface of the body that is plunged into it, and there adhere in ſo firm a manner, that there is no removing many of them without wholly taking off the ſurface of the body. The barely plunging a white ſubſtance into a coloured liquor is not however ſufficient for the *dyeing* it in many caſes. Indeed there are only a few colours which will ſtrike with this eaſe and facility; and the others require that the matter to be *dy'd* ſhould have firſt received the particles of another fluid, which is in moſt caſes a ſolution of alum and tartar in common water. And, according to the nature of the colour that is to be given the ſtuff afterwards, the alum is put in in large quantities, or the ſtuff boiled in the liquor a longer or a ſhorter time. After boiling in this liquor, a ſtuff is in the proper condition to receive the greater part of the common colours: but for blue, ſtuffs require no preparation at all; and for ſcarlet, the liquor in which they are firſt boiled is made without alum.

The matter of the ſtuff to be *dy'd* makes it neceſſary alſo to change the liquor in which it is to be boiled, or to vary the ingredients; and the greateſt naturaliſt, without a mechanical knowledge of *dyeing*, would be amazed to ſee, that if a ſkain of white wool, and another of white cotton, be plunged together into the ſcarlet *dye*, and this even after they have both received the ſame previous boiling and preparation, the ſkain of cotton would come out of the liquor as white as it was put in, while the wool comes out tinged to a beautiful fire colour. The dyer however ſees this every day without any admiration of the cauſe, and never troubling his thoughts about how it is done. He uſes it daily to *dye* any thing woollen to a ſcarlet colour, leaving a part white: in order to which, he knows there requires no more than that the part to be left white ſhould be of cotton.

Mr. Dufay ſuppoſing this to be owing to the cotton's imbibing much more ſlowly than the wool, the liquor in which they are both previouſly boiled to make them receive the colour, as cotton is well known not to take wet ſo ſoon as wool, ordered a ſort of cloth to be wove, the warp of which was wool, and the woof cotton; and ſending this to the fuller's, the two ſubſtances were ſo well blended together, that it became impoſſible for the one to receive the impregnation of any liquor without the other. With all theſe precautions however, the whole came out of the ſcarlet *Dye* in the ſame condition as if nothing had been done, the cotton remaining wholly white, and the wool being marked with fire colour and white; ſo that it may be eſteemed a certain fact, that the colour of cochineal cannot be given to cotton by the means of acids; the ſame alſo holds good of kermes and gumm-lac, both which are uſed inſtead of cochineal to *dye* in ſcarlet; but neither of theſe, any more than the cochineal, will *dye* cotton. It is not to be concluded from hence however, that cotton cannot be *dy'd* ſcarlet by theſe ſubſtances; the whole is, that it requires a different treatment; and as wool, to take the ſcarlet *dye*, requires only to be firſt impregnated with tartar; cotton requires to be firſt impregnated with alum, as wool does, for the generality of the other colours. The acid of ſea-ſalt, of vitriol, vinegar and verjuice, all ſerve to *dye* wool to a ſcarlet with cochineal, but none of theſe will make it give any tinge to cotton, to which alum alone can ſerve.

The ſame *Dye* will give very different colours to the different parts of a cloth, which have been differently prepared. And this gentleman ſhewed before the academy a piece of cloth, which he had careſully prepared in a different manner in the different parts, which being all plunged together into the *Dye*, when taken out and dry'd was found to be of a dirty red in that part where it had not been impregnated with any thing; and in the other parts, where it had been differently impregnated, was found of all the degrees of red, from a pale damask roſe colour to the deepeſt ſcarlet, and this while it had in every part been dipt an equal time in the ſame *Dye*. This equally holds good of the other colours. And in theſe experiments the dirty colours given to ſuch parts of the cloth as have received no previous impregnation, will be waſhed away and quite carried off, while the others remain in all their perfection.

Another circumſtance very worthy attention in the *dyeing* of ſcarlet is this, that the *Dye* is evidently compoſed of a clear or common water, in which the colouring particles are ſuſpended, and from which it is eaſy to ſuppoſe that they are ſeparated and applied to the ſtuff in *dyeing*. As this is naturally ſuppoſed to be the caſe in regard to all colours; ſo it appears very evidently to be a fact in this, ſince the colouring particles adhere in ſuch quantities to the matter, and ſeparate themſelves ſo readily and perfectly from the water, that after an hour and half's boiling of the *Dye* with a proper quantity of the ſtuff in it, the whole colour'd matter ſhall be attached to the ſtuff, and the remaining liquor be only clear water; and what

might appear wonderful is, that all the boiling in the world will never diſlodge any of the colour from the ſtuff, or occaſion its being received into the water again.

It might be ſuppoſed that this was wholly owing to the particles of ſalts, which had been imbibed into the ſtuff in its prior preparation; that theſe attracting the particles of the colour to the ſtuff, while the water of the *Dye* had none of them to cauſe ſuch an attraction in it, they did not remain in it. But this appears not to be the caſe, but that the ſtuff will attract the colour, whether it be previouſly prepared, or the preparation and the *dyeing* be all one act; ſince the dyers ſometimes *dye* ſcarlet at once in this manner, only plunging the ſtuff into a dye made of cochineal, a ſolution of tin mixed in a large quantity of water, with a ſmall quantity of ſal armoniac and cream of tartar. All theſe ingredients are mixed together before the ſtuff is put in; yet after it has boiled about an hour and half, all the colour is in the ſtuff, and the liquor is become colourleſs as water. The event is the ſame in the dyes made of woad and of indigo for the *dyeing* blue, and indeed in the greater part of other colours; but as the ingredients of theſe are not ſo pure as the cochineal, and there are uſually many heterogene particles among them, the liquor does not become ſo wholly colourleſs in theſe, as in the caſe of the ſcarlet. But the dyers, who well know that ſo long as there is any colour left in the liquor, ſo long the ſtuff will be profited by remaining in it, always take ſmall quantities out of it, and examining it by pouring it gently down againſt the light, they know when it is that the ſtuff has received all the tincture it can, by there being no more colouring matter ſuſpended in the *Dye*.

Experience ſhews, that all colours do not attach themſelves with equal readineſs to the ſtuff, or remain equally firmly united to it. Woad, indigo, cochineal, kermes, and many other colours, never reach farther than the ſurface of the ſtuff. The liquor of the *Dye* penetrates indeed perfectly through the body of it, but the colouring particles ſtopping at the ſurface become entangled there, and never penetrate, at leaſt not in any great quantity, to the central part, which remains either quite white, or only very ſlightly tinged. This however only happens to ſuch ſtuffs as are thick, and of a very cloſe texture: others are coloured throughout. And this is only the caſe in regard to ſome *Dyes*, not to all ſorts, ſince the moſt of the wood colours penetrate wholly through the ſtuff be it ever ſo thick, and colour it equally every-where. Whence it ſeems probable, that the colouring particles of the woods are either more minute and fine, or much more intimately blended with the water, than thoſe of cochineal, indigo, and ſuch others as do not penetrate beyond the ſurface.

It might ſeem ſtrange, that the ſtuffs which are thus readily coloured on the ſurface, ſhould not afterwards, by the continued boiling of the water, have the colouring particles carried farther down into the body, as the water continually penetrates the whole from each ſurface to the center, and might naturally be expected to carry a part of the colouring particles in along with it. But if we conſider the whole proceſs from the beginning, we find that the colouring particles are ſtrongly attracted by the ſtuff, and ſcarce at all by the water. Whence they almoſt immediately leave the water, and attach themſelves to the firſt part of the ſtuff they come in contact with, which is its ſurface; and when once fixed there, it is no wonder that the particles of water, ever ſo long paſſing by them, do not attract or take them away from this ſurface, as they muſt do in order to carry them in; ſince we have before had proof, that their attraction to the water is greatly weaker than that to the ſtuff. And the difference between the wool and the cotton, the one receiving, and the other not receiving at all the coloured particles in its natural ſtate, or with the ſame impregnation by means of which the other does, ſeems reſolvable into the ſame principle, that tho' the attraction in wool be much greater in regard to the coloured particles than that of the water, and therefore it robs the water of them; yet the attraction in cotton being leſs than in water, the colouring particles remain in the water without any tendency to attach themſelves to the cotton.

In *dyeing*, the ingredients uſed for the colours are well known to be of very different kinds. Some of them are ſuch as communicate a colour, which will a long time reſiſt the injuries of the air, and theſe are therefore called the good or ſtanding colours; and there are others which the bare expoſition to the air will deſtroy or deface in a very little time, theſe are therefore called the falſe or fading colours. In what manner is the action of the air upon theſe laſt to be explained? Does it take away, or carry off from the ſtuff, the very particles of the colours; or does it only break and deſtroy that beautiful and regular texture of each particle on which the colour depends? The dyers very often have recourſe to ſeveral ingredients, in order to produce one colour; and reaſon ſeems to urge, that one of theſe falſe or fading colours might be render'd laſting by mixing it with a permanent one: the dyers are alſo of this opinion. But it is nevertheleſs a wholly erroneous one; for repeated experiments have proved, that one of theſe falſe colours fades as ſoon, when it is mixed with a ſtanding or laſting colour, as when it is uſed alone. There are but few colours on which this experiment can be tried, ſo as to come to a regular deciſion. One of the principal is the mixing a blue and a yellow, for the producing a green. In this experiment, if the blue and the yellow be both ſtanding or permanent colours, the ſtuff will perfectly hold its colours, and ſucceed alike, whether it be *dyed* firſt blue, and afterwards yellow; or firſt yellow, and afterwards blue. But if one of the two colours be a falſe or fading colour, it is found that the green produced by the mixture will not ſtand, tho' the other be ever ſo good or permanent a colour.

There is a ſhorter way of trying the permanence of many colours of this kind than that of expoſing them to the air, ſince in boiling only five minutes in a pint of water, in which there has been diſſolved half an ounce of alum, they will loſe as much colour as they would have done by being expoſed two days to the air in ſummer. Some colours require different methods of trial, but this ſerves for almoſt all. The ſhades of blue, yellow, red and green, purple and green, are the fineſt colours to experiment theſe things upon, as the ſame previous preparation or impregnation of the ſtuff ſerves for both, and both depend upon blue for their baſis, the purple being made of blue and red, and the green of blue and yellow.

It ſhould not ſeem ſurpriſing, if the ſtuff be firſt dipped into a *Dye* of a ſtanding blue, and afterwards into a fading red or yellow, to turn it green or purple, that the action of the air, or boiling in alum water, ſhould carry off thoſe falſe colours, which had only been applied to the ſtuff after it was before ſaturated with a ſtanding colour. But it might be expected, that when the ſtuff was firſt impregnated with them, and afterwards had the blue added upon them, that either the blue muſt be the colour that went off, or that they muſt all remain. But, in effect, nothing of this difference is found, but the blue remains, while the fading colours go off, however or in whatever manner or order they are applied. Mem. Acad. Scienc. Par. 1737.

DYKE-*Reeve*, a bailiff or officer, that has the care and overſight of the *Dykes* and drains in deepening fens, *&c.* We find mention made of this officer anno 16 and 17 Car. 2. c. 11.

DYSENTERY *(Cycl.)* — In this diſorder, ſome, after bleeding and vomiting, give their patients ſmall doſes of calomel once a day, till their breath begins to be tainted; the purging being moderated by opiates, glutinous food, drink, and anodyne glyſters, which is the more neceſſary, as the guts in this caſe are eaſily irritated. Medic. Eſſ. Edinb. abridg. Vol. 1. p. 72. The vitrum antimonii ceratum has been found a moſt efficacious remedy in this diſtemper. See the article VITRUM *Antimonii ceratum.*

Repeated doſes of ipecacuanha, and of rhubarb with calomel, with opiates in the evening, have alſo been found ſucceſsful. Medic. Eſſ. Edinb. abridg. Vol. 1. p. 65. where it is obſerved, that aſtringent medicines, without gentle revulſions and evacuations, generally retard the cure.

Ipecacuanha and the ſimarouba have often had great effects in this diſtemper. See *Juſſieu* in Mem. Acad. Scienc. ann. 1729. This gentleman ſays that the ſimarouba may be compared to, and ſubſtituted for the *macer* of the antients, which is by ſome ſuppoſed to have been a ſpecific in this diſtemper. See the article SIMAROUBA.

Jo. Ge. Henr. Kramerus aſſures us, we may depend on the ſame effect in the cure of a *Dyſentery*, from the decoction of common millet ſeed, called St. Ambroſe's ſyrup, as is promiſed from the *ſimarouba* by Mr. Juſſieu. Med. Eſſ. Edinb.

Dr. Killner tells us of two people, who were cured of an epidemic *Dyſentery* by violent drubbing. Act. Acad. Nat. Curioſ. Vol. 4. Obſ. 113.

DYSESTHESIA, in medicine, is uſed for a difficulty of, or fault in ſenſation. *Blancard*, Lex. Med. in voc.

DYSEPULOTICA, in medicine, great ulcers beyond cure. Id. ibid.

DYSOREXIA, in medicine, a want of appetite, proceeding from an ill diſpoſition, or diminiſhed action of the ſtomach. Id. ibid.

DYSPEPSIA, in medicine, a difficulty of digeſtion in the ſtomach and guts. Id. ibid.

DYSPHONIA, in medicine, a difficulty of ſpeech from an ill diſpoſition of the organs. Id. ibid.

DYSPNOEA, in medicine, a difficulty of breathing, wherein the breath is drawn often and thick, occaſioned by the ſtuffing of the lungs. Id. ibid. See ASTHMA, *Cycl.* and *Suppl.*

DYSTHANATOS, a word uſed by the antient writers ſometimes to ſignify any diſeaſe which occaſions a painful and ſlow death, and ſometimes for the perſon dying in ſuch a lingring manner.

E.

EAGLE, *Aquila*, in zoology. See AQUILA.

EAGLE *Owl*, in zoology, a name given by ſome to the great horn owl, or bubo, which is of the ſize of an *Eagle*, and as voracious and deſtructive. *Ray*'s Ornithology.

EAGLES, a name found very frequently in the antient hiſtories of Ireland, and uſed to expreſs a ſort of baſe money that was current in that kingdom in the firſt years of the reign of Edward the firſt, that is, about the year 1272. There were, beſides the *Eagles*, lionines, roſades, and many other coins of the ſame ſort, named according to the figures they were impreſſed with. *Simon*'s, Hiſt. Coins.

The current coin of the kingdom was at that time a compoſition of copper and ſilver in a determined proportion, but theſe were ſo much worſe than the ſtandard proportion of that time, that they were not intrinſically worth quite half ſo much as the others. They were imported out of France, and other foreign countries. When this prince had been a few years eſtabliſhed on the throne, he ſet up mints in Ireland for the coining ſufficient quantities of good money, and then decry'd the uſe of theſe *Eagles*, and other the like kinds of baſe coins, and made it death, with confiſcation of effects, to import any more of them into the kingdom.

EAR (*Cycl.*)—By a ſtatute of Henry the VIII^th^, maliciouſly cutting off the ear of a perſon is made a treſpaſs, for which treble damages ſhall be recovered; and the offender is to pay a fine of 10 pound to the king. 37 Hen. VIII. c. 6. §. 4. In the index to the ſtatutes at large, it is ſaid, that this offence may be puniſhed as felony, by 22 and 23 Car. II. c. 1. ſect. 7. commonly called Coventry's act; but *Ear* is not mentioned in that ſtatute.

EAR *of Fiſhes*—All the cetaceous fiſhes have external meatus auditorii, or paſſages for hearing; but other fiſh have nothing of theſe external appearances, and ſeem neither to be intended by nature to make any ſounds, or to hear any. Though ſound being a tremulation in the air, it may be felt by them as motion, though not diſtinguiſhed as ſound. It may eaſily be proved, that they do not hear our voices in ſpeaking, by walking near the ſide of a pond or river well ſtored with fiſh about the edges, if the body and its ſhadow be kept out of their ſight, they will never ſtart at the voice.

Yet how far fiſhes are deaf and dumb, ſeems a queſtion not yet perfectly decided. See FISH.

EAR, in gardening, a name given to the ſeminal leaves of plants, or thoſe two green and ſucculent leaves which firſt appear from the ſeed, and are very different in all reſpects from thoſe which follow. Thus in the melon plants, the two firſt leaves are called *Ears*, and the leaves, with their ſtalks, which ſhoot out afterwards, are called knots, and denominated the firſt, ſecond, and third knot, according to their place, and time of growing. The cutting off every third knot in this plant, is the great means of procuring the fineſt and largeſt fruit. Phil. Tranſ. N°. 45.

Wounds of the EAR. Wounds of the external *Ear* are eaſily united by ſticking-plaiſters, unleſs the cartilage is entirely divided, and then it will require the help of the needle, and the application of vulnerary balſams, with the proper compreſſes and bandages. When the *Ear* is wounded in the neighbourhood of the meatus auditorius, great care muſt be taken to prevent the diſcharge of blood and matter into that paſſage, which would do great miſchief to the tympanum; but this may be done only by filling the internal *Ear* with lint or cotton. *Heiſter*. Surg. p. 81.

EAR, in anatomy—Mr. le Cat, in his treatiſe of the organ of ſound, has new figures of ſeveral parts of the *Ear*. Med. Eſſ. Edinb. abr. T. 2. p. 481. ſeq.

We have alſo ſome treatiſes on the *Ear* by Dr. Caſſehom, containing very minute deſcriptions of the parts. Ibid.

Running of the EARS, in infants. See INFANT.

EAR *Picks*—The Chineſe are particularly fond of entertaining themſelves with picking and tickling their *Ears*; this they do either for themſelves, or interchangeably for one another, and have a great number of inſtruments of peculiar ſhapes and ſtructure, invented for this purpoſe. Some years ago there was an India cabinet brought over from China, filled with the utenſils and inſtruments of the place, among which there were ſeveral of this kind, uſed to pick and cleanſe, as well as to tickle the *Ear*. One of theſe was made of a ſmall pearl, faſtened to the end of a horſe-hair, or hog's briſtle, the other end let into an ivory handle, and fitted to be uſed by the perſon's ſelf, as are moſt of the others on occaſion. Another was made of fine ſilver wire twiſted into a wreathe, and formed into a round loop at the top; this was alſo ſet into a handle for uſe. Another was made of a large piece of ſilver wire, flatted at the end, and ſet in the ſame ſort of handle; another was made of the ſame ſilver wire, but not flatted, but had its end made into a hook; another was very much of the nature of our *Ear-pickers*, but longer, and made of ſilver ſet in tortoiſeſhell; another was made of ſeveral hog's briſtles, ſet at the end of a ſort of handle, made like one of our pencils; another was of the ſame kind with this, but made of downy ſoft feathers inſtead of hog's briſtles.

Theſe, and many other inſtruments, are at this day uſed to the ſame purpoſe by the Chineſe; but Sir Hans Sloane very judiciouſly obſerves, that the uſe of them ſeems very prejudicial, for that, among many people in England who had applied to him on account of deafneſs, the far greater part were thrown into their complaints by too often picking their *Ears*, and thereby bringing humours, or ulcerous diſpoſitions, on them. Phil. Tranſ. N°. 246. p. 406.

EAR *Shell*, *auris marina*, in natural hiſtory, the name of a genus of ſhell-fiſh, the characters of which are theſe: It conſiſts only of one ſhell, or valve, and is of a flatted ſhape, in ſome meaſure reſembling that of the human *Ear*, and has an extremely wide mouth, or aperture, at its baſe, the wideſt of that of all ſhells, except only the patella or limpet, which is all mouth below. See Tab. of Shells, N°. 3.

Aldrovand and Rondeletius have given this genus the name of *patella fera*, the wild limpet; but in this they have been followed by no author, as it confounds the *auris marina* and *patella*, which are two abſolutely diſtinct genera. Theſe authors have alſo ranked both this and the limpet among the bivalve ſhells, but nothing can be more abſurd than this.

The French call it generally *oreille de mer*, and, in ſome places, *ormeau*. Bellonius calls it the great boufdin; and ſome of the Hollanders have given it the ſtrange name of the ſtock-fiſh. Hiſt. Nat. Eclairc. pt. 2. p. 243.

This genus of ſhells ſometimes yields ſmall pearls, the rudiments of which are very frequently ſeen in thoſe ſhells which have not perfect ones, and the whole inſide of the ſhell is of the colour of the fineſt mother of pearl. This alſo appears on the outſide, when the rough coat is ſo far eaten away by acids, as to leave this pearly ſurface bare, in this caſe it makes a very elegant appearance, being of the ſplendor of the moſt perfect mother of pearl both within and without, and it is frequently preſerved in cabinets in that ſtate.

The inſide and outſide of this ſhell are both ridged with very high ribs, which run from one ſide to the other, and there is in all theſe ſhells a row of holes near one edge, of which ſix are uſually open, and there are beyond theſe the marks of three or four others, which do not go through the ſhell. Theſe are form'd in the growth of the fiſh, which, as it enlarges, enlarges alſo the ſhell, and when a new rim is form'd, in which there is an open hole, one of the hinder ones is always cloſed up by the growth of freſh ſhelly matter over it. *Aldrovand.* de Aquat. *Rondelet.* de Aquat.

Liſter places the *auris marina* among the turbinated ſhells, and ſays, that this is its proper place, becauſe it is twiſted and claviculated, and therefore, as he thinks, very badly ranked with the patellæ. But it is to be obſerved, that, according to this rule, almoſt all ſhells would be found of the turbinated kind, up to the porcelain ſhells, or conchæ veneris, which have all a twiſted pyramid, or clavicule, which is flatted, and enters into the ſhell near the ſummit. *Liſter*. Hiſt. Conch.

There is one very ſingular ſpeciesof the *auris marina*, which differs from all the others in its length; this is a large kind, and is brought from the Eaſt Indies, but is not found in the European ſeas. We have, however, one of a ſomewhat longer form than the common kinds; this is ſmall, and very thin, and is ſingular in not having that fine pearly appearance on the inſide that the others have. The general ſpecies we ſee, are of four kinds. 1. Some have ſix holes. 2. Some have ſeven holes, and are more pearly than the reſt. 3. Some are of an oblong form: And 4. There is one ſpecies which has no mark of apertures at all. The known ſpecies under theſe diviſions, or genera, are theſe:

Of the ſix-holed kind we have only one ſpecies, which is the common one, called *auris veneris*. Of the ſecond kind, which have ſeven holes, we have, 1. The rugoſe and ſtriated *Auris*, which, when poliſh'd, appears ſmooth, and is kept in many cabinets as another ſpecies. 2. The green *Auris*. 3. The red *Auris*: And 4. The green and brown ſpotted *Auris*.

Of the third, or oblong kind, we have, 1. The oblong *Auris*, with an irregular baſe. 2. The oval *Auris*: And 3. The green *Auris*. Of the laſt kind, the only known ſpecies is the dull *Auris*, not pearly within, and without any apertures. This laſt is a very rare ſhell Hiſt Nat. Eclairc. pt. 2. p. 244.

EAR of *Corn*, in ſtone. See Tab. of Foſſils, Claſs 6.

EARINÆ *Veſtes*, among the antient Greeks, a habit worn in the ſpring, which was made of wool, and dyed green. The cuſtom of wearing green veſtments in this ſeaſon, has not been unknown in modern times.

Dempſter ſays, it was cuſtomary, in his time, for the king, and nobility of England, to go a hunting in the ſpring, dreſſed in green, that they might be of a ſimilar colour with the ſeaſon. *Hofm.* Lex. in voc.

The word comes from the Greek Ear, the *ſpring*.

EARING, in a ſhip, that part of the bolt-rope, which, at the four corners of the ſail, is left open, in the ſhape of a ring. The two uppermoſt parts are put over the ends of the yard-arms, and ſo the ſail is made faſt to the yard; and into the lowermoſt *Earings* the ſheets and tackles are ſeized, or bent at the clew.

EARTH (*Cycl.*)—*Figure of the* EARTH—That the figure of the *Earth* is ſpheroidical, is agreed upon by all: But whether it be an oblong, or oblate ſpheroid, i. e. whether the axis be longer or ſhorter than a diameter at the equator, has been for ſome time a matter of doubt.

Three ſeveral methods have been propoſed to determine this controverſy; 1. By experiments, as by the different lengths of pendulums vibrating ſeconds, in different latitudes. 2. The figure of the earth's ſhadow in lunar eclipſes: And 3. By the actual meaſurement of the lengths of a degree on the meridian, in different latitudes.

It is certain, if the lengths of the degrees of latitude decreaſe, as we go from the equator toward the poles, then the axis is greater, and the figure an oblong ſpheroid; but, on the contrary, if theſe lengths increaſe, as you remove towards the poles, the axis is leſs than a diameter at the equator, and conſequently the figure an oblate ſpheroid.

Mr. Caſſini, and others, judge the *Earth* to be of an oblong ſpheroidical figure; and the obſervations made in France, if entirely to be depended upon, prove this hypotheſis to be a matter of fact.

Sir Iſaac Newton, Mr. Huygens, and others, make the earth to be an oblate ſpheroid, higher at the equator than at the poles; and this figure of the *Earth* is undoubtedly the true one, if the obſervations lately made near the arctic circle be admitted as certain and exact.

Mr. Celſius takes notice that the inſtruments, aſtronomical obſervations, and trigonometrical operations, performed in France, render the obſervations there made uncertain.

The obſervations made at Tornea were undertaken at the charge of the king of France, by five ſkilful gentlemen, three of them members of the royal academy at Paris, who were joined by Mr. Celſius and the Abbè Outhier. The trigonometrical part of the work was performed near the river of Tornea, the direction of which is the ſame with the meridian of Tornea; the coaſts of the gulph of Bothnia being found very inconvenient for that purpoſe. By the favourable ſituation of five mountains, they formed eight triangles, which took in ſpace enough for their deſign. All the five gentlemen obſerved, one after another, each angle of theſe triangles, ſetting them down in writing ſeparately.

They afterwards determined the diſtance between Tornea and mount Kittis, under the ſame meridian, by a baſis, meaſured on the river, when frozen over, the length of which was 7406 toiſes 5 feet, by the firſt meaſurement; and, when meaſured again, was barely four inches over. This diſtance between the two places they found to be $55023\frac{1}{2}$ toiſes.

The firſt part of their work being thus finiſhed, the next was to find the difference of latitude of theſe two places; this they did by the help of a teleſcope, fixed to a ſector of nine feet, made at London, by the care and direction of Mr. George Graham, to whom the lovers of aſtronomy are indebted for the curious and well-contrived inſtruments with which he has ſupplied them. The ſtar they obſerved at Tornea was α *Draconis*. They repeated their obſervations three times, and the greateſt difference between them was but two ſeconds. Removing to mount Kittis, they took the ſame number of obſervations, of the ſame ſtar, without finding more than one ſecond of difference. The reſult was, that the amplitude of the arch, in the heavens, between Tornea and mount Kittis (allowing for the preceſſion of the equinox, and the time elapſed between the two obſervations, according to Mr. Bradley's Theory) was 57 minutes 26 ſeconds. Hence the magnitude of a degree, on the earth, interſecting the polar circle, was found to be $57437\frac{9}{10}$ toiſes, which is greater than a mean degree of France, or 57060 toiſes, by $377\frac{9}{10}$ toiſes; and differs 900 toiſes from what it ſhould have been, according to Mr. Caſſini's hypotheſis: And if the correction, according to Mr. Bradley's theory, were omitted, the difference would have amounted to above a thouſand toiſes; the conſequence of which is, that the *Earth* is not only flatted towards the poles, but that it is much more ſo than Sir Iſaac Newton or Mr. Huygens thought it.

This unexpected difference being ſo very great, made them reſolve upon a careful, as well as new kind of verification of the whole. In the firſt place, they repeated their aſtronomical obſervations three ſeveral times at Tornea and Kittis, with the ſame inſtrument, but on another ſtar, *viz.* δ *Draconis*: The difference of latitude between the two places was found to be the ſame, within three ſeconds and an half, with the firſt: They then not only examined the truth of their meridian line, the exactneſs of the ſector, in the different diviſions upon the limb, chiefly in the two degrees employed in obſerving α and δ *draconis*, but ſuppoſed that in their trigonometrical operations they had erred in each triangle, by twenty ſeconds in each of the two angles, and forty ſeconds in the third; and that all theſe errors tended to diminiſh the length of the arch; the calculation, upon this ſuppoſition, gives but $54\frac{1}{2}$ toiſes for the greateſt error that could be committed. See Phil. Tranſ. N°. 457. Sect. 1. compared with Mr. Maupertuis's fig. of the *Earth* determined, p. 162 of the Tranſlat. by Mr. Murdoch.

We have ſaid that Mr. Celſius doubted of the accuracy of the French obſervations, and he gives good reaſons for his doubts. Their angles were not accurately determined, and when theſe are properly corrected, thoſe very meaſures of a degree in the ſouth and north of France, brought to overturn Sir Iſaac Newton's theory, have, like the meaſures taken in Lapland, confirmed it. See Phil. Tranſ. N°. 457. Sect. 1. Mr. Celſius's diſſertation, entitled, *De obſervationibus pro figura telluris determinanda, in Gallia habitis diſquiſitio*, Upſal. 1738. 4°. may be farther conſulted.

By the obſervations in the north of France, extending from Paris to Dunkirk, a mean degree was found to conſiſt of 56960 toiſes. And by the obſervations made in the ſouth of France, from Paris to Collioure, near the Pyrenees, a degree was found to be 57097 toiſes. From whence it would follow, that the *Earth* is an oblong ſpheroid.

But Mr. Celſius obſerves, that the diſtance between the royal obſervatory at Paris, and the perpendicular to the meridian of Collioure, properly corrected, will amount to no more than 358980 toiſes. This, divided by the mean difference of their latitudes 6°. 19′. 11″. will give 56803 toiſes for the length of a degree, one with another, between Paris and Collioure, which is pretty near the truth, and leſs than the length of a mean degree, found by Mr. Picard, and rated at 57060 toiſes: So that the degrees decreaſe as you go towards the equator; and conſequently the *Earth* is higher there than at the poles, as Sir Iſaac Newton and Mr. Huygens determined. Phil. Tranſ. loc. cit.

The obſervations of ſome gentlemen of the French academy, who have been at the pains to re-examine the meaſures formerly taken in France, confirm the Newtonian theory.

And the obſervations made in Peru are an additional confirmation of the ſame. See Mr. Bouguer's book lately publiſhed.

The meaſure of a degree of the meridian in the latitude of 66°. 20′. was found to be $57437\frac{9}{10}$ French toiſes, but in the latitude of 49°. 21′. only 57183 toiſes. Suppoſing thoſe degrees accurately meaſured, the axis, or diameter, that paſſes through the poles, will be to the diameter of the equator as 177 to 178. Hence, the *Earth* will be 22 miles higher at the equator, than at the poles [a]. If the earth was of an uniform denſity from the ſurface to the center, then, according to the theory of gravity, the meridian would be an exact ellipſis, and the axis would be to the diameter of the equator, as 230 to 231, and the difference of the ſemi-diameter of the equator, and the ſemi-axis, would be about 17 miles [b]. —[a Treat. Pract. Geom. p. 44, 45. b Ibid. p. 45.] See the article DEGREE.

According to Mr. Maupertuis's meaſures, if the ſemi-diameter of the equator be $= 1$, and the ſemi-axis $= a$: Then will $1 - aa = 0.022$. See Mr. *Murdoch*'s Mercat. Sailing. p. 7.

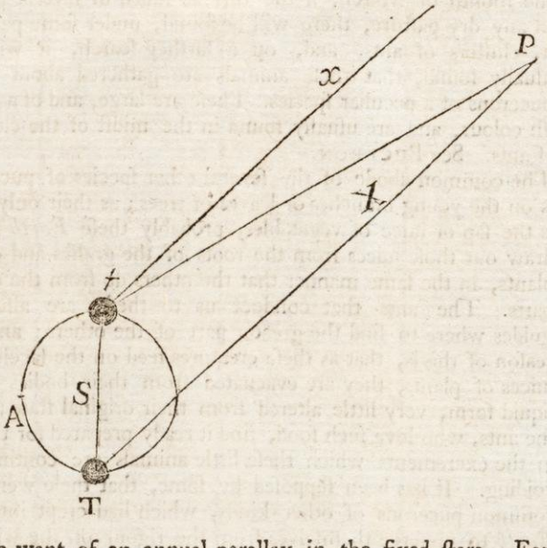
Or if the ſemi-diameter of the equator be to the diſtance of the focus of the generating ellipſis from the center, as m to 1, then will $mm : 1 :: 1000 : 22$. For, by the nature of the ellipſe, $1 : \sqrt{1 - aa} :: m : 1$, or $1 : 1 - aa :: mm : 1$; conſequently $mm : 1 :: 1 : 0.022$, or $mm : 1 :: 1000 : 22$. This is the analogy made uſe of to compute the meridional parts in a ſpheroid. See MERIDIONAL *Parts*.

Mr. Eiſenſchmidt having compared the meaſures of a degree, taken in different latitudes, by Riccioli, Snellius, &c. found that the lengths of degrees grew leſs towards the pole, and hence, admitting theſe meaſures to be exact, he juſtly inferred, that the figure of the *Earth* was oblong, and not oblate. This was the hypotheſis Mr. Caſſini endeavoured afterwards to confirm. Dr. Burnet, in his theory of the *Earth*, has mentioned Mr. Eiſenſchmidt and his concluſion; for which, both the Doctor, and the author he quotes, were roughly cenſured by Mr. Jo. Keill, who draws the contrary concluſion from Eiſenſchmidt's facts; but Keill himſelf was here greatly miſtaken: Eiſenſchmidt and Burnet were miſled by inaccurate meaſures, but did not draw falſe conſequences from thoſe ſuppoſed facts. Jo. Caſp. Eiſenſchmidii *diatribe de figura telluris elliptico-ſphæroide*, &c. Argentorati, 1691. 4°.

Changes of the EARTH—Mr. Boyle ſuſpects there are great, though ſlow internal changes, in the maſs of the *Earth*. He argues from the varieties obſerved in the change of the magnetic needle, and from the obſerved changes in the temperature of climates. But as to the latter, we doubt whether he could have diaries of the weather ſufficiently exact to direct his judgment. *Boyle*'s Works abr. vol. 1. p. 292, 293. See SINKING *of the Earth*.

Magnetiſm of the EARTH—The notion of the magnetiſm of the *Earth* was ſtarted by Gilbert; and Mr. Boyle ſuppoſes magnetic

magnetic effluvia moving from one pole to the other. See Works abr. vol. 1. p. 285, 290.



Dr. Knight alſo thinks, the *Earth* may be conſidered as a great loadſtone, whoſe magnetical parts are diſpoſed in a very irregular manner; and that the ſouth pole of the *Earth* is analogous to the north pole in magnets, that is, the pole by which the magnetical ſtream enters. See MAGNET.

He obſerves, that all the phæmomena attending the direction of the needle, in different parts of the *Earth*, in great meaſure correſpond with what happens to a needle, when placed upon a large terella; if we make allowances for the different diſpoſitions of the magnetical parts, with reſpect to each other, and conſider the ſouth pole of the *Earth* to be a north pole, with regard to magnetiſm. The *Earth* might become magnetical by the iron ores it contains, for all iron ores are capable of magnetiſm. It is true, the globe might notwithſtanding have remained unmagnetical, unleſs ſome cauſe had exiſted capable of making that repellent matter producing magnetiſm move in a ſtream thro' the *Earth*. See MAGNET.

Now the Doctor thinks that ſuch a cauſe does exiſt. For if the *Earth* revolves round the ſun in an ellipſis, and the ſouth pole of the *Earth* is directed towards the ſun, at the time of its deſcent towards it, a ſtream of repellent matter will thereby be made to enter at the ſouth pole, and come out at the north. And he ſuggeſts, that the *Earth*'s being in its perihelion in winter, may be one reaſon why magnetiſm is ſtronger in this ſeaſon than in ſummer.

The cauſe here aſſigned for the *Earth*'s magnetiſm muſt continue, and perhaps improve it from year to year. Hence the doctor thinks it probable, that the *Earth*'s magnetiſm has been improving ever ſince the creation, and that this may be one reaſon why the uſe of the compaſs was not diſcovered ſooner. See Dr. *Knight*'s *Attempt to demonſtrate, that all the Phænomena in Nature may be explained by Attraction* and *Repulſion*. Prop. 87. ſeq.

Motion of the EARTH—The annual motion of the *Earth* about the ſun is now generally admitted by aſtronomers. The principal argument againſt this annual motion of the *Earth*, is

the want of an annual parallax in the fixed ſtars. For let T A *t* repreſent the *Earth*'s orbit about the ſun S, T X the axis of the earth, and A *x* parallel to T *x*, will repreſent the poſition of the ſame axis at the oppoſite point *t*. Suppoſe T X to be directed towards the ſtar P; and it is manifeſt, that the axis of the *Earth* will not be directed to the ſame ſtar, when it comes to the ſituation *t x*, but will contain an angle *x t p* with the line *t* P, joining the *Earth* and ſtar, equal to the angle *t* P T, under which the Diameter T *t* of the *Earth*'s orbit appears to a ſpectator, viewed from the ſtar P. It might be expected therefore, that by obſerving the fixed ſtar P, from the different parts of the *Earth*'s orbit, we might judge of the angle T P *t*, and conſequently of the proportion of T P, the diſtance of the ſtar to T *t*, the diameter of the *Earth*'s orbit, or double diſtance of the ſun. Yet it is certain that aſtronomers have not hitherto been able to diſcover any difference in the apparent ſituation of the fixed ſtars, with reſpect of the axis of the *Earth*, or to one another, that can ariſe from the motion of the *Earth*: Tho', ſince the reſtoration of the Pythagorean doctrine of the *Earth*'s motion, they have taken great pains to examine the matter.

The ſeeming motion of the pole ſtar, obſerved by Mr. Flamſtead, was by ſome miſtaken for a proof of its annual parallax; but this phænomenon has ſince been accounted for in the moſt ingenious manner by Mr. Bradley, from the motion of light, combined with that of the *Earth* in its orbit. See LIGHT.

The objection to the *Earth*'s motion, from there being no diſcernible parallax of the fixed ſtars, is anſwered by obſerving, that the diſtance of the fixed ſtars is ſo great, that the diameter of the *Earth*'s orbit bears no ſenſible proportion to it; ſo that the parallax is not to be diſcovered by our exacteſt inſtruments. Nor is this immenſe diſtance of the fixed ſtars advanced by the Copernicans merely as an hypotheſis, for the ſake of ſolving the objection. For there ſeems great reaſon to ſuppoſe the fixed ſtars like to our ſun, and hence to conclude their diſtance to be vaſtly great, ſince they appear to us with ſo faint a light, and of no ſenſible diameter, even in the largeſt teleſcopes.

But from the diligence and accuracy of late aſtronomers, we learn ſeveral curious things in confirmation of the motion of the *Earth* about the ſun, and ſerving to ſolve this only material objection againſt it. See LIGHT.

EARTHS, in natural hiſtory, are the various ſpecies and kinds of earthy matter found in digging, or lodged on the ſurface of the terraqueous globe. Theſe are either ſimple, or compoſed of entirely ſimilar particles; or compound, having a mixture of heterogeneous ones, as ſand, or the like, among them.

Earths are defined to be friable, opake, inſipid bodies; not inflammable, vitrifiable by extream heat, diffuſible in water, and ſeparable from it by filtration.

The ſimple *Earths* are divided into two orders; and under thoſe into five genera. Of the firſt order are thoſe *Earths* which are naturally moiſt, of ſmooth ſurfaces, and of a firmer texture; and of the ſecond are thoſe which are naturally dry, of rough duſty ſurfaces, and of a looſer texture. Of the firſt of theſe orders, there are three genera, the boles, the clays, and the marles; and of the ſecond there are two, the ochres, and the tripelas. The ſeveral diſtinguiſhing characters of which are theſe.

Of the firſt order: 1. *Boles* are *Earths* moderately coherent, ponderous, ſoft, not ſtiff or viſcid, but, in ſome degree, ductile while moiſt, compoſed of fine particles, ſmooth to the touch, eaſily breaking between the fingers, readily diffuſible in water, and freely and eaſily ſubſiding from it. See BOLE.

2. *Clays* are *Earths* firmly coherent, weighty, and compact, very ſtiff and viſcid, ductile to a great degree while moiſt, ſmooth to the touch, not eaſily breaking between the fingers, nor eaſily diffuſible in water, and, when mixed in it, not readily ſubſiding from it. See CLAY.

3. *Marles* are *Earths* but ſlightly coherent, not ductile, ſtiff, or viſcid, while moiſt, moſt eaſily diffuſible in, and diſunited by water, and by it reduced to a ſoft, looſe, incoherent maſs. See MARLE.

Of the ſecond order are, 1. *Ochres*. Theſe are *Earths* ſlightly coherent, compoſed of fine, ſmooth, ſoft argillaceous particles, rough to the touch, and readily diffuſible in water. See OCHRE.

2. *Tripelas* are *Earths* firmly coherent, compoſed of fine, but hard, particles, and not readily diffuſible in water.

The compound *Earths* are two; the loams, compoſed of clay and ſand; and the moulds, compoſed of earthy and putrified vegetable and animal matters. See TERRA.

EARTH *of Malta*. See MELITENSIS *Terra*.

EARTH *of Nocera*. See NOCERIANA *Terra*.

EARTH *of Portugal*. See PORTUGAL *Earth*.

Lemnian EARTH. See LEMNIAN.

Livonian EARTH. See LIVONIAN *Earth*.

EARTH, among chymiſts—There is plainly a ſubtile *Earth*, which may be ſeparated from all animal and vegetable ſubſtances, and is the ſame in all, and is the baſis of all. This remains after the ſeparation of the other principles by chymiſtry, from all animal and vegetable ſubſtances, and neither coheres together, nor ſuffers any change in the fire. The aſſayers acknowledge no difference between the *Earth* of animals and vegetables, but make their teſts for the niceſt uſes equally of both. If water be poured on theſe aſhes, they acquire ſome degree of tenacity, ſo as to become capable of being formed into veſſels; but if oil be added, they cohere into a much ſtronger, and more compact maſs; hence it ſhould appear, that oil and *Earth* are the principles which give conſiſtence and tenacity to plants. This oil, as well as this *Earth*, ſeems the ſame in all, and poſſeſs nothing of the poiſonous or medicinal virtues of the peculiar plant, they being all ſeparable by decoction, diſtillation, and other proceſſes of that kind, and not remaining in the caput mortuum, which conſiſts of the *Earth*, and this connecting oil. Long drying will diveſt plants of all their virtues, ſo that nothing but theſe principles ſhall remain in them, theſe giving ſolidity and figure, the plant retains its former appearance, but only theſe remaining, it poſſeſſes none of its virtues. *Boerhaave*'s Chymiſt. part 2. p. 21.

To obtain this chymical principle pure and unmixed from the common analyſis of vegetables, and other bodies, let the remaining maſs, after diſtillation, be thoroughly calcined, then boiled in ſeveral waters, to get out all its ſalt, and after this dry'd in a clear fire, or in the ſun, and the dry'd maſs will be the pure earth. *Shaw*'s Lectures, p. 151.

EARTH *of Dew*, an *Earth* much valued by many of the chymical experimenters, and prepared in the following manner: A large quantity of dew is to be collected, and ſet in a wooden veſſel, in a cool ſhady place, covered with a canvas, to keep out duſt and flies, there will in time come on a putrefaction in the liquor. It is ſometimes three weeks, ſometimes longer firſt; during the time of this putrefaction, certain films are daily formed on the ſurface of the liquor, and theſe falling down to the bottom, one after the other, form, by degrees,

a ſediment of a ſort of mud. This is to be thrown away, and the dew, when ſeparated from it, is to be filtred clear, and evaporated to a dryneſs, the remainder is a greyiſh *Earth*, which is the true *Earth* of dew; this is very light and friable, and is of a foliated ſtructure in the maſs, looking like ſo many leaves of brown paper, ſpread very thin and even over one another. Phil. Tranſ. N°. 3.

This *Earth*, expoſed to a ſmart fire, looſes its foliated texture, and runs into a maſs, reſembling a mixture of ſalt and brimſtone melted together, but it is not at all inflammable. This, ground on a levigating ſtone, tinges the water to a purpliſh colour. A pound of this *Earth*, properly treated by calcination and elixiviation, will yield an ounce of a pure and white ſalt, ſomewhat reſembling nitre. The chymiſts have been at great pains to procure this *Earth*, but they do not ſeem yet to have made any very important uſe of it, and, in all probability, it is no other than that common ſpar which we know to be contained in all water, and which encruſts the ſides of our teakettles, and other veſſels, in which water is often boiled. We know, by manifold inſtances, that ſpar is rarifiable into vapour with water, and therefore it would be a greater wonder if dew were found not to contain it, than that it does.

EARTHS *of mineral waters*—All mineral waters contain *Earth* of ſome kind, though very different in quantity and in nature. Theſe are found, in different waters, of very different colours and appearances, ſome white, ſome grey, ſome yellowiſh, ſome reddiſh, and ſome brown. They are alſo as different in their qualities as in their form, ſome of them are ſoluble in acids, others are not ſo; ſome fuſible in the fire, others not; and ſome retain their natural colour after burning; others change it in the fire. By this we learn, that ſome are marly, others argillaceous, others ochreous, and ſome ſandy; others there are which are produced by the concretion of certain juices, ſaline or ſulphureous, and others not ſo. Some are ſimply mineral, others are metallic. And as many of theſe are very different from any of the known *Earths*, even in their pure and ſeparate ſtate, they are yet much leſs diſtinguiſhable when mixed one with another, as they very frequently are in the waters of even our common ſprings, much more ſo in the mineral medicinal ones.

The ſimple infuſions of certain ſulphureous mineral *Earths* may notably alter the waters of wells and fountains, without having any thing of thoſe *Earths* remaining, after their diſtillation, in the ſame manner as nothing is ſeparable, by art, from certain liquors, rendered emetic by antimony. The hot mineral waters may contract ſome alteration from the ſulphureous and bituminous matters which they meet with in their courſe; for theſe ſubſtances all contain ſubtile ſalts, which hot water may take up, and carry away with it.

Compound EARTHS, in natural hiſtory, are a claſs of foſſile bodies, uſually confounded with the genuine and ſimple *Earths*, as if ſubſtances of the ſame kind, but being of a very different nature and origin. They are foſſils compoſed of argillaceous and marly particles, ſeparated and divided by adventitious matter, and never found free from thoſe admixtures, or in the ſtate of pure ſimple marls or clays.

Of this claſs of foſſils there are two general orders; thoſe of the one are known by the name of loams, and are compoſed of ſand and clay; and thoſe of the other are called moulds; theſe are the *Earths* that vegetables grow in, and are compoſed of argillaceous and marly particles, ſeparated by ſand, ſmall pebbles, and the gritt of ſtone, and uſually intermix'd with, and enrich'd by, the putrify'd remains of animal and vegetable ſubſtances: Of each of theſe there are ſeveral genera. *Hill*'s Hiſt. of Foſſils. See the articles LOAM and MOULD.

EARTH *Bag*, in fortification. See SAND *Bag*.

EARTH *Banks*, in huſbandry, &c. are a very common fence about London, and in ſeveral other parts of England. Where ſtones are not to be had cheap, theſe are to be preferred to all other fences, both for ſoundneſs and laſting.

The beſt manner of making them is this: Dig up ſome turf in a graſſy place, a ſpit deep, or nearly to the breadth of the ſpade, and about four or five inches thick, lay theſe turfs with the graſs outward, even by a line on one ſide, and on the backſide of theſe lay another row of turf, having a foot ſpace of ſolid ground on the outſide, to prevent the bank from ſlipping in, if it ſhould any way be faulty. On the outſide of this make a ditch, or elſe let the ſides be lowered both ways with a ſlope two foot deep, and there will be no paſture loſt by the fence, becauſe it will bear graſs on both ſides.

The *Earth* that is dug out of the ditches, or from the ſlopes, muſt be thrown in between the two rows of turf, till the middle is made level with the reſt. Then lay on two more rows of turf in the ſame manner, and with more of the *Earth* fill up, and make level as before. Let this method be continued till the bank is raiſed four foot high, or more if neceſſary, only obſerving, that the higher it is to be carried, the wider the foundation muſt be made. As the bank is carried up, the ſides muſt not be raiſed perpendicular, but ſloping inward both ways, ſo that at the top it may be about two foot and a half wide. This ſort of fence, when made with leſs care, and faced with clay, is left naked, and ſerves very well in ſome places; but when it is thus managed with the turf, the joining of the ſeveral pieces are hid in a little time, by the growth of the graſſy part of the turf on each ſide, and it makes a beautiful fence, of as green and pleaſant a colour as the reſt of the field. *Mortimer*'s Huſbandry, 12.

The great improvement upon this plan, is the planting quickſets, or young white-thorn plants, in the middle of the top of the bank. The *Earth* on each ſide of theſe may be raiſed up with a ſort of wall, and the rain that falls all preſerved for the plants. This plenty of water, and depth of fine *Earth*, makes the young plants grow quicker and more vigorouſly than any other way; and the moſt beautiful of all hedges is propagated this way. When this ſort of hedge is young, there muſt be placed on each ſide of it a ſhort dry hedge, of about a foot high, to keep the ſheep from cropping the young plants, but this may be taken away after a little time.

There is one caution neceſſary in regard to the making of theſe banks, which is, that they muſt never be made in a very dry ſeaſon, becauſe if much rain ſhould follow, the *Earth* of the bank would ſwell and burſt out, or ſpoil the ſhape of the bank; but if this ſhould happen, it is eaſily enough repaired. This beautiful fence may be made at a ſmaller price than thoſe unaccuſtomed to theſe things may imagine. In good digging ground, where men work for fourteen pence a day, it may be made and planted with quick for two ſhillings a pole. It may be made proper for the keeping in of deer, only by the ſmall addition of planting, at every eight or ten foot diſtance, a poſt a little ſlanting, with a mortiſe in it; let this ſtand about two foot above the bank, and into the mortiſes all along, put a rail made of a bough of any tree, no deer will ever go over this, nor can they creep under it, as they often do when a pale tumbles down. The quick, on the top of this bank, may be kept clipped, and will grow very thick, and afford the beſt ſhelter for cattle of any fence in uſe with us. *Mortimer*'s Huſbandry.

EARTH *Pitch*. See PISSASPHALTUM.

EARTH *Pucerons*, in natural hiſtory, a name given by authors to a ſpecies of puceron very ſingular in its place of abode. In the month of March, if the turf be raiſed in ſeveral places in any dry paſture, there will be found, under ſome parts of it, cluſters of ants, and, on a farther ſearch, it will be uſually found, that theſe animals are gathered about ſome pucerons of a peculiar ſpecies. Theſe are large, and of a greyiſh colour, and are uſually found in the midſt of the cluſters of ants. See PUCERON.

The common abode of the ſeveral other ſpecies of pucerons is on the young branches or leaves of trees; as their only food is the ſap or juice of vegetables, probably theſe *Earth* kinds draw out thoſe juices from the roots of the graſſes and other plants, in the ſame manner that the others do from the other parts. The ants that conduct us to theſe, are alſo our guides where to find the greater part of the others; and the reaſon of this is, that as theſe creatures feed on the ſaccharine juices of plants, they are evacuated from their bodies in a liquid form, very little altered from their original ſtate; and the ants, who love ſuch food, find it ready prepared for them, in the excrements which theſe little animals are continually voiding. It has been ſuppoſed by ſome, that theſe were the common pucerons of other kinds, which had crept into the *Earth* to preſerve themſelves from the rigour of the winter. But this does not appear to be the caſe, for they are uſually found in places very diſtant from trees or plants on which they ſhould be ſuppoſed before to have fed; and it is very certain, that though many of theſe inſects are killed by the cold, yet many eſcape, and are found very early in the ſpring, ſucking the buds of the peach tree. There is no doubt of theſe creatures being in a feeding condition when under-ground, becauſe otherwiſe the ants would have no temptation to follow them; and it is equally certain, that the ſeveral ſpecies of the pucerons, like thoſe of the caterpillar kinds, have each their peculiar herbs on which they feed, many of them dying of hunger, rather than feeding on any other; and it is therefore not at all likely, that theſe *Earth* pucerons had been uſed to feed on leaves of trees and plants, and had left that food for the roots of graſs. *Reaumur*, Hiſt. Inſ. vol. 6. p. 79.

The opinion of their being a diſtinct ſpecies is alſo ſtrengthened by this, that there are many other ſpecies which find their nouriſhment at the roots of plants. Mr. Juſſieu diſcovered a peculiar ſpecies at the roots of the lychnis; and Mr. Reaumur ſeveral others at the roots of camomile, yarrow, and other plants. He goes ſo far as to believe, even that the number of ſubterraneous ſpecies may be equal to that of thoſe which are found above-ground, and that, upon the whole, the ſpecies of this little inſect may be equal in number to thoſe of the known plants, which, upon the moſt moderate computation, cannot be leſs than ſixteen thouſand. The ſeveral kinds found at the roots of particular plants may be diſtinguiſhed each by the particular name of the plant they feed on, while thoſe found under the turf, and feeding on the roots of graſs, may be called *Earth* pucerons.

EARTHQUAKE (*Cycl.*)—In the philoſophical tranſactions, N°. 462. Sect. 11. we have a journal of the ſhocks of *Earthquakes*,

snakes, as felt in New England: And in N°. 463. an account of one felt in Italy, in 1742.

EARTH *Worm*, a well known inſect, containing the parts of generation in both ſexes in each individual; long, deſtitute of feet, and of a reddiſh colour. They are, by ſome, eſteemed of great virtues in medicine, and are ſaid to be diuretic, diaphoretic, and anodyne, as alſo diſcutient, emollient, and openers of obſtructions; and are preſcribed in apoplexies, ſpaſms, and all nervous affections, and in the jaundice, dropſies, and colics. *Dale*, Pharm. p. 353.

EARTHING of a brick-kiln. See BRICK.

EASE *the Helm*, at ſea, imports to let the ſhip go more large, or more before the wind, or more larboard.

EASTERLING *Money*. See STERLING, *Cycl.*

EBBING and FLOWING *of the Sea*. See TIDES, *Cycl.*

EBDOMARY, *Ebdomadarius*, an officer, antiently appointed weekly in cathedral churches, to ſuperviſe the regular performance of divine ſervice, and preſcribe the particular duties of each perſon attending in the choir, as to reading, ſinging, and praying. To this purpoſe the *Ebdomary*, at the beginning of his week, drew up in form a bill, or writing, of the reſpective perſons, and their ſeveral offices, called *Tabula*, and the perſons there entered were ſtiled *Intabulati*. *Jacob* from *Baldock*'s Stat. Cath. of St. Paul.

EBDOME, Ἑβδόμη, in antiquity, a feſtival kept on the ſeventh of every lunar month, in honour of Apollo, to whom all ſeventh days were ſacred; becauſe one of them was his birthday, whence he was ſometimes called *Ebdomagenes*. For the ceremonies of this ſolemnity, ſee *Pott.* Archæol. Græc. l. 2. c. 20. T. 1. p. 385.

EBEREMORTH, or EBEREMORS, in our old laws, the ſame as *Eberemurdrum*, or *Aberemurder*. See ABEREMURDER.

EBEREMURDRUM, or ABEREMURDRUM, in our old writers. See ABEREMURDER.

EBOLICS, *Ebolica*, in pharmacy, medicines which help the delivery, in hard labour: Alſo medicines which cauſe abortion. *Blancard*, in voc. See ECBOLICS.

EBRICCATUM, a term uſed by Paracelſus to expreſs the partial loſs, or deprivation of reaſon, as it happens during drunkenneſs, but with the addition of the epithet *cæleſte* it ſignifies, with the ſame author, a much more exalted ſtate, a ſort of divine enthuſiaſm, or inſpiration, ſuch as the ſybils of old boaſted of, and, among the moderns, the French prophets, and ſome other religious ſects have pretended to. Paracelſus himſelf pretended, at times, to be be under ſome ſuch influence, but his mad fits ſeemed to have very little of inſpiration in them.

EBRILLADE, in the manege, a check of the bridle, which the horſeman gives to the horſe by a jerk of one rein, when he refuſes to turn. An *Ebrillade* differs from a *Saccade*, the latter being made with both reins at once, and the former only with one. Moſt people confound theſe two words under the general name of a check or jerk of the bridle, called in French *coup de bride*. It is a chaſtiſement, and no aid, and is diſuſed in academies. *Guillet.*

EBRIZIUS *Color*, a term uſed, by ſome of the old writers, to expreſs a very fine yellow. The word ſeems originally to have been obryzium, and was certainly derived from the *aurum obryzum*, or fine gold, of which this *Ebrizius* expreſſed the colour.

EBSEMECH, in chemiſtry, a word uſed by Langius, and ſome other authors, for quickſilver.

EBULLITION *of the Blood*, *Ebullitio Sanguinis*, in medicine, a term uſed by ſome of the old writers, to expreſs what they ſuppoſed to be the occaſion of the motion of the heart, which they attributed to a ſort of *Ebullition* of the blood contained there. Dr. *Lower* was the firſt who wrote againſt this ſyſtem, and proved not only that this *Ebullition* would be ineffectual to the end propoſed by it, as it would be as great an obſtacle to its ſyſtole, as they expected it to prove an aſſiſtance to its diaſtole; but that the heart evidently owed all its motions to its fibres and nerves, the motion of it being in all things conformable to that of other muſcles, and no more unintelligible than theirs. The whole motion of the heart indeed is its ſyſtole, for the diaſtole is no other than its reſtitution. There is a neceſſary commerce between the heart and brain, but both ultimately depend upon the ſtomach, as the conſtant purveyor and furniſher of the matter both of blood and ſpirits. Phil. Tranſ. N°. 45.

All the blood in the body paſſes thro' the heart thirteen times in an hour; and the florid colour of the arterial blood, which has been ſuppoſed by the arguers for the ebullitio ſanguinis to proceed from ſuch another principle, the accenſion, as they call it, in the heart, ariſes from the admixture of air with it in the lungs. The change of chyle into blood is another thing which has greatly perplexed theſe writers, and of which they have given as erroneous accounts as of the reſt. It is certain, that nothing paſſes from the ſpleen through the *vas breve* into the ſtomach, but that the ferment of the ſtomach proceeds immediately from the blood itſelf; the ſeparation of the chyle is performed in the inteſtines, and to facilitate its paſſage, it is diluted and refined by the juice of the pancreas ſecreted into the duodenum. This chyle is, by the ductus thoracicus above, tranſmitted into the blood and heart; and then, by degrees, and ſucceſſive changes, it is at laſt converted into blood, and ſerves for the nouriſhment of the ſeveral parts of the body. *Lower* de Corde.

EBULUS, *the dwarf Elder*, in medicine—The roots and leaves of dwarf alder are ſaid to be briſk cathartics. The flowers are eſteemed ſudorific, and the leaves, boiled till perfectly ſoft, make a good cataplaſm for the *ſciatica*.

EBUR *foſſile*, in natural hiſtory. See *Foſſile* IVORY.

EBUR *foſſile variegatum*, in the natural hiſtory of the antients, a name given to the ſubſtance which we now call the rough or native turquoiſe.

Foſſile ivory, and the bones of other animals, are frequently found bury'd at great depths in the earth, and are found to have preſerved their ſubſtance, texture, and colour in different degrees, according to the nature of the matter they happen to have lain among. Sometimes they are firm and ſolid, and ſcarce altered in colour, and ſometimes more or leſs hardened, and tinged to different colours by the different matter they have lain among.

Of this kind was the ſpotted foſſile ivory of the antients, which was in all reſpects the ſame with our rough turquoiſes of many places, which are no other than the teeth and bones of animals accidentally lodged in the way of particles of copper. Theſe are tinged more or leſs perfectly with a green or blue colour from theſe particles, and are often found of their native whitiſh caſt in the greater part of their ſubſtance, and only ſtreaked and ſpotted with ſmall variegations of a deep blue, which, by the aſſiſtance of a proper degree of heat, is diſlodged from theſe particular places, and diffuſed through the whole ſubſtance, tinging the whole with a fine pale blue. The antients have not been perfectly underſtood in their deſcription of this foſſile; for the Greeks, expreſſing its variegations by the word μέλανι, which is uſually tranſlated black, Pliny copies them in that ſenſe, and from him all the world have declared the variegated foſſile ivory of the antients, to be black and white. Theophraſtus however is the firſt who expreſſes the colours of this ſubſtance by the word μέλανι, and the ſame author, ſoon after expreſſing the male ſapphires, or thoſe of a deeper blue, by the ſame word; it is evident he could not mean by it any other than a deep blue, and plainly that what they called their variegated foſſile ivory, was no other than the rough turquoiſe. They ſeem however not to have known the art of diffuſing the colour through this ſubſtance by fire, and ſo converting it into a fine turquoiſe; but what they called callais was a turquoiſe of another kind, the botryoide copper ore, now uſually called alſo by the name of that gem. *Hill*'s Theophraſt. p. 94. See TURQUOISE.

ECACOATE, in zoology, a name by which the natives of ſome parts of America call the rattle-ſnake. See RATTLE-SNAKE.

ECALESIA, Ἐκαλησια, in antiquity, a feſtival kept in honour of Jupiter, ſurnamed *Hecalus*, or *Hecaleſius*, from *Hecale*, one of the borough towns in Attica. See *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 385.

ECASTOR, in antiquity, an oath wherein Caſtor was invoked. It was a cuſtom for the men never to ſwear by Caſtor, nor the women by Pollux. *Pitiſc.* Lex. Ant. T. 1. p. 703. in voc.

ECATESIA, Ἑκάλησια, in antiquity, an anniverſary ſolemnity, obſerved by the Stratonicenſians, in honour of Hecate.

The Athenians likewiſe had a public entertainment, or ſupper, every new moon, in honour of the ſame goddeſs. The ſupper was provided at the charge of the richer ſort, and was no ſooner brought to the accuſtomed place, but the poor people carried all off, giving out, that Hecate had devoured it. For the reſt of the ceremonies obſerved on this occaſion, ſee *Pott.* Arch. Græc. l. 2. c. 20.

ECATÆA, Ἑκάλαια, in antiquity, ſtatues erected to the goddeſs Hecate, for whom the Athenians had a great veneration, believing that ſhe was the overſeer of their families, and that ſhe protected their children. *Pott.* Arch. Græc. l. 2. c. 20. T. 1. p. 386.

ECATOMBÆON, Ἑκατομβαιων, in chronology, the firſt month of the Athenian year. It conſiſted of thirty days, and began on the firſt new moon after the ſummer ſolſtice, and conſequently anſwered to the latter part of our June, and beginning of July. The Bœotians called it *Hippodromus*, and the Macedonians *Lous*. See MONTH.

The word is a derivative from the Greek Ἑκατόμβη, an hecatomb, becauſe of the great number of hecatombs ſacrificed in it. *Pott.* Archæol Græc. l. 2. c. 26.

ECAVESSADE, in the manege, is uſed for a jerk of the caveſſon.

ECBASIS, Ἐκβασις, in rhetoric, is uſed for a digreſſion.

ECBOLE, Ἐκβολη, in rhetoric, is uſed for a digreſſion

ECBOLICS, *Ecbolica*, in the writings of the antient phyſicians, a term uſed to expreſs ſuch medicines as were given to promote delivery in child-birth. See DELIVERY.

ECBRASMATA. In the writings of ſome of the earlier phyſicians, a word uſed to expreſs eruptions, or puſtules, of a fiery and enflamed nature, appearing on different parts of the body. Virgil calls theſe ardentes papulæ, and ſeems to attri-

bute them to the wearing cloaths made of the wool of ſheep which had died of a murrain, which he there deſcribes.

ECBRYSOMATA, a word uſed by Galen, and the old phyſicians, for thoſe eminences or protuberances of the bones at the joints, which appear through the ſkin.

ECCATHARTICS, a name given, by different writers in medicine, to medicines of different kinds, and producing very different effects. We underſtand by the word ſimply purging medicines, and generally write it cathartics. Gorræus uſes it to ſignify ſuch remedies as are applied to the ſkin, to open the pores; ſome others mean deobſtruents of all kinds, by the word, and others have applied it to the medicines which promote expectoration.

ECCHYMOMA, in medicine, marks and ſpots in the ſkin, ariſing from the extravaſation of blood. *Blancard.*

ECCHYMOSIS (*Cycl.*)—An *Ecchymoſis*, or extravaſation of blood under the ſkin, is an accident too common, after bleeding in the arm. This ſometimes is ſo violent in degree, that the arm, after ſwelling, and becoming black and blue, is violently inflam'd, with acute pain, and either a ſuppuration, or beginning mortification. This accident frequently happens from the vein's having been cut quite aſunder in the operation, but oftener by the patient's uſing the arm too ſoon after bleeding, in violent and long exerciſes, in which the contractions of the muſcles make the veins ſwell, and force their blood through the orifice into the interſtices between the fleſh and ſkin.

In ſlight accidents of this kind there is no danger, the ſtagnating blood being eaſily diſperſed by a compreſs dipped in vinegar and ſalt, or in ſpirit of wine. And ſometimes it ſuppurates, and, making its way through the integuments, becomes naturally diſcharged, and the wound will heal with a diachylon plaiſter. But where the quantity of extravaſated blood is large, there is no hope of its being diſperſed ſo eaſily, but the diſorder generally terminates in an abſceſs or gangrene. To prevent theſe accidents, the ſurgeon's buſineſs is to ſcarify the livid parts, and apply warm fomentations. *Heiſter*'s Surgery, p. 285.

ECCLISIS, a word uſed by Hippocrates, and from him by many other of the old phyſicians, for a receſſion of a bone from its proper ſituation, that is a luxation.

ECCOPÆUS, the name of an inſtrument, deſcribed by ſome of the antient writers in medicine, and uſed for the ſame purpoſes for which the modern ſurgeons employ a lenticular or raſpatory. The antient inſtrument was a ſort of knife, with which they cut down morbid eminences of bones, or took out bones, in the caſe of a fractur'd ſkull.

ECCRIMOCRITICA, in medicine, ſigns to judge of a diſtemper, from particular excretions. *Blancard*, in voc.

ECCRINOLOGICA, a term uſed, by ſome writers, for that part of medicine which relates to the doctrine of excretions, or the diſcharge of any of the excrements out of the body.

ECCRISIS, a concretion of any excrementitious or morbid matter from any of the natural emunctories, as it happens in a perfect criſis. The matter thus excreted is alſo ſometimes called by this name.

ECDICI, Εκδικοι, among the antients, patrons of cities, who defended their rights, and took care of the public monies. *Hofm.* Lex. in voc.

ECDORA, a word uſed, by the antient phyſicians, to expreſs any kind of excoriation, but in a more particular manner that of the urethra.

ECDORIA, a term uſed, by the antient writers in medicine, for ſuch cauſtic or eſcharotic medicines, as have a power of taking off the ſkin.

ECDYSIA, Εκδυσια, in antiquity, a feſtival obſerved by the Phœſtians in honour of Latona. *Pott.* Archæol. Græc. l. 2. c. 20. T. 1. p. 387.

ECHAPE', in the manege, is uſed to denote a horſe, got between a ſtallion and a mare, of a different breed and country.

ECHAPER, in the manege, is uſed in the French academies for giving the horſe head, or putting on full ſpeed. Hence they ſay, *Laiſſez echaper de la main.*

ECHAUGUETTE, in the French military art, an elevated and covered place for a centinel. Richelet explains it by the Latin *ſpecula*, *excubiæ*. See GUERITE, *Cycl.*

Some diſtinguiſh the *Echauguette* from the guerite, giving the former name to centry-boxes made of wood, and ſquare; and the latter name to thoſe made of ſtone, and round. *Guillet.* in voc. *Guerite.*

ECHENEIS, in ichthyology. The antients have uſed this as the name of the petromyza, of ſome kinds; and Appian, in particular, plainly means by it our common lamprey.

ECHENEIS is alſo the name of a genus of fiſhes, the characters of which are theſe: The branchio ſtege membrane on each ſide contains about nine bones. The head is depreſſed, and marked on the upper ſide with tranſverſe rough ſtriæ. The body is oblong and roundiſh, but ſomewhat compreſſed. The back fin is oblong, and placed very far toward the tail. This is the fiſh called the remora by authors. Its under jaw is longer than its upper. It has a great number of teeth in both jaws. The colour of its body is hoary, and it has ſeven fins. Two pectoral ones, two ventral ones placed farther from the ſnout than the pectoral ones, one at the anus, one on the back, and one at the tail. The ſtriæ of the head are twenty-two in number, they are rough and tranſverſe, but are divided as it were into two ſeries by a middle longitudinal line. *Artedi*, Gen. Piſc. 11. See the article REMORA.

ECHIDNA, in natural hiſtory, a name given, by ſome authors, to the ſeveral kinds of ophites, or ſerpent ſtone, from Εχιδνα, a viper, or ſerpent.

ECHINI *Foſſiles*. It is a very remarkable obſervation of Auguſtino Scilla, that all thoſe foſſile *Echini* which he had found in the Meſſineſe and Calabrian hills, and about Malta, were, when bruiſed, as was frequently the caſe, always bruiſed by a perpendicular preſſure. The cruſt of all *Echini* has two centers, one directly oppoſite to the other, ſo that if they happened to lie in the liquid mud, in ſuch a manner as that the loweſt center was perpendicular to the horizon, they were bruiſed ſo as not to loſe their circular figure, only they were much compreſſed. If they are found, on the contrary, lying on one ſide, they are ſqueezed out of that ſhape, and the membranes of their ligatures are parted variouſly from each other, according to the variety of the ſituation of the ſhells in the mud, at that time. All which evidently ſhew, that however hard they are now, they were once ſoft ſhells, and that they were brought, in their perfect ſtate, into the places where we find them, not generated there, as ſome have idly imagined, and that, as the liquid mud, into which they were received, dry'd, the ſuperincumbent weight preſſed perpendicularly upon them, and they were ſqueezed, compreſſed, or hurt by it, in the poſture in which they then lay, and have ever ſince continued. See ECHINUS, *Cycl.*

It appears alſo, that their open mouths had, according to the ſituation in which the ſhell lay, received more or leſs of the liquid mud into them, and that ſometimes a greater, ſometimes a ſmaller, part of the ſhell became filled by it, and, according to the quantity of mud thus receiv'd, the preſſure from above has acted variouſly upon the ſhells containing it: Thoſe which have moſt of it having always ſuffered leaſt by this preſſure from above; and thoſe which have leaſt having ſuffered moſt. If we conſider that this mud, tho' liquid, when firſt received, had probably begun to harden into a ſolid maſs, before the weight from above affected it. It will be eaſy to conceive how, in this hardened ſtate, it made a counter preſſure againſt that from above, and ſo ſaved the containing ſhell in great part. *Aguſt. Scill.* de Petrifac.

ECHINI *Spatagi*. It is obſerved, that the foſſile *Echini ſpatagi* are very frequent in the iſland of Malta, and people who are for having all foſſile ſhells to be real terreſtrial bodies, produced of ſeeds in the earth, and never to have been parts of real animals, object to theſe having ever been ſuch, their being found ſo plentifully in this foſſile ſtate, and ſo rarely in the native or recent one. This is no objection of weight; becauſe the cornua ammonis give a much ſtronger, they being a more common foſſile, and never being found recent at all. This is no argument of weight, however, ſince it is eaſy to conceive, that the ſea, at the time of the univerſal deluge, might throw up ſhells from its deep bottoms, which we never can get at in fiſhing or otherwiſe. And Scilla has proved the abſurdity of the objection, in regard to the *Echini ſpatagi*, and ſhewn that thoſe people who raiſed it, have been led into it by their ignorance. For he has affirmed, that they may be picked up by hundreds at a time in the port of Meſſina, and that himſelf once took up more than a hundred recent ones in an hour.

The ſhells of this ſpecies, found foſſile in the iſland of Malta, are very frequently full of the marle, of which the upper ſtratum of that iſland conſiſts; and ſome of them are crack'd, and have been depreſſed a little inwards. This is an evident proof that they once were real ſhells, they having, in this caſe, given way, as far as the included marle would let them, on the preſſure of ſome external force. See Tab. of Shells, N°. 24.

ECHINITES, or ECHINITÆ, in natural hiſtory, the name given by authors to the foſſile ſhells of the ſeveral ſpecies of *Echini marini*, and to the ſtones formed in them. Of theſe there is almoſt an endleſs variety in the foſſile world. Many of thoſe which we daily find in our chalkpits are the ſame with thoſe now known to us in their recent ſtate, or living in the ſea; but we have numbers of others, of which our imperfect knowledge of the animal world gives us no certain account, in their recent ſtate.

The ſhells of ſome of theſe are found ſcarce at all altered from their original condition. In many others we have plated ſpar filling the places of the ſhells, and retaining every lineament of them. But their moſt frequent appearance is in the form of maſſes of hard flint, or other ſtone, which have been caſt and formed in them, having been received, while in a fluid ſtate, into the hollow of the ſhell, and therefore retaining all the lineaments of the inner ſurface. And, not unfrequently, theſe alſo are coated over with a ſparry or ſtony matter, ſupplying the place of the ſhell they were formed in; and having been made, by the inſenſible depoſition of hard matter, in the place of the particles of the ſhell inſenſibly waſting away, theſe retain all the lineaments of the outer part of the ſhell, as the formed flint does of the inner one. Sometimes pure cryſtal is found in the place of flint in theſe, and often cryſtal

but

but lightly debaſed by earth; and theſe make very elegant ſpecimens. *Hill*'s Hiſt. of Foſſils, p. 651.

The various genera of foſſile echini, or *Echinitæ*, are uſually known among authors by the names of *ſpatagi*, *cordati*, *galeati*, *pileati*, *diſcoides*, *ovarii*, *pentaphylloides*.

What is generally underſtood by the word *Echinitæ*, is a ſort of arched ſhells, or ſtones formed in them, covered with divers eminences and cavities, ſome of which are diſpoſed into beautiful lines, diverging from the ſummit; and always having two apertures, the one for the mouth, the other for the anus of the animal: Of theſe,

The *echini cordati* are ſuch as have a remarkable furrow on one ſide, or end, which is uſually broader than any other part of the body, and, by means of this furrow, repreſents, in ſome degree, the figure of a heart at cards.

The *galeati* are ſuch as have the baſis ſomewhat oblong, and the apertures; one in the very margin, and the other near the margin, on the oppoſite ſide. The *pileati* and *diſcoides*, are ſubdiſtinctions of this kind.

The *pileati* are higher, and approach to a conic figure.

The *diſcoides* are flatter, and more compreſſed.

The *ovarii* have only one aperture at the baſe, and have large and unequal tubercles and papillæ.

The *pentaphylloides* have rows of ſhort lines, which are ſo diſpoſed as to repreſent a cinquefoil leaf.

The *ſpatagi* is a very comprehenſive term, taking in moſt of the others as ſubdiſtinctions. It comprehends all that have two apertures in the baſe, and that are covered with ſmall tubercles. See Tab. of Foſſils, Claſs 9.

ECHINODERMA, in natural hiſtory, the name of the ſea animal more commonly known by the name of the *echinus marinus*, or ſea hedge-hog. Theſe are fiſh living in an arched ſhell, of various figures, according to the various ſpecies; and always, beſides a vaſt number of ſmaller protuberances and cavities, having two remarkable apertures, the one ſerving for the mouth, the other for the anus of the animal; which are variouſly placed in the different genera and ſpecies.

There are yet wanting, in natural hiſtory, the proper characters and diſtinctions of cruſtaceous and teſtaceous fiſhes, and, till that is fix'd, there is no ſaying whether theſe creatures belong to the teſtaceous or cruſtaceous tribe. The coverings of the pectuncles, and other fiſh, uſually diſtinguiſh'd with us by the name of ſhell-fiſh, are univerſally allowed to be all ſhells; and thoſe of the crab and lobſter kinds are called cruſts, or cruſtaceous covering: But the Echini marini are yet wholly undetermined by authors, as to which of theſe claſſes of animals they belong to. Pliny calls their covering ſometimes a ſhell, ſometimes a cruſt, uſing the words teſta and cruſta indifferently. Some allot them a place in the cruſtaceous tribe, becauſe they have teeth like thoſe of the cruſtaceous kinds, which the ſhell-fiſh want, but we are very far from knowing yet, whether the cruſtaceous, or the echini, have all of them teeth, or not.

Many affirm that the ſpines of the echini ſerve them in the place of legs; but there are many alſo who deny this, and ſome affirm, that they have, in the living fiſh, found legs in another part, affixed not to the ſhell, but to the body of the animal. *Klein*, Echinod. p. 4.

ECHINOMETRA, a name given by ſome to the ſeveral depreſſed ſpecies of the *Echinodermata*. See Tab. of Teſtaceous Animals, N°. 15, 16, 17, and the article ECHINODERMA.

ECHINOPHORA, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the roſaceous kind, being compoſed of ſeveral petals, arranged in a circular form, and theſe are collected into an umbellated head, and contained in the circuit of one common cup, which finally becomes an unicapſular fruit, containing an oblong ſeed.

The ſpecies of *Echinophora*, enumerated by Mr. Tournefort, are theſe: 1. The prickly ſea *Echinophora*, called by authors the prickly ſampire, and the ſea parſnep. 2. The parſley-leav'd *Echinophora*. *Tourn.* Inſt. p. 656.

ECHINOPHORA. According to Linnæus, the characters of this genus of plants are theſe: The general cup is an one-leav'd involucrum, divided into many ſegments of a turbinated form, containing many flowers, and ſurrounding the germens. The particular cup of each flower is very ſmall, compoſed of one leaf, divided into five ſegments, ſtanding upon the germen, and not falling with the flower. The ſeparate flowers are pentapetalous; the petals unequal, and ſtanding very wide aſunder at the mouth. The ſtamina are five ſimple filaments. The apices are of a roundiſh figure. The piſtil conſiſts of an oblong germen, placed under the cup, and within the general covering. The ſtyles are two, and are ſimple; the apices are alſo ſimple. The involucrum becomes finally indurated and echinated, and contains the ſeeds, which are of an oblong figure. *Linnæi* Gen. Plant. p. 525. *Tourn.* 423.

ECHINOPHORA, in ichthyology, a name given by Rondeletius to a ſpecies of ſea-ſnail, of the round-mouth'd kind, or claſs of the cochleæ lunares.

He calls it *Echinophora*, becauſe it is all over beſet with tubercles, but this is a very ill choſen name, as it confounds it with the echini, or ſea eggs; he had much better have called it cochlea tuberculoſa. See LUNARES, *Cochleæ*.

ECHINOPHTHALMIA, in the works of the antient writers on medicine, the name of a diſeaſe, which was an inflammation of that part of the eyelids, which is beſet with hairs, or on which the eye-laſhes grow.

ECHINOPUS, *globe thiſtle*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of a globoſe ſhape, and of the floſculous kind, being compoſed of a number of floſcules divided into ſeveral equal ſegments at the ends, and placed on the embryo ſeeds, but each having its peculiar ſquammoſe cup, which is affixed to the thalamus of the flower, and contains the embryo, when it has ripened into a ſeed. The ſpecies of *Echinopus*, enumerated by Mr. Tournefort, are theſe: 1. The common *Echinopus*, or globe thiſtle. 2. The great *Echinopus*, with white flowers, and blue ſtamina in the middle. 3. The leſſer *Echinopus*. 4. The fine-leav'd *Echinopus*, with violet-coloured flowers. 5. The leſſer *Echinopus*, with white flowers. 6. The leſſer annual *Echinopus*, with large heads. 7. The American ſhrub *Echinopus*, with flowers at the joints of the ſtalks, and with ilex leaves hoary underneath. *Tourn.* Inſt. p. 463.

ECHINUS, the hedge-hog. See ERINACEUS.

ECHINUS *Marinus*. See ECHINODERMA.

ECHIUM, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: The cup is an erect perianthium, divided into five tapering ſegments, and remains after the flower is fallen. The flower conſiſts of one petal, which forms a ſhort cylindric tube, with an erect edge widening by degrees, and divided into five ſegments, the two upper longer than the reſt, and the loweſt ſmaller than the reſt, and bending backward. The ſtamina are five tapering filaments of the length of the flower. The antheræ are oblong, and laid upon them. The piſtillum has four germina. The ſtyle is ſlender, and of the length of the ſtamina. The ſtigma is obtuſe and bifid. The cup ſerves in the place of a fruit, becoming ſtiff and rigid, and containing in its bottom four roundiſh and obliquely pointed ſeeds. *Linnæi* Genera Plant. p. 60.

ECHIUM, called in Engliſh *vipers bugloſs*, according to Tournefort is the name of a genus of plants, the characters of which are theſe: The flower conſiſts of one leaf, of a funnel ſhape, and a little crooked, the upper edge ſtanding much farther out than the inner one. The cup is divided, even to the baſe, into ſeveral ſegments, and from it there ariſes a piſtil, which is fixed in the manner of a nail to the hinder part of the flower, and is ſurrounded by four embryo's, which afterwards ripen into as many ſeeds. Theſe are of the ſhape of a viper's head, and remain in the cup, which becomes much enlarged to receive them. *Tourn.* Inſt. p. 135.

The ſpecies of *Echium*, enumerated by Mr. Tournefort, are theſe: 1. The great rough white flowered *Echium*. 2. The great rough blue flowered *Echium*. 3. The Portugal *Echium*, with very large leaves. 4. The common *Echium*. 5. The white flowered common *Echium*. 6. The broad-leav'd cretick red flowered *Echium*. 7. The variegated flowered cretic *Echium*. 8. The narrow-leav'd red flowered cretick *Echium*. 9. The hairy ſpotted wild *Echium*. 10. The large flowered ſea *Echium*. 11. The annual procumbent *Echium*, with blackiſh red flowers. 12. The narrow-leav'd hairy *Echium*. And 13. The roſemary-leav'd *Echium*.

Pliny has made a ſtrange miſtake in his account of this plant: He ſays, the antients were acquainted with two ſpecies of it, the deſcriptions of which he gives correctly enough from dioſcorides; but then he adds, that there is a third kind, called by ſome perſonata, a plant with extremely large leaves, and with burrs, or prickly nodules, by way of fruit.

It is clear from this, that the author confounded the words *Arctium* and *Echium* together, though ſufficiently unlike both in ſound and orthography, to have been diſtinguiſhed; and his third *Echium* is no other than the great arctium, or burdock. The flowers of the *vipers bugloſs* are ſuppoſed to poſſeſs the virtue of cordials, in the ſame degree with the borrage and bugloſs. Some authors greatly recommend a decoction of the dried plant in epilepſies. It is ſaid that very ſingular cures have been done by it.

ECHO (*Cycl.*)—There is an *Echo* at Bruſſels which anſwers fifteen times; but this is nothing when compared to one near Milan, where, upon firing a piſtol, fifty-ſix reiterations of the noiſe are heard, and when a louder piſtol was diſcharged, above ſixty reports were counted. The firſt twenty *echoes* were with ſome diſtinctneſs, but then, as the noiſe ſeem'd to fly away, and anſwer at a greater diſtance, the repetitions are ſo doubled, that they can hardly be all counted. Phil. Tranſ. N°. 480. p. 220.

ECHO, in muſic, pieces compoſed in imitation of *echoes*. *Broſſ.* Muſ. Dict. in voc.

Sometimes alſo the word *Echo* ſtands for *Piano*, intimating that the inſtrument, or voice, is to play or ſing after a ſoft and ſweet manner. Organs and harpſichords have what they call an *echo*-ſtop. Id. Ibid.

ECHPHYAS, an excreſcence, or appendix, a word uſed by many of the antient writers in medicine. The appendicula vermiformis is thus called by many authors.

ECHTHELYNSIS, a term uſed, by the antient phyſicians, for a laxneſs, or flabby ſoftneſs, of the fleſh of the legs, or any other part of the body. Some have alſo uſed the word to expreſs a fault in bandages, when too looſe.

ECLAMPSIS, a word uſed by Hippocrates in deſcribing the epilepſy, and, by moſt people, ſuppoſed, by a forced explanation, to mean the change which children undergo at the age of puberty, a time of great conſequence in this diſeaſe, at which nature ſhines forth in new luſtre, by the increaſe both of ſtrength and underſtanding. But the more natural and obvious ſenſe of the word ſeems to be the expreſſing thoſe reſplendent flaſhings and ſparklings of light which ſtrike the eyes of perſons ſubject to this diſtemper, and which are called by Cælius Aurelianus *ſcintillarum micæ* and *circuli ignei*: And the ſame author, in deſcribing one of his epileptic caſes, particularly mentions the flaſhings of lightning, as it were, which were frequent before his eyes. It is not to be omitted that Hippocrates and Galen have both alſo uſed this word in another ſenſe, to expreſs the higheſt degree of a fever, juſt before and at the criſis, when it is in its utmoſt degree of heat, and exerts itſelf with its utmoſt violence.

ECLECTICS, the name of a certain ſet of phyſicians among the antients, of whom Archigenes was one, who ſelected from the opinions of all the other ſects, that which appeared to them beſt, and moſt rational; hence they were called *Eclectics*, and their preſcriptions medicina eclectica.

ECLECTOS, a name given, by many writers, to that form of medicine which we call a *Linctus*; a compoſition, made to be gently ſwallowed down, in coughs, and the like diſorders, and uſually containing oil of ſome kind.

ECLIPSE (*Cycl.*)—In the philoſophical tranſactions, N°. 461. Sect. 9. we have a contrivance to repreſent ſolar *eclipſes*, by means of the terreſtrial globe, by Mr. Seguer, profeſſor of mathematics at Gottingen.

ECLISIS, a word uſed, by the antient phyſicians, for a general faintneſs and feebleneſs of all parts of the body. Hippocrates uſes it for a loſs of voice, with a general decay of ſtrength, and, in ſome other places, for a great weakening of the body, by violent diſcharges by ſtool.

ECLOGARII, among the antients, were perſons who excerped or picked out the beſt pieces of the books they read, which, for that reaſon, were called *Eclogues*, or ſelect pieces. See ECLOGUE, *Cycl.*

ECMARTYRIA, Εκμαρτυρια, in antiquity, a kind of ſecond-hand evidence, admitted in the Athenian courts. It was not founded on the knowledge of the witneſs himſelf, but on that of another perſon, who had been an eye-witneſs of the fact in queſtion, but was at this time either dead, or in a foreign country, or detained by ſickneſs; for, except in ſuch caſes, the allegations of abſent perſons were never taken for lawful evidence. *Pott.* Archæol. Græc. l. 1. c. 21. T. 1. p. 117.

ECNEPHIAS, a word uſed, by Galen, to expreſs a peculiar ſort of fever, which, he ſays, was at once hot and humid, and which he therefore reſembles, by the name, to the ſun breaking out from a watery cloud.

ECOUTE', in the manege, is uſed for a pace, or motion of a horſe, when he rides well upon the hand and the heels, is compactly put upon his haunches, and hears, or liſtens, to the heels or ſpurs; and continues duly ballanced between the heels, without throwing to either ſide. This happens when a horſe has a fine ſenſe of the aids of the hand and heel.

ECPHONESIS, Εκφωνησις, in rhetoric, the ſame with exclamation. See EXCLAMATION, *Cycl.*

ECPHRAXIS, in medicine, is a taking away obſtructions in any part. *Blancard.*

ECPHYSESIS, in medicine, is a diſeaſe in which the patient breathes thick.

ECPHYSIS, in anatomy, is any proceſs that coheres with, or adheres to a bone.

ECPIESMUS, Επισμος, in the antient writers of medicine, a word uſed to expreſs a diſtemperature of the eye, which conſiſts in a very great prominence of the entire globe of the eye, which is, as it were, thruſt out of its ſocket, or orbit, by a great flux of humours, or an inflammation.

ECPLEROMA, in the writings of the antient phyſicians, the name given to a kind of cuſhion of leather, ſtuffed with ſome firm ſubſtance, and fitted to the cavities of the armpits, uſed in reducing luxations of the humerus.

ECPLEXIS, in the writings of the antient phyſicians, a word uſed to expreſs a tranſport of mind, proceeding from ſome ſudden perturbation. Hippocrates and Galen uſe the word to ſignify a ſtupor, or ſtupefaction, in which the patient lies without motion, without ſpeaking or ſtirring, and with his eyes open.

ECPNEUMATOSIS, in medicine, the ſame with expiration.

ECPNOE, a word uſed by medical writers, to expreſs that part of reſpiration, in which the breath is expelled out of the lungs.

ECPTOMA, a word uſed, by the antient phyſicians, in three or four different ſenſes. It is ſometimes made to expreſs a luxation, or diſlocation of a bone. Sometimes it is uſed for the falling off of any corrupted part, ſometimes for the excluſion of the ſecundines after child-birth, and ſometimes for a falling down of the womb, or a deſcent of the omentum, or the inteſtine, into the ſcrotum.

ECPTOSIS, in ſurgery, the ſame with luxation.

ECPUCTICA, in the materia medica, are condenſing medicines. See INCRASSANTIA.

ECREGMA, properly the name of a part, piece, or ſegment of any thing; but Hippocrates has, in ſome places, uſed it as the name of an eruption.

ECRITHMUS, in medicine, an irregular pulſe, which obſerves no method, nor number, incident to any age. *Blancard.*

ECSTASIS *Cutis*, an extenſion of the ſkin, a term uſed by the antients, as the oppoſite to corrugatio, or wrinkling.

ECSTATICI, Εκστατικοι, in antiquity, a kind of diviners, who were caſt into trances or ecſtaſies, in which they lay like dead men, or aſleep, deprived of all ſenſe and motion, but after ſome time returning to themſelves, gave ſtrange relations of what they had ſeen and heard. *Pott.* Archæol. Græc. l. 2. c. 12. T. 1. p. 302.

ECSTROPHIUS, a name given by the antient writers in medicine, to any thing that threw out the internal tumours of the piles, ſo that external applications might be made to them.

ECTHLIMA, an ulceration ariſing from a violent compreſſion in the ſurface of the ſkin. *Blancard.*

ECTHYMA, a name given, by Hippocrates, to any puſtule, or cutaneous eruption.

ECTOMIAS, a name, uſed by the antient phyſicians, to expreſs a caſtrated animal.

ECTRIMMA, excoriation or galling. Hippocrates has uſed the word particularly to expreſs exulcerations of the ſkin about the os ſacrum, contracted by lying long in one poſture, in caſes of fractures of the thigh, or in lingering illneſſes, in which the patient is confined to his bed for a long time.

ECTROPIUM, that diſtemperature of the eyelids in which they are everted, or retracted, ſo as to ſhew their internal or red ſurface, and cannot ſufficiently cover the eye. Sometimes this is a ſimple and original diſorder, and ſometimes it is only a ſymptom of ſome other, as of an inflammation, ſarcoma, tumour, or the like. This ſometimes owes its original to the contraction of the ſkin of the eyelids, by the ſcar of a wound, ulcer, burn, *&c.* or to the induration and contraction of the ſkin, after an inflammation, and ſometimes it in a great meaſure proceeds from the injudicious uſe of aſtringent collyriums, or eye-waters.

When this diſorder is become inveterate, it is not eaſily cur'd; while recent, it is to be attempted by relaxing and elongating the ſkin of the eyelid, by the application of emollients, ſuch as the vapours of hot milk, or water, oil of almonds, mucilage of quince ſeed, and ointment of marſh-mallows. Theſe muſt be repeated every day, the ſkin of the eyelid drawn frequently towards its right poſition, and when the patient goes to bed, the eyelids ſhould be brought together, and reſtrained in their proper poſture by a plaiſter compreſs and bandage. But if all this fail, and the caſe yet appear not incurable, manual operation muſt take place.

The operation is performed in the following manner. Firſt a ſemilunar inciſion is to be made in the external ſkin of the eyelid, next its tarſus, or cartilaginous margin, making the angles of the inciſion, downward in the upper lid, and upward in the under, that by this means the ſkin may be elongated. If it does not appear ſufficiently let out by one inciſion, two or three more may be made, running parallel with the firſt, and at the diſtance of a ſmall packthread. When the eyelid is thus ſufficiently elongated, the inciſions muſt be dreſſed firſt with dry lint ſtuffed into them, and afterwards with lint, armed with ſome vulnerary unguent, which will prevent the ſkin from growing together again, and will occaſion new fleſh to be formed in the place, which will elongate the ſkin. Laſtly, to forward the extenſion and cure, a piece of ſticking plaiſter ſhould be faſtened to the eyelid, to keep it extended, and this muſt be continued till the eye will ſhut cloſe. When this caſe has continued from the patient's birth, the cure is very difficult, and it is a yet more hopeleſs caſe, when it happens to old people, from a weakneſs of the orbicular muſcle. *Heiſter*'s Surgery, p. 372.

ECTROTICA, a name given, by the antient phyſicians, to ſuch medicines as have power to occaſion abortion.

ECU *Antient*, in heraldry, a term ſignifying the antient ſhield. By this they mean the antique triangular-ſhap'd ſhield, on which the arms of the noble families of France have been painted, which ſerves very conveniently, where the arms conſiſt of a large number of figures, and that number not even. Thus, if five animals are to be repreſented, this kind of ſhield receives very conveniently three at the bottom, and two at the top; and if three, then one at the top, and two at the bottom. This ſhield is to be ſeen on old gems, and ſome ruins; but the modern ſhield, which is ſquare, and rounded, and pointed at the bottom, has baniſhed the uſe of this. *Niſbet*'s Heraldry, p. 12.

ECURIE, in the manege, the covert-place for the lodging or houſing of horſes. The word is French. We uſe *Stable* in common diſcourſe.

ECUYER, in the French manege, is uſed for the riding-maſter. Sometimes it denotes certain officers in the king of France's houſhold, who help the king in mounting his horſe and alighting, and follow him on horſeback, and carry his ſword. Theſe are called *Ecuyers de Quartier*.

Gentlemen-uſhers to the queen of France, and the maſters of the horſe to princes, and perſons of quality, are alſo called *Ecuyers*. Beſides theſe, there are others called *Ecuyers Cavalcadours*. See CAVALCADOUR. *Guillet*.

ECZEMA, a name given, by the antient phyſicians, to any fiery puſtule on the ſkin.

EDESSENUM, the name of a famous collyrium, reckoned among the number of the monohemera, or ſuch as cur'd certain diſorders of the eyes, in one day. It is ſuppoſed to have had its name *Edeſſenum* from the city of Edeſſa, where it was firſt invented, and in great uſe. Its compoſition was this: Take Gum arabic, tragacanth, ſarcocolla, acacia, and ſtarch, of each two drams, opium four drams, cerus eight drams, cadmia ſixteen drams; theſe were all to be reduced to a fine powder, and afterwards mixed with a ſufficient quantity of water, to be uſed to waſh the eyes.

EDGE *in with a ſhip*, in the ſea language, is ſaid of a chace, that is making up to him.

EDGINGS, in gardening, the ſeries of ſmall, but durable, plants, ſet round the edges or borders of flower-beds, *&c.* The beſt and moſt durable of all plants for this uſe, is box, which, if well planted, and rightly manag'd, will continue in ſtrength and beauty for many years. The ſeaſons for planting this are the autumn, and very early in the ſpring. And the beſt ſpecies for this purpoſe, is the dwarf Dutch box. The edgings of box are now only planted on the ſides of borders next walls, and not as was ſome time ſince the faſhion, all round borders or fruit-beds, in the middle of gardens, unleſs they have a gravel walk between them, in which caſe it ſerves to keep the earth of the borders from waſhing down on the walks in hard rains, and fouling the gravel.

In the laſt age, it was alſo a very common practice to plant borders, or edgings, of aromatic herbs, as thyme, ſavory, hyſſop, lavender, and the like: But theſe are all apt to grow woody, and to be in part, or wholly, deſtroyed in hard winters. Daiſies, thrift, or ſea julyflower, and chamomile, are alſo uſed by ſome for this purpoſe; but they require yearly tranſplanting, and a great deal of trouble, elſe they grow out of form; and theſe are alſo ſubject to periſh in very hard ſeaſons. *Miller*'s Gardener's Dict.

EDULCORATION, (*Cycl.*) in metallurgy, is the ſeparating, by a ſolution in water, the ſalts that have been left adhering to a body after any operation. This is properly a kind of moiſt ſolution, the ſaline parts adhering to bodies, not ſoluble in water, being by that menſtruum taken up, and eaten off from the body, and the ſolution afterwards ſeparated from the remaining ſolid, either by ſubſidence or filtration.

It is proper, in this operation, to enlarge the ſurface of the body to be edulcorated, by pounding it in a mortar, that the ſolution may have the ſpeedier ſucceſs; and for this purpoſe, it ſhould alſo be kept continually ſtirring with a ſtick, while the water is on it, that all the parts of the body to be edulcorated, which otherwiſe would ſome of them ſink to the bottom, and remain applied againſt the bottom of the veſſel it is perperform'd in, may be made equally at one time or other contiguous to the particles of the edulcorating fluid, by which all ſolutions are indeed greatly facilitated. Boiling water is alſo, in ſome caſes, requiſite, for the heat of that, by the inward motion, and rarefaction it occaſions, promotes, in an extraordinary manner, ſaline ſolutions.

A perfect ablution from the ſalt, however, is not always obtained by this method; for as every part of the menſtruum contains in it a proportionable quantity of the matter diſſolv'd, and there remains always ſome part of the menſtruum thus impregnated in the body to be edulcorated, it is evident that there alſo remains in it the proportionable quantity of ſalt for that menſtruum. Let us take, for inſtance, the alkaline ſalt in wood-aſhes, pour hot water on ſuch aſhes, and let them boil together for ſome time, then by decantation, or otherwiſe, ſeparate the lye or water impregnated with the ſalt of the aſhes, from the aſhes themſelves; there will remain, after all you can do to pour it off, at leaſt one fourth part of the lye among the aſhes, and of courſe a proportionable part of the diſſolved ſalt. Pour more water on this, and decant it off again, a quantity of ſalt, tho' much leſs than the former, will again remain; and ſo on, if the operation be repeated ever ſo often, only the ſalt will be in leſs and leſs quantity every time. Very frequent repetitions of this operation are therefore always neceſſary, and even where the operator has tir'd himſelf with them, a nice experimenter will always find ſome ſmall portion of the ſalt remaining.

To this remaining of the ſaline particles, in ſome degree, after ever ſo often repeated waſhings, is owing the great loſs artificers uſually find in reducing the calxes of gold and ſilver, made with acids. For the ſmall remainder of the acids which yet adhere, being agitated by an impetuous, and eſpecially if by an open fire, carry off in their evaporation a great many particles of the metals with them, not even excepting aqua fortis itſelf, which nevertheleſs is ſaid to be, nay, and really is, of a fixing nature, but that only in a certain degree. *Cramer*, Art of Aſſ. 196.

EEL, *Anguilla*, (*Cycl.*)—There is ſcarce any animal, the generation of which has ſo much perplexed and puzzled the thoughts of the learned and curious as this. Ariſtotle firſt gave birth to an opinion, that *Eels* were of no ſex, nor did propagate their ſpecies like other animals, but were equivocally gender'd of the mud: And as wild and abſurd a ſyſtem as this is, there have not been wanting many, even in theſe later and more enlightened times, who have given into it.

Eels are found in pools and ditches newly dug, and where no parent animals of the ſame kind could come to give them origin. This has given occaſion to people's falling into the opinion, that they were equivocally engender'd there: And Myllius, who has written of the generations of animals; and Morhofius of the tranſmutation of metals, have given a proceſs for the ſtocking any new pond with *Eels*, as they ſay it was at that time practiſed by the Dutch. The method was this:

In the months of May and June, ſome graſſy turfs are to be cut up early in a morning, at which time they ſuppoſe there falls a dew, which afterwards becomes enlivened into *Eels*: Theſe turfs are to be laid in a double row, with their graſſy ſides together, and are to be placed on the warmeſt ſide of the pond, or ditch. The heat of the ſun, they ſay, will there finiſh the formation of the *Eels*, and they will crawl down into the water, where they will live and grow. This proceſs ſeems much of the ſame kind with that for the making live crayfiſh, by bruiſing and burning the full grown ones, and then ſteeping them in water. This is gravely delivered by no leſs a man than Sir Kenelm Digby, but has few believers at this time. Phil. Tranſ. N°. 238. p. 93.

The preſent age has been ſo well inſtructed in the ſyſtem of animal generation, by the works of Swammerdam, Lewenhoeck, Malpighi, Redi, Ray, and a great number of other writers, of the ſame valuable ſtamp, that there is left no room to doubt but all animals are produced by the copulation of parents like themſelves; and the oddity of *Eels* being found in new ponds, is eaſily accounted for, when we know that Dr. Plot, and many others, have given accounts of whole droves of them leaving one ditch or pond, and croſſing the meadows together, to go to another. We know that the *Eel*, of all fiſhes, lives the longeſt out of water, and it is not difficult to conceive, that it may, without any inconvenience, ſpend ſo much time out of that element, as is neceſſary for the paſſing from one water to another; and when a parcel of theſe fiſhes have found a new pond, it is no wonder that they continue in it, ſince they feed on worms and other inſects of the earth; and there is probability that theſe may be found in peculiarly great abundance in a place where the earth has been newly diſturbed, and where they have not been prey'd upon.

Pliny tells us, that an *Eel* will live ſix days out of water without hurt; but this is not neceſſary for the poſſibility of their making the ſhort journey here mentioned. Geſner tells a ſtory from Albertus, of a parcel of *Eels* which, in a very cold winter, in the year 1125, not only left their natural element, but were found bedded together, in vaſt numbers, under a dry hay-ſtack.

Eels, by their ſhape and motion, which both reſemble thoſe of ſerpents, are much better qualify'd for living or travelling out of water than any other animal of the fiſh kind; but they do not ſeem the only ones; for we have, at this time, what are called foſſile fiſh, which are dug up out of the ſands, near rivers; and as long ſince as in the times of Theophraſtus, they were thought to be ſo numerous, that he has written a whole treatiſe concerning them, which he has entitled *De Piſcibus in Sicco viventibus*, of thoſe fiſhes which live out of water: And Aurelius Severinus has republiſhed this, with additions, in the Latin language, at Naples, in 1655. Ariſtotle tells us, that the Cerian and Paphlagonian fiſhes wander about upon the dry ſands, and return into the water occaſionally: And George Pictorius relates the ſame of fiſh of the river Cherati in Judea. Rondeletius aſſents to the poſſibility of this in particular fiſhes, and adds, that *Eels* have all the requiſites for it; their ſlit for the gills being very narrow, and calculated to prevent any too ſudden or forcible appulſe of the external air, which is what kills other fiſhes on their lying out of water. Phil. Tranſ. N°. 238. p. 97.

Tho' the learned world at this time generally allows, that *Eels* are produced like other animals, by parents of their own kind, yet there remain many doubts, about the manner in which this is performed, ſome allowing the *Eels* to be like the generality of other animals of different ſexes, in the different individuals; and others affirming that they are all hermaphrodites, each having the parts of generation of both ſexes. Rondeletius affirms they are of different ſexes: And Mr. Allen, who has given a very curious paper concerning them, in our philoſophical tranſactions, is of the ſame opinion;

and both ſay, that the parts of the ſexes may be diſcovered, on a careful inſpection, and ſome found to be males, and others females; but theſe parts are, in both ſexes, they ſay, buried in a large quantity of fat, and they are of opinion, that hence proceeded the miſtake of Ariſtotle and his followers, who, not being able to find theſe parts, concluded that they did not exiſt at all.

Among thoſe who allow the *Eel* to be produced like other animals, from animal parents, which have the ſexes, ſome are of opinion that they are viviparous, and others, that they are oviparous; but a gentleman of our nation, Mr. Chartwynd, ſeems to have determined this great controverſy, by obſerving, that if the aperture under the belly of the *Eel*, which looks red in the month of May, be cut at that time, the young *Eels* will be ſeen to come forth alive, after the operation. Mr. Allen alſo affirms them to be viviparous; but his obſervation concerning the place of their conception, does not appear analogous to that care and induſtry of nature, in providing convenient receptacles for the fœtus; neither is it conſonant to reaſon, that when nature has provided an uterus in all animals, not only the viviparous, but the oviparous, and even in inſects, that the *Eel* and the ſwordfiſh ſhould be without this part, as Bartholine ſuppoſes, much leſs that the guts, which are appointed by nature for the ſecretion of nouriſhment, and expulſion of the fœces, and which are in continual motion to anſwer theſe purpoſes, ſhould be deſtined in one ſingle animal to the reception of a fœtus. This gentleman mentions a ſlender gland lying near the bowels, and, in all probability, this was the uterus. For Mr. Lewenhoeck, who took much pains in examining this fiſh, ſays, that he found an uterus, not only in ſome, but in every *Eel* he examined, and he therefore concludes *Eels* to be hermaphrodites; nay, he goes ſo far as to ſuppoſe, that there are no male parts of generation, of the common form of thoſe in other animals, but that the office of theſe is performed by a liquor analogous to the male ſeed of animals, which is contained in certain glands, ſituated on the inſide of the uterus itſelf.

Nature having, in all animals, hitherto diſſected, been found to have provided in the females not only an uterus, but alſo two tubes, which, from Fallopius, the perſon who firſt diſcovered them, are called Fallopian tubes, and which ſerve to convey the ovum from the ovary into the uterus, the ſyſtem of Mr. Allen, and thoſe others who ſuppoſe the bowels the ſeat of generation in *Eels*, is rendered highly improbable, by the want of ſuch parts as theſe. This gentleman obſerves, that he had ſeen the embryos within the parent *Eel*, both in the egg and animal ſtate; that the eggs were always found to lie on the outſide of the inteſtines, and the young *Eels* within them. Now, as we have no idea how theſe embryos ſhould get within the gut, from an egg on the outſide, any more than how an egg ſhould come in that place, the whole ſyſtem of this gentleman, though favoured by many people, ſeems built on ſo bad a foundation, as not to merit any longer the countenance of the world. It is probable, that all his obſervations were founded upon errors, for it is a very common caſe to find *Eels* ſubject to worms in their guts, ſuch as we have, and of all the kinds that we are ſubject to; ſome of theſe might be eaſily miſtaken by the author of this ſyſtem for embryo *Eels*; and poſſibly the eggs he deſcribes on the outſides of the bowels, might be no other than ſmall lumps of fat.

The conger, or ſea *Eel*, uſually grows to a very great bigneſs; but the common freſh water *Eel* ſeems intended to have been limited to a certain ſmall ſize; yet, at times, there have been caught ſome which have greatly exceeded this their ſeemingly ſtated limit. The common ſize of the conger, or ſea *Eel*, at full growth, is the length of nine or ten foot, and the thickneſs of a man's thigh; and, when of this ſize, they will weigh from thirty to forty or fifty pounds: Though Salvian ſays, they uſually do not exceed thirty. Strabo tells us of ſome of them growing to eighty pound weight; but, by what we ſee of them, there is reaſon to believe, that between twenty-five and thirty pounds weight ſeems their natural ſtint, at full growth, and that thoſe which ſo much exceed it are like the monſtrous common *Eels*, accidentally encreaſed to a preternatural bulk. Pliny and Solinus talk of *Eels* of thirty foot long; but the largeſt we find, even of our monſtrous ones, come greatly ſhort of that. The conger always has a ſort of barbs; and an *Eel* that has not thoſe, may always be aſſuredly known by that character alone, to be a true freſh water *Eel*, though ever ſo large. Of this kind the Thames, and ſome other rivers about London, ſeem to have furniſhed the largeſt of any part of Europe. Mr. Dale commemorates the taking of two of theſe, in the philoſophical tranſactions; the one near Crickſea in Eſſex, was five foot five inches long, and meaſured twenty-two inches round. The weight of this was about twenty pounds, which is the ſtint that Aldrovand gives to the freſh water *Eel*, ſaying, that they ſometimes, tho' very rarely, do come up to this, but that they never exceed it. The other was caught near Maldon, and was ſeven feet long, twenty-ſeven inches in circumference, and its weight was thirty pounds. Out of its back and belly there were taken five pounds of fat. This creature ſeemed to have been brought down the river by the violence of ſome land flood, and was in a wounded condition when taken by the fiſhermen, having a hurt upon its back, which it ſeemed to have got in paſſing through ſome mill. Both this and the other were evidently freſh river *Eels*: And, long ſince theſe, ſo lately indeed as in this preſent year 1748, one of theſe large *Eels* was taken at Limehouſe, where it was left on ſhore by the tide; it was five foot ſix inches long, and as thick as a man's thigh; its weight was twenty ſeven pounds.

The fine ſilver *Eel* may be catched with many ſorts of baits, and with great eaſe to the fiſher. Powdered beef is the very beſt bait for many places; next after this are lobworms, minnows, or other ſmall fiſh, and, in the place of theſe, chickens guts, and even fiſh garbage will do. The *Eel*, for the ſix winter months, remains conſtantly buried in the mud; and even in warmer weather, this fiſh ſeldom appears above the bottom by day-light, ſo that night is the beſt time for fiſhing for it. The hooks may be bated, and thrown into the water at night, and the ends of the lines faſtened to the ſhore; and one general line may have a great many other ſhorter ones, with each its hook tied to it, depending on it. When theſe are laid in over night, they may be left to themſelves afterwards; and when they are taken up in the morning, the *Eels* will be found hung. A very good method for large *Eels* is this. Take five or ſix lines, each of them about ſixteen yards long, and at every two yards ſpace make a nooſe, and at every one of theſe nooſes hang on a hook, faſtened to a ſhort line of ſtrong ſilk; ſome uſe wire, but ſilk will anſwer the purpoſe, and give the fiſh leſs ſuſpicion, bait the hooks with millers thumbs, loaches, minnows, and ſmall gudgeons; let the long line be drawn quite acroſs the deepeſt part of the brook or river, and the two ends faſtened down, with a peg driven faſt into the ground on each ſide: Theſe are to be laid in at night, and the ſportſman muſt either ſit up and watch them, or elſe be up very early to take them up, for otherwiſe many of the *Eels*, which were hung, will be got away again; and what is moſt provoking is, that thoſe are the largeſt which thus eſcape.

With proper management and attendance, there will ſeldom fail being three or four *Eels* on each line. When there are very large *Eels* in any place, the beſt bait is a moderate ſized roach: This muſt be faſtened to a ſtrong ſingle night-line, and the hook muſt be hid in the mouth of the bait.

Eels have been obſerved to move directly upwards, and ſo to get over perpendicular obſtacles ſeveral feet above the ſurface of the water. They ſlide thus upwards with as great eaſe, ſeemingly, as if they had been going along the level ground. See Phil. Tranſ. N°. 482. Sect. 8.

The dried livers and galls of *Eels* are recommended by Mr. Boyle to aſſiſt women in a hard labour. *Boyle*, Works abr. Vol. 1. p. 93.

Indian EEL, *Anguilla Indica*, in zoology, the name of the Eaſt Indian *Eel*, of which there are two kinds, the one all over ſpotted with brown, and the other of a fine yellow colour, ſtreaked with red. The fleſh of this is not accounted wholeſome. *Ray*'s Ichthyogr. app. p. 3.

Sea EEL, *Anguilla Marina*, a fiſh common under holes of rocks, about the ſhores in many parts of the Eaſt Indies. It is of a duſky brown colour, variegated with rhomboidal ſpots, not unlike thoſe on the ſkins of ſnakes. The anterior part of its body is thin and ſlender, the hinder part very thick; its noſe is long, its mouth large, and commonly gaping open, and its teeth very ſharp, but very ſmall. It grows extremely fat, and is very wholeſome and well taſted; yet thoſe who kill a number of them are ſaid to be affected with tremors, and ſometimes with a drowſineſs, which however goes off without farther miſchief. *Ray*'s Ichthyogr. app. p. 3.

Microſcopic EELS *in four paſte*. The long bodied animalcules, diſcovered by the microſcope in vinegar, ſour paſte, and many other ſubjects, have, from their figure, been generally diſtinguiſhed from the reſt of the microſcopic animalcules, by the name of *Eels*. Theſe, and the other kinds, have been, by the moſt judicious naturaliſts, ſuppoſed to be produced of the eggs of other animalcules of the fly kind, floating in the air. But thoſe in paſte are diſcovered to be viviparous animals, producing living creatures of their own ſhape; whereas, were the uſual opinion juſt, they ought, according to the common courſe of nature, in the larger inſects, to be in the condition of flies, while in the ſtate of maggots, or butterflies in that of caterpillars, never producing their own likeneſs in theſe ſtates, but after ſeveral changes paſſing into flies.

On cutting one of theſe paſte *Eels* in two acroſs the middle, a long and ſlender tube is ſeen to ſhoot out from each of the divided ends, and a number of ſeeming ova iſſue from this; but theſe, examined ſtrictly, appear to be living *Eels* of different growths, and all included in their proper membranes; ſome move themſelves but ſlowly, while others coil and uncoil themſelves pretty briſkly, and the moſt mature are ſeen to make ſtrong efforts toward the diſengaging themſelves of their enveloping membranes, and at length ſucceed, and ſwim at liberty, like their parent animal. The tube thruſt out each way, on dividing the body, is properly the uterus of the animal. This, in the larger *Eels*, is eaſily ſeen to be full of dark ſpots, which are the embryo *Eels*, and theſe

theſe ſpots, with care, are alſo to be obſerved in the young ones, as ſoon as produced. Phil. Tranſ. N°. 478. §. 13.

EELS in vinegar. See VINEGAR.

EEL-*Fares*, is uſed for the fry, or brood, of *Eels*. Stat. 25 *Hen.* 8.

EEL *Pout*, in ichthyology, the Engliſh name of the muſtela fluviatilis, a fiſh of the gadus kind, according to Artedi, and diſtinguiſhed from the others by the name of the bearded gadus, with two fins on the back, and with both jaws of the ſame length. See GADUS.

This fiſh is caught in the Trent, and many other of our rivers, and in ſome places called a barbot.

The name is derived from the German name *Aelput*, which is, in that language, the name of the ſame fiſh, and is compounded of the words *Ael* an *Eel*, and *Puit*, or *Pudd*, a frog, ſo that the Engliſh word ſhould properly be the *Eel-frog*. It is commonly, when full grown, about fourteen inches long, and is ſlender in proportion to its length, and ſomething of the *Eel* ſhape, but too ſhort for its thickneſs, to be truly ſo. It is very ſoft and ſlippery to the touch, like the *Eel*, and is covered either merely with a ſlimy matter, or elſe with extremely minute ſcales. It is of the colour of a tench; its head is large and flat, its noſtrils ſmall and round, and its jaws beſet with very ſmall teeth, which make them feel rough like a file, and there is, beſide theſe, a ſemicircular ſpot in the palate, rough in the ſame manner. There are two fins on the back, and one on the belly, reaching from the anus to the tail, and it has a little beard from the extremity of the lower jaw, and between the noſtrils and end of the ſnout two others, and ſeven gills. *Willoughby*'s Hiſt. Piſc. p. 125.

EFFEMINATE, *Effeminati*, according to the vulgate, are mentioned in ſeveral places of ſcripture. The word is there uſed to ſignify ſuch as were conſecrated to ſome profane god, and proſtituted themſelves in honour of him.

The Hebrew word *Kadeſh*, tranſlated *Effeminatus*, properly ſignifies conſecrated, and hence was attributed to thoſe of either ſex, who publickly proſtituted themſelves, in honour of Baal and Aſtarte.

Moſes expreſsly forbids [a] theſe irregularities among the Iſraelites; but the hiſtory of the Jews ſhews, that they were notwithſtanding frequently practiſed [b].—[[a] *Levit.* xxiii. 18. [b] *Calmet.* Diction. Bibl. in voc.]

EFFERVESCENCE (*Cycl.*) ariſes from an inteſtine motion, excited in various fluids, either by the mixture of fluids with others of a different nature, or by dropping ſalts, or powders, of various kinds, into fluids. The two moſt common oppoſites, acids and alcali's, on being mixed, cauſe a great ebullition or frothing, but no great heat; but the ſolutions of ſome metals in aqua fortis, cauſe intenſe heat, and emit flame. The mixing aromatic oils with acid mineral ſpirits, actually kindle, and burn with violent exploſions; and ſome vegetable ſubſtances, putrefying with moiſture, will ſometimes heat ſo, as to kindle what lies dry about that part of the heap where the putrefaction happens. Thus heaps of dung will grow hot, and haycocks often kindle into actual fire. Phil. Tranſ. N°. 476. p. 475.

The principal bodies in which *Effervеſcences* happen, are, 1. Native vegetable acids, as moſt juices of trees, ſhrubs, and plants, that run in the ſpring: Moſt juices of unripe ſummer fruits: Particular juices, when ripe, as thoſe of oranges, lemons, citrons, tamarinds, ſorrel, wood-ſorrel, and crabs; fermented vegetables, as the meals when they turn ſour, Rheniſh and Moſelle wine, and tartar; vegetables twice fermented, native and diſtilled vinegars; the acids of animals, from tartiſh or acid vegetable aliment; as in the chyle, ſour milk, whey, buttermilk, and the whey thereof. 2. The native foſſile acids, as the acid of ſulphur, allum, or vitriol; or theſe acids, as they lie concealed in ſulphur, or vitriol ſtones, or as thence extracted by a violent fire, or a ſtronger acid, as in the ſpirit of nitre, ſalt, allum, vitriol, or ſulphur. 3. True fixed alcalies, made of any vegetable matter, by burning; the more volatile alkali's, whether ſpontaneous, as in garlick, onions, ſcurvygraſs, muſtard, &c. produced by putrefaction, from animal or vegetable ſubjects, or procured from the ſame by diſtillation and burning. 4. Certain bodies, improperly called alkalies, only on account of their agreeing with the genuine alkalies, in fermenting with acids; theſe are many of the boles, and other earths, bones, chalk, corals, crabs-eyes, horns, hoofs, and nails of animals, pearls, ſhells of fiſh, &c. ſtones, and teeth. 5. The ſeven metals. 6. The ſemi-metals, antimony, biſmuth, lapis calaminaris, hæmatites, lime, and the like. *Boerh.* Chem. pt. 2. p. 340.

Hence we have four general rules. 1. That the bodies of the firſt claſs almoſt conſtantly make an effervеſcence with thoſe of the third and fourth, either ſooner or later, and with more or leſs ſtrength, as they are in themſelves weaker or ſtronger; this *Effervеſcence* continues till the point of ſaturation is obtained, and then ceaſes, and at that time uſually the acrimony both of the one and the other of the ſubſtances is ſoftened. 2. The bodies of the firſt claſs make an *Effervеſcence* with thoſe of the fifth, though only ſome with others, and not univerſally; ſome do this with more, and others with leſs ſtrength, and, at the end, vitriols are uſually produced. 3. The bodies of the firſt claſs act in the ſame manner with thoſe of the ſixth. 4. The bodies of the third, fourth, fifth, and ſixth claſſes, being mixed together, are ſcarce found to make any *Effervеſcence*, hence acids are found to have this effect, in particular along with the reſt, though here it is limited. The beſt ſpirit of vinegar, poured upon oil of tartar *per deliquium*, makes no *Effervеſcence* at firſt, but it does afterwards, and, in doing it, weakens the alkali.

Pure volatile alkali, when freed from its oil, makes an *Effervеſcence* with diſtilled vinegar, but much more cold than heat ariſes in the ebullitions of this kind; whereas the generality of other *Effervеſcences* produce heat in various degrees, from the leaſt ſenſible warmth, up to actual flame. A dram of oil of cloves mixed with two drams of Glauber's ſpirit of nitre, raiſes a thick ſmoak, and in the midſt of it a ſtrong red flame, and the matter is reduced to a dry ſpungy maſs, in this caſe the *Effervеſcence* is not made with acid and alkali; but with acid, and a very rich oil. There are alſo too hard and cold bodies, *viz.* iron and ſulphur, which being ground together, and made into a paſte with water, make a ſpontaneous *Effervеſcence*, and will even produce actual fire and flame. *Boerh.* Chem. pt. 2. p. 340.

EFFERVESCENCE, in vintage, a term appropriated by Portzius and others to ſignify that working of wine, which is by ſome, though improperly, called fermentation, thereby confounding two very different things. Fermentation, according to theſe authors, is nothing elſe but the action and reaction of the internal parts of the acid and alkali of the fluids, by which the ſpirits are ſeparated without precipitation; whereas, they ſay, by *Effervеſcence* there are no ſpirits ſeparated, ſo that all fermentation is done by means of *Effervеſcence*; but all *Effervеſcence* does not amount to fermentation. Fermentations are properly the mutual ſtrugglings between contrary principles, as between acid and alkali, or the like; but *Effervеſcences* will happen between principles of the ſame kind, provided one be much ſtronger than the other. Thus a ſtronger acid poured upon a weaker, will raiſe an *Effervеſcence*, but no fermentation. The *Effervеſcence* of wine is not however of this kind, but the acid and alkali which are in them, muſt raiſe this by their action upon one another, the alkaliſate parts combating with the acid ones, till they have wholly ſated them, and then the *Effervеſcence* ceaſeth.

It has been obſerved by many, that wine in the caſks will always efferveſce, more or leſs ſtrongly, at the time of the bloſſoming of the vines. This has been ſuppoſed by the vulgar to be owing to ſomething of ſympathy, or ſuch hidden cauſes; but it is only owing to the heats of that ſeaſon which ſet the two ſalts at work upon one another. *Portzius* de Vin Rhenan.

EFFLUENT *Fever*, is ſometimes uſed for an inflammatory fever. Med. Eſſ. Edinb. abr. Vol. 2. p. 461.

Dr. Morgan propoſes to cure ſuch by ſweats raiſed by low cooling drinks.

EFFLUVIA (*Cycl.*)—The earth ſends forth *Effluvia* and ſteams in great abundance, and many things, attributed to other agents, are really performed by them. Dr. Woodward has very juſtly attributed great effects to them on foſſils of many kinds; and it is poſſible many more of the preſent appearances of ſubterranean bodies may be owing to them, than are at preſent imagin'd. The figures and delineations on ſtones, in form of trees and ſhrubs, have often their origin from theſe *Effluvia*, getting into the cracks of them; and it is poſſible that the ſtalactitæ, which we find on the roofs of caverns, may be in great part alſo formed by their means. Phil. Tranſ. N°. 169. p. 920.

In ſome places however we have inſtances of their effects on the ſurface of the earth. The many bubbling or boiling fountains which we ſee in England, and other countries, are principally occaſioned by the forcible burſting up of theſe *Effluvia* through the mud and water. Our burning well, in Lancaſhire, has no peculiar property in its water, but only an inflammable vapour riſes through it, making it boil and bubble on the ſurface of the water; and this vapour will, as ſoon as ſet at liberty from the water, take flame at a lighted candle. The famous boiling ſpring near Paroul, in the neighbourhood of Montpelier, which was ſo long ſuppoſed to be of a peculiar nature, was found by Mr. Ray to be but common water, through which a vapour of the ſame kind made its way. This has been ſince alſo farther confirmed by Dr. Robinſon, who obſerved that all the water thereabouts was more or leſs affected by this bubbling; the vapour making its way thro' the whole ſurface of the earth there. Water, taken up with an earthen veſſel, had none of this property, nor any peculiar taſte or virtue, and the ſand, or mud, from the bottom, had no effect upon other water. But what is a farther proof of the whole appearance being owing to *Effluvia* from beneath is, that the cracks of the earth all thereabouts perſpire ſtrongly a vapour of this kind; ſo that if little ſtraws, or ſticks, be laid upon the ſurface, they will be blown up; and if a hole be dug in the ground, in any part, and common water poured into it, it will boil up and bubble in the ſame manner as theſe

ſprings. The like ſort of ſprings are common in Switzerland, and ſome other places. Theſe are known to be owing to *Effluvia* from beneath, by the water of them being cold; but there are others which actually boil with an addition of heat, and are hot enough to boil an egg; ſuch are the famous boiling fountains of Solfatara near Naples, and ſome others; and in theſe it is evident, that ſomething elſe beſide cold *Effluvia* is concerned. Phil. Tranſ. N°. 169. p. 923.

From obſervation of theſe various ſprings, it is eaſy to find, that there muſt be a manifold variety in thoſe exhalations which produce the effects in them, ſome of them being cold and dry, and merely reſembling wind, as is the caſe of that of Peroul. Some being of an inflammable and bituminous nature, and yet actually cold, as ours in Lancaſhire, and ſome naturally hot, and impregnated with various principles, as thoſe in the ſweating vaults and caverns, and thoſe in the mountains of Italy, and in the vulcano's of Bajæ, Cuma, and Puzzoli. Others are of a poiſonous nature, containing particles of arſenic, ſulphur, and other minerals, that either kill or ſuffocate; theſe and other ſuch *Effluvia* may eaſily be ſuppoſed to influence the waters, through the beds of which they paſs.

It is very probable, that the mineral ſubſtance, called pyrites, may contribute greatly to the effects of theſe ſteams, for it is frequent almoſt every where, and when it has lain in ſuch places as it can be diſſolved in, it readily imparts its principal ingredients, which are ſulphur and vitriol, either to air or water, or to whatever elſe paſſes through, or comes into contact with it. And it is obſerved that the pyrites is found in great plenty all about Veſuvius, Solfatara, and other places where vulcano's are frequent. Phil. Tranſ. N°. 169. p. 926.

The wonderful extenſion of *Effluvia*, and the ſmall diminution of the body they iſſue from, is one of the ſtrangeſt problems in phyſicks. Mr. Boyle refers the doctrine of *Effluvia* to ſeveral heads, as to the ſtrange extenſibility of ſome bodies, while their parts yet remain tangible; the multitude of viſible corpuſcles that may be afforded by a ſmall quantity of matter; the ſmallneſs of the pores at which the *Effluvia* of ſome bodies will get in; and finally the great quantity of ſpace that may be filled as to ſenſe by a ſmall quantity of matter, when rarify'd or diſperſed. The efficacy of ſeveral *Effluvia*, and their acting on one another, is a ſecond thing as obſervable in regard to them. This is done by either the great quantity of corpuſcles emitted, or their penetrating or pervading nature, or elſe by their celerity, or other modification of their motion, or by the congruity or incongruity of their bulk and ſhape to the pores of the bodies they are to act upon; or by the motions of one part upon another, which they excite or occaſion in the body they work upon, according to its ſtructure; and finally by the fitneſs and power which they have to make themſelves be acted upon by the more catholic agents of the univerſe, which then aſſiſt them in their working.

The determinate natures of *Effluvia*, according to the principal inſtances we have of them, are reducible to theſe three heads: 1. That theſe *Effluvia* being, by condenſation, or otherwiſe, reunited, they appear to be of the ſame nature with the body that emitted them. 2. Their determinate nature may be ſometimes diſcovered by the difference that may be obſerved in their ſenſible qualities, foraſmuch as thoſe *Effluvia* which are endowed with them proceed from the ſame ſort of bodies, and yet thoſe afforded by one kind of bodies being in many caſes manifeſtly different from thoſe which fly off from another, this evident diſparity in their exhalation argues, that they retain diſtinct natures, according to the nature of each body from which they proceed. 3. We may diſcover this different nature of *Effluvia* from their effects upon other bodies than the organs of our ſenſes, conſidering that the effects which certain bodies produce on others by their effluviums, being conſtant and determinate, and always different from thoſe which other agents produce by their emiſſions on the ſame or other ſubjects, the diſtinct nature of the corpuſcles, emitted on this occaſion, may be ſufficiently judged of, were it only from this. *Boyle* on Effluvia.

EFFRACTURA, a word uſed by Ambroſe Parey for a peculiar ſpecies of fracture of the ſkull, in which the bone is at once broken and depreſſed. *Hofm.* Lex. in voc.

EFFRONTES, in church hiſtory, a ſect of heretics who ſcraped their forehead with a knife till it bled, and then poured oil into the wound. This ceremony ſerved them inſtead of baptiſm. See BAPTISM.

They are likewiſe ſaid to have denied the divinity of the Holy Spirit.

EFFUSION (*Cycl.*)—EFFUSION *of blood*, *effuſio ſanguinis*, in our old writers, is uſed for the mulct, fine, or penalty, impoſed for the ſhedding of blood. This the king uſed frequently to grant to lords of manors. Among others it was granted to the abbot of Glaſtenbury.

EFT, or EFF, in zoology, the name of a creature very common in all parts of England, and called alſo the *Newt*, and the *Swift*, and by others the common lizard, *lacertus vulgaris*.

The beak of this creature is oval and obtuſe, its back of a ruſty iron colour; its feet have each five toes, and are armed with very ſharp tho' ſmall claws. That toe which is in the place of the forefinger with us is the longeſt of all, and that which anſwers to our thumb is placed lower. *Ray*'s Syn. Quad. p. 264.

We have ſeveral ſpecies of this animal with us. 1. The common land *Eft*, with the black ſpotted belly. 2. The ſnake-like *Eft*, which is frequent in our heaths. 3. The ſmall brown land *Eft*. This is very ſcarce. 4. The yellow ſcaly land *Eft*, deſcribed by Plot in his hiſtory of Staffordſhire. And 5. The brown and black ſpotted water *Eft*. *Plot*'s Staff. p. 252.

The water *Eft* affords an excellent opportunity of ſeeing the circulation of the blood by means of the microſcope, particularly of the ſolar one. By this apparatus the veſſels are ſeen beautifully delineated on the ſkreen; and the tide of blood, in the large ones, is equal to that of the ſtream of water which is ſhewn, in hydroſtatical experiments, thrown out of a veſſel by condenſed air. In either of theſe caſes, you can ſee no appearance of ſeparate drops or globules, but the whole forms one continued body. In the leſſer veſſels the globules are ſeen paſſing along very ſwiftly, yet evidently ſeparate one from another: They are uſually of an oblong form, and reſemble what are called ant's eggs, and ſometimes they are ſeen continued into a ſort of chains, or like the beads of a necklace, each touching the other at the ends. But in this manner of obſerving the globules, there is never ſeen any comminution of them; and, in the common way, there is never obſerved any thing of this change of the ſhape of the globules: But every thing, in this manner of viewing them, is magnified to ſo great a degree, that it is no wonder the leaſt departure from the globular figure is eaſily ſeen in the narrow paſſages. Theſe globules are ſeen ſtanding almoſt ſtill for ſome time, and afterwards forming themſelves into a longer and narrower ſhape, till they have got by this ſtrait part of the veſſel, and there aſſuming their own form again, and going on with the ſame ſwiftneſs. But the moſt remarkable phænomenon of all, is the ſhape and odd motion of ſome of them near the extremity of the edge of the tail.

Theſe exactly reſemble the tadpole, both in figure and motion, except that they have not quite ſo much of the riggling motion of the tail as thoſe animals have, when in the water. The round part, or head of the globule, as it may be called by way of diſtinction, has exactly the ſame motion, and the whole globule greatly reſembles an animal of that figure roaming about for prey; and frequently turning to the right and left, as the animalcules in pepper water do; and they ſometimes will ſtop ſuddenly in the midſt of their courſe. It would be very natural for a haſty obſerver to declare theſe to be real animals, living in the veſſels of the creature, among the blood, as the animalcules do in the ſemen; but it ſeems not difficult to account for all the motions we ſee in them, on the mere principle of their being globules, without their having any ſort of animal life, and the ſtate of the blood, at that time conſidered, together with the ſtate of the veſſels, the effect will be eaſily conceived to proceed from plain and natural cauſes. It is to be obſerved, that the blood, at the time it found theſe globules, was near ſtagnating; and it will be found by experiment, that a drop of common water, on a ſmooth ſurface, as on a plane of glaſs, placed in a ſlanting direction, will move down it ſlowly, and with a ſort of tail, and will not run ſtrait down, but with the ſame ſort of meanders.

It is remarkable, that, in the tail of this animal, there ſeem a greater number of veſſels than are immediately neceſſary to the circulation of the blood; for, when thus examined, there will be often ſeen two parallel veſſels, in one of which only the circulation is perform'd, and this ſucceſſively in one and the other of the veſſels, the tide often leaving the one wholly empty, that had juſt before been full and circulating in the other. Phil. Tranſ. N°. 460. p. 728.

EFT *Stones*, in the materia medica of the American Indians, a name given to certain ſtones, ſaid to be found in the ſtomach of a certain ſpecies of water newt, or *Eft*, in the manner of the bezoars in other animals. The waters of Braſil, Cuba, and Mexico, abound with this ſpecies of *Eft*; but it does not ſeem well atteſted, that this ſort of ſtone was ever found in any of them by thoſe who have diſſected numbers of them, on purpoſe to ſearch for it. We have in Europe ſwallow ſtones, and other ſuch things, whoſe names, and their fabulous hiſtories, would import their being produced in animals. As many ſwallows have been deſtroyed in England, in looking for theſe ſtones, as newts in Mexico in looking for thoſe; and, by the appearance of the American as well as the European ſtones, they both ſeem to be dug out of the earth, and to have been once the teeth, or other parts, of fiſhes. *Redi* Experim.

The virtues of the *Eft-ſtone* of Mexico are celebrated by Ximenes, and all others who have been upon the ſpot. It is ſaid to be a certain remedy for the gravel, and all other nephritic complaints, and even to break and diſſolve the ſtone, when already concreted in the bladder. But this account of its virtues ſeems as improbable as that of its origin. Redi try'd theſe and many other ſtones of famous character

among writers, and found no effect in any of them. Theſe *Eft-ſtones* never produced any viſible effect in his trials, in nephritic complaints, nor the eagle-ſtone in womens labour, nor the ſtones ſwallowed by Caymans in quartans, tho' Menardes looks on theſe laſt as infallible in this caſe.

EGESTION, in medicine, the ſame with dejection.

EGG (*Cycl.*)—We have an account from no leſs an author than Wormius, of a woman's laying two eggs: They were brought into the world, he ſays, with a live child, by the common labour pains, and were of the ſize of a common hen's egg. The women, who attended the lying-in woman, broke the firſt, and found it to have a white and a yolk, like a hen's egg; but the other was preſerv'd whole, and given to Wormius, to enrich his collection of curioſities, where it remained ſome time, and was afterwards given to the king of Denmark, and preſerved in his muſæum at Copenhagen. There is at this time ſhewn there a ſeeming egg; but whether this was the real egg voided by the woman, or whether the ſtory of the other, which was broken, having a regular white and yolk, was true, it is not eaſy, at this time, to determine: Probably there has been either ſome miſtake, or ſome fallacy, in the affair.

The learned Mr. Monro has given us a ſummary of ſeveral obſervations made by the curious about eggs, and of the changes made in them by incubation, in order to determine the queſtion about the nutrition of the fœtus in oviparous animals. See Med. Eſſ. Edinb. vol. 2. art. 10.

Some part of the humours of the egg eſcapes thro' the ſhell, and is not ſupplied by any thing from without, as evidently appears from an egg's becoming ſo much ſpecifically lighter, as to ſwim in water after incubation, tho' it ſunk in it when recent.

The eggs of the ſmaller animals are not leſs taken care of by the female that lays them, than thoſe of larger ones. In the butterfly claſs, the eggs have no increaſe of bulk to arrive at, in the body of the female, all they have there to wait for, is to be fecundated by the male, and as ſoon as this is done, they are always ready to be laid. The female takes a proper time to lay them, and not only their number, but the nicety with which ſhe arranges them, and prepares for the family that is to be produced from them, makes this no ſmall ſpace. This is indeed the whole buſineſs of her life, and when they are all laid, ſhe dies.

The female does not depoſit them on any plant at random, on which ſhe happened to be placed when the male coupled with her, but ſearches out ſuch a ſpecies of plant for the leaving them on, as is what ſhe loved when in the caterpillar ſtate, and what the young caterpillars to be hatched from them, will be able to feed on, that they may find food ready for them at the moment of their birth. She does not ſcatter them about irregularly, and without order, but ſhe diſpoſes them with perfect ſymmetry, and faſtens them one to another, not by their own glutinous nature, but by a viſcid liquor, which ſhe ſeparates from her own entrails for that purpoſe. In many ſpecies alſo where the hinder part of the body of the female is covered with long hairs, ſhe, by degrees, throws off all thoſe hairs, and with them makes a neſt for the eggs ſhe is laying, where they are kept very ſoft, and ſafely, till the time of their hatching. Memoirs Acad. Scienc. Par. 1736.

The eggs of butterflies are of very different ſizes, according to the ſpecies; they are alſo of many different figures, ſome are ſpheric, others ſegments of ſpheres, others conic, in different forms and degrees; nor is this all, their ſurfaces are very different alſo in the different kinds. Some are elegantly wrought, as it were, ſome dented, and others more deeply notched at the ſides, and others channell'd or furrow'd all over; in ſhort, the moſt ingenious artiſt could ſcarce contrive ſo many various ornaments as there are on theſe eggs, all which alſo are inviſible to the naked eye, being diſcoverable no way but by the microſcope.

Preſervation of EGGS. Mr. de Reaumur, of the Paris academy, thinking nothing, that could be a public benefit, beneath the cognizance of a philoſopher, beſtowed conſiderable pains on the finding a method of preſerving eggs for a long time, and ſuceeded at length ſo far in it, as to be able to produce eggs of months, nay years old, which taſted as freſh and well as if they had been laid but the day before. The egg always is quite full, when it is firſt laid by the hen, but from that time it gradually becomes leſs and leſs ſo, to its decay; and however compact and cloſe its ſhell may appear, it is nevertheleſs perforated with a multitude of ſmall holes, tho' too minute for the diſcernment of our eyes. The effect of theſe, however, is evident by the daily decreaſe of matter within the egg, from the time of its being laid; a fluid matter is continually perſpiring thro' theſe perforations of the ſhell, which occaſions the decay, and this is carried on in a much quicker manner in hot weather than in cold. To preſerve the egg freſh, there needs no more to be done, than to preſerve it full, and ſtop its tranſpiration, and the plain and rational method of doing this, is by ſtopping up theſe pores, thro' which the matter tranſpires, with a matter which is not ſoluble in watery fluids, and therefore cannot be waſhed away by the matter perſpired by the egg; and on this principle, all kinds of verniſh, prepared with ſpirit of wine, will preſerve eggs freſh for a long time, if they are carefully rubbed all over the ſhell. This might ſeem to moſt people a very common and cheap ſubſtance, for this purpoſe, but the misfortune is, that in country places, where it ſhould be put in practice, no ſuch thing is to be had, and the poorer ſort of country people are not eaſily brought into the uſe of any thing they are not uſed to.

To obviate the difficulty ariſing from this, Mr. Reaumur thought of ſubſtituting in the place of verniſh ſome other ſubſtance, more common among theſe ſort of people, and ſoon found that another ſuhſtance, which is very cheap, and every where to be had, would very well ſupply the office of verniſh; for experiments proved, that any hard fat would have the ſame effect. Mutton fat may every where be had, and eggs carefully rubbed over with this, will keep as long as thoſe coated with verniſh. Common tallow, of which candles are made, ſerves equally well to the ſame purpoſe; but this might breed a diſtaſte in nice people; and the beſt of all fat for this purpoſe is found to be a mixture of that of mutton and of beef, theſe ſhould be melted together over the fire, and ſtrained thro' a linen cloth into an earthen pan; and a pot of five or ſix pounds of this may eaſily be kept in a farm-houſe, and will ſerve for a vaſt quantity of eggs. When it is to be uſed, the pan is to be ſet over a gentle fire till the whole is melted, which is done in a few minutes, and when thoroughly melted, an egg is to be dipped into it, and immediately taken out again, and it is then in a ſtate to keep perfectly freſh more than a twelve-month. The fat continues fluid a long time, and a great number of eggs may be ſucceſſively dipped into it, and it will ſerve again at other times for great numbers of others. Memoirs Acad. Scienc. Par. 1735.

The only difficulty attending this method is, that the eggs cannot eaſily be ſo plunged into the fat, as that all their ſurfaces ſhall be covered by it; for if they are held in a pair of pincers, the parts of the egg where the pincers touch will be bare; but this may be remedied by uſing ſuch pincers as touch only in ſmall points, and theſe bare ſpaces may eaſily have a little of the melted fat rubbed over them with a feather, or a pencil; or the eggs may be ſuſpended by a loop at the end of a thread, and, by that means, plunged in, and the thread being then coated over with the fat as well as the ſurface of the egg, will preſerve that part which it covers, as well as the coat of fat will the reſt. The great care is to uſe this means while the eggs are perfectly freſh; it ought indeed to be done on the very day when they are laid, for if the evaporation is begun, and the empty ſpace once made, there is room for a fermentation, which never terminates but in the deſtruction of the egg.

There is one advantage in this uſe of fat, rather than verniſh, which is, that the eggs rubbed over with it boil as quick as if nothing had been done to them, the fat melting off as ſoon as they touch the hot water; whereas the verniſh, not being ſoluble even in hot water, only becomes moiſtened by it, and ſtill hanging about the egg, prevents the tranſpiration of juices, neceſſary to bring the egg to that ſtate in which it is to be eat. When the egg, which has been preſerved by fat, is taken out of the water, there remains very little fattyneſs upon it, and what there does is eaſily wiped off with a napkin, the egg is as nicely freſh as if laid but the day before, and no palate can diſtinguiſh the leaſt taſte of fattyneſs in it.

The method of preſerving them by means of fat, is greatly preferable alſo to that by verniſh, when they are intended for putting under a hen to be hatched. So long as the egg remains in the ſtate of a freſh one, the embryo lives, either of the methods of preſerving them will therefore ſucceed ſo far as to keep the embryo ſtill living; but, when the hen ſits upon them, the warmth of her body cauſes a tranſpiration of their juices, which is eſſential to their hatching, and this cannot be done through the adventitious coat of fat or verniſh; but the fat eaſily melts off by the heat, while the verniſh remains on, and much impedes the progreſs of the chicken. If the heat of the body of the hen ſhould not be thought ſufficient to melt off the coat of greaſe, it may eaſily be taken away by dipping the egg in water, made juſt ſo warm as to melt the fat, without at all affecting the inſide of the egg, which cannot be done in regard to the verniſhed ones. Memoirs Acad. Scienc. Par. 1735.

There is one great advantage in this manner of preſerving eggs, which is, that we may thus have the eggs of foreign fowls preſerved upon the ſpot, and ſent over to us, which will be readily hatched by ſetting them under a hen, and will afford us a great variety of the birds of value from other countries, in the eaſieſt and moſt natural way, and, thus hatch'd with us, they will be much more likely to live, than if brought over alive. Eggs are infinitely more eaſily brought over in ſhips, than birds, as requiring, when thus managed, no care but a ſafe package; whereas the birds muſt be carefully watched, and fed, and very frequently they die, in ſpite of all the care that can be taken of them. Many very beautiful and valuable birds might thus be naturalized among us; and as we have already been able, without this ready means, to make paroquettes and Canary birds breed with us, there is no doubt

doubt but that we might, by this better way, breed many of the hardier birds, as the China and Egyptian hens, the partridges of other nations, as well as their pheaſants, and perhaps many other delicate fowls, of which we have not yet ſo much as the names with us. Theſe would eaſily be hatched with us by their eggs thus preſerved, and placed under ſetting hens, and when thus hatched in any conſiderable number, there is no doubt but that the males and females among them would propagate their ſpecies, and perpetuate themſelves among us, as the turkeys, and many other birds, originally of foreign extract, have at times done.

Hard fat is, of all the preſervatives of eggs, that which may be had more eaſily every where, which is very cheap, and which eaſily comes off from the egg; but it is very certain, that any matter which can prevent the tranſpiration of the egg, will equally well preſerve it; it is only neceſſary, that the ſubſtance uſed ſhould be naturally hard; oil, for inſtance, if rubbed over eggs, would, unqueſtionably, in a great meaſure, ſtop their pores, and prevent tranſpiration; but oil, being a fluid, would never remain upon every particular part as it ought to do, to preſerve it, and even the act of tranſpiration of the juices would be ſufficient to diſlodge the thin coat of oil, and make their way through it. Wax, or a mixture of wax and pitch, or reſin, are able to preſerve the egg as well as fat, but they are dearer, leſs ready at hand, and do not come ſo eaſily off from the egg in the dreſſing. All the aqueous gums, as gum arabic, and iſinglaſs, will preſerve eggs freſh much longer than they would naturally remain ſo, but not ſo long as the before mentioned ſubſtances. Memoirs Acad. Scienc. Par. 1735.

This method of preſerving is not ty'd down to eggs alone, but may be of great uſe in keeping all ſorts of ſubſtances where an internal fermentation is feared. Mr. Reaumur try'd on bodies of many different kinds, and found it ſucceed in all.

Artificial Method of hatching EGGS. See HATCHING.

Ant-EGGS. See the article ANT.

EGGS *of Flies*. After the congreſs with the male, the female fly is ſeldom ſo much as twenty-four hours before ſhe begins to depoſit her eggs on ſome ſubſtance proper to give nouriſhment to the worms that are to be produced from them.

Theſe eggs in general are white and oblong, but there are ſome of them which are ſingular, and vary from this form. The deſcription of one ſpecies of theſe may give an idea of the reſt, and it may not be improper to take, for this purpoſe, thoſe of the eggs of the fly found on hog-dung, and on other ſuch matters. This fly is of the claſs of the great blue fleſh fly, but differs from it in many particulars. Its body is more round, and a little hollowed on the belly ſide, eſpecially that of the male. The hinder end of the male is bent alſo into a ſort of hook. The wings croſs one another on the body, and exceed it in length. The male is yellow, often of a very beautiful, and ſomewhat reddiſh yellow. This colour is principally owing to a multitude of hairs with which the body is covered. The corcelet is of a paler yellow than the body, and has ſome ſlight tinge of brown with it. It has only a number of black hairs on it, fewer, and placed more diſtant than thoſe of the body. The female has much fewer hairs, and is browner than the male. *Reaumur*, Hiſt. Inſ. v. 4. p. 376.

Two pairs of theſe flies having been taken in the month of October, and ſhut up in a box, with a quantity of hog's dung, on which they were found, the females ſoon began to depoſit their eggs.

The eggs of this ſpecies are white and oblong, like thoſe of the great blue fleſh fly, but their figure has notwithſtanding ſomething very ſingular in it. At one end of each of thoſe eggs there are two little wings, which are ſeparated from one another in the manner of two horns, theſe do not reach beyond that end of the egg, and have their inſertion between that end, and the middle of the egg. Ibid. p. 377.

Thoſe wings ſeem formed of the ſame membrane, which makes the outer covering of the egg, but they ſeem to have no buſineſs to contain any part of the ſubſtance of the egg, or any thing neceſſary to the life of the embryo worm. The uſe of theſe wings, however, will be eaſily diſcovered, when we conſider that the fly, as ſoon as ſhe has laid them, always thruſts them into the dung: This is neceſſary to the future hatching, as the coat of the egg muſt neceſſarily be kept ſoft, otherwiſe the embryo could never force its way out of it. It is eaſy to conceive alſo, that if the whole egg were thus buried, the creature would be ſuffocated in the ſubſtance it was buried in, as ſoon as hatched. Nature has therefore ſo provided for its ſafety, that a part of the egg only ſhall be immers'd in the matter, and kept moiſt, and part remain out. This great proviſion is made by theſe wings, for the fly makes the egg enter the dung as ſhe lays it. It enters eaſily at its ſmaller end, which is the part firſt protruded from her body; but when it comes to be immerſed as far as theſe wings, the reſiſtance encreaſes, and the upper part of the egg remains open to the air. Ibid. p. 378.

The eggs are but a little time in hatching, and the growth, and all the changes of the animal, take up but a little time. The creature is found to make its way out of the upper part of the egg, and it is not more than three weeks from the laying the egg that is taken up, before the creature is ſeen in form of a perfect fly; if a female; and ready to depoſit hers. Ibid. p. 379.

Among the butterfly claſs, the female has but one congreſs with the male, and immediately after it begins to depoſit her eggs, and continues ſo doing, without interruption, till ſhe has finiſhed; but it is much otherwiſe with the two winged flies, for they, after having laid one ſet of eggs, have repeated congreſſes with the male for ſeveral days, and, after every one of theſe, lay a new ſet. Ibid. p. 380.

The eggs of the different ſpecies of the two winged flies, are of very different figures, and doubtleſs the great author of nature has had reaſons for allotting the peculiar form of each, tho' we cannot always determine what thoſe reaſons were.

Some ſpecies there are which faſten their eggs to the ſides of veſſels of water, theſe all lay oblong eggs, ſome of them, however, are perfectly ſmooth in all parts, and thoſe of other ſpecies ſmooth only on their inner ſurface, and ridged longitudinally on the other. What is alſo the more remarkable in theſe, is, that they all have a fine thin flake running down all along the two ſides, diametrically oppoſite, and theſe two bands ſurrounding the whole egg in this manner, have much the appearance of a caſe, and give the egg the appearance of being encloſed in a paper frame. 'Tis probable, that the uſe of this frame is to hold the body of the egg the better, faſtened againſt the veſſel; and probably thoſe eggs which have it not, are depoſited from the body of the female fly with a viſcous matter about them, in ſufficient quantity to faſten them on without this aſſiſtance. Ibid. p. 381.

Some eggs of the fly kingdom there are, which muſt neceſſarily be held faſt to ſome other body, in order for the worm to be able to make his efforts toward the opening of them, without carrying them away; and ſome of the ſpecies require much more ſtrong attachments of this kind than others. There is a fly a little ſmaller than the common great blue fleſh fly, but of the ſame genus, whoſe body is of a greyiſh brown, and the whole a mixture of grey ſpots upon a black ground. This ſpecies depoſits its eggs alſo on meat, but their figure is different from that of the eggs of the great blue fly. They are ſhorter than thoſe, and are larger in the middle than at either of the ends; they are alſo ſomewhat flatted, and one may diſtinguiſh on them two ſides; the one, which is more rounded and convex, is covered with very fine furrows, and the other, which is flatter, has only five high ridges, and conſequently only five furrows. Notwithſtanding theſe differences in the eggs of this ſpecies from thoſe of the common blue fly, the worms, hatched from them, ſeem much the ſame, and to undergo the ſame changes. Ibid. p. 382.

On the ſtalks of the common meadow graſſes there are alſo frequently found the eggs of flies depoſited in great numbers. Theſe, examined by the microſcope, have all the form of ſmall ſnow-white boats, or rather of ſmall ſhips, with the deck ſtanding up above their ſides. The places where they are lodged, ſhew evidently the care of the creature which laid them; the fly is not known, but they always produce a ſmall white worm, with a variable head, and two hooks. Ibid.

On other ſtalks of graſs, one may often ſee alſo yellow ſpots and blotches, which may naturally enough paſs with an incurious obſerver for maladies of the plants, but, when examined with the microſcope, all theſe appear to be, in reality, cluſters of eggs of the ſame boat-faſhion'd form, and amaſſed in different numbers; ſometimes alſo they are formed perfect and whole, and at others with their ends eaten. Theſe laſt are ſuch eggs from which the worms have made their way. Theſe worms are white, and have a variable head, armed with two hooks, but their changes are not known. *Reaumur*, Hiſt. Inſect. Vol. 4. p. 383.

EGGS *of Gnats*. There are few creatures in the winged kingdom more prolific than the gnat. Its whole ſeries of changes, from the egg to the perfect animal, is uſually accompliſhed in three weeks, or a month, and there are commonly ſeven generations of them in a year, in each of which every female is the parent of two or three hundred young ones, if all the eggs come to good. Theſe eggs are arranged by the animal in the form of a ſmall boat, and each ſeparate egg is of the ſhape of a ninepin; the thicker ends of theſe are placed downwards, they are all firmly joined to one another by their middles, and their narrower, or pointed parts, ſtand upward, and make the upper ſurface of the boat of eggs, as it were rough or prickly. *Reaumur*, Hiſt. Inſ. T. 4. p. 615.

When theſe eggs are examined ſingly by the microſcope, they appear not exactly of the ninepin ſhape; the larger end is rounded, and terminated by a ſhort neck, the end of which is border'd with a ridge which makes a kind of mouth. The neck of each of theſe is ſunk within the water on which the boat ſwims, for it is neceſſary that it ſhould keep on the ſurface, ſince, if wholly ſubmerged, the worms could never be hatched.

The arrangement of theſe eggs in ſuch nice and exact order, is a thing very worthy our admiration, and which cannot have been effected, but by the utmoſt care and caution in the creature, while in the act of laying them. It is only in the morning hours that the gnats are to be found laying their eggs, and then they will frequently be found about the ſurfaces of ſuch

waters as are in a proper condition to give ſupport to their young. The female gnat here places herſelf on a ſmall ſtick, the fragment of a leaf, or any other ſuch matter uſually near the water's edge, and places her body in ſuch a manner, that the laſt ring but one touches the ſurface of the water, the laſt ring of all, where there is the paſſage for the eggs, is turned upward, and every egg is thruſt out vertically, and the creature, when it is almoſt diſengaged, applies it againſt the ſides of the already formed cluſter, to which it readily adheres, by means of a mucilaginous ſticking matter with which it is naturally covered, like the eggs of many other inſects. Ibid. p. 619. The greateſt difficulty to the creature, is the placing the firſt laid eggs in a proper poſition to receive the reſt, and ſuſtain themſelves and them in a proper direction; theſe ſhe with great precautions, places exactly, by means of her hinder legs, and when a ſufficient number of them are thus arranged together, the reſt is eaſy, they ſerving as a ſupport to all the following. Ibid. p. 620.

EGILOS, in botany, a name given, by Serapion's Interpreters, to the plant which that author and Avicenna call alachuin. Their deſcriptions of the plant abundantly prove, that it is the ſame with the achillæa of the Greek writers, and this word *Egilos* ſeems only a barbarous name for that plant, formed on a miſ-ſpelling of the achillæa; the ſame authors give us fair ground for this ſuſpicion by another of their names, which is *ſidrichis*, this being plainly no other than a falſe ſpelling of *ſideritis*, *Woundwort*, another of the names of this plant, given it for the great virtue it was poſſeſſed of, in curing freſh wounds.

EGITILLIA, a name by which ſome have called the ſtone *Ægyptilla*. See ÆGYPTILLA.

EGOITOS, a term uſed by Van Helmont to expreſs the light of underſtanding, by which we reflect and reaſon within ourſelves.

EGRA *Water*, *Egrana Aqua*, the water of a medicinal ſpring, near that place, in the German dominions. It is famous for cleanſing the viſcera, obſtructed with viſcid matter, and is found of great ſervice in all hypochondriachal caſes, and in all diſeaſes ariſing from infarctions of the viſcera; it gently purges by ſtool; and affords a ſalt, known among the German writers by the name of *Egranum ſal*, which has the ſame properties, and is a ſort of native Glauber's ſalt.

The teſts which Hoffman gives, by which, to prove whether the *Egra water* be genuine, are theſe: 1. It makes a manifeſt ebullition, on mixing ſpirit of vitriol with it. 2. Oil of tartar, poured into it, makes no change in it, nor at all alters its pellucidity, whereas it turns almoſt all other waters milky or turbid. 3. When freſh taken from the ſpring, they become purple, on being mixed with powder of galls. But when this trial is made on them, after their being carried to foreign countries, unleſs they have been very carefully ſtopt, the purple colour does not appear. This is a proof that theſe waters contain but a very ſmall portion of that martial earth, which produces this effect in many others. 4. On mixing ſyrup of violets with them, there ariſes a ſlight green colour, which is a proof that the alkali predominates in them. 5. A ſolution of the vitriol of iron throws down a yellow ſediment, in form of little cluſters of ſmall particles; but this is not ſo much owing to any thing contained in the waters, as to the vitriol uſed in the experiment; the acid of that vitriol uniting with the alkaline ſalt in theſe waters, leaving the ferrugineous part of it to precipitate itſelf to the bottom, that being a ſubſtance not to be ſuſtained in water, when not in a ſtate of ſolution. 6. A pint of this water, chymically analiſed, affords twenty-four grains of a ſaline ſediment, which, on being mixed with oil of vitriol, produces no efferveſcence, nor emits any volatile fume; whence alſo it appears, that it contains no ſea ſalt in its natural form. *Hoffman*. Opera, T. 5. p. 143.

EGRA *Salt*, *Egranum Sal*, a name given by Hoffman, and other writers, to a purging ſalt, extracted from the waters of *Egra* by evaporation. The waters of this place are in great eſteem for many diſeaſes, and are, by Hoffman himſelf, in ſome reſpects, preferred to the pyrmont, as containing leſs ochre and calcarious earth. The ſalt is wholly of the nature of Glauber's ſalt, as is alſo that of many other ſprings thereabout, and even in our own country; the *nitrum calcarium* of Dr. Liſter being plainly the ſame with this, or Glauber's ſalt, produced in the bowels of the earth by a mixture of a vitriolic acid with that alkaline earth, which is the baſis of ſea ſalt. This ſalt, or one analogous to it, is found alſo concreted into a ſolid form in the earth in many places. There are accounts of it in the memoirs of the Paris academy, in Spain, in France, and in ſome parts of the Eaſt; and in England, we have earths which contain it. *Hoffman*. Oper. vol. 5. p. 143.

EGUILLETTE, in the manege. See YERK.

EIA, or EY, in our old writers, is uſed for an iſland. Hence the names of places ending in *ey*, denotes them to be iſlands. Thus, Ramſey, the iſle of rams, Sheppey, the iſle of ſheep, &c.

EIA is alſo ſometimes uſed for water, and hence the names of places near waters, or lakes, terminate in *ey*. *Du Cange*.

EJACULATOR, (*Cycl.*) in anatomy, a name given by Santorini to a muſcle of the pudenda, which he alſo calls in men the elevator urethræ, tho' in women he calls the ſame muſcle the depreſſor urethræ. Winſlow calls it the inferior proſtatic muſcle, and Albinus the *tranſverſus alter perinæi*, to diſtinguiſh it from the *tranſverſus penis* of others, which he calls *tranſverſus perinæi*.

EIDER, in zoology, the name of a ſpecies of ſea duck, called by Wormius *Anas plumis molliſſimis*, the ſoft feathered duck. The male and female differ very much in this ſpecies; the male very much reſembles the common duck; its beak is black, it has two oblong black ſpots, made of very ſoft feathers, running from the beak over the eyes, with a narrow white ſtreak in the middle of each; its neck, the lower part of its head, its breaſt, and the upper part of its back and wings, are all white, but the wings and tail are black. The female is all over of the ſame colour, a duſky brown, ſpotted with black. They build in the holes of rocks on the ſea ſhore, and lay abundance of eggs, which are very delicate and well taſted. Their feathers alſo are very remarkably ſoft, and fit for ſtuffing beds, &c. *Ray*'s Ornithology, p. 277.

EJECTIONE *Cuſtodiæ*, *Ejectment de Garde*, in law, a writ which lies againſt him, that caſts out the guardian from any land, during the minority of the heir. Reg. Orig. 162. Fitz. Herb. Nat. Brev. 139.

EIGNE, in law books, is uſed for eldeſt, or firſt-born. Thus we ſay, baſtard *Eigne*, and mulier *puiſne*, for the elder baſtard, and the younger lawfully born.

EILAMIDES, a word uſed by Hippocrates to expreſs the meninges, or membranes of the brain, the dura mater and pia mater.

EINBLINDER, in zoology, the name of a ſort of lamprey, without eyes, called by the writers on theſe ſubjects the lampetra cæca, or blind lamprey. It is very ſmall, not exceeding the common dew-worms in length or thickneſs. It has no ſcales, but its body is divided, by annular lines, into eighty-four rings, juſt in the manner of the large worms. Its mouth is in the under part of its head, and is round, and always open. It has a cavity in the middle of its head, like the reſt of the lampreys, for admitting water, and has ſeven gill-holes on each ſide. It has the common long fin running on the ridge of the back, but has no other, *Willoughby*'s Hiſt. Piſ. p. 107.

EINECIA, in our old writers, is uſed for primogeniture. It is ſometimes writ *Eſnecia*, and *Eſnecy*. See ESNECY.

EIRESIONE, Ειρεσιωνη, in antiquity, an olive branch bound about with wool, and crowned with all ſorts of firſt fruits, which was carrried in proceſſion in the Athenian feſtival, called *Pyanepſia*. Pott. Archæol. Græc. l. 2. c. 20. T. 1. p. 428. See PYANEPSIA, *Cycl.*

EISETERIA, Εισητηρια, in antiquity, the day on which the magiſtrates at Athens entered upon their office; upon which it was cuſtomary for them to offer a ſolemn ſacrifice, praying for the preſervation and proſperity of the commonwealth, in the temple of *Jupiter* Βελαίου, and *Minerva* Βελαία, i. e. the counſellors. Pott. Archæol. Græc. l. 2. c. 20. T. 1. p. 385.

ELÆAGNUS, in botany, a name uſed by ſome authors for the gale frutex, the Dutch myrtle or gaule. Merret. Pin. p. 82.

ELÆAGNUS, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: The cup is a one-leav'd perianthium, very ſlightly divided into four ſegments; it is placed erect, is ſhaped like a bell, is rough on the outſide, and coloured within, and falls before the ripening of the ſeed. There are no petals. The ſtamina are four very ſhort filaments, inſerted between the ſegments of the cup. The antheræ are oblong, and lie upon theſe. The germen of the piſtillum is roundiſh, and is placed below the cup. The ſtyle is ſimple, and ſcarce of half the length of the cup. The ſtigma is ſimple. The fruit is an oval obtuſe ſmooth drupe, punctated at the extremity. The ſeed is an oblong obtuſe nut. *Linnæi* Genera Plant. p. 51.

ELÆOMELI, in the writings of the antient phyſicians, the name of a ſubſtance, thus deſcribed by Dioſcorides. In Palmyra, a country of Syria, the *Elæomeli*, which is an oil thicker than honey, and of a ſweet taſte, flows from the trunk of a tree. Two cyathi of this oil, he adds, drank with a hemina of water, evacuate crude and bilious humours by ſtool. There was much good obtained from the giving this medicine, but it had this remarkble effect, that thoſe who took it were ſeized with a torpor, and privation of ſtrength for a time; this was, however, of no ill conſequence, but people knew of and expected it, and uſed always to keep thoſe perſons awake who had taken it, and the ſymptoms ſoon went off. The ſame author alſo adds, that the oil was ſometimes prepared from the buds of the tree, and ſuch of this kind was eſteemed the beſt that was old, thick, fatty, and not foul or turbid. It was judged of a heating nature, and frequently applied externally to the eyes, with good effect in the cure of dimneſs of ſight, and contributed to the cure of leproſies, and pains of the nerves. Hermolaus Barbarus has a ſtrange conjecture in regard to this ſubſtance, which is, that it was the ſame with the manna mentioned in ſcripture, only uſed in medicine inſtead of food; but the account Dioſcorides gives of the effects of it is a very ſufficient anſwer

to the abſurdity of ſuch an opinion. *Dioſcorides*, l. 1. c. 37.

ELÆOSACCHARUM. After the chemiſts had juſtly ſhewn phyſicians the ſpirit reſiding in eſſential oils, containing, in a ſmall volume, all the particular virtues of the plant, phyſicians prudently reflected, that they hence had an excellent inſtrument in their art, but that the ſpirit, as it remained in the unctuous tenacity of the oil, was not in a condition to be uſed with perfect ſafety, becauſe theſe oils were extreamly ſharp, and, by their tenacity remaining fixed to one part, they often cauſed inflammations. Hence they began to think of a method of rendering theſe oils miſcible with water, and thus uniformly conveying their virtues to the places intended; and this they found might be effected by means of ſugar. Grind an ounce of fine and dry loaf ſugar to an impalpable powder, in a glaſs mortar, with a glaſs peſtle, then add to it, by degrees, a dram of any eſſential oil, or half a dram, if the oil be very tenacious; continue rubbing them together till the oil be thoroughly mixed, and drank into the ſugar. The oil, in this operation, uſually diffuſes a fragrance to a great diſtance, wherefore, to prevent the loſs of its finer parts, the operation ſhould be performed as quick as poſſible, and the mortar covered, and the peſtle ſurrounded by a clean linnen cloth; and if a little quantity of the white of an egg be added in the grinding, and mixed in with the ſugar and oil, the oil thus becomes more eaſily miſcible, but the mixture will not keep ſo long without growing rancid. Thus ſugar, which is a pure ſoap, or a true eſſential oily ſalt, divides the glutinous tenacity of the oil, interpoſes itſelf between the principles thereof, unites them cloſely with itſelf, and makes an extemporaneous ſoap, which may be commodiouſly diluted with water for medicinal uſes. *Boerh.* Chem. pt. 2. p. 100.

Though this mixture is not ſo perfect as an actual ſoap, or true eſſential ſalt, yet it ſuffices for uſe; nor is there reaſon to apprehend any inconvenience from the ſugar in this preparation, for ſugar is unjuſtly ſaid to be unwholſome, as there are no ſolid proofs extant of this; on the contrary, it is a wonderful ſalt that perfectly mixes with water, and ferments therewith into wine, and yet, what is ſurpriſing, it appears oleaginous and perfectly inflammable in the fire, whence it is known to conſiſt of oil and ſalt.

If theſe *Eleoſaccharums* be carefully prepared, and put up in clean dry glaſſes, exactly cloſed with glaſs ſtoppers, they may be preſerved perfect a long time; and in this manner very effectual medicines may be eaſily carried from place to place, and, upon occaſion directly uſed upon a journey, by mixing a ſmall quantity of them in a glaſs of wine. An *Elæoſaccharum*, or mixture of the ſame nature, at leaſt, might be alſo made, by mixing an eſſential oil with a fixed alkaline ſalt, by grinding, by which means alſo a kind of ſoap is obtained; but alkali's, thus mixed, deſtroy the grateful properties of the eſſential oils, and change their natural taſtes and odours. Such mixtures alſo would preſently reſolve in the air, and thence be eaſily altered; but, by the method with ſugar, the phyſician may always readily prepare a medicine rich in virtues. If the *Elæoſaccharum* of mint, for inſtance, be diſſolved in mint water, then ſtrengthened with the addition of ſpirit of mint, and the mixture ſweetened with ſyrup of mint, the whole virtues of the plant will be thus obtained. *Boerh.* Chem. pt. 2. p. 100.

The ſaponaceous property of ſugar is very evident in this proceſs, this fits it for breaking, and dividing the body of the oils, as if they were in a manner fermented with it, and, at the ſame time, it is ſo far from diminiſhing the virtues of the oils, that it rather encreaſes them; hence the antients, who were unacquainted with ſugar, always uſed honey to this purpoſe; and hence we learn the virtue of ſugar in the body, where, being diluted with the natural juices, it affords a ſaponaceous lixivium, which, by the force of circulation, diſſolves viſcous and unctuous ſubſtances; whence it does not generate phlegm, but diſſolves it, nor does it encreaſe the bile, or itſelf turn into bile, as has been vulgarly ſuppoſed, but, on the contrary, it opens, attenuates, and divides that juice, tho' by diſſolving the oleaginous parts too much, it may occaſion leanneſs, as by atteneuating too much, it produces a weakneſs in the parts, and is thence improper in rickets and in the ſcurvy.

ELÆOTHESIUM, Ελαιοθεσιον, in antiquity, the place, or room, in the gymnaſium, where thoſe who were to wreſtle, or had bathed, were anointed. It was alſo called Αλειπτηριον. *Pott.* Archæol. Græc. l. 1. c. 8. p. 38.

ELANULA, in medicine, the name of a peculiarly hard allum.

ELAPHEBOLIA, Ελαφηβολια, in antiquity, a feſtival kept in honour of Diana Ελαφηβολος, i. e. the huntreſs, for which reaſon a cake made in the form of a deer, and upon that account called Ελαφος, was offered to her. For a farther account of it, ſee *Pott.* Archæol. Græc. l. 2. c. 20.

ELAPHEBOLION, Ελαφηβολιων, in antient chronology, the ninth month of the Athenian year. It conſiſted of thirty days, and anſwered to the latter part of our February, and beginning of March. See MONTH.

It was thus called from the feſtival *Elaphebolia* kept in it. See ELAPHEBOLIA.

ELAPHIS. See the article ELAPS.

ELAPHOBOSOUM, in botany, the wild parſnep. See PARSNEP.

ELAPHOCAMELOS, in zoology, a name by which ſeveral authors have called the Peruvian camel, uſually called *Glama*, and employed there as a beaſt of burthen. See GLAMA.

ELAPHONESUM *Marmor*, a name uſed by the antients to expreſs a ſpecies of marble, uſed in ſtatuary, and called alſo *Proconenſium Marmor*; it was of a bluiſh white, variegated with ſlender veins of black. See PROCONENSIUM.

ELAPS, or ELAPHIS, by ſome called alſo *Elops*, the name of a ſerpent deſcribed by many authors, and met with by Bellonius in the iſland of Lemnos. It grows to about three foot long, and is on the back of a dark grey, with three longitudinal black lines, running from the head to the tail, and on the belly of a bright yellow, according to Aldrovandus. The people of Lemnos call it *Laphiati*. *Ray*'s Syn. Anim. p. 290.

ELASMIS, in natural hiſtory, the name of a genus of foſſile bodies, of the talc claſs, the diſtinguiſhing characters of which are, that they are compoſed of ſmall plates, in form of ſpangles, each of which is either ſingle, and not farther fiſſile, or, if complex, fiſſile only to a certain degree, and that into ſomewhat thick laminæ. See Tab. of Foſſils, Claſs 1.

The word is derived from the Greek Ελασμὸς, a lamina, or plate. The ſeveral component parts of theſe maſſes being ſo many ſmall plates.

The bodies of this genus have been uſed to be named *mica*, *glimmer*, and *catſilver*, by authors, in the ſame manner with the *bractearia*. There are only four known ſpecies of this foſſil: 1. A bluiſh brown one, with ſmall ſpangles, found in Germany and England. 2. A dull pale red one, with variouſly ſized ſpangles, which ſeems peculiar to England. 3. An orange coloured one, with very large and very thick flakes, found in the Eaſt Indies, and containing ſome lead and a little ſilver. And 4. A bright purple one, a very beautiful ſubſtance, found on the ſhores of rivers in the Eaſt Indies, and in New Spain. The laſt ſpecies is uſed in the Eaſt Indies, as a medicine for the ſtone, the reſt have not been put to any medicinal or mechanical uſe. *Hill*'s Hiſt. of Foſſils, p. 84, 85, 86, 87.

ELASTICITY (*Cycl.*)—The *Elaſticity* of compreſſed air may be long preſerved. Dr. Deſaguliers tells us, he has kept ſeveral wind guns ſtrongly charged for half a year together, in which the air loſt none of its *Elaſticity*; others have found the air as ſtrong after a year. Nay, it is credibly ſaid, that a wind gun having been laid by and forgotten for ſeven years, did afterwards diſcharge its air as many times, and with as much force, as it uſed to do. Phil. Tranſ. N°. 454. §. 6. See SPRING.

ELATE, in natural hiſtory, a word uſed by the antient Greeks in three different ſenſes, the not attending to which has occaſioned ſome very notorious errors in thoſe who have quoted and commented upon their works. The common ſenſe of the word is the *fir tree*, and in this ſenſe alſo it is generally underſtood, and tranſlated from the original authors in whatever ſenſe they uſed it. We find by Theophraſtus, that the word *Elate* was however alſo uſed for the tender budds of the ſheaths, or caſes of the young leaves of the palm tree, when juſt budding out, theſe contained a fine viſcous matter, as thoſe of many of the trees of warm countries do beſide, and for this fragrant reſin they were much ſought after, and uſed in the ſweet unguents of the Eaſtern nations.

Pliny, finding mention of the word *Elate* on theſe occaſions, has underſtood it as meaning the fir tree, in ſome places, but, in others, finding it coupled with the palm, he has made it the name of a peculiar genus of palm, and created an imaginary plant, not ſeeing that it was only a name of the leaf buds of the common palm. From this tender bud of the palm being called *Elate*, there grew a cuſtom of calling ſeveral other young ſhoots of plants *Elate*, and, in fine, a peculiar kind of ſallad herb, that always uſed to be eaten while young, was called *Elate* by the Greeks. Heſychius tells us, that *Elate* was the common name both of the fir tree, and of a common ſallad herb; ſome have thought that the plant, now called *Elatine*, or *Fluellin*, was eaten by the Greeks in its young ſtate, and, if ſo, probably enough this was the very plant which they called *Elate*. We find Epicharmus mentioning the word *Elate* in this ſenſe; ſpeaking of the eſculent vegetables, he mentions the radiſh, *Elate*, and ſeveral others together. His commentators have taken great pains to alter the word into ſomething elſe, but we have ſufficient proof in Theophraſtus, and many others, that it is properly written as it ſtands, and that the author meant no other than the ſallad herb, then commonly known by that name.

ELATE is alſo uſed, by ſome authors, for a genus of plants, called by Linnæus *Phœnix*, and, in the *Hortus Malabaricus*, *Ratovindel*. Muſ. Cliffort 12. See PHOENIX.

ELATINE, *Fluellin*, in botany, the name of a genus of plants, character'd by Linnæus, and made to comprehend the potamopithys of Buxbaum, and the alſinaſtrum of Vaillant. The characters are theſe: The perianthium conſiſts of four roundiſh leaves of the ſize of the petals of the flower. The flower conſiſts of four oval obtuſe petals, expanded into a plane. The ſtamina are eight filaments, of the length of

the flower. The antheræ are ſimple. The germen of the piſtil is large, and of a globoſe, but ſomewhat compreſſed figure. The ſtyles are of the length of the ſtamina, they are four in number, and ſtand erect, and are of equal length. The ſtigmata are ſimple. The fruit is a large capſule, of a compreſſed orbicular figure, and is compoſed of four valves, and contains four cells. The ſeeds are numerous, and of a lunated figure, they ſtand erect, and ſurround the receptacle in a circular direction. *Linnæi* Gen. Plant. p. 173. *Buxbaum*, ap. Act. Petrop. *Vaillant* Bot. Baris 1. f. 6.

ELATINE, in medicine, is greatly recommended as an aperient, reſolvent, and vulnerary. Its ſimple water has been uſed for the ſame purpoſes, though it retains very little of the virtues of the plant. The infuſion is much better, and the expreſſed juice preferable ſtill. It is praiſed by ſome in leprous and ſcrophulous caſes; alſo externally for cancrous and other eating ulcers. An ointment is made of it for theſe purpoſes. At preſent, however, it is very little uſed. *Hill*'s Hiſt. Mat. Med. p. 377.

ELATITES, *Fir Stone*, in natural hiſtory, a name given by authors to that ſort of petrify'd wood which ſhews the lineaments of the fir tree wood, and has been originally either that or ſome wood of a like kind.

ELATITES was alſo a name uſed by the antients for an iron ore, eſteemed a ſpecies of hæmatites; it was of a yellowiſh white colour, and was more uſually called *Xanthus*. *Hill*'s Theophr. p. 98. See XANTHUS.

ELUTHERII *Cortex*, in the materia medica, a name by which ſome authors have called the *Caſcarilla*, or *Cortex Thuris*, called Indian bark. *Schroder*. Vol. 4. p. 166.

ELAWANDUM, in zoology, the name of a remarkable ſpecies of monkey, common in the iſland of Ceylon; its hair is whitiſh, or of a pale grey, and it has a long and beautiful black beard hanging from its chin. *Ray*'s Syn. Quad. p. 188.

ELDRIENE, in zoology, a name by which ſome call the ſmall fiſh, known in Engliſh by the name of the *Minnow*, and called by authors *Varius*, from the various colour of its ſides and belly. *Willughby*'s Hiſt. Piſc. p. 269. See the article VARIUS.

ELEATIC *Philoſophy*, among the antients, a name given to that of the Stoics, becauſe taught at Ἐλέα, in Latin *Velia*, a town of the *Lucani*. *Hofman*. Lex. in voc. See STOICS, *Cycl.*

ELECAMPANE, *Helenium*. See HELENIUM.

ELECTARIUM, the ſame as *Electuarium*. The latter has been the uſual way of ſpelling the word; but the late London pharmacopœia has adopted the manner of ſpelling it without the (u) as Cælius Aurelianus, who is the firſt author that uſes the word, always ſpells it in that manner. *Pemberton*'s Lond. Diſp. p. 233. See ELECTARY.

ELECTARIUM *e Scammonio*, a new name given, in the London pharmacopœia, to the compoſition commonly called *Electuarium Caryocoſtinum*. The compoſition is alſo ſo much altered, that inſtead of an ounce, a dram and half is now a common doſe. The preſcription for it is this: Take ſcammony an ounce and half, cloves and ginger, of each ſix drams, oil of caraway-ſeeds, half a dram, honey, half a pound: Mix all into an electuary. *Pemberton*'s Lond. Diſp. p. 336.

ELECTARY (*Cycl.*)— To make *Electaries* in perfection, where a ſyrup is the baſis of the compoſition, as in the *Electary* of ſaſſafras, and the like, the ſyrup ſhould be prepared in a cloſe veſſel, that none of the virtues of the ingredients may be loſt; the powders, to be afterwards added to this, ſhould be freſh, and very finely ſifted; the gums, when there are any in the compoſition, ſhould be well cleanſed and diſſolved in their proper menſtruums, and the whole muſt be reduced to a ſmooth maſs of ſuch a conſiſtence as will neither be ſubject to candy nor ferment.

Where ſyrups are uſed only to bring *Electaries* into form, care muſt be taken that they are not boiled too high, for that will ſubject them to candy in the *Electary*, and ſpoil the whole, as the being too low boiled, or thin, will leave them ſubject to ferment in hot weather, and afterwards grow ſour, ſo as to change, invert or deſtroy the nature of the medicine.

Electaries, made of the pulp of fruits, are leſs diſpoſed to keep than others, on account of the great tendency theſe ſubjects have to ferment and putrefy. Hence lenitive *Electary* can never keep long, eſpecially if made too thin.

Juſt the contrary of this is the caſe, however, with the capital *Electaries*, as Venice treacle, mithridate, and the like, for theſe require to be ſome time made, that the ingredients may digeſt or ripen, as it were, and grow mellow together, as the gums and ſpices that are in that compoſition keep it from any decay, provided the honey do not candy, which ſome prevent by uſing it unclarify'd; and if theſe *Electaries* prove too dry, they are to be moiſtened with Canary wine, and thus they improve by keeping. This, however, is not the caſe with the diaſcordium, which loſes of its aſtringency as the ingredients become mellow together; and this is much better made up with ſugar of roſes, or ſyrup of diacodium, inſtead of honey. *Shaw*'s Lectures, p. 209.

The way of powdering and ſifting the ingredients for *Electaries* is liable to loſe their finer and lighter parts, in form of a light duſt, and that of grinding them in an horſe-mill has the ſame inconvenience, with the additional one of a great quantity of ſtony matter mixing itſelf from the mill-ſtones with the powder. The beſt way would certainly be, by means of two iron rollers moving againſt one another in a cloſe box, as in the making of chocolate, and to grind together all the ingredients, with the honey and wine, and bringing all at once to a proper conſiſtence. Perhaps, indeed, a much better way than all, though a very troubleſome one, would be to get out the full virtues of all the ingredients ſeparately, in the form of extracts and eſſential oils, *&c.* and mix theſe with a proper quantity of honey, and, by this means, to concentrate the medicine, ſo that it might be given agreeably in very ſmall doſes.

ELECTI, in church hiſtory, a ſect of heretics who neither eat fleſh, nor married. See *Hofm.* lex in voc.

ELECTION (*Cycl*)—ELECTION *of a Clerk of Statutes Merchant*, in law, a writ that lies for the choice of a clerk aſſigned to take ſtatutes merchant. It is granted out of chancery, on ſuggeſtion that the clerk, formerly aſſigned, is gone to dwell at ſome other place, or is under an impediment to attend the duty of his office, or that he has not lands ſufficient to anſwer his tranſgreſſions, if he ſhould act amiſs. *Fitz. Herb.* Nat. Brev. 164.

ELECTION *of Eccleſiaſtical Perſons*. *Elections* for the dignities of the church ought to be free, according to the Stat. 9 Ed. 2. c. 14. If any perſons, that have a voice in *Elections*, take any reward for an *Election* in any church, college, ſchool, *&c.* the *Election* ſhall be void. And if any perſons of ſuch ſocieties reſign their places to others for reward, they incur a forfeiture of double the ſum; and both the parties are rendered incapable of the place. Stat. 31 *Eliz.* c. 6.

ELECTION *of a Verderor of the Foreſt*, (*Electione Viridariorum Foreſtæ*) in law, a writ that lies for the choice of a verderor, where any of the verderors of the foreſt are dead, or removed from their offices. This writ is directed to the Sheriff, and the verderor is to be elected by the freeholders of the county, in the ſame manner as coroners. New Nat. Brev. 366.

ELECTORS *of Members of Parliament*. See VOTE.

ELECTUARY. See ELECTARY.

ELEEMOSYNARIUS, in our old writers, is uſed for the almoner, or peculiar officer who received the eleemoſynary rents and gifts, and diſtributed them to pious and charitable uſes. There was ſuch an officer in all religious houſes. The biſhops alſo uſed to have their almoners, as now the king has. *Linn.* Provinc. Lib. 1. tit. 12. See alſo *Du Cange*, Gloſſ. Lat.

ELEGIA, in botany, a name given, by ſome authors, to the *Arundo Scriptoria*, or writing reed common in Greece and Italy. *Park.* Theatr. p. 1211.

ELEMENT (*Cycl.*)—See PRINCIPLE.

ELENCHUS, in antiquity, a kind of ear-rings ſet with large pearls.

ELEOSELINUM, in botany, a name by which ſome authors have called the paludapium or ſmallage. *Ger.* Emac. Ind. 2.

ELEPHANT, *Elephas*, in the Linnæan ſyſtem of zoology, the generical name of a diſtinct genus of the jumenta; it includes the *Elephant* and *Rhinoceros*. The characters which thoſe creatures have in common, and which make the diſtinction of this genus, are, that they have two paps placed on their breaſt, have no *dentes inciſores*, or cutting-teeth, and the *canine*, or dog-teeth, of the upper jaw, very long. The *Elephant* this author diſtinguiſhes by his ſnout. The rhinoceros he calls *Elephas naſo cornigero*, the *Elephant*, with the horn on his noſe. *Linn.* Syſtem Natur. p. 40.

Taming of ELEPHANTS. The method of taking and taming this creature, in the iſland of Ceylon, is as follows: The natives pitch upon a proper place for a warren, or park, which is broad at the entrance, and grows narrow farther in, till, at the end, it is ſo narrow, that an *Elephant* cannot turn himſelf, and it runs on of this narrowneſs ſo far, that twenty *Elephants* may ſtand in it one behind another. When the encloſure of this warren is finiſhed, all the people of the neighbouring places aſſemble, and make a circumference round the woods, where they know there are *Elephants*, which takes in, perhaps, ſixty miles. The men now ſtand at twenty-five yards diſtance, and kindle fires between them, and make all the noiſe they can, by ſhouting, blowing horns, beating drums, and the like, and, by degrees, approach nearer and nearer the warren. The *Elephants* run from the fires and noiſe, and conſequently can go no where but towards the warren, the men, who every way ſurround them, except on the warren ſide, follow upon them in this manner, till they come together, and make a ring, and the *Elephants* are driven into the encloſure. When theſe creatures perceive that they are thus taken, they make reſiſtance, and often turn upon the men, but there are always near the warren fences of poles, lying flat upon the ground, which the hunters need only raiſe up, and they keep in the prey, ſo that they can neither eſcape, nor injure them, they then purſue the *Elephants* with fire-brands,

and drive them into the narrow part where they cannot turn.

They are, from this place, taken one by one, and led to the ſtable, each between two tame *Elephants* bred for that purpoſe, the points of whoſe long teeth are cut; and theſe, if the wild *Elephant* be troubleſome, will lay hold of his trunk with theirs, and beat him with their teeth. A man, ſitting upon each of the tame *Elephants*, directs them by a ſtaff with a hook at the end, with which he occaſionally touches their heads, and orders them as he pleaſes, without bridle, or any other furniture. When they are brought into the ſtable, they are led between two poſts, with ſtakes put athwart before their breaſts, and under their bellies, and are ſo tied that they cannot ſtir, nor lie down upon the ground, for, if permitted to lie down, they would become ſorrowful, and refuſe to eat, and would die. They are here fed with the trunks of plantains, a food they much delight in, and when they have been kept thus about ſix weeks, they become tame enough for ſale. If not ſold at that time, they feed them about ſix weeks longer in the ſtable with coco-leaves, and they are, at the end of that time, perfectly tame as a ſpaniel, and will eat graſs with the oxen in the fields. Phil. Tranſ. Numb. 277. §. 1.

The *Elephants* of Ceylon have been ſo long hunted, that they now know man for their mortal enemy, and ſeldom fail to ſeize upon and kill him wherever they meet him; but if a man lie upon the ground, and pretend to be dead, they never meddle with him. Several people have, in this iſland, lain aſleep while *Elephants* paſſed by them, and ſome have only pretended ſleep, and a perfect ſtillneſs has always been found to preſerve them, even tho' the creature came up to examine them.

ELEPHANT *Caterpillar*, a name given, by ſome authors, to a ſpecies of inſect, commonly known in Ireland by the name of Connough worm, and ſuppoſed to be poiſonous to cattle which feed on it. See CONNOUGH *Worm*.

ELEPHANT's *Noſe*, or *Elephant's Neuſe*, as it is called by the Dutch, is a ſpecies of the acus, or needle fiſh, caught in the Eaſt Indies, ſo called from the reſemblance of its ſnout to the trunk of an *Elephant*. It is a very ſingular ſpecies, the lower jaw running out into a very long and ſharp-pointed ſpine. It is round bodied, and beautifully variegated with ſpots, and has on each ſide a green line running from head to tail. It is caught in ſalt waters. *Ray*'s Ichthyogr. app. p. 4.

ELEPHANTOPUS, in botany, the name of a genus of plants, the characters of which are theſe: The cup is an involucrum, compoſed of three broad and ſharp-pointed leaves, this is large and permanent, and contains ſeveral flowers. Within this ſtands the common cup, which always contains four flowers, and is of an oblong imbricated figure, compoſed of ſquamma of an oblong and ſubulated figure, and prickly at the ends. Theſe ſtand erect, and there are four of them longer than the reſt, and equal one to another. The flower is compound and tubular, and is compoſed of either four or five ſmall flowers, each of which conſiſts of only one petal, and is of a ligulated form, and has a narrow mouth ſlightly divided into five ſegments. The ſtamina are five very ſhort and capillary filaments, the antheræ are of a cylindric figure, and tubulate. The germen of the piſtil is oval and coronated. The ſtyle is capillary, and of the length of the ſtamina; and the ſtigmata are two, and are ſlender, and ſtand open. The cup remains unaltered, after the flower is fallen, and contains the ſeeds, which are ſingle and compreſſed, and crowned with a ſeries of ſhort hairs or briſtles. *Linnæi* Gen. Plant. p. 384.

ELETTARI, in the materia medica, a name uſed by ſome authors for the common ſmall cardamom of the ſhops. Hort. Mal. B. 11. p. 9.

ELEVATIO, in proſody, the ſame as *arſis*. See ARSIS, *Cycl.*

ELEVATOR (*Cycl.*)—ELEVATOR *Alæ naſi*, in anatomy, a name given by Cowper to one of the muſcles of the noſe, called by Winſlow the tranſverſalis, or inferior naris, and by Albinus the compreſſor naris. Coſſerius has deſcribed it under the name of the parvus naſi muſculus, and Fallopius under that of muſculus alius carneus naſi, and Riolanus by that of alius externus naſi.

ELEVATOR *Humeri*, in anatomy, a name given by ſome authors to a muſcle, now generally known under the name of the deltoides. See DELTOIDES.

ELEUTHERIA, Ελευθερια, in antiquity, a feſtival in honour of Jupiter Eleutherius, *i. e.* the aſſertor of liberty: It was kept at Platææ from almoſt all the cities of Greece.

This ſolemnity was inſtituted upon the defeat of Mardonius, the Perſian General, in the territories of Platææ, and was held every fifth year, and great prizes appointed to be contended for.

The Platæans had an anniverſary ſolemnity, called *Eleutheria*, kept in memory of thoſe that had valiantly loſt their lives in defence of their country's liberty. For the ceremonies obſerved at it, ſee *Pott.* Archæol. Græc. l. 2. c. 20. T. 1. p. 388. ſeq.

The Samians had another feſtival of this name, in honour of the god of love. And ſlaves, when they obtained their liberty, were wont to keep a ſtated holy-day in remembrance of the happy day on which they were made free. *Potter*, loc. cit.

ELFS *Arrows*, a name given by the people of ſome parts of Scotland, to certain ſtone weapons which they find, and which had been in uſe before tools and weapons of iron were uſed there. It is not only in Scotland that theſe are found, but in America, and many other places alſo. They are ſtiled by ſome ceraunia, and thunder-bolts, and are ſuppoſed to have fallen from the clouds in ſtorms of thunder; others, not leſs erroneouſly, ſuppoſe them to be natural foſſils; but their true origin is from the workmanſhip of man, out of common flints and other ſtones. It is probable that they firſt broke large flints to pieces, and then ſelecting ſuch of thoſe fragments as were of the neareſt approach to the ſhape they wanted, they finiſhed the forming them to their minds, by breaking off their angles, and hewing their edges with other ſtones of the hardeſt kinds they could get; in this manner they formed them into the heads of arrows, and other ſuch things, and we at this day find ſuch evident marks of that rude kind of rude workmanſhip upon them, that this cannot be doubted. Thoſe arrow-heads found in Scotland and Ireland are of a mixed grey and brown colour, like thoſe of ſome of the northern parts of America, that being the colour of the flints in thoſe places, as appears by breaking them. Thoſe of the Ladrones iſlands are uſually of a yellowiſh colour, and thoſe of many parts of America are of the ſame appearance. Others ſeem to partake of the nature of the onyx, or agate, having been hewn out of ſtones of that kind. Some of theſe are deeply bearded, others not at all ſo; and beſide the ſhort and broad ones, which are the moſt common kind, and were the heads of their common arrows, ſome are found which are much longer, and have been the heads of javelins; ſome alſo are broad and flat, and have ſerved as the heads of hatchets. In Perthſhire ſome red ones are found, which have the appearance of the heads of ſmall arrows. Brown and coarſe ſtones are found in New England, wrought into the heads of axes, and into wedges. Very ſmall arrow-heads, made out of a talky fiſſile ſtone, are found in Virginia and Barbadoes. Theſe were more eaſily made than any of the others, but they could be of leſs uſe, being not capable of ſo ſharp an edge as the finer and more homogene ſtones. In Ireland the browniſh flint they are made of is almoſt as pellucid as an onyx, and there ſeems to have been more work beſtow'd upon them there than in any other part of the world, ſome of them being very nicely ſhaped, and finely bearded all along the edges.

Stones have been found in Tuſcany ſhaped into hatchet heads, and theſe are generally very hard and heavy, containing iron, and being of the nature of a coarſe emery; and in the iſland of Guacu, one of the Ladrones, it is common to find ſtones of an oblong figure, thick in the middle, and tapering toward each end to an edge, ſo as to form a ſort of double edged hatchet-head. Theſe are always made out of a beautiful ſtone, of the jaſper kind; its ground is red, and it is variegated very beautifully with white and blue. It is ſuppoſed that the inhabitants had been uſed to employ theſe as ſtones to throw out of their ſlings, with which they are ſaid to have been very dexterous, and to have done great miſchief. *Woodward*'s Cat. Foſſ. Vol. 2. p. 52.

ELHANNE, in botany, a name given by ſome authors to the liguſtrum ægyptiacum, or eaſtern privet. *J. Bauhine*, vol. 1. p. 541.

ELICA *Paſhnum*, in natural hiſtory, a name given by the people of the Eaſt Indies, to a kind of red orpiment, found very frequently in that part of the world, and given internally, after calcination, in intermitting fevers.

ELICE, or HELICE, in botany, a name by which the antient Greek writers have ſometimes called the willow, tho' its more general name among them is *Hea*. Heſychius gives many inſtances of the willow being called *Helice*. The names of this tree have generally been ſuppoſed to be all derived from its quick growth. Its original name in the Greek *Hea*, from ἑᾶναι, to go ſwiftly. The Latin ſalix has alſo generally been ſuppoſed to be derived *a ſaliendo*, from its riſing up in height, by jumps at a time as it were. But this ſeems forced and erroneous, the preſent name *Elice* was derived from Ελκω, to draw, the lightneſs of the wood of this tree recommending it to the Greeks for their making carriages of all kinds of it. This, Theophraſtus tells us, was the principal uſe made of it in his time, and from this word *Elice*, the Latin ſelix and ſalix ſeem to have been derived.

The changing the termination é into x is nothing uncommon among theſe authors, for the maſtich of the Greeks was originally turned into maſtix in the Latin, the Delphici into into Delphix, and ſo on of the reſt of the like kind. As to the adding an S in the beginning, nothing was more common among the Latins in their derivatives, the ὄλκος of the Greeks was made the *ſulcus* of the Latins, the ὕλη, *ſylva*, and ſo of many other words.

ELIDRION, a word uſed, by the earlier writers in medicine, in ſeveral very different ſenſes; ſome uſing it as the name of maſtich, others of rhapontic, and others of crude mercury.

Some of the chymical writers have alſo made it expreſs a certain mixed metal, compoſed of three parts, one ſilver, another braſs, and the third Gold.

ELIGII *Morbus*, a name given by ſome medical writers to a *fiſtula*.

ELIGMA, a name given by Nicolaus, Myrepſius, and ſome other authors, to that form of medicine uſually now called a *Linctus*, or *Lambative*.

ELIQUATION, in metallurgy, is a ſeparation of the different parts of mixed bodies, by the different degrees of fire required to melt them. When the nature of ores, or of metallic mixtures, is ſuch, that while one part of them melts in the fire, the other more refractory and difficult of fuſion remains ſtill ſolid; the firſt, when the maſs is placed in a mild fire, flows out of the interſtices of the other, and is thus ſeparated from it. The perfection of this operation requires a different fluidity of the parts that conſtitute the maſs. Lead, for inſtance, melts into one maſs with copper, by a ſtrong fire, whereas theſe metals cannot diſſolve each other in a moderate one; but if the maſs, compoſed of both theſe, thus blended together, is afterwards expoſed to a mild fire on an inclined plane, the lead alone melts, the copper becoming only brittle and ſpungy, and remaining in its ſolid form, even when the lead has run out of it. This ſeparation, however, is not ſo perfectly made, but that there ever remains ſome lead in the copper, and ſome ſmall part of the copper is alſo carried away with the lead, wherefore it is neceſſary for this experiment, that the metals are not mixed in too minute proportions, for if one thouſandth part only of lead were to be mixed with copper, or the ſame ſmall proportion of copper with the lead, the ſeparation, by *Eliquation*, could not be effected.

It is generally neceſſary alſo, in order to make this operation ſucceed, to add ingredients that are capable either of deſtroying the force by which the different parts cohere together, or of procuring an eaſier flux of the metals; for the mixtures of the other metals will not be ſeparated like thoſe of copper and lead, without the admixture of other ſubſtances. For inſtance, gold, ſilver, and copper, melted together, and perfectly blended by that means with one another, remain in the ſame ſtate in any degree of fire; to make the *Eliquation* of the gold and ſilver, therefore, out of ſuch a mixture, the ſame additions muſt be uſed as in the operation of *precipitation by fuſion*. Sulphur added, in this caſe, does indeed diſpoſe the copper to abandon the gold and ſilver; but if theſe two, as it moſt commonly happens, are mixed in a very ſmall quantity with a very large one of copper, then you cannot yet obtain the ſeparation of them; for beſide, that very ſmall quantities are no more to be ſeparated here than in the former inſtance of copper and lead, ſulphur renders the copper fluid by almoſt the ſame degree of fire by which the ſilver and gold are melted; a conſiderable quantity of lead muſt therefore be added, in this caſe, that by the help of that addition, the gold and ſilver may be fuſed in a gentle fire, and the copper thus ſeparated from them.

Precipitations by this method, and by fuſion, are both of infinite uſe in metallurgy; for, by means of them, minute portions of gold and ſilver may, without any great expence, be ſeparated from a large maſs of other metals, which it has not hitherto been found poſſible to effect with advantage by any other method. *Cramer*, Art. Aſſ. 188.

ELIXIR (*Cycl.*)—ELIXIR *Aloes*, a name given, in the late London diſpenſatory, to the medicine commonly known by the name of *Elixir Proprietatis*, which is there alſo ordered to be made in the following manner. Take tincture of myrrh a quart, powder of aloes, and fine ſaffron, of each three ounces, digeſt them a due time, and then preſs off the tincture, and filter it for uſe. *Pemberton*'s London Diſp. p. 283.

ELIXIR *Paregoricum*, a name given, in the late London Diſpenſatory, to the *Elixir Aſthmaticum* of Quincey; which is there order'd to be made thus:

Take flower of benjamin, and ſtrained opium, of each a dram; camphire, two ſcruples; eſſential oil of anniſeeds, half a dram; rectify'd ſpirit of wine, a quart. Digeſt all together a proper time, and then ſtrain off the ſpirit. *Pemberton*'s Lond. Diſp. p. 283.

ELIXIS, a name given, by ſome of the old writers, to that form of medicine now called a *linctus*. See LINCTUS.

ELK (*Cycl.*)—The *Alce*, or *Elk*, is an animal ſo differently deſcribed by the antients, that it is evident they either knew very little of it, or elſe different writers have deſcribed different animals under this name. Pliny tells us, that the *Elk* reſembles the horſe, but that the length of the neck, and largeneſs of the ears, diſtinguiſh it. And Solinus, who is a copier of Pliny, afraid to give it ſo large a ſize, ſays, that it is like a mule. Theſe authors both add to this, what is ſaid alſo by many of the other Latin writers of the *Elk*, that its upper lip is ſo large, that it cannot feed without going backwards all the time. Pliny alſo, in another place, ſays this of the maclis, or machio, an animal of Scandinavia, which he deſcribes by hearſay, for he acknowledges, that it never had been ſeen at Rome, but ſays it was like the *Elk*. It is very poſſible, that this might be the *Elk* under another name. Other authors compare the *Elk* to the goat, and others to the ſtag, but they all ſpeak of its long neck. Some ſay it was of a ſimple duſky yellowiſh colour; and Cæſar, in his commentaries, ſays, on the contrary, that it was variegated with ſpots. Pauſanius tells us, that it was like the ſtag kind, but reſembled the camel in the length of its neck. It is probable that the *Elk* of Cæſar, and the *Elk* of Pliny and Solinus, are two different animals. See Tab. of Quadrupeds, N°. 6.

ELK in zoology, a name by which many have called the cygnus ferus, or wild ſwan. See the article CYGNUS.

ELKE is mentioned, in our ſtatutes, as a kind of yew to make bows of. 32 *Hen.* 8. cap. 9. *Cowel.*

ELLIPSIS, (*Cycl.*)—It has been long known, that if a parallelogram, circumſcribed about a given *Ellipſe*, have its ſides parallel to the conjugate diameters, then will its area be of an invariable or given magnitude, and equal to the rectangle contained by the axes of the figure: But this is only a caſe of a more general propoſition: For if, upon any diameter produced without the *Ellipſe*, you take two points, on each ſide of the center, at equal diſtances from it, and four tangents be drawn from theſe points to the *Ellipſe*, thoſe tangents will form a parallelogram, which is always of a given or invariable magnitude, when the *Ellipſe* is given, if the ratio of thoſe diſtances to the diameter be given. And when the ratio of thoſe diſtances to the ſemi-diameter is that of the diagonal of a ſquare to the ſide (or of $\sqrt{2}$ to 1) the parallelogram will have its ſides parallel to the conjugate diameters. Phil. Tranſ. N°. 468. p. 326.

Triangles, trapezia, or polygons, of any kind, may be determined, which, circumſcribed about a given *Ellipſe*, are always of a given magnitude. For

If, upon any diameter produced without the *Ellipſe*, any number of points be taken, on the ſame, or on different ſides of the center, at diſtances from it, that are each in ſome given ratio to that diameter; and from theſe points tangents be drawn to the *Ellipſe*, in any one certain order; the polygon, formed by theſe tangents, is always of a given magnitude in a given *Ellipſe*, and is equal to a polygon deſcribed by a ſimilar conſtruction about a circle, the diameter of which is a mean proportional betwixt the tranſverſe and conjugate axis of the *Ellipſe*.

The polygons inſcribed in the *Ellipſe*, by joining the points of contact (thus formed) and the ſectors, bounded by the ſemi-diameters, drawn to theſe points, are alſo of given or determined magnitudes; and the parts of any tangent intercepted betwixt the interſections of the other tangents with it, or betwixt theſe interſections and the point of contact, are always in the ſame ratio to each other in the ſame figure. See *Maclaurin*'s Fluxions, Vol. 1. p. 8. who obſerves that there is an analogous property of the other conic ſections.

ELLOTIA, Ἑλλώτια, among the Greeks, a feſtival in memory of Europa, Agenor's daughter; who was called Ἑλλωτις by the people of Crete. *Hofm.* Lex. univ. in voc.

ELLYCHNIOTOS, in the medical writings of the antients, the name of a ſort of tent uſed by the ſurgeons, and made of cotton or lint, rolled up into the form of the wick of a lamp or candle. See ELLYCHNIUM.

ELLYCHNIUM, a name given, by the antients, to that ſort of matter, whatever it was, which ſerved them in common uſe for the wicks of their lamps, and had, beſide this, its uſe in ſurgery. Galen expreſsly directs the uſe of the ſofteſt *Ellychnium*, ſuch as that of Tarſus inſtead of ſponge, in chirurgical caſes. But we are far from being aſcertained, at preſent, of what this *Ellychnium* of Tarſus was. Pliny mentions ſeveral kinds of *Ellychnia*, one compoſed of the fruit of the ricinus, which he particularly commends for its clearneſs; another of the papyrus, or paper reed; a third, of the downy matter from the plant called phlomis, and from this uſe of its down, afterwards lychnitis; and fourthly, a kind in which ſulphur was a very principal ingredient. He does not, however, give the epithet of Tarſenſe to either of theſe, or tell us of their being invented in, or brought from, Tarſus.

Galen is indeed the only author of early date that mentions the Tarſan kind, and that in two places: In the one of which he is talking of bringing ulcers to a cicatrix; and, in the other, of curing an œdematous ſwelling. In the laſt caſe he adviſes oxycrate to be applied, by wetting with it a ſponge, or elſe the Tarſan *Ellychnium*. The commentators have gueſſed differently as to the meaning of the word; and Cornarius ſuppoſes it to ſignify a ſort of ſpongy and light fungus, which, when properly wrought up, might be made to ſerve for the wicks of lamps, being very inflammable, as we well know many of the fungus's to be, particularly that ſort which the people of ſome countries call ſpunck, and uſe inſtead of tinder, to catch fire from the ſparks of flint and ſteel; and when in its natural lax ſtate, might, by its open ſpongy texture, be very well ſuited to imbibe any medicinal fluid, and retain it a long time, while applied to any diſeaſed part: Others have gueſſed it to be the xylon, or cotton of the antients; but from Galen's propoſing it to be uſed inſtead of ſponge, it ſeems much more probable to have been what Cornarius ſuppoſes. *Galen*, L. 13 and 14. *Cornar.* Comment. in 3. κατ. τοπ.

ELLIPOMACROSTYLA, in natural hiſtory, the name of a genus of cryſtals. The word is derived from the Greek

ἐλλιπὴς, imperfect, μακρὸς, long, and στυλος, a column, and expreſſes an imperfect cryſtal, with a long column. The perfect figure of cryſtal being a column terminated by a pyramid at each end, thoſe which want this character are eſteemed imperfect, and accordingly the bodies of this genus are defined to be imperfect cryſtals, with ſingle pyramids, one end of their column being affixed to ſome ſolid body; and compoſed of thin and ſlender hexangular columns, terminated by hexangular pyramids. Of this genus there are ſeveral ſpecies: 1. The common *ſprig cryſtal*, which is found in almoſt all parts of the world. 2. The purer pellucid colourleſs kind. This is common both in the Eaſt and Weſt Indies, and in ſome parts of Germany, and has been ſometimes found in *England*. 3. The dull whitiſh kind, with very ſhort pyramids. This is common in our mines, as alſo in thoſe of Germany. 4. The bright brown one, with a long pyramid. This is well known, among our lapidaries, under the name of *brown cryſtal*, and is found in the Eaſt and Weſt Indies, and in Sileſia and Bohemia, and ſometimes in England; of this there has lately been alſo brought over a very large quantity from the Scotiſh ſhore. 5. The dull brown kind, with a ſhort pyramid. This is often confounded with and miſtaken for the other, to the no ſmall loſs of the purchaſer. It is produced in great quantities in many parts of Germany. 6. The bright hexangular *brown cryſtal*, with a ſhort pyramid. This is a ſpecies ſubject to various tinges, and, among the reſt, very frequently to yellow, and has been of late cut by many of our lapidaries, under the name of the Saxon topaz. It is found in Saxony at Goſſelaer, and other places, and has lately been diſcovered alſo in America. 7. The bright brown kind, with a very long pyramid, called, by many of our jewellers, the *beryll*. This is found in Italy, and in ſome parts of Germany. 8. The whitiſh kind, with a very long pyramid, called the *iris* by authors. Some have indiſcriminately called all the cryſtals of this genus by the common name *iris*; but thoſe who firſt gave it, applied it only to this kind, which is particularly famous for giving the rainbow colours in reflection. It is common in Germany and Italy, and is ſometimes ſeen in England. 9. The yellow kind, with a ſhort pyramid, called the *citrine* by the jewellers. This is common in the Weſt Indies, and in Bohemia, and is of ſo beautiful a yellow, that ſtones for rings, cut out of it, when they have paſſed through two or three hands, are uſually miſtaken for topazes. And 10. That with a ſhort pyramid, and a thick reddiſh cruſt. This is found in Germany, Italy, France, and England, and is a very beautiful ſpecies. See Tab. of Foſſils, Claſs 3.

ELLIPOPACHYSTYLA, in natural hiſtory, the name of a genus of cryſtal. The word is derived from the Greek ἐλλιπὴς, imperfect, παχὺς, thick, and στύλος, a column, and expreſſes a cryſtal of the imperfect kind, with a thick column. The bodies of this genus are cryſtals, compoſed of an hexangular column, conſiderably thick and ſhort, and affixed irregularly, at one end, to ſome ſolid body, and terminated at the other by a hexangular pyramid. Of this genus, there are only two known ſpecies. 1. A bright and colourleſs kind, found in great plenty in New Spain, and in ſome other parts of America, but no where in Europe, ſo far as is yet known. And 2. A duſky brown kind, which is common in Germany, and is ſometimes found in England and Ireland. *Hill*'s Hiſt. of Foſſ. p. 182. See Tab. of Foſſils, Claſs 3.

ELM.—Mr. Dodart, in a diſcourſe made before the Paris academy, on the great fecundity of vegetables, and their prodigious encreaſe, choſe this tree as an example of it. He obſerved an elm of about ſix inches diameter in the body, and about twenty foot high to the branches, he ordered one of the branches to be cut off, and, without reckoning the ſeeds which had been ſhaken off by the blows of the weapon, or loſt by the fall, he counted the reſt only which remained on. This branch was about eight foot long, and on this there were 16450 ſeeds. Counting in a very moderate way, there muſt be reckoned, at leaſt, ten ſuch branches as this, on an elm of that growth. The product of theſe ten branches will be then 164500 ſeeds.

All the branches, which are ſhorter than eight foot, on the ſame tree, taken together, on the moſt moderate computation, muſt be allowed to make a ſurface more than double that of theſe ten branches. The product of this ſurface of the ſhort branches, therefore, will be 329000.

An *Elm* may very reaſonably be ſuppoſed to live a hundred years, and as the *Elm*, here mentioned, was but of twelve years growth, it cannot be ſuppoſed, in that ſtate, to be yet arrived at its middle degree of fertility in ſeeds; therefore the ſmalleſt addition that can be made to the 329000, will bring it to at leaſt 330000, for the mean yearly product of ſeeds of the tree; and to know what is the whole product of an *Elm* in ſeeds, according to this computation, this ſum muſt be multiplied by a hundred, the number of years of the duration of the tree. Thus the ſmalleſt amount will be thirty-three millions of ſeeds, produced by an *Elm* originally raiſed from one ſingle ſeed. Hiſt. Acad. Par. 1700.

This, however, is no more than the natural produce of the tree, in its wild ſtate; we all know very well, that proper management will make trees yield abundantly more fruit than they naturally would. Thus, if this *Elm*, at a proper ſtage of its growth, had been lopped off at the head, it would have puſhed out infinitely more numerous branches; and a ſet of theſe would have appeared in a circle round the trunk, at about half an inch from the place where it was cut off, and this would have been the caſe in whatever part, or at whatever height, it had been cut. All the trunk of the tree, from the ground up to the beginning of the natural eruption of the branches, being then full of theſe rudiments of branches, placed in circles, and ſeparated by circular ſpaces of about half an inch deep, compoſe ſo many circles of branches, or rudiments of branches, as there are half inches in meaſure from the ground up to the firſt natural rudiments; all theſe rudiments are formed, therefore, all ready to appear in form of compleat branches, and all contain, in miniature, their proportion of ſeeds, and any circle of them may be made to ſhoot out and appear, by only cutting off the trunk juſt above them; theſe are all, therefore, to be allowed really to exiſt, and all to be brought into the account of the providence of nature, in the fecundity of the tree, as all are formed and provided for it. There are therefore evidently contained, in this *Elm*, ſo many times thirty-three millions of ſeeds, as there are half inches in twenty foot, which was its meaſure from the ground to the firſt branches: That is to ſay, this tree contains actually in itſelf 15840000000 rudiments of ſeeds, or has ſo many bodies incloſed in itſelf, by each, or any one of which, it is capable of multiplying its ſpecies, and is capable of producing ſo great and aſtoniſhing a number of trees. The imagination is ſtartled at being conducted to ſo amazing a ſcene by reaſon.

What are we to think then of the immenſity of the works of the great creator of the univerſe, when we conſider that every one of theſe ſeeds contains in itſelf a tree, loaded with an equal number of ſeeds, and each of thoſe another tree, loaded in the ſame manner, and ſo on beyond the utmoſt extent of our capacity; and that conſequently here is a geometrical proportion, or progreſſion of increaſe, the firſt term of which is 1, the ſecond 15840000000, the third the ſquare of that number, the fourth the cube, and ſo on to infinity. Reaſon and imagination are loſt together in the immenſity of ſuch a calculation. Mem. Acad. Par. 1700.

All this is deduced from principles, every one, by the modeſt calculations of the author, reckoned much to low; but all that could be ſaid of this tree, muſt, in regard to the laſt calculation, fall infinitely ſhort of a calculation made from fern, a plant greatly more prolific in ſeeds than this tree.

ELM, among gardeners, &c.—All the ſpecies of the *Elm* may be propagated either by layers, or by ſuckers taken from the old roots; but as theſe are often taken up with very bad roots, and are therefore very ſubject to miſcarry, the method by layers is much the beſt, and is very eaſy to be practiſed, as a ſmall ſpace of ground would be ſufficient to furniſh nouriſhment for a number of ſtools, or roots for laying, which would annually yield a great number. The beſt ſoil for a nurſery of this kind, is a moderately light and dry hazel loam, and the beſt ſeaſon for laying the branches is autumn. When they have taken root, they ſhould be removed from the old plant, and ſet in rows in nurſery beds, where, after four or five years, they will be ſtrong enough to be tranſplanted into the places where they are to remain. In the planting them, great care is to be taken not to bury their roots too deep, which, when the ſoil is moiſt and ſtiff, often deſtroys them. The common *Elm* ſeldom produces ſeeds in great perfection, but the witch *Elm* produces great quantities of good ones, from which ſome people raiſe nurſeries of the trees. *Miller*'s Gardeners Dict. See ULMUS.

ELMOROSIA, a name given by the Moors to a diſh they are very fond of. It is made of pieces of beef, or of camel's fleſh, ſtewed with butter, honey, and water; ſome add rob of wine to it, and others garlick; but there is always added onions, ſaffron, and ſalt. Philoſ. Tranſ. N°. 253.

ELOANX, a name given by ſome writers to *auripigmentum*, or orpiment.

ELODES, in botany, an epithet given to a very ſoft and woolly ſort of St. John's wort, or *hypericum*.

ELODES is alſo uſed, among the antient writers in medicine, for a ſpecies of fever, attended with profuſe ſweats.

ELOHA, in ſcripture, the ſingular of *Elohi*, one of the names of God. See ELOHI.

ELOHI, ELOI, or ELOHIM, in ſcripture, one of the names of God. But it is to be obſerved, that angels, princes, great men, judges, and even falſe gods, are ſometimes called by this name. The ſequel of the diſcourſe, is what aſſiſts us in judging rightly concerning the true meaning of this word. It is the ſame as *Eloha*. One is the ſingular, the other the plural. Nevertheleſs *Elohim* is often conſtrued in the ſingular number, particularly when the true God is ſpoken of; but when falſe Gods are ſpoken of, it is conſtrued rather in the plural. *Calmet*. Diction. Bibl.

ELOI. See ELOHI.

ELOINE, in our laws, ſignifies to remove, or ſend a great way off. Thus it is ſaid, if ſuch as be within age be *eloined*, ſo that they cannot come to ſue perſonally, their next friends ſhall be admitted to ſue for them. Stat. 13 *Edw.* 1. cap. 15.

ELOME, a name given by ſome authors to orpiment. See AURIPIGMENTUM.

ELONGATA, in law, is a return of the ſheriff, that cattle are not to be found, or removed, ſo that he cannot make deliverance in replevin.

ELOPITINUM, a name given by ſome of the old chemiſts to vitriol.

ELOPS, Ἔλοψ, in zoology, the name of a ſerpent, otherwiſe called *Elaps*. See ELAPS.

ELOPS was alſo the name of a fiſh much eſteemed among the Greeks, and thought to be the ſame with the *Accipenſer*. *Hofm.* Lex. in voc. See ACCIPENSER.

ELOSSITES, in natural hiſtory, the name of a ſtone, mentioned with great reſpect by the writers of the middle ages; they have left us, however, ſo ſhort a deſcription of it, that it is impoſſible to determine what it was; they only ſay, that it was no very beautiful ſtone, but that, if worn in the pocket, it had a wonderful virtue in curing pains, and all other diſeaſes in the head.

ELPIS, a name given, by ſome of the chemical writers, to the ſcoriæ of ſilver.

ELPISTICI, Ελπιστικοι, among the Greeks, a ſect of philoſophers who made hope the ruling paſſion of mankind. *Hofm.* Lex. in voc.

ELTHYMUM, in the materia medica of the antients, a name given to the epithymum, or dodder, growing upon thyme. *Aviſenna*.

ELVELA, in botany, a name given by Linnæus to a genus of fungus's called, by Micheli, fungoidaſter, and fungoides. Theſe differ from all the other kinds of fungus's, in that they are ſmooth both on the upper and under ſide, having no marks of lamellæ, pores, or fibres, in any part.

ELVERS, an Engliſh name for a ſmall ſort of eels, caught in ſome parts of the kingdom, particularly about Glouceſter and Tewkſbury. Theſe are, in reality, young congers, or ſea eels. They get up into rivers while very ſmall. They are taken in prodigious numbers in the rivers, in dark nights, and are eſteemed a very delicate food. *Willughby*'s Hiſt. Piſ. p. 112.

ELUL, one of the Hebrew months, anſwering pretty near to our Auguſt. There are but nine and twenty days in it. It is the twelfth month of the civil year, and the ſixth of the eccleſiaſtical. Upon the ſeventh or ninth day of this month the Jews faſt, in memory of what happened after the return of thoſe who went to view the promiſed land. Numbers xiii, xiv.

Upon the twenty ſecond of this month the feſtival of the *xylophori* was obſerved, when wood was carried to the temple. Selden ſays, that it was celebrated on the eighteenth day of the month *ab*. On the twenty-ſixth of the ſame month, the dedication of the walls of Jeruſalem by Nehemiah was commemorated. *Joſeph*. l. 2. c. 17. p. 811. Nehem. xii. 27, *&c*. *Calmet*, Diction. Bibl.

ELUTRIATION, in metallurgy, is the ſeparating the lighter matters from the mixt ores of metals, by means of great quantities of fair water. Solid bodies, not diſſoluble in water, are by this operation ſeparated from each other by water very well ſtirred, ſo that the lighter and the finer parts are carried away with the water, and the heavier and more ſolid remain at the bottom of the veſſels.

Some of the ſtones, earths, and other bodies naturally mixed with the ores of metals, are much lighter than the metalline parts of thoſe ores, and are therefore very eaſily thus ſeparated from the reſt by this operation, either by barely pounding and waſhing them, or by firſt calcining them, and then extinguiſhing them in water, and afterwards waſhing them.

The kinds of ores proper to be made the ſubjects of this operation, are known from the great ſpecific gravity of the ore, which ſhews us that the metallic maſſes, adhering to their matrix, are firm and ſolid, and combined in large molecules, not ſmall, and ſcattered and diſperſed ſparingly through it; they are known alſo by the comparative lightneſs and brittleneſs of their ſtony matrix. Whether this laſt property be naturally inherent in the ſtony matter, or whether it be eaſily brought on by fire in calcination, for in each caſe it renders the comminution of the compound maſs eaſy. In this caſe, however, it is proper that the ore itſelf be of a nature ſufficiently fixed afterwards in the fire, and do not fly away in the roaſting.

When ſtones, containing ore in them, are light, and brittle, but hold a great quantity of ſulphur, and are interſperſed only with very minute maſſes of the metalline particles, or when theſe are incloſed in a very ponderous and hard matrix, not eaſily affected by fire, this method of ſeparation has no place. *Cramer*. Art. Aſſ. 195.

ELYCRYSUM, in botany, the name of a large genus of plants, the characters of which are theſe: The flower is of the floſculous kind, being compoſed of ſeveral ſmall floſcules, divided into ſegments, arranged in a ſtellated form at the ends; theſe ſtand on the embryo fruit, and are contained in a common ſcaly huſk or cup, which is of a very gloſſy and ſplendid appearance, and of a gold or ſilver colour, or of ſome other gaudy tinge. The embryos finally ripen into ſeeds, winged with down.

The ſpecies of *Elycryſum*, enumerated by Mr. Tournefort, are theſe: 1. The *Elycryſum*, called narrow-leaved citrine ſtæchas. 2. The *Elycryſum*, or citrine ſtæchas, with extreamly narrow leaves. 3. The *Elycryſum*, with a few oblong leaves, narrower than thoſe of the common citrine ſtæchas. 4. The Spaniſh ſea umbellated *Elycryſum*. 5. The Sicilian *Elycryſum*, with rough trifid leaves. 6. The Sicilian *Elycryſum*, with ſingle flowers, and leaves green on each ſide. 7. The broad-leav'd wild *Elycryſum*, with ſingle flowers. 8. The broad-leav'd wild *Elycryſum*, with larger ſingle flowers. 9. The broad-leav'd wild *Elycryſum*, with conglobated heads. 10. The ſmall branched water *Elycryſum*, with foliated heads. 11. The ſpiked *Elycryſum*, called the long-leav'd, or Engliſh upright cudweed. 12. The mountain *Elycryſum*, with round purpliſh flowers, called the mountain cudweed, or cat's-foot. 13. The mountain *Elycryſum*, with a round white flower. 14. The mountain *Elycryſum*, with a round bright red flower. 15. The mountain *Elycryſum*, with a round variegated flower. 16. The mountain *Elycryſum*, with long leaves, and purple flowers. 17. The mountain *Elycryſum*, with long leaves, and white flowers. 18. The oriental *Elycryſum*. 19. The broad-leav'd *Elycryſum*, called the broad-leav'd citrine ſtæchas. 20. The German *Elycryſum*, with a reddiſh yellow cup. 21. The German *Elycryſum*, with blood-red cups. 22. The wild narrow-leav'd *Elycryſum*, with conglobated heads. 23. The broad-leav'd American *Elycryſum*. 24. The long-leav'd erect *Elycryſum*, with conglobated heads. 25. The American *Elycryſum*, with a woolly and undulated leaf, like the roſe campion. 26. The American tree *Elycryſum*, with the ilex leaf. 27. The broad-leav'd woolly African *Elycryſum*, with a very large ſilvery cup to the flower. 28. The coris-leav'd ſhrubby African *Elycryſum*. 29. The roundiſh-leav'd hoary and woolly African *Elycryſum*. 30 The yellow-flowered ſweet-ſcented umbellated African *Elycryſum*. 31. The poley-leav'd yellow African *Elycryſum*. 32. The red-flowered narrow-leav'd hoary and woolly African *Elycryſum*. 33. The roſemary-leav'd African tree *Elycryſum*. 34. The plantain-leav'd African *Elycryſum*. 35. The very large-leav'd ſtinking African *Elycryſum*. 36. The dwarf *Elycryſum*. 37. The dwarf alpine *Elycryſum*, with capillaceous leaves. *Tourn*. Inſt. p. 452, 453.

ELYTRON, properly a covering of any ſort, and for any ſubſtance. Hippocrates has appropriated the word to ſignify the membranes which involve the ſpinal marrow.

ELZIMAR, a name given, by ſome of the chemical writers, to the flowers of braſs.

EMARGINATED *Leaf*, among botaniſts. See LEAF.

EMBALMING (*Cycl.*)—The way of *Embalming* dead bodies among the Egyptians was a follows: When a man died, his body was carried to the artificers, whoſe trade it was to make coffins; they took the meaſure of the body, and made a coffin for it, proportioned to its ſtature, the dead perſons quality, and the price that people were willing to give, for there was a great diverſity in the prices. The upper part of the coffin repreſented the perſon who was to be ſhut up in it, whether man or woman. If it was a man of condition, this was diſtinguiſhed by the figure which was repreſented on the cover of the coffin; there were generally added paintings and embelliſhments, ſuitable to the quality of the perſon. Vid. *Caſſian*. Collat. 15. c. 3. & *Cicero*, Tuſc. Quæſt. l. 1. *Herodot*. l. 2. c. 86. *Diodor*. l. 2. c. 5.

When the body was brought home again, they agreed with the embalmers, at what rate particularly they would have it *embalmed*, for the prices were different; the higheſt was a talent, twenty minæ was a moderate one, and the loweſt price was a very ſmall matter. The Egyptian talent is ſuppoſed to be worth three hundred pounds ſterling. They immediately ſent for a deſigner, who marked the body, as it lay extended, at the place where it ſhould be opened, on the left ſide, and the length of the inciſion. A diſſector, with a very ſharp Ethiopian ſtone, made the inciſion, and hurried away as faſt as he could, becauſe the relations of the perſon deceaſed, who were preſent, took up ſtones, and purſued him as a wicked wretch, with an intention to ſtone him.

This operation being finiſhed, the *Embalmers*, who were looked upon as ſacred perſons, entred to perform their office. They drew all the brains of the dead perſon through his noſtrils, with a hooked piece of iron, provided particularly for this purpoſe, and filled the ſkull with aſtringent drugs; they likewiſe drew all the bowels, except the heart and kidneys, through the aperture which they had made in the ſide. The inteſtines were waſhed in wine from the palm tree, and in other ſtrong and binding drugs. The whole body was anointed with oil of cedar, with myrrh, cinnamon, and other ſpices, for about thirty days, ſo that it was preſerved entire, not only without putrefaction, but had a good ſcent with it. Αιγυπτιοι δε τα εϋοδμα εξελοντες ταριχευσιν αϋλες. And the *Perſians*, as the ſame author *Sextus Empiricus* obſerves, were uſed νίτρῳ ταριχευειν. Sext. Empir. Pyrrhon. Hypoth. l. 2. c. 24. Bodies thus preſerved are called *Mummies*, from the *Arabic* word *Mam*, which ſignifies wax, this being an ingredient in the preparation.

After this the body was put into ſalt for about forty days: Where-

Wherefore when Moſes ſays, that forty days were employed in embalming Jacob, we are to underſtand him as meaning the forty days of his continuing in the ſalt of nitre, without including the thirty days paſt in performing the other ceremonies above mentioned, ſo that, in the whole, they mourned ſeventy days in Egypt, as Moſes likewiſe obſerves.

Afterwards the body was taken out of the ſalt, waſhed, wrapt up in linnen ſwadling bands, dipped in myrrh, and rubbed with a certain gum, which the Egyptians uſed inſtead of glue. Then the body was reſtored to the relations, who put it in a coffin, and kept it in their houſes, or in tombs made particularly for this purpoſe. There are ſome found, at this day, in Egypt, in chambers, or ſubterraneous vaults, which fully juſtify the truth of what is here ſaid.

They who were not rich enough to bear this expence, contented themſelves with infuſing, by a ſyringe, through the fundament, a certain liquor extracted from the cedar, and leaving it there, wrapt up the body in ſalt of nitre. This oil preyed upon the inteſtines, ſo that when they took it out, the inteſtines came along with it dried, and not in the leaſt putrefied. The body being incloſed in nitre, grew dry, and nothing remained beſides the ſkin glued upon the bones. They who were too poor to be at any conſiderable expence, did no more than cleanſe the inſide, by ſyringing a liquor into it; this done, they put the body, without further ceremony, into nitre for ſeventy days, in order to dry it. *Calmet.* Diction. Bibl.

It is no wonder that we find human bodies preſerved without corrupting for many ages, by means of ſpices, and other ingredients, proper to reſiſt putrefaction, applied with the niceſt care; but it is ſtrange that there ſhould be a ſort of *embalming* performed by nature, in ſome places, where bodies are preſerved merely by the virtues of the ſoil in which they lie, yet this is evidently the caſe in ſome inſtances. We have, in the philoſophical tranſactions, an account of a man and a woman who were loſt in the great ſnows on the moors of Hope, near the woodlands in Derbyſhire, on the fourteenth of January, 1674. Theſe perſons were not found till the third of the May following, at which time they ſmelt ſo ſtrong, that the coroner prudently ordered them to be buried on the ſpot. Theſe bodies lay buried in the peat moſs twenty-eight years before they were looked at again, when ſome people of the country, who had heard of the ſtrange virtues of the ſoil thereabouts in preſerving dead bodies, opened the ground, and found them no way altered, the colour of the ſkin being fair and natural, and the fleſh as ſoft as that of perſons newly dead. Phil. Tranſ. N°. 434. p. 415.

After this the place was remarked where they lay, and they were ſhewn for a ſight for twenty years, though they were much changed by having been ſo often uncovered in that time; and in the year 1716 they were found in the following condition: The body of the man was perfect, his beard was ſtrong, and about a quarter of an inch long; the hair of his head was ſhort. The ſkin of all parts was hard and tough, and of the colour of tanned leather, or of the wet in which it lay. He had on a broad cloth coat, which was as ſound and ſtrong as ever. The body of the woman had been taken out of the ground, and was much decayed, one leg was off, and the fleſh of it in a bad condition, but the bone was ſound, and the fleſh of one hand was decayed, but the bone alſo ſound, and, on her face, her upper lip and the tip of her noſe was decayed, but all the reſt ſound; her hair was long and ſpringy, like that of a living perſon. One of the teeth being at that time taken out of her mouth, was as elaſtic as a piece of ſteel, and would bend round the finger, but immediately recover its ſtrait ſhape again; but this quality it ſoon loſt when out of the ground. After this they were buried in Hope church, where, after a few years, they were found wholly conſumed.

In their firſt grave they lay at about a yard deep, and the ſoil was wet, but no water ſtood in the place. When the ſtockings were drawn off, the man's legs, which had never before been uncovered, were very fair; the fleſh, when preſſed with the finger, pitted a little, and the joints were moveable, without any ſtiffneſs, the other parts were much decayed. The people, at one time or other, had cut off and carried away the greateſt part of their cloaths as curioſities, but what was left was firm and good.

EMBASIS, in the writings of the antient phyſicians, the name of a large veſſel, in which they prepared their medicated baths, and which was capable of holding the perſon to be bathed at his full length.

EMBATTLED *Line*, (*Cycl.*) in heraldry, a term uſed to expreſs one of the common lines in coats of arms, repreſenting the battlements of a houſe, and ſaid to have been originally given to the families on three very different accounts. Some having obtained it for eminent ſervices, in attacking or defending the battlements of a caſtle, or other place of defence, in time of war; others for their eminence in the ſkill of architecture, and others only for being deſcended of antient and honourable houſes, none being ſuffered, in antient times, to imbattle their houſes, but thoſe who had great dignities, as the barons, and the like. Cambden proves this in his account of Tunſtall's ſeat in England, in which he expreſſes it as a ſignal mark of the royal favour, that he had liberty given to embattle it.

The heralds expreſs this embattled line by the term *crenelle*; and when it has the embattling on both ſides, which is the more rare, they then call it *bretеſſe*. *Neſbet*'s Heraldry. See BRETESSE.

EMBER (*Cycl.*)—EMBER-*Gooſe*, in natural hiſtory, a ſpecies of the wild gooſe, found in Zetland, that is ſaid to hatch her young under her wing. This is certain, that none ever ſaw her on the land, or out of the water, and that they have a cavity under one of their wings capable of containing a large egg. Phil. Tranſ. N°. 473. §. 8.

EMBERIZA, in zoology, a name, with the epithets of white and yellow, expreſſing the bunting and yellow-hammer. See BUNTING and YELLOW-HAMMAR.

EMBLEM (*Cycl.*)—According to Lord Bacon, *Emblems* are of uſe in the art of memory, as ſenſible objects ſtrike the mind ſtronger than what is intellectual. Thus, it is eaſier to retain the image of a ſportſman hunting a hare, of an apothecary ranging his boxes, an orator making a ſpeech, a boy repeating verſes, or a player acting his part; than the correſponding notions of invention, diſpoſition, elocution, memory, and action. Works abr. Vol. 1. p. 136. and Vol. 2. p. 475. Vol. 3. p. 106.

EMBRACE *a Volt*, in the manege, is uſed when a horſe, in working upon volts, makes a good way every time with his fore legs. The oppoſite term to embracing a volt, is beating the duſt, which is putting his fore feet near the place from whence he lifted them.

Embracing the ground is uſed in the ſame ſenſe with embracing the *Volt*. A horſe cannot take in too much ground, provided his croupe does not throw out; that is, does not go out of the *Volt*. See BEAT.

EMBRACERY, in law, the act or offence of embraceors. See EMBRACEOR, *Cycl.*

EMBRYO (*Cycl.*)—EMBRYO *Worms*. It is a matter of no ſmall curioſity, to obſerve the arrangement of the multitudes of the *embryo* worms, as they are lodged in the bodies of the viviparous two-winged flies.

An accurate diſſection of one of theſe little animals, ſhews very plainly the parts where the *embryo* worms are encloſed. This diſſection is eaſily made with a pair of fine pointed ſciſſars, taking off the whole upper ſhell of the body from the lower; and that part which covers the belly may be turned back upon the corcelet, without the internal parts being at all diſturbed by the operation, and the form and arrangement of the parts which contain the *embryo* worms in theſe, will be found very different from that of thoſe which contain the eggs in the common flies. In thoſe we find the eggs contained, as it were, in two bladders, and placed in two great parcels, one on the right ſide, and the other on the left; but, in the viviparous fly, nothing analogous to this is found; but the thing that moſt attracts the obſerver's eye is a ſort of band, or cord, which follows the whole circumference of the body, except that at the junction of the corcelet it leaves a little ſpace for the pulmonary veſſels. Examining more cloſely, one ſoon finds alſo that this circular band is not ſingle, but that it has ſeveral other convolutions within it, and is rolled in a ſpiral from the center of the body to the extremity of either ſide, and that it encircles a ſmall ſpace there, and afterwards makes five circles before it terminates.

What the ovarys are to the oviparous flies, that is this band to the viviparous, it is, in ſhort, the part where the *embryo* worms are encloſed, and is properly the womb of the inſect. Notwithſtanding that this appears no other than a cord, or band, as one views it in the body of the creature, the taking it out ſhews it to be a ſort of flat veſſel, but of ſome thickneſs, wound round like the ſpring of a watch, and containing, at different diſtances, a vaſt number of the *embryo* worms. This veſſel, drawn out and extended, often meaſures more than two inches in length, which is very conſiderable, in proportion to the length of the body of the fly, which is not more than about four lines. Ibid. p. 416.

Notwithſtanding the extream ſmallneſs of the worms contained in this part, they are very eaſily diſtinguiſhable from eggs, and cannot, by a nice obſerver, be taken for any other than *embryo* worms; the microſcope alſo puts this beyond all poſſibility of diſpute, ſince, in thoſe which are the moſt forward, and neareſt the time of their being depoſited from the body of the creature, one plainly diſcovers the rings of the body, and even the hooks with which almoſt all the fly-worms of the firſt claſs are armed at tne mouth. Ibid. p. 417.

One cannot, without amazement, conſider the number of *Embryos* contained within the body of one fly, of any one of theſe ſpecies; and yet another more ſtrange thing than this is, that notwithſtanding all this fecundity of the parent fly of this ſpecies, the flies of it are much more rare than thoſe of the cow-dung worm, in the parent fly of which are ſeldom found more than two large eggs: But the whole reaſon of this muſt be, that theſe worms of the viviparous flies are the deſtined food of ſome other creature, from which very few of them eſcape. Ibid.

Notwithſtanding that the uterus of theſe flies contains ſuch immenſe numbers of worms, and thoſe ſo cloſely arranged, yet each ſeparate *Embryo*, while there, has its diſtinct and peculiar ſkin, or film, in which it is encloſed.

Tho' the flies of the viviparous kind, hitherto mentioned, are all of a larger ſort, there are not wanting, even among the moſt minute ones, ſome of this kind. The common heaps of cowdung afford us myriads of extreamly ſmall worms, which, after a proper time, in that form, paſs into the nymph ſtate under a ſhell of their own ſkin, and thence into flies much ſmaller than the head of a pin, yet theſe the microſcope ſhews to be viviparous. Ibid. p. 428.

Nor are we to imagine theſe the ſmalleſt of this kind. To the great creator of all theſe, large and ſmall are the ſame; and as the microſcope has of late ages diſcovered to us millions of animals in liquors where we never ſhould have imagined we ſhould have found them, it is much more than poſſible, that multitudes of theſe, after having paſſed that part of their life we are acquainted with, under the form of water worms, may afterward become flies too minute for our obſervation; flies, to which the ſmalleſt of thoſe we know may be of an enormous magnitude, and that of theſe many may be viviparous. Ibid. p. 430.

EMBRYONATUM *Sulphur*, in the writings of ſome chemiſts, the name of one of the three general claſſes of *Sulphur* which they conſtitute. The firſt of theſe they call the univerſal *Sulphur*, or reſin of the earth; this is never united with any thing: By this they ſeem to mean what Boerhaave, and other late chemiſts, have called the vague acid. The ſecond is this ſame ſulphur united to metals and minerals; and the third is the ſame *Sulphur*, when ſeparated by art from theſe metals and minerals. This laſt ſeems ſulphur in its moſt advanced ſtate, and the ſecond kind is what they call the *Sulphur Embryonatum*, as it is in the metals, *&c.* in an embryo ſtate, and ready to be diſcloſed into its laſt form.

EMBRYULCUS, in ſurgery, the name of an inſtrument, in form of a ſort of crotchet, or hook, uſed for drawing out the fœtus in difficult labours.

EMERALD (*Cycl.*)—See SMARAGDUS.

Counterfeit EMERALD. The manner of making *counterfeit Emeralds* in paſte is this: Take cryſtal prepared two ounces, common minium, or red lead, four ounces; mix theſe well together, then add of good verdigreaſe two pennyweights, and crocus martis made with vinegar, eight grains. Mix all theſe well together, and ſet the whole in the hotteſt part of a potter's furnace. As long as the fire laſts it muſt be put into a ſtrong crucible, and covered with a lute. When it is cold take off the lute, and, if it is baked enough, it will be clear to the bottom; otherwiſe relute the pot, and put it into the furnace again. Twenty-four hours commonly is ſufficient for the making this; ſometimes it requires a little more. The paſte, thus made, is harder than ordinary, and is of a fine colour, and capable of a good poliſh. *Neri*'s Art of Glaſs, p. 128.

If the paſte be deſired of a very deep *emerald* colour, take prepared cryſtal one ounce; red lead, ſix ounces and a half; of verdigreaſe, three pennyweight and thirteen grains; and of crocus martis, made with vinegar, ten grains. This requires a longer baking than the other, and is leſs hard, though of a deeper colour. *Neri*, p. 129.

The proportions of theſe Ingredients may be varied at pleaſure, and the colour be made of all degrees of deepneſs; but the more lead is added, the more baking is required, and, after all, the paſte will be ſo much the ſofter.

EMERALD *Colour*, in the glaſs trade, the way of giving this beautiful dye to glaſs is this: In the pots of melted metal, made of palverine, and without manganeſe, when the matter is well purified, put a little crocus martis calcined with vinegar. About three ounces of this crocus is enough for a hundred weight of glaſs, let it ſtand till thoroughly mixed, then put into every hundred weight of metal two pound of calcin'd braſs; this muſt be added at ſix different times, letting the metal ſtand two hours every time. When this is all in, make a proof of the metal, and if it have any bluiſhneſs, add more crocus martis, a ſmall quantity at a time. When the whole is of a fine leek green, let it ſtand twenty-four hours to mix thoroughly, and then work it. *Neri*'s Art of Glaſs, p. 51.

EMERUS, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the papilionaceous kind, and the piſtil, which ariſes from the cup, becomes finally a ſlender pod, uſually containing cylindric ſeeds.

The ſpecies of *Emerus*, enumerated by Mr. Tournefort, are theſe: 1. The great podded ſcorpioide *Emerus*. 2. The low dwarf ſcorpioide *Emerus*. 3. The American *Emerus*, with crooked pods. *Tourn.* Inſt. p. 650.

EMERY, *Smiris*, (*Cycl.*) in natural hiſtory, medicine, *&c.* a kind of iron ore, diſtinguiſhed from all the others by its peculiar hardneſs. It cuts glaſs like a diamond; but makes no efferveſcence with any of the acid menſtrua.

Emery is ſaid to have a corroding and almoſt cauſtic quality; but this without any juſt foundation. It is recommended by the antients as an aſtringent and dentrifice. In this laſt intention, however, it muſt be uſed with great caution, as its hardneſs and ſharpneſs are ſuch, that it will be apt to wear off the enamel of the teeth. *Hill*, Hiſt. Mat. Med. p. 10. See SMIRIS.

EMETIC (*Cycl.*)—The antient phyſicians were very fond of *Emetics*, as preſervatives againſt diſeaſes, and Hippocrates, in particular, has recommended the giving them twice a month, during winter and in the ſpring. His *Emetics* were very eaſy, ſimple, and gentle ones. One very common preſcription, to this purpoſe, was a decoction of hyſſop, with an addition of ſo much vinegar and ſalt as would make the patient nauſeate it. This was to be taken by ſtrong and robuſt people, in the morning faſting, and, by the more weakly, after dinner or ſupper. Diodorus Siculus has aſſured us, that the great practice of the antient Egyptian phyſicians conſiſted in glyſters, vomits, and abſtinence. Aſclepiades, who was a great enemy to purges, yet often ordered his patients gentle vomits after ſupper.

The *emetic* medicines are of two very different kinds, ſome being naturally mild and gentle, others harſh and rough; of the former kind, warm water with butter, or the water of the naturally warm mineral ſprings, are often capable of doing very great ſervice. The medicine of the general uſe at preſent, ipecacuanha, ſeems of a happy middle nature between theſe, and the more rough ones, of which the vegetable kingdom afford us a great number, as aſarabacca, white hellebore, gamboge, and all the purges in too large doſes. The mineral world, however, affords much more numerous and more violent ones; ſuch are all the preparations of copper, and of the vitriols, the antimonial vomits, and the mercurial ones.

The antients, in violent diſeaſes, ſuch as madneſs, epilepſies, and ſome other diſorders, not attended with a fever, gave the white hellebore root as an *Emetic*, with great ſucceſs; but we now uſe remedies leſs dangerous, as death has been ſometimes known to have been the effect of this medicine. Our ipecacuanha is a celebrated remedy for fluxes, nor is the obſervation new, that vomits are the greateſt of all remedies in theſe caſes. Celſus, l. 1. c. 3. affirms, that vomits in general ſtop fluxes, yet always keep the body open. The country people, with us, frequently uſe aſarabacca as a ſuccedaneum, for the ipecacuanha. It is rougher, indeed, than that medicine, but, if taken in decoction, the boiling carries off its acrid and too pungent quality, and it retains its *emetic* power in a more gentle degree, and, with it, has a balſamic and corroborating virtue, and has been known to cure inveterate quartans, and to do great ſervice in jaundices and dropſies.

Among the antimonial vomits, the beſt is the *emetic* tartar, prepared from the crocus metallorum, not from the glaſs of antimony, for that makes it doubly rough and harſh in the working. Three or four grains of this alone, or yet leſs of it, mixed with ipecacuanha, are often given with great ſucceſs, and when the intention is to purge and vomit at the ſame time, then three grains of this *emetic* tartar, added to a ſolution of manna, prove an excellent medicine. In aſthmatic and pituitous caſes, the oxymel of ſquills is a very efficacious and perfectly ſafe medicine; but all the preparations of copper, and the rougher antimonial vomits, are to be rejected as being very dangerous and very uncertain, working either too little, or greatly too much, according to the ſtate of the humours in the ſtomach. The ſtronger *Emetics* beforementioned, as ſafe ones, are often neceſſary in caſes of poiſons, eſpecially of the narcotic kind, and the infectious particles received from the effluvia of perſons in contagious diſeaſes, which being ſwallowed into the ſtomach with the ſpittle, would otherwiſe infallibly create the ſame diſeaſe. In diſorders ariſing from a vitiated or thick bile, formed, as it were, into a kind of viſcid coagulum, and ſtopping up the biliary ducts, as is the caſe in jaundices, and ſome other complaints, *Emetics* are frequently uſed with great ſucceſs, after all the common methods have failed. In anaſarcas alſo, and leucophlegmaſies, and œdematous ſwellings of the parts, and in a curable aſcites, *Emetics*, exhibited in large doſes, uſually carry off by ſtool, though rarely by vomit, the aqueous ſerum from the liver, and the ducts and glands of the inteſtines, meſentery, and pancreas; nor are theſe the only caſes in which *Emetics*, properly adminiſter'd, are capable of doing very ſingular ſervice; but there ſtill requires great care and caution in the giving them, as it is an infallible rule, that the medicine which can do great good, may alſo do great harm. *Hoffm.* Medic. Rational Syſtem.

'Tis proper, in order to make *Emetics* work the more eaſily, always to give them in a liquid form, or in a ſufficient quantity of ſome moiſtening, relaxing, and fatty vehicle; for vomiting not only requires a ſtrong contraction of the pylorus, and bottom of the ſtomach, but alſo a relaxation of the ſuperior orifice of the æſophagus. During the operation of *Emetics*, and after it is over, the patient muſt be carefully guarded againſt the cold, and to abſtain from all cold liquors, from all hot or ſtimulating medicines, and from all violent emotions of the mind: And about four hours after the operation of a vomit is over, it is extreamly proper to drink half a pint of aſſes milk, if it can be readily had.

Whenever bleeding and vomiting are both neceſſary, bleeding ſhould always be done firſt. Sydenham, who very judiciouſly gives this caution, had been long uſed to give vomits in febrile diſorders; and in the ſmall pox, his uſual *Emetic* was the vinum benedictum, and, according to his own account of the ſucceſs, it does not appear that our ſubſtituting the ipecacuanha in its place has been of any ſervice to the world in theſe caſes.

The antients in general have recommended the giving vomits in

in tertians and quartans, before the coming on of the fit; and Alexander Trallian has been very earneſt in the recommending them on this occaſion. The practice is highly conſonant with reaſon, and all the known rules, and may be of great advantage not only in theſe, but in many other caſes, in which it is not at preſent thought of.

Dr. Harris has obſerved of the antimonial vomits, that they are very ſafe in the heat of ſummer, but very dangerous in colder ſeaſons. This author alſo recommends a decoction of the herb digitalis, or fox-glove, as a very ſafe, though powerful *Emetic*; and there is an account of another plant, uſually eſteemed of the dangerous kind, that is, the common creeping meadow crowfoot, from which a very ſafe and efficacious *Emetic* is to be prepared, and has been adminiſtered in many parts of England with great ſucceſs. The method of preparing it is only by diſtilling, in the common way, a ſimple water from the plant; this is very acrid and pungent to the taſte, and requires to be lowered, either by drawing a very large quantity from a little of the herb, or elſe by mixing common water with it. The method of giving it is this: Let the patient drink about a quart of warm water, then give an ounce of this diſtilled water, and the whole will be immediately brought up with great eaſe; and the whole operation is then over for that doſe, and the water and medicine are again to be repeated as often as is judged neceſſary. *Harris*'s Diſſertation.

If vomits operate too violently, common ſalt is a well known remedy. This ſeldom fails to check or ſtop them. Mild aromatics and opiates alſo have the ſame effect, and corroborating medicines, either taken internally, or applied by way of cataplaſm, or embrocation, to the region of the ſtomach.

Dr. Shaw thinks the moſt ſafe, gentle, and agreeable *Emetic* yet known, is an infuſion of the ipecacuanha root in white wine, without heat. This is made by putting two drams of the root, in fine powder, into half a pint of white Liſbon wine, and, after ſtanding two days, adding a freſh quantity of wine to the remaining powder, when this is poured clear off. Theſe wines are to be mixed together, and given in a doſe ſuited to the ſtrength of the patient. This is greatly preferable to the vinum benedictum, *emetic* tartar, and all the medicines of a like kind, which are attended with danger and uncertainty in their operation; and while we have this, there is no reaſon why all the violent *Emetics* ſhould not be wholly diſcarded the practice of phyſic. *Shaw*'s Lectures, p. 221.

EMETIC *Wine*.—Small doſes of *emetic* wine have been recommended as deobſtruent and ſudorific in ſlow fevers, in many chronical diſeaſes, and eſpecially in an obſtinate rheumatiſm. See Medic. Eſſ. Edinb. Abr. Vol. 1. p. 170. and *Huxham*, Obſ. de Aere & Morb. epidem.

EMEU, in zoology, the common name of the caſſowary, a large bird of the oſtrich kind. See the article CASSOWARY.

EMIR *Hadge*, the name of a highly dignified office in the eaſtern nations. He is the prince of the pilgrims that go to Mecca; and is named yearly from Conſtantinople, tho' he is generally left two years in his office to make amends for his great expence in equipage in the firſt; and ſometimes, if he have capacity, and intereſt at the porte, he is continued ſix years, but rarely longer, for if they conduct the caravan ſeven years, the Grand Seignior preſents them with a collar of gold, and it is ſaid that their perſons, after this, become ſacred, and they cannot be publickly cut off. This officer has command over the eſtates that go to Mecca. The perquiſites of his office, beſide what he is allowed by the porte, conſiſt in having a tenth of the effects of all the pilgrims who die in the journey. *Pocock*'s Egypt. p. 165.

EMISSARIUM, in antiquity, a ſluice, or drain, to draw off the water uſed in watering gardens, fields, &c. *Pitiſc.* Lex. Ant. in voc.

EMITES, in natural hiſtory, the name uſed, by ſome authors, for the chermites, a beautiful ſpecies of white marble, of which the tomb of Darius, and many other of the great works of antiquity were made. It was valued for its fine poliſh.

EMMELIA, Ἐμμέλεια, in antiquity, a dance peculiar to tragedy, which had all that gravity and dignity that was ſuitable to the action then repreſenting, and was deſigned to inſpire the audience with ſentiments of compaſſion and benevolence for the unfortunate and oppreſſed, with indignation againſt the guilty, and with love for virtue, and abhorrence for vice.

The movements of ſuch a dance as this, muſt have been very ſolemn and majeſtic, and have bore a great affinity to the action of an orator; it was the only one, excepting the military dances, that had the approbation of Plato. Mem. Acad. Inſcript. Vol. 2. p. 160. See DANCE, *Cycl.*

EMMIELLURE, in the manege, a kind of compoſition of honey, and other ingredients, uſed for ſprains and ſhoulder-ſplaits of horſes. See CHARGE.

The word is French, derived from *miel*, honey, which is a part of the compoſition.

EMODIA, in medicine, a word uſed, by ſome authors, to expreſs a ſtupor of the teeth.

EMPATTEMENT, in fortification, a term uſed by ſome to denote the ſame with *talus*. See TALUS, *Cycl.*

EMPEROR, (*Cycl.*) among Hebrew grammarians, is an appellation given to a ſpecies of accents ſerving to terminate a ſenſe compleatly, and anſwers to our point. See ACCENT, *Cycl.*

EMPETRON, in botany, a name by which ſome authors, as Dodonæus, &c. have called the kali, or glaſswort. *Ger. Emac.* Ind 2. See KALI.

EMPETRUM, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the apetalous kind, conſiſting of a number of ſtamina; but theſe are barren, the fruit appearing in other parts of the ſame plants. Theſe reſemble berries, and contain two or three hard or cartilaginous ſeeds.

The ſpecies of *Empetrum*, enumerated by Mr. *Tournefort*, are theſe: 1. The black-fruited mountain *Empetrum*, called berry-bearing heath, and 2. The white-fruited Portugal *Empetrum*. *Tourn.* Inſt. p. 579.

EMPETRUM is alſo a name uſed, by ſome authors, for the *alypum*, commonly called *herb terrible*. *Chabræus*, p. 48.

EMPHRACTIC, (*Cycl.*) *Emphractica*, in medicine, a name applied to ſuch external remedies as, applied to any part of the body, adhere firmly, and ſtop the pores.

EMPHRAXIS, in medicine, an obſtruction in any part.

EMPHRUE, in botany, the name given, by the people of Guinea, to a ſpecies of tree, the leaves of which they boil in wine, and give, as a great reſtorative, in caſes of weakneſs and decay. Its leaves are exactly of the ſhape of thoſe of the common mulberry, but they are not indented at the edge. Petiver has thence called it arbor Guineenſis mori folio non crenato. Philoſ. Tranſ. N°. 232.

EMPHYSEMA, (*Cycl.*) in ſurgery, a name given to any flatulent tumour, but peculiarly appropriated, by ſome writers, to a ſoft tumour, ariſing from air contained in the cavities of the membrana celluloſa. Hippocrates uſes the word to expreſs an inflation of the belly, and in ſome parts of his writings, in a more general ſenſe, for any tumour.

EMPIS, in natural hiſtory, the name given, by authors, to a large ſpecies of gnat, found about rivers and ponds; it is diſtinguiſhed from all the other kinds, by a circle of white paſſing round the middle of its body.

EMPLASTRUM *Attrahens*, the drawing plaſter, a plaſter ordered, in the late London pharmacopœia, to ſupply the place of the melilot plaſter, in the dreſſing of bliſters. The college are ſatisfied that the herb is of no ſort of uſe in the compoſition, and that very groſs abuſes are practiſed to give the green colour to the plaſter; for which reaſon they have ordered the plaſter to be now made in this manner: Take yellow reſin, and yellow wax, of each three pound; tried mutton ſuet, one pound; melt all together, and ſtrain while it is hot. *Pemberton*'s Lond. Diſp. p. 351.

EMPLASTRUM *Commune*, a name given, in the new London pharmacopœia, to what has been long called diachylon plaſter. The apothecaries had been long uſed to make this by a ſhorter way than was preſcribed them, and the college has now authorized that method, ordering it to be made of only a gallon of oil of olives, and five pounds of litharge, boiled together with about a quart of water, to keep them from burning till they are perfectly mixed, and have the conſiſtence of a plaſter. *Pemberton*'s Lond. Diſp. p. 352.

EMPLASTRUM *ex Ammonicaco cum Mercurio*, a form of medicine, in the late London diſpenſatory, ordered to be prepared in the following manner:

Take gum ammoniacum ſtrained, a pound; quickſilver, three ounces; ſimple balſam of ſulphur, a dram. Rub the quickſilver with the balſam of ſulphur, till it no longer appear, then add, by degrees, the gum ammoniac melted, and almoſt cooled again, and make the whole into a plaſter. *Pemberton*'s Lond. Diſp. p. 351.

EMPLASTRUM *Roborans*, the ſtrengthening plaſter, a form preſcribed in the London diſpenſatory, and ordered to be made thus: Take of the common plaſter two pound, of frankincenſe half a pound, of dragon's blood three ounces; melt the plaſter, and then add to it the other ingredients in powder. *Pemberton*'s Lond. Diſp. p. 358.

EMPNEUMATOSIS, in medicine, a word uſed, by ſome writers, to ſignify an inflation of the ſtomach; but by others, in a more general ſenſe, for inflations of the womb, or of any other part.

EMPORIUM, in medicine, is often uſed for the common ſenſory in the brain. See BRAIN.

EMPRION, in the medical writings of the antients, a word uſed to denote a peculiar pulſe, in which the artery is felt to be diſtended in one part more than in another, at every ſtroke, and, by that means, is made to reſemble any ſerrated body, or the light teeth of a fine ſaw.

EMPTOR *Familiæ*, *Buyer of a Family*, in the Roman law, he who purchaſed the inheritance of a perſon, or the privilege of being appointed his heir by will.

This was done with the ceremony of ſcales and weights, before five witneſſes, with the uſe of a peculiar formula of words.

Such *buyer* differed from the heir, *hæres*, as the teſtator, in ſome meaſure, alienated the right to the former, during his own life-time; whereas the latter had only a right by his death. *Briſſon.* de Formul. l. 7. p. 585. *Pitiſc.* Lex. Ant. T. 1. p. 713. voc. *Emptor*.

EMPTOR *Fiduciarius*, *Fiduciary Buyer*, he who receives a thing, in the way of pledge, till the money he has advanced

be repaid. *Salmaſ.* de Mod. Uſur. c. 14. *Pitiſc.* Lex. Ant. T. 1. p. 713. voc. *Emptor.*

EMPUSA, Εμπουσα, among the antients, a kind of hobgoblin, or bugbear, under the direction of Hecate, who uſed to ſend it to frighten people who laboured under misfortunes. *Hofm.* Lex. in voc.

ENAMEL (*Cycl.*)—The workers in *Enamel* muſt be very cautious of the good or bad qualities of the oil of ſpike they employ to mix their colours with. It is a thing very ſubject to adulterations. Sometimes with ſpirit of wine; ſometimes with oil of turpentine. In the firſt caſe it wants body, as there is uſually too much ſpirit added; and, in the latter, the ſmoak of the turpentine, when heated, ſpoils the colours. A ſmall mixture of ſpirit of wine does well; and the beſt method, for the nice artificer, is to refine the oil, and afterwards add to it ſuch a quantity of ſpirit as is found beſt.

The common matter, which is the baſis of all *Enamels*, is thus made: Take fine lead, thirty pound; fine tin, thirty-three pound; calcine theſe together in a kiln, then ſift them; boil this powder in water, in clean earthen veſſels, and pour off the water, which will carry with it the finer part of the calx; put freſh water on the remainder, boil it again, and pour off in the ſame manner; do this ſo long as the water will carry off any part of the calx. Recalcine the remaining matter, and waſh off its finer part in the ſame manner again, then evaporate all the waters, which have waſhed off the finer calx, and keep the fire low, towards the end of the operation, that the calx may not be waſted, this will be found, at the bottom, of an extream fineneſs.

Take of cryſtal frit, made with tarſo, and of this fine calx, each fifty pound, white ſalt of tartar, eight ounces; powder and ſift theſe, and mix them well. Put this mixture into a new earthen pot, give it a fire for ten hours, then powder it, and keep it in a dry covered place. *Neri*'s Art of Glaſs, p. 147.

This is the common plain *Enamel*, or matter, of which all the other *Enamels* are to be made. In the making theſe, the following general cautions are neceſſary to be obſerved. 1. That the pots muſt be glazed with white glaſs, and muſt be ſuch as will bear the fire. 2. That the matter of *Enamels* muſt be very nicely mixed with the colours. 3. When the *Enamel* is good, and the colour well incorporated, it muſt be taken from the fire with a pair of tongs. 4. The general way of making the coloured *Enamels* is this. Powder, ſift, and grind all the colours very nicely, and firſt mix them well with one another, then with the common matter of *Enamels*; then ſet them in pots in a furnace, and when they are well mixed and incorporated, caſt them into water, and, when dry, ſet them in the furnace again to melt, and, when melted, take a proof of it. If too deep coloured, add more of the common matter of *Enamels*, and, if too pale, add more of the colour.

Azure ENAMEL. To make this, take of the common matter of *Enamels*, four pound; zaffer prepared, two ounces; braſs thrice calcined, forty-eight grains. Mix all theſe well together, and melt them in the furnace in the uſual way. *Neri*'s Art of Glaſs, p. 150.

Black ENAMEL. To make the black *Enamel*, take of the common matter of *Enamels*, four pound; tartar, four ounces; mangeneſe, two ounces. Grind and mix theſe powders well with the matter of the *Enamel*, then ſet them in a furnace in a large pot; when melted and refined, caſt them into water, and, putting them again into the furnace, let them refine. *Neri*'s Art of Glaſs, p. 153.

Green ENAMEL. To make this, take of the common matter of *Enamels*, four pound; melt it, and caſt it into water, return it again to the furnace, and, when purified, add of braſs, thrice calcined, two ounces; crocus martis, made with vinegar, forty-eight grains. Mix theſe firſt in fine powder, and put this in at three ſeveral times; when all is well incorporated, take it from the fire. *Neri*'s Art of Glaſs, p. 157.

Milk-white ENAMEL. To make this uſeful colour in *Enamels*, requires no more than this; take the common matter of *Enamels*, ſix pound; manganeſe prepared, forty-eight grains; melt them in the furnace, caſt the whole into water, and afterwards return it again into the furnace, and, when refined, uſe it. *Neri*'s Art of Glaſs, p. 149.

Purple ENAMEL. To make this, take of the common matter of *Enamels*, ſix pound; of manganeſe, three ounces; braſs, thrice calcined, ſix ounces; mix all well together, and ſet them in a furnance, let them refine, then caſt them into water, return the matter to the furnace again, and, when thoroughly melted, take it out for uſe. *Neri*'s Art of Glaſs, p. 153.

This mixture, with a ſmaller proportion of braſs, makes the red *Enamel*.

Violet-coloured ENAMEL. The method of making the violet-coloured *Enamel* is this: Take of the common matter of *Enamels*, ſix pounds; of manganeſe prepared, three ounces; of thrice calcined braſs, forty-eight grains; mix the two powders well together, then mix the whole, put them into the furnace, and, when refined, caſt them into water, return the matter again to the furnace, and, when refined, take it out. *Neri*'s Art of Glaſs, p. 157.

Yellow ENAMEL. To make this, take of the common matter of *Enamels*, ſix pound; of tartar, three ounces; of manganeſe, ſeventy two grains; mix all well together, and put them into the furnace in a large pot, when refined, caſt them into water, then return them to the furnace again, and, when melted, take it out for uſe. *Neri*'s Art of Glaſs, p. 155.

ENARGIA, Εναργεια, in rhetoric, a figure, which, paſſing from the narrative ſtile, points out, and, as it were, ſets the ſubject before the eyes of the audience. *Voſſ.* Rhet. l. 3. p. 361.

ENCANTHIS (*Cycl.*)—This tubercle grows out either of the caruncula lacrymalis, or from the adjacent red ſkin, and is ſometimes ſo large, as not only to obſtruct the puncta lacrymalia, but alſo part of the ſight, or pupilla of the eye itſelf. In this diſorder the tears continually run down the cheek, which not only greatly deforms the eye and face, but often gives riſe to an ophthalmy.

The *Encanthis* is of two kinds, the one mild, and without hardneſs or pain, and the other malignant, livid, and painful; this laſt tends, in ſome degree, to a cancerous nature.

In the beginning of the mild *Encanthis*, it is beſt to ſcarify, and apply a mild cauſtic, as burnt allum, or vitriol, mixed with ſugar. This powder may be ſprinkled into the tumour, and carefully waſhed out of the eye afterwards with warm milk or water; but, if this is not ſufficient, it may be carefully touched with the common cauſtic; and, to give a turn to the humour, internal medicines, as purges, and the like, muſt be given, and iſſues, or ſetons, muſt be made. *Heiſter*'s Surgery, p. 373.

If theſe methods take no effect, and the tubercle is of a malignant kind, it is to be drawn out either with a hook, or a pair of plyers, or, if very large, by a threaded needle paſſed through it, taking hold of both ends of the thread, and gently raiſing it till it can be cut off; but, in this, great care is to be taken not to wound the lacrymal caruncle. If the tubercle appear livid and cancerous, it is by all means to be let alone, the irritating ſuch with medicines always is of very bad conſequence.

ENCARDION, in botany, a name given by the Greeks to what the Latins properly call the mediata in trees, the heart of the wood, or central hard part of it.

ENCATHISMA, in the medical writings of the antients, a term uſed to expreſs a ſort of bath, in which the patient was only to be plunged up to the belly.

ENCAUMA, in ſurgery, a name given, by ſeveral writers, to the puſtule, or excoriation, owing to a burn. The ſame word is uſed alſo by ſome as the name of a peculiar kind of ulcer of the eye. Aetius ſays, that the ſuperficial exulcerations of the eyes, which are owing to defluctions of humours, are called, by the authors who wrote in early times, by three names, according to their differences. 1. A *Caligo*. This is a ſuperficial ulcer, of a bluiſh colour, formed in the black of the eye, and covering moſt of it; when the pupil itſelf is affected by this, the ſight is uſually much impaired. 2. The *Nubecula*. This was a ſmaller, deeper, and whiter ulcer, formed alſo in the black of the eye. 3. The *Epicauma*. This was a roughneſs of the whole black of the eye, in which it appeared parched, or burnt, and was of a greyiſh colour over the entire ſurface. 4. The laſt of theſe diſorders was the *Encauma*. By this name they expreſſed an ulcer, which produced an impure and ſordid cruſt, either in the black or white of the eye, and uſually was produced by a fever. And the corroſion of the matter of this ſort of ulcer was ſo ſharp, that the coats of the eye were not unfrequently eaten through, and the humours fell out. *Aetius*, Tetrabibl. 2. c. 3.

ENCAUMA, in the old writers on medicine, is alſo uſed to expreſs the ſcoriæ of ſilver.

ENCAUSTUM *Sacrum*, a name given, by many authors, to that fine red colour, uſed for illuminating the capital letters in ſome old manuſcripts. The Latin writers have got a way of calling all thoſe liquid paints, which may be uſed by means of a pen, by the general name of atramenta, and we call them inks. Thus the tincture of logwood, or Brazil-wood, is called red ink; the tincture of fuſtic, brown ink; and the ſolution of gamboge, yellow ink. The Greeks expreſſed ink by the word *Melan*, which ſignifies only black, and the atramentum of the Latins is as plainly derived from atrum, ſignifying alſo black. The Greeks kept ſtrictly to this ſenſe of the word, and acknowledged only two kinds of ink, the graphicon, and the burſodepſicum; the firſt uſed in writing, and the other in dreſſing of leather. Some ſuppoſe that they mentioned a third kind, under the name of melan indicon, which many have been idle enough to imagine the ſame that we call by the name of Indian ink; but they have uſed the word melan not as a ſubſtantive, or the name of ink, but as an adjective, expreſſing deep blue, as Theophraſtus uſes it, ſpeaking of the deep blue of the fine ſapphire, and others of the violet. This red colour, uſed in the illuminations, was never called ink by the Greeks. Procopius calls it baphe, ſome

have called it coccus, and ſome cinnabar. It is ſaid that it was made of the purple colour, extracted from the murex, or purple fiſh, with ſome other additions. It is to be obſerved, that however well this colour, when laid on the parchment, or paper, might reſemble the colours of enamel, yet it was as improper to call it *Encauſtum*, which ſignifies a colour burnt in, as in enamelling, as it would have been to have called it atramentum, or ink.

ENCEINTE, in fortification, the wall, or rampart, which ſurrounds a place, ſometimes compoſed of baſtions and curtains, either faced or lined with brick, or ſtone, or only made of earth.

The *Enceinte* is ſometimes only flanked by round or ſquare towers, which is called a Roman wall.

ENCEPHALITES *Lapis*, in natural hiſtory, the name given, by authors, to a ſort of coarſe ſtone, ſuppoſed, in ſome degree, to reſemble the human brain. We have, in the foſſile world, many ſtones, named from the parts of animals, which they have, in reality, been form'd from, or owed their original to; and theſe are properly enough called by names denoting the things whoſe forms they wear: But it is a very wrong practice, from ſome ſlight external reſemblances, to give ſuch names to things that never can have been ſuppoſed to be ſo intitled to them. No one can be ſo abſurd as to imagine a human brain can be petrify'd, though a ſtone may accidentally ſomewhat reſemble its form. The perſon poſſeſſed of ſuch an accidental ſpecimen, ſhould have ranked it among the ſtones to which it properly belonged as a ſtone, whether a flint, a pebble, or a nodule, and have named, as an accident only, this form of it; not to have given it a peculiar denomination, as if it were a new ſpecies.

The reſemblances of things are not always to be depended upon, and are often more the effect of imagination in the poſſeſſor, than of any real likeneſs in the thing. Thus a collector of foſſils, in London, many years preſerved in his muſæum a handſome ſpecimen of the ſeptaria, or ludus helmontii, (the only one he chanced to have ſeen) under the name of petrify'd ſturgeon, from a fancied reſemblance of the ſepta of that ſtone, to the bands with which the people, who pickle ſturgeon, uſually tye the pieces up, to prevent their breaking.

ENCERIS, in pharmacy, a word uſed by Galen to ſignify ſmall concretions of wax, which formed themſelves in melted plaiſters, of which wax was one of the ingredients. As they cooled, the wax cooling firſt, and collecting itſelf into little grumes, which ſpoiled the conſiſtence and form of the whole compoſition.

ENCHELUS, in ichthyology, the name given, by Ariſtotle, Appian, and all the Greek writers, to the *eel*. See the article EEL.

ENCHESON, a French word, uſed in our law-books and ſtatutes, ſignifying the occaſion, cauſe, or reaſon, wherefore any thing is done. Stat. 5 Edw. 3. c. 3.

ENCHYMA, in the medical writings of the antients, a word uſed in ſeveral ſenſes. Some have made it expreſs only an infuſion; others have uſed it for what the modern phyſicians call *plethora ad vaſa*, that is, a fulneſs of the veſſels, ſimply conſidered, as relative to themſelves; and others have made it the name of certain forms of liquid medicines, to be injected into the ears, into the thorax, or any other part.

ENCHYMOMA, in the writings of the antient phyſicians, a word uſed to expreſs that ſudden effuſion of blood into the cutaneous veſſels, which ariſes from joy, anger, ſhame, or any other violent emotion of the mind, and is what we uſually call *bluſhing*.

ENCHYMOMA is alſo an afflux of the blood, whereby the external parts are rendered black and blue, as in the ſcurvy, blood-ſhot eyes, &c. *Blancard.* in voc.

ENCHYMONITES, in natural hiſtory, the name of a kind of ſtone, found in Macedonia, and ſome other places, which was alſo called pæonites and pæanites: It was ſuppoſed to be of great virtues to aſſiſt women in labour, and is deſcribed as itſelf often bringing forth young ones. Pliny, and many other of the antient writers, have mentioned ſtones bringing forth ſtones, and it has generally been underſtood, that they alluded to the ætites, or eagle-ſtone, in theſe accounts, as having a ſmall ſtone within it; but the ſame thing is ſaid of this *Enchymonites*, and that, with ſuch other particulars, as prove that it is not the eagle-ſtone that they mean by this. They ſay it was formed of congealed ice, that is, of water congealed into a ſolid body; and that it was found no where but in ſubterranean caverns. It ſeems, by this, to have been that ſparry ſtone which is really a congelation of the ſtony parts of water, and theſe ſtones formed into larger and ſmaller ſtalactites, or icicles, and the round ſtalagmitæ, or dropſtones, continually encreaſing, give great ſhew of reaſon to the opinion of their producing one another, the great ones throwing off the ſmaller, as if they were their offſpring. This gave opinion to the vulgar, that they were of a nature like parturient animals, and that they muſt be good, by ſympathy, for thoſe who were bringing forth children.

ENCHYSMA, the ſame with clyſter, or enema. See ENEMA.

ENCHYTA, in the medical writings of the antients, a name given to ſuch medicines as were injected into the eyes, or into any part.

Some alſo have uſed the ſame word to expreſs a ſort of funnel, contrived to convey the fumes of medicines to any part of the body.

ENCÆLIA, a word uſed, by many of the antient medical authors, to expreſs the viſcera, contained in the abdomen, or lower belly.

ENCONDRUS, in the old Greek writers, a word uſed to expreſs any thing made up of a great number of ſmall pieces, or flakes, or ſmall grains of any thing. The manna of the antients was not in large flakes, as we have it at preſent, but it was formed of a vaſt number of ſmall granules, and was therefore called by Dioſcorides, and ſome others of the Greeks, by this name. The word manna alſo ſignified, with them, the ſame thing, and they not only expreſſed the ſubſtance by it which we at preſent call ſo, but any other thing that was in ſmall flakes, or pieces, was called manna. Thus the manna thuris, ſo much talked of among the old Greeks, was only a collection of thoſe pieces which flew off from frankincenſe in the breaking. *Dioſcorides*, *Trallian*. See MANNA *Libanotis*.

ENCOPE, in ſurgery, an inciſion of any part, as in a gangrene, &c.

ENCRANIUM, in anatomy, the ſame with *Cerebellum*.

ENCRASICOLUS, the anchovy, a ſmall ſea fiſh, one of the harengiform kind, but wanting the row of ſerrated ſcales on the belly. They are caught in vaſt plenty in the Mediterranean, the Engliſh, and many other ſeas, and are well known in pickle in moſt nations of Europe. *Willughby's* Hiſt. Piſc. p. 228.

ENCRAULOS, in ichthyology, the name given, by Ariſtotle, and many other of the antient Greeks, to the fiſh which we call the anchovy. Authors deſcribe this under the diſtinct name of enchraſicholus; but Artedi proves it to be a ſpecies of the ſame genus with the herring, and calls it the clupea with the upper jaw longer than the under. This name carries a diſtinction with it that cannot be miſtaken.

ENCRINOS, in natural hiſtory, a name given by authors to a ſpecies of aſteropodium, or that plated and imbricated body which makes the baſe, or root, of the aſteria. This is compoſed of a number of ſmall plates, convex on one ſide, and concave on the other, and, when found in fair pieces, is ſaid very exactly to reſemble a part of a ray of the magellanic ſtar. See the articles ASTEROPODIUM and ASTERIA.

ENCRIS, in the medical writings of the antients, ſignifies a ſort of cake made of fine flour, mixed with oil, and ſweetened with honey.

ENCUMONIS, in natural hiſtory, a name given, by ſome of the old writers, to the ſparry incruſtations on the tops of grottoes, in ſome places, where they hang like icicles, or lie on the ground in globules, or little balls. The antients called it alſo enchymonites, and thought it poſſeſſed of great virtues for women, in the time of bringing forth children. Many of the virtues attributed to the eagle-ſtone, were, by the authors, meant of this. The account which the antients gave of theſe ſtones bringing forth one another, being ſuppoſed to allude to the eagle-ſtone, becauſe it has a ſmall ſtone in it. *Solinus*. See ENCHYMONITES.

ENCURECK, in natural hiſtory, a venomous inſect, found in Perſia, and ſuppoſed, by ſome, to be a kind of tarantula. It neither ſtings nor bites, but lets fall its venom like a drop of water, which cauſes inſufferable pain in the part for a time, and afterwards ſo profound a ſleep, that, we are told, nothing can raiſe the patient from it, but cruſhing one of thoſe creatures on the part affected. It is nevertheleſs ſaid, that the ſheep eat theſe inſects without damage. *Olearius* ap. *Boyle*, Works abr. Vol. 1. p. 37. Ibid. p. 38.

END *for* END, in the ſea language. When a rope runs all out of the block, that it is unreeved, they ſay it is run out *end for end*.

ENDECERES, in the naval architecture of the antients, a word uſed to expreſs a galley, which had eleven ſeries or tires of rowers. Thoſe with two or three tires were very much in uſe among the antients, and from thoſe to ſuch as had five or ſix tires. Thoſe of nine tires were ſometimes uſed, but it was very ſeldom; and thoſe of eleven, fifteen, and ſo on, were rather for ſtate than ſervice. We read of them carried ſo high, as to contain twenty, thirty, and forty rows of oars. One of this largeſt ſort was built for Philopater, which required four thouſand men. *Meibom.* de Trirem.

ENDEIXIS, in medicine, an indication of diſeaſes, whereby is ſhewn, what is to be done; as for example, a *Plethora*, or too great fulneſs of blood, indicates the opening of a vein. *Blancard*, in voc.

ENDEIXIS, Ενδειξις, in antiquity, an action brought againſt ſuch as affected any place, or thing, of which they were incapable by law. *Pott.* Archæol. Græc. l. 1. c. 23. T. 1. p. 125. See DISEASE.

ENDEMIAL *Diſeaſes*, a word confounded by ſome, in its ſenſe, with epidemic, but extreamly different in the ſignification correct authors put upon it. The epidemic diſeaſes being thoſe

thoſe which indifferently affect any nation, and ariſe from a fault in the air, or from other cauſes, and are contagious; but the endemic properly being thoſe diſeaſes which are in a manner national, and peculiar to the people of one place. *Junk.* Conſp. Med. p. 258.

ENDESIS, a word uſed, by Hippocrates, to expreſs that part of the foot where the bones of the tibia end, and which is connected by ligaments to the ankle.

ENDICA, a word uſed by the alchymiſts for the fæces which ſubſide to the bottom of the veſſel in infuſions; to ſome of which they attribute great virtues.

ENDIVIA *Marina*, the *Sea Endive*, in natural hiſtory, the name of a ſpecies of ſea plant, deſcribed by count Marſigli: There are two ſpecies of it, the one having broad and jagged leaves, reſembling thoſe of the vine, the other much narrower. This laſt kind grows on ſtones, ſhells, pieces of wood, or any other ſubſtances, accidentally found at the bottom of the ſea. It ſeldom grows in very deep water, and thrives beſt in places where the ſea is calm and quiet. It is of a duſky greeniſh colour, variegated in ſome places with yellow. It exactly reſembles the ſhape of the endive common in our gardens, and its leaves are cut and fringed in the ſame manner; but they are of ſo tender a ſubſtance, that a ſlight touch deſtroys them; they are indeed tenderer and more delicate than thoſe of any other known plant, either of the ſea or land. When this plant is examined by the microſcope, its ſurface is found to be compoſed of a great number of eminences, and cavities, or little holes, between and among them; and when the leaves are cut tranſverſely, there are ſeen a great number of glandules in them. *Marſigli*, Hiſt. de la Mer, p. 72.

ENDOSIS, in the medical writings of the antients, a word uſed to expreſs a remiſſion of any kind, as when a tumour, inflammation, or hardneſs of any part, becomes leſs violent; and when the patient becomes eaſier, after the exacerbations in fevers of the continual kind, and after fits of the intermittent.

ENDYMATIA, in antiquity, a kind of dance uſed among the Greeks. Mem. Acad. Inſcript. Vol. 14. p. 473. ſeq.

ENELIAXIS, Ενναλιαξις, or rather *Enyaliaxis*, Ενυαλιαξις, in antiquity, a feſtival in honour of *Enyalius*, whom ſome will have to be the ſame with Mars, others only one of his miniſters. *Pott.* Archæol. Græc. l. 2. c. 20. T. 1. p. 394.

ENEMA, *Clyſter*, a liquid form of medicine, intended to be thrown up the anus into the body. In Holland, England, and Germany, clyſters are given by means of a pipe of ivory faſtened to a bladder, the patient being made to lie on one ſide, and to retain the liquor as long as he is able. The French, and ſome other nations, uſe a ſort of ſyringe, holding a pint, or more, for this purpoſe; and this is evidently the better method, as, by this means, liquors are not only more quickly, but more forcibly thrown into the inteſtines, and are made to paſs farther than by the Engliſh method. Some alſo uſe a leather pipe of half an ell long, which is faſtened to the ſyringe, and to the pipe introduced into the anus, and by this means the patient can give himſelf the clyſter.

Great care muſt be taken in adminiſtring clyſters, that the liquor be neither too hot nor too cold, but only tepid, or moderately warm, both extreams being capable of doing great injury to the bowels.

Clyſters are properly uſed where a coſtive ſtate is to be removed, and the body rendered ſoluble. 2. For alleviating the pains ariſing from the colic, ſtone, dyſentery, violent hæmorrhoids, and other diſorders of the abdomen. 3. For making revulſions from the head in apoplexies, lethargies, deliriums, and other diſorders of that part. 4. In difficult labours, whether the fœtus be dead or alive, eſpecially if the mother be coſtive, as alſo for expelling the ſecundines, when they adhere too firmly to the womb, or remain longer behind than they ought. 5. Clyſters are able to nouriſh perſons, who, from their power of deglutition, being impair'd, muſt otherwiſe periſh of hunger; and for this purpoſe nouriſhing liquors muſt be uſed, ſuch as broths, and the like, to which a little wine may be added, if the nature of the caſe will allow it.

This practice of giving nutritive clyſters, is no new invention, but has been known even in the earlieſt times of which we have accounts; and though, both among the antients, and at this time, there have been ſome who have laughed at it as idle and ineffectual, yet experience has often proved the certain truth of it; and it is not to be doubted, indeed, when we reflect that there are, in the large inteſtines, lacteal veſſels, capable of abſorbing and conveying to the maſs of blood the nutritive liquors injected, by which means it frequently happens that the clyſter does not return, but is wholly retained.

A very remarkable clyſter, which ſeems to have been invented by the Engliſh, and, from us, propagated to other nations, is the ſmoak of tobacco. When all other clyſters have proved ineffectual for rendering the body ſoluble, in the iliac paſſion, and ſome other caſes, the end has ſometimes been obtained by injecting a large quantity of the ſmoak of tobacco, by means of a proper inſtrument. There are ſeveral kinds of inſtruments invented for this purpoſe, and deſcribed by Bartholine, Valentini, and others. The general method of making them is this: A box is provided, capable of holding about half an ounce of tobacco; this has two pipes, the one made of ivory, to be introduced into the anus, the other reſembles the mouth-piece of ſome muſical inſtruments, and, by means of blowing into this, the ſmoak of the lighted tobacco in the box is driven forcibly up the anus: This is to be continued till the patient find a ſtrong ſtimulus to go to ſtool, and if once doing it does not produce the effect, it is to be repeated till it ſucceeds. This is of prodigious ſervice in obſtinate incarcerated hernias of the ſcrotum. And Heiſter obſerves, that he always found it ſucceed ſo well, as never to reduce him to a neceſſity of having recourſe to the knife. When tobacco alone will not anſwer the purpoſe, other more ſtimulating ingredients may be added to it in the box; and this acrid ſmoak ſo contracts the diameters of the inteſtines, that the prolapſed ones are much more eaſily drawn back into the abdomen, than they otherwiſe could be.

Clyſters of the liquid kind are prepared of different ingredients, according to the intentions propoſed to be anſwer'd, and as, in practice, thoſe intentions are principally four, *viz.* To alter and change, to evacuate, to corroborate, and to mitigate pain, ſo clyſters are accordingly contrived to ſoften the indurated fæces, to correct the acrid, acid, and ſaline recrements, to evacuate the contents of the large inteſtines, and to corroborate the weak and languid fibres of the inteſtines in general, and ſo ſtrengthen their periſtaltic motion; or, laſtly, to mitigate the ſpaſms of their contracted coats, and relax their conſtricted fibres. *Hoffman.*

When clyſters are intended to lubricate and ſoften the dry and indurated fæces, or to obtund acrid, ſaline, corroſive, and acid humours, in the large inteſtines, they are to be prepared with the emollient ingredients, ſuch as broths, milk, decoctions of emollient herbs, as marſhmallows, and the like, with manna, oil, and the like aſſiſtances; and, as all theſe ingredients have a power of relaxing ſpaſms, as well as of ſoftening the fæces, clyſters of this kind are extreamly beneficial in all ſpaſmodic diſorders, fevers, pains, and caſes where the patient is coſtive, whether it be from ſpaſms of the inteſtines, or from induration of the fæces.

When the intention is at once to evacuate the inteſtines, and to carry off ſtagnant humours, then ſalts, added to the decoctions, admirably anſwer the end. Glauber's ſalt, Epſom ſalt, and ſal gem, are all uſeful to theſe purpoſes. In ſome caſes alſo ſal armoniac; And experience ſhews, that half an ounce of one of theſe ſalts, in a clyſter, will do more toward the evacuating the contents of the bowels, than four ounces of any of the common purging electuaries. Corroborating clyſters are to be prepared of the four greater hot ſeeds, bay and juniper berries, the carminative oils, *&c.* and in violent diſorders of the head, ſuch as apoplexies, palſies, lethargies, and the like, rue, marjoram, thyme, roſemary, and lavender flowers, are conveniently added to clyſters; as are mugwort, pennyroyal, feverfew, and the like. When there is any diſorder of the womb, or ſuppreſſion of the menſes, the clyſters of the ſedative kind are principally to be compoſed of oil, or the like fatty ingredients, and ſuch as conſiſt purely of oil alone, are found often to do wonders, in allaying the moſt violent pains.

ENEOS, a word uſed, by the antient writers on medicine, for a perſon born deaf, or unable to perform the common offices of life, for want of any of the principal organs.

ENERGETICAL *Bodies*, or *Particles*, are ſuch as are eminently active, and which produce manifeſt operations of various natures, according to the various circumſtances and motions of ſuch bodies, or particles.

ENGASTRIMANTES, Εγγαστριμαντεις, in antiquity, a deſignation given to ſuch diviners as were poſſeſſed with demons, which either lodged, or ſpoke within their bodies. *Pott.* Archæol. Græc. l. 2. c. 12. T. 1. p. 301.

ENGASTRIMYTHI, Εγγαστριμυθοι, in antiquity, the ſame with *Engaſtrimantes*.

ENGRAULIS, in zoology, a name given, by ſome authors, to the anchovy, called alſo, by ſome, lycoſtomus, and, by others, halecula. *Willughby*'s Hiſt. Piſc. p. 228. See ENCRASICOLUS.

ENGYTHECA, in antiquity, a cup-board, or place where cups and other veſſels uſed to be laid. *Pitiſc.* Lex. Ant. in voc.

ENHARMONIC, (*Cycl.*) in the antient muſic, was the name of one of their genera.

The intervals conſtituting the *enharmonic* genus, are the ſemi-tone minor, the *enharmonic* dieſis, and the third major. Phil. Tranſ. N°. 481. p. 272.

This is to be underſtood of what the *enharmonic* ought, accurately ſpeaking, to be. Salinas has thus defined it, and others after him. This diviſion is alſo approved of by Dr. Pepuſch [a]. The antients do not agree in the numbers, by which they expreſs theſe diviſions of the *enharmonic* genus; but the differences that occur are not ſufficient to conſtitute any ſubordinate ſpecies of the *enharmonic*; and therefore they agree

agree in not ſubdividing it [b].—[[a] Phil. Tranſ. ibid. [b] Vid. *Wallis*, appendix ad Ptolem. Harmon. p. 165, 166.]

ENGAMOS, in natural hiſtory, the name given by the people of ſome parts of Guinea, to a root very common there, and much reſembling our larger ſort of turneps, but not ſo ſweet or juicy: They commonly boil theſe with their pattatas, in the ſame kettle with their meat. The latter of theſe roots, which is conſiderably different from our potatoe, gives a fine flavour to the whole, and makes the broth and meat taſte as if roſe-water were added to it. The *Engamos* alſo partake of the flavour, and, in this caſe, become very agreeable. Phil. Tranſ. N°. 108.

ENHYDROS—Some of the antients have ſuppoſed this ſtone ſo called, becauſe its ſurface was always wet, as if by the effect of water ouzing from within. But Pliny tells us directly the contrary, that the water was contained within, and made no ſhew on the outſide, and that the ſurface of the ſtone was white and ſmooth. From this it appears, that the *Enhydrus* of the Romans, or at leaſt the kind known to Pliny, was not the ferrugineous one, common in our time, but the flinty kind. Of theſe we alſo have ſome in England. They are, as he ſays, white and ſmooth on the ſurface, and are flints perfectly round, covered with a white cruſt, of the bigneſs of a large apple, and containing a quantity of water, lodged in their central cavity, and rattling in it on ſhaking.

ENLARGE, in the manege, is uſed for making a horſe go large, that is, making him embrace more ground than he before covered. This is done when a horſe works upon a round, or upon volts, and approaches too near the center, ſo that it is deſired he ſhould gain more ground, or take a greater compaſs. To *enlarge* your horſe, you ſhould prick him with both heels, or aid him with the calves of your legs, and bear your hand outwards. If your horſe narrows, he is enlarged by pricking him with the inner heel, and ſuſtaining him with the outer leg, in order to preſs him forwards, and make his ſhoulders go. Upon ſuch occaſions the riding-maſters cry only *large, large*. See IN.

ENNEACTIS, in natural hiſtory, a name given, by Linkius, to a ſort of ſtar-fiſh, of the more branched or aſtrophyte kind, which has only nine rays, where they firſt part from the body, but theſe divide into a vaſt number of others afterwards.

ENNEAHAEDRIA, in natural hiſtory, the name of a genus of ſpars. The word is derived from the Greek ἐννέα, nine, and ἕδρα, a ſide.

The bodies of this genus are ſpars, compoſed of nine planes, in a trigonal column, terminated at each end by a trigonal pyramid. Of this genus there are four known ſpecies. 1. One with long pyramids, and a ſhort column, found in the mines of Germany, and ſometimes with us in Devonſhire and Cornwall. 2. One with very long and ſlender pyramids, and a ſhort column. This is found in the iron mines, in the foreſt of Dean. 3. A ſlender kind, with very ſhort pyramids, found in England and Germany, but no where ſo plentifully as in Ireland. 4. One with ſhort flat pyramids, and a ſhort column. This is very frequent in the mines of Goſſelaer in Saxony, and ſometimes is ſeen in *England*. *Hill*'s Hiſt. of Foſſ. p. 208.

ENNEANDRIA, in botany, a claſs of plants, with hermaphrodite flowers, and nine ſtamina, or male parts, in each.

The word is derived from the Greek, ἐννέα, nine, and ἀνὴρ, male. The plants of this claſs are the bay-tree, rhubarb, &c.

ENNEEMIMERIS is one kind of the *Cæſura* of a Latin verſe, where, after the fourth foot, there is an odd ſyllable ending a word, which helps to make the next foot with the following word; as in this inſtance,

Ille latus Niveum Molli fultus Hyacintho.

where all the four kinds of the *Cæſura* occur.

ENNEOPHTHALMOS, in zoology, a name given, by ſome, to the lamprey. *Willughby*'s Hiſt. Piſc. p. 107.

ENNERIS, in the antient ſhip-building, a name given to thoſe galleys, or veſſels, which had nine tires of rowers. Theſe were of a very conſiderable ſize; tho' Meibom has found ſo convenient a method of placing the rowers, that he has taken off very much from that immenſe height others ſuppoſed they had above the water. We read of the teſſaracontes, and other amazing veſſels of this fabric; that of Philopater having forty rows of oars, and that of Ptolemy Philadelphus thirty; and ſome others which are ſpoken of, twenty. It has been diſputed by many, whether ſuch large veſſels as thoſe were ever actually built, or uſed; but Meibom gives great reaſon to believe, that they really were, tho' he, at the ſame time, alledges againſt Salmaſius, and the more ſanguine admirers of the works of the antients, that very few veſſels were built larger than theſe *Enneres*, or nine tired ones, and proves it from Livy and Plutarch, and from Polybius. We are apt to admire, in many caſes, what we ought alſo to imitate, but never attempt it. This is the caſe in theſe galleys; and Meibom, who has given the rules of this antient naval architecture, is of opinion, that by imitating it at preſent, our modern galleys and galleaſſes might be built much more conveniently both for ſtrength and celerity, and alſo at leſs expence than they are at preſent. *Meibom*, de Trirem.

The modern form is indeed allowed to be better than theirs, but if, in the ſtructure, the proportion of the long ſhips of the antients were obſerved, we might greatly improve them; in our way of five men ſitting at one oar in the galleaſſes, much ſtrength is waſted to no purpoſe, becauſe they ſit too near to the fulcrum, or ſtay, whereas a ſmaller number of rowers, at a greater diſtance from the ſtay, would give more ſtrength, and throw the veſſel along much more ſwiftly, and would require leſs charge. Galleys of this ſort, thus managed at a ſmall expence, would be found of great uſe in the larger rivers, and in the ſhallow ſeas, and therefore convenient for the Baltic, the Britannic, and the Mediterranean ſeas, and would be the moſt uſeful of all veſſels for the tranſporting great numbers of forces.

ENOLMIS, Ενολμις, in antiquity, a deſignation given to Apollo's prieſteſs at Delphi, becauſe ſhe ſat on the tripod which was called *olmos*, ολμος. Hence alſo Apollo is called *Enolmos*, Ενολμος. *Pott*. Archæol. Græc. l. 2. c. 9. T. 1. p. 275.

ENORAINE, in the manege, a wither-wrung horſe, or one that is ſpoiled in the withers. The word is obſolete. *Guillet*.

ENORCHIS, in natural hiſtory, the name given, by many authors, to that ſpecies of *Ætites*, or eagle-ſtone, in which the callimus, or internal nucleus, is not looſe, ſo as to rattle in it when ſhaken, but remains fixed to one ſide. The Germans call this *Hodenſtein*. The outer cruſt is uſually of a whitiſh colour, and the internal nucleus is yellowiſh or browniſh, and it is uſually of the ſize of a pigeon's egg, and of the ſhape of the human teſticle; whence the name.

ENRICHING *Plants*, a term uſed, by the Engliſh farmers, to expreſs ſuch plants as are found to do good to land, rather than to exhauſt it, and in conſequence of which the ſame piece of land will produce a good crop of corn, tho' it would, without the aſſiſtance of their having been planted on it, have yielded a very poor one. The myſtery of this difference between plants, ſome of which are found to burn up, that is, impoveriſh land, while others enrich it, and leave it fitter for ſucceeding crops than they found it, had been long a perplexing thing to account for. Though it was eaſy to conceive that ſome plants might exhauſt the earth more, and others leſs, yet it was hard to conceive, while all exhauſted it in ſome degree, how any could leave it better than they found it; but this was at length explained by Mr. Tull. This author having obſerved, that breaking the earth, by digging, or horſehoing, between the plants, gave them great encreaſe, found that it was this practice that enriched the earth, and that, while corn and ſuch plants as ſtand cloſe, and cannot be hoed between, impoveriſh the ground, and ſuffer no means of enriching it again to be uſed, there were ſome other things, the crops of which being planted thinner, gave room to the earth to be plowed, dug, or hoed between, and that theſe were the plants which were called the enriching kind, by the farmers; and the whole ſecret lay in this, that the hoing, plowing, or otherways breaking the earth between them, in order to kill the weeds, enriched the ground greatly more, in proportion, than theſe plants exhauſted it; and the conſequence was, that though they had thriven very well, yet the earth was left richer than before, notwithſtanding all that they had imbibed from it. *Tull*'s Horſehoing Huſbandry, p. 37.

On this obſervation, this excellent author ſeems to have founded the ſyſtem of what he calls horſehoing huſbandry, concerning which he has written a large and uſeful treatiſe. He found that this ſtirring up of the earth enriched it ſo greatly, that, where it was uſed in a proper manner, the kind of plant need not be changed, but that the ſame earth would yield a ſucceſſive ſeries of crops of the ſame plant, and, that even without dunging, or ever lying fallow, and every crop, for a long time, would be better than the former ones. The method of ſowing, to this purpoſe, is not by ſcattering the corn with the hand, but ſowing it in rows, and leaving large intervals between, the naked earth of which might be turned up by the hoe. See the articles INTERVAL and HOING.

ENSAL, in the materia medica, a name uſed, by ſome authors, for the common ſmall cardamom of the ſhops. *Herman*. Muſ. Zeyl. p. 66.

ENSIFORM *Leaf*, among botaniſts. See LEAF.

ENSIGNS, in a ſhip, are thoſe colours which are placed in the ſtern, or poop. There are few ſhips, whether men of war, or merchants, but have their *Enſigns*. Their chief uſe is, that when any ſtrange ſhips meet at ſea, or make into any harbour, by heaving out the colours in the poop, that is, putting theſe *enſigns* abroad, they diſcover of what part and country they are. Thus the Britiſh heave out their colours with the union croſs; and ſo all other countries with ſome particular diſtinction, whereby they may be known. The *Enſigns* ſerve alſo for many other uſes. See FLAG, *Cycl.*

Roman ENSIGNS. See the article SIGNA.

ENS (*Cycl.*)—*En Sprimum Salium*, a name given by Paracelſus to a preparation of ſea ſalt, which he calls alſo a perpetual oil, and *ſal circulatum*, which ſee.

ENSTASIS, Ενστασις, in logic, a manner of replying to an opponent,

ponent, either by confuting his argument, or denying the juſtneſs of his concluſion. *Voſſ.* Ret. l. 3. p. 380.

ENSTASIS, in the writers of medicine, a term uſed to expreſs the ingreſs of moleculæ into the vacuity of the pores, which obſtruct them, and thereby cauſe diſeaſes. It is a word familiar with Eraſiſtratus and Aſclepiades, who was a follower of Democritus, and taught that moſt diſeaſes were cauſed by ſuch an ingreſs of matter into the pores. Thus Aſclepiades defined a phrenſy to be ſuch an *Enſtaſis* in the membranes of the brain. Plutarch, in his precepts of health, alſo mentions this *Enſtaſis*; and Galen, and Caſſius, who is ſuppoſed to have been of the ſect of the rationaliſts, expreſſes the ſame ſenſe by the ſame word.

ENTABLER, in the manege, is ſaid of a horſe whoſe croupe goes before his ſhoulders, in working upon volts: For, in the regular manege, one half of the ſhoulders ought to go before the croupe. Thus we ſay, your horſe *entables*; for, in working to the right, he has an inclination to throw himſelf upon the right heel; which fault you may prevent, by taking hold of the right rein, keeping your right leg near, and removing your left leg as far as the horſe's ſhoulder. A horſe cannot commit this fault without committing that called *Aculer*, but *Aculer* may be without *Entabler*. See ACULER.

ENTALI, in the materica medica, a name given, by ſome authors, to foſſile alum.

ENTALIUM, the *Pipe Shell*, in the materia medica, a ſhell of the ſame genus with the *dentalia*, being a ſpecies of the *tubuli marini*. It is frequent in the Eaſt Indies, and ſometimes is found on our own ſhores. The virtues aſcribed to it are the ſame with thoſe of the *dentalium*; but neither of them have any title to more than thoſe of alkaline abſorbents, like the other teſtaceous powders.

ENTASIS, *Diſtention*, a word uſed in various ſenſes, by different authors in medicine, but by moſt applied to the parts of generation. And thence *entatica* were medicines, in whatever form, meant as provocatives.

ENTERADENES, in anatomy, a name by which many authors have called the inteſtinal glands.

ENTEROMPHALUS, or HERNIA *Umbilicalis*, a rupture of the navel, or the bunching out of the guts at the navel, See HERNIA.

ENTERORAPHE, in ſurgery, a name given to the ſutures of the inteſtines.

ENTERTAINMENTS, *Epulæ*, among the antients, were of various kinds, as 1. Funeral *Entertainments*, *Epulæ funebres*. 2. *Entertainments* given by the huſband on bringing home his wife, called *Epulæ geniales*. 3. Thoſe beſtowed on the ſoldiers, called *Epulæ militares*; which was done before or after an engagement, or on occaſion of proclaiming the general *Imperator*. 4. Birth-day *Entertainments*, *Epulæ natalitiæ*.

There were many other kinds, denominated either from the place where, the perſons by whom, or the occaſion for which, they were given; for which ſee *Pitiſc.* Lex. Ant. in voc. *Epula* & *Cæna*.

ENTERENCHYTÆ, in medicine, a name given by authors to the ſeveral inſtruments contrived for throwing clyſters into the bowels, ſuch as the bladder and pipe, the ſyringe, and the like, for liquid clyſters, and the box with the double pipe for conveying the ſmoak of tobacco. See ENEMA.

ENTHALIUM, in natural hiſtory, a name given by ſome to a ſpecies of the tubuli marini, more uſually known by the name of penicillum marinum and pinceau de mer. *Klein.* de Tub. Mar. p. 1. See PENICILLI *Marini*.

ENTHEAMATA, in the antient writers of medicine, a word uſed to expreſs ſuch medicines as were immediately put into large freſh wounds, to ſtop the hæmorrhage, and prevent inflammation, or other bad conſequences.

ENTHETOS, in the writings of the old phyſicians, a name given to certain applications intended to be thruſt up the noſtrils to ſtop hæmorrhages.

ENTIER, in the manege, is uſed for a ſort of reſty horſe, that refuſes to turn, and is ſo far from following, or obſerving the hand, that he reſiſts it. If your horſe is *Entier*, and refuſes to turn to what hand you will, provided he flies, or parts from the heels, you have a remedy, by putting the Newcaſtle on him; that is, a caveſſon, made after the Duke of Newcaſtle's way.

The word is French, and is alſo uſed among them to denote a ſtone horſe.

ENTIERTIE, from the French *entier*, is uſed in our law-books in contradiſtinction to moiety, and denotes the whole. Thus a bond, damages, *&c.* are ſaid to be entire, when they cannot be divided or apportioned.

ENTORSES, iu the manege. See PASTERN.

ENTRANCE *of Hounds*, a phraſe uſed by our ſportſmen to expreſs the inſtruction of theſe creatures in the art of hunting. They are ſaid to be enter'd when they are thoroughly taught this.

The time of entering of hounds, is when they are ſeventeen or eighteen months old, they are then to be taught to take the water and ſwim; they are to be led abroad in the heat of the day, to enure them to fatigue and exerciſe, and they muſt be frequently led through flocks of ſheep, and warrens, to uſe them to be under command, and to know that they are to run at nothing but what the huntſman orders. They muſt be carefully inſtructed each to know his own name, and to underſtand the voice of the huntſman, and the notes of the horn uſed in the hunting, and finally to uſe their own voices in a proper manner.

The beſt time of entering them is about noon, and it ſhould be in a fair warm day, for if they be entered in the morning, they will give out when the heat of the middle of the day comes on. Take the moſt advanced, that the game may not ſtand long before them, and let them be well rewarded when all is over. This ought to be repeated at leaſt once a week, for two months ſucceſſively; by this means they will be ſo fleſh'd and ſeaſoned with what game you enter them at, that they will never afterwards leave off the purſuit. The new hounds ſhould always be entered with the beſt and ſtaunchеſt hounds that can be had, and there is not to be one barking dog ſuffered in the field on this occaſion.

Whatever chace the hounds are intended for, the hare is the beſt game to enter them at, becauſe, in this chace, they will learn all the turns and doubles that they can poſſibly meet with in any other kind, and how to come to the hollo. They will learn alſo, from this chace, to have a perfect and nice ſcent, and hard feet, by being uſed to highways, beaten paths, and dry hills. The hounds, when firſt entered, muſt have all the advantages given them that can be. When the hare is put up from her form, it muſt be obſerved which way ſhe went, and the ſcent muſt be left to cool a while, and then they muſt be laid in and helped, as much as can be, by wind, view, hollow, or pricking the paſſage; nor will it be amiſs, for the firſt time, to give them a hare tired the ſame morning in her courſe.

Care muſt be taken that they hunt fair and even, without lagging behind, ſtraggling on either ſide, or running wildly a-head, and if any of them are found faulty this way, they are to be beaten back into the pack, and forced to ſmell the ſcent among the reſt.

The ſame is to be done if they refuſe to ſtrike upon a default, but run on babling and yelping without the ſcent; by doing which they draw away the reſt of the dogs, till ſome of the elder ones take it: Then let them be cheriſh'd with horn and hollos. If any of the young whelps truſt more to their own ſcents than to the reſt of the pack, and are, in conſequence of this, thrown behind, and after this work out the default by their own noſes, and come to hunt juſt and true, they muſt, in this caſe, have all manner of encouragement and aſſiſtance, and be left to work it out at their own pace; for ſuch dogs as theſe can never prove bad ones, if they are not ſpoiled by the over haſtineſs and indiſcretion of their maſters. A little patience in the huntſman, and their own experience, will ſoon bring theſe to be the leaders of the pack.

When the hare is killed, the dogs muſt not be allowed to break her up, but they muſt be beaten off, and ſhe is to be ſkinn'd and cut to pieces by the huntſman, and the young hounds muſt be rewarded with the pieces.

Some are of opinion, that the beſt way to enter young hounds is to take a live hair, and trail her upon the ground, ſometimes one way, and ſometimes another, and then to draw her off to a convenient diſtance, and hide her, that the dogs, taking the ſcent, may follow all the traces through which ſhe was drawn, and, at length, find her.

The huntſman ought very well to underſtand the nature and diſpoſition of his hounds, in finding out the game; for ſome hounds are of that temper, that when they have found the ſcent, they will run forward with it, not making any noiſe, nor ſhew of the tail; others, when they have found a head, will ſhew the game, and ſome, having found the footings of the beaſt, will prick up their ears a little, and either bark, or only wag their ears, or the hinder part of their bodies. This difference of natural diſpoſition the huntſman is particularly to obſerve in the young and newly enter'd pack, otherwiſe he will never underſtand them, nor ever be able to hunt them to any credit or advantage.

Some hounds cannot keep the ſcent when they have it, but wander up and down, and hunt counter, taking up any falſe ſcent; and there are others which cannot hunt, either by ſcent or foot, but only in the ſight of the game. This would make very uncertain work of the chace, if a whole pack were ſuch; but where it is only a few, the reſt ſet them right.

For entering the hound at hart or buck, he ſhould be in the prime of greaſe, for then he cannot ſtand up, or hold the chaſe ſo long. The foreſt pitched upon ſhould have all the relays at equal diſtances, as nearly as may be; but then the young hounds ſhould always have ſome old ſtaunch ones to enter them, and they ſhould be led to the fartheſt and laſt relay, and the hart, or buck ſhould be hunted to them. Being come up, the old hounds ſhould be uncoupled, and when they have found the hart, and well enter'd the cry, then the young ones are to be uncoupled alſo, and if any of them are found to lag behind, they muſt be whipped and beaten forward.

In whatever place the hart is killed, the neck ſhould be immediately flay'd, and the hounds rewarded; for it is beſt al-

ways to do this while the flesh is hot. Another very good method of entering hounds at the buck, is to take one in the toils, or nets, and wound one of his legs so as to disable him from running either very swift, or very far; then let him loose, and first let a blood-hound trace the creature, then let loose all the young hounds, and when they have run down the animal, reward them with the neck.

Some enter their hounds within a toil, but this is a bad way, for the hart being, in this case, always in sight, and not able to run an end, makes a great number of doubles and turnings: This is very different from the chaces they are to meet with afterwards; and, when they find a hart run in the common way, strait forward, and out of sight, they will leave the chace, as unlike that by which they were taught.

It is observed, that whatever animal the hounds are intended to be employed in hunting, it must always be that animal that they are enter'd at; for it is found, that they are always afterwards most fond of that, whose flesh they were first rewarded with.

ENTRAVES, *Entravons*, in the manege. See LOCKS.

ENTREPAS, in the manege, is a broken pace, or going, properly a broken amble, that is neither walk nor trot, but has somewhat of an amble. This is the pace, or gait, of such horses as have no reins or backs, and go upon their shoulders, or of such as are spoiled in their limbs.

ENTRICHOMA, in anatomy, the name of the outer edge of the eyelid, on which the hairs grow.

ENTRING *a Ship*, in the sea language, the same with boarding her. See the article BOARDING.

ENTRING-*Ladder*, in a ship, is of two sorts; one is used by the ships sides, in a harbour, or in fair weather, for persons to go in and out of the ship; the other is made of ropes, with small staves for steps, and is hung out of the galley to enter into the boat, or to come aboard the ship from thence, when the sea runs so high, that they dare not bring the boat to the ship's side, for fear of staving her.

ENTRING *Ports*, in a ship. See PORTS.

ENTRING *Ropes*, in a ship. See ROPES.

ENTROCHUS, in natural history, the name of a genus of fossils, of a very regular figure and structure, supposed, by many authors, to be *lapides sui generis*, and stones in their native state. They are, however, in reality, the fossile remains of some marine animal, probably either of the echinus, or of the star-fish kind, filled like the fossile species of the echini, with a plated spar. Our imperfect knowledge in the animal history has not yet been able to ascertain to what creature they really belong; but their analogy with the other animal remains, found in the fossile world, plainly evince, that they are of that origin. They are cylindric columns, usually about a inch in length, and are made up of a number of round joints, like so many small wheels, or segments of cylinders. These joints, when found separate, and natually loose, as they sometimes are, are called *trochitæ*. They are all striated, from the center to the circumference, and have a cavity in their middle, which is sometimes found empty, but more frequently filled up with various matter, of the nature of the stratum, in which they have lain, or of other of the native fossile substances.

The *Entrochi* are composed of the same sort of plated spar with the asteriæ, and the spines and shells of the fossile echini; and this is in these usually of a bluish grey colour, and very bright and glossy, where fresh broken. They are subject to accidental injuries, like the other extraneous fossiles, which have been formed in animal moulds, and are frequently met with, compressed, or crooked. Their joints are not all of the same size, even in the same species; but, in the same specimen, some usually swell out much more, and are much larger, than the rest. The middle cavities of the *Entrochi* are of no determinate, or certain shape; they are, in some species, perfectly round, in others nearly, but not exactly of that shape; and in many they are pentangular, or of stellate figures of other numbers of angles, and resemble the shape of the asteriæ. See TROCHITÆ.

In many of the *Entrochi* also, a slight impression of a star is seen on each side the joints, and the *Entrochi* of this kind are distinguished, by some authors, under the name of *Entrocho asteriæ*. Most frequently the joints of the *Entrochi* are smooth, and the body even and simple; but sometimes there appear, on several parts, the rudiments of appendages, or branches, in the manner of the wires of the asteriæ, but these seldom run to any great length. *Hill*'s Hist. of Fossils, p. 633.

That the *Entrochi* are of marine origin, is evident from this, that they have not unfrequently sea shells found adhering to them, and, when these are broken off, there remain on the *Entrochi* no deficiencies, but the shells themselves shew that they have been form'd upon, and have grown to the *Entrochi*, there being always natural hollows in them, to answer to that part of the *Entrochus* from which they have been separated; whence it appears very plainly, that these *Entrochi*, however altered since in their substance, were, however, existing in their present shape, in those very seas where these shells had their growth.

There are not unfrequently found, among the *Entrochi*, larger or smaller fragments of plated bodies, which have plainly been once a part of the animal to which the *Entrochi* belonged, these being sometimes found affixed to them in their natural postures. These fragments are always composed of small flakes, of a convex or concave figure, laid in an imbricated manner over one another. The Germans call these bodies modioli; but they are ever so imperfect, that there can be no very probable conjecture founded on them, as to the nature of the body they have belonged to. Among the trochitæ, and modioli, there is also not unfrequently found, what may be called the inner nucleus of the *Entrochi*; this is a substance of stony, sparry, or other mineral structure, which has once filled up the cavity of one of these bodies, and has, since that time, been left naked by the outer substance of the *Entrochus*, having been destroyed, or worn away: This is exactly the same sort of fossil with the flinty echinitæ, and other casts of stone, made in the cavities of shells, since perish'd. This might sometimes be easily mistaken for a very different body from what it really is; but, at other times, it carries more traces of its original figure, the rounded parts of the several joints of the *Entrochus* being only worn away.

The entrocho asteriæ, as they are called, are sometimes plain *Entrochi*, with faintly stellate ends; but, at others, they have such elegant starry cavities and marks, with such precise and determinate angles, that they seem only to be asteriæ, surrounded by some foreign matter at every joint, and, by that, shaped into roundness.

We meet with the *Entrochi* of all the sizes, from that of a pin's head to a finger's length, and the thickness of ones middle finger. They are, in some places, found loose upon ploughed lands, in others they are lodged in great quantities in the strata of clay, and very often in stones of different kinds, and different hardness. The Derbyshire marble is extremely full of them, and owes its beauty, when polished, principally to them. *Hill*'s Hist. of Foss. p. 653.

Some of the Yorkshire *Entrochi* are swelled or tumid in the middle, and go off tapering to each end, and some others resemble the lapides judaici. These, however, are true *Entrochi*: They are jointed in the same manner with the rest, and consist of a small stalk, or pedicle, formed of three or four joints, and on this an oval body is placed, broken off at both ends. Some of these have also been the natural summits, or fastigia of the bodies, for they have a little jointed button on the top, hollow, and not seeming to have been divided, or broken off from any thing else. Phil Trans. N°. 100.

The hollows of the *Entrochi* are usually filled up with earthy or stony matter, but sometimes with another smaller *Entrochus*, so that they resemble a pair of screws, one nicely fitted into the other, and the one making a sort of pith to the other, and having gone regularly through its whole length.

The *Entrochi* possess all the medical virtues of other sparry petrifactions. See SPAR, BELEMNITES, OSTRACITES, *&c.*

ENTROCHO-*Asteriæ*, in natural history, the name given, by authors, to a peculiar kind of *Entrochus*, differing from the common kind, in having a stellar cavity, instead of a round one, in its center. See ENTROCHI.

ENTROCHUS *Pyramidalis*, a name given, by some of the writers in natural history, to the ortho-ceratites, or tubulus marinus concameratus, a species of shell-fish, not known to us in its recent state, but very common in the stones brought over from Sweden for pavements. *Klein.* de Tubul. Marin. p. 7. See TUBULUS *Concameratus*.

ENTROCHUS *Ramosus*, in natural history, the name of a fossile body, the several parts of which resemble the entrochi; but as they are joined together in this body, when perfect, they shew themselves in their proper light, and a sight of them, in this state, is sufficient to explode the opinion, advanced by some persons, of the entrochi being of a vegetable nature; or, as they have pleased to call them, rock plants. This fossile has evidently once been a stella marina, or sea star-fish, consisting of twenty rays, at the extremity of the body. The manner of insertion of these has been this: The body is of a pentagonal figure, and from this there have arisen five rays. These, at their extremity, have been divaricated, each into two, so as to make the number ten in the second progression, and each of these last being again divaricated into two at its extremity, the third and last progression is of twenty rays. All this is easily distinguishable in the fossile when perfect, and seems to have been the whole figure of the animal while living. The prototype, or living animal, however, is not found; but this is not an accident peculiar to this fossile, the cornua ammonis, and conchæ anomiæ, with many other bodies that have been once evidently shell-fish, being no where, at this time, found in their recent state, though so very numerous in the fossile world. This remarkable fossile star-fish is the body called, by some authors, *lilium lapideum*. *Keppeler*'s Epist. ad *Klein* de Entrochis.

ENTROCHORUM *Radix*, in natural history. See RADIX.

ENTRY (*Cycl.*)—ENTRY *in Casu Consimili*, in law, a writ that lies, where tenant for life, or tenant by the curtesy, aliens in fee, *&c.* He in reversion shall have this writ by Stat. Westm. 2. c. 24. See CASU *Consimili*, *Cycl.*

ENTRY *in Casu Proviso*, in law, a writ that lies where tenant

in dower aliens in fee, or for term of life, or of another's life; then he, in the reverſion, ſhall have this writ, provided by Stat. of Glouc. 6 Edw. 1. cap. 7. By which it is enacted, that if a woman alien her dower in fee, or for life, the next heir, &c. ſhall recover by writ of entry. And the writ may be brought againſt the tenant of the freehold of the land, on ſuch alienation, during the life of the tenant in dower, &c. New Nat. Br. 456. Theſe writs of *Entry* may be all brought, either in the *Per*, or in the *Cui*, or *Poſt*.

ENTRY *ad Communem legem*, in law, a writ of *Entry*, which lies where tenant for term of life, or for term of another's life, or by the curteſy, &c. aliens and dies, when he in the reverſion ſhall have this writ againſt whomſoever is in poſſeſſion of the land. New Nat. Br. 461.

ENTRY *ſine Aſſenſu Capituli*, in law, a writ of *Entry* that lieth where a biſhop, abbot, &c. aliens lands or tenements of the church, without the aſſent of the chapter or convent. F. N. B. 195.

ENTRY *ad terminum qui præteriit*, in law, a writ of *Entry* brought againſt a tenant for years, who holdeth over his term, and thereby keeps out the leſſor: And if the huſband and wife leaſe the wife's land for years, and the huſband dieth, and the tenant holds over his term, the wife may have a writ of *Entry ad terminum qui præteriit*, &c. But ſhe muſt count that ſhe and her huſband leaſed the land, &c. Alſo the grantee, in reverſion, may have this writ againſt the leſſee, or his aſſignee, &c. New Nat. Br. 447. 448.

ENTYPOSIS, in anatomy, the articulation of the ſhoulder with the arm.

ENULÆ *Radix*, *Elecampane*. See HELENIUM.

ENULION, a word uſed by ſome medical writers for the fleſh of the gums.

ENUMERATION, in rhetoric. See SYNATHROISMUS.

ENUR, a word uſed, by ſome of the chemical writers, to expreſs the occult, or unſeen vapour of water, of which they ſuppoſe ſtones to be produced.

ENURE, in law, ſignifies to take place, or be available; and is as much as to have effect. Thus, for inſtance, a releaſe made to tenant for life ſhall *enure*, and be of force and effect to him in the reverſion. *Littlet*.

ENXYLON, a name uſed, by the Greek authors, for a ſpecies of worm, or maggot, hatched from the egg of a beetle, and having its habitation in wood; which in this ſtate, it erodes and burrows into in various directions. The old Greeks called it alſo dex and thrips, and uſed the pieces of wood, eroded by it in remarkable figures, as ſeals. See the article THRIPS.

ENYSTRON, a word, uſed by Ariſtotle, for the ſecond ventricle, in ruminating quadrupeds, in which the food is elaborated and concocted.

EON, a word uſed, by ſome anatomical writers, to expreſs the whole ambit, or compaſs of the eye.

EPACTHES, Επαχθης, in antiquity, a feſtival celebrated in honour of Ceres, named Αχθεια, from Αχθος, *i. e.* grief, in memory of her ſorrow, when ſhe had loſt her daughter Proſerpine. *Pott.* Archæol. Græc. l. 2. c. 20. T. 1. p. 394.

EPAGOGION, a word uſed by Dioſcorides, and ſome other old writers, for the prepuce.

EPANADIPLOSIS, Επαναδιπλωσις, in rhetoric, the ſame with what is otherwiſe called *Epanalepſis*. See EPANALEPSIS.

EPANALEPSIS, Επαναληψις, in rhetoric, the repetition of the ſame word in the beginning of one ſentence, and at the end of another. Thus Virgil,

Ambo florentes ætalibus, Arcades ambo.

EPANAPHORA, Επαναφορα, in rhetoric, the ſame with *Anaphora*. See ANAPHORA, *Cycl.*

EPANASTASIS, a word uſed by Hippocrates, and others of the old phyſicians, for a critical tumour, or tubercle, in certain diſeaſes. Thus Hippocrates obſerves, that tumours about the eyes, upon the recovery of the patient, prognoſticate diarrhæas.

EPANASTROPHE, Επαναστροφη, in rhetoric, the ſame with what is otherwiſe called *Anadiploſis*. See ANADIPLOSIS.

EPANEYLOTOS, a ſort of wreathed bandage, deſcribed by Oribaſius.

EPANODUS, Επανοδος, in rhetoric, a repetition of the ſame words, in an inverted order; thus:

Nox brevis nimis, ah! nimis brevis nox. Voſſ. Rhet. l. 5. p. 298.

EPAPHÆRESIS, a term uſed, by Galen, for frequently repeated evacuations of the veſſels by phlebotomy.

EPAPHALESIS, in medicine, an iterated or repeated phlebotomy. *Blancard.*

EPARCHUS, Επαρχος, an officer under the Greek emperors of Conſtantinople, who had the command of the guards, or government of a province. *Hofm.* Lex.

EPARER, in the manege, is uſed to ſignify the flinging of a horſe, or his yerking and ſtriking out with his hind legs. In caprioles a horſe muſt yerk out behind with all his force; but in ballottades he ſtrikes but half out; and in croupades he does not ſtrike out his hind legs at all. All horſes that yerk are reckoned rude. See YERK.

EPARITA, in the materia medica, a name given, by Paracelſus, to a ſort of fine earth, of a liver colour, ſeemingly the ſame with the Tokay bole.

EPARMATA, in medicine, are tumours of the glandules, called *Parotes*, behind the ears. *Blancard.*

EPARSIS, in the medical writings of the antients, a word ſometimes applied indifferently to any tumour, but more uſually appropriated to a parotis.

EPEMBOLE, Επεμβολη, in rhetoric, the ſame with *Parembole*. See PAREMBOLE.

EPENCRANIS, a name by which ſome of the old authors, particularly Eraſiſtratus, have called the cerebellum.

EPENDYTES, Επενδυτης, among the Greeks, a garment worn under the *pallium*, and above the *interula*, or inner coat, called in Greek ὑποδυτης. *Hofm.* Lex. in voc.

EPERLANUS, in ichthyography, the name uſed, by moſt authors, for the common ſmelt. It is claſs'd, by the generality of writers on theſe ſubjects, among the truttaceous kinds, and is acknowledged to have a general external reſemblance to the ſalmon. Its characters, by which it is diſtinguiſhed from all the reſt of the truttaceous kinds, are, 1. That it is much ſmaller than any other. 2. It is longer and ſlenderer, in proportion to its ſize: And 3. It has a very grateful ſmell, which ſome have compared to that of the violet. Some authors have hence called it the viola, and others, particularly Schonefeldt, calls it the *ſpirinchus*. *Willughby*'s Hiſt. Piſc. p. 202.

EPERON, in natural hiſtory, the ſpur ſhell, ſo called from its reſembling, in ſome degree, the rowel of a ſpur. It is a ſpecies of ſnail, of the round-mouthed kind, or claſs of the cochleæ lunares; all its volutæ are ſurrounded with double rows of prickles. See LUNARES COCHLEA.

EPERVIERS, in natural hiſtory, a name given, by the French authors, to a claſs of butterflies, which make the ſixth in Reaumur's method. They have a way of poizing themſelves on the wing in the manner of kites, and other birds of prey; and always live upon the wing, never ſettling themſelves upon the flowers they feed upon, but keeping flying with a humming noiſe, like a humble bee, while they thruſt in their trunk, and ſuck the juices of the flower. *Reaumur*'s Hiſt. Inſect.

EPHÆTIUM, in botany, a name by which ſome authors have called the ranunculus, or crow-foot. *Ger.* Emac. Ind. 2.

EPHEBÆUM, Εφηβαιον, in antiquity, the place where the ephebi, or youth, exerciſed; or, as ſome ſay, where thoſe who deſigned to exerciſe, met, and agreed what kind of exerciſe they ſhould contend in, and what ſhould be the victor's reward. *Pott.* Archæol. Græc. l. 1. c. 8. p. 38.

EPHEBI, Εφηβοι, among the Athenians, a deſignation given their young men, when they arrived at eighteen years of age; at which time they had their names entered in a public regiſter. *Pott.* Archæol. Græc. l. 1. c. 9. T. 1. p. 48.

EPHEDRA, in botany, the name of a genus of plants, the ſpecies of which are theſe. 1. The *Ephedra*, or anabaſis of Bellonius, called, by ſome, the climbing ſea knot graſs. 2. The great ſea *Ephedra*, called the ſea grape, or great ſea knot graſs. 3. The dwarf ſea *Ephedra*. 4. The Spaniſh ſhrubby *Ephedra*, with very narrow and thick ſet leaves. *Tourn.* Inſt. p. 663.

EPHEDRA is alſo a name given, by many of the old writers on plants, to the *Equiſetum*, or horſe-tail. It ſeems only a corruption of the *Ephydrum* of the Greeks, which was given as a name to horſe-tail, becauſe of its growing in watery places. Pliny deſcribes, under this name alſo, a plant which, he ſays, hangs down in long and naked filaments from the branches of trees. This was certainly no other than our uſnea or hairy tree moſs, which reſembling the horſe-tails in the nakedneſs of the branches, was called by ſome other of its names, and finally by this, though very badly applicable to it. *Pliny.*

EPHELÆUM, in anatomy, is the place from which the hypogaſtrum, or lower part of the abdomen, to the ſecret parts. *Blancard*, in voc.

EPHELCIS, a word uſed, by the antient Greek phyſicians, ſometimes for the cruſt of an ulcer, and ſometimes for a ſmall abraſion, or bloody fragment, brought up by coughing in an hæmoptyſis.

EPHELIS, a name uſed, by the antient writers on medicine, for a diſorder of the face, brought on by the ſun, and drying winds, and of the nature of what we call ſun-burning. It was a certain roughneſs, hardneſs, and bad colour of the ſkin. The antients cured it by a mixture of honey, reſin, and ſal gemm.

EPHEMERA, (*Cycl.*) in medicine, the name of a ſpecies of fever, continuing the ſpace of one day, or ſometimes more; for the medical writers expreſs themſelves by ephemera ſimplex vel plurium dierum. It is, properly, an attempt of nature to eaſe herſelf of the load of a plethora, either by an abſolute diſcharge of part of the blood by an hæmorrhage, or, by reſolving it into ſerum, and expelling it in that form, the ſecretory, and excretory motions, being encreaſed beyond their natural degree. The diary fever, properly ſo called, laſts only twenty-four hours; but this differs in nothing, except the time of its duration, from the ephemeron plurium dierum, which commonly laſts four days. To this it is to be added, that ſome authors have called the ſudor anglicus,

Ephemera maligna, a malignant diary fever, as it generally deſtroyed the patient in the ſpace of one day.

The ſimple diary fever uſually ſeizes the patient without any preceding ſhivering, and immediately is attended with a degree of heat of the fleſh, which continues the ſame without intermiſſion or exacerbation, till the cloſe. This is uſually not very violent, and is always attended with pains in the head, ſometimes heavy and dull, ſometimes pulſative and very acute. Such perſons as fall into this fever, from drinking large draughts of cold liquors while they are hot, as is very frequently the caſe, always have a pain in the right hypochondrium. The face is red, and inflated in this diſeaſe, and there is a laſſitude and wearineſs in all the limbs, the pulſe is ſtrong and quick, the urine is of a deep orange colour, and depoſits a reddiſh ſediment. *Junker*'s Conſp. Med. p. 263.

This fever uſually goes off in a moderate ſweat, and ſometimes, tho' leſs frequently, by a hæmorrhage at the noſe. It is ever of ſhort duration, for, if it exceeds the firſt day, it is always terminated, at the utmoſt, on the fourth or fifth. There is either very little, or very bad ſleep, during the whole time. The patient often never cloſes his eyes at all, or, if he ſleeps a little, is never ſenſible himſelf that he has ſlept.

The perſons moſt ſubject to this fever, are young men, who have much blood, and feed heartily; and ſuch as have had any habitual diſcharge of blood ſtopped upon them, whether natural, as in the hæmorrhoidal, or menſtrual diſcharges; or artificial, ſuch as frequent bleeding, cupping, and the like. And thoſe who have thrown their blood into violent emotions, by the too free uſe of ſpirituous liquors, too violent exerciſe, unuſual watchings, long ſtay by large fires, a ſudden repreſſion of ſweats by cold water, or by violent paſſions, particularly anger.

Cauſes of it. The principal general cauſes of this fever, are a plethoric diſpoſition, and a commotion of the blood; the accidental ones are a high diet, and ſedentary life, great heat of the body, from violent exerciſe, and from the ſun in hot weather; violent ſweating or heating medicines, injudiciouſly adminiſter'd; and ſudden chilling of the body when much heated.

Prognoſticks in it. The ſimple *Ephemera*, when wholly left to itſelf, is of no danger, if the perſon be kept warm, and in a ſtate of reſt; and all that need be done, in common caſes, to aſſiſt nature in it, is the frequent drinking of warm diluting liquors. When it is improperly treated, or diſturbed by a wrong regimen, it often has worſe conſequences, and, indeed, the doctor often changes this into an inflammatory or ſynochal fever, properly ſo called. It is known, that matters are properly managed, and that nature is taking her due courſe, if the urine and ſweat are properly excreted.

Method of Treatment. When the peculiar diſpoſition of the blood, or other accidents, render this fever worſe than it naturally would be, the proper courſe is to attemperate the violent emotions of the blood with nitrous, and the fixed antimonial medicines, and occaſionally, with the gentle acids, ſuch as lemon juice, and the like: And indeed, in all caſes of this kind, the frequent uſe of warm and weak liquors, with lemon juice among them, is highly to be commended. The free eruption of the ſweat, by which nature attempts to eaſe herſelf of the diſeaſe, is to be promoted by the gentle ſudorificks; nitre, crabs-eyes, and a ſmall quantity of juice of lemons, juſt enough to ſaturate the alkali of the crabs-eyes, prove an excellent medicine, to be repeated in ſmall doſes every three or four hours; and, toward night, the ſudorificks ſhould be joined to theſe, ſuch as the contrayerva root, or the like. And when it is over, there ſhould be given a few doſes of ſome gentle purge, as an infuſion of rhubard and ſena, or the like. Bleeding is unneceſſary in this fever. *Juncker*'s Conſp. Med. p. 264.

EPHEMERON, a name given by authors to a ſmall fly, called, by us, the *day fly*. It is an inſect found about the mouths of the Rhine, and ſome other rivers in Germany, and ſeems a ſort of middle ſpecies between the may fly, common with us, and bred from the Cadew-worm, and the libella, or dragon fly. It has four wings, two long, and two ſhort; two ſhort horns, ſix legs, and two very long ſtrait hairs, iſſuing from the tail. They are ſeen flying about the ſurface of the water, about midſummer, for three days, and no longer; they eat nothing, and their only buſineſs is to drop their eggs on the ſurface of the water, after they have copulated. Theſe eggs, ſinking to the bottom, produce a ſort of worms, or maggots; theſe ſoon hollow themſelves cavities in the clay, where they remain three years, growing every year about an inch in length. When the worm is come to its full growth, it riſes to the ſurface of the water, about ſix o'clock in the morning, and there iſſues from it this fly, which lays its eggs, and dies about ſix o'clock the ſame night; ſo that the life of the creature, in the fly ſtate, is only about twelve. *Swammerdam*, Hiſt. Inſ.

EPHEMERUM, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the liliaceous form, and is compoſed of three petals, and ſtands on a three-leav'd cup. The piſtil finally becomes an oblong fruit, divided into three cells, and containing ſeeds like grains of wheat.

The ſpecies of *Ephemerum*, enumerated by Mr. Tournefort, are theſe: 1. The Virginian *Ephemerum*, with large blue flowers. 2. The Virginian *Ephemerum*, with large purple flowers. 3. The Virginian *Ephemerum*, with large deep blue flowers. 4. The Virginian *Ephemerum*, with ſmaller blue flowers. 5. The Virginian *Ephemerum*, with ſmaller purple flowers. 6. The Virginian *Ephemerum*, with ſmaller white flowers. 7. The Virginian *Ephemerum*, with bluiſh white flowers. 8. The Virginian *Ephemerum*, with white and violet-coloured flowers. 9. The American *Ephemerum*, with cannacorus leaves. 10. The Indian *Ephemerum*, with arum leaves. *Tourn.* Inſt. p. 367.

EPHIDROSIS, in the medical writings of the antients, a word uſed to expreſs a ſweat, ſometimes ſlight, and not critical, and, at others, a ſymptomatick one, appearing only on the head, neck, and breaſt. Theſe are both bad ſymptoms in many diſeaſes, tho' they are often miſtaken, by the injudicious, for good ſigns, and forwarded by hot medicines, to the deſtruction of the patient. See SWEAT and SWEATING.

EPHIPPITES, in natural hiſtory, the *ſaddle ſtone*, a name given, by authors, to a ſort of ſoft ſtone, with certain depreſſions, which give it the figure of a ſaddle. See HIPPURITES.

EPHYDOR, Εφυδωρ, in antiquity, an officer in the Athenian courts of juſtice, who was to provide the plaintiff and defendant with equal water hour-glaſſes. When the glaſs was run out, they were not permitted to ſpeak any farther; and therefore we find them very careful not to loſe or miſpend one drop of their water. Whilſt the laws, quoted by them, were reciting, or if any other buſineſs happened to intervene, they gave order that the glaſs ſhould be ſtopped. *Pott.* Archæol. Græc. l. 1. c. 21. T. 1. p. 118.

EPHYDRUM, Εφυδρον, in botany, a name given, by ſome of the Greek writers, to the plant now called equiſetum, or horſe-tail. It would have been well for the world, if the authors of antiquity would have confined themſelves to ſome one name, in regard to each plant they have deſcribed to us, ſince we then ſhould have had the advantage of all the knowledge they have left behind them; but, as it is, they call the ſame plant by ſo many names, and ſome of theſe often ſynonimous to other plants alſo, that it is not eaſy to ſay, of which they meant to ſpeak. We have no other plant, mentioned in them, under the name of *Ephydrum*, but the horſetail; and if they would therefore have confined themſelves to this name, for this plant, we ſhould always have underſtood what they meant by their accounts of its virtues; but ſome have called it Hippuris, and others from that word equiſetum; theſe alſo are ſo appropriated to the plant, that they probably would not have been miſunderſtood; But when they have called it ſymphytum and polygonum, the one the name of comfry, and the other of knot-graſs, though theſe names might be both as applicable to the horſetail, for its agglutinating quality, and for the multitude of joints in the ſtalk, as to the other plants deſigned by them; yet, as they were before the received names of other plants, it might have been eaſily foreſeen, that miſtakes would ariſe from the confuſed uſe of theſe words. See *Pliny*, *Dioſcorides*, *Theophraſtus*.

Pliny has miſtaken the meaning of the authors he takes his accounts from, on this occaſion, and gives the characters of the horſetail and knot-graſs, two as different plants as well can be, in the ſame deſcription; and conſequently that deſcription can ſuit with no plant at all. Dioſcorides ſeems alſo to have fallen into the ſame error, in regard to the common name ſymphytum, which was given to this plant, and to comfry and elecampane; he recommends the horſetail in difficulties of breathing, and ſeems to mean the elecampane, not the horſetail; though in the manner in which the paſſage ſtands, it can only be conſtrued of the horſetail. This plant, the comfry, and the elecampane, all were found to agree in the quality of agglutination, whence they had their name of ſymphytum; but their other virtues are ſo very different, that the perſon who ſhould give one for the other, would run into a very great error.

EPIALOS, in the medical writings of the antients, the name of a fever, in which the patient labours under a preternatural internal heat, while he at the ſame time ſhivers with cold. It has, by ſome, been called the ſhivering fever; and the Romans named it *quercera*. Galen ſays it proceeds from a putrify'd acrid phlegm. The word is, by ſome, alſo applied to any gentle fever, or feveriſh complaint, and, by others, to the cold or ſhivering fit preceding a fever. Hippocrates calls by this name that peculiar fever which attends young women, whoſe menſes are ſtopped by taking cold, or other accidents.

EPIBATÆ, Επιβαται, among the Greeks, marines, or ſoldiers who ſerved on board the ſhips of war. They were armed in the ſame manner as the land forces, only that more of them wore full or heavy armour. *Pott.* Archæol. Græc. T. 2. p. 140.

EPICALYMMA, a word uſed by ſome of the old writers on ſhell-fiſh, and not well underſtood by their commentators. Ariſtotle has the word in his treatiſe of animals, and gives a very good explication of its meaning. He ſays that the buccinum, the purpura, and all the ſtromboide ſhells have a ſort of covering with which they ſtop up the orifice of the ſhell at

pleaſure, and that under this is placed the tongue of the creature. *Ariſtotle.*

It is plain, from this, that the author meant by the epicalymma, that ſmall oval ſhelly ſubſtance, placed at the head of the fiſh, which we call the operculum, and with which it ſhuts up the mouth of the ſhell, when it retires into it. This operculum may be at any time ſeen in the common wilk, while freſh. And as this is the original author who uſed the word, we are always to underſtand the operculum to be meant by it, if the author, who uſes it himſelf, knew what was its true ſenſe.

EPICAUMA, in medicine, a cruſty ulcer that ſometimes happens to the black of the eye.

EPICHIROTONIA, among the Athenians. It was ordained by Solon, that once every year the laws ſhould be carefully reviſed, and examined; and if any of them were found unſuitable to the preſent ſtate of affairs, they ſhould be repealed: This was called επιχειροτονια των νομων, from the manner of giving their ſuffrages, by *holding up their hands.* See a farther account of this cuſtom in *Pott.* Archæol. Græc. l. 1. c. 26. T. 1. p. 142.

EPICHORDIS, in anatomy, a name given, by ſome, to the meſentery.

EPICLEROS, Επικληρος, among the Athenians, a daughter that had no brothers, and therefore inherited her father's whole eſtate. *Pott.* Archæol. Græc. l. 1. c. 24. T. 1. p. 127.

EPICRANIUM, in anatomy, a name given, by Albinus, to the fleſhy covering of the head, divided by authors into ſeveral different muſcles. The head is covered with a thin coat; the hinder parts of this coat are called the occipital muſcles, and the forepart the frontal muſcles.

EPICRASIS, in medicine, is a gradual evacuation of ill humours in the blood.

EPICRISIS, Επικρισις, in rhetoric, a clear and brief declaration of the ſpeaker's judgment, concerning the ſubject in hand: Thus, *ego ſic ſtatuo, in optimo imperatore quatuor has res ineſſe oportere,* &c. *Voſſ.* Rhet. l. 6. p. 495.

EPICYEMA, a word uſed, by Hippocrates, to ſignify a fœtus, or a falſe conception, or mole coming on after the conception of a former or regular fœtus.

EPIDAURIA, Επιδαυρια, in antiquity, a feſtival celebrated by the Athenians, in honour of *Eſculapius.* *Hofm.* Lex. in voc.

EPIDELOS, a word uſed, by Hippocrates, for a youth in the time of his growth, from the age of ſeven to that of fourteen. The ſame author alſo uſes it in a very different ſenſe, expreſſing by it the obſervable days in a diſeaſe, ſuch as the fourth, eighth, and eleventh, which indicate what ſort of criſis is to be reaſonably expected on the great critical day.

EPIDEMIA, Επιδημια, in antiquity, private feſtivals, and times of rejoicing, when a friend, or a relation, had returned from a journey. *Pott.* Archæol. Græc. l. 2. c. 20. T. 1. p. 394.

EPIDEMIA *Apollinis*, a Delphian feſtival, in memory of a journey of Apollo. *Potter*, loc. cit.

EPIDENDRA, in natural hiſtory, a word uſed by Sir Hans Sloan, and ſome authors beſide, to expreſs thoſe plants which grow upon others, ſuch as the miſletoe, which grows upon the apple-trees, &c. Theſe are more commonly diſtinguiſhed by the name of paraſitical plants.

EPIDICASIA, Επιδικασια, among the Athenians—Daughters inheriting their parents eſtate, were obliged to marry their neareſt relation; which gave occaſion to perſons of the ſame family to go to law with one another, each pretending to be more nearly allied to the heireſs, than the reſt. The ſuit was called Επιδικασιας δικη, and the virgin, about whom the relations conteſted, Επιδικος. *Pott.* Archæol. Græc. l. 1. c. 24. T. 1. p. 147.

EPIDROMUS, in the antient ſhipping, a ſail near the ſtern, which was the largeſt but one in the ſhip. *Pitiſc.* Lex. Ant. in voc.

EPIGLOUTIS, a word uſed, by ſome of the old writers in medicine, to expreſs the upper part of the buttock.

EPIGONATIS, a name given, by ſome anatomiſts, to the patella. See PATELLA.

EPIGONION, Επιγονιον, a muſical inſtrument among the antients, with forty ſtrings. Mem. Acad. Inſcript. Vol. 5. p. 167.

EPIGRAPHES, Επιγραφεις, among the Athenians, officers that rated all thoſe of whom taxes and contributions were required, according to every man's ability, kept the public accounts, and proſecuted ſuch as were behind-hand with their contributions. *Potter*, Archæol. Græc. l. 1. c. 14. T. 1. p. 81.

EPILEPSEY (*Cycl.*)—*Hofman* extols the uſe of ambergreaſe in this diſorder. Oper. Tom. 3. Sect. 1. c. 1. §. 4. as alſo of muſk, ib. §. 9. He recommends alſo the ſpirit of hartſhorn, or of ivory, either ſimple or ſuccinated. The decoctions of the woods, guaiacum, ſaſſafras, ſantals, &c. are alſo uſeful, ib. §. 4. He adviſes great caution in the uſe of opiates, in caſes of children, and weak perſons. Ib. Cautel. Pract. §. 5.

EPILESMON, a term uſed, by the old writers in medicine, to expreſs loſs of memory.

EPIMEDIUM, *Barrenwort*, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: The cup is a four-leav'd perianthium, the leaves of which are oval, obtuſe, hollow, and ſet wide open; they are ſmall, and are not placed alternately, under the petals of the flower, but one immediately under each. Theſe fall with the flower. The flower is compoſed of four petals, of an obtuſe oval form, ſomewhat hollowed, and ſpread open. It has alſo four nectaria, formed like ſo many ſmall cups; theſe are obtuſe at the bottom, and of the breadth of the petals on which they lean. They are affixed to the receptacle at their rims. The ſtamina are four pointed filaments, applied cloſe to the ſtyle; the antheræ are oblong, erect, and contain each two cells, they are bivalve and ſplit longitudinally. The germen of the piſtillum is long, the ſtyle ſhorter, and reaching to the length of the ſtamina; the ſtigma is ſimple. The fruit is an oblong, pointed pod, compoſed of one cell, but divided by two valves; the ſeeds are very numerous and oblong. *Linnæus*, Genera Plant. p. 47.

There is only one known ſpecies of this genus, which is thus characterized by Tournefort: The flowers conſiſt of four leaves, diſpoſed in form of a croſs; theſe are all tubulated. The piſtil ariſes from the cup, and, at length, becomes a pod unicapſular, and compoſed of two valves. *Tourn.* Inſt. p. 232.

EPIMELIS, a name given, by the old writers in medicine, to a ſpecies of medlar, or, as ſome will have it, to a kind of ſummer apple.

EPIMETRON, in antiquity, an allowance given the taxgatherers in the Roman provinces, over and above the juſt quantity of wine or grain they were obliged to furniſh. The *Epimetron*, or over-meaſure, in different provinces, was different, being always greater in thoſe that were remote, than in the nearer provinces. The different kinds of things wherein it was given, made likewiſe a difference in the quantity allowed. The reaſon of allowing an *Epimetron*, or overmeaſure, was to make good the leakage of the wine, and waſte of grain, that would neceſſarily happen by tranſporting it to Rome. *Pitiſc.* in voc.

The provinces whoſe taxes were converted into money, and paid in ſpecie, were free from the *Epimetron.* Id. ibid.

EPIMORIOS, an epithet given, by Galen, to certain differences in the pulſes, with reſpect to their inequality as to the time of their beating. All times, rythms, or modulations of the pulſe, according to number, conſiſt, he obſerves, of equal, or unequal proportions. Of equal, when the time of the diſtention is equal to that of contraction; and of unequal, when the one of theſe exceeds the other; and this inequality may be from certain or uncertain exceſſes The certain exceſſes may be either in multiple proportion, or as number to number, which is the epimorion.

EPIMULIS, a name given, by ſome anatomiſts, to the patella, or knee-pan.

EPIMYTHION, Επιμυθιον, in rhetoric. See FABLE, *Cycl.*

EPINEUCOS, in the old writers of medicine, a word uſed to denote a ſort of unequal pulſe, beating differently in the different parts of the ſame artery; as when it riſes ſtrongly againſt the two middle fingers of the phyſician who feels it, and weaker at the extreams; this ſort of pulſe is deſcribed by Galen as common to hectic patients, and is called alſo perineucos.

EPINEPHELOS, in the writings of the antient phyſicians, a term uſed to expreſs the cloudy matter ſeen floating in the urine in fevers, &c.

EPINEUX *des Lombes*, in anatomy, a name given by Winſlow, and ſome other of the French authors, to certain ſmall muſcles of the loins, not mentioned by the old anatomiſts; but called, by Albinus, *inter ſpinalis lumborum.*

EPINYCTIS, in the writings of the antient phyſicians, a term uſed to expreſs a ſort of malignant puſtule, which commonly breaks out in the night. It is uſually of about the bigneſs of a large pea, and is ſometimes white, ſometimes black, according to the nature of the humour it contains, and always has a violent inflammation all round it, when it is opened there is an efflux of ſanies, and a mucous exulceration is found within; it is attended with violent pain, and uſually breaks out in the upper parts of the body. This is the account Celſus gives of the *Epinyctis*; but Paulus and Aetius underſtand it rather to be a puſtule, which gives no great pain in the day, but is very troubleſome in the night. Both accounts, however, may be right, and it may both firſt appear, and be moſt painful in bed.

EPIPACTIS, in botany, a name uſed, by ſome, for the helleborine, or wild, or baſtard black hellebore. Rondeletius alſo uſes the ſame word as the name of the herniaria, or rupture-wort. *Ger.* Emac. Ind. 2.

EPIPEDOMETRY, in mathematics, ſignifies the meaſuring of figures that ſtand on the ſame baſe. *Harris.*

EPIPETRON, in botany, a name given, by Theophraſtus and Ariſtotle, to a plant, ſuppoſed by many to be the ſame with the empetrum of Dioſcorides. But there is great reaſon to doubt whether the *Epipetron* of the two older authors be the ſame plant; and whether, if they mean two different plants by this name, either of them agree with the empetrum of Dioſcorides.

corides. Theophraſtus ſays, that his *Epipetron* never flowers; and Ariſtotle ſays, that his *Epipetron* grows on rocky places, and continues to grow after it is taken up, as the orpin and ſome other plants will do.

EPIPETRON, in botany, a name by which ſome authors have called the epimedium, or barrenwort. *Ger.* Emac. Ind. 2.

EPIPHÆNOMENA, in the writings of the antient phyſicians, a term uſed to expreſs ſuch of the ſymptoms, in certain diſeaſes, as did not uſually appear till the time that the diſeaſe was actually formed, called alſo epiginomena.

EPIPHANIA, a word uſed, by ſome of the antient phyſicians, to expreſs the external habit of the body. Galen has the word from Theon.

EPIPHEOS, in botany, the name given by the antients to the dodder, or cuſcuta, which grew upon the ſhrub they called phæos. This was the ſtæbe of the modern Greeks, deſcribed by Honorius Bellus. It was a cuſtom, among the old writers, to name the cuſcuta, or dodder, from the plant it was found growing upon, as they ſuppoſed that it in ſome degree partook of the virtues of that plant; thus that which grew upon thyme was called epithymum, and that upon the nettle, epiurtica, and that upon flax, epilinum, ſo of many others.

The ſhrub pheos was alſo called ſtæbe by Dioſcorides and Theophraſtus; and hence this dodder was ſometimes called epiſtæbe. The epiſtæbe and epipheos were therefore evidently the ſame thing; but there is yet another name often given to it, which has occaſioned a very great confuſion among the antients themſelves; ſome, inſtead of epipheos, have called it hippopheos, perhaps by a mere corruption of the word, perhaps by deſign, as expreſſing its riding on the pheos, as on a horſe. The word hippopheos very often occurs in a different ſenſe. Theophraſtus, and others of the beſt writers, uſing it as nearly ſynonymous with the word pheos, but only expreſſing the larger plants.

Dioſcorides has mentioned the hippopheos and ſtæbe as the other antient Greeks have, but tho' they have all made theſe ſynonymous names expreſſing the ſame plant, he mentions them in different parts of his works, and ſeems to look upon them as having no alliance in their nature and virtues one with another. The ſtæbe he gives, in one place, as an aſtringent, and in another he mentions the hippopheos, or, as he calls it, the hippophaës, as a purge good to carry off redundant bile. The commentators have been ſtrangely perplexed to reconcile theſe paſſages, as the ſtæbe of all the antient Greeks beſide is equally the name of the pheos and the hippopheos; and Galen, Neophytus, and Heſichius, with all the other commentators of note, render both pheos and hippopheos by the word ſtæbe. But the caſe ſeems to have been, that Dioſcorides means both theſe plants by the word ſtæbe, and that his hippopheos, which he has ſeparated from that plant, and to which he has given ſuch different virtues, is the epipheos, or cuſcuta, growing upon the pheos or ſtæbe. See EPISTÆBE.

EPIPHLEBOS, in the writings of the old phyſicians, a term uſed to denote ſuch perſons as were lean, and of a hot temperament, and whoſe veins, for that reaſon, appeared uſually very turgid and prominent, in the hands, *&c.*

EPIPHYLLOSPERMOUS *Plants*, are the ſame with the capillaries, herbs which bear their ſeed on the back part of their leaves. See CAPILLARY.

EPIPLOCE, Επιπλοκη, in rhetoric, the ſame with *Climax*. See CLIMAX, *Cycl.*

EPIPOROMA, a word uſed, by Hippocrates, and the other old writers, for a callous concretion happening at, and moleſting the joints.

EPISARCIDIUM, a name given, by many of the old authors, to an anaſarca. See ANASARCA.

EPISCENIUM, Επισκηνιον, in antiquity, a place upon the top of the theatre, where all the machines for moving the ſcenes were kept. *Potter*, Archæol. Græc. l. 1. c. 8. p. 42.

EPISCEPSIS, Επισκηψις, in antiquity, an action brought to prove the *Diamartyria*, or proteſtation that the perſon deceaſed had left an heir, to be falſe and groundleſs. *Potter*, Archæol. Græc. l. 1. c. 24. T. 1. p. 128.

EPISCIRA, Επισκιρα, in antiquity, a feſtival celebrated at Scira in Attica, in honour of Ceres and Proſerpine. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 395.

EPISCION, a name given, by the old Greek writers, to the pubes.

EPISCIROSIS, Επισκιρωσις, the ſame with *Epiſcira*.

EPISCOPALES *Valvulæ*, called alſo, by ſome, valvulæ mitrales; two valves in the pulmonary vein, which prevent the reflux of the blood to the heart.

EPISCOPALIA (*Cycl.*)—Theſe cuſtomary payments have been otherwiſe called *Onus Epiſcopale*; and were remitted, by ſpecial privilege, to free churches and chapels of the king's foundation, which were exempt from epiſcopal juriſdiction. *Kenn.* Gloſſ. ad Paroch. Antiq.

EPISCOPISSA, a word uſed, by writers of the middle ages, to denote a biſhop's wife. *Hofm.* Lex. in voc.

EPISEMASIA, in medicine, is the very time that a diſeaſe firſt ſeizes a perſon, and is properly called *ſignificatio*. *Blancard.*

EPISPHÆRIA, in anatomy, are windings and turnings in the outer ſubſtance of the brain, that the ſanguiferous veſſels may paſs more ſecurely. *Blancard.*

EPISTÆBE, in botany, a name given to the cuſcuta, or dodder, found growing on the plant ſtæbe of the antient Greeks, that is, their pheos, or hippopheos, as the dodder growing on thyme is called epithymum, and that on flax epilinum. It were well if this cuſcuta had no other name, for great confuſion has ariſen from its being alſo called epipheos, or, as ſome write it, hippopheos, making it the ſame word with the name of the larger pheos. This has even led Dioſcorides into an error, who has deſcribed, probably, from ſome other author, the epipheos, under the name of hippopheos, not diſtinguiſhing it to be only cuſcuta growing on this plant, and has given it virtues well enough agreeing indeed with cuſcuta, but not at all with the hippopheos, as moſt authors underſtand that word, that is, the larger pheos. Himſelf alſo appears to have underſtood the thing he was deſcribing, not as what it really was, but as the ſhrub itſelf; but this may be the leſs wondered at, when we recollect that the ſame author, in his account of that common kind of cuſcuta, called epithymum, did not know what it was, but took it for a more than ordinary ſtout and hardy thyme, approaching to the nature of the thymbra, ſo his own words expreſs it, not at all underſtanding that it was a ſeparate plant, which poſſeſſed none of the qualities of thyme, nor was any more of its nature, than the moſs is of the nature of the oak, beech, or other tree, on which it chances to grow.

EPISTAPHILINS, in anatomy, a name given by Winſlow, and other of the French writers, to a muſcle called, by Morgagni, the columellæ muſculus teres, and the azygos uvulæ, which laſt name has been continued to it by moſt authors. Douglas calls it the palatoſtaphilinus; and ſome of the French, the muſcle de la luette.

EPISTITES, in natural hiſtory, the name of a ſtone, deſcribed by the writers of the middle ages, as being of a beautiful red, and ſhining very elegantly. It was renowned for its many magical virtues, according to the idle tradition of thoſe times; they ſaid it drove away all noxious animals, and kept off ſtorms from the place where any one was who had it about him.

EPISTOLARES, among the Romans, under-ſecretaries to the *magiſter ſcrinii epiſtolarum*, or ſecretary, who wrote the emperor's letters. They were thirty-four in number. *Danet.* See MAGISTER.

EPISTOMIA, in anatomy, are the utmoſt gapings and meetings of veſſels.

EPISTROPHE, Επιστροφη, in rhetoric, a figure wherein that which is ſuppoſed of one thing, is ſtrongly affirmed of another. Thus, *Are they Hebrews? ſo am I. Are they Iſraelites? ſo am I. Are they the ſeed of Abraham? ſo am I*, &c. *Voſſ.* Rhet. l. 5. p. 287.

EPITHEM (*Cycl.*)—There are, principally, three kinds of theſe external applications, the liquid, the ſolid, and the ſoft, or pultice kind.

The liquid epithems are ſometimes conſiderably thick; but when they are intended to penetrate deep, they are much better if very thin and fluid. And as the part to which the *Epithem* is immediately applied, is not what it is always intended to act upon, but ſomewhat lying deep within, the *Epithems* intended for this purpoſe ſhould conſiſt of the moſt penetrating ingredients; for which reaſon aſtringents and inſpiſſating remedies can be of no uſe in this form; ſince they cannot be abſorbed ſo deep, and indeed prevent their own ingreſs, by bracing up the mouths of the pores. Hot wine alone is ſometimes uſed as an *Epithem*; and frequently ſuch medicines as are not to be ſafely taken inwardly, ſuch as highly rectify'd ſpirits, preparations of lead, henbane, mandrake, and other poiſonous plants, and the like. But we are carefully to remember, in regard to theſe, that the pores are capable of abſorbing them, and ought therefore to know the effects they are capable of producing, when thus abſorbed in the body. As to the vehicles of liquid *Epithems*, they are very various, ſuch as linen or woollen cloaths, ſilk, ſtupes, toaſted bread, crumb of untoaſted bread, the dry *Epithems*, or bags, and ſometimes the hot liquor is tied up in a bladder, and that only applied to the part. When a great quantity of the liquor is to be uſed, flannel ſtupes do beſt; but, when the heat is to be long retained, and only the finer particles of the liquor admitted, then the bladder preſerves and retains beyond all other means.

Epithems are, in ſome caſes, to be applied hot, and in others cold; when the intention is powerfully to reſolve, penetrate, and attract, then thoſe of the hot kind are greatly to be preferred; but heat is injurious to parts conſtricted by intenſe cold, and thoſe that are cold, or, at leaſt, tepid, are to be uſed. Spirituous and volatile liquors are alſo eaſily diſſipated by heat, and all ſuch ought therefore to be applied either cold, or barely tepid.

The dry *Epithems* are medicated powders, uſually ſewed up in a cloth, and applied to different parts of the body; for this purpoſe the powders muſt be coarſe, ſince otherwiſe their particles would fall through the cloth; and ſometimes the liquid *Epithems* are added to the dry, to reduce the whole to a conſiſtence, ſuch as may be ſpread upon cloth, and applied.

The antients uſed chaff of wood to mix with their powders, in the *Epithems* of the coarſer kind, and cotton in thoſe which were finer. Among the dry *Epithems* is alſo to be accounted the uſe of a bag of hot ſand. This is of ſingular ſervice where heat is to be retained a long time; and ſometimes the liquid *Epithems* are added to this, its heat being of power to throw them much farther in, than they otherwiſe would reach. The bags in which any of theſe dry *Epithems* are put, muſt not be filled hard, but only the matter muſt be lightly put in, that they may remain pliant and ſpungy. Some make the bags, for dry *Epithems*, of ſilk, and ſome of woollen cloth; but linen, which has been much worn, is greatly preferable on all occaſions. The figure of the bag is to be accommodated to the part it is to be applied to, and the intention it is to anſwer. For the head, it is commonly made in the form of a hood; for the forehead, ſquare; for the heart, pyramidal; for the ſtomach, in form of a ſhield; for the liver, in form of a creſcent; and for the ſpleen, in ſhape of an ox's tongue. When the bags are ſmall, it is ſufficient to ſow up the end, when the matter is put in; but when they are large, they muſt be ſewed acroſs in ſeveral places, in the manner of quilting, to keep the matter equally diſtributed. When they are thus prepared, they are to be applied either alone, being firſt warmed, or moiſtened with any proper liquor. Pigeons applied to the feet are alſo properly a ſort of *Epithem.*

Volatile EPITHEM, *Epithema volatile*, a form of medicine preſcribed in the late London pharmacopœia, and ordered to be made of equal weights of common turpentine and ſpirit of ſal armoniac. The turpentine is to be kept continually ſtirring in a mortar, and the ſpirit gradually dropt in, till the whole is reduced to a white maſs.

The ſpirit of ſal armoniac, uſed in this mixture, muſt not be that made in the common way; with the addition of quick lime, but with the alkali ſalt. *Pemberton*'s London Diſp. p. 377.

EPITHESIS, in ſurgery, a word uſed, by ſome writers, to expreſs the reducing, or rectification, of crooked limbs, by means of proper inſtruments.

EPITHRICADIA, Επιθρικαδια, in antiquity, a feſtival in honour of Apollo. *Potter.*

EPITHYME, *Epithymum* (*Cycl.*)—Many of the writers of the middle ages have fallen into great errors about this plant, deſcribing it in their writings as a kind of thymum, or thyme, different from the common ſpecies, but not at all underſtanding that it was a plant of a wholly different kind, and that had no ſort of connection with the thyme, other than its growing on that plant, as the plant itſelf does on the earth. Some have ſuppoſed from this, that they meant an herb different from our epithymum, and that though the dodder, or cuſcuta, growing on thyme, be now called epithymum, yet, in other ages, a peculiar ſpecies of thyme itſelf was called by this name. To this it is eaſily anſwered, that the virtues of thyme are corroborative, carminative, and cordial, and that theſe muſt take place in all ſpecies of thyme, one as well as another; and that the virtues of cuſcuta, or dodder, are cathartic and cholagogue; and that theſe alſo muſt take place in dodder, grow it on what plant it will. Now the authors who deſcribe epithymum as a kind of thyme, ſtill give it the virtues of a cathartic, and particularly a purger of bilious humours, and not one of thoſe of the thyme itſelf: It is evident, from hence, that their deſcription was bad, and that their epithymum, was the ſame with ours, tho' they ſeem never to have ſeen it. It is to be obſerved, that, in all theſe falſe deſcriptions, the terms are very exactly the ſame. They all ſay it was more hard and woody than the common thyme, and approached to the nature of thymbra. This ſhews that they are all copied one from another, and the original we can trace up to an author, whom it grieves one to cenſure on ſuch an occaſion, no leſs than Dioſcorides being at the head of it. It is evident that this author had no knowledge of any ſuch plant as cuſcuta, or dodder, growing on the ſeveral other vegetables, on which ſome of his predeceſſors had found it, and preſcribed it in medicine. The dodder growing on the pheos, or ſtæbe, a prickly ſhrub of Crete, uſed by the fullers, was called, by the old writers, epipheos and epiſtæbe. Dioſcorides has written it hippopheus, the very name of the larger ſpecies of pheos, and yet has given it the purging virtues of cuſcuta; and, in the ſame manner, he has deſcribed the epithymum as a kind of thyme, more ſhrubby than the others, and reſembling thymbra. Theſe are his expreſs words, as well as thoſe of later writers; yet he has given this alſo its proper virtues, as dodder, ſaying, that it is a purge and a cholagogue, and thus has proved that he meant our cuſcuta, though he has deſcribed it in ſo very improper a manner.

EPITHYMUM, in medicine. See DODDER.

EPITROCHASMUS, Επιτροχασμος, in rhetoric, a figure wherein we ſlightly paſs over ſeveral things of great moment, by only mentioning them in general. Such is the ſaying of Cæſar, *veni, vidi, vici.* And the following paſſage of Virgil, Æn. 4.

——————*Faces in caſtra tuliſſem,*
Impleſſemque foros flammis, natumque patremque
Cum genere exſtinxem, memet ſuper ipſa dediſſem.
Voſſ. Rhet. l. 5. p. 374.

EPIZEUXIS, Επιζευξις, in rhetoric, a figure where the ſame word is repeated, without any others intervening: Thus, *age, age*; *adeſte, adeſte*; and that of Virgil, *nunc, nunc inſurgite remis*, are inſtances of it. *Voſſ.* Rhet. l. 5. p. 292.

EPNEUMATOSIS, in medicine, the ſame with expiration.

EPOBOLIA, Επωβολια, in antiquity, a fine laid upon thoſe that could not prove the indictment they had brought againſt their adverſaries.

It was ſo called, becauſe they were obliged to pay the ſixth part of the value of the thing they contended for, viz. an obolos out of every drachm. Some of theſe ſums were depoſited in all law-ſuits, a very few excepted, before the trial could proceed. *Potter*, Archæol. Græc. l. 1. c. 21. T. 1. p. 117.

EPOCHETEUSIS, a word uſed by Hippocrates, and others of the old writers in medicine, to expreſs the derivation of the blood, or juices, from one part to another.

EPODOS, in medicine, a word uſed to expreſs the curing of diſeaſes by incantation.

EPOICODOMESIS, Επωικοδομησις, in rhetoric, is ſometimes uſed for what is otherwiſe called *Climax*. *Voſſ.* Rhet. l. 5. p. 294. See CLIMAX, *Cycl.*

EPOMIS, in anatomy, a name given, by ſome authors, to a muſcle now generally known by the name of the *Deltoides*. See DELTOIDES.

EPOMPHALION, any medicine which purges, on being applied to the navel.

EPOPS, Επωψ, in zoology, a name by which ſome of the antient writers have called the bird we call the upupa, or hoopo. *Ray*'s Ornitholog. p. 100. See the article UPUPA.

EPOSILINGA, a word uſed, by ſome of the chemical writers, to expreſs the ſcales which fly off from iron, when hammered at the ſmith's forge.

EPOTIDES, in the antient ſhip building, two large thick pieces of wood on each ſide of the prow of a galley, which reſembled two ears, whence they had their name.

The *Epotides* were chiefly deſigned to ward off the blows of the roſtra of the enemies veſſels. *Pitiſc.* Lex. Ant.

EPSOM *Salt.*—What we now meet with, in the ſhops of chemiſts, under this name, is no other than a ſalt made from the bittern, or remaining brine after the making of common ſalt: But when the world was firſt made acquainted with a purging ſalt, under this name, it was truly what its name expreſſed, being really made from the purging waters of that place. This ſalt is bitter, and of a ſtrongly purging quality, and, when ſuffered to ſhoot freely, and its cryſtals at a due diſtance, it always form'd them into rectangular priſms, with four parallellogram planes; by this, and by divers other properties, it appeared evidently different from all other ſalts known at that time. It was ſuppoſed to partake of the nature of allum, and the waters of the place were called alluminous waters; but Dr. Grew has evidently proved the error of that opinion; others ſuppoſed this ſalt the ſame thing with the ſalt of lime, or the nitre of old walls, but this was equally erroneous. The beſt method of taking it was found to be diſſolving it in a proper quantity of its own water; by this means the water was made to work both more quickly and more effectually; and it proved of great ſervice in diſorders of the ſtomach, as want of appetite, and the like, and in colics, diabetes, the ſcurvy, and rheumatiſm, and many other chronic diſeaſes. Phil. Tranſ. N°. 216. p. 76.

Mr. Bolduc has given much the ſame deſcription of the manner of making *Epſom ſalt*, as Mr. Brown had done in Phil. Tranſ. N°. 337. §. 10. and N°. 378. §. 11; that it is the ſalt which cryſtalizes, after boiling to a due conſiſtence, the bittern, which is the liquor remaining in the ſalt-pans, after the ſea ſalt is ſeparated. See Mem. Acad. Scienc. 1731.

EPSOM *Water.*—This is a water eaſily imitated by art. By only diſſolving half an ounce of *Epſom* ſalt in a quart of pure water, made ſomewhat briſk or quick by a few drops of ſpirit of vitriol and oil of tartar, ſo as to let the alkali prevail. *Shaw*'s Lectures. p. 90.

EPTACTIS, in natural hiſtory, a name given by Linkius, and ſome other authors, to a ſpecies of ſtar-fiſh, of the aſtrophyte kind, whoſe rays, or branches, at their firſt going out from the body, are only ſeven in number; but which very ſoon ſpread into more. See STELLA *Marina*, and ASTROPHYTE.

EPULÆ, *Entertainments*, among the antients. See ENTERTAINMENTS.

EPULARES, in antiquity, an epithet given thoſe who were admitted to the ſacred *Epulæ* or entertainments, it being unlawful for any to be preſent at them who were not pure and chaſte. *Pitiſc.*

EPULETIC *Medicines*, the ſame with *Cicatrizantia*. See CICATRISIVE, *Cycl.*

EPULIDES, in ſurgery, certain fleſhy tubercles, or excreſcences of the gums: Theſe are of two kinds, ſome being of a

mild

mild nature, others painful, malignant, and inclining to be cancerous. Surgeons diſtinguiſh them alſo into the larger and the ſmaller, and the harder and ſofter; they are ſometimes ſupported by a broad, ſometimes by a narrow root. Theſe excreſcences not only deform the mouth, but hurt the ſpeech and maſtication, and are always beſt ſpeedily extirpated.

When they grow to a ſmall root, they are beſt extirpated by ligature, or tying a thread firmly about the root; but when the root is broad, they are beſt eaten off by cauſtics, as the oil of tartar, ſpirit of ſal armoniac, and the like, and when theſe mild ones prove ineffectual. It is beſt not to have recourſe to ſtronger, but to raiſe the tubercle with the hook or pliers, and carefully extirpate it with the knife, not cutting off the gums, ſo as to uncover the roots of the teeth, which would be probably attended with a caries of the bone. The blood ſhould be permitted to flow from theſe for ſome time, but if the hæmorrhage continues too long, the patient muſt waſh his mouth with hot red wine, with allum diſſolved in it, repeating it till it ceaſes. And afterwards tincture of myrrh, and honey of roſes, ſhould be uſed till the parts are perfectly well; and, if the tubercles ſhould ſprout up again, they ſhould be taken down in time by the ſame methods. *Heiſter*'s Surgery, p. 462. See alſo *Schelhammer* de Epulide.

EPULONES, in antiquity, a claſs, or order of prieſts, who had the management of feaſts, games, and feſtal ſacrifices, under their inſpection. *Pitiſc.* Lex. Ant. in voc.

EQUANT *Circle*, in the old aſtronomy, a circle deſcribed on the center of the *Equant*. Its principal uſe is to find the variation of the firſt inequality.

EQUATED *Bodies*. On Gunter's ſector there are ſometimes placed two lines, anſwering one another, and called *the lines of equated bodies*: They lie between the lines of ſolids and ſuperficies, and are noted with the letters D, I, C, S, O, T, for Dodecahedron, Icoſihedron, Cube, Sphere, Octahedron, and Tetrahedron.

The uſe of theſe lines are, 1. When the diameter of the ſphere is given, to find the ſides of the five regular bodies, ſeverally equal to that ſphere. 2. From the ſide of any of the bodies being given, to find the diameter of the ſphere, and the ſides of the other bodies, which ſhall be equal ſeverally to the firſt body given.

If the ſphere be firſt given, take its diameter, and apply it over in the ſector in the points S, S: If any of the bodies be firſt given, apply the ſide of it over in its proper points: So the parallels taken from between the points of the other bodies, ſhall be the ſides of thoſe bodies, equal ſeverally to the firſt body given.

EQUATION (*Cycl.*)—*Cubic* EQUATION. The ſecond terms of a cubic *Equation* being taken away, they may be all reduced to this form: $x^3 + ax + b = 0$. Where

$$x = \sqrt[3]{-\tfrac{1}{2}b + \sqrt{\tfrac{1}{4}bb + \tfrac{1}{27}a^3}} + \sqrt[3]{-\tfrac{1}{2}b - \sqrt{\tfrac{1}{4}bb + \tfrac{1}{27}a^3}}.$$

This rule is commonly aſcribed to Cardan, and from him has been called *Cardan's Rule*; but it is ſaid by ſome [a], that Tartalea was the inventor, and, by others [b], Scipio Ferreus, to whom, it is ſaid, Cardan himſelf aſcribes the invention.—[a *Lagni* Elem. d'Arithmet. & d'Algebr. p. 479. b *Wolf.* Elem. Matheſ. Tom. 1. p. 336. Edit. 2. and *Saunderſon*'s Algebra, p. 702.]

When, in a cubic *Equation*, $x^3 - ax \pm b = 0$, a is negative, the expreſſion $\sqrt{\frac{1}{4}bb + \frac{1}{27}a^3}$, will be transformed into $\sqrt{\frac{1}{4}bb - \frac{1}{27}a^3}$, which becomes impoſſible, or imaginary, when $\frac{1}{27}a^3$ is greater than $\frac{1}{4}bb$; for $\sqrt{\frac{1}{4}bb - \frac{1}{27}a^3}$ will then be the ſquare root of a negative quantity, which is impoſſible. And yet, in this caſe, the root x may be a real quantity. But algebriſts have not yet been able to find a real expreſſion of its value. This caſe is called the *irreducible*, *ireductible*, or *impracticable* caſe. See IRREDUCIBLE.

The irreducible caſe may be ſolved by the triſection of an arc, for which the reader may conſult Saunderſon's algebra, p. 713.

This method requires a table of ſines, and if ſuch be not at hand, we may have recourſe to Dr. Halley's univerſal method of extracting the roots of *Equations*, in the philoſophical tranſactions, or in Lowthorp's abridgment, Vol. 1. C. 1. §. xx. Vid. infra.

There are ſeveral other methods, of extracting the roots of cubic *Equations*, extant in books of Algebra.

Mr. Cotes obſerves, in his logometria, p. 29, that the ſolution of all cubic *Equations* depends either upon the triſection of a ratio, or of an angle. See this method explained and demonſtrated in *Saunderſon*'s Algebra, p. 718.

Biquadratic EQUATION.—Des Cartes gave a method of reducing biquadratic *Equations* to cubic. This method is explained in moſt treatiſes of algebra, ſince his time; and very clearly by the marquis de l'Hôſpital in his conic ſections, Art. 356. See alſo *Maclaurin*'s Algebra, p. 228. ſeq.

Hence a biquadratic *Equation* being propoſed, it may be ſolved, by reducing it firſt to a cubic *Equation*; and then finding the roots of this new *Equation*, by the triſection of an angle, or of a ratio. Theſe roots, ſo found, having a given relation to the roots of the propoſed biquadratic, theſe will alſo be given.

EQUATIONS *of higher Degrees*.—We have no univerſal rule to expreſs, algebraically, the roots of *Equations*, higher than biquadratic. But ſuch *Equations* may be ſolved univerſally in numbers, by Dr. Halley's method of approximation.

This method proceeds by aſſuming the root deſired, nearly, true to one or two places; which may be done by a geometrical conſtruction, or by a few trials; and then correcting the aſſumption, by comparing the difference between the true root and the aſſumed, by means of a new *Equation*, whoſe root is that difference, and which he ſhews how to form from the *Equation* propoſed, by ſubſtitution of the value of the root ſought, partly in known, and partly in unknown terms.

The Doctor's method will eaſily be underſtood by an example. See p. 9.

Dr. Brook Taylor found that this method was capable of a greater degree of generality, and that it was applicable, not only to *Equations* of the common form, that is, to ſuch as conſiſt of terms, wherein the powers of the root are poſitive and integral, without any radical ſign, but alſo to all expreſſions in general, wherein any thing is propoſed as given, which by any known method might be computed; if, *vice verſa*, the root were conſidered as given. Such are all radical expreſſions of binomials, trinomials, or of any other nomial, which may be computed by the root given, at leaſt, by logarithms, whatever be the index of the power of the nomial; as likewiſe expreſſions of logarithms, of arches by the ſines or tangents, of arcs of curves by the abſciſſæ, or any other fluents, or roots of fluxional *Equations*. See Phil. Tranſ. N°. 352. *Jones*'s Abridg. Vol. 4. c. 1. §. xvii.

The method of finding the roots of *Equations* by approximation, extends to all kinds of *Equations*, and though it be not accurately, yet it is practically true; as it gives the value ſought, to a very great degree of exactneſs, nay, to any aſſignable degree, if any one will take the pains of computation.

The method of Sir Iſaac Newton, and of Mr. Raphſon, is, in effect, the ſame as that mentioned in the Cyclopædia, under the head APPROXIMATION. See further in *Newt.* Meth. of Flux. and Mr. *Colſon*'s Comment. p. 186. But Dr. *Halley*'s Method is more expeditious in practice. See Phil. Tranſ. N°. 219. or *Lowthorp*'s Abridg. Vol. 1. c. 1. §. xx. The principles of theſe methods may alſo be found in Mr. Maclaurin's algebra, part. 2. c. 9. or in Mr. Simpſon's algebra, p. 147. ſeq. who gives ſeveral formulæ for the approximating to the roots of *Equations*. This gentleman has alſo another method for this purpoſe, which we ſhall mention further on.

Mr. Daniel Bernoulli, in the *Acta Petropolitana*, Tom. 3. p. 92. ſeq. has given a new and ingenious method of approximating to the roots of *Equations*, without any previous trials. The method is deduced from the nature of recurring ſeries. The book wherein it is publiſhed being in few people's hands, we ſhall here give a full account of this method.

Let the propoſed *Equation* be put into this form:

$$1 = ax + bxx + cx^3 + ex^4 +, \&c.$$

Then form a ſeries, beginning with as many arbitrary terms as the *Equation* has dimenſions, but with this condition, that if A, B, C, D, E, &c. denote the terms following each other in direct order, then muſt $E = aD + bC + cB + eA +$, &c. and let there be two proximate terms, M, N, in this ſeries ſufficiently continued; then will the antecedent M, divided by the conſequent N, be nearly equal to the required root.

For inſtance, let $1 = -2x + 5xx - 4x^3 + x^4$. Form a ſeries, beginning with four arbitrary numbers, 1 . 1 . 1 . 1 (as the propoſed *Equation* is of four dimenſions) and let a new term always be formed from the double of the laſt preceding, taken negatively, more the quintuple of the penultimate, leſs the quadruple of the antepenultimate, more the penantepenultimate. This ſeries will be 1 . 1 . 1 . 1 . 0 . 2 . — 7 . 25 . — 93 . 341 . — 1254, &c. and the approximated root of the *Equation* propoſed will be nearly $= -\frac{341}{1254}$.

Again, let $1 = x + 2xx + 3x^3 + 4x^4 + 5x^5$. Form a ſeries, beginning with five arbitrary terms, 1 . 1 . 1 . 1 . 1 . 1 . 15 . 29 . 71 . 183 . 477 . 1239 . 3171, &c. Here $\frac{1239}{3171}$ or $\frac{413}{1057}$ will be nearly equal to one of the roots of the *Equation*.

The root here found is the leaſt of the roots, without attending to the ſigns; that is, the root ſo determined is that which is leaſt diſtant from nothing.

To find the greateſt root of a propoſed *Equation*, let it be diſpoſed in the following manner:

$$x^m = ax^{m-1} + bx^{m-2} + cx^{m-3} \ldots\ldots + d.$$

Then form a ſeries, beginning with as many arbitrary terms as there are dimenſions in the *Equation*, ſo that if A, B, C, D, E, &c. denote ſo many contiguous terms directly following each other in the ſeries, E muſt be every where $= aD + bC + cB + dA$, &c. Laſtly, let there be two proximate terms, M and N, in this ſeries, ſufficiently continued, then will

will the conſequent term N, divided by the antecedent M, be nearly equal to the required root.

For inſtance, let us take one of the foregoing *Equations*, the leaſt root of which was found to be $-\frac{341}{1254}$; and let the *Equation* be thus diſpoſed:

$$x^4 = 4x^3 - 5xx + 2x - 1.$$

Then form this ſeries,

1 . 1 . 1 . 1 . 0 . — 4 . — 15 . — 41 . — 97 . — 209.

And $\frac{209}{97}$ will be nearly equal to the greateſt root of the propoſed *Equation*.

In the application of the rule for finding the leaſt root, the author obſerves, that ſome difficulties may ariſe in two caſes. Firſt, when the leaſt root of the *Equation* may be taken either affirmatively, or negatively. Secondly, when the leaſt root is imaginary, as if the *Equation* had theſe roots, $+\sqrt{-4}$, $-\sqrt{-4}$, and 5; of which the laſt is to be conſidered as greateſt, that is, according to his definition, as fartheſt diſtant from nothing.

In the firſt caſe, the alternate terms only are to be conſidered, and if they tend towards a conſtant ratio, while the contiguous terms deviate, it will argue an equality between the affirmative and negative root. And, in this caſe, a term in the ſeries muſt be divided by the alternate term following; and the ſquare root of the quotient will be the root of the *Equation*: For inſtance, if we had, $1 = -y + 4yy + 4y^3$; then forming a ſeries according to the firſt rule, we ſhall have

1 . 1 . 0 . — 4 . 36 . — 20 . 148 . — 84 . 596 . — 340. 2388, &c.

And the tenth term 596, divided by the alternate term following, or the twelfth, 2388, gives $\frac{596}{2388}$, or $\frac{149}{597}$, nearly equal to the ſquare of the required root, which will therefore be, nearly, $\pm\sqrt{\frac{149}{597}}$. This example ſhews that the rule approximates ſufficiently faſt; for the number found $\frac{596}{2388}$ differs from the truth only by $\frac{1}{2388}$, the true root being $\pm\frac{1}{2}$.

The inconvenience, here mentioned, might alſo be remedied, by taking $x = y \pm a$; and then finding the root of the tranſformed *Equation* by the firſt rule.

In the ſecond caſe, when the leaſt root is imaginary or impoſſible, it is to be conſidered whether the root will be affirmative or negative; if the former, put $x = y + a$, if the latter, $x = y - a$. And then the value of y may always be found by the rule; providing that a be aſſumed greater than x. But though we ſhall never be diſappointed by taking any greater number for a; yet it is to be obſerved, that the leſs $a - x$ is, the more eaſily and quickly will the ſeries tend to the required root. Some circumſpection is therefore requiſite.

For inſtance, let $1 = \frac{x + xx - x^3}{2}$.

If we form a ſeries without any previous examination, ſuch as

$$1 . 1 . 1 . \frac{1}{2} . \frac{1}{4} . \frac{1}{8} . — \frac{3}{16} . — \frac{9}{32} . — \frac{11}{64} . — \frac{17}{128} —, \text{ \&c.}$$

we ſhall never find any root, as the terms of the ſeries do not tend to any conſtant ratio. But ſuppoſing $x = y - 2$ (for it is viſible that the negative root cannot be great) we ſhall have

$$1 = \frac{15y - 7yy + y^3}{8}$$

or, to avoid fractions, ſuppoſe, $y = 8z$, that is, $x = 8z - 2$. Then we have

$$1 = 15z - 56zz + 64z^3.$$

From this *Equation* the following ſeries ariſes:

1 . 1 . 1 . 23 . 353 . 4071 . 42769 . 436151 . &c.

Hence $z = \frac{42769}{436151}$; and $x = -\frac{530150}{436151}$

For a ſecond example, take this *Equation*,

$1 = \frac{-x - xx + x^3}{2}$; from whence this ſeries ariſes,

$$1 . 1 . 1 . — \frac{1}{2} . \frac{1}{4} . \frac{5}{8} . — \frac{11}{16} . \frac{5}{32} . \frac{37}{64} . — \frac{91}{128} . \text{ \&c.}$$

Which gives no root; but taking $x = y + 3$ (as it appears that x muſt be affirmative) this *Equation* will ariſe, $1 = \frac{-20y - 8yy - y^3}{13}$, or rather taking $y = 13z$, that is, $x = 13z + 3$, we ſhall have $1 = -20z - 104zz - 169z^3$. This laſt *Equation* gives the following ſeries:

1 . 0 . 1 . — 20 . 296 . — 4009 . 52776 . — 688608

Whence $z = -\frac{52776}{688608}$; and $x = \frac{1379736}{688608} = 2{,}0036$ nearly; x being exactly $= 2$.

As to the caſe before mentioned, of the equality of two roots, it is alſo to be obſerved, that a like rule may be applied, where more than two roots are equal, providing they be real. But in caſe ſome of theſe equal roots ſhould be impoſſible, and the reſt real; as if $x^4 - 1 = 0$, where $x = 1$, $x = -1$, $x = \sqrt{-1}$, and $x = -\sqrt{-1}$, all which roots, by our author's definition, are to be conſidered as equal, or equally diſtant from nothing. We may obviate this inconvenience, by ſuppoſing $x = y \pm a$; which is therefore an univerſal remedy.

This will lead us to a method of extracting the roots of powers. For inſtance, if we wanted the cube root of 2.

Then $x^3 = 2$ or $1 = \frac{x^3}{2}$

The ſeries, formed according to this *Equation*,

$$1 . 1 . 1 . \frac{1}{2} . \frac{1}{2} . \frac{1}{2} . \frac{1}{4} . \frac{1}{4} . \frac{1}{8} . \frac{1}{8} . \frac{1}{8} . \text{ \&c.}$$

only ſhews, that $x^3 = 2$. But taking $x = y + 1$, the propoſed *Equation* will be tranſformed into the following, $1 = 3y + 3yy + y^3$. From whence this ſeries may be derived,

1 . 1 . 1 . 7 . 25 . 97 . 373 . 1435 . 5521 .

Therefore $y = \frac{1435}{5521}$; and $x = \frac{6956}{5521} = 1.2597$ nearly.

Again, let it be required to extract the biquadrate root of 20: then $x^4 = 20$, and ſuppoſing $x = y + 2$, we ſhall have

$1 = 8y + 6yy + 2^3y + \frac{1}{4}y^4$; from whence this ſeries is obtained, 0 . 0 . 0 . 1 . 8 . 70 . 610 . 5316 $\frac{1}{4}$. 46332 .

This gives $y = \frac{21265}{185328}\left(= \frac{5316\frac{1}{4}}{46332}\right)$ and $x = \sqrt[4]{2}\,\frac{21265}{185328}$.

Which root approaches very near to the truth; ſo that it is much to be doubted whether the ſame could be obtained ſo quickly, and ſo accurately, by any other method.

Suppoſe again, that the ſquare root of 26 were required. Then $xx = 26$. Let $x = y + 5$. And $1 = 10y + yy$. Hence we have the ſeries 0 . 1 . 10 . 101 . 1020 . 10301 . 104030.

Therefore $y = \frac{10301}{104030}$; and $x = \sqrt{26} = 5\,\frac{10301}{104030} =$ 5 . 09901951360, differing only by unit from 5 . 09901951359 found by the common method.

In the caſe where the greateſt root of the *Equation* is required, the like obſervations may be made, as when we ſeek the leaſt root, *viz.* that we may obviate all inconveniencies by ſuppoſing $x = y \pm a$. Both methods often take place without any preparation; ſometimes only one, and ſometimes neither; but this rarely. Both will ſucceed by a proper ſubſtitution of $x = y \pm a$, providing the *Equation* have real roots.

To avoid fractions in both caſes, ſuppoſe, firſt, the general *Equation* $a = bx + cxx + dx^3 +$ &c. where $a, b, c, d,$ &c. are integers; to which form all *Equations* may be reduced. Then we avoid fractions by ſuppoſing $x = ay$. In the ſecond method, we have the general *Equation* $ax^m = bx^{m-1} + cx^{m-2} \ldots\ldots + d$ where we may put $x = \frac{y}{a}$; but this ſubſtitution may often be well omitted.

It is to be obſerved, that this method may be ſometimes uſefully extended to literal *Equations*. Thus in the general cubic *Equation*, $1 = ax + bxx + cx^3$, form the ſeries 0 . 0 . 0 . 1 . a . aa . $aa + b$. $a^3 + 2ab + c$. $a^4 + 3aab + 2ac + bb$. $a^5 + 4a^3b + 3aac + 3abb + 2bc$, &c. then will the proximate value of $x = \frac{a^4 + 3aab + 2ac + bb}{a^5 + 4a^3b + 3aac + 3abb + 2bc}$.

The learned author of theſe methods afterwards applied them to the reſolution of infinite *Equations*; for which we muſt refer the reader to the Acta Petropol. Tom. 5. p. 63—82.

The ingenious Mr. Simpſon, gives us the following method for the ſolution of *Equations* in numbers, when only one *Equation* is given, and one quantity (x). to be determined.

Take the fluxion of the given *Equation*, ſuppoſing $\dot{x}$ to be the variable quantity; and having divided the whole by $\dot{x}$, let the quotient be repreſented by A. Eſtimate the value of x pretty near the truth, ſubſtituting the ſame in the *Equation*, as alſo in the value of A, and let the error, or reſulting number, in the former, be divided by this numerical value of A, and the quotient be ſubtracted from the ſaid former value of x; and from thence will ariſe a new value of that quantity, much nearer the truth than the former, wherewith proceeding as before, another new value may be had, &c. till we arrive to any degree of accuracy deſired.

For inſtance, ſuppoſe $300x - x^3 - 1000 = 0$. To find x, take the fluxion of the given *Equation*, and expunging $\dot{x}$, we have, $300 - 3xx = A$. It appearing, by inſpection, that $300x - x^3$, when $x = 3$, will be leſs, and when $x = 4$, will be greater than 1000, eſtimate x at 3 . 5, and ſubſtitute it inſtead thereof both in the *Equation*, and in the value of A. The error in the former $= 7 . 125$. and the value of the latter $= 263 . 25$: Wherefore taking $\frac{7 . 125}{263 . 25} = 0 . 027$ from 3 . 5, there remains 3 . 473 for a new value of x. With this proceeding as before, the next error, and the next value of A will be 0 . 00962518 and 263 . 815 reſpectively. Hence the third value of $x = 3 . 47296351$. which is true to 7 or 8 places.

The propoſed *Equation* need not always be delivered from radicals, though this be ſometimes convenient, yet it is alſo ſometimes inſupportably tedious. Thus, if we had the *Equation* $\sqrt{1 - x} + \sqrt{1 - 2xx} + \sqrt{1 - 3x^3} - 2 = 0$; the clearing it from ſurds would be very tedious; but Mr. Simpſon's method gives the root without any previous reduction.

The like is to be obſerved, when two *Equations* are given, and as many unknown quantities (x and y) are to be determined. For all which we refer to the author himſelf, in his eſſays printed 1740. p. 82. ſeq.

The old method of Vieta, for ſolving adfected *Equations*, was extremely tedious. It was formed by analogy, from the common method of extracting the roots of pure powers. See Vietæ Oper. Math. ap. Elzev. p. 173. or *Wallis*'s Algebra, *Oughtred*'s Clavis, *De Lagny* Elemens d'Arithm. & d'Algebr. p. 515, *&c.*

EQUATION *of the Center*, in aſtronomy.—This *Equation* not being conſtant, there is a place in the planet's orbit where it is greateſt. Hence ſeveral queſtions in aſtronomy ariſe; as, what is the greateſt *Equation* for every planet? To what mean anomaly does this *Equation* correſpond? Alſo, as the greateſt *Equation* is determined by the excentricity of the planets orbit, it may be reciprocally requiſite to determine the excentricity by the greateſt *Equation*.

The rigorous ſolutions of theſe queſtions being no where extant, Mr. Euler has enquired into them, in Mem. de l'Acad. de Berlin. Tom. 2. p. 225. ſeq. Where he ſolves the following problems.

1°. To find the true and mean anomaly, correſponding to the planet's mean diſtance from the ſun; that is, when the planet is in the extremity of the conjugate axis of its orbit.

2°. The excentricity of a planet being given, to find the excentric anomaly correſponding to the greateſt *Equation*.

3°. The excentricity being given, to find the mean anomaly correſponding to the greateſt *Equation*.

4°. From the ſame data to find the true anomaly correſponding to this *Equation*.

5°. From the ſame data to find the greateſt *Equation*.

6°. The greateſt *Equation* being given to find the excentricity. Mr. Euler obſerves, that this problem is very difficult, and that it can only be ſolved by approximation, and tentatively, in the manner he mentions. But, if the excentricity be not great, it may be then found directly from the greateſt *Equation*. Thus, if the greateſt *Equation* $= m$, and the excentricity $= n$, then,

$$m = 2n + \frac{11}{48}n^3 + \frac{599}{5120}n^5 +, \&c.$$

Whence by converſion

$$n = \frac{1}{2}m - \frac{11}{768}m^3 - \frac{587}{2^{10}\cdot 15}m^5 -, \&c.$$

Where the greateſt *Equation* m, muſt be expreſſed in parts of the radius, which may be done by converting the angle m, into ſeconds, and adding 4.6855749 to the logarithm of the reſulting number; for this will be the logarithm of the number m.

The mean anomaly to which this greateſt *Equation* correſponds, will be, $x = 90° + \frac{5}{8}m - \frac{5}{2^9\cdot 3}m^3 - \frac{1}{2^9\cdot 5}m^5 -$, *&c.*

Whence, if to 90° we add $\frac{5}{8}$ of the greateſt *Equation*, we ſhall ſufficiently approximate to this mean anomaly.

Mr. Euler gives us a table, in which may be found the greateſt *Equations*, the excentric and mean anomalies, correſponding to theſe greateſt *Equations*, for every hundredth part of of unity, which he ſuppoſes equal to the greateſt excentricity, or when the diſtance of the foci and the tranſverſe axis become infinite. The laſt column of his table alſo gives us the logarithm of that diſtance of the planet from the ſun, where its *Equation* is greateſt. By the help of this table, any excentricity being given, we may find the greateſt correſponding *Equation*, by interpolation. But the principal uſe of the table is, to determine the excentricity when the greateſt *Equation* is known, and Mr. Euler thinks the queſtion inſoluble without this help. See the Table, lib. cit. p. 245. ſeq.

EQUESTRIA, among the Romans, a place in the theatre, where the equites, or knights, ſat. *Hofm.* Lex. in voc.

EQUESTRIAN (*Cycl.*)—EQUESTRIAN *Cohort*, in antiquity. See COHORS *Equitata*.

EQUESTRIAN *Games*, *ludi Equeſtres*, among the Romans, horſe-races; of which there were five kinds, the *prodromus*, or plain horſe race, the chariot race, the decurſory race about funeral piles, the *ludi ſevirales*, and the *ludi neptunales*. *Pitiſc.* Lex. Ant. in voc.

EQUINUS *Barbatus*, a kind of comet. See HIPPEUS, *Cycl.*

EQUIRIA, in antiquity, a feſtival inſtituted by Romulus, in honour of Mars, at which there were horſe races. *Pitiſc.*

EQUISELL, in ichthyology, a name given, by Gaza, and ſome other writers, to the dorado, or dolphin: The coryphæna with the forked tail of Artedi. See CORYPHÆNA.

EQUISELIS, in natural hiſtory, the name of a large fly, of the ſize of a hornet, but having only two wings and no ſting. It otherwiſe much reſembles the common hornet in ſhape. This fly is found only in Macedonia. We have alſo, in England, flies which nearly reſemble the hornet, waſp, and bee, but in their wanting ſtings, and having only two wings.

EQUISELIS, in ichthyography, a name uſed, by ſome authors, for the hippurus, a ſea-fiſh, caught on the Spaniſh ſhores, and ſuppoſed by many to be the ſame with the dorado. *Willughby*'s Hiſt. Piſc. p. 213. See the article HIPPURIS.

EQUISETUM, *Horſetail*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the apetalous kind, being compoſed of a number of ſtamina, each furniſhed with a muſhroom-like head, and all diſpoſed in a ſort of ſpiked form. Theſe flowers are barren, and the ſeeds of the ſame ſpecies grow on plants of a very different figure, which have no flowers, and only produce black rough ſeeds. To this it is to be added, that the plant conſiſts of ſeveral joints, one received into another, in the manner of larger and ſmaller tubes. See Tab. 1. of Botany, Claſs 15.

The ſpecies of *Horſetail*, enumerated by Mr. Tournefort, are theſe: 1. The marſh *Horſetail*, with long branches. 2. The marſh *Horſetail*, with ſhorter branches. 3. The field *Horſetail*, with very long briſtles. 4. The wood *Horſetail*, with very ſlender briſtles. 5. The ruſh-like naked, or not branched *Horſetail*. 6. The great marſh *Horſetail*. 7. The great naked, but branched *Horſetail*. 8. The ſmall naked variegated *Horſetail*. *Tourn.* Inſt. p. 532.

The common great marſh *Horſetail* is uſed in medicine as an aſtringent and vulnerary. Schroder recommends it in all kinds of hæmorrhages, and exulcerations of the kidneys and bladder.

EQUITATA *Cohors*, in antiquity. See COHORS *Equitata*.

EQUUS, the *Horſe*, in the linnæan ſyſtem of zoology, this makes a diſtinct genus of animals, of the jumenta kind, the characters of which are, that the creatures have two paps, ſituated in the groin, the dentes inciſores are ſix in each jaw; the canine, or dog-teeth, are placed at a diſtance from the others, and are but little longer than they. According to theſe characters, the author includes in this genus, the horſe, the aſs, the wild aſs, and mule, and the zebra, or, as he calls it, the ſtriped horſe. *Linnæi* Syſtem. Natur. p. 40.

EQUUS *Marinus*, in zoology, a name given, by ſome, to an animal very different from the hippopotamus, or river horſe, and more uſually known by the name of the morſe. See MORSE.

ERA, in chronology. See ÆRA, *Cycl.*

ERANDGAAS, in zoology, the name of a fowl, of the gooſe kind, deſcribed by ſome authors. It is ſaid to be ſomewhat ſmaller than the common wild gooſe. Its head grey, and its neck adorned with a red ring. Its breaſt, wings, and neck, are grey, and its feet red. Mr. Ray much ſuſpects the account of this bird. *Ray*'s Ornithol. p. 308.

ERANTHEMUM, in botany, a name given, by ſome authors, to the flos Adonis, or red maithes. *J. Bauhin.* vol. 3. p. 129.

EREBENNUS, Ερεβεννὸς, a name given by Galen, and ſome other of the Greek writers, as a diſtinctive epithet for the black chamæleon thiſtle, which was eſteemed poiſonous, and was by this word diſtinguiſhed from the ægleus, or ἀιγληὶς, or white chamæleon, which was an eſculent plant, and uſed by ſome as an antidote. It has happened, however, that the white chamæleon thiſtle has been by ſome called a poiſon, as well as the black, but this is only owing to a miſtake of Pliny, in ſuppoſing the effects of birdlime to have been attributed to this plant, becauſe yielding a viſcous, but ſafe gum, at its root. It was called, by ſome, ixios chamæleon. *Galen.*

ERECT *Leaf*, *Erectum folium*, among botaniſts. See LEAF.

EREGMOS, a word uſed, by the antients, to expreſs a bean decorticated, and broken into ſmall pieces, in order to be boiled in ptyſans. This name was not, however, kept ſtrictly to this ſenſe, but they applied it indifferently to all the leguminous fruits, broken in the ſame manner. Foëſius will have it to ſignify bean meal, but others are againſt this; and Galen, in ſome places, uſes it only to expreſs a bean divided into two parts.

ERETHISMOS, a word uſed by Galen and Hippocrates, to expreſs any thing that irritates. Galen ſays, that Hippocrates means by it alſo every thing that reduces the habit of body to an infirm ſtate, among which are to be reckoned, before all other things, irritating, acrimonious, and pungent humours in the ſtomach and bowels, particularly in the mouth of the ſtomach, worms aſcending from the inteſtines into the ſtomach, nocturnal itchings of the whole ſkin, or of ſome part of it, which, by their irritation, and prevention of ſleep, greatly exhauſt ſtrength.

ERETRIA *Terra*, *Eretrian Earth*, in the materia medica, the name of a very peculiar kind of bole, dug in the Negropont, near the antient *Eretria*, and once in great uſe as an aſtringent and a ſudorific.

The antient writers in medicine all mention the *eretrian* earth; and Dioſcorides and Galen deſcribe two kinds of it, a grey and a white. The grey is what is properly diſtinguiſhed by this name, being an earth of a different kind from all the other boles. The white, though the antients ſeem not to have obſerved it, yet was plainly, from their own deſcriptions, the ſame with the white bole armenic, tho' found in a different place. *Hill*'s Hiſt. of Foſſ. p. 5.

The grey, or genuine *eretrian* earth, is a fine and pure greyiſh white earth, moderately heavy, naturally of a ſmooth ſurface, of a friable texture, eaſily crumbling to pieces between the fingers, but not ſtaining the ſkin in handling; it ſticks firmly to the tongue, but melts into a butter-like ſubſtance in the mouth; it burns to a perfect ſnow white, and effervesces violently

violently with aqua fortis. But what abundantly diſtinguiſhes it from all other earths, is, that if a little wetted and drawn over a plate of braſs or copper, ſo as to mark a line, the mark will, a little after, appear bluiſh. This is recorded of it ſo early as in the writings of Dioſcorides, and experiment proves it to be true. It ſeems plainly owing to an alkaline quality in the earth; this it plainly manifeſts, by its fermenting ſo ſtrongly with acids; and it is a well known thing, that alkalies draw a blue tincture from copper.

The antients all eſteemed it a great medicine, and were particularly careful in their way of preparing it for uſe, by frequent waſhing. It is now unknown in the ſhops; but its highly alkaline quality, in which it is ſo much ſuperior to all the earths now in uſe, might make it worth the bringing into uſe again, and it may ſtill be had in its old place, in almoſt any quantities.

ERETIA *Terra alba*, in the materia medica, a name by which the antients called the white bole armenic, a ſmall quantity of which was alſo found near *Eretria*. *Hill*'s Hiſt. of Foſſ. p. 8.

ERGALIA, a word uſed, by the alchemiſts, to expreſs that part of their treatiſes which explains the inſtruments employ'd in their operations.

ERGASIMA, a name given by Dioſcorides, and other of the antients, to a very foul and coarſe kind of myrrh.

ERGASTERIUM, a word uſed, by the writers in chemiſtry, ſometimes to expreſs the whole elaboratory, and ſometimes that part of a furnace on which the bottom of the retort, copell, or crucible, is to reſt in an operation.

ERGASTINÆ, Εργαστιναι, in antiquity, a ſelect number of virgins employed in weaving Minerva's peplos, or robe, which was carried in proceſſion at the Athenian feſtival *Panathenæa*. See PEPLOS, *Suppl.* and PANATHENÆ, *Cycl.*

ERGASTULUM, among the antients, a houſe of correction, or work-houſe, where ſlaves, by the private authority of their maſters, were confined, and kept at hard labour, for ſome offence. It was likewiſe called *Sophroniſterium*. *Hofm.* Lex. in voc.

ERGATIA, Εργατια, in antiquity, a Laconian feſtival, in honour of Hercules. *Pott.* Archæol. Græc. l. 2. c. 20. T. 1. p. 394.

ERGOT, in the manege, is a ſtub like a piece of ſoft horn, about the bigneſs of a cheſnut, placed behind and below the paſtern joint, and commonly hid under the tuft of the fetlock. To *diſ-ergot*, or take it out, is to cleave it to the quick with an inciſion knife, in order to pull up a bladder full of water, that lies covered with the *Ergot*. This operation is ſcarcely practiſed at Paris, but in Holland is frequently performed upon all four legs, with intent to prevent watry ſores, and foul ulcers.

ERICA, *Heath*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the campaniform kind, and conſiſts of one leaf, from the bottom of which there ariſes a piſtil, which finally becomes a fruit, uſually of a roundiſh figure, and, when ripe, opening into four parts, and divided into four cells, each of which contains a number of ſmall ſeeds.

The ſpecies of *Erica*, enumerated by Mr. Tournefort, are theſe: 1. The common purple-flowered ſmooth *Heath*. 2. The common ſmooth *Heath*, with white flowers. 3. The tamariſk-leav'd hairy *Heath*. 4. The great coris-leav'd white *Heath*. 5. The great purple *Heath*, with longer leaves. 6. The juniper-leav'd many flowered *Heath*. 7. The foreign ſhrubby *Heath*. 8. The greater *Heath*, with purpliſh green flowers. 9. The great beſom *Heath*, with deciduous leaves. 10. The ſquare-leav'd blackiſh red beſom *Heath*. 11. The dwarf *Heath*, with a grey bark, and flowers like the arbutus. 12. The dwarf *Heath*, with a grey bark, and white arbutus-like flowers. 13. The Engliſh hairy *Heath*. 14 The purple-flowered three branched *Heath*. 15. The three-leaved procumbent *Heath*, with fleſh-coloured flowers. 16. The green-flowered procumbent *Heath*. 17. The procumbent *Heath*, with pale purple flowers. 18. The great flowered *Heath*, with myrtle-like leaves, hoary underneath. 19. The green African *Heath*, with very narrow and ſhort leaves, and cluſtered flowers. 20. The African *Heath*, with hairy flowers diſpoſed along the branches. 21. The hoary African *Heath*, with very narrow leaves. 22. The African *Heath*, with ſhort capillaceous leaves, and roundiſh purple flowers. 23. The ſmall-leav'd African *Heath*, with round whitiſh flowers. 24. The juniper-leav'd African *Heath*, with long ſpiked flowers. 25. The coris-leav'd African *Heath*, with long ſpiked flowers. The juniper-leav'd African *Heath*, with oblong flowers, diſpoſed in umbells. 27. The coris-leav'd African *Heath*, with long purple flowers growing from the alæ of the leaves. 28. The coris-leav'd African *Heath*, with ſhort flowers growing from the alæ of the leaves. 29. The bladder flowered coris-leav'd African *Heath*. *Tourn.* Inſt. p. 602.

ERICA *Marina*, *Sea Heath*, a name given, by many authors, to a very beautiful ſea plant, of the fucus kind, called by Mr. Ray, and ſome others, *fucus ericæ folio*. This differs ſo much in bigneſs, in different places, that it has been ſuſpected to be of two diſtinct ſpecies; thoſe plants of it which are found about the ſhore ſeldom exceeding ten inches in length, and thoſe in deeper water often growing to three foot.

It is compoſed of a vaſt number of ramifications; the bottom ſtalk is woody, and often of the thickneſs of a man's little finger, yet even in theſe there is no diſtinction of nerves or fibres, the large branches are rough and knotty, and ſend off many other ramifications, the larger of which are round, but the extream ones flat.

At different ſpaces over this plant, one obſerves certain knots, or tumours; theſe are no other than the branch in that part ſwell'd, and the uſe of the ſwelling is to contain the capſules which encloſe the ſeed; theſe, and their arrangement in theſe ſwellings, are wholly like thoſe of the common fucus, and there are uſually ten or twelve capſules contained in every ſwelling, or bladder of the ſtalk. They are not arranged in any regularity in the ſwelling, but are always found nearer the upper than the lower extremity of it. The ſeeds are round, and a very great number of them are contained in every capſule.

The ſwellings which contain theſe capſules, are ſometimes placed at conſiderable diſtances from one another on the ſtalks of the plant, and ſometimes they ſtand ſo cloſe, as to repreſent the beads of a necklace. Some branches of the plant alſo are very full of them, and others ſcarce have any at all upon them. Sometimes the bladders are found empty on this plant, as they are in the common ſea wrack; but, in this caſe, there may always be ſeen the marks of the places where the capſules have once been, though ſince periſhed by ſome accident. Mr. Reaumur, who gives this deſcription of this plant, never ſaw its flowers; but there ſeems no doubt but that they are compoſed of ſhort filaments, like thoſe of the other plants of this kind; and his not examining the plant at a proper ſeaſon, was probably the reaſon of his not finding them, for the flowers and ſeeds of theſe plants are uſually both large enough to be ſeen by the naked eye; and when the ſeed is ſo in moſt caſes, the flower is alſo. Mem. Acad. Par. 1712.

ERICA, in ichthyology, a name given by Gaza, and ſome others, as the interpretation of the chalcis of Ariſtotle, that is, as the name of the common herring.

ERICERUM, a name given by Aëtius, and other authors, to a ſort of collyrium, uſed in weakneſſes of the eyes, in which the herb erica, or heath, was an ingredient.

ERIGERUM, or SENECIO, *Groundſel*, beat into a very coarſe pulp, and applied cold to the pit of the ſtomach, has had very good ſucceſs in curing of agues. It is to be uſed only on the days free from the fit. It vomits ſtrongly ſome hours after application. See Medic. Eſſ. Edinb. Vol. 2. art. 5. or Abridg. Vol. 1. p. 203. See SENECIO.

ERINACEA, in botany, the name of a genus of plants, the characters of which are theſe: The flowers and fruit are the ſame with thoſe of the broome; but the whole plant is ſo beſet with prickles, as to reſemble a hedgehog. *Tourn.* Inſt. p. 646.

The ſpecies of *Erinacea*, enumerated by Mr. Tournefort, are theſe: 1. The Spaniſh *Erinacea*, with bluiſh purple flowers, and 2. The Cretic *Erinacea*, called, by ſome, the Cretic tragacanth.

ERINACEUS, in zoology, the name of the common hedgehog. The head and ſnout of this animal reſemble thoſe of a hog, but the noſtrils, and extremity of the ſnout, have more reſemblance to thoſe of a dog; the ears are very broad, and like thoſe of the mouſe kind, and its eyes are ſmall and prominent. Its legs reſemble thoſe of the dog, and each foot has five toes, all armed with ſharp claws; of theſe the hinder is ſhorter than the reſt. Its head, back, and ſides, are covered with ſharp ſpines, and its belly, throat, and legs, with ſoft white hair.

Authors deſcribe two ſpecies of hedgehog, the one the canine, or dog kind, the other the hog kind. In England we have only the canine kind, which is the above deſcribed; and Mr. Ray much queſtions whether there be any other kind in being. *Ray*'s Syn. Quad. p. 231.

In the Linnæan ſyſtem of zoology, the *Hedgehog* makes a diſtinct genus of animals, in which the author includes the armadillos. The characters of the animals of this claſs are theſe: They have eight paps, two of which are ſituated on the breaſt, and the other ſix on the belly; and their body is cloathed or defended with a ſort of armour. *Linnæi* Syſtem. Naturæ, p. 37.

ERINACEUS is alſo a name given by Dillenius, and ſome other botaniſts, to the pectinated agarics, called, by others, *hydna*. Theſe differ from the agarics, properly ſo called, which are lamellated underneath, and from the others, which are porous, for theſe are echinated, or beſet with pointed prickles.

ERINOPTERUS, the *Privet Fly*, in natural hiſtory, the name of a ſmall ſpecies of fly, which is all over of a ſilver colour, and of a duſty appearance. It looks, as it ſits, like a fragment of a white feather. Its wings are divided into ſeveral long ſegments, like thoſe of birds feathers, and ſeem, in the ſame manner, compoſed of long feathers, tho' that is not really

rea ly the caſe. It is found very frequently in gardens, particularly on the privet hedges, and on the ſingle ſhrubs of that ſpecies.

ERINUS, in botany, a name given by Linnæus to a genus of plants, called, by Tournefort, and other authors, ageratum. *Linnæi* Gen. Plant. p. 301. See AGERATUM.

ERIOPHORUM, in the Linnæan ſyſtem of botany, the name of the cotton-graſs, or cotton-ruſh, common in marſhy places, and called linagroſtis by other writers. This is, by that author, made a diſtinct genus of plants, whoſe characters are, that the flower cup is an imbricated ſpike, made up of oblong oval ſcales, a little bent in, and ſeparating the flowers. It has no petals. The ſtamina are three capillary filaments; the antheræ are erect and oblong. The germen of the piſtil is extremely ſmall; the ſtyle is thread-like, and of the ſame length with the ſcales of the cup; the ſtigmata are three, longer than the ſtyle, and bent backward. The ſeed is three-corner'd, pointed, and covered with hairs longer than the ſpike. *Linnæi* Genera Plant. p. 12.

ERIOPHORUS, in botany, a name given, by Vaillant, to a genus of plants, ſince deſcribed by Linnæus, under the name of andrygala. See ANDRYGALA.

ERIOX, or EROX, in ichthyology, a name given by Albertus, and ſome other authors, to the common ſalmon, called, by others, *anchorago*, and *ſalmo*. See SALMO.

ERISTALIS, in natural hiſtory, the name of a ſtone, mentioned by Pliny and the antients, and of which a very memorable quality is recorded by them, which is, that tho' it was naturally white, it would become red, as if with bluſhing at any immodeſt action, or even thought of the perſon who wore it.

ERISTICI, in botany, ſuch authors as have attempted the ſtudy of that ſcience in a philoſophical way, and have been publickly engaged in diſputes about the true foundation of its ſeveral diſtinctions, &c. *Linnæi* Fund. Bot. p. 1.

ERITHACE, a name given, by the antients, to the yellow matter collected on the hinder legs of the bees, after their excurſions in ſearch of the materials for their hives; we uſually eſteem this to be real wax, and the French call it *cire brute*, or rough wax: It is very certain, however, that tho' the matter, of which wax is to be formed, is contained in this ſubſtance, yet the Dutch, and ſome other nations, have the moſt juſt idea of it, in calling it *pain des abeilles*, or the food of the bees.

This ſubſtance is only the farina of flowers, and no experiment has been able to ſeparate real wax from it. The moſt probable opinion concerning it, is, that it ſerves the bees as food, and that, after this, it is converted, in their bowels, into the ſubſtance called wax. *Reaumur*'s Hiſt. Inſ. Vol. 10. p. 50.

ERITHACUS, in zoology, a name by which many have called the red breaſt, or, as it is more commonly called, in Latin, the *Rubecula*. See RUBECULA.

ERIX, a word uſed, by Galen, to expreſs the ſuperior part of the liver.

ERMESIA, the name given to a compoſition uſed among the antients, and famous for its effect in making people beget handſome children. It conſiſted of honey, myrrh, ſaffron, and palm wine, all beat together. This maſs was to be taken, mixed in milk. The women took it as well as the men, and many had great faith as to its effects.

ERMINEUM *Animal*, the *Ermine*, or creature whoſe ſkin is the *Ermine*, ſo much eſteemed as a fine furr.

This creature is properly a ſpecies of weaſel, and is called by Mr. Ray, and other authors, *muſtela candida*, the white weaſel. It is in all reſpects like the common weaſel, and is all over of a pure ſnow white, except the tip of the tail, which is of as beautiful a black, and that it has a little yellowiſh grey about the eyes, and a mark, or ſpot, of the ſame colour, on the head, another on the ſhoulders, and a third near the tail. Its colour is, however, very different in degree and elegance, according to the ſeaſon of the year. It is frequent about rivers, and in meadows, in thoſe countries which produce it, and feeds on moles, mice, and other ſmall animals. *Ray*'s Syn. Quad. p. 198.

ERNES, in our old writers, ſignify the looſe ſcattered ears of corn that are left on the ground, after the binding or cocking of it.

It is derived from the old Teuton *Ernde*, harveſt; *ernden*, to cut or mow corn: Hence to *ern* is, in ſome places, to glean. *Kennet*'s Gloſſ. in voc.

ERODINUM, a word uſed, by ſome of the enthuſiaſtic writers in alchemy, to ſignify the prognoſtic, good or bad of any operation.

EROSUM *Folium*, among botaniſts. See LEAF.

EROTESIS, Ερωτησις, in rhetoric, the ſame with interrogation. See INTERROGATION, *Cycl.*

EROTIA, Ερωτια, a feſtival among the Greeks, in honour of Cupid, being celebrated every fifth year with ſports and games. *Pott.* Archæol. l. 2. c. 20.

EROTIDIA, Ερωτιδια, the ſame with *Erotia*. See EROTIA.

EROTYLOS, in natural hiſtory, the name of a ſtone of which we have no deſcription left us, but which the antients are ſaid to have uſed in divination.

ERRATIC (*Cycl.*)—ERRATIC *Fevers*, in medicine, a term uſed to expreſs ſuch fevers as, according to the language of medical writers, obſerve no regular type, that is, are not determinate either in their attacks, or in their general period: They are thus called by way of diſtinction from the typic fevers, which are regular in both. *Junker*'s Conſp. Med. p. 252.

ERRHINA, (*Cycl.*) *Errhines*, in the materia medica, medicines deſigned to purge away pituitous humours from the head, without making the patient ſneeze, tho' to be taken up the noſe. They are either liquid, ſoft, or ſolid.

The liquid are made of the juice of cephalic cleanſing herbs, extracted by wine, or other liquors; to which ſpirit of wine is ſometimes added; or of a decoction of fit ſimples, to which are ſometimes added juices, honey, ſyrup, and powders.

The ſoft are made of powders, with honey, oil, or juices, boiled to a kind of ointment.

The ſolid is given either in the form of a powder, and that has place, eſpecially in medicines, which provoke ſneezing; or in form of a pellet, and it is called *naſale*, and is prepared of fit powders, mixed with viſcid extractions from ſeeds, gums, roots, &c. with wax, or with turpentine. *Blancard.* Lex. Med. in voc.

ERRIPSIS, in medicine, is uſed in different ſenſes, ſometimes for a weakneſs of the whole body, ſometimes only of ſome one part. When applied to the whole body, it expreſſes that utter dejection and proſtration of ſtrength which makes a man fall down like a dead carcaſs; and, when applied to the eyes, it expreſſes ſuch a debility, as renders it impoſſible to keep them open.

ERRONES, *Erratic* or *Wandring Stars*, in aſtronomy, the ſame with planets. See PLANETS, *Cycl.*

ERROR *Loci*, a term often uſed by Boerhaave. This author obſerves, that in the body there is a decreaſing ſeries of veſſels; by which he means, that the firſt orders of the veſſels are adapted to receive the red globules of the blood, while the reſt are, perhaps, ſmaller, and receive only the ſerum, the next in order the lymph, and the next the yet finer fluids. Now when the red globules of blood are propelled into the veſſels deſtined only to receive the ſerum, or when the ſerum gets into thoſe veſſels in which a finer fluid only ought to circulate; this he calls an *Error Loci*, and attributes much to it.

ERVA *Baboſa*. See CARAGUATA.

ERVA *De Sancta Maria*, a name by which ſome authors have called the dracontium, or great garden dragons. *Piſo*, p. 240.

ERUCA, the *Caterpillar*. See CATERPILLAR, *Cycl.*

The *Caterpillar* ſtate is that through which every butterfly muſt paſs before it arrives at its perfection and beauty, and in the ſame manner all the known winged animals, except only the puceron, paſs through a reptile ſtate, none of them, except this, being produced in their winged form. The change from caterpillar to butterfly was long eſteemed a ſort of metamorphoſis, a real change of one animal into another; but this is by no means the caſe. The egg of a butterfly produces a butterfly, with all the lineaments of its parent, only theſe are not diſcloſed at firſt, but, for the greater part of the animal's life, they are covered with a ſort of caſe, or muſcular coat, in which are legs for walking, which only ſuit it in this ſtate; but its mouth takes in nouriſhment, which is conveyed to the included animal, and, after a proper time, this covering is thrown off, and the butterfly, which all the while might be diſcovered in it by an accurate obſerver, with the help of the microſcope, appears in its proper form. Before it paſſes into this ſtate, however, there requires a time of reſt for the wings to harden, and the ſeveral other parts to acquire their proper firmneſs; this is tranſacted in a time of perfect reſt, when the animal lies in what is called the nymph or chryſalis ſtate, in appearance only a lump of unenlivened matter. There is a ſettled and determinate time for each of theſe changes in every ſpecies, but in the ſeveral different kinds the periods are very different. Some caterpillars are produced from the eggs of their parent butterfly in ſpring, as ſoon as the trees, on whoſe leaves they are to feed, begin to bud; after a life of thirteen days, they paſs into their chryſalis ſtate; and, after remaining at reſt three weeks in that, they iſſue forth with wings, with all the beauty of their parents. *Reaumur*, Hiſt. Inſ. Tom. 2.

As ſoon as they arrive at this their final ſtate, their wings are ſcarce dry before they ſeek to copulate to propagate their ſpecies; this done, the male dies, and the female only lives to depoſit her eggs, and then follows him. This is their whole buſineſs in this ſtate, and they are ſo ſenſible of it, that they ſeem weary of a uſeleſs life, as ſoon as they have done; nature, never intending that they ſhould eat in this ſtate, has given them no organs for that purpoſe; ſo that they muſt neceſſarily die of hunger ſoon, could they eſcape their natural death, or the great devourers of them the birds. Many ſpecies of theſe ſpring butterflies have no farther being, except in the embryo included in the egg, till the ſucceeding ſpring; they lay their eggs very carefully, and in extreamly nice order, round about the ſtalk of a perennial plant, or the young branch of a tree, and there they remain thro' the heats of the

ſummer, and colds of the winter, and are never hatched till the ſucceeding ſpring; and though thus expoſed, it is obſervable, that the ſevereſt winters do them no harm. Other ſpecies of theſe are ſooner hatched from the egg, and live the remainder of the ſummer on the leaves of the tree. They, after this, paſs the whole winter in the caterpillar ſtate, uſually hiding themſelves in ſome ſheltered place, covered with webs of their own ſpinning. Theſe remain torpid all the winter, and, at the return of ſpring, leave their webs as the others do their eggs, and feed a few weeks longer, after which they paſs through the chryſalis ſtate to their perfect form. The butterfly of this ſpecies, therefore, enjoys a much longer time of life than the other which remains ſo long in the egg; tho' the ultimate duration of the animal, from its excluſion from the parent, till its death, is much the ſame; ſo great a part of it being paſſed in the egg ſtate by the one, and ſo ſmall a part by the other. *Reaumur*, Hiſt. Inſ. Tom. 2.

Other ſpecies of theſe animals remain the whole winter in the chryſalis ſtate, and are butterflies in ſpring, and, after paſſing the middle of ſummer in the egg, are caterpillars in the autumn. The difference of this ſtage of life is remarkably great, in proportion to the whole duration of the animal; in ſome ſpecies it does not exceed a fortnight, and in others continues eleven months. Mr. Reaumur, however, tried the experiment of lengthening the lives of ſome of theſe animals, by continuing them longer in their living ſtate, and ſucceeded in it, as well as in ſhortening the general duration of others, by making their paſſage out of the chryſalis earlier than it would naturally have been, and theſe, as ſoon as they came out of this ſtate, copulating, depoſiting their eggs, and dying, the term of their total duration was made ſhorter than the year.

There is no ſign of ſex in the animal, while in the caterpillar ſtate; the propagation of the ſpecies is the buſineſs of the creature in its ultimate perfection, and, till that, theſe parts are never excluded. One female butterfly, when ſhe has been impregnated by the male, will produce three hundred or four hundred eggs, or even more. While the young ones, produced from theſe eggs, remain in the ſtate of caterpillar, there is no union of the ſexes, no inclination for it between them, nor any deſires, except of food. But tho' the caterpillar is cold in this reſpect, the butterfly, or ultimate ſtate of the animal, is as remarkably warm. Scarce is this creature out of the ſhell of the chryſalis, which, is as it were, its egg, ſcarce are its wings dry enough for flight, before it mounts into the air to ſeek the female. Its deſire of food is now no more, it has now no idea of eating, nor any organs for it; its whole deſire is that of the propagating its ſpecies. The moment it finds a female, it attacks her, and ſhe as readily conſents. From her, in a few minutes, he flies in ſearch of another, thence to another, and ſo on for his whole life; all the ſex being his concubines, and all ready to receive and love him.

There is no way of knowing the different ſexes of theſe little creatures, by viewing the parts; but the whole figure and manner of the animal makes the difference. The females are always larger than the males; they are alſo more ſlow in their motions; and ſome of them have no wings, or, at the utmoſt, only very ſmall ones. The males, however, have a ſort of beards, more beautiful than the autennæ, or horns of the females; the female is much ſtronger, as well as bigger, than the male, and not unfrequently, at the approach of danger or diſturbance, flys away with him in the time of copulation. Some join their bellies in the copulation, ſome hold their bodies directly oppoſite to one another; and, in ſome ſpecies, the male all the time claps his wings, whereas in others he remains perfectly ſtill. On diſſecting the female, her uterus affords an aſtoniſhing ſight; the number of eggs in the tubes is amazing; but theſe have not all the ſame figure; and in ſome ſpecies, as the ſilk worm, *&c.* the eggs are of a beautiful blue; if any yelloviſh ones are ſeen among them, they are judged to be defective. The outer covering of the egg is not a ſhell, but a more tough and leſs hard ſubſtance, more reſembling leather; and there is almoſt an infinite variety in their ſhapes; in ſome ſpecies they are round, in ſome cylindric, in ſome pyramidal, in others cylindric and elegantly ridged and ſtriated; in ſome the ſurface is perfectly even and ſmooth, and in others, beſides theſe indentings, there are numerous little protuberances uſually of regular figures, and diſpoſed with perfect regularity. The care of all the butterfly tribe, to lodge their eggs in ſafety, is ſurpriſing. Thoſe whoſe eggs are to be hatched in a few weeks, and are to live in the caterpillar ſtate during part of the remaining ſummer, always lay them on the leaves of ſuch plants as they know will afford them a proper nouriſhment; but, on the contrary, thoſe whoſe eggs are to remain unhatched till the following ſpring, foreknowing that the leaves of trees fall off in winter, always lay them on the branches of trees and ſhrubs, and uſually are careful to ſelect ſuch places as are leaſt expoſed to the rigours of the enſuing ſeaſon, and frequently cover them from it in an artful manner. Some make a general coat of a hairy matter over them, taking the hairs from their own bodies for that purpoſe; others hide themſelves in hollow places in trees, and in other ſheltered cells, and there live in a ſort of torpid ſtate the whole winter, that they may depoſit their eggs in the ſucceeding ſpring, at a time when there will be no ſeverities of weather for them to combat. The day butterflies only do this, and of thoſe but a very few ſpecies; but the night ones, or phalenæ, all without exception, lay their eggs as ſoon as they have been in copulation with the male, and die immediately afterwards. *Reaumur*, Hiſt. Inſ. T. 2.

The *Erucæ* furniſh us with an inſtance of the falſity of that rule eſtabliſhed by moral writers, that man is the only animal that deſtroys his fellow creature, which, they ſay, even the ſavages of the deſarts ſpare. It is a very certain truth, that many animals feed on the weaker of their own ſpecies. The pike, among fiſh, is an inſtance of it; but nothing gives ſo clear a view of it, as the examining theſe leſſer animals.

It is well known that the common and natural food of theſe creatures is the leaves and verdure of vegetables, yet as weak and harmleſs as they ſeem, they will many of them deſtroy their fellows whenever they get an opportunity. Reaumur gives us an inſtance of this in twenty caterpillars of the oak, which he kept in a box, with a ſufficient quantity of their natural food, yet their numbers daily decreaſed, till at length there remained only one.

He obſerved that the manner of their preying on one another was this; the ſtronger ſeized the weaker by the throat, and there giving him a mortal wound, left him to die at leiſure, only watching him all the time; but as ſoon as he was dead, the murderer immediately began eating him, feeding upon the entrails and juices, and leaving only the ſkin, with the head and feet. This is, however, only the caſe in ſome few ſpecies, the generality of theſe animals being very peaceable, and many ſpecies living comfortably together in the ſame place, without feeding upon, or at all moleſting, one another. Theſe ſpecies however, tho' freed from theſe dangers, are expoſed to others of a much more terrible kind; the worms or maggots of ſeveral ſorts of flies are frequently found about them, ſome preying upon their outſide; others lodged within them, under the ſkin, but both kinds eating the poor defenceleſs creature up alive. Thoſe which feed on the outſides are eaſily diſcovered, the others are more hid, and frequently the caterpillar, which ſeems very hearty and vigorous, and very fleſhy, ſhall be found, upon opening, to be a mere ſkin, the internal parts being all eaten away, and all the food that he ſwallows ſerving only to feed a vaſt number of worms, or maggots, which crawl about at liberty within him. Theſe devouring worms are of many different ſpecies, ſome being of the gregarious, ſome of the ſolitary kinds, and ſome ſpinning webs of their own ſilk to transform themſelves in, others undergoing that change without any ſuch covering. The beautiful cabbage caterpillar is one of thoſe unhappy kinds which frequently are infeſted with the gregarious kinds, large numbers of which ſpin themſelves webs one after another, and afterwards come out in the ſhape of the parent fly, to whoſe egg they owed their origin. *Reaumur*, Hiſt. Inſ. vol. 2. p. 1. p. 211.

Theſe inteſtine enemies are a ſure prevention of the butterfly's appearing at its proper time; and as many of the former naturaliſts, who knew what butterfly to expect from a peculiar ſpecies of caterpillar which they preſerved, often ſaw a parcel of flies come out in the place of it, they having no idea that the fly had laid its eggs in the fleſh of the poor creature, ſuppoſed that this was one of the natural transformations of the creature, and that certain ſpecies of caterpillars ſometimes produced butterflies, ſometimes ſmall flies. Goedart imagined that the poor caterpillar was ſo careful for theſe its children, as to ſpin them their ſilky bed, or covering, out of its own bowels.

Theſe, and many other deſtroyers, among which the birds are to be reckoned in the principal place, ſerve a noble purpoſe in preventing the too great numbers of theſe miſchievous animals. Their uſual habitation being the leaves and flowers of plants, they are, in their feeding, much expoſed to all thoſe deſtroyers; yet nature has taken care to preſerve a great number, by making many of them ſo exactly of the colours of the leaves they feed on, that they are not eaſily diſtinguiſhed from them; and by giving others a caution of keeping on the under part of the leaves, and being, by that means, out of ſight. But ſome ſpecies are much leſs expoſed, and of much more miſchief to the plants they feed on, by devouring more eſſential parts of them. Of theſe ſome eat the roots, and others the interior part of the trunk, deſtroying the veſſels that imbibe, and thoſe that diſtribute the juices. Theſe are different from the common caterpillars, in that their ſkin is much leſs, tough, and hard, and theſe are ſecure from our obſervation, and, in general, from their great deſtroyers the birds. They are not, however, abſolutely ſafe from the common dangers of the other ſpecies, for there are a kind of worms that find their food and habitation even in the bodies of theſe. Their habitations are the branches of the oak, elm, and poplar, when they begin to decay in the middle. They uſually lodge themſelves in the blea, and are able to pierce the hardeſt wood when they have occaſion to change their habitation. Some of the largeſt ſpecies of caterpillars that we know of, live in this manner; and it may be known that they are in poſſeſſion of

a branch, by ſeeing a quantity of duſt continually iſſuing out of a hole in the bark. Mr. Reaumur obſerved this in the branch of an apple tree in his garden, and tying a bag of linen over the hole, he caught the animal in its winged ſtate, and it proved to be a large kind of greyiſh phalæna. Three or four other kinds of theſe wood caterpillars have been diſcovered at different times, but it is ſo very difficult to find them, or to get at them when found, that probably there are many ſpecies of them yet unknown. *Reaumur*, Hiſt. Inſ. vol. 2. p. 1. p. 288.

The root caterpillars, and thoſe which live within the branches of plants, are much more eaſily found out. The roots of ſcrophularia, and the ſtalks of lettuces, and ſome other plants, afford caterpillars which ſeem all of the ſame ſpecies. Thoſe found in the lettuces are extremely plentiful ſome years, and deſtroy vaſt quantities of that plant. Theſe uſually have their firſt habitation in the ſtalk, near the root, and they increaſe it in ſize as they grow and feed. The ſkin of this kind is white and tranſparent, but has a few brown ſpots; theſe finally produce a ſmall phalæna. The ſame ſpecies is ſometimes found in the ſtalks of elecampane; and it is well known that there is another kind which lives always in the heads of the thiſtle kinds. Theſe, and a few others, are the known ſpecies of this kind; but as the habitation of all theſe is ſo much out of the common road, that nothing but the greateſt accidents can diſcover it, it is very probable that there yet remain many kinds unknown. The fruits of ſeveral kinds become alſo the food and lodgement for ſeveral ſpecies of caterpillars; and it is ſingular among theſe, that they will eat indifferently of ſeveral kinds of fruit, as pears, plums, apples, and peaches, whereas the generality of the common caterpillars that feed on leaves, are allotted only ſome one peculiar kind, and will rather die than eat of any other, tho' this is not a rule without exception even in them.

Nothing more ſurpriſes us, in regard to inſects, than their induſtry, and in this the caterpillars yield to no kind; not to mention their ſilk, the ſpinning of which is one great proof of it. The ſheaths and caſes which ſome of theſe inſects build for the paſſing their transformations under, are, by ſome, made of the ſilk, with their own hair mixed, with pieces of bark, leaves, and other parts of trees, with paper, and other materials, and the ſtructure of theſe is well worthy our attention.

There are others whoſe workmanſhip, in this article, far exceeds theſe. There is one which builds in wood, and is able to give its caſe a hardneſs greater than that of the wood itſelf in its natural ſtate. This is the ſtrange horned caterpillar of the willow, which is one of thoſe that eat their exuviæ. This creature has extremely ſharp teeth, and with theſe it cuts the wood into a number of ſmall fragments; theſe fragments it afterwards unites together into a caſe, of what ſhape it pleaſes, by means of a peculiar ſilk, which is no other than a tough and viſcous juice, which hardens as it drys, and is a ſtrong and firm cement. This alone, however, would probably not ſuffice to give the work a due ſtrength and ſolidity, were it practiſed on the rough pieces of wood, as they are cut from the tree, becauſe it would only act upon the ſuperficial part of each piece. In order, therefore, to make it ſink into the very ſubſtance of every fragment, the creature moiſtens every one of them, by holding them ſucceſſively a conſiderable time in its mouth. By this means they are penetrated with the ſalival moiſture, and their pores give eaſy acceſs to the viſcous fluid they are afterwards to be impregnated with. The ſolidity of the caſe being thus provided for, we are to conſider, that the caterpillar encloſed in it is to become a butterfly, and the wonder is, in what manner a creature of this helpleſs kind, which has neither legs to dig, or teeth to gnaw with, is to make its way out of ſo firm and ſtrong a lodgement as this, in which it is hatched. It has been ſuppoſed by ſome, that the butterfly, as ſoon as hatched, diſcharged a liquor which ſoftened the viſcous matter that holds the caſe together, and ſo its ſeveral fragments falling to pieces, the way out lies open. This is evidently the truth of the caſe, tho' thoſe who ſuppoſed it, did it by mere conjecture; for, on a ſtrict examination, this liquor is always to be found in the animal, and is of the moſt proper kind for ſuch a ſervice. Reaumur judged, from the effects, that this liquor muſt be of a ſingular nature, and very different from the generality of animal fluids; and on diſſecting this creature in the caterpillar ſtate, there will always be found, near the mouth, and under the æſophagus, a bladder, of the bigneſs of a ſmall pea, full of a limpid liquor, of a very quick and penetrating ſmell, and which, upon divers trials, proves to be a very powerful acid; and, among other properties, which it has in common with other acids, it ſenſibly ſoftens the glue of the caſe, on a common application. Phil. Tranſ. N°. 469. p. 463.

It is evident that this liquor, beſide its uſes to the caterpillar, remains with it in the chryſalis ſtate, and is the very thing that gives it a power of diſſolving the ſtructure of the caſe, and making its way through in a proper manner, at the neceſſary time. Dr. Boerhaave has adopted the opinion, that there are no true acids in animals, except in the ſtomach, or inteſtines; but this familiar inſtance proves the error of that determination.

Near the head, on the under part of the firſt ring of the body, there is placed a ſort of fleſhy protuberance, or nipple, while the creature is in the caterpillar ſtate. This nipple, in its common ſtate, is hid within the fleſh, and only appears on preſſing the body of the animal. This is not peculiar to this caterpillar, for many other kinds have an organization of this kind, tho' not all. In ſome it is ſingle, in others double, in ſome others divided into three parts, and in this particular inſtance, into four.

Mr. Reaumur, in the ſecond volume of his hiſtory of inſects, has given a full account of the changes, and manner of living, of theſe little, and generally eſteemed contemptible animals; not any of which may not afford great ſubject of admiration in the mind of a curious enquirer into the works of nature; but, among the great number he has there deſcribed, there are ſome which appear ſo very ſingular, as to call for a more than ordinary attention. Of theſe, one very remarkable one is the ſpecies which, from is manner of carrying its head and the fore part of its body erect, he has called the ſphinx. A ſecond is extreamly remarkable in its hinder part, where it carries two long and immoveable pipes, ſtanding in a line with the body. Theſe are plainly hollow, and, when the animal pleaſes, there iſſues out from them a kind of tail, which is very long and flexible, and turns with great eaſe any way the creature pleaſes. The uſe this is deſigned by nature for, ſeems the wiping off any thing, that may incommode the creature, from any part of its body. Mr. Reaumur never ſaw this tail proceed out of more than one of theſe pipes at a time; but it ſeems probable that there is a tail to each pipe, ſince their ſtructure ſeems wholly the ſame, and it is eaſy to ſee of what great uſe this part may be to the creature that poſſeſſes it.

There is alſo another caterpillar to which the author has given a name, as to the ſphinx, from its peculiar attitudes; this he calls the ziczac. This creature is diſtinguiſhed from all the other caterpillars by the ſtrange and unnatural motions (as they appear to us) into which it is continually twiſting and bending its body.

Beſide the common actions of all the caterpillar kind, which are daily ſeen, and the cauſes and ends of which are evidently known, there are others which are very myſterious. Some caterpillars ſpin all the way as they walk, and leave behind them, wherever they paſs, a thread of ſilk, which marks their journey. A waſte of this kind might appear, at firſt ſight, very unnatural, and very prejudicial to the creature; but nature has provided for it by a proper ſupply; and if we trace the creature's journey till we chance to ſee it fall by accident, we ſhall then ſee that this thread is not abſolute waſte, for it then preſerves the creature, being faſtened to the leaf and twigs it paſſes over, and being of ſtrength to ſupport the hanging weight of the animal, without breaking. It in this manner ſtops the creatures fall, for it is in its own power to ceaſe ſpinning when it pleaſes; and if it does not wholly ceaſe, ſo that the fall is not entirely ſtopp'd, it is, however, at leaſt, made very eaſy. Nor is this all the advantage, for it can, if it pleaſes, by means of this thread, re-aſcend to the place from whence it fell, by ſeizing the thread between its legs, and by the help of its head and theſe, gathering up the thread, and replacing itſelf on the leaf; when it is ſafely got up again, it diſengages its legs from the thread, and continues its motions as before, and ſeems no way affected by the accident.

Another very curious and myſterious artifice, is that by which ſome ſpecies of caterpillars, when the time of their changing into the chryſalis ſtate is coming on, make themſelves lodgements in the leaves of trees, by rolling them up in ſuch a manner, as to make themſelves a ſort of hollow cylindric caſe, proportioned to the thickneſs of their body, well defended againſt the injuries of the air, and carefully ſecured for their ſtate of tranquillity. The niceſt pair of hands could not roll up theſe leaves more elegantly than it is done by theſe little creatures, which have neither hands, nor any thing analogous to them, for the doing it with.

Theſe caſes have ſometimes five or ſix turns, and the manner of the creature's performing the work is this; when it is to be done, the caterpillar places itſelf on the upper ſide of a leaf, at ſuch a diſtance from the edge, that it can, at pleaſure, reach it with its head, and in turning itſelf round, it can then bring this edge of the leaf to another point, or place, exactly oppoſite to it. It then draws lines from this edge of the leaf to this before-mentioned point; and, doing this all the way along the leaf, its narrowneſs toward the point makes it form a cloſe caſe there, tho' it did not ſo where it began. It ſtrengthens this firſt bending of the leaf by many parallel threads, and when it has perfectly ſecured it, it then faſtens other threads to the back part of the leaf in this already half form'd circle, and fixing thoſe to another point, it draws them as tight as it can, and the bending of the leaf is finiſhed, and the caſe of the animal form'd. The ſame method repeated makes the ſeveral after turns, and, by this ingenious contrivance, the lodging is at length compleatly finiſhed.

The creature continually adds to the ſtrength of its threads, by bringing others acroſs them in different directions, and ſo continues it, that in the five or ſix rolls that it makes, every one makes the force of the laſt, or more inner one, uſeleſs.

The caſe being thus compleated with walls ſo many times doubled,

doubled, the creature enters it, there to ſuffer its deſtin'd change. In this caſe, however, the covering it has made ſerves it not only for a lodging, but alſo for food; for ſo long as it finds it neceſſary to eat, it may feed upon the walls of its caſtle, in a prudent manner, not devouring too haſtily, for all may be eaten away, except the outer one of all, which is of itſelf alone ſufficient for the purpoſe. It is probable, that every caterpillar who makes a caſe of this kind, makes it of a ſufficient number of turns, or doubles, to ſerve the neceſſary calls of its future hunger, and, in many of the ſmaller kinds, the ſtrength of the whole is little or nothing impaired by their eating, ſince they eat only the parenchymatous ſubſtance of the leaves, without touching the ribs, which are the main ſtrength and ſupport of the whole.

Beſide theſe caterpillars, which in this manner roll up the leaves of plants, there are other ſpecies which only bend them once, and others which, by means of thin threads, connect many leaves together to make them a caſe. All this is a very ſurprizing work, but all much inferior to this method of rolling.

The different ſpecies of caterpillars have different inclinations, not only in their ſpinning, and their choice of food, but even in their manners and behaviour one to another. They are all hatched from the eggs of butterflies, many ſpecies of which always depoſit a great number of eggs on the ſame place. Theſe all hatch very nearly at the ſame time, and it would be very natural to ſuppoſe, that the young brood, in all the ſpecies, ſhould be enclined to continue and live together. But this is not the caſe, the different ſpecies have their different inclinations, and conduct themſelves always in in the ſame kind by the ſame ſtated rules. Some never part company from the time of their being hatch'd to their laſt change, but live and feed together, and undergo together their laſt change into the chryſalis ſtate. Others ſeparate one from another as ſoon as able to crawl about, and each hunts its fortune ſingle; and there are others which regularly live to a certain time of their lives in community, and then ſeparate each to ſhift for itſelf, and never to meet again in that ſtate.

Thoſe which live wholly together, begin by forming a line, with their little bodies, upon a leaf, their heads ſtanding all regularly even, and in this manner they move and eat together; and often there are ſeveral ranges of this ſort, which make ſo many phalanxes, in an order as regular as the military one, and eat into the leaf they ſtand on with perfect equality.

This is the caſe with many, while young, which, when they grow larger, firſt make one common habitation, ſurrounded by a web, which is the joint work of them all, and within which there is a peculiar neſt of every one, of its own ſpinning, When they have made this common lodging, they ſeparate, and each takes its courſe over the tree, or buſh, for food, well knowing where they are all to meet. In this manner, many hundreds of theſe animals form a ſort of republic, where every thing is carried on in perfect order and regularity, and the ſeparate cell of each, in the general habitation, is finally the place where it is to paſs, in tranquillity, its change into the chryſalis ſtate. There are other ſpecies of caterpillars which do not ſeparate from one another, even for theſe neceſſary occaſions of feeding, and their transformation: Theſe live their whole time together, and are uſually found in their ſtate of chryſalis all huddled together, and their caſes frequently ſticking to one another, and numbers of them making only one confuſed maſs.

There is one thing yet to be obſerved, in regard to the cuſtoms and manners of theſe little animals, this is the regularity of their marches. Nothing can produce an union between a number of ſubjects, ſo well as an abſolute obedience to ſome one chief; and this is regularly obſerved by theſe communities of caterpillars. When they have occaſion to change their quarters, one of their number, who ſeems to have the ſole power and direction of the rout, marches ſingly firſt whichever way he pleaſes. He is followed by two others, who keep their bodies very nicely in the ſame direction with his, and, after theſe, there follows a large party; theſe regulate their motions by the former, and ſo the order is continued through the whole company. When the leader turns to the right, or to the left, the whole body is immediately ſeen to do the ſame; when he ſtops, they all immediately ſtop, and march again the moment that he begins to advance. This chief ſeems, however, to be no particular favourite, nor to have any laſting power, but it ſeems mere chance that conſtitutes him in his poſt. This, however, is always certain, that while he is in power, the reſt are perfectly obedient. *Reaumur*, Hiſt. Inſ. T. 2.

Caterpillars are very deſtructive and pernicious in gardens, particularly thoſe of two ſpecies. The one of theſe is that which afterwards becomes the common white butterfly. This is of a yellowiſh colour, ſpotted with black, and infeſts the leaves of cabbages, cauliflowers, and the Indian creſs, of which it eats off all the tender parts, leaving only the fibres entire, ſo that whole plantations are often ſeen deſtroyed by them in autumn, eſpecially ſuch as are near large buildings, or are crouded with trees. There is no remedy againſt this evil, but the pulling the creatures off before they are ſpread from their neſts, and watching the butterflies, which are daily, in the hot weather, depoſiting their eggs on theſe plants. Theſe, however, feed principally on the outſide of the leaves of the plants, and are therefore the eaſier taken off; but the other kind lives near the center, and therefore is with much more difficulty diſcovered. This is much larger, and the ſkin is very tough, and of a brown colour. It is called, by the gardeners, a grub, and is extreamly pernicious. The eggs which produce it are uſually depoſited in the very heart, or center, of the plant, particularly in cabbages, and the creature, when form'd, and grown to ſome ſize, eats its way through all the leaves, and leaves its dung in great quantity behind it, which ſpoils the cabbage. This inſect alſo burrows under the ſurface of the ground, and makes ſad havock among young plants, by eating off their tender ſhanks, and drawing them into the holes. This miſchief is chiefly done in the night; but wherever a plant is ſeen thus deſtroyed, if the earth be ſtirred with a finger an inch deep, the creature will be certainly found, and this is the only way of deſtroying them. *Miller*'s Gardner's Dict.

When theſe inſects attack fruit trees, the beſt method of driving them off is this; boil together a quantity of rue, wormwood, and the common tobacco, of each equal parts, in common water; make the liquor very ſtrong, and ſprinkle it on the leaves and young branches every night and morning, during the time when the fruit is ripening. *Munting*, de Plant.

ERUCÆ *Aquaticæ*, *Water Caterpillars*.—It might ſeem incredible that there is any ſuch creature as a caterpillar, whoſe natural habitation is under water; but experience and obſervation prove that there are ſuch, and that they feed on the water plants as regularly as the common kinds do on thoſe at land. Theſe are not named at random, like many of the aquatic animals of the larger kinds, the ſea wolf, and the ſea horſe, *&c.* which might as well be called any thing elſe as wolves and horſes, but they are properly what they are called, and do not reſpire in the manner of the fiſh tribe, but by their ſtigmata, as other caterpillars. Mr. Reaumur, in his obſervations, met with two ſpecies of theſe, the one upon the potamogiton, or pond-weed, the other upon the lenticula, or duckmeat. Theſe are both very induſtrious animals; but the firſt being much the larger, its operations are more eaſily diſtinguiſhed.

This, though truly an aquatic animal, ſwims but badly, and does not at all love to wet itſelf. The parent butterfly lays her egg on a leaf of the potamogiton, and, as ſoon as the young caterpillar is hatched, it gnaws out a piece of the leaf of a roundiſh ſhape. This it carries to another part of the ſame leaf, and lays it in ſuch a manner, that there may be a hollow between, in which it may lodge. It then faſtens down this piece to the larger leaf with ſilk of its own ſpinning, only leaving certain holes at which it can put out its head, and get to gnaw any of the leaves that are near. It eaſily gets out, though the aperture be naturally ſmall, ſince a little force from its body bends up the upper leaf, and bends down the lower, both being flexile, and when the creature is out, it has a ſort of down that defends itſelf from being wetted, and the natural elaſticity of the leaves, and of the ſilk, join the aperture up again, ſo that no water can get in. The leaves of this kind of plant are alſo naturally very ſlippery, and not eaſily wetted by water. It ſoon happens, that this habitation becomes too ſmall for the animal, in which caſe it makes juſt ſuch another, and after that, at times, ſeveral others, each being only made fit for it at the ſize it is then of. The changes of this creature into the chryſalis and butterfly ſtate, are in the common method. The butterfly gets out of a chryſalis which was placed on the ſurface of the water, the lightneſs of the animal eaſily ſuſtains it on the water till its wings are dried, and it then leaves that element never to return to it again. Mem. Acad. Par. 1736.

ERUCÆ *Sylveſtres*, *Wood Caterpillars*. See WOOD.

ERUCA, *Rocket*, in botany, the name of a genus of plants, the characters of which are theſe: The flower conſiſts of four leaves, and is of the cruciform kind. The piſtil ariſes from the cup, and becomes, at length, a pod, divided into two cells by an intermediate membrane, and uſually containing roundiſh ſeeds. To theſe marks it is to be added, that all the plants of this genus have the ſame peculiar taſte.

The ſpecies of *Rockett*, enumerated by Mr. Tournefort, are theſe: 1. The broad-leav'd white flowered garden *Rockett*. 2. The garden *Rockett*, with leaves divided into ſegments. 3. The broad-leav'd, narrow podded *Rockett*, called the *Rockett* gentle, or Roman *Rockett*. 4. The daiſy-leav'd *Rockett*. 5. The fine leav'd perennial yellow flower'd *Rockett*. 6. The great yellow *Rockett*, with rough ſtalks. 7. The ſmaller yellow wild *Rockett*, with ſhepherd's purſe leaves. 8. The Indian tawny-leav'd *Rockett*. *Tourn.* Inſt. p. 226.

ERUCAGO, in botany, the name of a genus of plants, of which there is only one known ſpecies. The characters of this are theſe: The flower conſiſts of four leaves, diſpoſed in form of a croſs; and the piſtil ariſes from the cup, and afterwards becomes a remarkable pod, of the ſhape of a ſquare club, which is divided into four cells, and contains roundiſh

and roſtrated ſeeds. This plant has been called, by other authors, the ſquare podded rockett, and the echinated muſtard. *Tourn.* Inſt. p. 232.

ERUPTIONS, in infants. See INFANTS.

ERVUM, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the papilionaceous kind, and from its cup ariſes a piſtil, which finally becomes a pod, undulated on each ſide, and, as it were, knotty; it contains ſeveral roundiſh ſeeds. To this it may be added, that the leaves grow in pairs on the ribs. *Tourn.* Inſt. p. 398.

The ſpecies of *Ervum*, enumerated by Mr. Tournefort, are theſe: 1. The true *Ervum*, called, by ſome, the orobus, with jointed pods. 2. The true *Ervum*, with purpliſh flowers. 3. The *Ervum*, with ſmall ſeeds: And 4. The *Ervum*, with obtuſe triangular ſeeds.

ERYNGIUM, *Eringo*, in botany, the name of a peculiar genus of umbelliferous plants, the characters of which are theſe: The flower is of the roſaceous kind, conſiſting of ſeveral petals, the points of which uſually turn inwards, and which are arranged, in a circular order, on a cup that afterwards becomes a fruit, compoſed of two ſeeds: Theſe are ſometimes foliated, ſometimes plain, of an oval figure, while in their involucrum, which they, however, often throw off, and then appear like corns of wheat. To this it may be added, that the heads of flowers have all a circle of leaves placed under them.

The ſpecies of *Eryngium*, enumerated by Mr. Tournefort, are theſe: 1. The ſea *Eryngium*. 2. The Portugal *Eryngium*, with larger leaves. 3. The common *Eryngium*. 4. The Portugal *Eryngium*, like the common kind, but with broader leaves. 5. The blue alpine *Eryngium*, with dipſacus heads. 6. The very prickly alpine *Eryngium*, with long ſhaped, dipſacus-like heads. 7. The broad leav'd plane *Eryngium*, with round heads. 8. The broad leav'd plane *Eryngium*, with white flowers, and greeniſh white ſtalks. 9. The baſtard *Eryngium*, produced from the ſeeds of the plane kind. 10. The blue mountain *Eryngium*. 11. The blue alpine *Eryngium*, with larger and paler heads. 12. The ſmall Portugal blue *Eryngium*, with longer leaves. 13. The leſſer plane *Eryngium*. 14. The dwarf mountain *Eryngium*. 15. The Sicilian *Eryngium*, with pſyllium heads. 16. The ſtinking American *Eryngium*. 17. The ſweet-ſcented ſmall marſh *Eryngium*. 18. The Portugal erect marſh *Eryngium*, with pſyllium heads. 19. The horned Portugal marſh *Eryngium*, and 20. The procumbent Portugal marſh *Eryngium*. *Tourn.* Inſt. p. 327.

The root of *Eryngium* is attenuant and deobſtruent, and is therefore eſteemed a good hepatic, uterine, and nephritic. Its whole virtue, it is to be obſerved, conſiſts in the external or cortical part.

ERYNGIUM is alſo a name given, by ſome of the old authors, to aloes, a medicine as different from the root of this name as any one thing can well be from another.

There are ſeven different ſpecies of the *Eryngium* plant propagated in the gardens of the curious, but the common ſea kind is the only one of any uſe. The roots of this are in great quantities, both dried and candied in the ſhops; they may all be propagated, either by parting their roots, or ſowing their ſeeds; but the firſt is the moſt convenient and expeditious method. This is to be done in February, or in the beginning of March, before the plants have ſhot out their leaves; and the ſoils they moſt delight in are gravel and ſand, but in dry ſeaſons they require a great deal of watering. The ſecond year after their removal from the old plant they will flower, but the flowers are not ſo ſtrong as in the older plants. They ſpread very much at the root. *Miller*'s Gardener's Dict.

There is a very remarkable tradition, among ſome authors, concerning this plant, which is, that if a goat happens to take into its mouth a head of the *Eryngo*, the whole flock that he is with will all ſtare upon him with aſtoniſhment, and ſtand as if rooted to the earth. Ariſtotle is the firſt author we find aſſerting this, and after him Caryſtius in his book *De Admirabilibus*. Pliny has not omitted this wonderful ſtory, but he has ſtrangely miſrepreſented it in the telling: He ſays, that if any perſon takes one of the goats of a flock by the beard, the reſt will all ſtand as if rooted to the earth with aſtoniſhment. It will not be eaſy for the unlearned reader to find how this ſtory can be the ſame with the other, but the whole is eaſily explained by obſerving, that Pliny's careleſſneſs, has made him tranſlate the word πρυγγον, a beard, inſtead of a plant. This appears, by comparing his tranſlation with the original, to have been plainly the caſe; and he adds, from ſome other author, that the ſame thing happens when any one of them chances to bite a certain herb; but he does not name the word *Eryngium*, which he had juſt before tranſlated a beard, as the name of the plant, but omits to mention what it was.

Theophraſtus has the ſame ſtory of the goats, but his manner of telling it very plainly ſhews, that he underſtood it from his maſter Ariſtotle, as ſpoken of the goats eating *Eryngo*, not being taken by the beard. For he expreſsly ſays, that as ſoon as the creature has taken this plant into its mouth, it ſtops, and ſo do all the reſt. The whole of this ſtrange ſtory may have no more in it, than that as ſoon as one of theſe creatures, who has been browſing upon other herbs, chances to take a head of this into his mouth, the thorns about it prick him, and he ſtops ſhort, and the reſt of the flock, being timorous animals, ſtop alſo till they ſee whether any danger threatens them.

ERYSIMUM, *Hedge Muſtard*, in botany, the name of a genus of plants, the characters of which are theſe: The flower conſiſts of four leaves, which are diſpoſed in form of a croſs. The piſtil ariſes from the cup, and finally becomes a pod, divided into two cells by an intermediate membrane, and containing ſmall roundiſh ſeeds. To this it may be added, that the *Eryſimums* have all a peculiar general appearance. They gave, 1. The common *Eriſymum*. 2. The *Eryſimum* with pods, reſembling thoſe of rockett. 3. The horned *Eryſimum*. 4. The great broad-leav'd ſmooth *Eryſimum*. 5. The greater narrow-leav'd *Eryſimum*. 6. The Pyrenæan horned *Eryſimum*, with leaves like thoſe of woad. 7. The perennial *Eryſimum* of the Pyrenæan mountains, with dandelion leaves. *Tourn.* Inſt. p. 228.

ERYSYMUM, in medicine, is famous as an attenuant. It reſolves tough humours in the lungs and fauces, and promotes expectoration in a very remarkable manner. It is good in aſthmas, inveterate coughs, and hoarſeneſs. We uſed to have a ſyrup of it in the ſhops, but it is now diſuſed.

The *Eryſimum* is recommended by Dr. Stahl for ſcirrocancrous tumours, taken internally, and alſo externally applied to the tumour. We have two hiſtories of its good effects, by Mr. Bingert, in Act. Med. Berol. dec. 3. vol. 1. p. 59.

ERYSIPELAS (*Cyc.*)—In *eryſipelatous* fevers, which are juſtly ranked among the exanthematous kind, the blood and humours being in an intenſe motion, an acrid ſerum of a ſulphureous and cauſtic nature is, by that means, propelled to the ſurface of the body, and produces a ſwelling, accompany'd with redneſs, heat, and pain.

This fever is far from being innocent and ſimple, as it is generally thought, and is often violent and dangerous, nay mortal, and, in ſome caſes, appears to be nearly allied to peſtilential fevers, the moſt formidable of all diſorders. The ſymptoms in both are of the ſame kind, and on the third or fourth day the morbid matter in both is thrown out to the ſurface, and the violence of the ſymptoms on this ſomewhat abates. But the great difference is, that the one is contagious, the other not ſo, and the peſtilential is much more fatal than the other uſually is found to be.

Phyſicians diſtinguiſh the *Eryſipelas* into two kinds, the ſimple, and the ſcorbutic. The ſimple or genuine *Eryſipelas* affects only the ſurface of the body, and eaſily gives way to proper remedies, in a ſhort time; but the ſpurious, or ſcorbutic kind, is more deeply rooted, and hard to be removed. There is alſo a third kind, called an exulcerated *Eryſipelas*, in which the eruptions are yellow, and contain an acrid pungent humour, which gives a terrible gnawing pain. This diſeaſe affects every part of the body, but particularly the face, and happens at all times of the year, but moſt frequently at the cloſe of ſummer. It ſometimes ſpreads over the whole face, and ſwells and inflames it in ſuch a manner as to endanger ſuffocation. It often ſeizes people in a moment, while they are abroad, and is called by the country people a blaſt; it, in reality, differs very little from the effects of the ſtings of waſps and bees, except that the heats often riſe into puſtules. One kind of *Eryſipelas* wholly reſembles the ſtinging of nettles; this is uſually brought on by drinking, and is very troubleſome, the pimples appearing and diſappearing at times, ſometimes for a long while together.

However mild the more common kinds of this diſorder may naturally be, yet ill management will make even the ſlighteſt of them dangerous, and the ſtriking the eruptions in has been often known to be of fatal conſequence. Hoffman mentions a patient he knew, who by taking a vomit, and a draſtic purge, in the time of the eruption, had an inflammation of the ſtomach brought on, and died in a few days. In many kinds of the *Eryſipelas*, nature does much, and, with a little proper aſſiſtance, the whole terminates kindly in a ſhort time; but the bad kinds, nay, and too often the beſt, when treated unſkilfully, turn to violent burning fevers, and the eruptions to gangrenes.

The true method of curing an *Eryſipelas* conſiſts in three intentions; firſt, that the febrile motion of nature be by no means hinder'd, but rather promoted, if it be found defective, and only reduced to a due temperament, if exceſſive. Secondly, that the ſubtle cauſtic matter be corrected, and prepared for ſecretion and excretion; and thirdly, that the inflammatory ſtagnation of putrid and cauſtic lymph in the external parts be diſcuſſed, and perfectly expelled. Bleeding in an *Eryſipelas* is ſometimes beneficial, ſometimes hurtful, and a good general rule is to order it in plethoric habits, and perſons accuſtomed to drink ſpirituous liquors, but to forbid it in others. When the inflammation is mild and gentle, it may ſometimes be removed by external warmth alone, but when it is more violent, it requires the help of internal, and ſometimes external remedies: Of the internal kind, the *mixtura ſimplex* is one ſtanding good medicine, and of the external, an oint-

ointment made of elder bark, or the rob of elder, are known to have performed great cures.

There is, beſide the common kinds of the *Eryſipelas*, yet one more to be mentioned, which is always very terrible, and often fatal; this is an *Eryſipelas* of the lungs. In this caſe the patient is ſeized with a highly burning fever, and an acute pain both in the anterior and poſterior parts of the body, but eſpecially about the ſpine. He always holds his neck ſtrait upright when he breathes, and his noſtrils dilate with an exceſs of heat and pain, and, in the more advanced ſtages, his tongue hangs out of his mouth like that of a dog that pants with heat and wearineſs. He vomits ſometimes bile, and at other times phlegm, and is ſubject to very frequent faintings: He coughs much, and either ſpits not at all, or elſe a yellowiſh or bloody matter. This diſeaſe almoſt always proves mortal, and the only accident that can give the patient the leaſt hope, is its quitting the internal parts, and ſhewing itſelf on the ſurface.

Heiſter thinks that the grand intention, in the curing this diſorder, muſt be to dilute the inſpiſſated blood, and break and divide it where it ſtagnates and is obſtructed. Plenty of thin and weak drinks are therefore to be adminiſtred, by which a gentle and laſting ſweat may be excited, and the teſtaceous powders, and nitrous medicines, are frequently found alſo to have great and good effects. If the inflammation be but very ſlight, it is often cured by external warmth; but when warmth alone does not prove ſufficient, cloths, with the rob of elder ſpread upon them, are found of great benefit, being laid warm on the part, and kept on by warm compreſſes, and the proper bandages. Ointments made of the middle green bark of elder, are alſo very beneficial; and notwithſtanding that many do not approve the practice, yet ſpirit of wine camphorated, with a mixture of ſaffron and Venice treacle, are found often of very great ſervice, applied warm with coarſe paper, or with linen rags: And a mixture of lime water, and ſpirit of wine camphorated, often does great ſervice. It ſometimes happens, that an *Eryſipelas* comes to ſuppuration; and from this generally ariſe the moſt untractable ſpreading and eating ulcers. In this caſe, the ulcer is to be carefully cleanſed, and dreſſed with ointments of ceruſs, red lead, or litharge, and plaſters of the ſame ingredients; and muſt, at the ſame time, take internal remedies to ſweeten the blood, ſome gentle purges, and a ſtrict regimen in regard to diet. *Heiſter*'s Surgery, p. 193.

ERYSIPELATODES, in medicine, is a ſwelling like that of the *Eryſipelas*, tho' with eaſier ſymptoms; and therefore may be taken for a kind of *Baſtard Eryſipelas*; in this the ſkin is of a more dark colour.

ERYTHOXYLUM, in botany, a name uſed, by ſome authors, for the tree called arbor braſilia by others, the wood of which is the common brazil wood. *Herm.* Par. Bot. p. 2. p. 333.

ERYTHREMA, a word uſed, by the old writers in medicine, to expreſs a redneſs of the cheeks, occaſioned by the violent heat in fevers. Some alſo have applied the ſame word in the plural number, to the red inflammatory eruptions in an eryſipelas. See ERYSIPELAS.

ERYTHRINA, in botany, a name given, by Linnæus, to a genus of vegetables, called by Tournefort, Dillenius, and the generality of other writers, corallodendron, and coral. *Linnæi* Gen. Pl. p. 342. *Tourn.* 446. *Dillen.* Hort. Elth. 20. See CORALLODENDRON.

ERYTHRINUS, in ichthyology, the name of a fiſh, called by ſome authors alſo the *Rubellio*, *Travolino*, and *Alboro*, or *Arboro*, by the Venetians. It is a ſmall fiſh, ſomething like the aurata or gilthead in ſhape, but much ſmaller, and of a pale red colour all over. Its tail is very forked; its noſe conſiderably ſharp, and its eyes very large, and with ſilvery iriſes, with ſometimes a ſlight tinge of red among the white. The mouth is ſmall, and the fore teeth broad, the hinder ones are rather tubercles than teeth. The coverings of the gills are ſcaly. It has only one back fin, the anterior rays or nerves of which are prickly, the others ſoft and ſmooth to the touch. *Rondelet.* de Piſc. l. 5. c. 13. p. 144.

ERYTHRODANUM, in the materia medica, a name by which ſome authors have called the rubia tinctorum, or madder. *Ger.* Emac. Ind. 2.

ERYTHROPHTHALMUS, the *Red Eye*, in zoology, the name of a fiſh of the bream kind, called, by ſome, Rootang, which, in the German language, ſignifies the ſame. It very much reſembles the common river bream in ſhape, but that it is ſomewhat thicker. The fins are all red, and the whole body of the fiſh is ſtained with a very elegant red, but no part of it ſo much as the iris of the eyes. When the ſcales are off the body is of a greeniſh hue, and it has a yellow ſpot under the tongue. It much reſembles the river mullet in ſome particulars, but it is of a more beautiful colour, and its eyes are more red. Its largeſt ſize ſeems a foot in length. It is a well taſted fiſh, and ſpawns in May, under cover of the roots of trees. *Ray*'s Ichthyography, p. 249.

ERZ, or ERZI, in the botanical writings of the antients, a word uſed originally by the Hebrews, and by them made the name of the cedar. The Arabian phyſicians Serapio and Aviſenna uſe it alſo as the name of the cedar, but they do not keep ſtrictly to this, its proper meaning. They call common reſin, or colophony, by the name retenegi, and tell us that it is produced by the *Arz* or *Alarzi*. Hence it is plain, that they confounded together the names of the pine and fir kinds with the cedar; but this is not peculiar to them, for we find Pliny making the cedria, or reſin of the cedar, and the cedrelæum, or oil ſeparated from it in melting, to be the ſame with the common pitch and piſſelæum ſeparated from it; and even the Greeks, as well as Latins in general, have confounded and blended together all the trees which produced pitch or reſin, and we find the fir, the pine, the cedar, and the turpentine tree, all called by the ſame general names.

ESAPHE, a word uſed by Hippocrates, to expreſs the touching the mouth of the uterus, in order to diſcover its ſtate or diſeaſes.

ESCH, in ichthyology, a name given, by Hildegard and others, to the fiſh we call the grayling, or umber, and the generality of authors, the thymallus. It is of the coregonus kind, and is diſtinguiſhed by Artedi by the upper jaw being longer, and the back fin containing twenty-three bones. The Germans call it aſch, and the Italians temello.

ESCHARA, in botany, the name of a genus of plants, the characters of which are theſe. They are of a ſtony, or coral-like hardneſs, and reſemble a woven cloth in their texture. *Tourn.* Inſt. p. 576.

The ſpecies of *Eſchara*, enumerated by Mr. Tournefort, are theſe. 1. The common retiporous *Eſchara*. 2. The foliaceous retiporous *Eſchara*. And 3. The great black hat-faſhion'd retiporous *Eſchara*.

ESCHAROPEPA, a word uſed, by the old writers in medicine, to expreſs a coarſe kind of barley meal, which had been torrified over the fire.

ESCHAROTIC (*Cycl.*)—A compoſition of ſulphur, roſin, and honey, proves an *Eſcharotic*, with little or no pain. *Le Dran.* Obſ. Chir. Tom. 2. Obſ. 100.

ESCHATON, in muſic, the difference between the dieſis enharmonica and the hyperoche; that is, what remains, after taking the difference between the ſemi-tone minor and dieſis enharmonica, from the latter. *Henfling* in Miſc. Berolin. Vol. 1. p. 279, 280.

Thus the difference between the ſemi-tone minor and the enharmonic dieſis is $\frac{25}{24} : \frac{128}{125} = \frac{3125}{3072}$, and this taken from the dieſis, is $\frac{128}{125} : \frac{3125}{3072} = \frac{393216}{390625}$. This interval is about $\frac{53}{100}$ of a comma, as will eaſily appear by logarithms. Mr. Henfling has taken notice of this interval. He calls it *Eſchaton*, from its being the leaſt and the laſt interval that occurs in his ſyſtem. The word is Greek, ἔσχατον. Ibid. p. 265. ſeq. See INTERVAL.

ESCHEL, in mineralogy, a term uſed, by the ſmalt workers, to expreſs a ſort of grey ſubſtance reſembling aſhes, which is uſually mixed with the ſmalt when in fuſion. This is carefully ſeparated from it, before it is powdered for uſe, otherwiſe it would debaſe the colour. Phil. Tranſ. N°. 396.

ESCLAME, in the manege, an obſolete French word, formerly uſed to ſignify a light bellied horſe.

ESCROW, a deed delivered to a third perſon, to be the deed of the party making it, upon a future condition, when ſuch a thing is performed; and then it is to be delivered to the party to whom made. It is to be delivered to a ſtranger, mentioning the condition; and has relation to the firſt delivery. 2 Roll. Abr. 25, 26. 1 Inſt. 31.

ESCULUS, in botany, a name given, by many authors, to the phagus, or ſweet oak, called alſo the eſculent oak. *C. Bauhin.* Pin. p. 320.

ESEBON, a name given by ſome of the chemical writers, to common ſea ſalt.

ESNECY, *Æſnecia*, *Dignitas Primogeniti*, in law, a private prerogative, allowed to the eldeſt *Coparcener*, where an eſtate is deſcended to daughters for want of heirs male, to chuſe firſt after the inheritance is divided. *Fleta.* l. 5. c. 10.

Jus Eſneciæ is *Jus Primogenituræ*; in which ſenſe it may be extended to the eldeſt ſon, and his iſſue, holding firſt: In the ſtatute of Marlbridge, c. 9. it is called *Initia pars hereditatis*. Co. Lit. 166.

ESOX, in ichthyology, the name of a genus of fiſhes, the characters of which are theſe: They are of the malacopterygious or ſoft finned kind. The branchioſtege membrane contains fourteen bones. The body is oblong; the back fin not large, and is placed very near the tail. The ſpecies of this genus, enumerated by Artedi, are theſe: 1. The *Eſox* with a depreſſed ſnout; this is the common pike, the lucius of authors. The lower jaw is longer than the upper, and the vertebræ are ſixty-one in number. 2. The *Eſox* with a cuſpidated long, ſlender, and cylindric ſnout; this is the acus primus of authors, and is called, in Engliſh, the garfiſh. The lower jaw is longer than the upper. It is evident that authors of old times diſtinguiſhed but very badly the characters of fiſhes, when they called this and the ſyngnathus by the ſame name acus. 3. The *Eſox* with the upper jaw longeſt, and with the tail ſquare. This is the fiſh called by Liſter, in his appendix to Willughby, the acus maxima ſquammoſa.

This grows to more than two feet in length; the mouth opens very wide, and the ſcales ſtand very thick and cloſe, and in a very beautiful order. *Artedi*, Gen. Piſc. 10.

The word *Eſox* is truly Roman. Pliny, and other of the antient Latin authors, have uſed it as the name of the ſame fiſh. It ſeems to have been derived from the verb *Eſito*, to eat; for all the ſpecies of this fiſh are very voracious.

ESPALIERS, *(Cycl.)* in gardening, are rows of trees planted in the manner of hedges; either to ſurround a whole garden, or the ſeveral quarters of it. They are trained up flat and in a cloſe hedge, and ſerve not only for fruit bearing, but alſo to ſhelter and defend the tenderer plants kept within the quarters. They are moſt commonly made of fruit trees trained up to a lattice of wood-work, formed either out of aſh-poles, or ſquare pieces of fir-wood, and their moſt uſual office is the ſheltering, and at the ſame time hiding the quarters of kitchen-gardening.

The trees principally planted for *Eſpaliers* now, are apples and pears and ſome plumbs. The apples intended for *Eſpaliers*, ſhould be grafted on crab-ſtocks, for large gardens, and for ſmaller on codling-ſtocks. The trees for the ſame hedge in an *Eſpalier*, ſhould be all ſuch as are of the ſame age, from the grafting; and produced from the ſame ſtocks, that ſo the hedge may be the more regular. The more quick-growing, and ſpreading ones, muſt be planted at twenty-two feet aſunder, and thoſe of ſmaller growth, at ſixteen or eigtheen; the walk between them in a large garden ſhould be ſixteen feet wide, and if the *Eſpaliers* are intended to be carried up high, it ſhould be more, that both hedges may have the benefit of the ſun.

The beſt ſorts of apples for *Eſpaliers*, are the golden pippen, the nonpareil, the rennet griſe, the aromatic pippen, the Holland pippen, the French pippen, Wheeler's ruſſet, and Pile's ruſſet; for the naming and pruning of theſe trees, ſee the articles PRUNING and APPLES.

The pears fitteſt for *Eſpaliers*, are the ſummer and autumn kind; for the winter ones never ſucceed well. Theſe, if deſigned for a ſtrong moiſt ſoil, ſhould be on quince ſtocks; but if for a dry ſoil, more free ſtocks ſhould be choſen. The diſtance for pears grafted on free ſtocks ſhould be eighteen feet, and for the moſt vigorous ſhooters, it ought to be twenty-five feet. And the beſt kinds of pears for this purpoſe, are the jargonelle, the blenquette, the poire ſans peau, the ſummer boncretien, Humbden's bergamot, the poire du prince, burre du roy, the St. Michael, the le marquis, the monſieur Jean, and the creſſane.

The third year after the trees are planted, the frame-work of the *Eſpalier* ſhould be made. Till this time the young ſhoots ſhould only be trained to upright ſtakes, nailing them with liſt to different heights of theſe, as nearly as can be in an horizontal direction. The beſt way of making the wood-work is of aſh-poles, which are not only cheap, but ſtrong and durable; the branches are all to be trained horizontally to theſe, and none ſhould be ſuffered to croſs one another, nor to come too near. In the trees which produce large fruit, no branches ought to be nearer to each other than eight inches, in the ſmaller fruited ones five or ſix inches is ſufficient; the advantages of the trees planted in *Eſpaliers*, over thoſe propagated as dwarfs, in the place of which theſe have been introduced, are many and very great. They take up very little room in a garden, and are of no injury to the plants cultivated in the quarters; and the fruit is always more regularly ripened and better taſted, as the ſun and air can have every way free acceſs to it. *Miller*'s Gardners Dict.

ESPHLASIS, a term uſed by the old writers in medicine, for the receding inward of the ſkull in depreſſions from contuſions.

ESPLEES, *Expletiæ*, from *Expleo*, in law, the products which ground or land, &c. yield; as the hay of the meadows, the herbage of the paſture, corn of the arable, rents, ſervices, &c. and of an advowſon, the taking of tithes in groſs by the parſon; of wood, the felling of wood; of an orchard, the fruit growing there; of a mill, the taking of toll, &c. Theſe and ſuch like iſſues are termed *Eſplees*. And it is obſerved, that in a writ of right of land, advowſon, &c. the demandant ought to alledge in his count, that he or his anceſtors took the *Eſplees* of the thing in demand; otherwiſe the pleading will not be good. Terms de Ley, 310.

Sometimes this word hath been applied to the farm, or land, &c. themſelves—*Dominus E. habebit omnia expletias & profi-cua de corona emergentia.* Plac. Parl. 30. *Edw.* 1.

ESPOUSALS, *Sponſalia*, in law, a contract or mutual promiſe between a man and a woman to marry each other. Marriage or matrimony is ſaid to be an *Eſpouſal de preſenti*. *Wood*'s Inſt. 57.

ESQUIAVINE, in the manege, an old French word ſignifying a long and ſevere chaſtiſement of a horſe in training him.

ESSATUM, a word uſed by ſome of the chemical writers, to expreſs the medicinal power or ſanative property reſiding in ſimple medicines.

ESSAY *(Cycl.)*—ESSAY-*Hatch*, is the miners term for a little trench or hole, which they dig to ſearch for *ſhoad* or ore. See TIN.

ESSEDARIUS, among the Romans, a gladiator, who fought in a car, or chariot. See Hiſt. Acad. Inſcript. Vol. 2. p. 376. ſeq.

ESSENCE *(Cycl.)*—ESSENCE *of Wine*, a term uſed by Paracelſus, and ſome of the German chemiſts ſince his time, to expreſs what is called ſometimes the philoſophical ſpirit of wine, or the ſpirit of wine of the antients. It is not a diſtilled ſpirit like what we call ſpirit of wine, but approaches more to what Stahl has greatly recommended to the world, under the name of concentrated wine, or wine whoſe ſtrength has been reduced to a ſmaller compaſs, by the ſeparating its aqueous part only by freezing. Stahl recommends the immediately expoſing wine to the froſty air on this occaſion, but the proceſs ordered by Paracelſus for the preparation of this liquor is more tedious. He orders that the fineſt and beſt flavoured wine be choſen, that it be put into a glaſs filling it up three parts in four, and the neck being then ſealed hermetically, it is to be put into horſe dung for three months, and then expoſed to the froſty air for a month, after which the ice is to be thrown away, and the liquid part, which is the Eſſence, preſerved. *Shaw*'s Chemical Eſſays.

ESSENDO *Quietum de Tollonio*, in law, a writ to be quit of toll, and lies for citizens and burgeſſes of any city or town that by charter or preſcription ought to be exempted from toll, where the ſame is exacted of them. Reg. Orig. 258.

ESSENTIA *Dulcis*, in chemiſtry, a name given by Kunkel, and ſome others of the German authors, to a menſtruum of which they relate wonderful effects; but the preparation of which ſeems hitherto a ſecret. They ſay this menſtruum has nothing acid or corroſive in it, but that it approaches to the nature of ſpirit of Wine, yet, that it is capable of diſſolving the moſt denſe metals, and of converting any of them into a pure white ſalt, which has all their virtues, but nothing of that vitriolic acrimony, which they have when prepared the common way. The ſalts of mercury and of gold thus prepared, have great praiſes beſtowed on them, and are ſaid to cure epilepſies, the venereal diſeaſe, and many other diſtempers, without any violence or danger. *Kunkel*, de Salis Metal. See the article METAL.

ESSENTIAL *Oils*. See OILS *Eſſential*.

ESSERE, SORA, and SARE, in medicine, are little puſhes or wheals, ſomething red and hard, which quickly infect the whole body with a violent itching, as if one were ſtung with bees, waſps, flies, or nettles; yet they vaniſh after a little time, and leave the ſkin as ſmooth and well-coloured as before. It differs from an *Epinyctis* in this, that an *Epinyctis* ſweats out matter, but an *Eſſere* does not. *Blancard.*

ESSLISORS, in law, perſons appointed by a court of law, to whom a writ of *venire facias* is directed, to impanel a jury, on challenge to the ſheriff and coroners. They are to return the writ in their own names, with a panel of the jurors names. 15. *Edw.* 4. 24. pl. 4.

ESSOIN *(Cycl.)*—ESSOIN *de malo Villæ*, in law, is when the defendant is in court the firſt day, but gone without pleading; and being afterwards ſurprized with ſickneſs, &c. cannot attend, but ſends two *Eſſoiners*, who openly proteſt in court that he is detained by ſickneſs in ſuch a village, that he cannot come, *pro lucrari & pro perdere*; and this will be admitted: for it lieth on the plaintiff to prove whether the *Eſſoin* is true or not.

ESTABLISHMENT *of Dower*, in law, is the aſſurance and ſettlement of *Dower*, made to the wife by the huſband, on marriage: and *aſſignment of dower*, ſignifies the ſetting it out by the heir afterwards, according to the *Eſtabliſhment*. Brit. cap. 102, 103.

ESTACHE is uſed, in our old writers, for a bridge, or ſtank of ſtone and timber. *Cowel.*

ESTERLING *Money*. See STERLING, *Cycl.*

ESTIÆA, Εστιαια, in antiquity, ſolemn ſacrifices to Veſta, called in Greek Εστια, of which it was unlawful to carry any away, or communicate any part to any beſides the worſhippers. *Pott.* Archæol. Græc. l. 2. c. 20. T. 1. p. 396.

ESTIATORES, Εστιατορες, among the Athenians, perſons appointed by lot to provide an entertainment for the whole tribe. Beſides thoſe appointed by lot to this office, others voluntarily undertook it to ingratiate themſelves. *Potter*, Archæol. Græc. l. 1. c. 15. T. 1. p. 86.

ESTIMIONE, in natural hiſtory, a name by which ſome call the harmeſion. See HARMESION.

ESTIVAL *Occident*. See OCCIDENT.

ESTIVAL *Orient*. See ORIENT.

ESTRAC, in the manege, ſignifies a horſe that is light bodied, lank bellied, thin flanked, and narrow cheſted. See BELLY.

ESTRAPADE, in the manege, is the defence of a horſe that will not obey, but to get rid of his rider, riſes mightily before, and while his fore hand is yet in the air, yerks furiouſly with his hind legs, ſtriking higher than his head was before; and during this countertime goes back rather than advances.

ESULA, *(Cycl.)* in botany, a name given by many authors to ſome of the ſmall ſpecies of ſpurge. See the article TITHYMALUS.

ESULA *Rara*, in botany, a name given by John Bauhine and ſeveral other authors to a plant, called alſo by ſome *alypum*, but properly a ſpecies of dog's bane, and diſtinguiſhed by Mr. Tournefort by the name of *apocynum maritimum venetum ſalicis folio flore purpureo*, or the purple flowered ſea dog's bane of Venice with willow like leaves. See APOCYNUM.

Esu-

ESULÆ *Radix*, in the materia medica, the name of a root of a plant of the ſpurge kind ſometimes uſed in medicine. The root conſiſting of a cortical part and an inner ſticky one, the bark only is uſed, and ſuch ſhould be choſen as is new dried, and of a reddiſh colour without and within, and ſuch as when held in the mouth affords a very diſagreeable taſte, with very great acrimony. It is a very violent purge, and has been ſaid to have performed cures in dropſical caſes, when more gentle medicines have proved ineffectual. It is a good method to macerate it a day or two in vinegar before it is uſed.

The plant which produces it is, the *Eſula riveri et officinarum* of Mr. Ray, it is cultivated by ſome curious people in their gardens. *Pomet*'s Hiſt. of Drugs, p. 30.

ETAPPIER, in war. See ETAPPE, *Cycl.*

ETHESIUS *Lapis*, a name given by ſome authors to the chryſolite.

ETHMOIDES *(Cycl.)*—The figure of this bone is very ſingular, and may be ſaid to be in ſome meaſure cubical. This bone may be divided into a middle, and two lateral portions; in the middle three parts may be diſtinguiſhed, an upper, a middle, and a lower. The upper part of the middle portion is an eminence called criſta galli, which is often ſolid, ſometimes however it has been found hollow in ſeveral degrees and perforated by a ſmall opening which communicates with the frontal ſinuſes: a groove is ſometimes alſo met with in its anterior edge which leads to the ſpinal or blind hole in the os frontis. The middle part of this portion is a ſmall horizontal plate perforated by ſeveral holes, and called lamina cribroſa; and in its back part it has a little notch for its articulation with the ſphenoidal bone; this lamina may be called the body of the bone, as being what principally ſupports all the other parts of it.

The lower part is a perpendicular lamina, which makes part of the ſeptum narium: The edge of this is rough and uneven, for its better connection with the verna: The lateral portions of the ethmoidal bone, are by far the moſt conſiderable if we regard ſize only; each of theſe may be divided into two, one ſuperior, which is the largeſt, and which may be called the labyrinth of the noſtrils, it being full of turnings and windings, and irregularly cellular; and one inferior in the ſhape of a ſhell. It is a very tender and delicate ſtructure, tho' compact and without any diploe, being almoſt all compoſed of thin bony plates. It is joined to the os frontis, os ſphenoides, oſſa naſi, oſſa maxillaria, oſſa unguis, oſſa palati, and verna; the uſes of it are to be a very principal part in the organ of ſmell, and to give a very great extent to the pituitary membrane, in a ſmall compaſs. *Winſlow*'s Anatomy, pag. 29.

ETHOLOGUS, among the antients, a mimic or actor who could repreſent all the various habits and diſpoſitions of the mind. *Pitiſc.*

ETHOPOEA, among the antients, ſignified the art of repreſenting or imitating the manners and geſtures of any perſon ſo perfectly, that the original might be known by the repreſentation. *Pitiſc.*

ETINDROS, a name given by the writers of the middle ages, to a ſtone which they ſay is as clear and pellucid as cryſtal; and which when expoſed to the air was continually ſeen to exſudate drops of water by reaſon of its cold. We are rather apt to believe it was by reaſon of its heat, and that the writers of theſe dark ages had collected this account from ſome author, who only called ice by this name.

ETRUSCA *Terra*, in the materia medica, a kind of bole of which there are two ſpecies, the white and the red; theſe are called by many authors, the *terra ſigillata alba & rubra magni ducis*, as they are brought to us ſealed with different impreſſions.

The white Tuſcan earth is a denſe and compact ſubſtance of a dull deadiſh white, which in drying acquires ſome degree of yellowneſs; it is of a ſmooth ſurface, and does not ſtain the fingers in handling. It is not eaſily broken, and but ſlightly adheres to the tongue, and freely melts into a ſubſtance like butter in the mouth. It makes a ſlight effervеſcence with acid menſtruums. *Hill*'s Hiſt. of Foſſils, p. 4.

The red Tuſcan earth is an impure bole, very heavy and of a ſomewhat lax texture, and of a pale red colour. It is naturally of a ſmooth ſurface, breaks eaſily between the fingers, and is apt to ſtain the hands; it adheres ſtrongly to the tongue, and melts freely in the mouth, and has a ſtrongly aſtringent taſte, but leaves a ſandy harſhneſs between the teeth. It makes no effervеſcence with acid menſtrua. Theſe are the characters by which both theſe earths may be known from others of the ſame colour; they are both dug in ſeveral parts of Italy, particularly in the neighbourhood of Florence: They are kept in the ſhops there, and preſcribed with ſucceſs in fevers of many kinds, and in diarrhæas, dyſenteries, and the like caſes. *Hill*'s Hiſt. of Foſſils, p. 12.

ETYMOLOGICON is uſed for a book containing the etymologies of any language. See ETYMOLOGY, *Cycl.*

EUANTHI *Colores*, in painting, a term uſed by the Greeks to expreſs what the Romans call the floridi colores: theſe were ſuch colours as had a remarkable brightneſs in their works. The other coarſer and duller colours the Romans called auſteri colores, and the Greeks bathyci. Of the firſt ſort were cinnabar, lapis armenus, chryſocolla, minium, indigo, and purpuriſſa, according to the Romans; but the Greeks, as we find by Dioſcorides, made cinnabar one of the auſtere colours.

EVANTO, a name given by ſome authors to the panthera lapis.

EVAPORATION, *(Cycl.)*—The *Evaporation* of fluids is generally ſuppoſed an effect of heat, but experience proves that cold which is juſt a contrary cauſe is able alſo to produce the ſame effect, and that in a very conſiderable degree; the *Evaporations* of liquors in the ſevereſt froſts being at leaſt equal to thoſe when the air is in that degree which we call temperate. An ounce of water by weight being ſet out at ſix in the evening to freeze, Mr. Guateron found that by eight of clock the next morning, it was reduced to a ſolid lump of ice, and had loſt twenty-four grains in weight; and this ice being thawed into water with all poſſible caution, the water weighed twelve grains leſs than the ice. The ſame experiment repeated ſeveral times always gave the ſame phænomenon, only in different degrees; the loſs of quantity being always greater as the weather was more ſevere, or the wind higher. This effect is alſo different in different fluids. This gentleman ſet out to freeze at the ſame time an ounce of common water, the ſame quantity of nut oil, the ſame of brandy, the ſame of oil of turpentine, and the ſame of mercury. The water froze almoſt immediately and loſt ſix grains in weight; and the oil of nuts in the ſame time loſt eight grains; the brandy and the oil of turpentine loſt twelve grains each; but oil of olives and the mercury ſeemed rather to have encreaſed than diminiſhed in weight. The next morning, the loſs of the water was thirty-ſix grains; that of the nut-oil was forty grains, tho' it had not been frozen; and the loſs of the brandy and oil of turpentine was fifty four grains each, tho' neither had been at all frozen; the mercury and the oil of olives remained as before. The greater cold, and more rough winds always encreaſed the *Evaporation*, and the leſſer cold and calmer weather made it leſs. Water when reduced to the ſtate of ice does not ceaſe to *evaporate*: for this ice of an ounce of water had loſt thirty-ſix grains from eight of clock in the morning to three in the afternoon, and thirty-ſix more between that and eight at night; and during the night the *Evaporation* had not been continued in any leſs degree, and upon the whole, an ounce of ice was found to loſe by *Evaporation* a hundred grains in twenty-four hours. Mem. Acad. Par. 1709.

EVASION, *Evaſio*, in law, is uſed for any ſubtil endeavouring to ſet aſide truth, or to eſcape the puniſhment of the law; which will not be endured. Thus if a perſon ſays to another that he will not ſtrike him, but will give him a pot of ale to ſtrike him firſt; and accordingly he ſtrikes, the returning of it is puniſhable; and if the perſon firſt ſtriking be killed, it is murder: for no man ſhall evade the juſtice of the law, by ſuch a pretence to cover his malice. 1 *Hawk.* P. C. 81.

EUCHYMIA, in medicine, a good temper of the blood, or other juices and fluids in an animal body.

EUCLABRIS, in antiquity, a table whereon the ſlaughtered victim was ſpread, in order to have its inteſtines carefully inſpected. It was from this table that the veſſels uſed in ſacrifices were called *Euclabria*.

EVERRIATOR, in antiquity, an officer who was obliged in a ſolemn manner to cleanſe ſuch houſes as were defiled by dead bodies, called *domus funeſtæ*. *Pitiſc.* Lex. Ant. in voc.

EVERRICULUM, in ſurgery, the name given by Paré to a ſort of ſpeccellum or ſpoon, uſed to clear the bladder of gravel and grumes of blood left in it after the operation of lithotomy.

EVES-DROPPERS, in law, ſuch perſons as ſtand under the *Eves* or walls of a houſe, by night or by day, to hearken after news, and carry it to others, and thereby cauſe ſtrife and contention in the neighbourhood. *Terms de Ley*, 317. They are puniſhed in the court leet by fine, by the Stat. Weſtm. c. 33.

EUEXIA, in medicine, a good ſound habit of body.

EUGENIA, in botany, the name given by Micheli and Linnæus to a genus of plants deſcribed in the Hortus Malabaricus. The characters are theſe: The perianthium conſiſts of one leaf divided into four, oblong, obtuſe, concave, and permanent ſegments. The flower is compoſed of four oblong, and hollow obtuſe petals twice as large as the ſegments of the cup; the ſtamina are a great number of ſlender filaments inſerted in the cup and reaching the length of the flower; the antheræ are ſmall. The germen is of a turbinated form, and is placed below the cup. The ſtile is ſimple and of the length of the ſtamina; the ſtigma is ſimple; the fruit is a coronated drupa of a quadrangular figure containing only one cell, in which is contained a large roundiſh and ſmooth nut. *Linnæi*, Gen. Plant. p. 211. *Micheli*, Nov. Gen. p. 108. Hort. Mal. v. 1. p. 17, 18. v. 4. p. 6, 7.

EUMARIDES, among the antients, a kind of ſhoes common to men and women. *Hoffm.* Lex. in voc.

The *Eumarides* were uſed for pomp and delicacy, being neat and painted with various colours. Id ibid.

EUMECES, in the writings of the antient naturaliſts, the name of a ſtone which Pliny tells us reſembled a flint, and was found in Bactria; the antients had an idle opinion, that if laid under the head, it occaſioned true and prophetic dreams, foretelling to the perſon the more remarkable future events of his life.

EUMENIDES, in antiquity. See FURIES, *Cycl.*

EUMENIDEIA, Ευμενιδεια, in antiquity, an annual feſtival obſerved in honour of the furies. It was otherwiſe called

Σεμνων Ἐριδων, becauſe the Athenians called the furies, Σεμναι Θεαι, i. e. *venerable Goddeſſes*. *Pott.* Archæol. Græc. l. 2. c. 20.

EUMETRES *Beli*, in natural hiſtory, the name given by the antients to a gem which the Aſſyrians held ſacred to their God, and which many other nations learned from them, to ſuppoſe very powerful againſt magick. Many have ſuppoſed this to be the ſtone we now call occulus beli; but this is an error, ſince Pliny, in his account of the *Eumetres*, ſays, that it was of a very fine green. It was probably a gem of the emerald kind, that ſtone having ever been in very high eſteem in the eaſtern part of the world, as it is alſo to this day.

EUNOFIUS, a name given by ſome authors to the ætites or eagle ſtone.

EVOCATI, among the Romans, ſoldiers who having ſerved their time in the army, went afterwards voluntiers at the requeſt of ſome favourite general. *Hoffm.* Lex. in voc.

EVOCATION, *Evocatio*, among the Romans, a religious ceremony always obſerved by them at undertaking the ſiege of a town, wherein they ſolemnly called upon the gods and goddeſſes of the place to forſake it and come over to them. Without the performance of this ceremony, they either thought that the place could not be taken, or that it would be a ſacrilege to take the gods priſoners.

The form of *Evocation* uſed at taking the city of Carthage is related by Macrob. Sat. III. 9. in the following words. *Si deus, ſi dea es, cui populus, civitaſque Carthaginienſis eſt in tutela, teque maxime ille, qui urbis hujus, populique tutelam recepiſti, precor, venerorque, veniamque a vobis peto, ut vos populum civitatemque Carthaginienſium deſeratis, loca, templa, ſacra, urbemque eorum relinquatis, abſque his abeatis: eique populo, civitatique metum, formidinem, oblivionem injiciatis, proditique Romam ad me meoſque veniatis; noſtraque vobis loca, templa, ſacra, urbs acceptior, probatiorque ſit: mihi quoque, populoque Romano, militibuſque meis præpoſiti ſitis, ut ſciamus, intelligamuſque*, &c. *ſi ita feceritis, voveo vobis templa, ludoſque facturum.*

They always took it for granted that their prayer was heard, and that the gods had deſerted the place and came over to them, provided they were able to make themſelves maſters of it. *Pitiſc.* Lex. Ant. in voc. *Deus.*

EVOCATORIÆ *Epiſtolæ*, among the Romans, letters ſent by the emperors to command the attendance of any perſon; or letters granting licence to any one to wait on the emperor; every perſon not being allowed this privilege till they had deſired and obtained the *Evocatoriæ Epiſtolæ*. *Hoffm.* Lex. in voc.

EVOLUTE, *Evoluta (Cycl.)*—The variation of curvature of the line deſcribed by the *Evolution* of a curve, is meaſured by the ratio of the radius of curvature of the *Evoluta*, to the radius of curvature of the line deſcribed by the *Evolution*. See *Mac Laurin*'s Flux. Art. 402. Prop. 36.

EUÆMIA, a word uſed by Tremelius, and ſome other writers, to expreſs a good and healthy ſtate of the maſs of blood.

EUONYMUS, the *Spindle-Tree*, in the Linnæan ſyſtem of botany, this makes a diſtinct genus of vegetables; the characters of which are theſe. The cup is a flat perianthium, compoſed of one leaf divided into four ſegments which are of a roundiſh figure. The flower is compoſed of four flat oval petals, longer than the ſegments of the cup, and ſpread wide open; the ſtamina are four upright pointed filaments ſhorter than the cup, and ſituated on the germen of the piſtill; the antheræ are double. The germen of the piſtill is pointed; the ſtyle is ſhort and ſimple; the ſtigma is obtuſe; the fruit is a quadragonal, juicy capſule, of a different colour from the reſt of the ſhrub, and having four angles, four points, and four cells, with their valves. The ſeeds are ſingle, of an oval figure, and encloſed in the cup. *Linnæi* Genera Plantarum, p. 48.

According to Tournefort's method the characters are theſe. The flower is of the roſaceous kind, being compoſed of ſeveral petals arranged in a circular form; the piſtil ariſes from the cup, and finally becomes an angular membranaceous fruit divided into different cells and containing oblong ſeeds.

The ſpecies of *Euonymus* enumerated by Mr. Tournefort are theſe.

1. The common *Euonymus* with red fruit. 2. The black fruited *Euonymus*. 3. The broad leaved *Euonymus*. 4. The pyracantha-leaved American *Euonymus*, with ever-green leaves and red verrucoſe fruit. 5. The African *Euonymus*, with ſhining ſerrated leaves. 6. The broad-leaved cluſtery American *Euonymus*, with pentangular blackiſh purple fruit. *Tourn.* Inſt. p. 647.

It is generally ſuppoſed that the *Euonymus* of the antients is the ſame plant that we at this time call by this name. The words of Theophraſtus have probably given occaſion to this opinion; as they ſound at firſt reading like words expreſſing the characters of the fruit of this tree; but on a cloſer inſpection, they will be found to expreſs a fruit of a very different kind. This author ſays, that the fruit of the *Euonymus* is like the pod of the ſeſamum, marked with four protuberant ribs, and hard within, and divided into places for four orders of ſeeds. It is plain by this, that as their ſeſamum bore an oblong pod marked with four ribs, ſo as to ſeem of a quadrangular figure; ſo did their *Euonymus*, and that in this long pod there were four orders of ſeeds, each of theſe orders containing a great many ſeeds. Now the fruit of our *Euonymus* is ſhort and not at all like a pod, and contains only four ſeeds and not four orders of ſeeds: there is alſo this farther proof of our *Euonymus* not being that of the antients, that ours is a wholeſome food to cattle, and they are very fond of cropping it whenever they can reach it, and never get any hurt by it; whereas the *Euonymus* of the Greeks was poiſonous to cattle, according to Theophraſtus. *Pliny*, *Theophraſtus*. See FUSANUS.

EUPATORIUM, in botany, the name of a genus of plants, the characters of which are theſe; the flower is of the floſculous kind, and is compoſed of a number of ſmall corollulæ, from each of which there grows a long capillament bifid at the end. Theſe are divided into many ſegments, and ſtand on embryo ſeeds, being contained in a long ſcaly and cylindric cup: the embryos afterwards become ſeeds winged with down.

The ſpecies of *Eupatorium* enumerated by Mr. Tournefort are theſe.

1. The common *Eupatorium*. 2. The *Eupatorium*, with long wrinkled leaves and purple ſtalks. 3. The larger *Eupatorium*, with great long and wrinkled leaves and green ſtalks. 4. The nettle-leaved New England *Eupatorium*, with purple flowers and ſpotted ſtalks. 5. The hairy betony-leaved *Eupatorium* of New England, with white flowers. 6. The perfoliate Virginian *Eupatorium*, with very long pointed ſage-like leaves. 7. The mullein-leaved *Eupatorium* of Virginia. 8. The ſoft hairy nettle-leaved American *Eupatorium*. 9. The ſhrubby American *Eupatorium*, with atriplex leaves and white flowers. 10. The purple flowered American *Eupatorium*, with ſlix-weed leaves. 11. The purple flowered ſhrub American *Eupatorium*, with ground-ivy leaves. 12. The American *Eupatorium*, with butter-bur leaves. *Tournef.* Inſt. p. 455.

EUPATORIUM, or the common hemp agrimony, ſtands recommended as a hepatic and vulnerary, and has been alſo uſed in catarrhs; but it is at preſent very little known in the ſhops.

EUPETALOS, in natural hiſtory, the name of a gem deſcribed by the antients as famous for its variety of colours. Pliny L. 37. C. 10. tells us that it ſhewed at once blue, fire colour, red lead colour, and yellow. It ſeems to have been the opal, and that Pliny's deſcription of it in this place was taken from ſome author he did not perfectly underſtand, as is the caſe in many of his accounts from the Greeks.

EUPHEMISMUS, Ἐυφημισμος, in rhetoric, a figure which expreſſes things in themſelves diſagreeable and ſhocking, by terms implying the contrary quality; thus, the Pontus, or black ſea, having the epithet of ἄξενος, (i. e. inhoſpitable) given it on account of the ſavage cruelty of thoſe who inhabited the neighbouring countries; this name, by *Euphemiſm*, was changed into that of *Euxinus*. Thus Ovid. Triſt. l. 3. eleg. 13.

Dum me terrarum pars pene noviſſima Ponti,
Euxinus falſo nomine dictus habet.

In which ſenſe, it only makes a ſpecies of irony. But every *euphemiſm* is not irony; for we ſometimes uſe improper and ſoft terms in the ſame ſenſe with the proper and harſh. See *Voſſ.* Rhet. l. 4. p. 186. ſeq.

EUPNOEA, in medicine, is a right and natural reſpiration.

EUPORIA, in medicine, is an eaſy preparation of medicines, or the eaſineſs of their operation. *Blancard.*

EUPHORBIA, in botany, a name given by Linnæus and others to the *Euphorbium* plant, and to ſome ſpecies of the tithymalus and tithymaloides of Tournefort. See TITHYMALUS and TITHYMALOIDES.

The curious in gardening propagate twelve ſpecies of the *Euphorbium* plant in their ſtoves; they are all natives of very warm climates, and being replete with a milky juice, they require very little water; nor muſt they ever be planted in a rich ſoil, which is very hurtful to them. The proper ſoil for them is a mixture of one half ſea-ſand, one quarter light freſh earth, and one quarter lime-rubbiſh. This ſhould be mixed three months before it is uſed, and very frequently turned in the mean time. *Miller*'s Gardners Dict.

The plants are propagated by planting in this ſoil, their cuttings, in the months of June and July. Theſe ſhould always be taken off from the old plant at a joint, and ſhould be laid by for a week in a dry ſhady place before they are planted, that the part cut off from the old plant may have time to harden and dry. They ſhould then be ſet in very ſmall pots and have a little water to ſettle the earth to their roots. They are after this to be ſet for a day or two where they may have the morning ſun, and after this to be plunged into a hot bed of tanner's bark, and ſhaded in the great heats of the day. In ſix weeks will have ſhot out their roots, and are then to be treated as the cereus's and other ſucculent plants of the ſame kind.

EUPHRASIA, *Eye-bright*, in botany, the name of a genus of plants the characters of which are theſe; the flower is of the perſonated kind, divided into two lips, and having the upper one placed erect and divided into ſeveral ſegments. The lower one divided into three principal ſegments, each of which is alſo bifid. The piſtil ariſes from the cup, and is fixed in the manner of a nail to the back part of the flower: this finally

finally ripens into a capſule of an oblong ſhape, containing ſmall ſeeds.

The ſpecies of *Eye-bright*, enumerated by Mr. Tournefort, are theſe: 1. The common *Eye-bright*. 2. The white-flowered more branched meadow *Eye-bright*. 3. The leſs branched *Eye-bright*, with a bluiſh purple flower. 4. The ſmall alpine yellow-flowered *Eye-bright*. And 5. The narrow-leav'd *Eye-bright*, with finely divided leaves. *Tourn.* Inſt. p. 174.

Eye-bright is much recommended in diſorders of the eyes, eſpecially weakneſs and dimneſs of ſight. It is given in ſeveral forms, but the powder of its leaves is thought moſt effectual, as well as ſafeſt, the doſe being from one to three drams. *James*, Med. Dict. in voc.

EUPHROSYNUM, in botany, a name uſed by Pliny, and ſome other authors, for the common borage. *Ger.* Emac. Ind. 2. See BORAGE.

EUREOS, in natural hiſtory, the name of a ſtone, deſcribed by Pliny, and ſeeming plainly to be the ſame with the tecolithus, which he mentions in another place, and to be the ſtone now called *lapis Judaicus*, and known at this time to be the petrify'd ſpine of a ſort of echinus marinus, or ſea urchin. Pliny ſays it was ſhaped like the ſtone of an olive, that it was regularly ſtriated, in the manner of ſome ſhells, and that it was of a whitiſh colour, but not perfectly white. No one can miſs ſeeing that this is a good deſcription of the *lapis Judaicus*; and we are not to ſuppoſe it otherwiſe, becauſe Pliny has before deſcribed that ſtone under another name, without any reference to this; ſince we are to conſider that Pliny was the general collector of the natural hiſtory of his time, and took his accounts of things from different authors then extant, who did not pay the regard to one another that the modern writers do, of referring to each others work, ſo that Pliny has often mentioned the ſame thing twice under two names, as he found accounts of it in two different authors, without perceiving that they were deſcribing the ſame ſtone. This particular is but one inſtance of a thouſand, that might be brought of this; and much error has got into the world by means of it.

EURICHORIA, a word uſed, by ſome of the old writers in medicine, to expreſs an internal ſinus, or cavity in ulcers, *&c.*

EURYNOMIA, Ευρυνομια, in antiquity, an anniverſary ſolemnity in honour of Eurynome, by ſome thought to be the ſame with Diana, by others one of Oceanus's daughters. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 397.

EUSEBES, the name of a ſpecies of marble, mentioned by Pliny; he has given us no deſcription of it, but only tells us, that there was a ſeat made of it in the temple of Hercules at Tyre, from which the prieſts pretended that the gods uſed to ariſe.

EUTHANASIA, in medicine, a ſoft and quiet death, or paſſage out of this world.

EUTHYMIA, Ευθυμια, among the Greeks, ſignified ſuch a diſpoſition, or ſtate of the mind, as could not be ruffled either by good or bad fortune, by ſickneſs or health, good or evil. Mem. Acad. Inſcript. Vol. 14. p. 131.

EUTROPHIA, in medicine, is uſed for a due nouriſhment of the body.

EWAGE, *Ewagium*, in our old writers, the ſame with *Aquage*, which is toll paid for water-paſſage. It is derived from the French *eau*, water.

EXACTIS, in natural hiſtory, a name given by Linkius, and ſome other authors, to a ſpecies of ſtar-fiſh, of the more branched kind, whoſe rays are ſix in number, when they firſt part from the body, but very ſoon branch out into a great number more. See the article STELLA *Marina*.

EXACTOR *Regis*, in law, the king's exactor, or collector. Sometimes it is taken for the ſheriff. But generally, *Quicunque publicas pecunias, tributa, victigalia & res fiſco debitas exigit, proprie nominatur exactor regis.*

EXANASTOMOSIS, in medicine, is an opening of the extremity of the veſſels. *Blancard.* Lex. Med. in voc.

EXANNUAL *Roll*, in the old way of exhibiting ſheriff's accounts, the illeviable fines and deſperate debts were tranſcribed into a roll, under this name; which was yearly read, to ſee what might be gotten. *Hale*'s Sher. Acc. 67.

EXAUCTORATIO, among the Romans, differed from *miſſio*, or a diſcharge. In the latter, the ſoldiers were quite diſmiſſed from the ſervice; and this was done after they had ſerved twenty years: But in the former caſe, they only loſt their pay, being ſtill kept under their colours or *vexilla*, tho' not under the eagle, *aquila*, which was the ſtandard of the legion. Whence, inſtead of *legionarii*, they were called *ſubſignani*, and were ſtill retained till they had either ſerved out their time, or had lands aſſigned them. The *Exauctoratio* commonly took place after they had ſerved ſeventeen years. *Pitiſc.* Lex. Ant. in voc.

EXCHEQUER (*Cycl.*)—The court of *Exchequer* is an antient court of record, for all matters relating to the revenues of the crown. Vid. 4 Inſt. 103. 2 Inſt. 104, 105, 551.

In the *Exchequer* there are ſeven courts, 1. The court of pleas. 2. The court of accounts. 3. The court of receipt. 4. The court of *Exchequer* chamber, being the aſſembly of all the judges of England for matters in law. 5. The court of *Exchequer* chamber, for errors in the court of *Exchequer*. 6. The court of *Exchequer* chamber, for errors in the king's bench. 7. The court of equity in the *Exchequer* chamber. Vid. New Abr. Law, vol. 1. p. 597.

By the 33d Hen. 8. cap. 39. the court of *Exchequer* has power to diſcharge all debts and duties due to the king, upon any equity diſcloſed; and it is by virtue of this act, that they diſcharge recognizances; and it ſeems, by the ſaid act, they may diſcharge penal laws made before this ſtatute; but all penal laws made after the ſtatute cannot be diſcharged, but muſt be compounded.

The court of *Exchequer*, in Scotland, has the ſame power, authority, privilege, and juriſdiction over the revenue of Scotland, as the court of *Exchequer* in England has over the revenues there; and all things and matters competent to the court of *Exchequer* in England, ſo far as they relate to the king's revenue, are likewiſe competent to the *Exchequer* of Scotland. The judges are likewiſe inveſted with the power of paſſing ſignatures, gifts, and tutories, and to reviſe and compound them in the ſame manner as was done by the Lord High Treaſurer, commiſſioners of the treaſury, and court of *Exchequer* in Scotland, before the union. All ſerjeants at law, barriſters at law, of five years ſtanding, in any of the four inns of court of England, and advocates of five years ſtanding, in the college of juſtice in Scotland, are qualified for being barons of this court; whoſe commiſſions are *Quam diu ſe bene geſſerint. Chamberl.* Pr. State of Gr. Br. p. 386.

EXCIPIENT, in pharmacy, a term uſed to expreſs that ingredient in a compound medicine, the buſineſs of which is to receive all the reſt; ſuch is the conſerve in electuaries, the ſyrup in boluſſes, *&c.*

EXCISION, in ſurgery, the cutting out, or cutting off any part of the body.

EXCLUSORIUM, in medicine, a name uſed, by ſome, for ſuch drugs, or compoſitions, as are capable of producing abortion.

EXCUSATI, in church hiſtory, a term uſed to denote ſlaves, who flying to any church for ſanctuary, were excuſed and pardoned by their maſters; but theſe were obliged to take an oath to that purpoſe before they could have them again; and, if they broke the oath, they were puniſhed and fined as perſons guilty of perjury. *Hofm.* Lex. in voc.

EXCUTIA *Ventriculi*, the *Stomach Bruſh*, a name given, by modern ſurgeons, to an inſtrument made of ſoft briſtles, formed into a bundle, and fixed upon a flexible braſs wire, for cleanſing the throat, or even the ſtomach.

The *ſtomach bruſh* is compoſed of ſoft hair faſtened together into a bundle by a twiſted braſs or ſteel wire, and the handle or ſtem of it is inveſted with ſilk. This has been greatly recommended, by ſome, to remove foreign bodies out of the fauces and æſophagus; and, to ſcower the ſtomach. The method of uſing it is this:

The patient is firſt to drink a ſmall draught of warm water, then the bruſh is to be received into the œſophagus, and gently protruded down into the ſtomach, by twiſting round and round its handle, and, when in the ſtomach, it is to be drawn up and down many times, like the ſucker in a ſyringe, and at length wholly extracted. The advantages ſaid to ariſe from this, are very great, ſuch as the prolonging life to a great age, and the like; but few people have been willing to try the effects of ſo diſagreeable and troubleſome an operation. Wedelius and Teichmeir have written expreſs treatiſes on this inſtrument, and one of them has attempted to prove it no new contrivance, but a thing very early known, deſcribed, and uſed in phyſic. *Heiſter*'s Surgery, p. 2. p. 2.

EXECRATION, *Execratio*, among the antients, a kind of puniſhment, conſiſting of direful curſes and marks of infamy. Livy relates an inſtance of it, which was uſed againſt Philip, king of Macedon, by the Athenians. A general aſſembly of the people being called, they made a decree, that all the ſtatues and images of that king, and of all his anceſtors, both of the male and female ſex, ſhould be demoliſhed, and their very names razed; that all the feſtivals, ſacred rites, prieſts, and whatever elſe had been inſtituted in honour of him, ſhould be profaned; that the very places where there had been any monument or inſcription to his honour, ſhould be deteſtable, and that nothing ſhould be ſet up, or dedicated in them, which could be done in clean places; and laſtly, that the public prieſts, as often as they prayed for the Athenian people, allies, armies, and fleets, ſhould as many times deteſt and execrate Philip, his children, kingdom, land and ſea forces, and the whole race and name of the Macedonians. *Hoffm.* Lex. in voc.

Cornelius Nepos, in his life of Alcibiades, calls it *devotion*.

At the taking and demoliſhing of a city, it was frequent to pronounce direful curſes and execrations upon whoever ſhould endeavour to rebuild it; which ſome imagine was the reaſon that Troy could never be raiſed out of its aſhes, tho' ſeveral perſons attempted it, being devoted to eternal and irreparable ruin by Agamemnon. This ſeems to have been a very antient cuſtom, and derived from the eaſtern nations; for we find Joſhua, at the deſtruction of Jericho, to have

fixed an imprecation upon the perſon who ſhould rebuild it, which was accompliſhed in Hiel the Bethelite many ages after. *Potter*, Archæol. T. 2. p. 97.

EXECUTIONE (*Cycl.*)—EXECUTIONE *Judicii*, in law, a writ directed to the judge of an inferior court, to do *Execution* upon a judgment therein, or to return ſome reaſonable cauſe wherefore he delays the *Execution*. F. N. B. 20.

If *Execution* be not done on the firſt writ, an *alias* ſhall iſſue, and a *pluries*, with this clauſe, *Vel cauſam nobis ſignifices quare*, &c. And if, upon this writ, *Execution* be not done; or ſome reaſonable cauſe returned why it is delayed, the party ſhall have an attachment againſt him who ought to have done the *Execution*, returnable in B. R. or C. B. New Nat. Br. 43.

EXEMPLIFICATIONE, in law, is a writ granted for the exemplification of an original record. Reg. Orig. 290.

EXERCISE, (*Cycl.*) in the military language, is uſed for the practice of all thoſe motions, actions, and management of arms, whereby a ſoldier is taught the different poſtures he is to be in under arms, and the different motions he is to make to reſiſt an enemy. Theſe he muſt be perfect in, before he be fit for ſervice.

EXERGASIA, Ἐξεργασια, in rhetoric, the ſame with *expoſition*. See EXPOSITION, *Cycl.*

EXFOLIATIVUM, the name of a chirurgical inſtrument, uſed to take off the vitiated ſurfaces of bones, and uſually called a raſpatory at this time.

EXFREDIARE, in our old writers, denotes the breaking of the peace, or committing open violence. Leg. H. 1. c. 31.

The word is formed from the Saxon *Frede*, peace.

EX GRAVI QUERELA, in law, a writ that lies for him to whom any lands or tenements in fee are deviſed by will, (within any city, town, or borough, wherein lands are deviſable by cuſtom) and the heir of the deviſor enters, and detains them from him. Reg. Orig. 244. Old Nat. Br. 87. And if a man deviſes ſuch lands or tenements unto another in tail, with remainder over in fee, if the tenant in tail enter, and is ſeized by force of the intail, and afterwards dieth without iſſue, he in the remainder ſhall have the writ, *ex gravi querela*, to execute that deviſe. New Nat. Br. 441. Alſo where a tenant in tail dies without iſſue of his body, the heir of the donor, or he who hath the reverſion of the land, ſhall have this writ, in the nature of a *Formedon* in the reverter. Ibid.

EXHALATION. See VAPOUR.

EXHEBENUM, in natural hiſtory, the name of a white and ſmooth ſtone, uſed by the antient artificers in poliſhing gold. It ſeems to be the ſame with the lapis Samius, a ſmall ſmooth ſtone which they often found in the Samian earth.

EXHIBITION, (*Cycl.*) *Exhibitio*, in our old writers, is uſed for an allowance of meat and drink, ſuch as was cuſtomary among the religious appropriators of churches, who uſually made it to the depending vicar. The benefactions ſettled for the maintaining of ſcholars in the univerſities, not depending on the foundation, are alſo called *Exhibitions*. Paroch. Antiq. 304.

EXHORTATION, *Hortatio*, in rhetoric, differs only from *ſuaſion*, in that the latter principally endeavours to convince the underſtanding, and the former to work on the affections. *Voſſ.* Rhet. l. 1. p. 31.

EXILIUM, in law, ſignifies a ſpoiling: And, by the ſtatute of Marlbridge, it ſeems to extend to the injury done to tenants, by altering their tenure, ejecting them, *&c.* And this is the ſenſe that *Fleta* determines; who diſtinguiſhes between *vaſtum*, *deſtructio*, and *Exilium*. For he tells us, that *vaſtum* and *deſtructio* are almoſt the ſame, and are properly applied to houſes, gardens, or woods; but *Exilium* is when ſervants are enfranchiſed, and afterwards unlawfully turned out of their tenements.—*Vaſtum & deſtructio fere æquipollent, & convertibiliter ſe habent in domibus, boſcis & gardinis; ſed* Exilium *dici poterit, cum ſervi manumittuntur, aut a tenementis ſuis injurioſe ejiciuntur.* Flet. l. 1. c. 11.—*Venditionem vel* Exilium *non faciant de domibus, boſcis vel hominibus*, &c. Stat. Marlb. c. 25.

EXITERIA, Ἐξιτηρια, in antiquity, oblations or prayers to any of the gods for a proſperous expedition or journey. *Pott.* Archæol. Græc. l. 2. c. 20.

EXOCÆTUS, in ichthyology, the name of a genus of fiſhes, of the malacopterygious or ſoft fin'd kind, the characters of which are theſe: The branchioſtege membrane contains ten bones, four of which are broad, and are covered by the opercula of the gills, and all of them are very difficult to be counted. The pectoral fins are very long. There is but one fin on the back, and that is placed toward the lower part of it. The ſcales are large. Artedi enumerates only two ſpecies of this genus: The firſt is the common mugil alatus of authors, or the flying fiſh. The ſcales of this are large, it reſembles the mullet in ſhape; the head and body are compreſſed, the ſnout is ſubacute, and the lower jaw is, when the mouth is opened, ſomewhat longer than the upper. The eyes are not covered with a ſkin. The mouth is ſmall, and has no teeth, and the tongue is ſlender. The back fin is very ſmall, and has thirteen bones. The pectoral fins reach to the tail, and have ſixteen articulated bones, or, at leaſt, nodoſe ones, divided at the end into ſeveral ramifications. The belly is flat, and the anus is but a little way from the tail. The inteſtine is ſingle, running ſtrait from the throat to the anus. The ſecond ſpecies of the *Exocætus* is the anguilla of the Venetians. This is a ſmall fiſh of a ſilvery colour, and pellucid; the mouth is large, and looks upward. The eyes are large. It has black ſpots on the back. The pectoral fins have each fourteen bones. This ſecond ſpecies ſeems to belong to the genus of the gobii. See Tab. of Fiſhes, N°. 41. *Artedi*, Gen. Piſc. 6.

EXODIARIUS, among the Romans, the perſon who, after the drama or play was ended, ſung the *Exodium*. See EXODIUM, *Cycl.*

EXOLICETUS, in natural hiſtory, a name uſed, among the writers of the middle ages, to expreſs a ſmall ſtone which had ſuch a variety of colours, that it dazled, as they ſay, peoples eyes in looking at them. It is ſaid to have been found in Lybia. The name is probably only a corruption of the hexacontalithos of Pliny, and the older writers; and this ſeems to have been no other than a name for the opal.

EXOMIS, in antiquity, a ſtrait narrow garment through which the ſhoulders appeared. It had ſomething in common with the tunic, and ſomething with the pallium. *Pitiſc.* Lex. Ant. in voc.

EXOMPHALIS, the name of a diſtempered ſtate of the body in ſome fœtus's, in which the viſcera, or part of them, are contained in a bag or ſack hanging out from the navel. In one of theſe caſes, which Mr. Mery has given an account of, the infant was born alive, but died after fourteen hours; the tumour was very large, and, on opening it, the liver, ſpleen, ſtomach, and inteſtines, were found all incloſed in it, yet its aperture at the navel was but little more than an inch in diameter. The moſt natural conjecture, in this caſe, ſeemed that the viſcera had been forced out of the body by ſome accident during pregnancy, and that the peritoneum, as they inlarged in growth, had extended itſelf, by degrees, to the dimenſions of this ſack. But, on a ſtrict enquiry, the ſack was found to be compoſed of a double membrane, ſo that it could not be a production of the peritoneum, which is ſingle, but it muſt neceſſarily have been an extenſion of the membranes of the placenta, which, uniting, form the umbilical cord; and it was not leſs eaſy to determine, that the viſcera could not have been forced out of the body, when at any conſiderable growth, as the aperture was ſo ſmall, the liver alone being of ſix times its diameter. It appears, therefore, that in theſe caſes the viſcera get out while very ſmall, and grow and enlarge in their unnatural ſituation. The parent of the infant, being aſked if ſhe had received any injury during her pregnancy, could not recollect any, but only obſerved that, while young with child, ſhe had been very ſtrongly affected by the ſight of the entrails of an ox hanging out of its belly at a butchers. Mem. Acad. Par. 1716.

EXONEIROSIS, a nocturnal pollution, or emiſſion of the ſemen in dreams. This, if it happen but rarely, is uſually a ſign only of redundant vigour; but if it happens frequently, is a ſign of a weakneſs of the ſeminal veſſels, which is moſt frequently the caſe.

EXONERATIONE *Sectæ*, in law, a writ that lay for the king's ward, to be freed from all ſuit to the county-court, hundred-court, leet, *&c.* during the wardſhip. F. N. B. 158.

EXONYCHOS, in botany, a name given, by ſome of the antient writers, among whom are Dioſcorides and Pliny, to the Gromwel or Lithoſpermum; it had this name from its ſeeds, the hardneſs and texture of which were ſuppoſed to reſemble the exterior part of the human nail; hence this name was compoſed of ἔξω and ὄνυξ: But ſome authors ſuppoſing this not ſufficiently expreſſive of the hardneſs of the ſeed, have called it ægonychon, reſembling it to a goats claw, as that animal, being continually among rocks, its hoof, or claw, was ſuppoſed harder than that of other animals, whoſe feet were not uſed in ſuch hard places.

EXOPHTHALMIA, in medicine, is a protuberance of the eye, out of its natural poſition.

EXORMISTOS, in ichthyology, a name given, by ſome of the old writers, to that ſpecies of the *petromyzon* which other authors call the *lampetra fluviatilis*, and we in Engliſh the lampern. This is diſtinguiſhed by Artedi by the name of the *petromyzon*, with only one ſeries of ſmall teeth in the verge of the mouth, and ſome large ones below. See the articles MUSTELA, LAMPETRA, and PETROMYZON.

EXOS *Piſcis*, in ichthyology, a name given by Geſner and Rondeletius, to the fiſh which we call the huſo, or ichthyocolla piſcis, from the drug called ichthyocolla or iſinglaſs being procured from it. It is properly a ſpecies of the accipenſer, and is diſtinguiſhed from the common ſturgeon by its having no tubercles. See ACCIPENSER.

EXOSTOSIS, (*Cycl.*) is properly an acute eminence, or exceſcence, puſhing preternaturally above the bone, but creating ſometimes no diſturbance, pain, or deformity, and unaccompanied with a caries or ſpina ventoſa. When this is the caſe, it is always beſt to let it alone, for the attempt to remedy often proves much worſe than the diſeaſe, and, by laying the bone bare, a caries, or other inconvenience, is brought on. On the other hand, when this diſorder occaſions pain, or deformity, or impedes any action, or produces other miſchief, it

may be remedied by taking off the protuberant part of the bone, in the same manner as in cases of the spina ventosa. *Heister*'s Surgery, p. 267.

EXOSTRA, in the antient theatre, a place where such parts of the play were recited, as were supposed to be acted privately in the house.

EXOSTRA was likewise the name of a warlike engine used in the sieges of towns. *Pitisc.* Lex. Ant. in voc.

EXOUCONTII, in church history, a kind of Arian heretics, who maintained that the son of God was made out of nothing. ἐκ των ὐκ ὀντων. *Hofm.* Lex. in voc.

EXPANSION (*Cycl.*)—Solid bodies, as well as fluid, easily *expand* with heat; this is proved by this easy experiment: Let an iron ring be made, just capable of admitting one end of a solid rod of the same metal. Then heat that end of the rod in the fire, and, when red hot, it will be found too large to go into the ring, though as soon as it is cold, it will again readily go through it. This appears to be the property of all solid bodies, on being heated, tho' cedar wood has, upon some trials, been thought not to *expand* with heat, or contract with cold. *Shaw*'s Lectures, p. 27.

EX PARTE TALIS, in law, a writ that lies for a bailiff or receiver, who, having auditors assigned to take his account, cannot obtain of them reasonable allowance, but is cast into prison. The course, in this case, is to sue this writ out of chancery, directed to the sheriff to take four mainpernors to bring his body before the barons of the exchequer, at a certain day, and to warn the lord to appear at the same time. F. N. B. 129.

EXPECTORANTS. As all substances which promote excretion, do not operate in the same manner, since some render the matter moveable, and dispose it for evacuation, others open the emunctories, that it may be separated from the juices, and others stimulate the vessels and ducts to an excretory motion, so *Expectorants* operate in the same variety of manners. For if the humour secreted be thin and acrid, and the pores of the glands, from which it is to be thrown, be too much constricted, those medicines are to be given to promote expectoration, which relax, soften, and widen the passages, obtund the acrimony of the humours, and coagulate the too thin and fluid parts of them. To this purpose liquorice root, sperma ceti, saffron, mallows, red poppies, oil of almonds, and the styrax pill, may be given; but when a large quantity of thick and viscid matter is lodged in the bronchia of the lungs, and impedes respiration, then some stimulus to respiration becomes necessary, and expectoration must be assisted by substances which can resolve the tough and viscid matter. For this purpose decoctions of scabious and the other pectoral herbs, with the terra foliata tartari, solutions of crab's-eyes, and antimoniated nitre, are very proper. The nervous coats of the bronchia are also stimulated to an excretory motion by a certain acrid, subtle, and oleous principle, found in gum ammoniac and benjamin, and the like stimulating gums.

The roots of elecampane, and florentine orris also, and all the preparations of sulphur, serve excellently to this purpose. And where a yet stronger stimulus is required, as in a pituitous asthma, oxymel of squills, and the spiritus asthmaticus, which is prepared with gum ammoniacum and crystals of copper, are found remedies of very great power. Great caution is necessary hence in the exhibition of *Expectorants*, and the practitioner who gives the common medicines, known by that name, at random, and without informing himself thoroughly of the nature of the case, is likely to do great mischief, instead of good, by them. In coughs of the moist and chronical kind, as also in a pituitous asthma, in which large quantities of phlegm fall into the bronchia of the lungs, sweet substances, linctus's, and oily medicines, weaken the stomach, whose strength and tone are already too much impaired, diminish the appetite, digestion, and chylifaction, and not only promote the generation of more recrementitious matter, and the increase of the disease, but also dispose the patient to a cachexy, or to œdematous tumors, or a dropsy. In these cases, it is therefore much more proper to use balsamic pectorals, and such as are grateful to the stomach. *Hofm.* Med. Ration. Syst.

Expectorants ought to be cautiously used in a phthisis, in spittings of blood, and in dry coughs, difficulties of breathing, and violent pains in the breast, which rather arise from a congestion of blood, than from matter to be expectorated; and *Expectorants*, whether of the softening or the stimulating kind, must certainly add to the congestion of the blood and humours, rather than to the relief of the patient.

In pleurisies and peripneumonies also *Expectorants* are to be very cautiously used in the beginning; lest by their means the inflammatory stagnation of the blood should be encreased. But when these disorders are upon the decline, and the greater part of the inflammatory matter is discussed, then they are very properly and commodiously used to draw the viscid and concocted matter out of the pulmonary canals.

EXPENDITORS, in law, are the persons appointed by commissioners of sewers to pay, disburse or expend the money collected by the tax for the repairs of sewers, &c. when paid into their hands by the collectors, on the reparations, amendments, and reformations ordered by the commissioners; for which they are to render accounts when thereunto required. Laws of Sewers, 87, 88.

These officers are mentioned in the statute 37 H. 8. c. 11. and other statutes. The steward who supervises the repair of the banks and water-courses in Rumney-Marsh is likewise called the *Expenditor*.

EXPENSIS *Militum non levandis*, &c. in law, an antient writ to prohibit the sheriff from levying any allowance for knights of the shire, upon those that hold lands in antient *demesne*. Reg. Orig. 261.

There is also a writ *de expensis militum levandis*, for levying expences for knights of the parliament. See EXPENSIS, *Cycl.*

EXPILATOR, in the civil law, a peculiar kind of thief or robber. See EXPILATION, *Cycl.*

Besides the meaning put upon *Expilation* in the Cyclopædia, it was used in a more special manner to signify a robbery committed by night; whence an *Expilator* was looked upon as a greater criminal than a common thief.

The *Expilators* were so called from their robbing and stripping people of their cloaths. *Pitisc.* Lex. Ant. in voc.

EXPLEES, in law, the rents or profits of an estate, &c. See ESPLEES.

EXPONENT, (*Cycl.*) in arithmetic and algebra. *Exponents* are commonly written above, and somewhat towards the right hand of the number or quantity whose power they express. Thus 3^5, a^5, signifies the fifth power of 3, and of a.

EXPOSING (*Cycl.*)—EXPOSING *of Children*, a barbarous custom practised by most of the antients, excepting the Thebans, who had an express law to the contrary, whereby it was made capital to expose children, ordaining, at the same time, that such as were not in a condition to educate them, should bring them to the magistrates, in order to be brought up at the public expence. *Pott.* Archæol. Græc. T. 2. p. 333.

Among the other Greeks, when a child was born, it was laid on the ground, and if the father designed to educate his child, he immediately took it up, but if he forbore to do this, the child was carried away, and exposed. *Pitisc.* Lex. Ant. in voc. *Expositio.*

The Lacedemonians indeed had a different custom, for, with them, all new-born children were brought before certain tryers, who were some of the gravest men in their own tribe, by whom the infants were carefully viewed, and if they were found lusty and well favoured, they gave orders for their education, and allotted a certain proportion of land for their maintenance; but if weakly, or deformed, they ordered them to be cast into a deep cavern in the earth, near the mountain Taygetus, as thinking it neither for the good of the children themselves, nor for the public interest, that defective children should be brought up. *Pott.* loc. cit.

Many persons *exposed* their children only because they were not in condition to educate them, having no intention that they should perish. It was the unhappy fate of daughters especially to be thus treated, as requiring more charges to educate and settle them in the world than sons. *Pott.* loc. cit.

The parents frequently tied jewels and rings to the children they *exposed*, or any other thing whereby they might afterwards discover them, if providence took care for their safety. Another design, in adorning these infants, was either to encourage such as found them, to nourish and educate them, if alive; or to give them human burial, if dead. *Pott.* T. 2. p. 334.

The places where it was usual to *expose* children, were such as people frequented most. This was done in order that they might be found, and taken up by compassionate persons, who were in circumstances to be at the expence of their education. With this intention the Egyptians and Romans chose the banks of rivers, and the Greeks the highways. *Pitisc.* loc. cit.

EXPOSITION, *Expositio*, in rhetoric, is sometimes used for *division*. See DIVISION.

EXPOSTULATION, *Expostulatio*, in rhetoric, a complaint addressed to a person from whom we have received some injury. It varies according to circumstances. See *Voss.* Rhet. l. 3. p. 420.

EXPRESSION (*Cycl.*) — *Diversifying of* EXPRESSION, in rhetoric. See DIVERSIFYING.

EXPROBRATION, *Exprobratio*, in rhetoric, is the reproaching a person with ingratitude, and unmindfulness of some particular benefit conferred upon him. See *Voss.* Rhet. l. 3. p. 422.

EXQUIMA, in zoology, the name of a species of monkey common on the coast of Guinea. The hair on its back is of a reddish brown, and looks as if it had been singed or burnt, and resembles a rusty iron colour; among this there are a number of small white spots; its belly and chin are wholly white, and it has a very beautiful beard of a snow white, composed of hair of two finger's length, and always lying as neatly and regularly as if it were combed. When this creature is provoked, it draws back its lips, and, shewing all its teeth, shuts its jaws very nimbly, and chatters remarkably loud. It is very nimble, and

and leaps ſurpriſingly; it feeds on the fruits it finds in the woods. *Ray*'s Syn. Quad. p. 156.

There is alſo another ſpecies of this creature in Guinea of the ſize of the former, and of a blackiſh brown on the greateſt part of the body, but of a bluiſh grey on the belly, and the lower half of its tail is of a ſort of tawney colour; its mouth and noſe are blue, and its cheeks adorned with a multitude of yellow hairs cluſtered together like thoſe of a goat's beard. Its legs and feet are wholly black, it is a ſprightly animal, and ſkips and plays like the other; beſides theſe there is alſo a third of the *Exquima* kind ſmaller than the others, and of a mixt colour of brown, yellow, and grey; this has a long tail, a ſmall head, and no beard.

EXSIBILANTES, in antiquity, a kind of hiſſers, who, in the theatre, and other public auditories, uſed to make a noiſe with their feet, and even ſometimes beat the ſeats with battons. *Pitiſc.* Lex. Ant. in voc.

EXSUCCATIO, a word uſed by ſome chirurgical writers to expreſs an *enchymoſis*, or ſugillation. See the article ENCHYMOSIS.

EXSUFFLATION, a ceremony obſerved in baptiſm, by which the candidate was ſuppoſed to renounce the devil. See BAPTISM.

EXTEND, in the manege. To *extend a horſe* is an expreſſion uſed by ſome, to import the ſame with making a horſe go large. See LARGE.

EXTEND, in law. See EXTENDING, *Cycl.*

EXTENDENTIUM *Interior*, in anatomy, a name given by Spigelius and others to a muſcle of the wriſt, called by Albinus ulnaris externus, and by Winſlow and others cubitalis externus. See CUBITALIS *externus*.

EXTENDI *Facias*, in law, a writ of extent, whereby the value of lands is commanded to be made and levied, *&c.* Reg. Orig.

EXTENSION *(Cycl.)*—The infinite diviſibility of *Extenſion* has been a famous queſtion in all ages. The doctrine of mathematicians on this head is not eaſy to reconcile with the tenets of ſome philoſophers. Thoſe who hold that all *Extenſion* and magnitude are compounded of a certain *minima ſenſibilia*, and that a line for inſtance cannot increaſe or decreaſe, but by certain indiviſible increments or decrements only, muſt conſiſtently with themſelves affirm, that all lines are commenſurable to each other, contrary to the tenth book of Euclid; who demonſtrates, that the diagonal of a ſquare is incommenſurable to its ſide. But if all lines were compoſed of certain indiviſible elements, it is plain one of thoſe elements muſt be the common meaſure of the diagonal and the ſide. This is a gordian knot which none of the philoſophers have yet thought fit to untie. An ingenious author of this age, who has ſaid ſeveral plauſible things againſt the doctrine of mathematicians, aſks, when it is ſaid or implied that ſuch a certain line delineated on paper contains more than any aſſignable number of parts, whether any more in truth ought to be underſtood, than that it is a ſign indifferently repreſenting all finite lines, be they ever ſo great; in which relative capacity it contains *i. e.* ſtands for more than any aſſignable number of parts? and whether it be not altogether abſurd to ſuppoſe a finite line conſidered in itſelf, or in its own poſitive nature, ſhould contain an infinite number of parts? But we own ourſelves at a loſs to ſee how, ſuppoſing a line diviſible into any aſſignable number of parts in its relative capacity only, will ſolve the difficulties attending Euclid's doctrine of incommenſurables, which neither this author nor any other has yet been able to refute. Suppoſing, for inſtance, a line in its own poſitive nature to contain but 10 parts, and ſuppoſe a ſquare formed on this line, this ſquare muſt neceſſarily contain 100 parts. The diagonal of the ſquare muſt have ſome length; but what? Shall we ſay 14 or 15 parts, if the firſt, the ſquare of the diagonal muſt contain 196 parts; if the ſecond, it muſt contain 225 parts, neither of which numbers are double of 100, the parts contained in the ſquare of the ſide. Now it is moſt evident without any intricacy of geometrical demonſtration, that the ſquare of the diagonal of every ſquare muſt be preciſely double of the ſquare itſelf. But farther, ſuppoſing the ſide to contain 100 parts, it is eaſily ſeen as before, that the diagonal can neither be expreſſed by 141 nor by 142; and there can be no fractions in the expreſſion, each part by the ſuppoſition being indiviſible. This leads us to the ſame abſurdity as before, with this addition; that as neither 141 nor 142 are in proportion to 100, as 14 or 15 are to 10, it follows that the Iſoſceles triangle which is the half of a great ſquare is not ſimilar to the Iſoſceles triangle, that is the half of a leſſer ſquare. But can any thing be more inconceivable, more repugnant to the moſt obvious notions of ſimilar figures than this?

But it may be worth while to hear this author himſelf, in another part of his works, urging his difficulties againſt the commonly received doctrine of mathematicians. He obſerves, the infinite diviſibility of finite *Extenſion*, though it is not expreſsly laid down either as an axiom or theorem in the elements of geometry; yet is throughout the ſame every where ſuppoſed, and thought to have ſo inſeparable and eſſential a connection with the principles and demonſtrations in geometry, that mathematicians never admit it into doubt, or make the leaſt queſtion of it. And as this notion is the ſource from whence do ſpring all thoſe amuſing geometrical paradoxes, which have ſuch a direct repugnancy to the plain common ſenſe of mankind, and are admitted with ſo much reluctance into a mind not yet debauched by learning; ſo is it the principal occaſion of all that nice and extreme ſubtilty, which renders the ſtudy of mathematics ſo difficult and tedious. Hence, ſays he, if we can make it appear, that no finite *Extenſion* contains innumerable parts, or is infinitely diviſible, it follows that we ſhall at once clear the ſcience of geometry from a great number of difficulties and contradictions, which have ever been eſteemed a reproach to human reaſon, and withal make the attainment thereof a buſineſs of much leſs time and pains, than it hitherto hath been.

Every particular finite *Extenſion*, which may poſſibly be the object of our thought, is an idea exiſting only in the mind, and conſequently each part thereof muſt be perceived. If therefore I cannot perceive innumerable parts in any finite *Extenſion* that I conſider, it is certain they are not contained in it; but it is evident, that I cannot diſtinguiſh innumerable parts in any particular line, ſurface, or ſolid, which I either perceive by ſenſe, or figure to myſelf in my mind: wherefore I conclude they are not contained in it. Nothing can be plainer to me, than that the *Extenſions* I have in view are no other than my own ideas; and it is no leſs plain, that I cannot reſolve any one of my ideas into an infinite number of other ideas, that is, that they are not infinitely diviſible. If by infinite *Extenſion* be meant ſomething diſtinct from a finite idea, I declare I do not know what that is, and ſo cannot affirm or deny any thing of it. But if the terms *Extenſion*, parts, and the like, are taken in any ſenſe conceivable, that is, for ideas; then to ſay a finite quantity or *Extenſion* conſiſts of parts infinite in number, is ſo manifeſt a contradiction, that every one at firſt ſight acknowledges it to be ſo.

He whoſe underſtanding is prepoſſeſt with the doctrine of abſtract general ideas, may be perſuaded, that (whatever be thought of the ideas of ſenſe,) extenſion in abſtract is infinitely diviſible. And one who thinks the objects of ſenſe exiſt without the mind will perhaps in virtue thereof be brought to admit, that a line but an inch long may contain innumerable parts really exiſting, tho' too ſmall to be diſcerned. Theſe errors are grafted as well in the minds of geometricians, as of other men, and have a like influence on their reaſonings; and it were no difficult thing to ſhew how the arguments from geometry made uſe of to ſupport the infinite diviſibility of *Extenſion*, are bottomed on them. At preſent we ſhall only obſerve in general, whence it is that the mathematicians are all ſo fond and tenacious of this doctrine.

The theorems and demonſtrations in geometry are converſant about univerſal ideas, which is to be underſtood in this ſenſe: To wit, that the particular lines and figures included in the diagram, are ſuppoſed to ſtand for innumerable others of different ſizes; or in other words, the geometer conſiders them abſtracting from their magnitude; which doth not imply that he forms an abſtract idea, but only that he cares not what the particular magnitude is, whether great or ſmall, but looks on that as a thing indifferent to the demonſtration. Hence it follows, that a line in the ſcheme, but an inch long, muſt be ſpoken of, as though it contained ten thouſand parts; ſince it is regarded not in itſelf, but as it is univerſal only in its ſignification, whereby it repreſents innumerable lines greater than itſelf, in which may be diſtinguiſhed ten thouſand parts or more, though there may not be above an inch in it. After this manner the properties of the lines ſignified are (by a very uſual figure) transferred to the ſign, and thence through miſtake thought to appertain to it conſidered in its own nature.

Becauſe there is no number of parts ſo great, but it is poſſible there may be a line containing more; the inch line is ſaid to contain parts more than any aſſignable number; which is true, not of the inch taken abſolutely, but only for the things ſignified by it. But men not retaining that diſtinction in their thoughts, ſlide into a belief that the ſmall particular line deſcribed on paper contains in itſelf parts innumerable: There is no ſuch thing as the ten thouſandth part of an inch; but there is of a mile or diameter of the earth, which may be ſignified by that inch. When therefore I delineate a triangle on paper, and take one ſide not above an inch, for example, in length to be the radius; this I conſider as divided into ten thouſand or an hundred thouſand parts, or more. For tho' the ten thouſandth part of that line conſidered in itſelf, is nothing at all, and conſequently may be neglected without any error or inconveniency; yet theſe deſcribed lines being only marks ſtanding for greater quantities, whereof it may be the ten thouſandth part is very conſiderable, it follows, that to prevent notable errors in practice, the radius muſt be taken of ten thouſand parts, or more.

From what hath been ſaid the reaſon is plain why, to the end any theorem may become univerſal in its uſe, it is neceſſary we ſpeak of the lines deſcribed on paper, as though they contained parts which really they do not. In doing of which, if we examine the matter throughly, we ſhall perhaps diſcover that we cannot conceive an inch itſelf as conſiſting of, or being diviſible into a thouſand parts, but only ſome other line which is far greater than an inch, and repreſented by it. And that when we ſay a line is infinitely diviſible, we muſt mean a line which is infinitely great. What we have here obſerved

ſeems to be the chief cauſe, why to ſuppoſe the infinite diviſibility of finite *Extenſion* hath been thought neceſſary in geometry. The ſeveral abſurdities and contradictions which flowed from this falſe principle might, one would think, have been eſteemed ſo many demonſtrations againſt it; but, by I know not what logic, it is held that proofs à poſteriori are not to be admitted againſt propoſitions relating to infinity. As though it were not impoſſible even for an infinite mind to reconcile contradictions; or, as if any thing abſurd and repugnant could have a neceſſary connection with truth, or flow from it. But whoever conſiders the weakneſs of this pretence, will think it was contrived on purpoſe to humour the lazineſs of the mind, which had rather acquieſce in an indolent ſcepticiſm, than be at the pains to go thro' with a ſevere examination of thoſe principles it hath ever embraced for true.

Of late the ſpeculations about infinities have run ſo high, and grown to ſuch ſtrange notions, as have occaſioned no ſmall ſcruples and diſpute among the geometers of the preſent age: Some are of great note, who not content with holding that finite lines may be divided into an infinite number of parts, do yet farther maintain, that each of thoſe infiniteſimals is itſelf ſubdiviſible into an infinity of other parts, or infiniteſimals of a ſecond order, and ſo on *ad infinitum*. Theſe, I ſay, aſſert there are infiniteſimals of infiniteſimals of infiniteſimals, without ever coming to an end. So that according to them an inch doth not barely contain an infinite number of parts, but an infinity of an infinity of an infinity *ad infinitum* of parts. Others there be who hold all orders of infiniteſimals below the firſt to be nothing at all, thinking it with good reaſon abſurd, to imagine there is any poſitive quantity or part of *Extenſion*, which, though multiplied infinitely, can never equal the ſmalleſt given *Extenſion*. And yet, on the other hand, it ſeems no leſs abſurd, to think the ſquare, cube, or other power of a poſitive real root, ſhould itſelf be nothing at all; which they who hold infiniteſimals of the firſt order, denying all of the ſubſequent orders, are obliged to maintain. Have we not therefore reaſon to conclude, that they are both in the wrong, and that there is in effect no ſuch thing as parts infinitely ſmall, or an infinite number of parts contained in any finite quantity? But you will ſay, that if this doctrine obtains, it will follow the very foundations of geometry are deſtroyed: And thoſe great men who have raiſed that ſcience to ſo aſtoniſhing an height, have been all the while building a caſtle in the air. To this may be replied, that whatever is uſeful in geometry and promotes the benefit of humane life, doth ſtill remain firm and unſhaken on our principles. That ſcience conſidered as practical, will rather receive advantage than any prejudice from what hath been ſaid: But to ſet this in a due light, may be the ſubject of a diſtinct inquiry. For the reſt, tho' it ſhould follow that ſome of the more intricate and ſubtil parts of ſpeculative mathematics may be pared off without any prejudice to truth; yet I do not ſee what damage will be thence derived to mankind. On the contrary, it were highly to be wiſhed, that men of great abilities and obſtinate application would draw off their thoughts from thoſe amuſements, and employ them in the ſtudy of ſuch things as lie nearer the concerns of life, or have a more direct influence on the manners.

If it be ſaid, that ſeveral theorems undoubtedly true are diſcovered by methods in which infiniteſimals are made uſe of, which could never have been, if their exiſtence included a contradiction in it. I anſwer, that upon a thorough examination it will not be found, that in any inſtance it is neceſſary to make uſe of or conceive infiniteſimal parts of finite lines, or even quantities leſs than the *minimum ſenſibile*: Nay, it will be evident this is never done, it being impoſſible. Thus far D. *Berkeley*.

On the other hand it is obſerved by an eminent mathematician, that geometricians are under no neceſſity of ſuppoſing that a finite quantity or *Extenſion* conſiſts of parts infinite in number, or that there are any more parts in a given magnitude than they can conceive or expreſs: It is ſufficient that it may be conceived to be divided into a number of parts equal to any given or propoſed number, and this is all that is ſuppoſed in ſtrict geometry concerning the diviſibility of magnitude. It is true, that the number of parts, into which a given magnitude may be conceived to be divided, is not to be fixed or limited, becauſe no given number is ſo great but a greater than it may be conceived and aſſigned: But there is not therefore any neceſſity for ſuppoſing that number infinite; and if ſome may have drawn very abſtruſe conſequences from ſuch ſuppoſitions, geometry is not to be loaded with them. See Mr. *Maclaurin*'s Treatiſe of Fluxions, Art. 290.

Though geometricians are under no neceſſity of ſuppoſing a given magnitude to be divided into an infinite number of parts, or to be made up of infiniteſimals, they cannot ſo well avoid ſuppoſing it divided into a greater number of parts than may be diſtinguiſhed in it by ſenſe in any particular determinate circumſtances. But they find no difficulty in conceiving this; and ſuch a ſuppoſition does not appear repugnant to the common ſenſe of mankind, but on the contrary to be moſt agreeable to it, and to be illuſtrated by common obſervation. It would ſeem very unaccountable, not to allow them to conceive a given line, of an inch in length for example, viewed at the diſtance of ten feet, to be divided into more parts than are diſcerned in it at that diſtance; ſince by bringing it nearer a greater number of parts is actually perceived in it. Nor is it eaſy to limit the number of parts that be perceived in it when it is brought near to the eye, and is ſeen through a little hole in a thin plate; or when by any other contrivance it is rendered diſtinct at ſmall diſtances from the eye. If we conceive a given line that is the object of ſight to be divided into more parts than we perceive in it, it would ſeem that no good reaſon can be aſſigned, why we may not conceive tangible magnitude to be divided into more parts than are perceived in it by the touch, or a line of any kind to be divided into any given number of parts, whether ſo many parts be actually diſtinguiſhed by ſenſe, or not. If the hyperbola and its aſymptote were accurately deſcribed, they would ſeem to ſenſe to join each other, at various diſtances from the center, according to the different circumſtances in which they might be perceived; but we may conceive the ordinate at the point where they ſeem to join to have a real magnitude, in the ſame manner as we conceive a given line to ſubſiſt when it is carried to ſo great a diſtance that it vaniſhes to ſight, or any ſmall particle (as an atom in the ſun-beams) to exiſt, tho' it eſcape the touch, or have no tangible magnitude. It may perhaps illuſtrate this, if it be it conſidered, that the curve cannot be ſaid to meet its aſymptote in this caſe, in the ſame ſenſe that a circle is ſaid to meet its diameter, which it appears to interſect in all caſes, whatever the diſtance or poſition of the figure, or the acuteneſs of the ſenſe may be; whereas the ordinate of the hyperbola that vaniſhes to ſight at a great diſtance, becomes viſible at a leſs diſtance; and may be diſtinguiſhed into more and more viſible parts, in proportion as it approaches to the eye, or the ſenſe is more acute. And ſurely it muſt be allowed that there is ground for a difference between a line that eſcapes the ſight and vaniſhes, becauſe of its diſtance from the eye, and a line that in no caſe can ever be perceived, or can be ſuppoſed to have any exiſtence. Perhaps it will be ſaid by ſome, that, ſtrictly ſpeaking, it is not the ſame line that in thoſe different circumſtances has a greater and leſs number of viſible parts. In anſwer to this, it is ſufficient for our purpoſe to obſerve, that as there can hardly be any philoſopher but will allow that there is ſome ſenſe in which it is the ſame inch-line that has more viſible parts at eight inches diſtance from the eye than when it is held at the length of the arm; ſo it is not incumbent on us to explain in what ſenſe this is to be underſtood according to every ſcheme of philoſophy: It is enough that this ſenſe muſt be ſuppoſed to be plain and obvious, as it is univerſal, and that geometricians ought to be allowed to conſider lines and figures in this ſenſe as well as every body elſe. Philoſophers and the vulgar equally conceive the ſun and planets, and the other objects of their obſervation and enquiries, to be the ſame bodies, when ſeen at different diſtances or different times: And if they were not allowed to conſider thoſe bodies as made up of more parts than are perceived by ſenſe, and geometricians were under the ſame limitations as to magnitude in general, they would not be a little perplexed; nor is it the more intricate and ſubtile part of thoſe ſciences only that would be thus pared off. The learned author above-mentioned tells us, "That the magnitude of the object which "exiſts without the mind, and is at a diſtance, continues al-"ways invariably the ſame[a]." He ſeems to ſpeak of tangible magnitude. It is not our buſineſs here to enquire how, according to his doctrine, tangible magnitude can be conceived to exiſt without the mind any more than viſible magnitude. This conceſſion perhaps is made only for the ſake of his argument in this place; but the evidence for the exiſtence of ſuch an object may very well be ſuppoſed to approach to that which we have for the exiſtence of any other objects that are not immediately perceived by us. And ſince he admits it, and argues from it, in this treatiſe; it would ſeem that ſome invariable magnitude is to be allowed, which we apprehend by the ſight, though not immediately; and that this magnitude may be conceived to be divided into any given number of parts, from the demonſtrations propoſed by geometricians on this ſubject[b]. In applying which, it ought to be remembered, that a ſurface is not conſidered by them as a body of the leaſt ſenſible magnitude, but as the termination or boundary of a body; a line is not conſidered as a ſurface of the leaſt ſenſible breadth, but as the termination or limit of a ſurface: Nor is a point conſidered as the leaſt ſenſible line, or a moment as the leaſt perceptible time; but a point as a termination of a line, and a moment as a termination or limit of time. In this ſenſe they conceive clearly what a ſurface, line, point, and a moment of time is[c]; and the *poſtulata* of Euclid being allowed and applied in this ſenſe, the proofs by which it is ſhewn that a given magnitude may be conceived to be divided into any given number of parts, appear ſatisfactory: And if we avoid the ſuppoſing the parts of a given magnitude to be infinitely ſmall, or to be infinite in number, this ſeems to be all that the moſt ſcrupulous can require.[d]—[[a] New Theory of Viſion, §. 55. [b] Ibid. §. 54. [c] The Analyſt, §. 31. [d] Mr. *Maclaurin*'s Treat. of Fluxions, Art. 290, 291.]

EXTENSION *of fractured Limbs*, in ſurgery. When the fractured bones maintain their natural ſituation, the ſurgeon has nothing to do but to apply a proper bandage to keep them in it; but when the

the fractured parts recede from one another, ſome degree of *Extenſion* is neceſſary, which muſt always be ſuited to the diſtortion of the limb. The greater diſtance there is between the extremities of the divided parts of the bone, ſo much the ſhorter will the limb become from the natural contraction of the muſcles, and the *Extenſion* muſt be proportionably the greater; but, in theſe caſes, every thing is to be done tenderly, and with great care. 1. The patient is to be kept very firm and ſteady; the poſture of the body muſt be, in this operation, different, according to the different circumſtances of the caſe; ſometimes ſitting, and ſometimes lying, are the moſt proper. 2. An aſſiſtant muſt ſupport the limb with his hands, both above and below the fractured part. 3. The perſon who holds the lower part of the limb, muſt extend it ſtrongly and equally, till the fractur'd bone can be replaced; but when the ſurgeon is called at ſome diſtance of time from the accident, and a tumour and inflammations are come on; it is beſt, in ſuch caſe, to defer the *Extenſion* of the parts till theſe ſymptoms are removed, by letting blood, looſening the bowels, giving the patient large quantities of aqueous fluids, and preſcribing the proper internal remedies for abating inflammations, and fomenting the parts with warm diſcutient decoctions. Theſe applications will uſually ſucceed ſo well as to take down the inflammation, in twenty-four hours, in ſuch a manner, that the *Extenſion* of the limb may be ſafely attempted; but when they do not take place ſo ſuddenly, they are to be repeated till they have the deſired effect; and where the common fomentations fail, the following has often very great and happy ſucceſs: Take two or three handfuls of ſcordium, and boil them for about a quarter of an hour in a pint of water, with ſix ounces of rectify'd ſpirit of wine, afterwards mix with it an ounce of common ſalt, and half an ounce of ſalt petre, and uſe this to the inflamed fractur'd limb. To make the proper *Extenſion* of a limb, the ſurgeon muſt, while it is kept at its proper length by two aſſiſtants, direct it with his hands, ſometimes a little one way, ſometimes another, putting it into different poſitions, as the nature of the caſe ſhall require, till the parts have recovered their natural ſituation. This will be known by the remiſſion or abſence of pain, and by obſerving, that the fractur'd limb is of the ſame length with the ſound one; and if theſe ſigns of ſucceſs, in the operation, are wanting, there is great reaſon to ſuppoſe, that the operation is as yet ineffectual, and the *Extenſion* is to be repeated or continued till the bones are evenly and properly replaced. *Heiſter*'s Surg. p. 108.

EXTENSOR (*Cycl.*)—EXTENSOR *Digitorum Communis*, a compound muſcle, very much reſembling the perforatus and perforans, and lying on the outſide of the fore arm, between the ulnaris externus and radialis externus. It is fixed above, by a tendinous extremity, to the poſterior and lower part of the external or great condyle of the os humeri; and, by a tendinous adheſion on each ſide, to the ulnaris and radialis externus. It has likewiſe ſometimes a ſmall inſertion in the radius; it is divided into four muſcles, like the perforatus and perforans, and four long ſlender ſmall tendons. Three of theſe tendons paſs through the common external annular ligament of the carpus; and the fourth, which goes to the little finger, and which has ſometimes its fleſhy portion diſtinct from the reſt, paſſes thro' a particular ring of the ſame ligament. Afterwards theſe four tendons ſeparate as they go to the fingers, and, in their paſſage, communicate with each other by oblique tendinous ſeries, chiefly near the heads of the metacarpal bones. The tendons of the middle and little finger are ſometimes double, and yet communicate with the reſt.

Each tendon having reached the baſis of the firſt phalanx, is ſlightly inſerted therein by ſome lateral expanſions, fixed in each ſide of the baſis; from thence it advances to the head of the ſame phalanx, where it is divided into two flat portions, which, at the articulation of the firſt phalanx with the ſecond, leave ſome diſtance between them. About the head of the ſecond phalanx they unite again, and are fixed in the convex ſide near the baſis in the third phalanx. The ſeparation of the two portions is, in ſome ſort, rhomboidal, and each portion is ſtrengthened by a common tendon of the lumbricales and interroſſei, and in the ſmall ſpaces between them are ſmall tendinous fræna, more or leſs tranſverſe. *Winſlow*'s Anatomy, p. 199.

EXTENSOR *Digitorum Pedis longus*, a long muſcle, fleſhy in its upper part, but tendinous in the lower, lying between the tibialis anticus and peronæus maximus. It is fixed above by fleſhy fibres in the outſide of the head of the tibia, and inſide of the head of the fibula, in the upper part of the interoſſeous ligament, thro' three fourths of the length of the fibula, and thro' the ſame ſpace, in the tendinous ſeptum belonging to the anterior angle of that bone. It ſeems to mix ſome fibres on each ſide with the two firſt peronæi and tibialis anticus, and is very cloſely united with the peronæus maximus. It contracts in breadth a little above the annular ligament, and, in paſſing through it, is divided into three tendons, the firſt of which is afterwards again divided into two. Theſe four tendons are inſerted along the upper or convex ſide of the bones of the four ſmall toes. *Winſlow*'s Anatomy, p. 222.

EXTENSOR *Digitorum Pedis brevis*, a ſmall complex muſcle, lying obliquely on the convex ſide of the foot, called alſo *pedicus*. It is fixed in the upper and outer ſide of the anterior apophyſis of the aſtragalus, and in the adjoining part of the upper ſide of that bone. Thence it runs obliquely inwards, and is divided into four fleſhy portions, which terminate in four tendons. The firſt is inſerted in the upper part of the firſt phalanx of the great toe, and the other three, joining with thoſe of the *Extenſor longus*, are inſerted along the convex ſides of all the phalanges of the three following toes. When there is a fifth tendon, which ſometimes happens, it goes in the ſame manner to the little toe. *Winſlow*'s Anatomy, p. 223.

EXTENSOR *Indicis proprius*, a ſmall long muſcle, with a long ſlender tendon, lying a little obliquely on the lower and outer half of the fore arm, between the ulna and the fore finger. It is fixed by its fleſhy body, a little higher than the loweſt third part of the outſide of the ulna, below the inſertion of the *Extenſor pollicis*, and it has likewiſe a ſmall adheſion to the interoſſeous ligament. From thence it runs down, ending in a diſtinct tendon, without any communications, which having paſſed through the annular ligament of the *Extenſor communis*, afterwards joins that tendon which goes to the index. *Winſlow*'s Anatomy, p. 200.

EXTENSOR *Minimi Digiti proprius*, a collateral or auxiliary muſcle of the *Extenſor communis*, of which it appears almoſt always to be more or leſs a portion. It is fixed along the ſuperior external half of the ulna, from whence its long ſmall tendon runs down in company with the fourth tendon of the *Extenſor communis*, all the way to the little finger, where it joins it, and is inſerted with it. Sometimes this muſcle is wanting, in which caſe the *Extenſor communis* ſends a double and ſometimes a treble tendon to the little finger. *Winſlow*'s Anatomy, p. 200.

EXTENSORES *Pollicis Manus*, two very diſtinct muſcles, the firſt, or longeſt of which, is ſometimes more, ſometimes leſs, and ſometimes altogether divided into two, in which caſe theſe muſcles are three in number. They are ſituated obliquely between the ulna and the convex ſide of the thumb.

The *extenſor primus* is a long muſcle, more or leſs double, and is fixed above by fleſhy fibres, firſt to the outſide of the ulna, near its upper extremity, below the anconæus minor and inſertion of the ulnaris externus; next to the interoſſeous ligament, under the ſupinator brevis; and laſtly, to the middle part of the outſide of the radius.

From thence it runs down, and paſſes anteriorly over the lower part of the radius, and tendons of the ſupinator longus and radialis externus; and being gradually divided, it terminates in two long flat tendons, more or leſs ſubdivided, which paſs together under a particular annular ligament, being only parted by ſepta or fræna belonging to that ligament. The firſt of theſe two principal tendons is inſerted in the edge of the baſis of the firſt phalanx, near the large tranſverſe ligament of the carpus; when this tendon is ſubdivided, the other portion of it is fixed in that bone of the carpus which ſuſtains the thumb. The other principal tendon, which often belongs to a muſcle entirely diſtinct from the former, is fixed in the convex ſide of the baſis of the ſecond phalanx, where it joins the tendon of the extenſor ſecundus. On account of theſe different inſertions of the two tendons, this muſcle is, by ſome authors, deſcribed as two.

The *Extenſor ſecundus* is ſhorter than the firſt; it is fixed to the ulna below the former, and above the inſertion of the *Extenſor indicis proprius*; and likewiſe to the neighbouring part of the interoſſeous ligament. From thence it runs down obliquely on the middle part of the radius, where it has alſo a ſmall adheſion; after this it paſſes thro' the ſmall channel in the ſtyloide apophyſis of the radius, thro' the annular ligament belonging to the tendons of the radialis externus, and over theſe tendons, being parted from them by a ſmall ligamentary ſeptum. It is inſerted in the convex part of the third phalanx near its baſis, having, as it paſſes over the ſecond phalanx, joined the ſecond or collateral tendon of the firſt *Extenſor*, more or leſs. *Winſlow*'s Anatomy, p. 196.

EXTENSOR *Pollicis longus*, a thin ſingle muſcle, lying between the tibialis anticus and *Extenſor digitorum longus*, by the laſt of which it is almoſt hid. It is fixed to the inſide of the fibula, near the interoſſeous ligament, from the neck down to the loweſt quarter of that bone; to the interoſſeous ligament thro' the ſame ſpace, and a little to the lower extremity of the tibia next the fibula. It there ends in a conſiderable tendon, which paſſing through a diſtinct ring of the common annular ligament, and then through a membranous vagina, is inſerted in the baſis of the firſt phalanx of the great toe, and continued up to the ſecond. *Winſlow*'s Anatony, p. 221.

EXTENSOR *Proprius Auricularis*, in anatomy, a name given, by Albinus, and ſome other late authors, to one of the muſcles of the hand, called by Cowper, and others, the *Extenſor minimi digiti*. Vid. *Supra*.

EXTENSOR *Tarſi*, in anatomy, a name given by Douglaſs, and ſome others, to a muſcle, more generally known by the name of the plantaris. See PLANTARIS.

EXTERMINATION, or EXTERMINATING, (*Cycl.*) in algebra, is uſed for taking away. Thus algebraiſts ſpeak of *exterminating* ſurds, fractions, and unknown quantities, out of equations. See *Maclaur.* Algebr. part 1. ch. 12. where

we

we have ſome general theorems for the *exterminating* unknown quantities in given equations.

EXTERNUS *(Cycl.)*—EXTERNUS *Duverni*, a name given by Douglaſs to one of the muſcles of the ear, called by Cowper and others *obliquus auris*, and by Albinus *Externus mallei*.

EXTERNUS *Mallei*, in anatomy, a name given by Albinus to one of the muſcles of the ear, called by others *obliquus auris* and *muſculus Externus auris*.

EXTINGUISHING *of Fires*.—The world has long been in an opinion, that a more ready way than that in general uſe, might be found for *extinguiſhing* fires in buildings, and it has been generally attempted upon the doctrine of exploſion. Zachary Greyl was the firſt perſon who put this plan into execution with any tolerable degree of ſucceſs. He contrived certain engines eaſily manageable, which he proved before ſome perſons of the firſt rank, to be of ſufficient efficacy, and offered to diſcover the ſecret by which they were contrived, for a large premium given either from the crown or raiſed by a ſubſcription of private perſons. But this ſcheme meeting with no better ſucceſs than things of this nature uſually do, he died without making the diſcovery: Two years after this the people who had his papers found the method, and it was ſhewn before the king of Poland and a great concourſe of nobility at Dreſden, and the ſecret purchaſed at a very conſiderable price. After this the ſame perſon carried the invention to Paris and many other places, and practiſed it every where with ſucceſs.

The ſecret was this. A wooden veſſel was provided holding a very conſiderable quantity of water, in the center of this there was fixt a caſe made of iron plates and filled with gunpowder; from this veſſel to the head of the larger veſſel containing the water, there was conveyed a tube or pipe, which might convey the fire very readily thro' the water to the gunpowder contained in the inner veſſel. This tube was filled with a preparation eaſily taking fire and quickly burning away; and the manner of uſing the thing was to convey it into the room or building where the fire was, with the powder in the tube lighted. The conſequence of this was, that the powder in the inner caſe ſoon took fire, and with a great exploſion burſt the veſſel to pieces and diſperſed the water every way; thus was the fire put out in an inſtant, tho' the room was flaming before in all parts at once. The advantage of this invention was that at a ſmall expence and with the help of a few people, a fire in its beginning might be extinguiſhed; but the thing was not ſo general as it was at firſt expected that it would prove, for tho' of certain efficacy in a chamber or cloſe building, where a fire had but newly begun, yet when the miſchief had encreaſed ſo far that the houſe was fallen in, or the top open, the machine had no effect. This was the thing firſt diſcovered by Greyl, and from which our chemiſt Godfrey took the hint of the machine, which he called the water-bomb, and would fain have brought into uſe in England. Act. Eruditor. Ann. 1721. p. 183. See the article WATER-*Bomb*.

EXTINGUISHMENT *(Cycl.)*—EXTINGUISHMENT *of Common*, in law. By purchaſing of lands wherein a perſon hath common appendant, the common is *extinguiſhed*. Cro. El. 594. A releaſe of common in one acre, is an *Extinguiſhment* of the whole common. *Shower*'s, Rep. 350. And where a perſon hath common of *Vicinage*, if he incloſes any part of the land, all the common is extinct. 1 *Brownl.* 174. If a man hath a high-way appendant to land, and afterwards purchaſeth the land wherein the high-way is, the way is extinct.

EXTINGUISHMENT *of Liberties*, in law. If liberties and franchiſes granted by the king, come again to the crown, they ſhall not be *extinguiſhed*; but it is otherwiſe in the king's grants of felon's goods, waifs, ſtrays, wrecks, *&c.* 9 Rep. 25.

EXTIRPATIONE, in law, a judicial writ, either before or after judgment, that lies againſt a perſon, who when a verdict is found againſt him for land, *&c.* doth maliciouſly overthrow any houſe, or *extirpate* any trees upon it. Reg. Jud. 13. p. 56.

EXTRACT *(Cycl.)*—Mr. Geoffroy who well knew the value of this form of medicine, attempted to improve upon the common method of making *Extracts*, and ſucceeded greatly to his wiſhes; the conſequence of which was his preſenting to the academy of ſciences at Paris his method of doing it.

The hint was taken from a method uſed by the Count Lagarais, to make what he called his eſſential ſalts of plants; which were only dry extracts, prepared by powdering the ſubſtance, and then keeping it in continual motion for ſix or ſeven hours in ſome common water, by means of a chocolate mill turned by a large horizontal wheel; after the matter had ſubſided for an hour, the remaining liquor was poured off and evaporated over a balneum mariæ, or in the ſun, and a valuable dry *Extract* prepared. The method of this proceſs made it impracticable in large quantities of medicines, and Mr. Geoffroy removed the great difficulties that attended it by proving from repeated experiments, that boiling or infuſing the ſubſtances in hot water, extracted from them all that was got out by the long motion of the mill; as was inſtanced in the moſt familiar manner, in the common way of making tea and coffee, which were found to impregnate water with as much of their virtue by the methods of infuſion and decoction, as by ever ſo long an operation in the Count's method. The expence of making *Extracts* of this kind, cannot but be greater than that of managing the ſame medicines any other way; but the eaſe of taking, and the ſmall doſe, cannot but ſufficiently recommend them; and according to Mr. Geoffroy's method, the ſick may prepare them for himſelf. Mr. Geoffroy gives ſome examples of his ſucceſs in theſe preparations.

He took a dram of ſena in powder, and pouring on it a quantity of hot water he left it in infuſion twenty-four hours, then filtering the infuſion he evaporated the liquor in a balneum mariæ, to the thickneſs of a thin ſyrup, and ſpreading this over the bottoms of two or three broad earthen plates he evaporated the remaining humidity over the ſame balneum, and procured twenty-four grains of a dry *Extract*, wholly reſembling Count Lagarais's ſalts, and operating in the ſame manner and with the ſame virtue as a dram of ſena; whether taken in powder, or bolus, or diſſolved in any fluids, in any of which forms it had nothing of the nauſeous taſte of ſena.

The reaſon of ſpreading the remainder of the firſt evaporation on earthen plates is, that unleſs it be thus extended in a thin cruſt it will not dry regularly. The leaves of gratiola, which are a ſtrong purge, being treated in the ſame manner, gave the ſame quantity of a dry *Extract*, which proved a good purge in a doſe of eight, ten, or twelve grains.

Other purgative medicines ſucceeded on trial in the ſame manner; and every one muſt be ſenſible of the value of theſe preparations, which will operate gently, yet ſufficiently in a ſmall doſe and in form of a taſteleſs powder; when he conſiders the neceſſity of giving purges to children; and the antipathy many people have to the taking large doſes of nauſeous cathartics. Memoirs Acad. Scienc. Par. 1738.

The Peruvian bark, whoſe virtues are ſufficiently known, is another medicine very formidable from its large doſe. It uſed to be common to take two drams of it at once in powder when it came firſt into practice; but this doſe was found inſupportable, and infuſions in wine and in water, and *Extracts* made in the common way, were uſed in its ſtead: all theſe however ſtill required large doſes, and retained the diſagreeable taſte of the medicine; but this is perfectly remedied by this method of making a dry *Extract*, which reduces every doſe of the bark to one third of the quantity, and cures as certainly, as when taken in ſubſtance in the whole, ſince the the juices of the ſtomach could have extracted no more virtue from the powder, than the water in the infuſion from which this *Extract* was made does. The utmoſt care in making an *Extract* from a dram of the bark with ſpirit as well as water, can procure only twenty-four grains, the remainder being an inſipid and uſeleſs matter; it is plain therefore that the whole virtue of the dram lies in this twenty-four grains, and ſince this can be ſeparated by water and given alone, why ſhould the palate be offended, or the ſtomach loaded with ſuch a quantity of uſeleſs matter, as two thirds of every common doſe. It is very plain that the method of preparation of even theſe *Extracts* is very troubleſome, but it is much leſs ſo than that of Count Lagarais's ſalts, as it ſpares the buſineſs of the mill; but the ſmallneſs of the doſe and eaſe of taking the medicines uſually moſt of all diſliked, when reduced to this form, muſt recommend it to thoſe who are to give them to nice palates or tender conſtitutions.

EXTRACTS of writings or records, are notes thereof. See ESTREAT, *Cycl.*

EXTRACTA *Curiæ*, in our old writers, the iſſues or profits of holding a court, ariſing from the cuſtomary fees, *&c.* *Paroch.* Antiq. 572.

EXTRACTOR, in midwifry, an inſtrument contrived to extract children in caſes of difficult births. We have the deſcription of a forceps for extracting children by the head, when lodged low in the pelvis of the mother, in the Medic. Eſſ. Edinb. Vol. 3. Art. 20. See alſo the Abridgment of this book Vol. 2. p. 438. where ſome alteration is mentioned of this inſtrument from Giffard's midwifry, and an improvement of it by Mr. Freke.

EXTRACTUM *Catharticum*, a form of medicine in the London Diſpenſatory, intended as an equivalent for the *Extractum Rudii*, commonly called Rudius's pill: it is made in this manner, take ſocotrine aloes an ounce and half, pith of coloquintida ſix drams, ſcammony, and the leſſer cardamom ſeeds huſked, of each half an ounce, proof ſpirit a pint; pour the ſpirit on the coloquintida cut ſmall, then add the ſeeds bruiſed; draw a tincture with a gentle heat continued four days, then to the tincture preſſed out, add the aloes and ſcammony firſt ſeparately reduced to powder, and theſe being diſſolved draw off the ſpirit, and reduce the maſs by evaporation to the conſiſtence of a pill. This is for many reaſons a better compoſition than the Rudius's pill. *Pemberton*'s, Lond. Diſpenſ. p. 168.

EXTRAMUNDANE *Space* is the infinite, empty, void ſpace, which is by ſome ſuppoſed to be extended beyond the bounds of the univerſe, and conſequently in which there is really nothing at all.

EXTRA-PAROCHIAL, ſignifies to be out of any pariſh; thus, where any thing is privileged, and exempt from the duties of

a parish, it is said to be *Extra-parochial.* Stat. 22. & 23. *Car.* 2.

EXTRAVASATED *Blood.* In the contusions, fissures, depressions, fractures, and other accidents of the cranium, one or more of the blood vessels distributed on the dura mater are frequently divided. The blood that is discharged from these vessels greatly oppresses the brain and disturbs its offices, frequently brings on pains and other mischiefs, and often death itself, unless the patient be timely relieved. If the quantity of *extravasated* blood be ever so small, it will certainly corrupt, and affect the meninges, and the brain itself with the same disorder; and from hence will proceed violent inflammations, deliriums, and ulcers, and finally death; and this will frequently be the case, after a violent blow upon the cranium, though the bone should escape without injury. In these injuries of the head, the blood is spilt either between the cranium and the dura mater, or between the dura and pia mater, or between the pia mater and the brain, or lastly into the sinuses of the brain. Either of these cases is attended with very great danger, but the deeper the extravasation happens, so much greater must the danger be. Blood *extravasated* in the cavity of the cranium, will be discovered from the violence of the symptoms that succeed a blow on the head; as if the patient lies still without sense or motion, if blood flows from the mouth, ears, or nose; if the eyes are much inflamed and swelled; if vomitings succeed; when upon the remission of these symptoms the patient complains of a remarkable heaviness of head, sleepiness, vertigo, blindness, spasms, and disorders of this kind. When the quantity of *extravasated* blood on these accidents is very considerable, and oppresses the cerebellum, the patient dies upon the spot; but when it is not in a very large quantity, or does not affect the cerebellum, life still remains, but the symptoms just mentioned come on. In this case, if no fissure or contrafissure is to be found, nor any external injury on the integuments of the head after a violent blow, it proves very difficult to find in what part of the head the extravasation is seated. It will be proper in this case first to shave the head all over, and then thoroughly to examine it, for if any part is softer than ordinary, or is enlarged, or red from stagnating blood, it is plain that this is the part that has received the injury. But if neither this way, nor by enquiry among the persons present at the accident, you can get light into the affair, it will be proper to cover the whole head with an emollient plaister, laying over it medicated bags of herbs, *&c.* well heated. This application will in a few hours time produce a tumour and softness upon the injured part. Sometimes the patient also, tho' he lies speechless, and seemingly senseless, will be continually puting his hand to the injured part; and if either side of the patient has lost sense or motion, and is become paralytic, it is an apparent sign, whatever some might think to the contrary, that the injury has been received on the contrary or sound side. If after accidents of this kind you can discover any wound in the skin, that must be enlarged with the knife till the injury on the cranium, of whatever kind it be, is come at.

When the seat of the injury is discovered, the first intention is to discharge the *extravasated* blood, and then to clean the wound, and remove all splinters, or extraneous bodies. Some have recourse on these occasions to the instant use of the trepan; but patients have been often very successfully recovered without it. It is therefore best first to open a vein, and take away as much blood as the strength of the patient will permit; this will take off the impetus of the vessels, and prevent the *extravasation* of more blood. Prescribe after this a brisk purge to lessen the quantity of the fluids; foment the head with medicated bags, and apply a melilot plaister to it; endeavour to rouse the patient by volatile applications to the nostrils, such as sal volatile, spirit of sal armoniac, or spirit of hartshorn; and give frequently attenuating fluids, such as the decoctions of betony, sage, rosemary, lavender-flowers, sassafras, and the like. This method does not immediately produce the desired effect, but is to be continued for some time, and the prescriptions frequently repeated, particularly when the bad symptoms seem by degrees to abate; and if the patient finds relief from the first bleeding, it will be proper to repeat it a second or third time, especially if he be of an athleletic constitution. When notwithstanding this method, the symptoms are found however rather to encrease than abate, it will be necessary to make a perforation in the cranium with the trepan, to give a passage for the discharge of the confined grumous blood, and when there is no finding out the part affected, the skull must be perforated in several parts till the right is found. *Heister*'s Surg. p. 90.

EXTRAVERSIO, in chemistry, a term used to express the rendering manifest any thing saline, alcaline, or acid, concealed in mixed bodies; and is just the reverse to one of the species of concentration, which hides these qualities.

EXTREME *(Cycl.)*—Extremes, in right angled spherical trigonometry. When one of the five circular parts of a right angled spherical triangle, *viz.* (the three sides and two oblique angles, for the right angle is neglected) is pitched upon for the middle term, then the two circular parts lying immediately next to it are called *Extremes conjunct*; and the two parts remote from the assumed middle part, or not immediately next it, *Extremes disjunct.* See Spherical and Triangle, *Cycl.*

EXTREMITIES *of Figures*, in painting, is used for the head, hands, and feet. These should be drawn with more nicety and exactness, or more terminated than other parts; and thus help to render the action more expressive.

EXTUBERANCES, in medicine, are swellings forth, or risings up in the flesh, or other parts of the body.

EXUCONTIANI, a branch of Arian heretics. See Exucontii.

EXVERRÆ, in antiquity, a kind of brush used in cleansing houses, out of which a dead person had been carried. *Pitisc.* Lex. Ant. in voc.

EXUPORA, in botany, a name by which some authors have called the verbena or common vervain. *Ger.* Emac. Ind 2.

EXUVIÆ *(Cycl.)*—The outer integument of the body, which in man and other larger animals is so durably fixed on the body, is in many of the animals of the reptile kind much more loosely fixed, and is changeable several times during the period of their lives. The serpent kind all shift their skins several times in their lives, and the water-newt has been lately observed to do the same; but no creature in the world does it so often as the caterpillar, almost every species of these insects throwing off their old skin once in ten or twelve days, or less; and this in such a manner as is extremely worthy an attentive observation. Malpighi observed that the common silkworm changed its skin four times during its continuance in that state; the first of these changes happening at eleven or twelve days from its appearance from the egg, and the others at the distance of five or six days each; and probably the rest of the caterpillar kind observe nearly the same periods.

Neither is this change of the skin confined to the few creatures we have mentioned; but among the whole insect class, the most numerous of that of all animated beings we know, there is scarce one species every individual of which does not throw off its skin, once at least, before it arrives at its full growth. The term changing the skin is scarce expressive enough for this operation in the caterpillar kinds; for the creature throws off the external covering of every the minutest part and organ of its body, and the skins they thus deposit have so much the appearance of a compleat insect, that they are very often mistaken for such, presenting us with every thing that we see in the external appearance of the living animal. If the caterpillar has been one of the hairy kinds, the skin which it throws off is hairy, containing the integument as it were of every hair and of each of the legs; and even the claws and other parts which are not visible without the assistance of a microscope, are as plain in this as in the living animal. But what is most of all amazing, is to find that the very solid parts which form the head are also found in the *Exuviæ*, the skull and teeth being plainly distinguishable in them; it is easy to conceive that this must be a strange operation, for an animal in this manner to withdraw the several parts of its body out of their sheaths and cases which they have plainly been fitted into in so nice a manner, and particularly the throwing off an old skull and teeth to make way for new ones, seems an act beyond all comprehension. The operation however appears as tedious and painful to the animal as we can expect; if we examine it strictly, a day or two before this change happens, the creature always refuses to eat, and loses its former activity, either never walking at all, or at the utmost but very slowly; tho' they do not move out of their places, however, they are very full of some particular motions in their body, they turn themselves about from side to side, and often elevate their back and then gently depress it again; they frequently raise up their heads and strike them down rudely against the thing they stand upon, and frequently the anterior half of the body is raised from the place, and thrust very briskly backwards and forwards from side to side, for three or four times together. These are the more obvious motions, but beside these there are other less sensible ones within every ring, these are separately inflated and contracted again alternately, and by this means the skin is greatly loosened from them, and by these motions and the remaining without food, it is that the body by degrees disengages itself from the skin. *Reaumur*, Hist. Ins. V. 1. p. 1. p. 225.

Those caterpillars which live in communities retire into their web which serves them for a habitation, at the time that they are to get off their skins; and those who live solitary and have no such web always spin themselves a silky net-work over the stalk or leaf of a plant, at the time that their change of skin is approaching; the use of this is to entangle their legs in, that they may give a resistance to the motions afterwards to be made by the body in order to throwing off this covering. When the time of the change approaches, all the colours of the skin grow faint and lose their beauty, being deprived of the power of receiving juices for its nourishment, and becoming as it were dry. The skin is then in the condition of the leaf of a tree, which receives no more nourishment and is drying and ready to fall off; and when the creature continues its swelling and shrinking in again of its several rings, at this time the skin being no longer supple or extensible as before, cracks along the middle of the rings on the back of the animal. The second or third ring from the head are always the

part where the crack begins, and immediately on its opening, the new ſkin is ſeen within, and looſe from it, and is eaſily known by the freſhneſs of its colours. As ſoon as the opening is once made, the creature eaſily enlarges it, thruſting up its body, in part, out at the crack, and making it ſerve in the office of a wedge, to enlarge and lengthen out the ſlit; by this means the creature ſoon extends the crack thro' four rings, and it has then a ſpace large enough for it to draw out its whole body at. The firſt efforts are made at the head, which, by ſeveral motions and turnings about, is at length made to be looſened, and finally drawn wholly out of the old ſkull, and elevated through the crack. This is then laid ſoftly upon the old ſkin of that part, and the ſame ſort of motions in the tail end, diſengaging that, in a little time it is alſo drawn out, and in the ſame manner laid ſmoothly and evenly upon the old ſkin. As difficult as this laſt operation may ſeem, it is very ſpeedily effected. It takes the animal indeed many days to prepare for it, but when the crack is once made in the ſkin, the whole remaining work is done in leſs than a minute. The beſt method for obſerving this amazing work, is by ſeeking out a neſt of thoſe caterpillars that live in communities. Theſe are very common in gardens, and in the hedges; and, as many hundreds of them change their ſkin in one day, it is eaſy to be apprized of their being about it, by ſeeing the ſkins hang upon the web; and if they are watched, upon that ſignal, the whole will be ſoon ſeen performed by ſeveral of them, often by many at a time. *Reaumur*'s Hiſt. Inſ. vol. 1. p. 229.

The hairs which are found upon the caſt ſkins of the hairy caterpillars, ſeem, at firſt ſight, to be like the other part of that *Exuvia*, only the caſes or coverings of thoſe parts, in the incloſed inſect; but, in reality, this is found not to be the caſe in regard to them, whatever it be in all the others.

Mr. Reaumur obſerved three or four hairy caterpillars, at the time when they were juſt preparing for their change; and when they ſhewed the very firſt ſigns of its approaching, by ceaſing to eat and move, he cut, with a fine pair of ſciſſars, many of the hairs off, as cloſe to the body as he could. When the change was perfected, and this ſkin thrown off, he examined the hairs of the parts, correſponding to thoſe he had cut them ſhort upon in the old ſkin, while yet upon the animal. If theſe had been the caſes of the new hairs, thoſe muſt certainly have been cut ſhort with them; but, on the contrary, they were found, in the caterpillar, as long in thoſe parts as in any others. It appears from hence, that though all the other parts thrown off are but the ſheaths and caſes to what they covered, yet the hairs are real and ſolid things themſelves; and hence it appears, that the creature, when hatched from the egg, muſt have all its ſkins perfectly formed, one lying under another, and each furniſhed with its covering of hairs, ſo that the old ones are to fall off with the old ſkins, and the new ones to appear with the new; and probably theſe may be one great means of forcing off and diſlodging the old ſkin from every part, by the creature's erecting them in part. *Reaumur*'s Hiſt. Inſ. vol. 1. p. 241.

In making theſe hairs, however, ſo great a means of getting off the ſkin in the hairy caterpillars, we ſeem to leave the ſmooth ones a much harder taſk to execute the ſame operation without theſe aſſiſtances; but probably the ſame ſort of mechaniſm is uſed by all, and all are furniſhed with the ſame ſort of means to accompliſh it, tho' theſe are leſs obvious in ſome than in others.

Many of thoſe caterpillars which appear ſmooth to the naked eye, are found to be really hairy, when examined by the microſcope; and others are covered with a ſort of little eminences or protuberances, which may very well ſerve to the ſame purpoſes in diſlodging the old ſkin.

When a nice diſſection of the upper ſkin is made longitudinally in the place where the crack is to happen for the animals getting out of its old ſkin, and this is done in a caterpillar juſt going to change, the ſkin may be, with care, taken clean off, and the arrangement and diſpoſition of the hairs on the new ſkin, while under cover of the old one, is eaſily ſeen. The hairs on this are diſpoſed in the moſt nice and artful manner imaginable, for their lying ſmooth under the upper ſkin. It is well known that theſe grow all in ſeparate tufts, and each of theſe tufts of hair are found diſpoſed in ſuch directions, that they never lie upon one another, but together form one ſurface, ſome being laid toward the back, others toward the belly, and ſome in other leſs regular directions. Some caterpillars have large tufts of hairs near their heads or tails, or both. Theſe reſemble true feathers, and muſt take up much more room under the ſkin than the others, yet theſe, as well as the ſingle hairs, are contained under the ſkin; for if thoſe of the old ſkin be cut off a few days before the change, the new ones will not be found mutilated by that means, but as long and perfect as if nothing had been done. And theſe alſo, on taking off the upper ſkin, are ſeen laid in a beautiful order on the under one, in the animal, before the change of its ſkin.

One thing very remarkable, in regard to this change of the ſkin in theſe animals, is, that they always appear, immediately after their coming out of the old one, much larger than they did before. The thick tufts of hair on ſome might ſeem to occaſion this appearance; but it muſt be a reality, ſince it is an obſervation as old as Malpighi, that the very head and ſkull are greatly larger, after this change, than they were immediately before. This, however, will be underſtood, if we conſider the operation of the crayfiſh in changing its ſhell. It in the ſame manner is found to appear much larger, when out of the ſkin, than before; and this is, in both caſes, owing to this, that the body had grown ſo much, that it was too big for its covering, which appears to be the principal reaſon of its quitting it. While it remained in it, however, the parts were all compreſſed together, and forced to lie in that narrow room, but as ſoon as the external covering, which occaſioned that compreſſion, is off, every part diſtends itſelf to its proper ſize, and the creature therefore appears much larger than it did before.

It is very certain, that ſo large a ſkull, being of a hard ſubſtance, in the caterpillar, could not have been compreſſed into or contained in the ſmaller, before the change: But the real fact is, that the new ſkull never hardens till the change approaches, and then but imperfectly. It acquires, at that time, thro' neceſſity, from the ſhape of the place it lies in, an oblong form; and in this ſhape is found, a few hours before the old ſkin is caſt off, not incloſed within it, but extending itſelf under the ſkin of the firſt ring of the body. When the old ſkull is thrown off, with the ſkin, the new one is as yet ſoft, and ſoon becomes of its proper rounded figure. *Reaumur*, Hiſt. Inſ. vol. 1. p. 243.

EY, in our old writers, the ſame with *inſula*, an iſland; from which comes *eyet*, a ſmall iſland or iſlet, vulgarly called *eyght*.

EYE (*Cycl.*)—It is no uncommon thing for the *Eyes* to be terribly moleſted by extraneous bodies, accidentally fallen into them, ſuch as a bit of ſand, a ſplinter of wood, the cutting of a quill, or of one's nails, a ſmall inſect, or the like. The moſt eaſy method of getting theſe bodies out, is the opening and extending the eyelid with one's fingers, and agitating it, holding the head down; by this means the foreign bodies are often waſhed out of the *Eye*, by the encreaſed flux of tears, without much difficulty. If this does not ſucceed, the beſt method is next to blow ſome levigated crabs-eyes, or the like fine powder, under the eyelid, that this, being waſhed out by the tears, may carry alſo the other bodies out with it. *Heiſter*'s Surgery, p. 364.

If all this fails, the eyelid muſt be gently and carefully lifted up, and the offending body ſought for, and carefully taken out with the end of a probe, or the like inſtrument. Or another method, is the dipping a fine pencil bruſh, or a ſmall piece of ſponge, tied to a ſmall ſtick, into warm water, and paſſing it under the eyelid, and by that means puſhing the offending matter out. Lime, or any other acrid ſubſtance, ſhould always be waſhed out with milk, or milk and water, and the *Eye*, after theſe accidents, be waſhed with a collyrium made of roſe water, with a little of the white of an egg beat up in it, and a ſmall admixture of ſaccharum ſaturni, or powder of tutty, and if there be any conſiderable inflammation, it will be proper to bleed.

It is well known, from inſpection, and from the writings of anatomiſts, that there are two veins which run one on each ſide the noſe, thro' the canthi majores, or greater corners of the *Eyes*; theſe proceed partly from the forehead, and partly from the *Eyes*, and, like the frontal vein, diſcharge their blood down into the external jugular veins. Bleeding in theſe canthal veins has been approved of by all occuliſts, for inflammations, and other diſorders of the *Eyes*, tho' perhaps with very little ſolid foundation. When this operation is to be performed, a ſtricture is made about the neck, and when the inciſion has been made, the patient muſt hold his head in a proper poſition for the blood to flow, without being troubleſome to his *Eye* or mouth; and when the neceſſary quantity of blood has been diſcharged, a thick triangular compreſs muſt be applied, and ſecured on, with a proper bandage. *Heiſter*'s Surgery, p. 282.

Running of the EYES, in infants. See INFANT.

Scarification of the EYES is a chirurgical operation, by many confounded with that of bleeding in the eyes, but improperly enough, ſince the parts of the operation are different; for bleeding is confined, in this organ, to the white of the eye alone, whereas ſcarification is practiſed as well upon the inner ſurface of the eyelid, as on the white of the eye; and they are alſo performed by different inſtruments.

This is no new operation, ſince Hippocrates, Celſus, *&c.* all preſcribed it, but, of later ages, it grew much into diſuſe.

To perform this operation, the patient is to be ſeated in a good light, and his head held ſtill by an aſſiſtant, while the ſurgeon preſſes his thumb and forefinger on the eyelids, ſo as to open them, and turn them outward, that their interior red ſurface may come into view, this is much more conveniently performed on the under than on the upper eyelid. When the ſurface is thus turned up, the ſurgeon draws the ſcarifying inſtrument backward and forward over it with great ſwiftneſs, as alſo over the white of the *Eye*, if there be occaſion, and, by this means, opens all the turgid veſſels, and makes them bleed

bleed plentifully; this ſhould be promoted by fomenting the *Eye* with a ſpunge dipped in warm water. *Heiſter*'s Surgery, p. 379.

When the operation is over, great care is to be taken, that the wounded parts do not cohere together; the patient muſt move the eyelids about at times to prevent this, and the eye, when bound up at night, muſt have a piece of gold-beater's ſkin applied between the eyelids and the *Eye*.

Many different inſtruments have been uſed for the making the ſcarification. Hippocrates uſed a prickle of a thiſtle, and Celſus and Ægineta, a ſteel raſp. Others have choſen the ſtalks of the naked horſetail, called ſhave-graſs, which do very well; but the beſt of all inſtruments is a beard of barley or rye; theſe beards are furniſhed with rows of ſharp teeth or hooks, and ten, twelve, or fifteen of theſe, are to be cut, and tied together by a ſtring, ſo as to reſemble a bruſh, the teeth of each beard being turned outward all round. Their ſlender ends, in this caſe, form a ſort of handle, by which the body of the bruſh may be moved about.

Contuſions of the EYE. When the *Eye* is, by any accident, contuſed, it will be entirely deprived of ſight, unleſs the contuſion be ſlight, or the proper remedies inſtantly applied. If the *Eye* have received a very ſlight contuſion, it will be proper to waſh it frequently, for the firſt day, with cold ſpring water, laying on it linnen rags, wet with the ſame: On the next day it muſt be rubbed externally with camphorated ſpirit of wine, and covered up with ſtuphs wrung out of decoctions, made in wine of eye-bright, ſpeedwell, hyſſop, ſage, chamomile flowers, and fennel ſeeds; but if theſe things are not to be had, bolſters dipped in warm wine muſt be applied, and renewed very often, and, if the patient be of a plethoric habit, bleeding is alſo neceſſary. If the contuſion of the *Eye* is ſo violent, that you can plainly ſee the extravaſated blood thro' the cornea, and all objects appear red to the patient, a vein muſt be opened either in the foot or neck, the *Eye* muſt be kept continually fomented with warm ſtuphs, wrung out of the ſame decoctions as are before mentioned, and the feet muſt be bathed in warm water two or three times a day, and a few drops of pigeons blood muſt be, two or three times a day, put into the *Eye*; and if all theſe attempts prove fruitleſs, you may very probably ſucceed, by making an opening in the cornea with a lancet. *Heiſter*'s Surgery, p. 97.

Wounds of the EYE. If the *Eye* is wounded, but not ſo as to let out the vitreous or cryſtalline humour, the wound muſt be anointed two or three times a day, with a feather, or fine rag, well dipped in the white of an egg, or elſe in a mucilage made of quince ſeeds, or of fleawort ſeeds, in roſe water; and, after each dreſſing, a compreſs is to be laid on, well ſaturated with a collyrium, made of the whites of eggs. N°. 2. Two ounces and a half of roſe water, half a dram of oil of roſes, and three grains of camphor, well mixed together, and thoroughly ſhook up every time it is to be uſed. If the accident is attended with any great degree of inflammation, as is very frequently the caſe, it will be proper to cover the ſmall compreſs, firſt laid over the *Eye*, with a larger, dipped in warm ſpirit of wine, with camphor. The bowels muſt, in this caſe, be kept open, and the patient blooded, if of a plethoric habit. And if it happen, that the cryſtalline humour, or any part of it, ſticks in the orifice of the wound, it muſt, in this caſe, be pulled out, that it may not bring on a deformity, or worſe miſchief, to the *Eye*. *Heiſter*'s Surgery, p. 80.

Falling out of the EYE. See PROLAPSUS *Oculi*.

Eyes of FISH. Theſe differ ſo much in the ſeveral kinds, that they make a very eſſential part in their deſcription, and often are characters ſufficient for the diſtinguiſhing the ſpecies. Their differences are in regard to their figure, ſituation, proportion, and integuments. In regard to their figure, ſome are flat and depreſſed, as is the caſe in the greater number of fiſhes. 2. Some are convex, as is the caſe in the pleuronecti of many kinds; the *Eyes* of theſe much reſemble thoſe of quadrupeds, the others are very different. 3. Some are rounder than ordinary, as in the Cyprini, conger and petromyzon; and laſtly, ſome are oblong, as the *Eyes* of the eſoces. *Artedi*, Ichthyolog.

Theſe are the differences of the *Eyes* of fiſh, as to figure: In regard to their ſituation they alſo differ as much: 1. In moſt fiſh they are placed in the ſides of the head; inſtances of this poſition are ſufficiently common. 2. In ſome they are placed both in the upper part of the head, as in the uranoſcope, or ſtar-gazer. 3. They are, in ſome, placed very cloſe to one another, as in the pleuronecti, and, in others, they are ſet at very remarkable diſtances, as in the clariæ. They differ alſo greatly in proportion, in reſpect to the body of the fiſh. Thus they are very ſmall in the whales, and other cetaceous fiſhes; and they are as remarkably large in the apua, boops, and gaſteroſteus.

The *Eyes*, in fiſh, differ alſo greatly in regard to their integuments. In ſome fiſh they are free, and are only covered with their proper membranes, as in the ſalmon, cyprini, *&c.* 2. They are, in ſome, covered in part with the ſkin of the head, as in the clupea, mackrel, *&c.* 3. In ſome they are wholly covered with the ſkin of the head, as with a ſort of veil. Examples of this kind there are in the ſyngrathi, pleuronecti, petromyza, and others.

The pupil of the *Eye* is, in moſt kinds of fiſh, either round or oblong; but in ſome, as in the ſalmons and coregones, they run out into an acute angle in the anterior part. The colour of the iris, in ſeveral fiſh, is ſo very diſtinct, that it makes a very obvious and diſtinctive character.

The *Eyes* of almoſt all fiſh are without eyelids, properly ſo called; but ſeveral kinds have, beſide the membranes, and common tunics, a ſort of tranſparent membrane, with which the *Eye* is in part, at times, covered. The cetaceous fiſhes, in particular, ſeem to have real eyelids: Tyſon has demonſtrated them in his accurate and excellent anatomy of the phocæna.

EYES *of Flies*. Every naturaliſt has obſerved, that the *Eyes* of flies are of a reticulated texture; and each reticulated *Eye*, of this kind, is truly an aſſemblage of multitudes, often of many thouſands of ſmall but perfect *Eyes*. The reticulated *Eyes* of flies are large, not only in proportion to the ſize of the creature, but abſolutely and in themſelves. But the ſeveral ſmall *Eyes*, of which they are compoſed, are remarkably minute, in compariſon with thoſe of the butterfly claſs.

Many of the butterfly claſs have, in each of their reticulated *Eyes*, many thouſand ſmall *Eyes*; but the fly claſs greatly exceed them in number of theſe, as many of the *Eyes* of theſe are three times as large as thoſe of the butterflies, and beſides, that each ſmaller *Eye* is vaſtly more minute than the ſmall *Eyes* of the butterflies.

That part of each ſide of the head of a fly which is cut, as it were, into a multitude of ſmall facets, is one of the reticulated *Eyes* of the creature, and is uſually ſomewhat elevated above the ſurface of the reſt of the head, but differently, and of a different form and extent in the ſeveral different flies. *Reaumur*'s Hiſt. Inſ. vol. 4. p. 239.

It is the cuſtom of nature to allot two of theſe reticulated *Eyes* to each fly, and, as they each contain ſuch a vaſt multitude of ſmaller but perfect *Eyes*, one would imagine this to be very ſufficient for all the occaſions of the animal. There are, however, notwithſtanding, certain flies of the ephemeron, or day-fly kind, which have four of theſe reticulated *Eyes*, two of which are placed as is uſual in the fly kind, and are but of ſmall extent; the other two have each the appearance of a ſort of turban, and are placed one beſide the other, upon the upper part of the head.

Theſe have each much of the figure of a muſhroom, the head of it extended a little beyond the ſtalk, and the upper convex ſurface, cut into almoſt an innumerable quantity of facets. Id. Ibid. p. 240.

The firſt pair of the reticular *Eyes* of this fly, which are placed as thoſe of the other flies, are, in colour brown; thoſe of the muſhroom form are of a very beautiful citron colour, and as tranſparent as the moſt pellucid reticular *Eyes* of the other flies; for, among the various ſpecies of flies, ſome have theſe *Eyes* much more tranſparent than others.

The fly, thus remarkably furniſhed with *Eyes*, is produced from a worm of the ſame kind with the common ſpecies of ephemerons; its body is of a pale yellow, and its wings white; the two inferior ones of theſe are ſo ſmall, that they are not eaſily diſtinguiſhed.

Among the fly claſs, theſe reticular *Eyes* are, in different ſpecies, of different colours; there are ſome which have them brown, others yellow, others green, and others red, and this in all the different ſhades of thoſe colours.

Some of them have alſo the gloſs of metals highly poliſhed, others afford us a view of changeable colours, and others have arrangements of different colours, but thoſe fixed and invariable. Id. Ibid. p. 241.

The *Eyes* of one ſpecies of the gad fly, ſo troubleſome to oxen, have ſtreaks of red, green and brown, placed alternately.

One would imagine, that, as every fly has two of theſe reticular *Eyes*, each compoſed of ſuch a multitude of real *Eyes*, they could have no occaſion for any *Eyes* beſide theſe; but ſo it has not appeared to the great hand that formed them, for they have, many ſpecies of them at leaſt, other *Eyes* beſide theſe.

The *Eyes*, already deſcribed, are properly called reticular ones, and, to avoid confuſion, it will be neceſſary to know the other *Eyes*, which are extremely different from thoſe, by ſome determinate name. Theſe other *Eyes*, when examined by the beſt microſcopes, appear of a perfectly ſmooth, gloſſy, and poliſhed ſurface, but plain and ſimple, without the leaſt appearance of a reticulated texture. Theſe are alſo much ſmaller than the reticulated *Eyes*, and may therefore be called, by way of diſtinction, the ſmaller *Eyes*, or the ſmooth *Eyes*. *Reaumur*'s Hiſt. Inſ. v. 4. p. 241.

Mr. De La Hire ſeems to have been the firſt perſon who diſcovered theſe little ſmooth *Eyes*, in the fly race. He obſerved three of them diſpoſed in a triangular form, on the back part of the heads of theſe little creatures. When he found that three ſmall convex ſhining bodies were uſually ſituated in this part, he ſoon diſcovered that they were tranſparent, and thence naturally judged them be of the ſame nature with the corneæ of our *Eyes*, and really to ſerve the ſame office to the creature poſſeſſed of them. Id. Ibid. p. 242.

We find three of theſe ſmooth *Eyes* placed triangularly on the back part of the head of vaſt numbers of the genera of flies,

flies, as well of the two-winged, as of the four-winged kinds; but there are alſo ſome flies of both theſe claſſes, in which they are wanting.

All the ſpecies of gnats, and all the ſpecies of tipulæ, are without theſe ſmooth *Eyes*. The heads of theſe ſpecies of flies are very ſmall, in proportion to the bulk of their body, and are, in a manner, covered with their reticular *Eyes*, which in ſuch a manner meet and touch one another, as to leave no room nor occaſion for the ſmooth *Eyes*.

Theſe flies have the want of their ſmall *Eyes* amply made up by the ſize and extent of the larger; but there are ſome other kinds which want them, but have not this advantage in their place. Of the two-winged flies, with ſhort bodies, the gad flies want theſe *Eyes*; and, among the longer-bodied, and four-winged kinds, the flies, produced from the puceron eaters, want them.

Notwithſtanding, therefore, that many ſpecies of flies have theſe *Eyes*, there are yet ſo many that want them, that if M. De La Hire's opinion, that the reticulated *Eyes* of flies were not true *Eyes*, held good, there muſt be very many of theſe inſects blind. Id. Ibid. p. 243.

Tho' moſt of the flies that have theſe *Eyes*, have three of them, and thoſe triangularly placed, yet there are ſome that have more, and ſome that have leſs, than that number. A certain fly which has two filaments attach'd to the hinder part of its body, and its hinder pair of legs faſtened to the annular portion of its body, has four of theſe ſmooth *Eyes* placed at the four corners of a ſquare; the two anterior tolerably large, and the two poſterior ſo ſmall as to be ſcarce diſtinguiſhable. And other flies, as the papilionaceous ones, produced of water worms, have only two of them. Ibid.

The poſition of theſe *Eyes* varies alſo in the different ſpecies of flies which are poſſeſſed of them, for tho' their uſual place is in the hinder part of the head, there are ſome which have them before. Some ſpecies of the ephemerons have three of theſe *Eyes*, which may be called large, in regard to their uſual ſize in other flies. The one of theſe is placed in the middle of the forehead; the other two at the roots of the antennæ, placed ſideways by them, but a little more backward. This ſpecies has two reticular *Eyes* beſide theſe, but they are ſmaller than is uſual in that ſpecies of fly. Ibid. p. 244.

Theſe *Eyes* are not peculiar to the fly claſs alone, ſome other of the inſects which have reticular *Eyes*, have theſe alſo, among which are the graſshopper, in which they are placed near the noſe.

Notwithſtanding that theſe *Eyes* are not well diſtinguiſhed in flies, without the aſſiſtance of glaſſes, they may, however, ſerve very well for the diſtinctions of genera, among thoſe ſpecies which have them. Id. Ibid. p. 245.

Theſe *Eyes*, though very ſmall in themſelves, yet, in compariſon with the ſingle *Eyes*, which form the reticular ſort, they are very large. See INSECT.

EYES *of Horſes*, in the manege, &c. Theſe ſhould be bright, lively, full of fire, pretty large, and full; but not too big, gogling, or ſtaring out of the head. They ſhould alſo be reſolute, bold, and briſk. A horſe, to appear well, ſhould look on his object fixedly, with a kind of diſdain, and not turn his eyes another way.

In the *Eye* of a horſe is diſcovered his inclination, health, and indiſpoſition. When the *Eyes* are ſunk, or that the *Eyebrows* are too much raiſed up, and, as it were, ſwelled; it is a ſign of viciouſneſs and ill nature. When the pits above the *Eyes* are extremely hollow, it is, for the moſt part, a certain ſign of old age: This, however, does not hold of horſes got by an old ſtallion; for theſe have them very deep at the age of four or five years, as alſo their eyelids and eyebrows wrinkled and hollow.

Two things are chiefly to be conſidered in the *Eye* of a horſe, *viz.* the cryſtalline part, and the bottom or ground. The cryſtalline, or moſt tranſparent part, ſhould, for clearneſs, reſemble a piece of rock cryſtal, otherwiſe the *Eye* cannot be good. When this part is reddiſh, it is a ſign that the *Eye* is inflamed, or elſe, as ſome pretend, influenced by the moon. When it is of the colour of a withered or dead leaf, upon the lower part, and troubled on the upper, it infallibly ſhews that the horſe is lunatic; which diſtemper continues no longer than while the humour actually poſſeſſes the *Eye*.

As to the ground, or bottom of the *Eye*, which is properly its pupil, or apple, it ſhould be large and full, and ought to be carefully inſpected, that there be no *dragon*, as it is called, on it. This is a white ſpot, or ſpeck, which at firſt appears no bigger than a grain of millet, but grows to ſuch a bigneſs, as to cover the whole apple of the *Eye*. It is incurable, never failing to make a horſe blind in the *Eye* where it is found. If the whole bottom of the *Eye* be white, or of a tranſparent greeniſh white, it is a bad indication, tho' perhaps the horſe is not as yet quite blind: However, it ought to be obſerved, that if you view a horſe's *Eyes*, when oppoſite to a white wall, the reflection of it will make their apples appear whitiſh, ſometimes inclining to green, tho' they be really good. When this is perceived, you may try whether his *Eyes* have the ſame appearance in another place.

In caſe you perceive, above the bottom of the *Eye*, as it were, two grains of chimney-ſoot fixed thereto, it is a ſign the cryſtalline is tranſparent; and if, beſides this, the ſaid bottom be without ſpot or whiteneſs, then you may infer that the *Eye* is ſound.

You ought alſo to examine, whether an *Eye* which is troubled, and very brown, be leſs than the other; for if it be, it is irrecoverably loſt.

All *Eyes*, which are ſmall, narrow, and have long pupils, run a greater riſk of loſing the ſight than any others. See BLINDNESS.

The diſeaſes of the *Eyes*, in horſes, proceed either from a defluxion, or from ſome external hurt. In the former caſe, the *Eyes* are watery, hot, red, and ſwollen, the diſtemper advancing by degrees; in the latter, the malady comes ſpeedily to a height, and the ſkin on the outſide of the *Eye* is peeled off.

If the diſtemper takes it riſe from a rheum, or defluxion, it is to be conſidered, whether it proceeds from the *Eye* itſelf, or from another aggrieved part: In the latter caſe, the redreſſing of the part will ſet the *Eye* free; in the former, it is proper to cool the horſe's blood with an ounce of ſal prunellæ, mingled every day with his bran; and when it leſſens his appetite, to change it for liver of antimony, till he recovers his ſtomach.

For ſore *Eyes*, where a ſkin is growing over them, the following receipt is recommended: To the white of an egg add a little fine powdered ſalt; then ſet this on the fire till it be reduced to a powder. This, mixed with a little honey, is to be put into the horſe's *Eye* with a feather. If it is found inſufficient to eat off the ſkin, the powder alone muſt be blown into the *Eye* with a quill.

In caſe of a blow on the *Eye*, take honey, and, having added a ſmall quantity of powder of ginger, put it into the horſe's *Eye*; or elſe take hog's-lard, with the oil of roſes and elder, of each an equal quantity; then, having melted them together, anoint the *Eye* therewith.

Some horſes have naturally tender weeping *Eyes*, which void a ſharp eating humour; theſe are eaſily cured by waſhing or bathing them every morning and evening with brandy. See HORSE.

EYE *of the Branch of a Bridle*, in the manege, is the uppermoſt part of the branch, which is flat, with a hole in it, for joining the branch to the head-ſtall, and for keeping the curb faſt.

We ſay alſo, *a horſe unſhod of one eye*, which is a rallying expreſſion, importing that he is blind of an eye.

EYE *of a Bean*, in the manege, is a black ſpeck, or mark, in the cavity of the corner teeth, which is formed there about the age of five and an half, and continues till ſeven or eight. And 'tis from thence that we uſually ſay, ſuch a horſe marks ſtill, and ſuch a one has no mark.

EYE *of a Pear*, the extremity oppoſite to its ſtalk. See the article PEAR.

EYE, in a ſhip. The hole wherein the ring of the anchor is put into the ſhank, is called the *Eye of the anchor*; and the compaſs, or ring, which is left of the ſtrap to which any block is ſeized, is called alſo the *Eye of the ſtrap*.

EYE *of a Tree*, a ſmall pointed knot, to which the leaves ſtick, and from which the ſhoots or ſprigs proceed.

EYE-*Bright*. See EUPHRASIA.

EYE-BROWS *Wounded*. In wounds of this part, great care muſt be taken to guard againſt inflammations, leſt the *Eyes* ſhould partake of the injury; all hot and ſharp things muſt be avoided, in eating and drinking, and the patient ſhould be blooded, if plethoric; the wound muſt be dreſſed with vulnerary balſams, and the dreſſings covered with compreſſes, dipped in camphorated ſpirit of wine. If the wound be large, and the *Eyebrow* entirely divided, it will be neceſſary to uſe the ſuture and dreſs over it, with a vulnerary balſam, covering both *Eyes*, and keeping them as much as poſſible from motion. *Heiſter*, Surg. p. 79.

EYE-LIDS *Wounded*. Wounds, either of the upper or lower *Eyelid*, will not readily heal, not ſo much from the thinneſs of the parts, as from the great quantity of fluids with which the *Eye* is continually moiſtened. It is neceſſary, therefore, firſt to foment the part with decoctions of chamomile, hyſſop, or eyebright, till the flux of the blood is ſtopped, and the wound well cleanſed; then if the wound is tranſverſe, it muſt be ſtitch'd up in the middle with a fine needle, and ſprinkled over afterwards with the powder of comfrey root, gum arabic, or other ſuch medicines, or anointed with balm of Gilead, or Peru, or Capivi, laying over theſe applications a plaſter of Diachylon, and tying it up in ſuch a manner, that the *Eye* may have very little power to move about. If the wound is made lengthways, it will require ſeveral ſtitches, and muſt be dreſſed over them as before. *Heiſter*'s Surgery, 79.

EYE-GLASS, in our double microſcopes, is uſually a lens convex on both ſides; but Euſtachio Divini long ſince invented a microſcope of this kind, the power of which he places very greatly above that of the common ſort; and this principally depending on the *Eye-glaſs*, which was double, conſiſting of two plano-convex *glaſſes*, ſo placed as to touch one another in the middle of their convex ſurface. This inſtrument is

ſpoken

ſpoken of, with great credit, by Fabri in his optics, and is ſaid to have this peculiar excellence, that it ſhews all the objects flat, and not crooked, and takes in a large area, tho' it magnifies extremely much. Phil. Tranſ. N°. 40.

EYE-SUCKER, in natural hiſtory, a ſmall ſea inſect, which is ſometimes found fixed by the ſnout to the *Eyes* of ſprats; whence it has received its name,. It is about three inches in length, whereof the head is one quarter part. The body is ſomewhat thicker than a hog's briſtle, and of a pleaſant green colour. Phil. Tranſ. N°. 472. §. 7.

EYERY of hawks. See AERY, *Cycl.*

EYESS, a young hawk newly taken out of the neſt. See the articles FALCON and HAWK.

EZQUADUITL, a name by which ſome authors have diſtinguiſhed the tree from which we have the common dragon's blood of the ſhops. *Hernand.* p. 59.

F.

F, in the Italian muſic, is often uſed inſtead of *forte*. See FORTE.

FF, in the Italian muſic, ſtands for *forte forte*, and intimates to play very ſtrong and loud. *Broſs.* Dict. Muſ. in voc.

FABA, bean, in botany. See BEAN.

FABA *purgatrix*, in the Materia Medica, the fruit of a ſpecies of *Ricinus*. See RICINUS.

FABACIUM, a word uſed by the antients to expreſs a ſort of food then in uſe, which was a kind of cake made of bean meal.

FABAGO, in botany, the name of a genus of plants, the characters of which, are theſe. The flower is of the roſaceous kind, conſiſting of ſeveral leaves, diſpoſed in a circular form. The piſtill ariſes from the cup, and finally becomes a ſeed veſſel of the ſhape of a cylinder, with ridges marking it into a ſort of pentangular form. It is quinquecapſular, it ſplits open in five places when ripe, and uſually contains flattiſh ſeeds. To theſe marks, it is to be added, that the leaves ſtand in pairs on the ſtalks.

We know only one ſpecies of this genus; called by different authors, *Fabago*, *Copparis fabaginea*, and *Copparis portulacæ folio*, and in Engliſh *Bean-capers*. *Tourn.* Inſt. p. 258.

FABALIS *lapis*, in natural hiſtory, a ſtone mentioned by many antient authors of repute, as found in the river Nile; of the ſhape of a common bean, and of a black colour. They ſay it had the virtue of curing dæmoniacs, and that dogs dare not bark, if it was laid before them. Theſe and many other like virtues, are attributed to this ſtone, to the great diſgrace of the ſober authors who relate them. The ſtone ſeems to have been of thoſe extraneous foſſils, which Dr. Hill has called *Ichthyperia*, from their having been formerly parts of the boney palates of fiſhes which feed on the ſhell-fiſh kinds; and other authors ſiliquaſtra, from their reſembling the pod of the lupine or bean.

FABARIA, in botany, a name given by ſome authors to the telephinum, or orpine; and by which it is in ſome places call'd in the ſhops. *Rupp.* fl. Jan. p. 103.

FABARIÆ *calendæ*, among the Romans, the calends of June, ſo called becauſe the beans being then firſt ripe, ſome of them were offered to the goddeſs Carna, the wife of Janus. *Hofm.* Lex. in voc.

FABATARIUM, among the antients, ſignifies, according to ſome, a large veſſel, in which beans were kept. Others will have it to have been a kind of diſh or plate into which bean-pulſe was put and offered to the houſehold gods. *Pitiſc.* Lex. Ant. in voc.

FABER, in ichthyography, the name of a fiſh, commonly known in England by the name of the doree, and called by ſome authors *gallus marinus* and *peſce di ſanto pietro*. It is a ſhort and very broad and flat fiſh, being every where of the ſame thickneſs, and ſomething approaching to the plaiſe in figure, but ſwiming upright. Its head is large and very much flatted, its mouth extremely wide, and its eyes large. Its ſides are of an olive colour, beautifully variegated with a bluiſh white; and in the middle of each ſide, there is one large black ſpot of the ſize of a ſilver two-pence. It has two fins on the back, the anterior is the higher, and has ten rigid ſpines, accompanied with ſofter and very large rays, which bend into the form of a reaper's ſickle. The tail ends in a circular figure. At the root of the hinder fin, there is on each ſide a row of ſmall hooked ſpines, bending obliquely, and furniſhed with other ſmaller and finer ſpines on their ſides; and the belly fin which is ſituated behind the anus, has a like ſeries of ſpines on each ſide. From the gills to the belly fins there are alſo two muſcular rows, and in the middle of theſe, there are two larger and ſharper thorns. The hinder part of the head alſo terminates in two ſpines, and lower down at the membranes of the gills, there are alſo on each ſide two more ſpines, the one ſhort and erect and the other larger and procumbent. Its uſual ſize is from ſix to ten inches in length, and it is commonly nearly half as broad as long. See Tab. of Fiſhes, N° 50. *Ray*'s Ichthyograph. p. 294.

The fleſh of the *faber* is well taſted, and by many preferred to that of the turbot. It is caught in the Mediterranean and other ſeas, and is not uncommon on the Cornwall coaſt, and other of the Engliſh ſhores.

The two ſpots on the ſides of this fiſh have given foundation to ſeveral ſtories, the principal of which are, that St. Chriſtopher when he carried our Saviour acroſs the water, caught hold of one of theſe fiſh in his hand, as he went thro', and left the marks of his fingers on all the race of it. And that St. Peter fiezing upon this fiſh at the command of our Saviour to get the money for the tribute penny, left on it an eternal memorial of that memorable incident, hence people have called it the Chriſtopher-fiſh and the St. Peter's fiſh.

FABER *Indicus*, the *Indian doreè*, a fiſh caught in many parts of the Eaſt Indies, and called by the Dutch there, the meer haen, the ſame with the Abacatuaia of Margrave, caught in the Braſilian ſeas. *Ray*'s Ichthyog. Append. 3. See ABACATUAIA.

FACE (*Cycl.*) — FACE, in the military language, a word of command; thus, *face to the right*, is to turn upon the left heel, a quarter round to the right. *Face to the left*, is to turn upon the right heel a quarter round to the left.

FACE *of a gun*, in the artillery, the ſurface of the metal at the extremity of the muzzle of a piece.

FACE *of a plant*, a word uſed by Tournefort and many other botaniſts to convey an idea of that general appearance of plants, which ſhews a ſameneſs in thoſe of the ſame genus, and a diverſity from other genus's, though not eaſily characterred in words, yet very obvious to an eye accuſtomed to theſe reſearches. Thus all the ſpecies of wormwood have the ſame general face, by which they may be taken to be ſpecies of the ſame genus, and ſo of many more; nay in ſome caſes, whole genera and even claſſes, have the ſame kind of family face, as it may be called, by which they may be known: as the umbelliferous plants, except the perfoliata, and a few other inſtances.

It has been attempted by many to make this general face an indicatory note of the virtues of the plant which wears it, and there would certainly be this great advantage in it, if it could be brought to any degree of certainty, that the moſt obvious of all diſtinctions, would be applied to the moſt valuable office: but tho' an abſolute certainty cannot be arrived at in an attempt of this kind, yet allowing for the poſſibility of a few exceptions, general conjectures may be made on the following rules, which will rarely fail. The umbelliferous plants before mentioned, make a very large claſs, and it is their general and obvious character to have their ſeveral flower branches ariſe from one center, and expand into an umbrella, every one having a tuft of flowers at the end; theſe flowers conſiſt of five leaves, and the ſeeds are naked and double, and the leaves of the plants are generally deeply divided, as in parſly, carrots and the like.

This is a general face of a plant not eaſy to be miſtaken, and all the plants which have this face are endowed with the virtues of carminative medicines. They expel wind and are good in the colic and other the like diſeaſes. The ſeeds of moſt of theſe are uſed, and of ſome the roots. The ſeeds of aniſe, caraway, cummin, and the like, are all ſeeds of umbelliferous plants, and the root of angelica is another inſtance of their efficacy. But as an exception to this general rule, the hemlock and hemlock dropwort may be produced, which are poiſons.

The verticillate plants are another claſs, which are eaſily known by their general face; their flowers ſtanding in ringlets round the ſtalks, and being labiated or of ſome ſuch form. The leaves alſo in moſt of theſe plants ſtand in pairs and they have generally an aromatick ſmell. As the virtues of the umbelliferæ lie in the roots and ſeeds, ſo do theſe in the husks of the flowers. It has been a common opinion, that the flowers of theſe plants contained their virtues, but this is erroneous. The flowers of ſage are almoſt inſipid, but the husks taſte very ſtrongly. Theſe plants in general are poſſeſſed of the ſame virtues, and are all of a middle degree between the carminatives before mentioned and the ſpices. They are properly aromaticks, and are all good in nervous diſeaſes, as epilepſies, palſies and the like; one of them which is called mother of thyme, is alone a remedy for the night-mare, a troubleſome diſeaſe, that often baffles other medicines; and the flowers of roſemary, lavender, ſage and the like, may ſtand as inſtances of the virtues of this claſs; and mint, pennyroyal, hyſſop, &c. in their leaves are of great virtue, and a pleaſant flavour.

The ſiliquoſe plants have alſo a ſame general face. Their flowers are compoſed of four leaves, and their ſeeds contained in long pods, or in ſhort and thick ſiliculæ. In theſe plants the ſeeds are found to contain the principal virtue in ſome, and in others the leaves: ſome have alſo virtue in their roots, but the flowers of all are neglected. Muſtard, creſſes and the like, have their virtue in the ſeeds, and ſcurvy-graſs in its leaves, horſeradiſh in the roots, yet all have the ſame general virtue, they are hot like the two laſt tribes, but they exert their power in a very different manner: it conſiſting in a diuretick volatile ſalt, and they are all good in the ſcurvy, dropſy, jaundice, &c. and have been uſed in theſe caſes at all times. Philoſ. Tranſ. N°. 255. p. 200.

External FACE, *Facies externa*, was uſed by Tournefort and other botaniſts, to expreſs the general external appearance of a plant; and by the Ichthyologiſts to expreſs a general form or figure in certain fiſhes, by means of which, they agree with ſome and diſagree with others; and according to which like-

neſs, or diſſimilitude, ſome authors of the late ages have arranged them into genera. This general figure in fiſhes conſiſts in the ſhape of the head and body, and the ſhape, ſize and proportion of the fins and tail, and tho' very obvious, is very indiſtinct; it being in many caſes where two fiſhes have the ſame general *external face*, yet hard to ſay on a cloſe examination, in what it is, that the likeneſs conſiſts. The authors who founded the diſtinction of the genera of fiſhes on theſe external reſemblances, ran into very great errors; for it is not enough in a generical diſtinction for the character to be obvious, but it muſt alſo be preciſe and determinate. What this *Facies externa* had in the firſt of theſe requiſites, it often wanted in the laſt; and in general, it has been found to be no true baſis of diſtinction.

Many fiſh have the *Facies externa*, or general appearance ſo alike, as to be eaſily coupled at ſight into the ſame genus, and that juſtly, as they really belong to the ſame, when more preciſely referred to it, according to their natural and more eſſential character. Of this kind, are the gadi, the clupeæ, the ſalmons, the petromyzæ, the coregones, the pleuronectæ, the rays, and many of the cyprini. In theſe the *Facies externa* is of real uſe, as it is an obvious mark, and leads to the road of truth; but there are beſide theſe many other fiſhes, which though they are truly of the ſame genus, yet differ extremely in their ſeveral external appearances, ſo that any method founded on the *Facies externa* muſt ſeparate them, though nature had really joined them in their real characters. The tench and the trutta lacuſtris, or lake trout, are in regard to their *Facies externa*, extremely alike one to the other, yet here this obvious character deceives us; for the tench is a ſpecies of the cyprinus, and the other a true and genuine ſalmon, two genera of fiſhes eſſentially and very widely different, tho' this method of judging by the external appearance, would have coupled together fiſh belonging to them both. In the ſame manner, the ſcorpæna and the cattus are very like one to the other in their external appearance, but when nicely examined according to the rules of Ichthyology, they are found to belong to two very different genera, and to have very little real likeneſs. From theſe and numerous other examples of a like kind, it evidently appears, that as the *Facies externa* cannot be depended on for the eſtabliſhing the genera of fiſhes, ſome more eſſential characters muſt be enquired after, for the regular and natural completing this neceſſary buſineſs. Therefore the generical characters of fiſh are to be ſought after, in their external and invariable parts, and they are to be arranged into families and genera, according to the agreement of theſe in number, ſituation, figure and proportion. Among all theſe, the characters taken from the number of the parts, where that is certain and invariable, are moſt valuable, as they moſt readily offer themſelves to the eye, and are leaſt of all liable to errors. *Artedi* Ichthyol.

FACETS, (*Cycl.*) among jewellers, a name given to the ſmall triangular faces, or planes, both in brilliant and roſe diamonds. In brilliants there are two ſorts, *skew* or *skill facets*, and *ſtar facets*. *Skill facets* are divided into upper and under.

Upper skill FACETS, are wrought on the lower part of the bezil, and terminate in the girdle.

Under skill FACETS, are wrought on the pavilions, and terminate in the girdle.

Star FACETS, are wrought on the upper part of the bezil, and terminate in the table. *Jeffries* on diamonds. See DIAMONDS.

FACETANUS *lacertus*, in zoology, the name of a peculiar ſpecies of lizard, called at Rome and Naples, the tarantola. See TARANTOLA.

FACK, in a ſhip, is any one round of a cable, when it is quoiled up out of the way.

FÆCES (*Cycl.*)—There have been many opinions of the great power of an oil to be drawn from the *human fæces*, one of which is the effect it is ſuppoſed to have on crude mercury, in fixing it at once into pure ſilver. Mr. Homberg was applied to, with great aſſurances of ſucceſs on this occaſion, and heartily engaged in it. The neceſſary characters of the expected oil were, that it ſhould be colourleſs as water, and void of ſmell; he at length found the way of procuring ſuch an oil as this, but when he had got it, it had not the properties expected in it. As the method of working on this diſagreeable matter, however at length furniſhed him with a very fine phoſphorus, it may be worth the attention of the curious.

An obſervation which he made very early in theſe reſearches was, that ten or twelve ounces of this ſubſtance, when the humidity was evaporated in a balneum mariæ, did not leave more than an ounce or thereabout of dry matter; yet all it loſt in this great evaporation, proved to be only its water, which when the receiver was examined, proved to be very clear and pellucid, and inſipid to the taſte, but ſmelling conſiderably ſtrongly of the matter it was made from. The ſalt, oil and earth of the ſubſtance, all remained behind, and it is remarkable, that all theſe do not make up above one eighth at the utmoſt, often but a tenth or twelfth of the whole. When this was afterwards more nicely examined, the ſalt in it was found to be about equal in quantity to the earth, and both theſe together, to be nearly equal to the oil. The oil of the *fæces* ſimply diſtilled, always appears black and ſtinking. Mr. Homberg to prevent theſe ill qualities, diſſolved it in warm water, allowing a pint to every ounce of the matter. This liquor was then filtered and evaporated to a pellicle, after which it yielded regular cryſtallizations of ſalts, adhering to the ſides of the veſſels; theſe may properly be called the eſſential ſalt of the *fæces*. This ſalt has ſome reſemblance of nitre, and in the manner of that ſalt, melts in the fire, but the flame of the fæcal ſalt is red and dull, whereas that of the ſalt petre is white and very lively; the reaſon of this difference evidently is, that in the one of theſe ſalts there is a large quantity of an oily matter, and in the other there is ſcarce any at all.

This ſalt diſtilled in a glaſs retort, affords toward the end of the operation, a reddiſh fœtid oil; this is preceeded by an aqueous liquor of an acrid and acid taſte. As this oil was not white or limpid, nor ſcentleſs, Mr. Homberg after ſeveral repetitions of the diſtillation, gave over the operation, and went to work again upon the matter ſimply dry'd in the balneum mariæ, and mixed with different intermediate ſubſtances as quick lime, lime extinguiſhed by the air, alum, colcothar, powder of bricks and the like; but all theſe operations only produced an oil more thin and fluid than the former, which ever ſo often repeated rectifications, only rendered clearer, not limpid, nor without its ſtinking ſmell, which it retained to the laſt.

In the diſtilling the fæcal ſalt alone, the matter in the retort always took fire at the time of the riſing of the oil; and in theſe diſtillations of the dried matter with the mixtures of alum or colcothar, when the whole was over, and the veſſels cold, on the opening them, the caput mortuum always in a few minutes took fire on being expoſed to the air. This flame often burſt the retort, and ſometimes when it did not do that, there came out a great body of flame at its mouth; and after that, the remainder at the bottom of the veſſel appeared for ſome minutes ignited in the manner of a burning charcoal.

Still however, the deſired limpid oil was not found; and as it had not been obtained by violent fires, the next trial was made by the gentler means of fermentation, by which the ſeveral principles of a mixed body are uſualy ſeparated one from another, by ſlow and gentle means. The matter was diſtilled to a dryneſs in a balneum mariæ, and afterwards the dry reſiduum being powdered, was mixed with ſix times its weight of its own diſtilled water, and put into a large cucurbit which being ſtopped by another glaſs and ſo made a double veſſel, was kept three months in a gentle balneum mariæ, the water of it being never made more hot than ſo as that one's hand might bear it; after this, a head being luted on to the cucurbit, the diſtillation was performed in the ſame balneum with a gentle fire; the aqueous humidity which came over was ſomewhat turbid, but had loſt its ſtink, having only a faint weak ſmell. This water on trial, proved an excellent coſmetick, by degrees recovering the skin to a delicate whiteneſs and ſoftneſs, tho' before ever ſo much impaired by weather. The remainder in the bottom of the cucurbit was found to have loſt juſt one twentieth part of its weight, and had wholly loſt its diſagreeable ſmell, being become ſomewhat fragrant and agreeable, with an aromatick flavour; the veſſel in which this proceſs had been performed being ſet by open in a corner of the laboratory, acquired after ſome time ſo ſtrong a ſcent of ambergriſe, that it was not to be endured, and was forced to be removed out of the laboratory. Any perſon would have thought it a veſſel in which ambergriſe had been made into eſſence. What can be more wonderful than that a ſimple digeſtion ſhould be thus of power to change one of the moſt diſagreeable ſmells in nature, into the ſcent of one of the fineſt perfumes. Mem. Acad. Par. 1711.

The dry matter taken out of the cucurbit was powdered and put by two ounces at a time into glaſs retorts that held about a pint and half of water, and diſtilled in a ſand heat; there firſt aroſe a little water, but after this came an oil perfectly colourleſs and limpid as water. The ſame degree of fire being continued, there afterwards aroſe an oil as red as blood: the receiver was changed, and theſe two oils kept aſunder; the firſt had ſcarce any ſmell, and what it had was aromatick, and the latter was very fætid and empyreumatick. The white or limpid oil being rectified, there was found to be produced of it, one ounce from every nineteen ounces of the dried matter; but even the fineſt and moſt colourleſs of this oil, will after about a year's keeping become red and change its grateful odour into an empyreumatick ſmell. The change of colour always begins at the bottom of the vial, and it gradually reddens all the way up to the ſurface of the oil. The reaſon appears to be this, that there was originally contained in this pure limpid oil, ſome ſmall quantity of the red oil in diſſeminated particles, and unperceived there, but that in long ſtanding theſe particles being different from the others, collected themſelves together, and by their weight ſubſided to the bottom of the veſſel, where by degrees they contaminated the oil next above them, and by degrees the whole quantity. Thus was the deſired oil obtained, but it had not the properties required of it, nor could by any means be made to effect any change

change in mercury; but by a few days digeſtion, either with that or any other metal, it always became red as blood and afterwards black. The caput mortuum of theſe oils left in the retort, is one of the fineſt of all phoſphori, it takes fire immediately on coming in contact with the air. Mem. Acad. Par. 1711.

FÆSTING-*men*. See FASTERMANS, *Cycl.*

FÆX *Vitri*, in chymiſtry, a name given by Rulandus and ſome other of the writers, unto the common nitre or ſaltpetre, and by others to pot-aſh.

FA FINTO, *a feigned* F, in the Italian muſic, is what we commonly call the flat of any note. *Broſ.* Dict. Muſ. in voc. See FLAT.

FAG, is uſed for a knot or excreſcency in cloth. Stat. 4. Edw. 4. c. 1.

FAGARA, in the Materia Medica, the name of a fruit reſembling the Cubebs, found in the Philippine Iſlands. The part of this fruit which contains the principal virtue, is the outer rind; this is tender and blackiſh and of an aromatick and ſomewhat acid taſte. When the berries are ripe, they eaſily break, and diſcloſe a black ſhining, ſolid kernel, void of taſte and ſmell. The berries according to Aviſenna, are heating and drying and good for a cold, weak ſtomach, to help digeſtion, and are aſtringent to the bowels. They were once much uſed, but of late are ſcarce known in the ſhops.

FAGGOT (*Cycl.*) — There is a thing worth obſerving to the owners of woods, in the article of the making up the underwood into *faggots*. The workmen when they have bound up the *faggot*, trim off the ſuperfluous branches from the ſides and end to make it more neat, and theſe they add to the middle of the next; but they are of little or no advantage there, and ought to be left on the ground, for being ſmall they would ſoon rot there, and would manure the ground ſo as to be of more advantage to the next growth, than is eaſily imagined. The leaves of the trees falling to the earth, manure it very much, but this is nothing to the advantage of theſe little pieces of wood: any rotten wood but in a moderate quantity, will turn a common bad earth, into good garden mould, and the growth of the young trees is more forwarded by this manure where it is left, than by any other means that can be uſed to it. We always ſee the land where wood-ſtacks have ſtood, enriched to a ſurpriſing degree by them, and the ſame advantage will be, wherever wood of any kind is left to moulder and rot upon the ground. *Mortimer*'s Husbandry, v. 2. p. 68.

FAGONIA, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, conſiſting of ſeveral petals, arranged in a circular form. From the center there ariſes a piſtil, which finally becomes a roundiſh fruit, pointed at the end, ſtriated and multicapſular, being compoſed of ſeveral ſmall vaginæ or caſes, each of which contains one roundiſh ſeed. *Tourn.* Inſt. p. 265.

The ſpecies of *Fagonia* are two.

1. The cretick prickly *Fagonia*, called by authors the prickly candy trefoil; and 2. The Spaniſh ſmooth *Fagonia*.

FAGOPYRUM, *Buckwheat*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the apetalous kind, being compoſed of ſeveral ſtamina ariſing out of a cup, divided into five ſegments at the edge. The piſtill finally becomes a triangular ſeed, which remains in a capſule, that was originally the cup of the flower; to this it is to be added, that the flowers grow in tufts, and the roots are fibrous. The ſpecies of *Fagopyrum* enumerated by Mr. Tournefort are theſe, 1. The common erect *Fagopyrum*. 2. The common wild climbing *Fagopyrum*, called black bindweed. 3. The great climbing American *Fagopyrum*.

The common *Fagopyrum* or buckwheat, is cultivated in many parts of England, and is a very great improvement of dry barren lands. The beſt ſeaſon for the ſowing it, is in May, and one buſhel of the ſeed is enough for an acre; the ground is to be dreſſed for it exactly as for barley, and if the ſoil is not very clean, it will yield a very large increaſe, as fifty buſhels an acre, and is excellent food for hogs and poultry. The flower of it is alſo very white, and mixed with wheat flower is eaten in ſome counties, and when broken in a mill, makes a fine addition to corn for horſes, making them ſoon grow fat. It is commonly late in the ſeaſon before it is ripe, but it is in no danger from ſtanding; when it is cut, it is uſually laid many days to dry before it is houſed. Beſides theſe uſes, ſome people ſow it very thick, and ſuffer it to grow up till it is near flowering, they then plough it in, and it makes a very good land for wheat or rye.

FAGOTTINO, in the Italian muſic, a name uſed for the ſingle curtail, which is a muſical inſtrument ſomewhat like the baſſoon. *Broſ.* Dict. Muſ. in voc.

FAGOTTO, in the Italian muſic, the name of the double curtail, being as big again as the fagottino, and in reality the ſame with a baſſoon. *Broſ.* Dict. Muſ. in voc.

FAGUS, *the Beech*, in botany, the name of a genus of trees, the characters of which are theſe. The flower is of the glomerated amentaceous kind, being compoſed of a great number of ſtamina, which ariſe from a bell-faſhioned cup. The embryo fruits grow in different parts of the tree, and finally become a hard and callous fruit of a pointed form, opening at the top into three parts, and containing two trigonal ſeeds. There is no other known ſpecies of this tree, but the common one. *Tourn.* Inſt. p. 884. See Tab. 1. of Botany, Claſs 19. and BEECH.

FAHNELEN, FANÆLEN, or VANLEHEN, among the Germans, a kind of greater fiefs, which the emperor alone could confer.

This was done by the delivery of a ſtandard, whence they had the name of *Fahnelen*, i. e. *feuda vexilli*. We find them mention'd in the golden bull of the emperor Charles IV. an. 1356. *Feudis principum exceptis, & illis quæ* Vanlehen *vulgariter appellantur, quorum inveſtituram & collationem ſoli imperatori, vel regi Romano ſpecialiter reſervamus. Du Cange*, Gloſſ. Lat. in voc. The word is more uſually written *Fahnlehn*.

FAIDA, in our old writers, is uſed for malice or deadly feud. Leg. Hen. 1. c. 88.

FAILURE *of Record*, in law, is uſed when an action is brought againſt a man, who alledges in his plea matter of record in bar of the action, and endeavours to prove it by the record. The plaintiff replies *nul tiel Record*, that is, he denies there is any ſuch record. Upon which the defendant has a day given him by the court to bring it in; and if he fails to do it, he is ſaid to fail of his record, and the plaintiff ſhall have judgment to recover. Terms de Ley.

FAINT *Pleader*, in law, a fraudulent, falſe, or colluſive manner of pleading, to the deceit of a third perſon. Againſt which among other things was made the ſtatute, 3 Edw. 1. c. 29.

FAINTS, in the diſtillery, the weak ſpirituous liquor that runs from the ſtill in rectifying the low wines, after the proof-ſpirit is run off. *Shaw*'s Lectures, p. 217.

FAINTS is alſo the laſt runnings of all ſpirits diſtilled by the alembick. The clearing the worm of theſe, is ſo eſſential a point in order to the obtaining a pure ſpirit by the ſucceeding diſtillation, that all others are fruitleſs without it.

FAINT *viſion*, in optics. See VISION.

FAINTING. See LIPOTHYMIA and SWOONING.

FAIT, *factum*, in law, is uſed for a writing lawfully executed to bind the parties thereto. See DEED, *Cycl.*

FAITHFUL, a deſignation the mahometans aſſume to themſelves. *Hoſm.* Lex. in voc. *Credentes*. See MUSSULMAN. *Cycl.*

FAITIERE, in natural hiſtory, the name of a ſpecies of ſhell-fiſh, called by many authors, by a much leſs determinate name concha imbricata. The French have thus called it, from the word *Faitage*, which in the ſame language, ſignifies the roof of a houſe. The ſhell is of the bucardium, or ox-heart kind, and has ſeven longitudinal ribs, and a great many laminæ running tranſverſely acroſs them, ſo that it greatly reſembles the roof of a houſe, where the rafters and croſs beams are ſeen while it is not covered with tiles.

FAITOURS, is uſed in the ſtat. 7. Ric. 2. cap. 5. for evil doers; and may be interpreted idle livers, from (ſays the author of the *Terms de Ley*) *Faitardiſe*, which ſignifies a kind of ſleepy diſeaſe, proceeding from too much ſluggiſhneſs. In the forementioned ſtatute it ſeems ſynonimous with vagabond.

FALANG, in our old writers, is uſed for a jacket or cloſe coat. *Blount*.

FALANGIE, in the materia medica, a name given by ſome of the antients to the ocymum or baſil. The *Falangie musk* is the ſweet ſcented baſil. Some of the commentators on the works of Aviſenna, have ſuppoſed, that the fruit called fal, was the ſeed or fruit of this plant; and that the word was only an abbreviation of *Falangie*, but this is by no means right. See FEL.

FALCADE, in the manege. A horſe makes *falcades*, when he throws himſelf upon his haunches two or three times, as in very quick curvets, which is done in forming a ſtop, and half-ſtop. A *falcade* therefore is the action of the haunches, and of the legs, which bend very low as in curvets, when you make a ſtop or half ſtop.

They ſay, this horſe ſtops well, for he makes two or three *falcades*, and finiſhes his ſtop with a peſate. This horſe has no haunches, he'll make make no *falcades*. The *falcades* are ſo much the prettier, that in making his haunches are low. Stop your horſe upon the haunches, in making him ply them well, ſo that after forming his *falcades*, he may reſume his gallop without making a peſate, that is, without ſtopping, or making one time. And thus he will make an half ſtop. See STOP, HAUNCHES and TIME.

FALCANOS, a name given by ſome of the chymical writers to arſenic.

FALCATA, in our old writers, was uſed for the graſs freſh mowed, and laid in ſwathes.

FALCATOR, in our old writers, the ſervile tenant who performed ſervice of falcature.

FALCATURE, *Falcatura*, in our old writers, ſignifies one day's mowing of graſs; a cuſtomary ſervice to the lord by his inferior tenants. *Kennet*'s *Gloſs.* in voc.

FALCINELLUS, in zoology, the name of a bird in ſome ſort reſembling the herons, but with a ſhorter beak. It is of a very beautiful colour, a fine gloſſy green with an admixture of a purpliſh tinge; the head and neck are brown, but the upper part of the throat whitiſh with black ſpots; its beak is

like

like that of the curlew, very long, very ſlender and crooked, its legs moderately long; as this bird grows older, it becomes of a browenr hue. It is called by ſome, ardea nigra, the black heron, and by the Italians acion negro. *Ray*'s Ornitholog. p. 218.

FALCO, the *Falcon*, in the Linnæan ſyſtem of zoology, this makes a diſtinct genus of birds of the hawk kind, the characters of which are, that theſe have on their feet three toes before and one behind, none of which are moveable backwards. The birds of this genus are the eagle, the vulture, the buzzard, the kaſtrell hawk and the lanio. *Linnæi* Syſtem Naturæ. p. 44.

The *Falcon* is a bird of prey of the hawk kind, much eſteemed for its ſtrength and activity. There are many ſpecies of this bird, but when the word *Falco* is uſed ſingly without any diſtinctive addition, it is meant of that ſpecies called by authors, the *Falco peregrinus*, from its travelling into different countries, at different ſeaſons of the year.

It has very long and large wings, reaching when folded to the tip of the tail. Its ſhoulders are very large, its tail very long and ending like the ſparrow-hawks in a point, its end being white, variegated with orange coloured ſtreaks. Its feet are of a greeniſh or bluiſh yellow, its neck is long, and its head and back of a pale dove colour. There is a variety of this bird, which are of a much blacker colour on the back, and has been erroneouſly eſteemed by ſome a different ſpeices, probably it is only owing to the difference of age or ſex. This bird is caught in France, Germany and elſewhere, but it is not well known where it builds. It feeds on ducks, geeſe and other large birds. *Ray*'s Ornitholog. p. 43.

The *Falcon* is of the long winged hawk kind, uſed in the diverſion of hawking. There are ſeveral ſpecies of *Falcons*. 1. The *Falco peregrinus*, or common *Falcon*. 2. The ſacer, called *Falco ſacer* by authors. 3. The *Jerfalcon* or *Gyrfalco*. 4. The *Mountain Falcon*. 5. The *Gentle Falcon* or *Falco gentilis*, ſuſpected by Mr. *Ray* to be the ſame with the common or firſt kind. 6. The *Haggard Falcon*, remarkable for the ſhortneſs of its neck. 7. The *White Falcon*, all over of a pure ſnow white. 8. The *Stone Falcon*, of a deep blackiſh blue. 9. The *Tunis* or *Barbary Falcon*, which reſembles the common kind, but is ſmaller. 10 The *red Falcon*, much reſembling the common kind but ſpotted with a reddiſh colour, and the red and creſted Indian *Falcon*, which ſeem to be the male and female of the ſame ſpecies. *Ray*'s Ornitholog. p. 40. to 48. See the articles GYRFALCON, SACRE, LANNARIUS, &c.

The gentle *Falcon* is the moſt valuable of all theſe, as being the moſt tame and managable, and the moſt hardy, enduring all weathers without hurt. This kind of *Falcon* has a natural inclination to fly the heron every way, and is moſt excellent at the brook or river fowling, and eſpecially at the larger birds, as at the ſhovel, wild gooſe and the like. If ſhe be an eyeſs ſhe may be ventured at the crane, otherwiſe ſhe will not be ſo hardy.

Hawks in general prove courageous or cowardly all their lives accordingly as they are firſt quarried; and if they are taken out of the eyrie before they are fully ſumm'd and well penn'd, their wings will never grow to perfection. Their legs alſo will grow crooked, and their train will be full of taints. *Falcons* of one and the ſame kind are called by the ſportſmen by very different names, and eſteemed of ſeveral different kinds according to the places and time of their reclaiming, and the countries from whence they came. Thus the names mewed hawk, ramaged hawk, ſoar hawk, and eyeſſe, came into the world; and theſe are again divided into large hawks, wean hawks and ſlender hawks. All theſe have different mails and plumes, according to the country from whence they come; ſome are black, ſome brown: they have alſo each, its different diſpoſition, ſome being beſt for the field, and others for the brook or river. Different names are alſo given to *Falcons*, according to their different age and time of taking. The *Falcon* is called an eyeſſe, as long as ſhe remains in the eyrie, theſe are always troubleſome in their feeding, they cry very much, and they are not entered without great difficulty, but being once well entered, they prove excellent hawks for the heron and all the large fowl, and are very hardy and full of courage.

The ſecond name given this bird is the ramage *Falcon*. This name ſhe retains from the time of her leaving the eyrie during the months of June, July, and Auguſt. Theſe are always hard to be mann'd; but being reclaimed, they are not inferior to any hawk. The third is the ſoar hawk, ſo called in September, October, and November. Theſe birds keep for a whole twelvemonth the firſt feathers, which they have on when they leave the eyrie, and do not molt them. Theſe are therefore called the ſoar feathers. The fourth is termed the murzarolt or carviſt, quaſi carry-fiſt; for they muſt at this time be almoſt continually carried on the fiſt. They are thus called from January to the middle of May. Theſe are uſually great baters, and very little eaters; they are ſubject to ſeveral troubleſome diſorders, particularly to the ſilanders, more than any other hawk, and they are very ſeldom brought to good. The fifth name is the entermew. They are called by this name from May till December, becauſe all that time they are caſting their coats. Theſe would be excellent hawks if they could be truſted, but they are unſteady. They muſt be kept hard under, and the falconer muſt make his fiſt their perch. The hawk newly taken muſt have all new furniture, and muſt be often ſtroaked with a ſtick to accuſtom her to be gentle. She muſt alſo have two good bells, that ſhe may be well heard when ſhe ſtirs or ſcratches; and her beak and talons muſt be cut a little, but not ſo near as to make them bleed. If there be a ſoar *Falcon* taken that has already croſſed the ſeas, ſhe is uſually very hard to be broken; but that being well done, ſhe is the beſt of all hawks. Her food muſt be good and warm, and it muſt be given her at leaſt three times a day. It ſhould be pigeons, larks, or other live birds; for ſhe muſt be broke by degrees from her accuſtomed manner of feeding. The hawk muſt always be fed with hoop and lure, that ſhe may always know when you will give her meat. She muſt then be gently unhooded, and two or three bits being given her, ſhe muſt be hooded again. And in the night let her rooſt on a perch near ſome perſon's bed, that ſhe may be often waked in the night. When by theſe means ſhe becomes tame and gentle, her uſual food may be changed, and a ſheep's heart given her. After this ſhe may be unhooded in the day-time, but not in company; and after giving her a bit or two, ſhe muſt be hooded again, and then a little more given her. After this by degrees ſhe will be taught to eat before company, and then the buſineſs of taming her will be ſoon accompliſhed. Till ſhe is thoroughly manned, ſhe muſt be born continually on the fiſt, and fed in company, giving her in the morning about ſun riſe a wing of a pullet, and every evening the foot of a hare or rabbit cut off above the joint, ſlead and laid in water, which having ſqueezed give it her with the pinion of a hen's wing. It is beſt to give the hawk waſhed meat, and after this plumage, according as ſhe ſeems to be foul within. She is then to be hooded, and nothing more ſhould be given her till ſhe gleams after caſting: but when ſhe has gleamed and caſt, ſhe ſhould then have ſome hot meat given her toward evening eſpecially, and be made to eat it in company. When ſhe is well reclaim'd, mann'd, and ſharp ſet, ſhe may be fed on the lure.

FALCONE, in zoology, a name by which ſome authors have called the milvus or flying-fiſh. *Willoughby*'s Hiſt. Piſc. p. 283. See the article MILVUS.

FALD-*Fee*, or FALD-*Fey*, was antiently uſed for a rent or fee paid by ſome cuſtomary tenants, for liberty to fold their ſheep upon their own land.

FALDELLA, a word uſed by ſome of the writers in ſurgery for a ſort of compreſs made of liſt contorted together in ſeveral doubles.

FALDUSTOR was antiently uſed to ſignify the higheſt ſeat of a biſhop encloſed round with a lattice. *Blount*.

FALDWORTH, among our old writers, was uſed to ſignify a perſon of age, ſufficient to be reckoned of ſome decennary. *Du Cange*, Gloſſ. Lat. in voc.

FALL, a meaſure of length uſed in Scotland, containing ſix of the ells of that country, each of which is equal to 37 $\frac{2}{10}$ Engliſh inches. Tr. Pract. Geom. p. 3. See MEASURES.

FALL, among ſeamen, denotes that part of the rope of a tackle which is haled upon. They ſay alſo that a ſhip hath *Falls* when ſhe is not *fluſh*, but hath riſings of ſome parts of her decks more than others. Alſo a ſhip is ſaid to *fall off*, when being under ſail, ſhe keeps not ſo near the wind as ſhe ſhould do.

FALL *not off*, at ſea, a word of command from him that conds the ſhip, ſignifying as much as, keep the ſhip near the wind.

FALLOPIAN *Tube* (*Cycl.*) — It is no uncommon thing for a fœtus to be retained in one of theſe tubes inſtead of being in the womb. But there is in the memoirs of the Paris academy a very remarkable account of one contained, not in the tube itſelf, but in a ſack or bag, formed by the external membrane of the right tube. The egg having by ſome unhappy accident faſtened itſelf between that membrane and the inner one, the external membrane became monſtrouſly dilated, as the fœtus in growing naturally preſſed upon that on which it reſted. At the expiration of the ninth month, the ſurgeon who attended the woman, found that it was impoſſible ſhe ſhould be delivered; though he could not gueſs the true circumſtances of ſo unhappy a caſe. He obſerved at the ſame time a tumor near the navel, from which there oozed out a ſerous humour. He was determined to open this tumor with all the neceſſary precautions; and having done ſo, he took out by this means the fœtus, which was dead, and had been ſo a long time. Mem. Acad. Par. 1714.

FALLOW (*Cycl.*)—FALLOW-*Finch*, in zoology, a name of the acanthe, more commonly called the wheat-ear, and by ſome authors Octiflora. See WHEAT-*Ear*.

FALLUM, in ſome of our law lexicographers, is ſaid to be a ſort of land; and for proof of this they quote the *Monaſticon Anglicanum*—De duobus acris & viginti *fallis* in, &c. *Jacob*. But from this paſſage it would rather ſeem that *fallum* ſignified a meaſure of land, as well as *acra*. And to this day a *fall* is a meaſure of land in Scotland. See FALL.

FALSE (*Cycl.*)—False *Gallop*, in the manege. See Gallop, *Cycl.*

False *Alarm*, in war, a feigned, or a miſtaken alarm. See the article Alarm.

False *Judgment*. See Falso *Judicio*, *Cycl.*

False-*Sheat*, on board a ſhip. See Sheat.

False-*Stem*, in a Ship. See Stem.

False *Tokens*, in law, is uſed where perſons get money or goods into their hands by forged letters, or other counterfeit means. This is puniſhable by impriſonment by Stat. 33 Hen. 8. c. 1.

False *Tone*, in muſic.—Some call the interval of two ſemi-tones major by this name; but others, more properly call it a diminiſhed third. Vid. *Ozanam*, Dict. Math. p. 653. See Interval.

FALSIFY, in law, is uſed for proving any thing to be falſe. Hence we find

Falsifying *a Record*, for ſhewing it to be erroneous. Thus lawyers teach, that a perſon purchaſing land of another, who is afterwards outlawed of felony, &c. may *falſify* the record, not only as to the time wherein the felony is ſuppoſed to have been committed, but alſo as to the point of the offence. But where a man is found guilty by verdict, a purchaſer cannot *falſify* as to the offence; though he may for the time where the party is found guilty generally in the indictment, becauſe the time is not material upon evidence. 2 Hawk. Pl. Crown, 459. We alſo meet with

Falsifying *a Recovery*. Thus, it is ſaid, the iſſue in tail may *falſify* a recovery ſuffered by tenant for life, &c.

FALSO *Bordone*, in the Italian muſic, is uſed to denote the burden or ground baſs of a ſong, when it is not exact to the rules of harmony, *i. e.* when the notes move all the ſame way, as is often the caſe in the pſalms, and other parts of divine office. The name is more particularly given to a certain harmony produced by the accompanyments of ſeveral ſixths following one another, which make ſeveral fourths between two higher parts; becauſe the third part is obliged to make thirds with the baſs. *Broſſ.* Muſ. Dict. in voc.

FALUN, a word uſed in many parts of France, as the name of a particular ſort of manure of lands, which is dug out of the earth, and is no other than fragments of ſea ſhells bury'd at conſiderable depths, and amaſſed in prodigious ſtrata in many parts of that kingdom. Theſe they ſpread upon the lands in the manner of dung; and being as it were calcined and very friable, they readily diſſolve, and are the fineſt manure of any for ſome ſoils.

FALX (*Cycl.*)—Falx, the *ſickle fiſh*, in ichthyology, a ſmall fiſh of the tænia kind, common about the ſhores of the Mediterranean; but ſeldom brought to ſale becauſe of its glutinous nature, being wholly converted into a ſort of glue, when dreſſed. It is a ſoft and ſmooth oblong fiſh, and has its name from its reſembling a ſickle in figure. It is often of an ell long, and with that length is not above the breadth of one's hand. It is of a ſilvery colour, but its back fin is red. Its eyes are large, and its head very ill ſhaped. The common people call it the marmot fiſh. *Willoughby*, Hiſt. Piſc. p. 117.

FAMES *Canina*, exceſſive appetite, in medicine. See Orexis, Canine, and Bulimy.

FAMILIA (*Cycl.*)—Familia, in natural hiſtory, a term uſed by authors to expreſs a certain order of animals, or other natural productions, agreeing in their principal characters, and containing numerous individuals, not only different from one another, but that in whole ſets, ſeveral numbers being to be collected out of the ſame family, all of which have the family character, and all ſome ſubordinate diſtinction peculiar to that whole number; or though found in every individual of it, not found in thoſe of any others.

It has been too common to confound the words, claſs, family, order, &c. in natural hiſtory. But the determinate meaning of the word *Familia* ſeems to be that larger order of creatures, under which claſſes and genera are ſubordinate diſtinctions. Among the quadrupeds, the ſeveral genera of the unguiculated creatures agree one with another in many general characters common to all; and in which they differ from the ungulated animals, which have alſo their ſeveral peculiar characters common to all, and yet different from all thoſe of the others. Theſe naturally conſtitute certain larger diviſions into *Families*, and no one would ever break through theſe, or bring the cat and the horſe into the ſame *Family*.

In the ſame manner, in ichthyology, there are ſeveral genera of fiſhes, which agree perfectly in certain common characters, and diſagree from all others in them. The bream and the herring, though very different in genus, may yet be brought into the ſame *Family*, both having many characters in common, as well as many different ones; but no one would ever be for bringing the herring and the whale into the ſame *Family*. The arrangement of natural bodies into theſe *Families*, or general and larger claſſes, is of the utmoſt uſe to natural hiſtory, when it is properly done, and the diviſions are genuine and natural; when otherwiſe, it is hurtful.

Theſe diviſions of animals into *Families* are of two kinds, the one artificial or hypothetical, the other natural. The artificially contrived *Families*, or claſſes of bodies, are founded on certain accidents of the things under conſideration, not made from the parts of the bodies themſelves. Of this artificial kind are thoſe diſtinctions ſo much in uſe among the old naturaliſts, founded on the place of growth and time of flowering of plants, the time and manner of bringing forth in animals, the food of creatures, and their different magnitudes. And to theſe falſe foundations for general diviſions may be added thoſe founded on the number of certain external parts of the creatures.

The abſurdity of the firſt of theſe methods is eaſily ſeen, ſince it requires a prior knowledge of the objects before they come under our conſideration. If an unknown plant, mineral or animal be offered to a naturaliſt, how is he to inform himſelf of its time of flowering, its place of production, or its manner of bringing forth its young. And as this is impoſſible, it is alſo impoſſible that he ſhould ever refer to its *family*, or trace it out among the individuals of it. As to the latter method of making the number of certain external parts, the character of a *family*, it is eaſy to ſee the abſurdity of it in regard to the fiſhes, for the fins of theſe animals are not always the ſame in number, in the different ſpecies truly and properly belonging to one genus. Thus the pearch, gadus, ſyngnathus, and many others have more or fewer fins, in the ſame genus. Theſe are the errors of the artificial or hypothetical claſſes and *families* of natural bodies.

The natural *families* are liable to no ſuch objections. In theſe all the genera refered to the ſame *family*, agree perfectly and punctually in their principal parts; the ſeveral individuals of which theſe *families* are compoſed, being reduced into genera; theſe are to be arranged into their proper claſſes, according to their mutual agreements; and of theſe claſſes, the ſmaller the number, the eaſier and plainer will be the whole method. Theſe natural *families* can be only founded on eſſential characters, and in the quadruped kingdom, they are to be taken either from the figures of the hoofs or claws, or from the teeth. In birds, the figure and proportion of the beak, is a very proper character; and in fiſhes, the figure of the head, and the ſituation of the tail, are to be conſidered; and are ſtable and eſſential characters. The whole animal world may eaſily be thus reduced to *families*, and from thoſe to claſſes, genera, and ſpecies, and the ſtudy of nature rendered much more regular and eaſy, than it can be by any artificial diviſions. *Linnæi* Faun. Suec. *Artedi* Ichthyolog.

FAN, *Flabellum* (*Cycl.*)—That this machine was known to the antients, is very evident from what Terence ſays,

Cape hoc flabellum, *& ventulum huic ſic facito.*

And Ovid Art. Amand. 1. 161.

Profuit & tenues ventos moviſſe flabello.

Theſe *fans* of the antients were made of different materials, but the moſt elegant were compoſed of peacocks feathers, or perhaps painted ſo, as to repreſent a peacock's tail. *Pitiſc.* Lex. Ant. in voc. *Flabellum.*

FANIONS, ſmall flags carried along with the baggage. See Flag.

FANTASIA, in the Italian muſic, ſignifies *fancy*, and is uſed for a compoſition, wherein the compoſer ties himſelf to no particular time, but ranges according as his fancy leads, amidſt various movements, different airs, &c. This is otherwiſe called the *capricious ſtyle:* before ſonnatas were uſed there were many of this kind, ſome of which remain even now. *Broſſ.* Dict. Muſ. in voc.

FANTOME *corn*, in husbandry, a term uſed by the farmers in ſome of our counties for lean, light and lank corn, as they call in the ſame places fantom fleſh, that which is lean and poor, and can hardly hang on the bones. *Ray*'s Engliſh Words, p. 17.

FANUM, among the Romans, a temple or place conſecrated to ſome deity. The deified men and women among the heathens had likewiſe their *Fana*; even the great philoſopher Cicero, erected one to his daughter Tullia. Mem. Acad. Inſcrip. vol. I. p. 488. ſeq.

FARAND MAN, in old writers, a traveller or merchant ſtranger, to whom by the law of Scotland juſtice ought to be done with all expedition, that his buſineſs or journey be not hindered. *Skene* de verb. ſignificat.

FARCIMINALIS *tunica*, the ſame with the *Allantoides.*

FARCEY. We have in the Philoſophical Tranſactions, an account of a horſe being cured of this diſeaſe by hemlock. The diſcovery was accidental, the maſter of the horſe riding near a place were hemlock grew abundantly, ſuffered his horſe to eat greedily of it, and he became better from that time, and in a few days was wholly cured. We generally eſteem hemlock a poiſon, but beſide this proof of its ſalutary effect, it is well known, that its ſeeds are eaten by ſome birds, particularly by the buſtards in very great quantities, and that without any harm.

FARDINGEL was the fourth part of a yard land, or of a plough land, according to Spelman. Vid. *Du Cange*, Gloſs. Lat. voc. *Ferdingel.*

FAREN, in Ichthyology, a name given by the Swedes to a fiſh peculiar to their country. It is of the genus of the cyprini, and is diſtinguiſhed by Artedi, by the name of the yellow ey'd cyprinus, with twenty-ſeven bones in the pinna ani.

FARFARA, a name given by ſome of the antient botaniſts to the plant we call coltsfoot, from the river Farfarus, mentioned by Ovid, as remarkable for its ſhady banks, which afforded a very large quantity of this plant. Pliny mentions this plant with much confuſion, calling it alſo farfano and fargugio, and forgeting that he had before deſcribed it under the name of tuſſilago or belchion. See the article TUSSILAGO.

FARFRUGUM, in botany, a name by which ſome authors have called the caltha paluſtris, or marſh marygold. *Ger.* Emac. Ind. 2.

FARFUGIUM, in botany, a name by which ſome authors alſo call coltsfoot. *Ger.* Emac. Ind. 2.

FARINA (*Cycl.*)—The manner of gathering and preſerving the *Farinæ* of plants for microſcopic obſervations is this; gather the flowers in the midſt of a dry ſunſhiny day, when the dew is perfectly off, then gently ſhake off the *Farina*, or lightly bruſh it off with a ſoft hair pencil, upon a piece of white paper; then take a ſingle talc or iſinglaſs between the nippers, and breathing on it, apply it inſtantly to the *Farinæ*, the moiſture of the breath will make that light powder ſtick to it. If too great a quantity be found adhering to the talc, blow a little of it off; and if there be too little, breathe on it again, and take up more. When this is done put the talc into the hole of a ſlider, and applying it to the microſcope, ſee whether the little grains are laid as you deſire, and if they are, cover them with another talc, and fix the ring; but be careful that the talcs do not preſs upon the *Farina*, ſo as to alter its form. *Baker*'s Microſcope, p. 249.

For the appearances of the *Farinæ* of a great many plants, ſee Tab. of Microſcopical Objects, Claſs 2.

The *Farina* of plants has been ſometimes found to have an effect on neighbouring plants. Thus we read of ruſſetings changed by the *Farina* of a neighbouring tree; and we have obſervations of peaſe of different colours infecting one another in the like manner. Phil. Tranſ. N°. 477. Sect. 7.

FARINA *fœcundans*. See PULVIS *fœcundans*.

FARINAGIUM, in our old writers, denotes toll of meal or flower.

FARIO, in zoology, a term for a ſalmon when about half grown, after it is paſt the ſtate in which it is called a *ſalar*, and before it is of the full growth. *Willough.* Hiſt. Piſc. p. 189. See SALMON.

FARLEU, money paid by tenants in the Weſt of England, in lieu of a heriot. In ſome manors of Devonſhire, *Farleu* is often diſtinguiſhed to be the beſt goods; as heriot is the beſt beaſt, payable at the death of a tenant. *Cowel.*

FARM (*Cycl.*) — It is commonly allowed that a *Farm* ſhould make three rents as they expreſs it, one for the landlord, one for the charges, and one for the farmer to live upon; but it is very ſeldom that a *Farm* will conſtantly do this, or is to be maintained at that charge. In a *Farm* of one hundred pound a year, if the land is worth twenty ſhillings an acre, a hundred pound may defray the charges of it; but if in a *Farm* of the ſame rent the land be worth but ten ſhillings an acre, a hundred and thirty pounds a year muſt be allowed for the charges of this or nearly ſo, and two hundred and fifty acres of ſuch land, muſt be reckoned to a *Farm* of a hundred pounds a year, or elſe the farmer will be ruined, if it be not very improveable land.

FARMER, he that tenants a farm, or is leſſee thereof.

Alſo generally every leſſee for life, years, or at will, is called *Farmer*. Terms de Ley.

As this word implies no myſtery, except it be that of husbandry, husbandman is the proper addition for a *Farmer*. 2 *Hawk.* Pl. Crown, 188.

FARMER, in mining, is the lord of the field, or one that *farms* the lot and cope of the king. *Houghton*'s compl. Miner in the Explan. of the Terms.

FARNIA, or FARNIA *Italorum*, a name by which ſome authors have called the bitter oak: the cerrus, agylops, and aſpris of other writers. *Chabræus*, p. 55.

FARRA, in Ichthyology, a name given by authors to a ſpecies of the *coregones*, not differing eſſentially from the *lavaretus* or *benola*. This ſpecies has had a great number of different names, and been deſcribed as five or ſix different fiſh. But all the deſcriptions of the ſeveral authors agree to prove it to be that ſpecies only of the coregoni, which Artedi has diſtinguiſhed by the name of the coregonus, with the upper jaw longer and flat, and with fourteen rays in the back fin. This name equally agrees with the ſeveral deſcriptions of the *farra* or *ferra*, bezola, laveratus, &c. and they agree in all the eſſential characters with one another. See the article LAVARETUS.

FARRIER (*Cycl.*) — FARRIER's *Pouch*, in the manege, a leathern bag in which they carry drivers, nippers, ſhoes for all ſizes of feet, good ſharp nails, and all that is proper for new ſhoeing a horſe that has loſt his ſhoe upon a road. If you have no *Farrier* with you, you muſt always have in your equipage a *Farrier's Pouch* well provided, and a groom that knows how to drive nails.

FARTHEL, or FARTHELLING, among ſeamen, was uſed for the ſame with what they commonly call *furl* or *furling*; which is taking up the ſails, and binding them cloſe to the yards.

FARTHING (*Cycl.*)—FARTHING *of Land* ſeems to differ from *Farding-Deal*. See FARDING-*Deal*, *Cycl.*

For in a ſurvey book of the manor of Weſt Hapton in Devonſhire there is an entry thus, A. B. holds ſix *farthings* of land at 126 *l.* per ann. *Blount*. So that the *farthing* of land muſt have been a conſiderable quantity, far more than a rood.

FARTHING *of Gold*, a coin uſed in antient times, containing in value the fourth part of a noble, or 20 *d.* ſilver, and in weight the ſixth part of an ounce of gold. It is mentioned in the Stat. 9 Hen. V. c. 7. where it is enacted, that there ſhall be good and juſt weight of the noble, half noble, and farthing of gold.

FARUNDEL *of Land*, the ſame with *Farding-deal*. See FARDING-*deal*, *Cycl.*

FASCETS, in glaſs-making, the irons thruſt into the mouths of the bottles when made, to remove them into the annealing tower. *Neri's* Art of Glaſs, Appendix.

FASCIA (*Cycl.*)—FASCIA *lata*, a muſcular ligament very conſiderable both for its extent and ſtrength, being made up chiefly of two planes of fibres, of which the external are more or leſs longitudinal, the internal more or leſs tranſverſe. It is farther ſtrengthened in ſome places by a great number of other fibres, which augment its thickneſs, and form particular expanſions. The tranſverſe fibres are much ſtronger than the longitudinal. It is fixed above to the edge of the criſta of the os ilium, from the large tuberoſity to the anterior ſuperior ſpine, to the ligamentum fallopii, and to the aponeuroſis of the obliquus externus of the abdomen, on which it runs up by a thin lamina. It is likewiſe fixed in the lateral inferior part of the os ſacrum, and to the neighbouring parts of the ligaments, by which that bone is connected to the oſſa ilium and iſchium; from whence it advances over the glutæi and thigh, between the membrana adipoſa and muſcles, all the way to the anterior and outer parts of the knee. It is very thin on the patella, but may be ſeparated from it. It is alſo continued over the external anterior part of the tibia, covering the muſcles which lie there, and is ſtrongly inſerted in the head of that bone, and in the upper part of the fibula. It ſends off elongations, which, like ſo many ſepta, run in between the muſcles, and ſometimes meet in ſuch a manner as to form vaginæ. It is ſtrongeſt on the anterior and outer parts of the thigh, growing gradually thinner on the inner and back parts. It is ſtrongly inſerted in the linea femoris aſpera, between the vaſtus externus and biceps, forming a ſort of ſeptum between theſe muſcles. It furniſhes particular vaginæ to the muſcles which lie on the inſide of the thigh; and though theſe vaginæ are thin, they are pretty ſtrong, being chiefly made up of tranſverſe fibres. *Winſlow's* Anatomy, p. 204.

FASCIATION, in ſurgery, is the binding of ſwathes about a limb that is to be cured.

FASCICULATA *folia*, among botaniſts. See LEAF.

FASSETS, among jewellers. See FACETS.

FASSUS, in our old writers, is uſed for a faggot of wood. Mon. Angl.

It ſeems to come from the French *faiſſeau*.

FAST *Ground*, or FAST *Country*, a term uſed by ſome of our miners to expreſs what others call the *ſhelf*. In digging, they frequently, after paſſing the ſeveral ſtrata, which have been diſturbed, and give proofs of having been toſſed about in the waters by their irregularity, meet with plain, firm, regular and ſolid ſtrata, which evidently ſhew that they have undergone no change ſince their original formation and inſtitution. The workmen, who are very good philoſophers in this reſpect, aſſign the different ſtructure they thus find in the upper and lower ſtrata of the earth to its juſt cauſe, that is, the deluge; and determine, that all they find irregular has been waſhed up and depoſited there again in the time of that cataſtrophe; but that the ſhelf or *faſt Country* is in its natural ſtate and poſition. They obſerve, in favour of this opinion, that their loads of ore run very irregularly in the irregular ſtrata, but much more regularly in the ſhelf or *faſt Ground*. Phil. Tranſ. N° 69.

FASTIGIATI *Furni*, in chemiſtry, furnaces fitted with ſeveral aludels.

FASTING has been practiſed by moſt nations from the remoteſt antiquity. Some divines even pretend to find its origin in the earthly paradiſe, where our firſt parents were forbidden to eat of the tree of life. But is not this to confound *faſting* with abſtinence? However, certain it is, that the church of the Jews has obſerved *Faſts* from their firſt eſtabliſhment. Moſes appointed one ſolemn *Faſt* before the feaſt of expiation, and others were inſtituted by the following prophets on different occaſions; ſo that in the time of Zacharias there were four regular *Faſts*, *viz.* in the months June, July, September and December. To theſe they have ſince added three others, in memory of ſore diſtreſſes they have at different times ſuffered. Beſides theſe there were various kinds of *Faſts*, ſome for devotion, others for the new moons; and ſome among them kept an anniverſary *Faſt* in memory of the tranſlation of the Septuagint, in order to expiate the baſe compliance of their

doctors for a foreign prince, and the outrage offered to the dignity of their law, which, in their opinion, was only designed for themſelves: *Non fecit taliter omni nationi.*

There is no occaſion to deſcribe exactly the various obſervances that accompanied theſe acts of humiliation, as being known to every body. 'Tis known their abſtinence laſted 27 or 28 hours, beginning before ſun ſet, and not ending till ſome time after ſun ſet next day. On theſe days they were obliged to wear white robes in token of their grief and repentance; to cover themſelves with ſackcloth, or their worſt cloaths; to lie on aſhes; to ſprinkle them on their head; and, on great occaſions, upon the ark of the covenant. Some ſpent the whole night and day following in the temple, or ſynagogue, in prayers and other devotions, barefooted, with a ſcourge in their hands, of which they ſometimes made good uſe to rouze their zeal. Laſtly, in order to compleat their abſtinence, at night they were to eat nothing but a little bread dipped in water, with ſome ſalt for ſeaſoning; except they choſe to add to their repaſt ſome bitter herbs and pulſe. Thoſe that would be particularly informed of theſe auſterities may conſult Maimonides, Leo of Modena, and Buxtorf.

The Egyptians, Phœnicians and Aſſyrians, neighbours to the Jews, had alſo their *Faſts*. The *Faſt* of the Ninivites, occaſioned by the preaching of the prophet Jonas, is too well known to be inſiſted on. The Egyptians, ſays Herodotus, ſacrifice a cow to Iſis, after having prepared themſelves by *Faſting* and Prayer: a cuſtom that he likewiſe aſcribes to the women of Cyrene. According to Apuleius, whoever had a mind to be initiated in the myſteries of Cybele were obliged to prepare themſelves by *faſting* ten days. Porphyry carries the matter ſtill farther, affirming that the Egyptians, before their ſtated ſacrifices, always *faſted* a great many days, ſometimes for ſix weeks, and that the leaſt behoved to be for ſeven days; during all which time the prieſts and devotees not only abſtained from fleſh, fiſh, wine and oil, but even from bread and ſome kinds of pulſe.

Nor were the Greeks without their *Faſts*. Ariſtotle informs us, that the Lacedæmonians having reſolved to ſuccour a city of the allies, ordained a general *Faſt* thro' the whole extent of their dominions, without excepting the domeſtic animals; and this they did for two ends, one that they might ſpare proviſion in favour of the beſieged, and the other to draw the bleſſing of heaven on their enterpriſe. The Athenians among others had the Eleuſinian and Theſmophorian *Faſts*, the obſervation of which, was accompanied with ſtrict *faſting*, particularly among the women, who ſpent one whole day ſitting on the ground in a mournful dreſs, without taking any nouriſhment; on which account, this day was called νηστεια. The Grecians had theſe religious auſterities from the Egyptians, Eumolpus and Erechtheus having communicated them to the Athenians; by whoſe means they were ſpread through all the ſtates of Greece. Jupiter too, had his *Faſts*, as well as Ceres; for his prieſts in the iſle of Crete were by their rules obliged to abſtain all their lives from fleſh, fiſh and baked meats.

In a word, all the Pagan deities, whether of the male or female ſex, required this duty of thoſe that deſired to be initiated into their myſteries, of their prieſts and prieſteſſes that gave the oracles, and of thoſe that came to conſult them.

In Italy *faſting* was obſerved much in the ſame way. The inhabitants of Tarentum, being beſieged by the Romans demanded ſuccours from their neighbours of Reggium, who immediately ordained a *Faſt* throughout their whole territories, with the ſame intention as the Lacedæmonians, viz. to render the gods favourable, and to ſpare proviſions for their allies. Their enterpriſe having had good ſucceſs by their throwing a convoy with proviſions into the town, the Romans were obliged to raiſe the ſiege: And the Tarentines in memory of this deliverance, inſtituted a perpetual *Faſt*. So that here we have two *Faſts* for the ſame event; that obſerved by thoſe who were the means of obtaining the deliverance, and that obſerved by them who received it. The Roman ſenate, Livy tells us, being alarmed by many prodigies happening in a train one after another, order'd the decemviri to conſult the Sibylline books; who having executed their commiſſion, declared that to prevent the fatal conſequences, it was neceſſary to eſtabliſh a *Faſt* in honour of Ceres, to be obſerved every fifth year. That Jupiter had ſtated *Faſts* at Rome, appears from the following paſſage of Horace, where a mother is introduced praying to Jupiter for the recovery of her ſon from a quartan ague, and promiſing that the patient ſhould purify himſelf in the Tiber, on the morning of the *Faſt* day ſacred to that god.

Frigida ſi puerum quartana reliquirit, illo
Mane die quo tu indicis jejunia, nudus
In Tiberi ſtabit.

Faſting muſt have been very ſacred at Rome; ſince we find it practiſed by kings and emperors. Numa Pompilius, Julius Cæſar, Auguſtus, Veſpaſian and others, we are told had their ſtated *Faſt* days: and Julian the apoſtate was ſo exact in this obſervance, as even to outdo the prieſts themſelves, and the moſt rigid philoſophers.

In a word, every country, nation and religion have had at all times, their prieſts, druids, gymnoſophiſts and philoſophers, who diſtinguiſhed themſelves by their frugality, auſterity and abſtinence. The practice of the Pythagoreans is well known; their whole life was a continued lent, but with this difference between them and us, that they believed the uſe of fiſh equally unlawful with that of fleſh. They lived entirely on bread, fruits, and pulſe, with great ſobriety, in imitation of their maſter Pythagoras; though in this reſpect they muſt have fallen far ſhort of him, if we may believe Diogenes Laertius, who ſays, that he continued his *Faſts* for no leſs than forty days. Apollonius Thyaneus, one of his moſt famous diſciples, could never by all his endeavours equal his maſter in this point, though his *Faſts* greatly exceeded the ordinary intervals.

The gymnoſophiſts, or brachmans, reckoned *faſting* among their religious duties. Father le Comte, in his memoirs, tells us, that the Chineſe have at all times had regular *Faſts*, with forms of prayers, for preſerving them from barrenneſs, inundations, earthquakes, and ſuch like public calamities. The Mahometans too, who poſſeſs ſo large a part of Aſia and Africa, have times of *faſting*, called by them *Ramadan*, as regular as we have Lent. And their derviſes are remarkable for their mortification and *faſting*. *Comte*, Mem. T. 2. p. 142.

It was not unuſual among the antients to *faſt* on account of dreams. Sometimes to have the interpretation of them, ſometimes to obtain good and prophetic ones, being perſuaded that to obtain ſuch they muſt obſerve a ſtrict regimen both as to the quantity and quality of their food; for, according to the rules of the onirocritic art, it was neceſſary they ſhould be free from the fumes of meat, and in ſuch a calm, ſerene ſtate, as never fails to accompany a frugal life, that they might receive the impreſſions of the aerial ſpirits in all their perfection.

Faſting was alſo thought an infallible antidote againſt the fatal conſequences of terrible dreams. A piece of ſuperſtition that prevails to this day among the Jews, who, though expreſsly forbid to *faſt* on Sabbath days, think themſelves at liberty to diſpenſe with this duty, when they happen to have frightful and unlucky dreams the night preceeding, that threaten them with great misfortunes. On ſuch an occaſion as this, they obſerve a formal *Faſt* the whole day; and at night the patient having invited three of his friends, addreſſes himſelf to them ſeven times in a very ſolemn manner, ſaying, *May the dream I have had prove a lucky one!* And his friends anſwer as many times, ſaying, *Amen, may it be lucky, and God make it ſo!* After which, in order to encourage him, they conclude the ceremony with theſe words of Eccleſiaſtes, *Go, eat thy bread with joy*, and then ſet themſelves down to table.

The antients, both Jews and Pagans, had alſo their *Faſts* for purifying the body, particularly the prieſts, and ſuch as were any wiſe employed at the altars: for when nocturnal diſorders happened to theſe, it was unlawful for them to approach all the next day, which they were bound to employ in purifying themſelves. On which account, at great feſtivals, where their miniſtry could not be diſpenſed with, it was uſual for them, on the eve thereof, not only to *faſt*, but likewiſe to abſtain from ſleep for the greater certainty. To this purpoſe the high prieſt had under-officers to wake him, if overtaken with ſleep; againſt which other preſervatives were alſo made uſe of. See Mem. Acad. Inſcript. T. 5. p. 38, ſeq.

Mr. Bayle obſerves, that whole books have been written on long *Faſting*. Cyriacus Lentulus has compoſed one, *de prodigioſis inediis*. Fortunius Licetus, Profeſſor of medicine at Padua, beſides a great many others, has publiſhed one book in folio, *de iis qui diu vivunt ſine alimento*, or *de feriis altricis animæ*.

Among theſe long *Faſters* a great many impoſtors have been diſcovered. Fabricius Hildanus, Langius, and ſeveral other authors, relate inſtances of ſuch. Velſchius, a German phyſician, found in a manuſcript of the Augsburg library, a very curious account of a young woman that lived in the time of the emperor Maximilian, who had acquired a great reputation for holineſs, by making people believe that ſhe had *faſted* ſix years. The cheat was diſcovered by the emperor's ſiſter; upon which the girl being baniſhed, ſhe married, and was guilty of ſo many acts of adultery and other crimes, that ſhe made her husband run mad, and was herſelf at laſt condemned to be drowned.

We are not however to paſs the ſame judgment on the following remarkable inſtance of *faſting*, which is related by a perſon of credit, and inſerted in the Nouvelles de la Repub. de Lett. for February 1685.

A madman of Haerlem, believing himſelf to be the true Meſſiah, reſolved, in imitation of our Saviour, to *faſt* forty days and forty nights. Great pains were taken to make him eat, but all to no purpoſe; for, excepting a little water, which he took rather to waſh his mouth than to drink, and ſmoking tobacco, he took no kind of nouriſhment from the ſixth of December 1684, to the fifteenth of January 1685. He even refuſed water wherein they had put any ſpirits or broth. In order to find out if there was any cheat in the caſe, his cloaths and

and place of confinement were carefully ſearched, but nothing found; nor could any thing be conveyed to him in the night time. Beſides, as a proof of his abſtaining from all manner of food, his excrements gradually diminiſhed, and at laſt entirely ceaſed; which happened ſoon after the commencement of his *faſting*.

When the forty days were expired, he prepared himſelf to eat; but refuſed to take broth, which they had got ready for him in order to open the paſſages, and facilitate digeſtion: inſtead of this, he ordered ſome haſty-pudding to be made of a conſiſtence capable of being cut into pieces when cold. It is remarked, that he ſuffered very much from gripes for ſome days thereafter; which going off, he continued to eat as before; but his madneſs remained ſtill the ſame.

FASTING-*Men*, ſee FASTERMANS, *Cycl.*

FAT (*Cycl.*)—We have an obſervation by Mr. Schulze of wax paſſing through the coats of the arteries and veins, when theſe veſſels were injected; of which that coloured with red loſt its colour, while the green kept it. Hence he endeavours to account for the ſecretion of *Fat*, and the production of an œdema. See Com. Lit. Norimb. 1731. Semeſt. 1. Specim. 5.

Mr. Hunauld has the following obſervations on the *Fat* of the body: 1. That though fœtus's and children have much *Fat* under the skin, yet they have only a ſmall piece or two (*pelotons*) at the baſe of the heart; whereas lean, adult bodies have *Fat* all round the baſe, on the veſſels that go out of the heart, and accompanying the larger coronary veſſels, and at the point of the heart. 2. That the omentum of very young children has no *Fat*, and their meſentery very little. 3. That in many people the *Fat* under the skin is exhauſted, while the bowels are overcharged with it. 4. The exterior part of the tunica cellularis is the firſt filled with *Fat*, and the laſt emptied of it. From which, and ſeeing aponeuroſes and membranes ſpread over ſo many muſcles, he concludes, the common opinion of muſcles being lubricated by the *Fat*, to be ill founded. See Mem. Acad. Scienc. 1732.

FAT *of Whales*. See the article BLUBBER.

FATHER-*Laſher*, in ichthyology, an Engliſh name given to a fiſh, called by ſome authors, though improperly, ſcorpœna and ſcorpius marinus. It is properly of the cottus kind, and is named by Artedi the ſmooth cottus without ſcales, with ſeveral ſpines upon the head, and with the upper jaw a little longer than the under. It more reſembles the ſmall fiſh we call the bullhead or miller's thumb than the ſcorpæna. *Arted.* Gen. Piſc. p. 34. See COTTUS and SCORPÆNA.

FATTENING *of Horſes*. The being able to do this ſpeedily is one of the greateſt arts our dealers have, and indeed one of the greateſt niceties of the whole management of that creature. Many methods have been preſcribed, but the following ſeems moſt to be depended on. Take elecampane, cummin-ſeed, tamarisk and aniſeed, of each two ounces; common groundſel, one handful. Boil all theſe very well, with two handfuls of garlick ſcraped and cleaned, in a gallon of good ale; ſtrain the liquor well off, and give the horſe a quart of it every morning made hot; keep him warm after it. After he has taken this for four or five mornings, he may be turned out to graſs, or kept in the houſe, as the ſeaſon will permit. But whenever provender is given him, a quantity of a powder is to be prepared of equal parts of cummin-ſeeds and elecampane, and give him half an ounce of it every time, ſprinkling it in by degrees as he eats, that he may not nauſeate the whole.

If this method does not ſucceed in a ſhort time, then take two ſpoonfuls of diapente; brew it in a pint of ſweet wine, and give it the horſe for three mornings. This will take off any inward ſickneſs, and make the other things take effect. After this feed him with good provender three times a day, that is, after his watering in the morning, after his watering in the evening, and at nine o'clock at night. If he does not eat the provender well and freely, it muſt be changed for ſome other kind.

If all this does not ſucceed, let the horſe be blooded; and then take half a buſhel of coarſe barley-meal, put it into a pail full of water, and ſtir the whole together very well; then let it ſettle by ſtanding. Pour off the clear liquor into another veſſel, and let him drink it for his common drink, and eat the remainder which falls to the bottom of the pail. If he refuſe to eat this alone, there may be ſome bran mixed among it. This ſhould be given him three times a day, morning, noon, and night. If he does not rightly take to the meal with the bran, ſome oats muſt be mixed with it, and this will readily bring him to feed on it. But which ever way is uſed, they muſt be by degrees diminiſhed in quantity, till at length he is brought to eat the meal alone; for that is the thing that muſt fatten him up. Care muſt be taken that the barley is ground freſh every day as it is uſed, for it quickly grows ſour; and when this has once been the caſe with one parcel, no art will ever bring the horſe to touch any of it afterwards. Scarce any horſe but will be well *fatten'd* by keeping him to this diet for about twenty days.

Barley ground in this manner cools and purges the creature; but the greateſt efficacy, as to the *fattenning* him, lies in the water, which by this management takes up all the rich part of the barley into itſelf. When the horſe grows luſty on this diet, it muſt be taken from him by degrees, giving him at firſt oats once, and barley-meal twice a day; and then oats twice, and the barley-meal once, till he is perfectly weaned from it. In the mean time he muſt have good hay, and he muſt not be rid; only it will be proper to walk him gently about an hour or two in the heat of the day. If it be found that the horſe wants a good ſmart purging during the time of his continuing in the barley diet, the beſt time to give it him is after the firſt eight days, and the following is a very proper ſort of phyſic. Take of the fineſt aloes one ounce, agarick in powder half an ounce, and powder of florentine orrice one ounce. Let all theſe be mixed together, and put into a quart of milk warm from the cow. This will work very briskly; and after it is over, the uſual diet is to be continued. If horſes of value were to be kept to this diet once a year, it would make them leſs hot and dry, and not ſubject to many diſeaſes which they are troubled with at preſent, and would be particularly uſeful after campaigns and long journeys. If the horſe loſes his appetite by this diet, it will be proper to tye a chewing ball to his bit, renewing it ſo often till at length he begins to feed heartily on the barley; for theſe balls at once reſtore appetite, and are themſelves of a *fattening* nature. See the article CHEWING *Ball*.

FAVIFORM, in ſurgery, a term uſed to expreſs certain ulcers, which when preſſed upon with the finger emit a ſanies thro' ſeveral ſmall holes in the manner in which honey, on preſſing the comb, iſſues out of the cells.

FAVILLÆ *Salis*, in natural hiſtory, a name given by Vitruvius, and ſome of the more antient writers, to the natrum or nitre of the antients. Our chemical writers, who have been uſed to delight much in hard names, have applied the ſame phraſe to expreſs our nitre: but this is a very different ſalt from the other.

FAVISSÆ, in Roman antiquity, large vaults under ground in the area of the capitol.

Such a ſuperſtitious veneration did the Romans pay to every thing that belonged to their capitol, and to the religious ceremonies there performed, that they carefully depoſited the old ſtatues and other ſacred utenſils, when they happened to be broken, or any wiſe render'd unſerviceable, in theſe vaults; not daring either to deſtroy, or convert them to any other uſe. *Pitiſc.* Lex. Ant. in voc.

FAVONIUS, among the Romans, the wind which blew directly from the weſt. *Hofm.* Lex. in voc.

FAVORITO, in the Italian muſic, is an epithet given to ſuch parts of any compoſition as are performed to the greateſt advantage. Thus, *Choro favorito* is a chorus in which are employed the beſt voices and inſtruments to ſing the recitativos, play the ritornellos, *&c.* This is otherwiſe called the little chorus, or *choro recitante*. *Broſſ.* Muſ. Dict. in voc. See RECITANTE.

FAUSSE *Chenille*, in natural hiſtory, a term uſed by Mr. Reaumur, and other of the French writers, to expreſs a large claſs of worms produced from the eggs of ſeveral ſpecies of four wing'd flies. Theſe worms have greatly the appearance of caterpillars in their general form, ſo that they have deceived many writers on inſects into an opinion that they really were ſo. Their bodies are long in the manner of the caterpillar, and they are compoſed of ſeveral rings or joints. The skin is of the ſame conſiſtence with that of the caterpillar's; and in many ſpecies the creature is variegated with beautiful colours diſpoſed in the ſame manner as thoſe of the ſmooth caterpillars uſually are. Both theſe kinds of inſects have a great number of legs, and thoſe of two kinds; ſome membranaceous, and others ſcaly. Both the worm and the caterpillar have each ſix of the ſcaly legs; but the membranaceous ones are different in number, and are alone ſufficient to conſtitute a difference between them. The caterpillars have never more than ten of theſe, which with the ſcaly ones make ſixteen; the utmoſt number of the legs of any caterpillars. But theſe worms have always at leaſt twelve of the latter kind of legs, which with the ſix ſcaly ones make the whole number eighteen; and many ſpecies have fourteen, ſixteen, or eighteen of the membranaceous ones alone. The membranaceous legs of the worms differ alſo from thoſe of the genuine caterpillars, in that they are not furniſhed with the hooks at their ends, which thoſe of the latter have.

The legs therefore alone give a ſufficient baſis of diſtinction between the caterpillar and the *fauſſe chenille*, or caterpillar worm. But there is a yet more obvious diſtinction between them in the ſhape of their heads; and by this they may always be known from each other at firſt ſight. The heads of the various ſpecies of caterpillars are of ſeveral very different ſhapes; ſome are ſhort, others long; ſome more, ſome leſs flatted; and ſome terminate in a ſharp point, while others are diſtinguiſhed by a ſort of ſlit or diviſion in the back part. Theſe differences are found in the ſeveral kinds of the genuine caterpillars; but the heads of all the *fauſſe chenilles* are of one ſhape, and that very different from all theſe; they are round and very convex, ſo that they appear a part of a ſmall ſphere. The mouth of theſe and of the genuine caterpillars are wholly alike,

alike, and the ſtigmata are placed in the ſame manner. The eyes however of the two kinds ſufficiently diſtinguiſh them; the *fauſſe cheville* having only two, and thoſe very large and prominent, and placed on each ſide of the head; whereas the caterpillar has five eyes on each ſide of its head, and thoſe placed in a circular direction, and too ſmall to be ſeen without the aſſiſtance of glaſſes.

The *Fauſſe Chenilles* are a claſs of animals almoſt as numerous as the caterpillars. They are eaſily diſtinguiſhed into ſeveral genera, according to the different number of legs, as thoſe with eighteen legs, thoſe with twenty, twenty-two, and twenty-four. The *fauſſe chenille* of the alliaria is of this laſt kind. They are of ſeveral colours in the different kinds; ſome are white, ſome brown, others black, but the greateſt number of all are green. There are many of a ſlate colour, or bluiſh black variegated with ſtreaks and ſpots of brown, and other colours. And beſide theſe, there are others variegated on ſeveral other grounds; in general, however, they are much inferior in beauty to the caterpillars. The colours of theſe inſects are however very indiſtinct marks to diſcern them by, ſince they are not permanent, but the creature varies them at different times of its life. Theſe inſects, like the true caterpillars, change their skin ſeveral times in their lives, and with it they change their colours alſo. The young ones of theſe animals are always much more handſome than thoſe more grown; for at every change of the skin there is a loſs of ſome of the variegations; and uſually at the laſt change they are all gone, and the creature puts on a colour different from any that it had before. This is an obſervation of the accurate Vallisnieri, who gives an inſtance of it in a worm caterpillar of the elder. This creature, while young, is of a fine green, with a long ſtreak of brown running all the way down the back; but after the laſt change of its skin, it appears without the ſtreak, and all over of a pale yelloviſh hue.

Theſe creatures differ from the common caterpillars in their manner of remaining on the leaves of a plant. The caterpillar is always extended at its full length, whether it is eating or not; but the *fauſſe chenille*, though it extends its body to the full length while eating, always rolls it up into a ſpiral when at reſt, making ſeveral circular turns with it, of which the head is at the end of the outermoſt, and the tail in the very center of the inner one. They give themſelves various odd contortions when they are ſeizing on their food; and it is a very whimſical ſight to obſerve twenty or thirty of them, in thoſe kinds which live in ſociety, attacking the different portions of the ſame leaf all at once, and each giving its body ſome odd turn at the ſame time. This is a common ſight on the leaves of the oſier; a whitiſh green kind, being very frequent in large companies on that tree, and often ſeen thus feeding in coveys. It is remarkable, that as the caterpillar feeds indifferently on every part of the leaf, this animal uſually attacks only the edges.

Some ſpecies of theſe animals feed only early in the morning, and as the leaves are then wetted with the dew, they cannot avoid taking in a large quantity of water with their food; in conſequence of which, when they are examined afterwards, their bodies are frequently found cover'd with drops of a thick and viſcous water of an ill ſmell. It ſeems probable, that the abundant aqueous matter in this caſe finds its way out at thoſe numberleſs apertures in the skin, at which the creature takes in the air: theſe inſects, as well as the caterpillars, having very numerous tracheæ.

The generality of the animals of this claſs feed on the leaves of plants and trees, but there are ſome which affect other parts of them. There are a ſmall ſpecies very frequently found living within the young branches of the roſe tree, which often deſtroy that part of the ſhrub. Others are found lodg'd in young pears, apples, and other fruit. They ſeem to have been placed there when very young, and always deſtroy the fruit, occaſioning its falling off from the ſtalk before half grown. Some ſpecies of them are alſo found on the leaves of trees, which are render'd tumid, and make what are called leaf galls, theſe being often inhabited by animals of this claſs, in particular the leaf galls of the willow. The creature, when it finds the time of its change into the nymph ſtate approaching, gives itſelf the trouble of forming a caſe in which it may paſs into that ſtate, and remain in it during the deſtin'd time without being ſubject to external injuries. It ſpins a web of ſilk for this purpoſe of the ſhape of a little egg. This on the outſide ſhews nothing remarkable; but when cut open, it is found to be compoſed of two different ſubſtances, at leaſt of two ſubſtances of very different workmanſhip, though the materials are the ſame in both. The outer caſe is reticulated, and formed of very ſtrong threads wove into a looſe open network; but the inner one is formed of extremely fine threads, and thoſe wove into a cloſer ſtuff than all that the loom can come up to. The outer ſtrong and coarſe web was plainly intended for no other purpoſe but for the better defending and preſerving them from injuries. And theſe two diſtinct caſes do not any where adhere to one another, but barely touch; ſo that on pulling aſunder the outer one between the fingers, the inner one comes out whole. The ſtrength of this exterior ſhell is extremely neceſſary, as alſo the cloſe texture of the inner one, for the defending the incloſed animal in the nymph ſtate from ſeveral devouring inſects. The ants in particular are very fond of theſe nymphs, and will hunt out the caſes where-ever they are to be found; and if they can eat their way through them, are ſure to make a meal of the incloſed creature.

The roſe worm or *fauſſe chenille* is very ſingular in the manner of its performing this great work. This is a ſmall greeniſh ſpecies often found on the leaves of the roſe, and famous for the various odd attitudes into which it twiſts its body occaſionally. It uſually carries its tail erect, and often in the ſhape of the letter S. This ſpecies, tho' green on the ſides and belly, is yelloviſh on the back, variegated with ſeveral ſpecks of black or deep brown, from each of which, there grows a long hair. This creature when the time of feeding is over goes into the ground in order to ſpin its double web. The external one is of a reddiſh brown, and the internal one whitiſh. Theſe when taken out of the earth are uſually foul'd with ſmall particles of dirt, ſo that to have them in perfection, it is beſt to keep the animal in a box, where it will ſpin them perfectly clear. There are ſome ſpecies of this animal, that hide themſelves in the holes of trees, and in the cavities between the bark and the wood, and theſe never ſpin any outer web, but are found incloſed in the fine thin internal one alone. They all, after having paſſed a proper time in this ſtate, ſome only a few weeks, others a whole winter, become four winged flies.

The flies produced of theſe inſects are of that kind which have no trunks, but have a ſtrong tooth on each ſide of the head, which meeting one with the other in the middle of the mouth, are able to cut any thing to pieces that the creature has occaſion to make its way through. The firſt uſe of theſe is the eating a hole through the double web, in which the creature finds itſelf encloſed at its birth. All the flies of this kind, have a general reſemblance one to another, and may be known to belong to the ſame family, tho' they are very different in colour, and other obvious characters. They are never very handſome, and are all as it were ſtupid, having very little motion, and ſtanding readily at any time to be caught between the fingers. Their wings always are croſſed over the body and form a ſort of raiſed covering over it; they are not ſmooth and even, as thoſe of moſt other flies, but have prominencies and cavities, and ſeem as if they had been but ill expanded at the time of the creatures hatching from the nymph ſtate. *Reaumur*'s Hiſt. Inſ. v. 9. p. 133.

The ſeveral ſpecies of theſe flies, which are very numerous, differ much leſs from one another, than the creatures do in their reptile ſtate. They are of different colours indeed in their bodies and wings, and have ſome of their eſſential parts of different ſtructure, but they are often very like one another in the fly, when they have been extremely different in the worm ſtate, ſo that their difference in colour, &c. are not always to be expected in the ſeveral ſpecies, which are ever ſo diſtinct. The bodies of ſome are black, thoſe of others are greeniſh, and thoſe of others yelloviſh, and the wings in general are colourleſs and tranſparent, tho' in ſome, they are tinged with grey, and in others with yellow, the *antennæ* are alſo very different in the ſeveral kinds, in ſome they are granulated and in others they are of the elevated kind, the antennæ of the male and female of the ſame ſpecies often differ alſo very conſiderably.

All the females of theſe flies are oviparous, no one ſpecies producing living worms; and as theſe eggs muſt neceſſarily be lodged in cavities or niches, made in the ſtalks or leaves of living plants, nature has provided this creature with two inſtruments, which are deſtined for this ſole purpoſe, and which are real ſaws made in the niceſt manner, with extremely ſmall teeth. The creature has the power of uſing both theſe at once, and conſequently can make an aperture with great eaſe, that ſhall be ſufficient to lodge its eggs in. Notwithſtanding that there are many different ſpecies of flies which have this ſort of inſtrument, and ſeveral of them are extremely frequent on one of the moſt common of all our garden ſhrubs, the roſe-tree; yet no author had obſerved this elegant and wonderful inſtrument, till the time of Vallisnieri, who has deſcribed and figured at large the weapons of a roſe-tree-fly, produced from a falſe caterpillar of that ſhrub, with two rows of teeth, one on each ſide in the manner of the ſaw of the ſerra piſcis, or ſaw-fiſh. It muſt be obſerved, that there are different ſpecies of this inſect, ſince Mr. Reaumer's figures and deſcriptions from the inſtruments we ſaw on the fly of the ſame tree, expreſs only one row of teeth in the ſaw, and make it like our common hand-ſaws with a plain back. It is neceſſary to have recourſe to the microſcope in order to ſee diſtinctly this ſingular inſtrument, yet the naked eye alone, ſhews ſo much of it, as to eaſily engage us in a deſire of knowing it better. If the body of the fly be ſqueezed gently, there will be ſeen an opening between two plates of a hollowed figure, which are ſituated near the anus, and this opening gives a ſight of a fine brown point of a ſlender body to be ſeen within; on farther preſſing the body of the fly, the whole inſtrument, of which this is the point, is forced to ſhew itſelf, and the whole ſaw is placed before the eyes. The two hollow pieces which opened in order to ſhew

it, are only intended by nature as a caſe for it at ſuch times as it is not in action. It has been before obſerved, that in all theſe ſpecies of flies produced from the *fauſſe chenilles*, the male has a long and ſlender body, the female a ſhort and thick one. As the uſe of this ſaw, is the making a proper hole for depoſiting the eggs in, the female is the only ſex that has any uſe for it, and therefore, the ſhort bodied flies are the only ones in which it is to be looked for. If we examine the others in the ſame manner, we find inſtead of the ſaw, only two hooked bodies deſtined for the male to ſieze the female with in order to copulation, and between theſe there may be diſtinguiſhed the aperture at which the male part is thruſt out in the action. See the article ROSE-FLY.

FAUX-BOURDON, *baſtard humble-bee*, a name given by *Reaumur* and other French naturaliſts to the bees uſually called by us drones, and by the common people of that nation bourdons, confounding them with the common humble-bee under that name. Theſe are much larger than the common bees, they never work, and uſually bear the proportion of about one to ten of the working bees of the hive, when moſt frequent. They are the male bees. The working ones are of no ſex at all. The female bee is but one in a ſwarm, and all theſe are of no other uſe to the community, than the fœcundating the vaſt number of eggs included in her body. Theſe bees as they never work, ſo they never eat any of the yellow matter brought home on the thighs of the other bees, and called rough wax, or bees-bread, but feed only on the honey. This is certain from the opening their bodies. Mr. *Reaumur* who opened ſome hundreds of them on different occaſions, always found honey in their ſtomachs and inteſtines, but never met with the leaſt morſel of the rough wax there.

FAUX-PUCERON, in natural hiſtory, a name given by *Reaumur* and others to a genus of inſects much reſembling the *pucerons* in many things, but differing in ſome material circumſtances. The two principal kinds of theſe are found on the back of the leaves of the fig-trees, and in little hollow balls at the ſummits of the branches of box, formed of the upper leaves vitiated by the biting of theſe creatures. See FIG-*Inſect*, and GRUB *of the box*.

FEAL, was antiently uſed for faithful: hence the tenants by knights ſervice uſed to ſwear to their lords to be *feal* and *leal*, that is, *faithful* and *loyal*. *Spelm.* de Parliam. 59.

FEAR. This paſſion has been found to leſſen perſpiration and urine. See PERSPIRATION.

FEATHER, in the manege, a ſort of natural frizling of the hair, found in many parts of a horſe's body, but more commonly between the eyes. Many are of opinion, that when the *feather* is lower than the eyes, it is a ſign of a weak eye-ſight; but this remark is not always certain.

Roman FEATHER, called in French, *epee Romaine*, is a *feather* upon a horſe's neck, being a row of hair turned back and raiſed, which forms a mark like a ſword blade, juſt by the mane.

Mid FEATHER, in the Engliſh ſalt works. See the article MID.

FEAZING, at ſea, is the revelling out of the cable or any great rope at the ends.

FEBRIS, *fever*, in medicine. See FEVER.

Ephemera FEBRIS. See the article EPHEMERA.

FEBRIS *inteſtinalis*. See INTESTINAL *Fever*.

FEBRUARY, *Februarius*, in the Roman chronology, the ſecond month of their year, ſo called from *Februa* a feaſt held therein. See FEBRUA, *Cycl.*

In the firſt ages of Rome, *February* was the laſt month of the year and preceeded January, till the decemviri made an order that *February* ſhould be the ſecond month of the year, and come after January. *Hofm.* Lex in voc.

FEDOA, in zoology, a name uſed by Geſner and ſome other authors for the Godwit, more commonly called ægocephalus. *Geſner* de Avib. See ÆGOCEPHALUS.

FEEDERS, in mining, a term uſed to expreſs the ſeveral ſmall channels in the ſides of a mine ſeeming to open into it, as brooks into rivers in their courſe. The miners in moſt counties, call theſe the *feeders* of the load.

FEEDING *of fiſh*. The owner of fiſh-ponds will find this an article very worthy his conſideration, as the trouble or expence of it are very little, and the profit very great. In a ſtew thirty or forty carps may be kept up from October to March, without any other food than what they will find there for themſelves. And by fiſhing with trammels or flews, it will be proper in March or April to take from the larger waters, ſome to repleniſh the ſtews; but after this, from March to October it is neceſſary to feed them as much as to feed chickens that are coop'd up, and it will turn to as good account. The care of doing this, is beſt committed to the gardener, who is always at hand and on the ſpot; for the regular ſerving them is of the utmoſt conſequence.

Any ſort of grain is good to feed them with, eſpecially peaſe and malt coarſe ground, and grains after brewing while they are freſh and ſweet are very proper; but it is to be obſerved, that one buſhel of malt not brewed, will go as far as two buſhels of grains. Chippings or raſpings of bread ſteep'd in the droppings of malt liquors, eſpecially of ale, are very good for carp. The quantity of theſe ſhould be about two quarts a day, to thirty carps, and it is better to have it given twice a day, that is, morning and evening, than all at once. Peaſe or other ſeeds or grains boiled and prepared for the food of carp, may be let down into the water on a ſquare board like a trencher, ſupported by four ſtrings, one at each corner, and with ſome leads faſtened to its bottom to ſink it at a proper depth; it is to be ſupported by a pole or otherwiſe, and it is a very entertaining ſight to obſerve the manner in which they will come all about it, and take off their food.

When large ponds which contain great numbers of fiſh are to be fed in this manner, it will be ſome expence to the owner; but on taking out the fiſh, and obſerving how they thrive by it, this will be eaſily born with.

Grains are the cheapeſt and moſt ſtaunch food that can be procured for fiſh, and where breweries are near, they are eaſily had, but even in country places it will be eaſy to agree with the neighbouring families who brew, to throw their grains into the pond at a certain price. Carp and tench will be fed like fowls in this manner. Pike alſo may be fed with eels to fatten them quickly, and with any other fiſh at other times. Pearch are not at all proper for this ſort of management.

FEEL, in the manage, they ſay to *feel* a horſe in the hand; that is, to obſerve that the will of the horſe is in the rider's hand, that he taſtes the bridle, and has a good *appui* in obeying the bit.

To *feel* a horſe upon the haunches, is to obſerve that he plies or bends them; which is contrary to leaning or throwing upon the ſhoulders.

FEELERS, *antennæ*, in natural hiſtory, are the horns as they are uſually called upon the heads of inſects.

The word *antennæ* is derived from the Latin *ante* before, and *teneo* to hold or carry; or poſſibly may have been given them from ſome ſort of reſemblance to the part of a ſhip, known in navigation by the ſame name. The *antennæ* in various inſects are extremely various, and in moſt very beautiful; they not only differ in the inſects of different claſſes, but frequently in the different genera of the ſame claſs, tho' never in the ſame ſpecies.

The *antennæ* of flies may ſerve to diſtinguiſh ſeveral genera of thoſe inſects. 1. There are ſome flies which have articulated ones. Theſe are compoſed as it were of ſeveral vertebræ, or of ſeveral ſmall bodies joined end to end, as the beads in a necklace. Of theſe ſome have the beads if they may be ſo called, larger, and others ſmaller. Theſe *antennæ* are uſually much thicker at their origin, than at their extremity. *Reaumur's* Hiſt. Inſ. v. 4. p. 138.

2. There are other flies which have their *antennæ* compoſed like thoſe of the former, of a ſeries of beads or vertebræ, but have them ſmalleſt at their inſertion, and gradually growing larger and larger toward their extremities. The fly produced from the formica leo, has *antennæ* of this kind.

3. Others have their *antennæ* in form of feathered beards; ſeveral of the ſmall flies, gnats, and ſome of the tipulæ have *antennæ* of this kind beautifully plumed.

4. Others have what may be called priſmatic *antennæ*; theſe are articulated, and near their inſertions and extremities are much ſmaller, than in any other part of their length. Of this kind are the *antennæ* of a ſmall tipula which is produced from the worm that eats the oak agarick. Ibid. p. 139.

5. Other flies have branched or forked *antennæ*, each compoſed of two pieces, and appearing double. Ibid.

6. Others, of which there are many ſpecies both among the two winged and four winged flies, have *antennæ* extremely ſhort and thick. Theſe have not above two or three articulations; two or three beads, if they may be ſo called, placed on one another, forming in them a ſupport, or kind of pedeſtal for one much larger than the reſt, by which the *antenna* is terminated. This laſt bead has often the figure of a little battledore, for which reaſon theſe *antennæ* may properly enough be called the battledore kind.

This laſt piece which gives name to theſe *antennæ* is fixed by one part of its edge in the uppermoſt bead of the pedeſtal, which is ſplit to receive it. Sometimes this laſt piece is of an orbicular form, but often it is oblong and elliptic, and in many ſpecies of a priſmatic figure, and in ſome the laſt bead is of the ſame figure with the reſt that compoſe the whole *antennæ*.

Examined with the help of glaſſes, each of theſe extreme bodies is ſeen to have a large hair affixed to it; and this hair is ſometimes ſo divided as to appear like a feathered *antenna*. The two winged fly which reſembles the ſcorpion fly, gives us an example of this; the hair is there ſingle, as it is alſo in the fly produced from the rat-tailed worm. The common houſe fly has its *antennæ* in form of priſms, and a branched hair is produced from their baſe. Ibid. p. 140.

7. Another ſort of *antennæ* there are, very proper to diſtinguiſh certain kinds of the two winged flies, as thoſe which ſuck the blood of oxen or horſes. The *antennæ* of theſe are ſomewhat of the nature of the battledore *antennæ*, but the body which terminates them, has in it ſomething very different from that

which

which terminates theſe. It has ſomething of the figure of a creſcent; and from the baſe of this ſort of creſcent there is produced a ſhort branch, which ſeems to have been cut off. The end of this creſcent, examined with the help of glaſſes, appears articulated, whereas moſt of the battledore *antennæ* have their terminating piece not articulated.

The ſize of the *Antennæ* of ſome flies may alſo ſerve for a diſtinction, as may alſo the manner in which they carry them. The ichneumon flies have theirs in continual motion, making a kind of inceſſant vibrations with them.

The *Antennæ* are of very various forms and ſhapes in different genera of the ſame claſs of animals, and are very judiciouſly made by Reaumur the characters of different genera of the butterfly kinds, among which there are almoſt an infinite variety of them.

The *Antennæ* of inſects in general differ from horns, in that they are moveable at the baſe; and have beſide that power, a number of articulations all along their ſtructure, by means of which they are alſo capable of being turned about any way at the pleaſure of the animal. The differences of their figure and ſtructure in the butterfly claſs, which are made the marks of the different genera, are theſe. Thoſe of the firſt genus are of an equal thickneſs from their origin, till they arrive near their extremity. In all this part they are cylindric, but they are terminated by a large head, and in the whole reſemble a club. Theſe have been called clavated *antennæ* by authors in general; but Reaumur chuſes to call them the button'd *antennæ*. The buttons that terminate theſe *antennæ* are of a very different figure in the various ſpecies. Many of them are oblong and oval, and reſemble an olive. Others are ſhorter and truncated, and reſemble an olive cut off near the middle, their extremity being flat and circular. The buttons, as well as the cylindric part of theſe *antennæ*, are compoſed of ſeveral parts or joints fitted to one another at the ends. The button alone is uſually compoſed of ten, twelve, or fifteen of theſe joints, the pedicle or body of the *antenna* of twenty, thirty, or more. The joints which compoſe the buttons are ſhort and annular, thoſe which form the pedicles are cylindric, being much more ſlender and longer than theſe. Many of the *antennæ* of this genus, when viewed by the microſcope, appear to be beſet with hairs, and many others are perfectly ſmooth. The greater number of the day butterflies, which we ſee continually ſettling upon flowers and plants, are of this kind as to their *antennæ*.

The *Antennæ* of the ſecond genus of butterflies are, in general, much ſhorter in proportion to the body of the animal than the former. But what diſtinguiſhes theſe from all other *antennæ* is, that they gradually increaſe in thickneſs from their inſertion, till they come very near the point or extremity; but there they are terminated by a ſlender ſpine, which iſſues from the lower part, and is ornamented at the end with a round tuft of hairs. Theſe Reaumur calls the club *antennæ*, as they much reſemble the figure of the club, which painters and ſtatuaries put into the hands of Hercules.

When one of theſe *antennæ* is viewed by the microſcope, its extremity is ſeen to be rounded or cylindric, but the bottom near where it joins the head is flatted. Theſe ſort of *antennæ* are found on thoſe ſpecies of butterflies, which we frequently ſee buzzing about flowers, and never ſettling on them, and whoſe wings make a noiſe like thoſe of a humble-bee.

The *antennæ* of the third genus of butterflies are of the nature of the former, inſomuch that they gradually increaſe in thickneſs as they go from the head, but they ſoon terminate the increaſe; and at a ſmall diſtance from their origin their diameter begins to decreaſe, and is carried on in a ſmaller ſize to the extremity, where it terminates in an oval point. It has no cluſter of hairs at the end in the manner of the former. Theſe ſort of *antennæ* are in ſome ſpecies twiſted alſo, ſo as to repreſent the horns of a ram. Theſe are found on ſeveral of the butterflies which frequent our meadows.

The fourth genus have *antennæ* which terminate in a ſharp point. In this they reſemble thoſe of the ſecond genus; but they differ from thoſe, and from all others, in that at a little diſtance from their origin they become very thick, and continue of this diameter the greateſt part of their length, or very nearly to their end, where they turn a little, and terminate in a fine ſharp point; and this ſometimes ſupports another point formed of a cluſter of hairs in the manner of a pencil. Theſe hairs are always of an extreme fineneſs. Theſe *antennæ* have alſo this peculiarity, that their upper ſurface is rounded, but their other part is formed of two regular equal planes. There enter into the compoſition of theſe, as well as of the *antennæ* of other kinds, a vaſt number of ſmall parts, which are nicely jointed at the ends one to another; and on the two flat ſides of each of theſe joints, the microſcope diſcovers two ſeries of fine hairs, which ſtand in an elegant order. Each is placed near the outer edge of the plane it ſtands upon; and the points of each ſeries converge and meet together at ſome height, ſo as to form a ſort of cover'd alley all along the *antenna*, reſembling the ſhady walks in a garden, where the trees planted on each ſide join at the top. Many of the larger ſpecies of butterflies have theſe ſort of *antennæ*; they are uſually thick, but ſhort in proportion to the length of the creature's body. Mr. Reaumur has very properly called theſe priſmatic *antennæ*, as in the greater part of their ſurface they are regularly of a priſmatic figure.

The *Antennæ* of the fifth genus are thoſe which are larger at their origin than in any other part, and gradually diminiſh from thence to their extremity, where they terminate in a point; and in general all thoſe which are no larger near their extremity than in any other part. Theſe Mr. Reaumur calls the conic *antennæ*, or the quadrated ones, becauſe they are eaſily ſeen to be compoſed of a ſeries of granules joined one to another, and running like the beads of a necklace from the baſe to the point, only becoming ſmaller and ſmaller all the way. In ſome of theſe the ſeveral granules they are compoſed of are round, in others they are flatted, and in ſome they very nicely reſemble the joints of the vertebræ. There are a great variety of ſpecies of butterflies, which have theſe kind of *antennæ*, and in ſome they are very long, in others they are as remarkably ſhort.

The ſixth genus of *Antennæ* are thoſe of the moſt ſurpriſing ſtructure; theſe are properly called the plumoſe or feathered ones. Theſe appear to the naked eye to be each compoſed of a ſtalk or pedicle, which continually diminiſhes in ſize from the baſis to the extremity; and from each ſide of this pedicle there grow plumes placed in the manner of thoſe on the barrel of a quill, only that they do not ſtand ſo cloſe together. Thoſe at the baſe of the pedicle are but ſhort, but from that part they become gradually more and more ſhort, till at length they have ſcarce any diſcernible length at the extremity. The microſcope however is neceſſary for the giving a true idea of the ſtructure of theſe ſort of *antennæ*. When viewed in that manner, the pedicle is ſeen to be compoſed of a great number of joints, and the plumage that grows from it is truly of the nature of that of a common bird's feather; every filament being really a feather in itſelf, and having its barrel and its plumage as in birds. The butterflies which have theſe *antennæ* are eaſily diſtinguiſhed as to ſex, the males always having larger and more beautifully plumed *antennæ* than the females, and the plumes upon them ſtanding out in a much bolder manner. The *antennæ* of this genus, as well as of the others, are moveable at their baſe, and the butterflies often carry them erect, often laid down flat and cloſe upon their bodies. Some carry them in the manner that a hare does its ears; and, as they are moveable alſo, ſome haſty obſervers have fancied that theſe creatures had ears. What is moſt of all remarkable in theſe is, that every filament of their plumage is moveable on its baſe in the ſame manner with the whole *antennæ*, and the creature often cloſes them all together, and often expands them more or leſs wide, and ſtops the ſeveral filaments all together in any angle that it pleaſes. But it ſeems as if the animal had no power of moving them ſingly, but that the whole ſeries on both ſides always muſt bend inward, or expand together, ſo that they always ſtand in even rows.

Theſe are the variations of nature in theſe ſmall parts of theſe ſmall animals. They are plainly many of them put together with great artifice and nicety; but we are yet at a loſs to know to what end or purpoſe theſe nice organizations were given them, or why all this has been done by that great hand which does nothing in vain. Different people have formed very different gueſſes as to their uſes. Some have thought them intended to defend the eyes; but though this might ſeem probable in regard to the ſhort plumoſe ones, it can never hold good in the ſlender and ſmooth ones, which can be of no ſuch ſervice. Others have thought them made for wiping and cleaning the eyes. But this is an unneceſſary office, and one they are wholly unfit for: And the forelegs of the creature are always ready for ſuch a purpoſe, and are render'd much fitter for it by the hairs with which they are cover'd, than the *antennæ*, which in moſt caſes are compoſed of joints, and are by no means adapted to ſuch uſes. Others have called them *feelers*, and ſuppoſe that the creature uſed them, as a blind man does a ſtaff, to feel out the way, leſt it ſhould run againſt any thing that would hurt it. But theſe creatures have eyes enough to ſee with; and any one who will obſerve them while they walk, will find that they do not protrude theſe before them, but often keep them erect upon the head. If this were their ſole purpoſe, it is alſo eaſy to ſee that all that beautiful variety in their forms could not have been neceſſary. Poſſibly they may be the organs of ſmelling, ſince we evidently find that many inſects have this ſenſe in a very exquiſite degree, and yet we ſee no external organs, except theſe, to ſerve for it.

It is poſſible that this may be their uſe, but it is mere conjecture; and indeed the bodies of inſects are throughout made of parts ſo different from ours, that we can probably form no more idea of the uſe of their organs, than a man born deaf can of that of the ear. They may have ſenſes different from ours, and theſe may be the organs of them; or the hearing or ſmell may be performed by them.

The pedicles or ſtalks of the ſeveral *antennæ* of butterflies are always hollow, and many of them are ſmooth and gloſſy reſembling horn. Of this kind are moſt of the plumoſe *antennæ*.

And

And the buttons of the *antennæ* of thoſe kinds which have ſuch, are always fleſhy and juicy, ſo that when preſſed, different fluids are forced out of them, firſt a white, then a yellow one, and finally a black. When the creature is held under water with only the *antennæ* above, it is common to ſee bubbles of air diſcharged from the joints and buttons; how far theſe obſervations may aſſiſt in the determining their uſe, is left to farther enquiries.

FEET. See the article FOOT.

FEL, in the materia medica of the antients, the name of a fruit much uſed by them in ſtomachic medicines, but very badly deſcribed to us. All that we know of the matter is, that there were three fruits brought from the Indies at that time, and called *bel*, *fel* and *ſel*; they were all of the ſame virtues, and ſeemed nearly allied to each other in all reſpects. Serapio tells us, that the fruit *fel* was the ſize of the piſtachia nut, and ſomewhat reſembled it in ſhape; and Aviſenna tells us, that it was an Indian medicine, bitter, and hot like ginger; and that it was uſed as a ſtomachic. He alſo ſays the ſame thing of the other two fruits, whence it appears, they were nearly the ſame thing.

It is to be obſerved however, that inſtead of this fruit, the ſame Aviſenna ſometimes mentions another medicine brought from the ſame place under this name. This he ſays, had the virtues of mandrake, and was of a cold and ſleepy nature. In another part of his works, the ſame author confounds theſe two ſo different plants, under the ſame name of *fael*. He ſays, that the *fael* is a fruit over which there is a rind, in colour reſembling the rind of the hazel-nut; that in ſhape it is very like the piſtachia-nut, and has within it a kernel like the pine-kernel, which was by ſome at that time called the granum regium, or royal grain: the colour of this kernel he ſays, was a mixture of red, white and yellow, and that it was this kernel alone, that poſſeſſed the virtues of the fruit. He adds, that this is a hot medicine, and immediately afterwards ſays, that it is a known medicine in the Indies, and poſſeſſes the virtues of the mandrake, and its fruit. This is an evident contradiction to its being hot in its nature; but it is meant of another fruit called by the ſame name. This latter *fel* is mentioned by none of the Arabians but Aviſenna; but the chapter after this is alſo on the feleros. He calls it fael, and in this he deſcribes it in the ſame manner that the others do, and proves it to be the ſame with ours, and very different from the plant, which he ſays, poſſeſſes the virtues of mandrake. See SEL.

FEL *terræ*, *gall of the earth*, a name by which ſome authors have called the ſmall centaury, becauſe of its great bitterneſs. *Ger. Emac.* Ind. 2.

FELAGUS, in our law books, was uſed for a companion, or friend who was bound in the decennary for the good behaviour of another. In the laws of king Ina, it is ſaid, if a murderer could not be found, the parents of the perſon ſlain ſhould have ſix marks, and the king forty; if he had no parents, then the lord ſhould have it; *Et ſi dominus non habet*, Felagus *ejus*. Leg. Inæ cap. 15.

Felagus is ſaid to be, *quaſi fide cum eo ligatus*.

FELE *homagers*, was antiently uſed for the faithful ſubjects. But it ſeems the word ſhould be written *feal* homagers. See FEAL.

FELIA, a name by which ſome of the chymical writers have called the ſulphurated or ſulphureous waters.

FELIS, the cat, in the Linnæan ſyſtem of zoology, is the title of a diſtinct genus of quadrupeds; but the author does not confine it to the cat alone. Many other of the quadrupeds having the ſame general characters, and being properly of the ſame genus. The characters are theſe. The creatures have eight paps, four on the breaſt, and four on the belly; and their feet are adapted for climbing. Of this genus are the common houſe-cat, which he names the *felis* cauda elongata auribus æqualibus; and the two lynxes, which he diſtinguiſhes by the general title of *feles* auribus penicilli formibus, cats with penciled ears. The firſt of theſe, the lynx cervarius, he calls the *felis cauda colore ruffeſcente maculato*; and the other the *felis cauda colore albo maculato*, the red ſpotted, and black ſpotted ſhort tailed cat.

FELIS *volans*, the *flying-cat*, in natural hiſtory, the name of an animal deſcribed by Scaliger, and ſuppoſed to be what we now call the flying-ſquirrel, a ſpecies of ſquirrel which has a looſe membrane on each ſide, which it can diſtend at pleaſure, and by means of which it takes ſuch long leaps, that it ſeems to fly. See SQUIRREL.

FELIS *zibethicus*, in zoology, a name given by many to the creature which produces the perfume called civet, and which we uſually call the civet-cat, but very improperly, it being rather of the dog kind. See ZIBETHICUM *Animal*.

FELLING *of timber*. Many circumſtances are well known and conſtantly obſerved in the *felling* of timber for building, which though to a haſty obſerver, they might appear trifling, yet prove on experience, to be of the utmoſt conſequence. One thing obſerved by Mr. De Buffon, which very greatly encreaſes the ſolidity and ſtrength of timber, is that the trees intended to be fell'd for ſervice, ſhould firſt be ſtripped round of their bark, and ſuffered to ſtand and die upon the ſpot before the cutting. The ſappy part, or blea of the oak, becomes by this management as hard and firm as the heart, and the real ſtrength and denſity of the wood has been proved by many experiments, to be greatly increaſed by it; nor is this a practice of any detriment to the proprietor, ſince the remaining ſtumps of theſe trees ſend up their young ſhoots as vigorouſly, as if they had been cut down in their natural condition. Memoires de l'Acad. Scienc. Par. 1739.

When any tree is to be cut down for timber, the firſt thing to be taken care of is a skilful disbranching ſuch limbs as may endanger it in its fall. Many trees are utterly ſpoiled for want of a previous care of this kind. In arms of timber that are very great, it is always neceſſary to chop a ſink in them cloſe to the bole, and then meeting it with downright ſtrokes, it will be ſevered from the tree without ſplitting. In *felling* the tree, take care always to cut it as cloſe to the ground as poſſible, unleſs it is intended to be grubbed up; and the doing this is of advantage both to the timber, and to the wood; for timber is never ſo much valued, if it be known to grow out of old ſtocks. When an oak is down, the bark is to be ſtripped off, and ſet ſo that it may dry well. Trees that are nine inches girt about a yard from the ground, are commonly reckoned timber trees, but none under this ſize, becauſe ſuch will be about ſix inches girt in the girting place, when the bark is off: the knowledge of this will ſave the trouble of climbing up to meaſure them. The common method of ſelling timber is as it ſtands, but the ſeller is liable to great cheat and impoſition in this reſpect. It is ſold either by the load or ton, forty foot is reckoned a ton in ſome places, and fifty a load; and in others fifty is the ton, and the load is but forty; ſo that whoever ſells timber ſtanding, ſhould mention how many foot he means in the ton or load. The trees when *fell'd* are meaſured either by girth or ſquare meaſure; it is uſually reckoned, that forty foot of round timber, or fifty foot of hewn or ſquare timber weighs the ſame, that is, twenty hundred. And this is uſually accounted a cart load; and as they ſeldom ſtrip the bark off from elm, the buyer commonly allows an inch for the bark, which is a great deal more than it comes to; and therefore if the owner can ſtrip off the bark in the meaſuring place, which ſhould be about the middle of the tree, it will be much the better.

Some allow four foot out of every load for aſh, and five foot for oak and elm; and as for the computation of the feet, if it is ſquare meaſure, the ſquare is taken by a pair of callipers, or by two rules clap'd to the ſide of the tree, meaſuring the diſtance between them, and if the ſides are unequal, they add them together, and take half the ſum, which they account the true ſide of the ſquare.

If girth meaſure be uſed, they do it by girting the middle of the body of the tree with a line, and taking a quarter part of this girt for the ſquare, meaſuring the length from the butt end ſo far forwards, till the tree comes to be but ſix inches in the girth, that is, twenty-four inches in circumference; and if the trees have any great boughs which are timber, that is, which hold ſix inches girth, they meaſure them by themſelves, and then add them to the whole. For the caſting up the contents of this, they make uſe of Gunter's line, upon which, if a pair of compaſſes be extended from twelve, to the number of inches contained in the ſquare, they place one foot of the compaſſes at the length, and keep the ſame extent with them; if the ſquare is under twelve inches, the compaſſes are to be returned twice toward twelve; if above that, they are to be turned twice from twelve, and it will ſhew the contents. This is the common practice of meaſuring, and therefore the ſeller muſt generally acquieſce in it, but it is a very falſe way, being one fifth part leſs than the whole. *Mortimer's* Husbandry, v. 2. p. 94. See TIMBER.

FEMBLE, the name given by the common people of Lincolnſhire to the female hemp. There is no country where hemp ſucceeds better than in this, and great quantities are anually raiſed there.

FEME *covert* (*Cycl.*) — By the law of England, a *feme covert* committing a bare theft in company with, or by coercion of her husband, is not deemed guilty of felony; neither does ſhe become acceſſary to a felony, by receiving her husband who has been guilty of it, as he does by receiving her. But if ſhe commit a theft by the bare command of her husband; or treaſon, murder, or robbery in his company, or by his coercion, or keep a bawdy-houſe with him, ſhe is puniſhable in the ſame manner, as if ſhe were ſole. And generally if ſhe be guilty of any offence not capital, ſhe may be indicted, &c. without making the husband a party. But if ſhe incur the forfeiture of a penal ſtatute, the husband muſt be made defendant in the action or information. *Hawk.* Pl. of the Crown. B. 1. ch. 1.

FEMOREUS, in anatomy, a name given by ſome of the authors on theſe ſubjects to a muſcle, more generally called the *crureus* or *cruralis*. See CRUREUS.

FEMORIS *quartus*, in anatomy, a name given by Veſalius and others to one of the muſcles of the thigh, called by the later writers from its ſhape *pyriformis*.

FEMORIS *fextus*, in anatomy, a name given by Spigelius and others to a muſcle, now generally called the iliacus internus. See ILIACUS.

FEMORIS *os*. See Os *Femoris*.

FEM-OWL, an Engliſh name uſed in Shropſhire, and ſome other counties for the caprimulgus, a goat-ſucker, called alſo the churn-owl. It is a very beautiful bird, and more reſembles the cuckow than the owl kind. *Ray*'s Ornitholog. p. 70. See CAPRIMULGUS.

FEMUR *moventium fextus*, in anatomy, the name given by Veſalius and ſome others, to the muſcle now called the pſoas magnus. See PSOAS.

FENCES (*Cycl.*) —The incloſures of grounds are in ſome places made by ditches full of water, and in others by walls either of ſtones alone, or of ſtones and earth. Where theſe materials are in plenty, they make very good *fences*, but in other places, the common method is by quick hedges. To raiſe theſe, a ditch is dug and a bank thrown up, and on this the young trees are regularly planted. The white thorn is the beſt of all trees to plant for a *fence*, being a tolerable quick grower, and laſting a long time, and making a very handſome *fence*. It will ſucceed on any ſoil where a ditch and new bank are made, except it be wholly of gravel or ſand, and even in this caſe it will thrive, if there happen a rainy ſeaſon after the planting of it.

Some raiſe it by ſeeds, and others by young plants; the latter is the moſt expeditious way, for the ſeeds lie two years in the ground before they ſhoot, but they grow very faſt after two or three years. Some prepare the haws, or fruit of the white thorn, by tying them up in a hair bag, and ſoaking them all winter; after this if they are ſown in February or March, they will come up the firſt year, and grow better than any other way.

Where ſets are ſcarce, it is a good way when the underwoods are *fell'd*, or rather the year before, to ſow haws and ſloes in them, and they will furniſh a ſupply of young plants for hedges, without doing the woods any harm, becauſe they may be drawn before they come to be too large. The white thorn is alſo of conſiderable value in ſome ſort of works; its root becomes very beautifully vein'd when old, and elegant boxes and combs are made of it. It is uſed by ſome alſo, in the buſineſs of enlaying, and would be more ſo, if its beauty were more known. The crab and the ſloe-tree, or black thorn, come next in value to the white thorn, for quicks for fences. *Mortimer*'s Husbandry, p. 7.

The crabs are to be ſown by kernels, pulp and all, and they will come up the firſt year; and a ſet of young crabs planted thick enough, make an excellent *fence*. The black thorn is not ſo much approved, becauſe it is not ſo ſure of growing, and if it does, its roots ſpread, and it's apt to run in too much upon the land. The buſhes of black thorn are however the beſt of any for dead hedges, and for mending of gaps; and they have another advantage over the white thorn, which is, that cattle are not ſo apt to crop them. The black thorn will grow on any ſoil that the white will, but the richer the mould is, the better it will thrive.

Holly is another excellent ſhrub for a *fence*; it is indeed greatly the beſt of all the *fence* buſhes, but it grows ſo ſlow, and is ſo uncertain, that the farmers are afraid of waiting for it, or of truſting to it; but where it ſucceeds, it makes amends for the delay in its thickneſs, ſtraitneſs and ſtrength. It is to be raiſed like the white thorn, either by ſets or berries, and the berries in the ſame manner lie two years in the ground before they come up. It will grow on any ſoil, even on the drieſt gravel, or among ſtones and rocks. It delights moſt in light grounds. If it be raiſed in plants, they ſhould be about the thickneſs of a man's thumb, and planted in a moiſt ſeaſon, either in ſpring or autumn: they muſt be ſhaded well with ſtraw or halm after they are ſet, and muſt be carefully watered, as ſoon as they begin to ſhoot, otherwiſe they will all periſh.

If any of them ſeem to periſh, they muſt be cut off cloſe at the roots, and they will often ſprout out vigorouſly thence again. The ground muſt be dug up all about them at times, which very greatly promotes their growth; and the farmer muſt keep his ſheep from them, for they are very fond of cropping the young ſprouts.

Field mice are apt to gnaw the roots of the holly in hard winters, and many of theſe trees are ſuppoſed to be killed by the froſt, when the teeth of thoſe little vermin have really done the miſchief.

The beſt way of raiſing a *fence* of theſe trees, is to plant them with the quick or white thorn, four plants of that to one of holly, theſe will thrive very well together, and while the white thorn grows very ſpeedily, the holly will take its time; as this grows large, the white thorn may be pulled up between by degrees, till at length, there is only the holly left; and if this is found not thick enough, the boughs of it which grow neareſt the ground, may be laid down and covered with earth, and they will ſend up innumerable ſuckers, which will fill up all the gaps.

Beſide theſe there are very good *fences* made of furz, of alder, and even of elder, in ſome places on proper ſoils. See INCLOSURE.

FEN-*cricket*, a name given by ſome people to the gryllotalpa. See GRYLLOTALPA.

FENGELD, in our antient writers is uſed for a tax or impoſition raiſed for repelling of enemies. *Blount*.

It comes from the Saxon *feind* an enemy, and *geld*, money.

FENNEL *giant*, in botany. See FERULA.

Hog-FENNEL. See PEUCEDANUM.

Sweet-FENNEL. See FINOCHIA.

FENS (*Cycl.*) —What the farmers call *fens* or *fenny* lands, are of two kinds. Firſt, thoſe which are only drowned by upland floods and great rains, and are very large and lie upon the levels, ſo that the water cannot run off from them, but muſt be there till the hot weather and winds dry it off; and, ſecondly, thoſe that are conſtantly wet, only that in dry times they are ſhallower covered with water than in others. In draining of theſe ſorts of lands, which is the only means of making them uſeful to the world, two things are to be conſidered, firſt the laying them perfectly dry, which can only be effected by the making cuts and drains for the carrying off the water from their loweſt parts, and thence from the whole. Or ſecondly, the taking off from them the great additional wetting they have from land floods, and long continued rains. The firſt method makes a perfect cure, the other is only a temporary relief, and makes the lands more ſerviceable in dry times, and leaves leſs for the ſun to dry up.

Whatever is attempted in regard to the draining of *fens*, the loweſt part of the ground is to be found out firſt, and the overflowing from great rains, and from land floods muſt be provided for, in the carrying off that way; for ſhould this be neglected all the labour and coſt employed on the other principle would be thrown away. If it is found that this can be done, there muſt afterwards be cut a large drain through the middle of the land, and ſeveral ſmaller drains from all parts communicating with this.

The great drain muſt be dug deep enough to drain the whole level, and this and all the others, muſt be made narroweſt at the head, and wider all the way to the mouth, where they muſt be wideſt of all.

Theſe drains muſt be all well cleanſed from mud and weeds every ſpring and autumn, and the water from land floods muſt be kept from coming in upon theſe lands, as much as poſſible, that there may be the leſs to be drained off; the lower edges of the *fen* land muſt be for this purpoſe guarded with banks to turn the water into other channels. In Eſſex they have many lands that lie below the high water mark, and are above the low water mark, and have land floods or fleets running through them, which make a ſort of ſmall creek. Theſe lands they have a very eaſy way of draining, though they are naturally very moiſt when they firſt encloſe them from the ſea; they do it with a bank, which they extend from one ſide of the land they deſign to take in, to the other, excepting a ſpace that they leave, where the creek or land floods, run into the ſea. They then prepare a wooden frame, well planked, and of conſiderable thickneſs, fitted to the head of the creek, and capable of ſhutting it wholly up; in this frame they make ſeveral holes, in which are placed wooden troughs, made each of four boards, and ſuited in ſize and number to the quantity of water that is to be diſcharged through them from the land floods. Each of theſe trunks is open toward the creek, but on the ſea ſide, it has a door or flap, which opens when the land flood preſſes againſt it, and gives it free paſſage out, but when the ſea water is riſen to the height of it and preſſes it, it is ſhut by the force, and no ſea water is let in. When this head is prepared, they let it in, and ſtopping up the whole creek, they continue the banks on each ſide till they meet it: thus all the land floods are let out at low water, and not a drop of ſea water can be admitted, ſo that the lands are kept dry and uſeful, which were before rendered uſeleſs, by being drowned with ſalt water, at every high water mark. The freſh water of the creek is thus kept unmixed with the ſea water, and therefore affords good drink for the cattle, which is commonly very difficult to be had in this ſort of lands, the tides ſpoiling what freſh waters there are, every time they come up. *Mortimer*'s Husbandry.

The wet grounds called *fens* in Lincolnſhire and elſewhere in England, bring many advantages to the inhabitants of thoſe counties. Fowl and fiſh are very plentiful in them. The pike and eels are large and eaſily caught, but they are uſually courſe. The duck, mallard and teal are in ſuch plenty, as is ſcarce to be conceived; they are taken in decoys, by prodigious flocks at a time. They ſend theſe fowl to London from Lincolnſhire, twice a week on horſeback, from Michaelmas to Lady-day, and one decoy will furniſh twenty dozen, or more, twice a week, for the whole ſeaſon in this manner. The decoy-men contract with the people who bring them to London at a certain rate, and they are obliged to take the whole number that is catched off their hands. Two teal are uſually reckoned equal to one duck, and ſix ducks and twelve teal are accounted a dozen of wild fowl; and the uſual market price is about nine ſhillings, for ſuch a dozen. About Mid-

ſummer when the moulting ſeaſon is, a great number are deſtroyed alſo by the people of the neighbourhoods. The poor birds at this time are neither able to ſwim nor to fly well; and the people going in with boats among the reeds, where they lie, beat them down with long poles. A little before Michaelmas, vaſt flights of theſe birds arrive at the decoys from other places; they ſoon grow fat in them, and continue there a prey to the maſters or owners, as long as the decoys are unfrozen, but when they are iced over, they fly away again, and go to the neighbouring ſeas for food. Philoſ. Tranſ. N°. 223.

The *fens* alſo abound in a ſort of herbage that is very nouriſhing to cattle: ſheep and horſes always grow fat upon it. Theſe *fens* are common, and the owners of cattle mark them, that they may be known. It is remarkable, that though all is open, the cattle uſed to one particular ſpot of ground, ſeldom leave it, but the owner may find them always in or near the ſame place. The *fens* have many large and deep drains. In theſe the pike and eels grow to a vaſt ſize; and they are full of geeſe which feed on the graſs, but theſe eat rank and muddy, and may even be ſmelt as ſoon as a perſon comes into a room where they are roaſting. But the people have another very great advantage in theſe, beſide the eating them, that is, their feathers and quills; and the produce of theſe is ſo great, that the cuſtom-houſe books in the town of Boſton ſhew, that there are frequently ſent away in one year, three hundred bags of feathers; each bag containing a hundred and a half weight. Each pound of feathers, brings in the owner two-pence, and it may be thought ſtrange by people unacquainted with theſe things, but it is a certain truth, that the owners pull them five or ſix times a year for the feathers, and three times for their quills. Each pulling comes to about a pound, and many people have a thouſand geeſe at a time, or more. They are kept at no charge, except in deep ſnowy weather, when they are obliged to feed them with corn.

Oats alſo grow very well in many of the *fen* countries, and in good ſeaſons bring great increaſe and advantage to the owner. There is alſo another vegetable of great profit to them. This is the *rapum ſylveſtre*, the ſeed of this, they call cole-ſeed; and they make an oil from it of great uſe in trade. They grind the ſeed between two large ſtones, the one ſtanding perpendicularly on the other. The ſtones are made of a ſort of black marble, and are brought from Germany. They ſometimes turn them by ſails, and ſometimes by the drains which carry off the water from the *fen* lands.

The *fens* lying low and being of a vaſt extent, are very ſubject to be overflowed by waters from the neighbouring high countries, and though great care and expence is uſed to keep them dry, they are often like a ſea, and the ſheep are obliged to be carried off in boats, and the people to live in their upper rooms and be ſupplied with proviſions alſo by boats.

FEODAL, *feodalis* or *feudalis*, of or belonging to a feud, or fee. Hence *feudal* ſervices, &c. See FEUDAL, *Cycl.*

FEODALITY, the fealty paid to the lord by his feudal tenant. See FEALTY, *Cycl.*

FEODATARY, or FEUDATARY. See FEODARY and FEUDATARY, *Cycl.*

FEODITAS, in old writers, is ſometimes uſed for *fidelitas*, or fealty. See FEALTY, *Cycl.*

FERÆ, in the *Linnæan* ſyſtem of zoology, one of the orders of animals; the characters of which are, that they have ſharp teeth, the fore-teeth are ſix in number, and the canine or dog teeth longer than the reſt. Of this order are the bear, the lion, the tyger, the cat, the weaſel, the didelphis or philander, the otter, the ſea-calf, the dog, the badger, the hedgehog, the mole, and the bat, which this author makes not a bird, but a quadruped with its fore-feet expanded into a ſort of wings.

FERALIA, among the Romans, a feſtival kept in honour of the dead. Vid. Mem. Acad. Inſcript. T. 1. p. 43.

FERDELLA *terræ*, was uſed antiently for a quarter or fourth part of a yard land — *decem acræ faciunt* ferdellam, *quatuor ferdellæ faciunt* virgatam, & *quatuor virgatæ faciunt* hidam, & quatuor hidæ faciunt feudum militare. *Spelm.* and Du Cange, in voc.

FERDFARE, in our old writers, is uſed for being diſcharged from going to war — *quietantiam* eundi in exercitum. *Fleta*, Lib. 1. c. 47. *Du Cange.* in voc.

FERETRUM, among the Romans, the bier uſed in carrying out the bodies of the dead; which duty was performed by the neareſt male relations of the deceaſed: thus, ſons carried out their parents, brothers their ſiſters, &c. *Hofm.* Lex. in voc. See BURYING and BURIAL.

FERIJEE, in the dreſs of the Egyptians, is a ſort of skirt worn over another garment, and made either of black woollen, or of other coloured cloth furred, this by the more genteel people is left open before. It ſomething reſembles a night-gown. *Pocock*'s Egypt. p. 189.

FERLING, in our old ſtatutes, is uſed for the fourth part of a penny. Aſſiſ. panis & cerevis. 51 Hen. 3. *Blount.*

FERLINGATA *terræ*, in our old writers, according to Blount, is the ſame as *ferlingus* terræ, which lord Coke on Littleton ſays, was a quarentine, or thirty-two acres of land. But according to the authorities quoted by Du Cange, Gloſſ. Lat. voc. *Quarentena*, it contained but 40 perches.

FERLINGUS *terræ*. See FERLINGATA *terræ*.

FERME *a ferme*, in the manege, ſignifies to exerciſe in the ſame place without ſtirring or parting.

FERMENT, (*Cycl.*) a name given by our writers on brewery, and the like ſubjects, to ſuch matters of whatever kind, as when put to a rightly diſpoſed fermentable liquor, will cauſe it to *ferment* much ſooner, and much faſter than it would of itſelf, and thus ſhorten the operation of making the liquors from them.

Thoſe things are called *ferments* in an alluſive ſenſe, which when added to the liquor, only correct ſome fault therein, and by removing ſome obſtacle to the fermentation, forward it by ſecondary means; as alſo ſuch as being added in time of fermentation, make the liquor yield a larger proportion of ſpirit, and give it a finer flavour; all theſe additions have the name of *ferments* among our diſtillers, but all the laſt improperly. The primary uſe of *ferments* is, to ſave time, and make diſpatch of buſineſs, while they only occaſionally and accidentally give a flavour, or add to the quantity of the ſpirit; and accordingly all fermentable liquors, may without the leaſt addition, only by a due application of heat, be brought to ferment more perfectly, though it will be more ſlowly than with the addition of any *ferment*. The general *ferments* uſed on theſe occaſions are the flowers and fæces of fermentable liquors generated, thrown up or depoſited, during the time of the fermentation in that liquor, or after the end of it. There are two of theſe *ferments*, procurable in large quantities, and at a ſmall price; theſe are beer yeaſt, and wine lees. A prudent and artificial management of theſe, might render the buſineſs of the brewery for diſtillation, as in the buſineſs of the malt-diſtiller, &c. much more eaſy and advantageous. It has always been found a great difficulty to procure theſe *ferments* in proper quantities, and preſerve them always ready for uſe; and this has been a great diſcouragement to the buſineſs, and hence ſome have been reduced to contrive artificial *ferments*, or to form mixtures or compounds of particular fermentable ingredients; but this has been attempted without any great ſucceſs, all theſe mixtures falling ſhort even of the common baker's leaven in their uſe. Whoever has a turn for making experiments, and attempting improvements of this kind, will find it much eaſier and more advantageous to preſerve and raiſe nurſeries of the common ones, than to deviſe mixtures of others. Yeaſt may be preſerved by freeing it from its moiſter parts; this may be done by the ſun's heat, but it will be ſlowly, and imperfectly. The beſt method is by gentle preſſing it in canvas bags; thus the liquid part in which there is ſcarce any virtue, will be thrown off, and the ſolid will remain behind in form of a cake, which may be packed in a barrel or box, and will keep a long time ſweet and fragrant, and fit for the fineſt uſes; and the ſame method may be uſed either with wine-lees, or the flowers of wine.

The former may be brought from abroad in this manner with great eaſe; and the latter may be made with us from the lees, by only diſſolving them in warm water, and ſtirring them about with a ſtick; by this means the lighter and more moveable and active part of the lee will be thrown up to the top, and may be taken off and preſerved in this manner abovemention'd in any quantity that ſhall be deſired. By this means an eaſy method is found of raiſing an inexhauſtible fund, or a perpetual ſupply of the moſt uſeful *ferments* may be readily formed in the way of ſucceſſive generation, ſo as to cut off all future occaſion of complaint for want of them in the buſineſs of diſtillation. It muſt be obſerved, that all ferments abound in eſſential oil much more than the liquors which produce them; whence they very ſtrongly retain the particular ſcent and flavour of the ſubject from which they were made. 'Tis therefore requiſite, before the *ferment* is apply'd, to conſider what flavour ought to be introduced, and accordingly what ſpecies of *ferment* is moſt ſuited to the liquor. The alteration thus cauſed by *ferments* is ſo conſiderable, as to determine or bring over any naturally fermentable liquor of a neutral kind, to be of the ſame nature with that which yielded the *ferment*. This is an obſervation of greater moment than will be preſently conceived, as not only opening a new ſcene in the buſineſs of diſtillery, but alſo in ſome other buſineſs depending on *fermentation*.

The benefit of this however does not extend to malt treated in the common way for the ſpirit, nor to any other matter which does not naturally yield a tolerably pure and taſteleſs ſpirit; as it otherwiſe makes not a ſimple, pure and uniform flavour, but a compound and mixed one. How far the fine diſtiller may apply it, deſerves his conſideration; and whether our crab ſpirit and cyder ſpirit, which have little flavour of their own, may not by this artifice, and ſome other little additions, be brought nearly into the ſtate of ſome foreign ſpirits now very highly eſteemed.

When the proper ſort of *ferment* is thus pitched upon, the operator is next to conſider its quantity, quality, and manner of application. The quantity muſt be proportion'd

tion'd to that of the liquor, to its tenacity, and the degree of flavour it is intended to give, and to the diſpatch required in the operation. From theſe conſiderations he will be able to form a rule to himſelf; but till ſuch a rule is formed, or, in order to the forming of it, proper trial will ſhew how much ſuffices for the purpoſe. The way is to begin with a little, and to add more occaſionally, the weight of the whole being noted beforehand; ſo that on weighing the remainder after the proper quantity is taken away, it will be found how much exactly has been uſed out of it for the buſineſs.

Among the ſeveral ingredients of which *fermentable* liquors are made for the ſervice of the diſtillery, treacle requires more *ferment* than almoſt any other. This is not wonderful on a juſt conſideration of the nature of the ſubject, ſince the manner in which that concrete juice is made, muſt render it greatly unfit for *fermentation* afterwards, though the original product of a vegetable juice very much diſpos'd to it in its own nature. The ſtrength of the fire uſed in the ſugar-making, and its long continuance and almoſt immediate contact, and the lime and other alkalies uſed in refining the ſugar, that is, in making the treacle, do ſo condenſe, indurate, and ſcorch the body of this juice, and abſorb its acid, that it is ſcarce to be expected that it ſhould *ferment* at all, even with the addition of jalap, or other powerful ſaline and acid or acrid ſtimulators, which tend to break the viſcous and aduſt connections of the particles.

The greateſt circumſpection and care are neceſſary in regard to the quality of the *ferment*, if a pure and well flavoured ſpirit be required. It muſt be choſen perfectly ſweet and freſh, for all *ferments* are liable to grow muſty and corrupt; and if in this ſtate they are mixed with the *fermentable* liquor, they will communicate their nauſeous and filthy flavour to the ſpirit, which will ſcarce ever be got off by any ſubſequent refining. If the *ferment* be ſower, it muſt by no means be uſed to any liquor, for it will communicate its flavour to the whole, and even prevent its riſing to a head, and give it an acetous, inſtead of a vinous tendency. When the proper quantity of a ſuitable and well condition'd *ferment* is got ready, it muſt be put to the *fermentable* liquor in a ſtate barely tepid, or ſcarce lukewarm. The beſt manner of putting them together, ſo as to make the *fermentation* ſtrong and quick, is this:

When the *ferment* is ſolid, it muſt be broke to pieces, and gently thinn'd with ſome of the warm liquor: but a compleat or uniform ſolution of it is not to be expected or deſired, as this would weaken its efficacy for the future buſineſs. The whole intended quantity being thus looſely mixed in ſome of the lukewarm liquor, and kept near the fire, or elſewhere, in a tepid ſtate, free from too rude commerce of the external air, more of the inſenſibly warm liquor ought at proper intervals to be brought in, till thus by degrees the whole quantity is ſet at work together.

When the whole is thus ſet at work, and ſecured in a proper degree of warmth, and kept from a too free intercourſe with the external air, it becomes as it were the ſole buſineſs of nature to finiſh the operation, and render the liquor fit for the ſtill. In this eaſy manner the whole end of *fermentation* would be anſwered. But during the whole courſe of the operation, there are ſeveral other things that may be added with ſome particular view, as either to increaſe the quantity of ſpirit, or give it ſome agreeable flavour. Theſe additions may ſometimes require ſome alteration in the general method laid down above, though upon the whole it is right. *Shaw*'s Eſſay on Diſtilling. See ADDITIONS.

FERMENTS *in the Earth.* It is very probable, that the natural *ferments* in the earth may be of more conſequence than is generally ſuppoſed, and tend to elucidate many things, which at preſent appear very myſterious. The different fruitfulneſs of different ſpots of the ſame ſort of land may be owing to this, as alſo the different temperature of the air at the ſame time in places very little diſtant from one another. The effluvia ſent up by ſome of theſe, not only diſſolve ſnow that falls on them, but even melt it in the air as it approaches, and cauſe it to fall in rain, not in ſnow. And often in two places within a mile or two of each other, there ſhall be a diſparity of heat and cold no way elſe to be accounted for, ſince there is often no difference of ſhade or ſhelter.

In Scotland there are large tracts of land, where the ferment is ſo ſtrong, that the earth lets a perſon in up to the ankles as he walks; and generally, at about a foot depth under this, there is found a ſtratum of pebbles, ſo cloſe ramm'd together, that they ſeem an artificial cauſeway. This land, though of no greater depth than a foot, is found very rich for garden plants, and even for fruit-trees. Phil. Tranſ. N° 110.

FERMENTATION (*Cycl.*) is often confounded with *Effervescence*, but a great difference is made between theſe by the chemiſts.

Fermentation is that ſpontaneous inteſtine motion, which, in the degree of heat of the univerſal temperature of ſubterraneous caverns, will, in a few hours, bring on ſuch a change in vegetable juices, or in water charged with a ſtrong tincture of vegetable particles, (for *fermentation* is confined to the vegetable kingdom ſolely) as from a vapid muſt or wort quenching fire, to make it become more or leſs inflammable, as it is impregnated with more or fewer of the vegetable particles, and in the alembic to afford that volatile, ſubtil, inflammable liquor commonly called vinous ſpirit. The heat produced by *fermentation* never exceeds that of the human body. Phil. Tranſ. N° 476. p. 474. ſeq. See EFFERVESCENCE.

The juices of plants are ſtrangely alter'd by *fermentation*, and are ſuſceptible of many, and thoſe very various changes from it. And it is not only the juices of fruits that are thus to be wrought upon, as thoſe of apples, pears, grapes, and the like, in the common way; but there is an artificial change to be made in the ſeeds of plants by what is called malting. And it is not grain alone that is thus to be wrought upon, but any other ſeed whatever may be made to yield its juices and virtues freely to water by this proceſs. The juices of roots alſo, for inſtance, that of liquorice, will be wrought upon in the ſame manner; and the juices of the bodies of trees, as of the birch, and the like. If in the month of March a hole be bored into the body of a birch-tree, and this hole be ſtopped with a cork, through the middle of which there is thruſt a quill open at both ends, the juices of the tree will drop out at the quill at the rate of a large drop every ſecond of a minute, and a great quantity will in fine be obtained in this manner. This liquor is not unpleaſant to the taſte, and looks tolerably clear, reſembling water into which a little milk had been ſpilt. There are many ways of *fermenting* this juice, by all of which it is converted into a ſort of wine. Theſe are well known; but there is another remarkable property in our maples, both the common ſmall kind, and the great one which we call the ſycamore: theſe being tapp'd in the ſame manner, will bleed freely in winter; and their juices, after a hard froſt breaks, will flow out in ſo copious a manner, as is ſcarce to be conceived. The willow, the poplar, and the wallnut-tree will all bleed alſo; and *fermentation*, of which their ſeveral juices are eaſily ſuſceptible, will turn them all into palatable and ſtrong wines.

Some of the proceſſes in chemiſtry ſeem to prove, that *fermentation* is not confined to animal and vegetable ſubſtances, but that minerals are alſo liable to ſomething of it. If an ounce of lead and an ounce of biſmuth be melted together in an iron ladle, and an ounce of quickſilver be heated in another ladle, and all three mixed together, this makes an amalgamation, which appears perfectly homogeneous, and paſſes through leather in a running form, without leaving any thing behind. But this mixture being ſuffer'd to ſtand quiet for ſome hours, a groſs matter will ſeparate from it by degrees, and float upon the reſt, which will now run eaſily through leather, and leave the groſs matter behind. Here appear all the requiſites of *fermentation:* 1. A fluid form. 2. An uniform matter. 3. An inteſtine motion; and, 4. An actual ſeparation of a groſſer matter leaving a thinner behind. *Shaw*'s Lectures, p. 139.

FERMENTED *Liquors.* All *fermented* liquors abound with an over-proportion of water; and if a very conſiderable quantity of it were taken away, they would become not only richer, but more durable, provided that ſo much of the aqueous humidity was retained, as was juſt ſufficient to preſerve the vinous conſiſtence, to keep the ſaline part fluid, and to retain the ſlimy and unctuous parts expanded and mixed among the reſt. But as an actual and truly ſaline matter abounds in wine and in vinegar, and that of an acid, auſtere, and tartarous kind; when the ſpirituous part is drawn away, the wine becomes ſurpriſingly more auſtere; and when a large quantity of the watery part is ſeparated, this ſuperabundant ſaline, tartarous matter coagulates into a cryſtalline form, and either falls to the bottom, or ſticks to the ſides of the cask. For the ſubtile, oily matter, which makes the ſpirituous part in wine, blunts and takes off from a tartarious acidity, in the ſame manner that the addition of ſpirit of wine blunts, ſheathes, and dulcifies the acid, corroſive parts of ſpirit of nitre in making the ſpiritus nitri dulcis. But this tartarious ſalt abounding alſo with an over proportion of ſo groſs and unctuous matter, cannot be diſſolved or diluted without a very large proportion of water, which being taken away, it preſently converts into dry and ſolid cryſtals, as is the known caſe of cream of tartar. Hence proceeds the effect before obſerved, that the auſterity and roughneſs of wine, are the more preſerved, the more the wine is deprived of its ſpirituous parts. This experiment is familiar in our kitchens where wine being burnt or boiled into ſauce, is found to have a much greater degree of auſterity, than the ſauce and wine had before it had undergone the action of the fire, and loſt its ſpirituous part.

When the water is even by diſtillation plentifully drawn off from wine, not of a terreſtrial and chalky, but of a tartareous nature, a beautiful tartar will be found to cryſtalize, among the remaining maſs, in a conſiderable proportion. But tho' this ſuperfluous water, that generally dilutes the wine and weakens its taſte might be advantageouſly ſpared from it, and it would then become much more rich and noble, and at the ſame time more ſmooth and ſoft, through the loſs of ſome conſiderable portion of its tartar; yet this ſeparation cannot be effected by diſtillation, becauſe that carries away other parts

as well as the water, and damages the whole, by taking off what ought to be the moſt carefully preſerved. The ſpirituous part is the life of all fermented liquors, it keeps the whole together, and in a manner embalms and renders them durable and not ſubject to corruption; it alſo in a great meaſure gives them that aromatic refreſhing and reſtorative virtue, and the beſt effects they have on the human body. Nor is this all, but the intimate and ſubtil union of this ſpirituous part with the reſt, is perfectly the ſole and entire cauſe of both the former effects, ſo that it by no means ſuffices to have the ſpirit barely preſent among the other parts, for then it might be drawn off and poured back again, without any damage to the wine; but the eſſential union is here diſſolved by taking it away, and can never be reſtored again by a ſimple reaffuſion. 'Tis therefore deſtructive of the end propoſed, thus to break and diſſolve the texture of the wine, and this entirely ſubverts and deſtroys its nature. This inevitably proves the caſe, whenever wine is evaporated or diſtilled, which conſtantly requires a degree of heat capable of raiſing water into vapour, and hence the ſpirituous part being greatly lighter than the aqueous, flies off together with it, or before it, and the wine is left diſſolved in its texture, and without its ſoul. Upon this, the remaining ſaline unctuous maſs is ſo diſturbed, as no longer to remain connected, but it becomes thick and turbid, and afterwards runs impetuouſly into a kind of corruption, attended with acidity and ropyneſs. All theſe circumſtances ſhew, that tho' the condenſing of wines by taking away their ſuperfluous humidity would be a very deſirable thing, yet it is by no means to be done by evaporation.

FERMENTING. In the *fermenting* of malt for the diſtilling the ſpirit, the meal of unmalted corn is found neceſſary to be mixed with the malt, to prevent its over *fermenting*, and throwing off the matter of the ſpirit; but as diſpatch is required in this caſe, a good quantity of yeaſt is added to quicken the *fermentation*, ſo that it may be finiſhed in two or three days. More yeaſt is to be added if the weather be cold, and leſs if it be hot: the reverſe of this is to be underſtood of meal, more of which, is to be added in hot weather to check, and leſs in cold to haſten the operation, which in the preſent caſe is deſigned to be violent, contrary to what ought to be obſerved in the *fermentation* of wines, where the ſlower the operation is performed, the better the liquor will prove, and this may indeed hold here alſo in a leſs degree, for it is poſſible to ferment the waſh ſo violently, that it ſhall ſoon end in putrefaction. *Shaw*'s Lectures, p. 216.

FERN, *Filix*, in botany. See FILIX.

The ſeeds of the ſeveral ſpecies of *fern* were wholly unknown to the antients. Swammerdam in his *Biblia Naturæ*, claims to himſelf the honour of having firſt diſcovered them; but it appears from Hook's works, that Dr. William Cole ſent an account of the ſeeds of ſeveral of the plants of this kind to that author, in 1669, whereas Swammerdam declares his diſcovery of them, to have been in 1673; ſo that it is plain that Dr. Cole's was prior to his by ſome years. Swammerdam is an author of that ſtrict probity, that there is no room to doubt, but that he ſpoke what he thought to be true; and it is even poſſible, that he might have diſcovered them ſooner than the time he mentions; but however that be, it appears from the later obſervations of the ingenious Dr. Miles, that his accounts are extremely accurate, and juſt. The ſeed-veſſels of the common *fern*, the Engliſh and foreign maiden-hairs, the wall-rue, harts-tongue and the like plants, are all alike in their general form, their only differences being in the ſize, and in their arrangement on the plants. The number or quantity of the ſeeds is very different in different plants, but Mr. Miles obſerves, that the fewer ſeeds there are in any ſpecies, there is always the more in quantity of a ſort of ſpungy or fungous matter, which forms a kind of tubercle, not unaptly reſembling what is called jews-ears, which ſeems a ſubſtance intended for the ſheltering the ſeeds.

In the female *fern* and Engliſh maidenhair, the whole ſurface of the leaf on the under ſide, ſeems covered with a congeries of ſeeds, ſo that they guard one another, and therefore have leſs occaſion for a covering of fungous matter of this kind; yet even on theſe plants when the ſeeds are fallen off, there are found ſmall membranes, a little curled, looking as if they had been raiſed with the edge of a fine penknife, from the ſkin of the leaf, not unlike the pieces of ſkin that are raiſed off from the hand, in the trying a penknife or other ſharp inſtrument. In the common male *fern*, there are found at the proper ſeaſon, ſeveral brown ſpots placed in a regular manner; theſe are of a pale brown colour, and are principally compoſed of this fungous matter, the ſeed-veſſels being ſmall and inſerted round it. Phil. Tranſ. N°. 461. p. 774.

Theſe ſeed-veſſels conſiſt of a ſtalk by which they are inſerted into the leaf; this repreſents an elaſtic cord, and is ſurrounded by a great number of annular ribs, reſembling the cartilages of the aſpera arteria, and indeed nothing in nature ſo exactly reſembles this cord or ſtalk, as the wind-pipe of a ſmall bird. This cord encircles the globular membranous pod wherein the ſeed lies, adhering to it, and dividing it into two hemiſpheres. See Tab. of microſcopical Objects, Claſs 2.

The pod is compoſed of a fine whitiſh membrane, ſomewhat like that which lines the inſide of a pea-ſhell; the ſeeds are irregular in ſhape, and of a reticulated ſurface. The moſt advantageous way of viewing this is to uſe the common microſcope for opake objects, putting on a ſmall magnifier, and laying the ſeeds with their capſules, &c. as taken from the back of the plant, on a piece of poliſhed ivory. The proper time of the year is in the beginning of September, and then if the plant be newly gathered, the ſeed-veſſels often burſt while they are under inſpection, and ſhew a very elegant appearance. The manner of this burſting of the pod, which is the method nature has taken for the ſcattering and diſperſing of the ſeed, is this; the cord becomes extended in ſome one part, and ſoon after breaks aſunder, this by expanding burſts the pod into two parts, and by continuing to expand itſelf as it departs from a curve, and approaches to a right line, it rends itſelf away from the globular pod, till it be at length wholly diſengaged from it; and then, as there can be no farther reſiſtance given to its expanding, it ſuddenly flies off, and with a ſort of jerk, becomes quite ſtrait at once. By this laſt action the capſules are ſhook, and the ſeeds are diſcharged out of them on the plate of ivory, in the ſame manner as the grains of wheat or barley, would be thrown out of a bowl placed on a table, by the ſhaking of the bowl. This is a beautiful phænomenon in the minute ſeed-veſſel of the *fern*, and is frequently ſeen when the ſeeds are freſh gathered, as then the cords and capſules are green and juicy, and the burſting goes on gradually; but when they are dry and criſp, there is nothing of this ſeen, for the burſting is inſtantaneous, and the ſeeds are toſſed ſo far by it, that none of them fall within the area taken in by the lens. When the pod and cord are but juſt ripened, they ſometimes are twenty minutes in burſting, and the whole method of the proceſs, is then diſtinctly and beautifully ſeen. This whole mechaniſm would be ſeen in a much more perfect and beautiful manner, if it were poſſible to get off the ſeed-veſſels from the leaves without injuring them in doing it; for the common way of getting them off, is by rubbing the leaves, and this muſt neceſſarily burſt a great number of them; in this method they are ſeen to fly off from the leaves in form of a fine duſt or powder, and often get into the pores of the skin and become as troubleſome as cow-itch. Philoſoph. Tranſ. N°. 461. p. 782.

FERN, in husbandry. The common *female fern* is a very miſchievous and troubleſome weed to the farmers, being very difficult to deſtroy, where it has any depth of ground to root in. Its root will often penetrate to eight foot deep, and ſpreading a great way, they will riſe again to the ſurface, and ſend up new plants at a conſiderable diſtance. In graſs land the beſt way of deſtroying it, is mowing the graſs, three times a year in Spring, in May, and in Auguſt. Dung and aſhes are very good manure for lands which abound with it, but the beſt of all things for deſtroying it, is urine. *Fern* cut up when the ſap is in it, and laid to rot upon the ground, is a very good manure for land, and will mellow it ſo as to prevent its binding. Trees planted where *fern* grows, are obſerved to thrive very much, even tho' it be upon a hot gravel; the reaſon of this is, that the *fern* ſhades the roots, and keeps them moiſt and cool. *Mortimer*'s Husbandry, p. 316.

The poor people in many parts of the north of England, uſe aſhes of *fern* inſtead of ſoap, for waſhing their clothes; they cut the plant green, and then burn it to aſhes, and make them up into balls with water; they dry theſe in the ſun, and keep them ready for uſe. Scotch ſheep put into a land where there is much *fern* growing among the graſs, generally deſtroy it in a little time, partly by their dung and urine, and partly by treading it down.

FERNS, in medicine. All the ſpecies of *fern*, and other vegetables, which carry their ſeeds on the back of their leaves, as moonwort, and the like plants, poſſeſs the ſame general virtues of drying and ſtrengthening the viſcera, eſpecially the ſpleen.

Dwarf FERN. See FILICULA.

FERN-*aſhes*. The aſhes of the common *female fern* produce a very ſingular phænomenon in the common way of treating them and their ſalt. If a large quantity of theſe aſhes are procured, and the ſalt to the quantity of ſeveral pounds extracted from them in the common way, it will ſucceed better than in ſmaller quantities. The greater part of this ſalt being dried, if the remainder, which is more moiſt, be expoſed to the air to receive ſome of the vapours of it, this will ſoon become fluid, or an oil, as it is very improperly called by deliquium. The reſt of the lixivium, which will be very heavy, and of a deep blood-red, or claret-colour, being ſet by in a glaſs veſſel unſtopped for five or ſix months, there will be found at the bottom of the liquor, a very large quantity of ſalt precipitated to the thickneſs of about two inches of the bottom of the veſſel. The lower part of this will have all the foulneſs, and appear diſcoloured; but the upper part will be extremely pure and white. From the ſurface of this part, there will grow up a number of plants, in appearance ſtanding erect, and at ſmall diſtances from one another. Theſe are only the laſt cryſtallizations of the ſubſiding or ſeparating ſalt, but they have a regularity that is very ſurpriſing, they vary conſiderably in ſize and weight, but are all of the ſame ſhape, exactly reſembling

ſembling ſo many plants of the common unbranched *fern*, ſending out a great number of regular leaves on each ſide the ſtem. Theſe ramifications of the ſalt, will remain many weeks in this perfection if the veſſel be not ſtirred; but they are ſo tender, that the leaſt motion deſtroys them, and they after this, never will form themſelves again. Phil. Tranſ. N°. 105.

FERN-*oil*, in pottery, a name given by our merchants who have been in China, to a ſort of varniſh, which the Chineſe uſe in their porcelain manufactories. It is alſo called lime-oil, and is a thing ſo eaſily made, that it would be worth attempting what might be done with it, in our imitations of the porcelain. They make it in this manner; they take a large quantity of *fern* well dried, and ſpreading a covering of it over a piece of ground ſufficient for the quantity of oil they intend to make, they lay upon this a coat of large lime-ſtones, newly calcined into lime; on theſe they ſprinkle with the hand a ſmall quantity of water juſt to ſlake them. They cover this bed of lime with another of *fern*, and ſo on, till they have raiſed it to eight or ten foot high; they then ſet fire to the *fern*, this burns away in a little time, and leaves a mixture of the lime and its own aſhes. This mixture is laid in the ſame manner between beds of more *fern*, and burnt again. This operation is repeated five or ſix times. Obſerv. ſur les coutom. de l'Aſie.

When the laſt calcination is finiſhed, the mixture of lime and aſhes is carefully gathered up and thrown into large veſſels of water, and with every hundred weight of it, they put in one pound weight of kekio; they ſtir the whole together, and when the coarſer part has ſubſided to the bottom, they take off the finer which ſwims at the top in form of a fine cream, and putting it into another veſſel of water, they let it ſubſide to the bottom by long ſtanding; they then pour off the water and ſave the reſiduum in form of a thick oil.

This they mix with the oil of ſtone, prepared by powdering and waſhing in the ſame manner a particular ſort of ſtones, and with this they cover all the veſſels that they intend to varniſh. The *fern* aſhes have a very great ſhare in the advantage that this oil has over our common varniſhes; and the Chineſe tells us, that they once inſtead of *fern* uſed the wood of a tree, called ſe tki, and they ſuppoſe that the ſuperiority of the old porcelain over the preſent, is owing to the uſe of this tree inſtead of the *fern*; but is now too ſcarce among them. The new manufacture which we have at Briſtol, excels every thing that has been done of the like kind, in the beauty of the varniſhing; and it is ſaid, they have founded their advantage on an imitation of this, and the Chineſe oil of ſtone. Theſe two oils, as they are called, are always mixed together, and they muſt be carefully preſerved of the ſame degree of thickneſs, or elſe all the varniſhing will not be even.

FERN-*root*, was frequently preſcribed by the antients in diet-drinks, for removing obſtructions, and in chronic caſes of all kinds; but it is much diſuſed at preſent. The country people, indeed, eſteem it a ſovereign remedy for the rickets in children; they alſo give it in powder to deſtroy worms.

FEROENSIS *marga*, in natural hiſtory, a name given by ſome authors to a marley earth, found principally in the fiſſures and cavities of ſtone, and called by the generality of later naturaliſts, *agaricus mineralis*, and *lac lunæ*, and by the antients, *terra* or *creta ſeleneuſiaca*. *Hill*'s Hiſt. of Foſſ. p. 48. *Charlton* of Foſſ. p. 48. See LAC *Lunæ*, *Cycl.* and *Suppl.*

FERRA, in zoology, the name of a fiſh, called alſo by ſome *guiniad*, and caught both in the lakes and rivers. It is of the truttaceous kind, and is uſually of a foot or a little more in length, and in the ſhape of its body much reſembles the ſalmon. Its back is brown, its belly white, its ſcales are of a moderate ſize; its upper jaw hangs a little over the under, and its mouth is very like that of the common herring; it has no teeth, the belly is ſomewhat flatted, not running to an edge, the top of the head is of a faint blue, full of dusky ſpots; the eyes are very large, and there is on each ſide a ſtrait line running from the angle of the gills to the tail; the tail is forked. It is a very well taſted fiſh, and uſually is ſeen ſwimming in large ſhoals. Pimble-meer in Merionethſhire, is the place where the greateſt quantities of it are taken, but it is alſo caught in Cumberland, and ſome of the northern counties of England, and called there the ſchelley. *Willoughby*'s Hiſt. Piſc. p. 183.

FERRARIA, in botany, a name uſed by ſome authors for agrimony, and by others, in particular by Lobel, for the ſcrophularia, or fig-wort. *Ger. Emac.* Ind. 2.

FERRET, *viverra*. This creature has but one note in her voice, which is a ſhrill, but ſmall whining cry. The female uſually brings forth ſeven or eight young ones at a time; ſhe carries them in her body forty days; the young ones are blind for a long time after they are littered. When they are tamed they are to be fed with milk, and with barley-bread; they will faſt a long time; when they walk they ſet up their back, which is otherwiſe ſo long, that it would be troubleſome to drag it on; when they are touched they ſmell very diſagreeably; they naturaly ſleep very much. The *ferret* is a bold and audacious animal, and is an enemy to almoſt all others, It does not eat the fleſh of the creatures it kills, but ſucks their blood.

When the warrener has occaſion to uſe the *ferret* to catch rabbets, he firſt makes a noiſe in the warren to frighten them all into their holes, then he pitches his nets, and having muzzled the *ferret* that he may not bite the rabbets, he turns him into their holes to frighten them out, and then the dogs drive them into the nets that are ſet for them. See VIVERRA.

FERRETS, in glaſs making, the irons with which the workman tries the melted metal to ſee if it be fit to work.

It is alſo uſed for thoſe irons which make the ring at the neck of bottles. *Neri*'s Art of Glaſs, Appendix.

FERRETES *d' Eſpagne*, in natural hiſtory, a name given by authors to certain ſtones of a regular figure, found on the ſides of a rock in Spain; and, as has been ſince diſcovered, very plentifully on the bottom and ſides of the Fontaine de Salut, near Bagneres in France, and in other places in the country thereabout. In the firſt bath through which the largeſt of the two branches of this ſpring flows, there are found at different times great numbers of theſe *ferretes*: they are ſmall ſtones of the colour of ruſty iron, and of a regular figure, being either parallelopiped with oblique angles, of which the ſides are unequal, or ſmall ſolid bodies with ſix ſides, only differing from cubes or dice in this, that the ſurfaces are not perfectly perpendicular to one another, but a little inclined; they are alſo commonly longer than they are broad, and broader than they are high. The largeſt of theſe fall ſhort of an inch in meaſure, being about eleven lines in length, nine and a half in breadth, and ſix in heighth, but they are uſually a great deal ſmaller, and are ſometimes found in cluſters, a hundred or more together; and ſome of them have ſhining ſkins ſeeming of a metallic ſubſtance. Theſe ſtones are not only found in the bath, but in the digging a way for a common road, from the town of Bagneres to it, they were found lodged in their proper ſtratum. The workmen here met with a bed of a ſoft kind of ſlate of a bluiſh colour, but lighter than that of the common ſlate. The whole rock they worked through, was compoſed of layers or beds of this, lying almoſt parallel over one another. The ſubſtance of the ſlate ſeemed to be a compoſition of fibres or ſtrings, laid regularly ſide by ſide, by one another, and all equally inclined to their beds or layers. Whence it comes that upon breaking them with a hammer, the pieces ſometimes are pretty like the figure of a regular parallelopiped with oblique angles. Upon a narrower examination of this ſort of ſlate, there are uſually found in it, a great number of parallelopiped ſtones, like thoſe before ſpoken of, only ſmaller; and ſeveral little black ſpots diſcovered in other parts of the ſtone when they are examined with glaſſes, prove alſo to be regularly figured bodies of the ſame kind.

Every one of theſe ſtones ſo long as it remains in the rock, is always found between two bundles or cluſters of tranſparent fibres, of which generally one is placed on the one, and the other on the oppoſite ſide; theſe cluſters of fibres are largeſt in the largeſt ſtones, however they are always found even about the ſmalleſt in ſome quantity.

In ſome of theſe ſtones, the tranſparent fibres of which every cluſter is compoſed, have left a vacancy in the middle of themſelves; this ſort of fiſſure being coloured with a ferrugineous matter, and now and then with metallic and ſhining veins, it is not a very improbable conjecture, that the uſe of the tranſparent fibres is that of ſtrainers, which ſuffer nothing to paſs through them to the little ſtones, but ſuch particles as are proper to advance their growth. In pieces of a harder ſlate near the ſame place, there are alſo frequently found ſmall ſtones of the ſame figure but of a braſſy colour, theſe alſo are attended with the like cluſters of tranſparent fibres. Philoſ. Tranſ. N°. 472. p. 30.

Great quantities of ferrugineous ſtones are alſo found in large maſſes in all the rocks about the fountain de Salut; and it is very probable, that the water of this ſpring, runs through a bed of this ſort of ſoft ſlate before deſcribed, in which theſe regular ſtones are lodged, and from which it may very eaſily looſen and detach them in its paſſage, and ſo bring them along with it. The bundles of tranſparent fibres are faſtened very firmly to the ſlate, but very ſlightly to the ſtone that they ſurround; whence it is very evident, that if theſe ſtones are thus detached by the water, they muſt come alone, not with that matter joined to them.

FERRETTO, in the glaſs trade, a ſubſtance which ſerves to colour glaſs. This is made by a ſimple calcination of copper, but it ſerves for ſeveral colours. There are two ways of making this: the firſt is this, take thin plates of copper, and lay them on a layer of powdered brimſtone, in the bottom of a crucible, over theſe lay more brimſtone, and over that another layer of the plates, and ſo on alternately, till the pot is full. Cover the pot, lute it well, place it in a wind furnace, and make a ſtrong fire about it for two hours. When it is taken out and cooled, the copper will be found ſo calcin'd, that it may be crumbled to pieces between the fingers, like a friable earth; it will be of a reddiſh, and in ſome parts a blackiſh colour. This muſt be powdered and ſifted fine for uſe. *Neri*'s Art of Glaſs, p. 30.

The other way is leſs eaſy, but it makes a more valuable *ferretto*. It is this; make a number of ſtratifications of plates of copper and powdered vitriol alternately in a crucible, which place on the floor of the glaſs furnace near the eye, and let it ſtand there three days, then take it out, and make a new ſtratification with more freſh vitriol, and calcine it again as before, repeat this operation ſix times, and a moſt valuable *ferretto* is produced.

FERRIFIC *cauſe*, a term uſed by ſome writers to expreſs that principle, to which what they call the production or generation of iron in burnt bodies, in which no iron could be diſcovered before burning, is owing. It is the general opinion of the preſent philoſophers, that this iron thus diſcovered in the aſhes of plants, and the like burnt ſubſtances, really exiſted there before, and only needed the diſunion of the concreted body, to the bringing of its parts together. If this be the caſe, there is evidently no production of iron in the caſe, and therefore the term *ferrific* is a word without meaning. Becher however, in his ſupplement to his Phyſica Subterranea, is of a very different opinion, determining, that the iron is really produced in theſe caſes, during the action of the fire; and that by the tranſmutation of ſome other matter into iron; and from this he argues the poſſibility of gold-making among chymiſts by tranſmuting ſomething elſe into gold, as ſome other ſubſtance is in this caſe tranſmuted into iron.

The experiments he has given us accounts of to prove this *ferrific* cauſe or principle, were made with brick-earth, a ſubſtance which he ſuppoſes to contain no iron in its native ſtate, any more than a plant or an animal does. He took common brick-earth, and after drying, powdered and ſifted it, then mixing it with as much linſeed oil as ſerved to make it into paſte, he rolled it up in little balls, and put them into a retort; the retort being filled with theſe balls, the diſtillation was made in an open fire for two hours.

The diſtillation being finiſhed, there was found in the receiver a quantity of oil, of the nature of the oleum philoſophorum, and the balls being poured out of the retort, were found to be black, not red, as would have been the caſe if the clay had been burnt alone in an open fire. Theſe balls were then beaten to powder, and the powder thoroughly wetted with common water, and finally as much water added to this paſte, as made it thin and fluid. The heavy matter was ſuffered to ſettle, and the turbid water poured off, and this repeated with freſh water ſo often till the liquor came off clear. The earthy part being thus waſhed away, there remained at the bottom of the veſſel a heavy blackiſh powder which being dried and laid upon a paper, was found to be in great part attracted by the loadſtone, that is, a conſiderable part of it was real iron.

Having thus produced iron where he ſuppoſed there was none before, and eſteeming from this, that the ſulphureous ſpirits may be fixed by a certain earth as their matrix; he uſed the ſame method with a great number of other minerals, ſulphur's and mercury itſelf, and accordingly melted various minerals with various earths and clays, and as he aſſures us, by theſe experiments diſcovered many real tranſmutations.

The truth of all the reſt, ſeems to depend on the exactneſs of this firſt experiment with the brick clay; and the whole that can be deduced from that falls to the ground, if there be any ferrugineous matter contained in either the oil or the earth: the oil need not be enquired into; but it being the general opinion of the world, that common brick earth, always contains iron, it will be neceſſary to invalidate that received opinion, before any thing can be judged from the experiment, which ſeems only to prove, that fire does to this earth, what it does to an ore.

Many even of the richeſt ores of this metal not at all anſwering to the magnet in their crude native ſtate, and even the pooreſt doing this in part after having paſſed the fire, it may poſſibly be found on experiment, that common brick clay is a poor iron ore; but experiments only muſt be the proof of this.

FERRUGINOUS *waters*. See STEEL *Waters*.

FERRUM *Equinum*, *horſe-ſhoe vetch*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the papilionaceous kind; its piſtil which ariſes from the cup, finally becomes a flat pod, divided into ſeveral lunated articulations, and in ſome degree reſembling a horſe-ſhoe, containing ſeeds of the ſame form.

The ſpecies of *horſe-ſhoe vetch* enumerated by Mr. Tournefort, are theſe: 1. The *horſe-ſhoe vetch*, with ſingle pods. 2. The *horſe-ſhoe vetch*, with many pods on the ſame pedicle. 3. The German *horſe-ſhoe vetch*, with pods growing on the tops of the branches. *Tourn.* Inſt. p. 480.

FERTILITY (*Cycl.*) — Nothing can produce *fertility*, in either ſex, but what promotes perfect health; nothing but good blood, ſpirits and perfect animal functions, that is, high health, can beget perfect fecundity; and therefore according to Dr. Cheyne, all means and medicines, all noſtrums and ſpecifics to procure fertility, different from thoſe which procure good blood, and ſpirits, are errant quackery and cheating. He ſays that water drinking males, are very rarely infertil; and that if any thing in nature can prevent *infertility*, and bring fine children, it is a milk and ſeed diet, perſevered in by both parents. See Nat. Meth. of curing, p. 281, 287.

FERULA, (*Cycl.*) *fennel giant*, in botany, the name of a genus of the umbelliferous plants, the characters of which are theſe:

The flowers are of the roſaceous kind, being compoſed of ſeveral leaves arranged in a circular order on a cup which afterwards becomes a fruit compoſed of two very large flat and thin ſeeds of an oval figure, which often depoſit their covering. To this it is to be added, that the leaves are either like thoſe of fennel, or broader, and then reſembling thoſe of parſley.

The ſpecies of *ferula* enumerated by Mr. Tournefort, are theſe: 1. The female *ferula* of Pliny, with broad and rounded ſeeds. 2. The galbaniferous *ferula*, called alſo *ferulago* by ſome authors. 3. The blueiſh green leav'd *ferula*, with a broad oblong ſeed, called by ſome thapſia ferulacea. 4. The ſmaller *ferula*, with flowers at every joint, called by ſome the fennel leav'd libanotis. 5. The finer leaved *ferula*. 6. The Spaniſh *ferula*, with ſhining leaves. 7. The *ferula* with narrow and ſhining leaves. And 8. The hard and harſh *ferula*, with ſhort and rigid leaves. *Tourn.* Inſt. p. 320.

FERULÆ, a word uſed by the antients to expreſs the horns growing on the deer or ſtag, at the age of two years. Theſe horns are at this early time unbranched, and ſome have ſuppoſed, that Pliny meant by the word ſubulo, the deer in this ſtate; but as he ſays, that nature has given the *ſubulo* ſimple or unbranched horns, he certainly means it of the horns as they always remain on the animal, not as they are for a time, as in this caſe. It is plain, that ſome of the antient Latin writers, have called the young ſtag, ſubulo; but others, and indeed authors in general mean a wholly different creature by this name; and ſome have ſo far miſtaken Pliny's expreſſion of cornua ſimplicia, which he attributes to the ſubulo, as to ſuppoſe he meant, that each of theſe animals had only one ſingle horn, and therefore have made it a name for the unicorn. Pliny ſays, that the ſubulo is of the ſame genus of animals with the ſtag; but he does not mean by this, that it is the ſame ſpecies, for if he had, he would have expreſſed himſelf ſo. No one would call a calf a creature of the ſame genus of animals with the bull, or a colt a creature of the ſame genus with a horſe, but would naturally ſay, they are the young of that animal.

FERULACOLI, in botany, a name by which ſome authors have called the thlaſpi, or treacle muſtard. *Ger. Emac.* Ind. 2.

FERULAGO. See FERULA.

FERZAA, in natural hiſtory, a name given by the Perſians to that gem, which we call the turguoiſe or Turkey ſtone; a blue opake and ſoft gem.

FESSIER, in anatomy, the name given by the French writers to what others call the glutæus, or according to Riolanus, the glautius. There are three muſcles of this name among authors, the glutæus major, medius; and minor, and the French call them the grand, moyen, and petit *feſſier*.

FESTA *in cappis*, in middle age writers, grand holidays, in which the whole choir of cathedrals wore caps.

FESTING *men*. See FASTERMANS, *Cycl.*

FESTING-*penny*, earneſt given to ſervants when hired or retained. It is ſo called in ſome northern parts of England, from the ſaxon *feſtnian*, to faſten or confirm.

FESTUCA, in the Linnæan ſyſtem of botany, the name of a kind of oat graſs, which makes a diſtinct genus of plants; the characters of which are, that the calyx is a many flowered glume, and is bivalve, erect, and contains the flowers ranged together in a ſlender ſpike; the valves are ſtrait, oblong, pointed, without awns or beards, and the lower is the ſmaller. The flower is compoſed of two valves, the lower is the larger, this is of the ſhape of the cup, but it exceeds it in ſize, it is ſomewhat cylindrical and pointed, and is terminated by a ſtrait beard or awn. The ſtamina are three capillary filaments, ſhorter than the flower, the antennæ are oblong; the Germen is of a turbinated form, the ſtyles are two in number, and are ſhort and bent backward, the ſtigmata are ſingle, the flower cloſely ſurrounds the ſeed, which is ſingle, oblong, ſlender, extremely ſharp pointed at each end, and marked with a longitudinal furrow. *Linnæi* Genera Plantor. p. 15.

FEUDAL (*Cycl.*) — As the northern nations brought in the uſe of coats of arms by preſerving down in their families, the armorial bearings of their anceſtors ſhields, &c. as hereditary marks of honour, ſo they alſo brought in the *feudal* law, by means of which, arms grew up to farther perfection, as is evident by many armorial figures of antient families, repreſenting the acknowledgements and ſervices they were obliged to perform to their own lords and ſuperiors.

Thus roſes, cinquefoils, ſpur-rowels, bows and arrows, hunting-horns, ſhips, and the like figures, were expreſſive of the ſervices they were bound to do their lord, and hence theſe figures have become common in arms throughout all Europe.

For

For inſtance, the old barons of Arran and Lorn were obliged to furniſh their lord with a ſhip in time of war; and thence, it is that their arms carry ſhips or lymphods to this time.

FEVE, in natural hiſtory, a name firſt given to the chryſalis of the ſilk-worm, and from thence to all chryſaliſes of the butterfly kind; in which ſenſe it is now received and uſed with the moſt accurate writers, and made a ſynonymous term with the word chryſalis and aurelia. See the article WEB-*caſe*.

The caterpillar putting off its own form to appear in this, and the expanding of this into the butterfly, have been ſuppoſed ſudden changes of one animal into another; but this is a very incorrect way of thinking, for each of theſe is the ſame animal in its different ſtages of growth. We call the creature hatched from the egg of a butterfly, a caterpillar; and it goes under this name till the chryſalis ſtate, but it is eaſy to ſee that this creature is a butterfly all the time under the maſk of a caterpillar. We know that the caterpillar changes its ſkin four or five times during its living in that ſtate, and that all theſe ſkins are at firſt produced with it from the egg, lying cloſely over one another. It parts with or throws off all theſe one by one, as the butterfly, which is the real animal all this time within, grows more and more perfect in the ſeveral firſt changes. When it throws off one, it appears in another ſkin of exactly the ſame form; but at its final change from this appearance, that is, when it throws off the laſt ſkin, as the creature within is now arrived at ſuch a degree of perfection as to need no farther taking of nouriſhment, there is no farther need of teeth, or any other of the parts of a caterpillar. The creature in this laſt change, proceeds in the very ſame manner as in all the former, the ſkin opening at the back, and the animal making its way out in this ſhape. If a caterpillar when about to throw off this laſt ſkin, be thrown into ſpirit of wine, and left there for a few days, the membranes within will harden, and the creature may be afterwards carefully opened, and the chryſalis taken out, in which the form of the tender butterfly may be traced in all its lineaments, and its eyes, legs, &c. evidently ſeen. It is not neceſſary however to ſeize upon this exact time for the proving the exiſtence of the chryſalis or butterfly in the caterpillar, for if one of theſe animals be thrown into ſpirit of wine, or into vinegar, ſome days before that time, and left there for the fleſh to harden, it may afterwards be diſſected, and all the lineaments of the butterfly traced out in it; the wings, legs, antennæ, &c. being as evident here, and as large as in the chryſalis. *Reaumur*'s Hiſt. Inſect. v. 1. p. 2, 28.

It is very plain from this, that the change of the caterpillar into a chryſalis is not the work of a moment, but is carrying on of a long time before, even from the very hatching of the creature from the egg. The parts of the butterfly are not however diſpoſed in exactly the ſame manner while in the body of the caterpillar, as when left naked in the form of the chryſalis; for the wings are proportionably longer and narrower, being wound up into the form of a cord, and the antennæ are rolled up on the head; the trunk alſo is twiſted up, and laid upon the head; but this in a very different manner from what it is in the perfect animal, and very different from that which it lies in within the chryſalis; ſo that the firſt formation of the butterfly in the caterpillar by time arrives at a proper change of the diſpoſition of its parts, in order to its being a chryſalis.

It is plain, that the butterfly is, in all its parts, in the caterpillar, in all its ſtates; but that this becomes more eaſily traced, as it grows nearer to the time of the chryſalis. The very eggs hereafter to be depoſited by the butterfly are alſo to be found not only in the chryſalis, but in the caterpillar itſelf, arranged in their natural, regular order. They are indeed in this ſtate very ſmall and pellucid; but after the change into the chryſalis, they have their proper colour.

As ſoon as the ſeveral parts of the butterfly therefore are arrived at a ſtate proper for being expoſed to the more open air, they are thrown out from the body of the caterpillar, ſurrounded only with thin membranes; and as ſoon as they are arrived after this at a proper degree of ſtrength and ſolidity, they labour to break through theſe thinner coverings, and to appear in their proper and natural form. The time of their duration in this ſtate of chryſalis is very uncertain, ſome remaining in it only a few days, others ſeveral months, and ſome almoſt a year in appearance. But there is a fallacy in this, that many are not aware of. It is natural to think, that as ſoon as the creature has incloſed itſelf in its ſhell, be that of what matter it will, it undergoes the change into the chryſalis ſtate. And this is the caſe with the generality; yet there are ſome which are eight or nine months in the ſhell before they become chryſaliſes, ſo that their duration in the real chryſalis ſtate is much ſhorter than it naturally appears to be. When they arrive at the time of their quitting this ſtate, or throwing off this laſt envelopement, the operation is much leſs different than that of the leaving the caterpillar ſtate to appear in this. The change of the chryſalis into the butterfly is always made within the ſhell that covers it. In many ſpecies therefore, in order to ſee in what manner it is performed, one of theſe muſt be carefully taken out of its ſhell; or elſe one of the angular ones choſen, which have no ſhell at all, but hang themſelves by the tail naked to a beam, or other thing; or, finally, one of thoſe which are only covered with a few looſe hairs inſtead of a ſhell: in this caſe, a little attention will ſhew the whole progreſs of the change. Mr. Reaumur carefully watched the auriculated caterpillar of the oak into its ſeveral changes, and particularly from its chryſalis, which is of this laſt kind, into the fly; and has given an account of the method of this, as an inſtance of the general courſe of nature in theſe operations.

The membranes which envelope the creature in this chryſalis ſtate are at firſt tough and firm, and immediately touch the ſeveral parts of the incloſed animal; but by degrees, as theſe parts harden, they become covered, ſome with hairs, and others with ſcales. Theſe, as they continue to grow, by degrees fall off the ſeveral particular membranes which cover the parts on which they are placed, to a greater diſtance, and by degrees wholly looſen them from the limbs. This is one reaſon of thoſe membranes drying and becoming brittle.

There is alſo another, which is, that the inſide of this whole caſe was at firſt full of a viſcous liquor, which kept it moiſt and ſupple; but in the progreſs of the growth of this animal, the liquor is all received into its veſſels, and the skins are left quite dry. When by theſe means the parts of the butterfly have grown to their due ſtrength, and the membranes have at the ſame time grown extremely weak and thin, it is no difficult matter for the creature, at a proper time, to make its way through them. Every time that it moves, though ever ſo little, any of its limbs, or ſwells out any other part of its body, it occaſions the membranes to burſt and crack at once in ſeveral different places; and the ſame motions continued or repeated, occaſion the aperture to enlarge by degrees, till at length it is big enough for the whole limb; and, finally, for the whole animal to come out at. But it is remarkable, that the places in which the ſhell breaks are always the ſame in the ſame ſpecies; and that they are always formed by a number of cracks begun in the ſame place, and propagated in the ſame direction.

On the back of the chryſalis there is always a part called the corcelet, which is not divided into rings in the manner of the reſt of the body, but is formed of one ſimple flat cruſt. This part is larger in ſome ſpecies, and ſmaller in others: but in all it ariſes from the upper rings of the back, and terminates at a part of the ſummit of the chryſalis, which may be called its front. The firſt of theſe parts is placed over the corcelet of the butterfly, the latter or front over its eyes and antennæ. The corcelet joins itſelf on each ſide to the membrane that covers the wings. It ſeems indeed to be prolong'd to the belly, and folded over it. The belly of the chryſalis is that part of it which is contained between the wings and the forehead, reaching down to the part where the bottoms of the wings croſs over one another, or at leaſt where they meet. This part contains the legs, antennæ, and trunk of the inſect, all extended at full length. See AURELIA. The French call that part of the membrane which covers the belly, the breaſt piece. In order to deſcribe the manner in which the chryſalis is open'd to let out the butterfly, it is neceſſary to know theſe ſeveral parts of it under diſtinct names.

The middle of the upper part of the corcelet is uſually marked with a line, which runs in a longitudinal direction; and this part is always more elevated than the reſt, even in the conic kinds, which are no otherwiſe angular. This line is in ſome very bold and plain, in others it is ſo faint as not to be diſtinguiſhable without glaſſes; but it is always in the midſt of that line that the ſhell begins to open. The motion of the head of the butterfly backwards firſt occaſions this crack, and a few repetitions of the ſame motions open it the whole length of the line.

A very gentle motion ſerves to this purpoſe; and when the corcelet is by this means divided into two pieces, the crack becomes much wider, and ſhews a thin down that covers the body of the butterfly. After this the piece, which makes the front of the chryſalis, ſplits into two pieces in the ſame manner; and after this the corcelet is ſeparated at its edges, and the front at its anterior part from the breaſt piece, and this hangs only by its point. Thus is an opening found for the creature's getting out: this had not been worthy ſo particular a deſcription, but that it is always regularly the ſame in all reſpects.

As theſe cracks between the ſeveral pieces enlarge with thoſe in their midſt, they ſhew more and more of the body of the animal; and as the leaſt force imaginable is ſufficient to ſeparate entirely parts which hang together ſo very ſlightly as theſe ſeveral pieces now do, the creature in moving itſelf ever ſo gently upwards makes its way out.

The clearing itſelf however entirely is a work of more time in this caſe, than is the paſſing of the chryſalis out of the body of the caterpillar. In that caſe there is a crack ſufficiently large in the ſkin of the back, and the whole chryſalis being looſe comes out at once. But in this caſe every particular limb, and part of the body, has its ſeparate caſe; and though theſe are almoſt inconceivably thin and tender, yet it is neceſſary

ceſſary that every part be drawn out of them before it appear naked to the open air. As ſoon as all this is effected, and the animal is at full liberty, it either continues ſome time upon the remains of its covering, or creeps a little way diſtant from it, and there reſts. The wings are what we principally admire in this creature. Theſe are at this time ſo extremely folded up, and placed in ſo narrow a compaſs, that the creature ſeems to have none at all; but they by degrees expand and unfold themſelves, and, finally, in a quarter of an hour, or half an hour at the utmoſt, they appear at their full ſize, and in all their beauty. The manner of this ſudden unfolding of the wings is this: the ſmall figure they make when the creature firſt comes out of its membranes, does not prevent the obſerving that they are at that time conſiderably thick. This is owing to its being a large wing folded up in the niceſt manner, and with folds ſo arranged, as to be by no means ſenſible to the eye, for the wing is never ſeen to unfold; but when obſerved in the moſt accurate manner, ſeems to grow under the eye to this extent. When the creature is firſt produced from the ſhell, it is every-where moiſt and tender, even its wings have no ſtrength or ſtiffneſs till they extend themſelves; but they then dry by degrees, and with the other parts become rigid and firm. But if any accident prevents the wings from expanding at their proper time, that is, as ſoon as the creature is out of its ſhell, they never afterwards are able to extend themſelves, but the creature continues to wear them in their contracted and wholly uſeleſs ſtate; and very often when the wings are in part extended before ſuch an accident happens, it ſtops them in a partial extenſion, and the creature muſt be contented to paſs its whole life with them in that manner.

FEVER (*Cycl.*) — Riverius reckons above thirty different kinds of *fevers*, and Sydenham has increaſed them to double that number; but certainly phyſicians have obſerved ſomething common to all theſe diſeaſes, which made them denominate them *fevers*. A late author thinks, that the conſideration of what conſtitutes a *fever*, which he thinks very ſimple and obvious, with its true cauſes and genuine effects, will give a more juſt and clear notion of the diſeaſe, and lead to a more rational practice, than all that has been ſaid by authors at ſo great length on theſe ſubtile and unneceſſary diſtinctions. He thinks the moſt natural and uſeful diviſion of *fevers* is into continued and interrupted; and he conceives they may all when conſidered ſimply, and not as the effect of another diſeaſe, be reduced to one or other of theſe two ſorts. Medic. Eſſ. Edinb. vol. 1. p. 264, 265.

In every *fever* from an internal cauſe, the three chief obſervables are theſe. Firſt, an univerſal trembling, and then an encreaſed heat, and quick pulſe; a *fever* almoſt always begins with a cold or ſhivering, and ſoon after the pulſe growing quicker, affords the primary diagnoſtic of a *fever*. The health of the patient ſeems to be the primary aim of nature in *fevers*, tho' they often terminate in death.

The general cure of *fevers* is comprehended in conſulting the ſtrength of nature, in correcting and diſcharging the acrimony of the blood, in diſſolving groſs humours, and expelling them, and in mitigating the ſymptoms. If the ſymptoms run too high, and nature grows exorbitant, abſtinence, ſmall liquors, bleeding and cooling clyſters are to be uſed; and if nature be too ſluggiſh, ſhe muſt be excited by cordials and aromatics. *Allen*'s Synopſis, p. 6.

By Dr. Brown Langriſh's ſtatical experiments made on the blood of people in acute continual *fevers*, compared with what he ſays of the blood of three young men in perfect health; it appears that in ſuch *fevers*, the ſerum is in leſs proportion, and the craſſamentum is more viſcid and tenacious, than in health. The indications of cure from which are plain. See his *Modern Theory and Pract. of Phyſ.* p. 68. and 74.

By the chemical analyſis, it is proved, that in acute *fevers* the ſaline and ſulphureous parts abound more than in health; and that the urine is impregnated more and more with theſe ſaline and ſulphureous principles, as the ſymptoms abate upon a criſis by urine. Ibid. p. 80, 94.

Signs of FEVERS. Theſe are an accelerated progreſſive motion of the blood, diſtinguiſhed by the quickneſs of the pulſe; this is ſucceeded by an increaſed heat in the body, and immediately after this, the tonic motion of the parts is either conſtringed or relaxed. This is ſeen in the face; in the firſt caſe it becomes red and bloated, in the latter thin and pale: theſe ſymptoms are ſucceeded by an immoderate thirſt, and a loathing of food of all kinds, an abſence of ſleep, and a peeviſhneſs or uneaſineſs in the temper, with an extreme ſenſibility of every thing, and a neglect of the common buſineſs of life; after this there is a great loſs of ſtrength, and an inaptitude to any motion; a ſenſation of pain in ſome part; a very uneaſy and difficult reſpiration, a ſweating more than uſual, and finally there is a change in the urine, its colour being uſually very high, and its conſiſtence thicker, than that of perſons in health.

Cauſes of FEVERS. Theſe are an overheating the blood by exerciſe, and thus throwing it into violent commotions; violent and ſudden cooling of the body when very hot; the abuſe of ſpirituous liquors, and the eating large quantities of foods hard of digeſtion; a watchfulneſs beyond the uſual cuſtom, ſuch as long ſitting up by the ſick, or the like; and a ſuppreſſion of any accuſtomed evacuation, particularly of habitual hæmorrhages by the noſe or other parts. Beſide theſe the paſſions of the mind very frequently throw people into *fevers*; and it is obſerved alſo, that perſons often accuſtomed to have *fevers*, are much more eaſily thrown into them on ſlight accidents, than any others. To all theſe cauſes, is to be added that of contagion.

Prognoſtics in FEVERS. All *fevers* are in their nature ſalutary, being the means nature uſes to rid herſelf of ſomething that oppreſſes her, yet they are often fatal in the event; but this is rather to be attributed to the fault of the conſtitution, than of the *fever*. The cauſe of the diſeaſe being impeded, and other diſeaſes coming on, the patient often dies under them; ſo that the moſt judicious phyſicians obſerve, that people rather die with a *fever*, than of a *fever* in theſe caſes.

It is to be obſerved in general, that of the great number of perſons who have *fevers*, very few proportionably die of them.

Fevers very often are cured by nature alone, and go off very happily only by the patient's abſtinence, a quiet ſtate, and keeping up the natural evacuations. In this manner great numbers recover without the help of medicines, a number almoſt as great is deſtroyed by medicines, which when adminiſtred by perſons who have not ſufficient judgment, interrupt nature, and prevent the neceſſary excretion. *Fevers* go off according to the language of phyſicians, either by a criſis or lyſis; in the firſt caſe they leave the patient at once after the critical days; in the other, they only wear off gradually, growing ſlowly leſs and leſs violent. The acute *fever* uſually goes off in the firſt way; the intermittents in the other. Critical evacuations of whatever kind, when they happen in ſufficient quantity, bring with them a ſort of inſtantaneous cure; the patient becoming well and eaſy from them, though immediately before, he was in the utmoſt anxiety and uneaſineſs. No *fever* ever goes off without ſweating, and a change in the urine. But in *fevers* in general, the ſweats do not come on at firſt, but afterwards; and in general, the ſweats never come on during the violence of the burning heat, but when that remits a little, the ſweat breaks out. If it appears during the exceſſive heat, the preſage is bad, at leaſt it is of no uſe or good to the patient. Sweats coming on at a proper time, and flowing to a proper degree, bring on recovery; but when they are ſuppreſſed, the diſeaſe becomes worſe, there is a pain and laſſitude in the limbs, and the diſeaſe is protracted in length, and from an acute, becomes a ſlow *fever*. If alſo there be no change perceived in the urine, and the heat do not exceed the ordinary ſtandard, it is a fatal prognoſtic for the patient; and the old phyſical axiom is uſually verified, that while the pulſe and the urine are well in *fevers*, the patient dies.

A dejection of ſpirits in a *fever*, and a melancholy ſtate coming upon a perſon uſually chearful when well, is always a bad omen.

The ſeveral different kinds of *fevers* have their ſtated times in which each attacks the patient. Tertians uſually ſeize people about dinner-time, and are particularly common about the period of the vernal equinox. Quartans uſually make their firſt attack about four or five o'clock in the afternoon, and are more common in autumn than at any other ſeaſon of the year. The ſynocha or continent *fever*, expreſly ſo called, uſually attacks perſons in the morning before day break. Bilious *fevers* uſually make their firſt attack about the time of ſun riſe, and are moſt common in the midſt of ſummer. The catarrhal *fevers* finally, moſt commonly attack perſons in the evening, and they are moſt frequent about the equinoxes. The more any *fever* departs from its uſual courſe, the worſe is the prognoſtic; any *fever* when it has been improperly treated by medicines becomes much more ſtubborn and difficult of cure, than when it has been left to itſelf. The particular medicines which diſturb the courſe of nature in *fevers*, and by that means render them more difficult of cure, are aſtringents, too powerful abſorbents, opiates, &c. And it is obſerved that when *fevers* go off happily and eaſily, eſpecially when they go off of themſelves without medicines, the patient always enjoys a better ſtate of health after, than he had before. *Junker*'s Conſp. Med. p. 257.

Method of cure in FEVERS. The phyſician in all *fevers* is to endeavour to make himſelf the ſervant and aſſiſtant of nature; what nature endeavours in the beginning and increaſe of the diſeaſe is to prepare, diſpoſe and ſearch the noxious matter; and in the ſtate and decline of it, to eliminate and evacuate the matter ſo prepared by the proper paſſages. The whole buſineſs of art is therefore to aſſiſt nature in theſe two efforts of ſecretion and excretion of the matter.

The method of doing this in every particular ſpecies of *fever* is to be ſeen under their ſeveral particular heads; but as we are here treating of *fevers* in general, it may be proper to give the method of treating them as *fevers*, without running into the ſeveral ſub-diſtinctions.

The remedies which we are to give to aſſiſt the ſecretion and

preparation of the morbid matter, are the moiſtening things in general; ſuch are a ſufficient quantity of warm and weak fluids, as the common barly water, and the like; and teas made of the common herbs of ſage, mint, baum, &c. with the milder alexipharmic roots; with theſe alſo are to be given the gentle reſolvents, ſuch as are able to break the thick and tough conſiſtence of the humours. Of this kind are the temperate alexipharmic roots eſpecially, as they are alſo endowed with a diuretic virtue. Such are the roots of elecampane, pimpernel, butterbur, and the like. Scordium is alſo by ſome greatly commended in this intention. Theſe may be conveniently given in decoctions or infuſions; and with theſe powders are to be given compoſed of the abſterſive and digeſtive ſalts, ſuch as tartarum vitriolatum, and the like, mixed with ſuch things, as have a power of obtunding and incraſſating the acrid and thin ſulphurous ſaline humours; ſuch are the the abſorbent powders of oiſter-ſhells, crab's claws, and the like. Theſe ſhould be firſt ſated with lemon juice, and then mixed with a little nitre, and with the beforementioned ſalts, they make an excellent medicine. Theſe may be given, every three, four, or ſix hours, as the urgency of ſymptoms require, and a draught of the decoction before preſcribed, given after them. Emulſions of ſweet almonds, and the cooling ſeeds are alſo very proper between whiles.

The medicines by which the phyſician is to aſſiſt nature in her following buſineſs of excretion, are the gentle diaphoretics, among which, the diaphoretic antimony, when truly prepared, holds a very high place. The alexepharmics, which have alſo a diuretic virtue, ſuch as the mixtura ſimplex, when faithfully prepared and lightly camphorated, are very proper; and the bowels are in the mean time to be kept open by emollient glyſters. Theſe things are proper in all *fevers*, but in ſome alſo vomits, gently laxative medicines and bleeding, are extremely proper: thoſe however are not to be admitted at random in all kinds. All violent medicines are to be dreaded in *fevers*, for nature uſually attempts to do her office placidly and quietly in theſe caſes, and ſuch medicines violently diſturb her motions, and often bring on miſchiefs, which ſhe would have wholly avoided. For this reaſon, vomits tho' they are by ſome given indiſcriminately in all *fevers*, are to be very cautiouſly meddled with; and there are in reality only a few *fevers* in which they can be allowed to be proper: for in acute legitimate *fevers*, the cauſe of the diſeaſe never lies in the primæ viæ, and the violent emotions in vomiting, not only dreadfully diſturb the ſtomach and bowels, but occaſion a fullneſs of the veſſels about the head and neck, with various diſorders of the head in particular. In bilious *fevers* the cauſe is indeed evidently in the primæ viæ, but even in theſe, it is not ſo diſpoſed as to be ſo ſafely thrown up by vomit, nor can the inflammatory ſtate of the patient, at that time properly bear ſuch a violent ſhock. In intermittents, vomits are never proper unleſs in tertians, for the cauſe in the other does not lie in the primæ viæ; and even in tertians it may be diſpoſed to evacuation by gentler means, and without the violent tumult that a vomit occaſions in the body. Acrid purges alſo are in general to be avoided in *fevers*; bleeding though abſolutely neceſſary in ſynochal or continent *fevers*, is not adviſeable in many others, and very often the opening a vein and taking away too little blood, is the occaſion of congeſtions of blood in the head, whence ariſe deliriums and other dreadful ſymptoms. The giving the hot ſudorific medicines before the proper time, greatly diſturbs nature, and brings on many ill conſequences. *Junker*'s Conſp. Med. p. 261.

In all *fevers* the drinking plentifully of warm weak liquors, is attended with many good conſequences; the patient is always refreſhed by it, the febrile heat is mitigated, and reſt is promoted, and the proper and neceſſary ſweats forwarded. The ſymptoms of *fevers* are never to be ſo regarded as to prevent the due attention to the principal point, nor is the phyſician to be alarmed at them. Want of appetite and thirſt with long watchings, are not to be attacked with particular medicines, but looked on as mere ſymptoms, that will hereafter go off of themſelves; and inquietude of mind ſhould have no other medicine, than ſerious advice of the harm it will do. Sudden cooling of the body in all *fevers*, is a very dangerous thing. The patient is to be adviſed to ſwallow his liquids gently not haſtily. Volatile ſalts have been with many of a long time in great uſe in *fevers*, but they are uſually attended with bad conſequences afterwards, many perſons having been thrown into œdematous ſwelling of the legs and feet, and ſome into an abſolute aſcites, only by the uſe of theſe in *fevers*.

Acids in general are by many very much dreaded in *fevers*, but there is no real ground for this; on the contrary, in ſanguineous *fevers* during the time of the violent heat, and immoderate thirſt, they are found of the greateſt uſe and benefit. Spirit of vitriol or of ſulpur, lemon-juice, with that of barberries, are all found very beneficial; only in caſes where there is a cough, the vitriolic acid is to be avoided, becauſe it uſually irritates that ſymptom, and lemon-juice ſweetened with ſugar alone, is to be given. The uſe of aſtringent medicines though too common, yet is extremely improper in all *fevers*; for in all theſe caſes, the ſecretions and excretions all require to find the ways open; but theſe are all obſtructed by aſtringents, and violent ſymptoms are brought on by this means, and often death. But in ſtubborn intermittents, where the peccant matter is diſcharged, and yet theſe ſymptoms remain merely from their having become habitual; theſe aſtringents may be allowed of, and are indeed not only ſafe, but of the greateſt uſe. *Junker*'s Conſp. Med. p. 263.

Nitre is an admirable medicine in *fevers* in general; it agrees with all temperaments, but principally with the hot; when taken in ſolution with warm and weak liquors it always gently opens the bowels, and when given in powders, it more than all other things obtunds the acrimony of the humours.

In feveriſh diſorders accompanied with hæmorrhages, the arnica vera, has been recommended. See ARNICA *vera*.

Benign catarrhal FEVER, in medicine, the name given by authors to a *fever* extremely different from the malignant one of the ſame denomination, which is alſo called by way of diſtinction petechialis. This is the diſeaſe deſcribed in the writings of the antients, under the name of febris quotidiana continua. It is properly a continual ſymptomatic *fever*, in which nature is labouring of herſelf to correct the vitiated lymph, whether its faults be in quality, or only in motion. This is done by increaſing the ſecretory and excretory motions beyond their natural ſtandard, but yet not to any great violence. The difference between this and the malignant kind, though ſo very great, as to make them appear wholly different ſpecies, yet it is only in degree. *Junker*'s Conſp. Med. p. 313.

Signs of it. This *fever* always attacks people in an evening; and is principally frequent in the ſpring and autumnal ſeaſons. A gravedo and coryza either preſage it, or are immediately joined with it, and the patient is afflicted with a hoarſeneſs, and difficulty of ſwallowing, he feels alſo a kind of inflammation, or as it were a St. Anthony's fire within his throat, and a weight in the breaſt; and is attended through the whole courſe of the diſeaſe with a violent cough, which brings up nothing, and with a remarkable univerſal languor of the body. Pains in the back attended with ſhiverings, frequently alſo attend the firſt attacks of this *fever*, and continue half an hour, ſometimes an hour; theſe are ſucceeded immediately by a heat, but that not violent, and this brings on a ſenſe of ſtraitneſs over the breaſt, a difficulty of breathing, and in ſome people, a continual reaching to vomit. This heat endures fewer or more hours, according to the degree of the plethora. The pulſe is frequent and quick, the appetite is weak, the ſtrength fails, and the ſleep becomes unquiet and diſturbed, the head rather feels weak than painful, and ſometimes vomitings, often diarrhæas, ſoon ſucceed theſe complaints. Sweats are frequent and copious, and the urine, which is of an orange colour, as it is in all inflammatory *fevers*, has this peculiar in this caſe, that it depoſits a bluiſh white skin, beſide the roſe coloured ſediment.

Perſons ſubject to it. Theſe are principally thoſe of a ſanguine or phelegmatic habit, and ſuch as have a very faulty ſerum; ſuch as are obliged by their uſual occupations to expoſe their head and neck much to the cold; thoſe who have had the itch, or any other violent cutaneous eruption ſtruck in upon them; and thoſe who are watchful long in the night, and drink too much wine.

Cauſes of it. Theſe are frequently violent and ſudden cooling of the body, as when hot with exerciſe, by drinking large draughts of cold liquors; the acrid matter uſed to be thrown off by a coryza, driven back; and all things which any way impede natural and healthful perſpiration.

Prognoſtics in it. The ſimple catarrhal *fever* often goes off very happily without the aſſiſtance of medicines, only by obſerving a good regimen; but notwithſtanding this natural mildneſs, it often becomes dangerous to particular conſtitutions, and by means of improper treatment; but the more it recedes from its natural mildneſs, and the more intenſe the heat is, the greater fear there is of ſome of the viſcera being injured. The happieſt event of it is, by a daily reſolution and ſucceſſive diſſipation of the morbific matter.

Method of treatment. The fault of the lymph in this diſeaſe uſually conſiſting in its viſcous and mucous texture, this is to be relived by alexipharmics, and the like medicines. The roots of elecampane, pimpernel, and vincetoxicum are famous for doing great ſervice in theſe caſes; and to theſe may very properly be added, the ſaline digeſtives; ſuch as nitre and the tartarum vitriolatum. The mixtura ſimplex is alſo to be given in doſes of twenty-five drops, twice or oftener in a day. The cough is to be moderated by liquorice, emulſions of ſweet almonds, oil of almonds and barley-water, water-gruel or the like. The bowels are alſo to be gently kept open by a laxative diet, a frequent drinking of weak and emollient liquors, and by clyſters at proper times.

Malignant Catarrhal FEVER, in medicine, the name of a *fever* extremely different from the ſimple *catarrhal fever*, and greatly more dangerous. This is alſo called by ſome the *petechial catarrhal fever*. It is a diſeaſe in which nature is endeavouring, by increaſing the ſecretory and excretory motions, to elimi-

eliminate the catarrhal, acrid and active matter. This is unquestionably the same species of *fever* with the simple one of this name, but extremely different in degree, and is often even epidemical. This is called by some the *febris Hungarica*, and *febris castrensis*, or *camp fever*: but the latter appellation is used to express it in its very worst state, and when attended with its most terrible symptoms. The petechiæ or spots in this *fever* are to be carefully distinguished from those in the common scorbutic cases. *Junker*'s Consp. Med. p. 317.

Signs of it. These are the same with those of the simple *catarrhal fever*; but with this only difference, that in this case there are also violent anxieties of the mind, a sudden resolution of the strength, a continual difficulty of breathing, and a loathing of all kinds of food. This last symptom usually continues till the eleventh day. The patients are also subject to frequent faintings, and are usually delirious, and complain of very sharp pains in the back, and at the joints. After these symptoms the petechiæ usually appear; these are little red spots on the breast, *&c.* resembling fleabites. When hot medicines are given, the petechiæ are enlarged. Aphthæ and quinseys are also very frequent attendants on this *fever*; and diarrhæas sedom fail of appearing at some stage of the disease, and are often critical.

This *fever* seldom attacks the patient with a shivering. It is very contagious, in the manner of other malignant fevers, and has this peculiar circumstance, that it is very often complicated with other diseases, and according to the seasons and other accidents frequently appears under their form. In February, March and April, it often wears the appearance of a pleurisy; in May and June, it often affects the symptoms of the cholerica febris; and at this season of the year is often, in the beginning, attended with terrible hæmorrhages. In July and August, a dysentery is frequently joined with it; and, in the winter months, it generally has a bad cough attending on it. Persons of tender habits are much more subject to this disease from infection, than those who are of a hardy and robust make. But, as it is contagious, it at times spares no age, sex, or constitution, that come in the way.

Causes of it. The most frequent causes of this disease are, a fermentaceous and putrid exhalation in the air, and the contagion from the bodies and effluvia of the sick. And in this last case, a natural terror of receiving the infection is often found to make people more subject than ordinary to receive it. And to these are to be added the eating vitiated and fermenting provisions, and the sudden cooling of the body when very hot with labour or exercise, and frequent and violent passions suppressed.

The spots which appear on certain days in this disease are not essential to it, though common; and hence the *fever* is rather called by accurate writers, *febris petechizans*, than *petechialis*: they are a relief to the patient, if they are not violently repelled, or some other way improperly treated. When they appear earlier than the seventh day, they are also observed to be worse presages than when they appear on, or after it. When the spots appear in very great numbers, they usually fly back again, and the patient is much endanger'd by it. And when they are of a bright red, and after three or four days appearance go off again, and leave the patient better than before, they are a sure good prognostic. But if they are of a livid or black colour, they are a very bad omen; and when after the eruption the person does not find himself relieved, the consequence is often a miliary purple fever. Lightheadedness before the seventh day is less dangerous than if it does not happen till after it. Diarrhæas in all other eruptive *fevers* are a very bad symptom, and often presage the death of the patient. But that is not the case in this; they sometimes prove critical, and carry off the disease. But when that is not the case, they are of no bad effect, and are always better for the patient than an obstinate costiveness. But it is to be observed, that though these Diarrhæas, when they come naturally, are of great relief in many cases, and of no harm in others; yet art is not here to be used as nature, and no purging medicines are by any means to be given to bring on a laxity of the bowels.

Method of cure. Gentle evacuations are to be brought on by such medicines as encourage perspiration, and promote urine. Absorbents saturated with acids, as crab's eyes sated with lemon juice, are of service; and to these should be joined a small quantity of nitre. Cooling emulsions are also to be given at times, and spirit of wine camphorated is to be rubbed on the head to mitigate the violent head-achs. And Stahl greatly recommends, in the case of a too violent diarrhæa, the use of powders made of purify'd nitre and mountain crystal. In cases of obstinate costiveness, clysters must be injected as often as is found necessary. And when there is a complaint of soreness in the fauces, and difficulty of swallowing, astringent gargarisms are to be used. *Junker*'s Consp. Med. p. 322.

Choleric FEVER, in medicine, the name of a *fever*, called also by some a bilious *fever*, and by others a causus; though the generality of writers distinguish the cholorica *febris* from the causus. All bilious *fevers* are properly species of acute *fevers*, and owe their origin to distemperatures of the bile, at times when the aliments are in a state of fermentation in the stomach and intestines.

The causus is distinguished from the cholerica *febris*, properly so called, by its being ever much more violent and dangerous, and by the excretions which attend it. For in the choleric *fever*, the vitiated gall and other bilious excretions are always plentifully voided, sometimes upward, sometimes downward, and sometimes both ways. In the causus, the matter is more usually detained in the body, and rarely voided otherwise than by vomiting, and that usually only in small quantities, and in the beginning of the distemper.

Signs of it. The general signs of the cholerica *febris* and causus are a remarkable anxiety, and frequent complaints about the breast, as of a straitness and painful heat. A violent heat on the inside of the mouth, and insatiable and intolerable thirst, trembling and convulsive motions of the joints, and violent deliriums. Dryness of the mouth and tongue are often so terrible in this disease, that the skin cracks with it; and often the whites of the eyes, sometimes the whole body becomes yellowish. The peculiar and appropriated symptoms of a cholerica *febris*, strictly so called, are an universal languor and debility of the limbs.

A severe shivering first seizes the patient, and is soon succeeded by a very violent heat, and raging pain in the head; and, after the two first days, there usually are very terrible strainings and reachings to vomit. The matter brought up at these times is caustic, acrid, and bilious, and inflames and even ulcerates the fauces; and, if voided upon a stone floor, effervesces violently. If this vomiting abates, there immediately comes on a diarrhæa attended with a tenesmus, occasioned by the irritation of this sharp matter in the rectum. Faintings also are very frequent in this disease, especially where the vomitings do not bring up a sufficient quantity of the offending matter. The peculiar and appropriated signs of the causus, strictly so called, are these: a violent and insatiable thirst, greater than that in any other *fever*. The bowels are always bound, and it is but very seldom that there is any tendency to vomit. The urine is reddish and turbid, and after standing some time deposits a red sediment. Often there is a sensible pain and soreness in the præcordia, so that the patient cannot bear the least touch upon the breast; and usually, in the course of the disease, there are faintings and violent convulsions.

Persons most subject to this disease are such as eat largely, and drink heavy and imperfectly fermented liquors after it. The cholerica *febris*, properly so called, is most frequent with those of a cholerico-sanguineous habit, and such as feed on high season'd meats, and drink abundance of wine or other strong liquors; and is often brought on such persons by their falling into violent passions after a full meal. The causus peculiarly attacks the people of melancholic habits, who are much inclined to passion, but suppress it, and who are naturally costive. *Junker*'s Consp. Med. p. 273.

Prognostics in it. The simple choleric *fever* is attended with great danger, if not timely undertaken to be cured. But the causus is yet more fatal than it, and from as old time as Hippocrates's days has been accounted among the *febres lethiferæ*, or fevers that very frequently kill the patient.

In many *fevers* nature is able to help herself, and succeeds best of all when left alone. But these are of that number of distempers in which the assistance of art is absolutely necessary, and out of which nature very seldom brings the patient safely when unassisted. The happiest turn this *fever* can take, is the copious discharge of the peccant matter by vomit; for when it goes downward, the febrile heat always increases, and the symptoms in general usually grow worse. When the reachings are violent, and the matter brought up is but small in quantity, then the patient is usually subjected to painful hiccoughs and dangerous syncopes and convulsions. When much bile is thrown up by vomit, and that not very badly colour'd, and there is no diarrhæa, there is then little danger from the disease; and, in general, costiveness in the state of the disease is more eligible than a tendency to stools. The more violent the delirium is in these diseases, and the longer continued, always the greater is the danger to the patient. And if the pains and burning heat suddenly cease, and a shivering and dejection of the spirits succeed, there is no doubt of a gangrene being coming on within. *Junker*'s Consp. Med. p. 277.

Method of Cure. The cure of these diseases consists in the mitigating the violent sharpness of the humour, and promoting its evacuation. And, finally, in abating the burning heat brought on by it. The utmost endeavours are first to be made to correct and alter the morbific matter. To this purpose, the several preparations of nitre, with the testaceous powders and mucilaginous ptysans, with small mixtures of lemon juice, and frequent draughts of cooling and diluting liquors, are to be given moderately warm. If the costiveness be too violent, clysters of broth must be injected, with the addition of a little oil and salt; and, if necessary, small doses

of rhubarb. To quell the febrile heat and emotion of the blood, the miſtura ſimplex may be given with great ſucceſs; and there is often a ſenſible good effect from the application of rags wetted in camphorated ſpirit of wine, to the pit of the ſtomach. After the morbific matter is evacuated, the reachings to vomit may be allayed by gentle opiates. All hot medicines change the bilious *fevers* into inflammatory ones, and the common ſudorifics drive the morbific matter into the blood, and uſually bring on almoſt immediate diſcolourings of the ſkin, like thoſe of the jaundice. Bleeding, though performed ever ſo early in the diſeaſe, ſeldom does any good, except only in remarkable plethoric habits.

Inflammatory FEVERS. See INFLAMMAMORY.

Hectic FEVER. See HECTIC.

Intermittent FEVER. In intermitting *fevers*, it ſeems from Dr. Langriſh's experiments, that the craſſamentum of the blood is not ſo viſcid and tenacious, neither is the ſerum ſo bilious, ſaline and acrid, as in acute continual *fevers*. The red globules abound more, and the cruor is more viſcid and tough in quotidians than in tertians, and in tertians, than in quartans. Mod. Theor. & Pract. of Phyſ. p. 229.

The cold bath has been preſcribed with ſucceſs, as a ſtrengthner to thoſe who were recovering from obſtinate intermitting *fevers*, to prevent a return of the diſeaſe. See Dr. Huxham's Obſ. de Aere & Morb. Epid.

Miliary or purple FEVER, *purpurea febris*. See PURPUREA *febris*.

Petechial FEVER. See *malignant catarrhal* FEVER.

Scarlatina FEBRIS. See SCARLATINA *febris*.

Quotidian FEVER. See the article QUOTIDIAN.

Slow FEVER, *lenta febris*, in medicine, a term uſed to expreſs an increaſed motion in the blood, by which nature is endeavouring to retrieve herſelf from the congeſtion or ſtaſis of the blood in ſome of the principal viſcera, and preſerve the part from the danger that threatens it from ſuch a ſtaſis.

The *febris lenta* properly and diſtinctly ſo called, differs from the hectic *fever* in its origin; for it is generally produced by the degeneration of diary *fevers*, ſynochæ, or quotidians improperly treated, and by the common intermittents violently and injudiciouſly ſuppreſſed by aſtringents; but the hectic *fever* is connected with the terrible accidents of vomicæ, empyemas and apoſtematous inflammations of the viſcera. Nor do they differ leſs in the continent cauſe; for in the *ſlow fever* there is not yet any actual hurt in the viſcera, but only a tendency toward it, and ſuch a diſpoſition as may naturally bring it on; but in the hectic there is always either an obſtinate ſchirrus or an apoſtem, or a ſimple or fiſtulous ulcer. *Junker*'s Conſp. Med.

The ſymptoms of theſe diſeaſes differ alſo as much as their cauſes; for in the *febris lenta* they are all mild, and in the hectic, all terrible and violent. The *febris lenta* never is ſo violent a diſeaſe, as to confine the patient long to his bed, and uſually grows milder in the continuance, than at firſt; but on the contrary, the hectic ever grows worſe by duration; and finally, the *febris lenta*, in all caſes except where it ariſes from the improper uſe of aſtringents in intermittent caſes, is attended with profuſe ſweats; whereas the hectic unleſs when urged by medicines of a wrong kind, is a dry heat, and never throws out any ſweats till in the laſt ſtages. In ſlow *fevers* of this kind, the ſtools are thin and not frequent, and uſually have a mucous matter mixed with them. In the hectic when compleat, there uſually come on violent diarrhæas, which carry off the patient. The *lenta febris* is ſubject to degenerate into other diſeaſes, and frequently returns into the diſtemper from which it firſt aroſe; but the hectic is ſubject to no tranſmutations. And finally, the *lenta febris* often goes off happily of itſelf, nature making her way through the obſtruction, and compleating the cure. The hectic is uſually fatal.

Signs of the febris lenta. Theſe are a preternatural heat often ſcare ſenſible to others, but very troubleſome to the patient; a dryneſs of the mouth, and continual thirſt; a loſs of appetite, and waſting the ſtrength; a general dulneſs of the face, except for a fluſhing of the cheeks; a waſting of the fleſh; violent ſweats in the night; and a redneſs and foulneſs of the urine when firſt made, but afterwards a precipitation of a pale red ſediment, and the remainder then is clear above.

Perſons ſubject to it. Theſe are principally young men who are of a plethoric habit, and who have had an ephemera or ſynocha, or ſome other *fever* of that kind, improperly treated with too hot medicines; and ſuch as in *fevers* of other kinds where nature produced copious ſweats, have ſuppreſſed them either by medicines, or by an improper regimen; and finally people worn down and exhauſted by violent hæmorrhages.

Prognoſtics in it. This kind of *fever* when it ariſes from an intermittent, and in fine returns into its old ſtate again, is attended with very little danger, but there is much more danger where it continues long in its own appearance, or where it degenerates as it too frequently does in an acute one. The degeneracy of this *fever* into a hectic, is of all other conditions of it, the moſt dangerous, and this is not always readily diſtinguiſhed: this is to be ſuſpected for the caſe, when the patients appetite returns, and yet all the ſymptoms continue; and eſpecially if there be added to them a ſhort cough, and a difficulty of reſpiration; and when there is a ſenſation of a weight in the abdomen, and it is painful to lie otherwiſe than on one ſide or in ſome particular poſture.

Method of cure. The firſt thing to be done is to attempt the reſolving the ſtaſis, as by pimpernel and elecampane roots, by the gentle alexipharmics, and by the neutral ſalts, as the tartarum vitriolatum, and the like. The viſcid foulneſſes left by intermittent *fevers*, are to be carried off by firſt attenuating and inciding them by the gums, as ammoniacum, and the reſt; and the tone of the viſcera is to be finally re-eſtabliſhed by the gentler chalybates and ſtomachics.

When the caſe ariſes from an acute *fever*, powders of tartar of vitriol, crabs-eyes, and diaphoretic antimony, with gentle cathartics in the intermediate days, will often complete a cure: when it ariſes from an intermittent, no happier means can be deviſed for the cure, than the bringing it back to its old ſtate of the intermittent again. Etmuller ſays, that the volatile alkali's, ſuch as ſpirit of ſal armoniac, have a great power this way; and Stahl propoſes to effect it by a habitual drinking an infuſion of elecampane, pimpernel, centaury, orange-peel and ſenna, with a ſmall quantity of rhubarb and black hellebore in wine.

Finally, when this caſe has been brought on by violent hæmorrhages, the analeptics alone are to be depended upon, with the teſtaceous powders to abate the ſweats, and the lighter tinctures of ſteel to reſtore the loſt tone of the ſolids. *Junker*'s Conſp. Med. p. 384.

It is obſerved in the periodical eſſays of Edinburgh, that in the ſlow *fevers* which prevailed in and near that place, November 1731, attended with a violent pain in the head, a ſmall quick pulſe, deliriums and watchfulneſs; ſeveral of the elder ſort died; but of the younger, many voided worms and recovered. See Med. Eſſ. Abridg. vol. 1. p. 66.

FEVERFEW, in botany. See MATRICARIA.

FEVILLEA, in botany, the name of a genus of plants, called by Plumier nhandiroba; the characters of which are theſe. It produces male and female flowers diſtinct on the ſame plant; in the male flower the perianthium is campanulated, it is compoſed of one leaf, and is round at the bottom, but expanded at the mouth, where it is divided into five ſegments. The flower conſiſts of one leaf, and is of the rotated kind. It is lightly divided into five ſegments at the edge; theſe are convex and rounded, and the umbilicus is covered with a double ſtar. The ſtamina are three filaments. In the female flowers the cup is the ſame as in the male, the flower itſelf is alſo the ſame, but that the ſtar which cloſes the baſe is compoſed of five cordated leaves. The fruit is a very large fleſhy berry with a hard bark, and is of an oval obtuſe figure, and ſurrounded with the calyx. The ſeeds are flatted and of an orbicular form. *Linnæi* Gen. Plant. p. 439. *Plumier* 27.

FIARSING, in ichthyology, a name given by the Swedes and Danes to the fiſh generally called the *draco marinus*, and *araneus marinus*; the ſea-dragon, and the ſea-ſpider. It is a ſpecies of the trachinus according to Artedi, and is diſtinguiſhed from the others, by its lower jaw being longer than the upper, and without beards.

FIAT, in law, is uſed for a ſhort order or warrant of ſome judge, for making out and allowing certain proceſſes. Thus if a certiorari be taken out in vacation, and teſted of the precedent term, the *fiat* for it muſt be ſigned by a judge of the court, ſome time before the eſſoin day of the ſubſequent term, otherwiſe it will be irregular. There is no need for the judge to ſign the certiorari itſelf, but only where it is required by ſtatute. 1 *Salk.* 150. 2 *Hawk.* P. C. 289.

FIATOLA, in zoology, a name given by the Italian fiſhermen to the ſtromateus. *Willoughby*'s Hiſt. Piſc. p. 156. See the article STROMATEUS.

FIBER, the *beaver*, a very remarkable creature of which many ſtrange things are recorded by authors. It is uſually about three foot long in body, ſometimes conſiderably more, and its weight from twenty-five to thirty-five pounds. Its head is broad and flatted, its eyes ſmall and black; its ears are ſmall, ſhort and round, and hairy on their outſide; and it has two dentes inciſores, which are very broad and prominent, and have their ends oblique, as if made for cutting; theſe are of a fine yellowiſh red on their outer ſurface, but of a fine ivory white within; the neck is ſhort and thick; the fore feet are divided each into five toes armed with obtuſe claws; theſe ſerve the creature in the place of hands, and it uſes them in the manner of the ſquirrel for lifting up its food to its mouth; the order and diſpoſition of the fingers, and the ſhape of the palm in theſe much reſembles that of the human hand; the hinder feet are extremely different from theſe, and have the toes connected by a ſtrong tough membrane, in the manner of the feet of geeſe, &c. theſe have broad and flat claws like thoſe of the monkey kind.

The hairs which cover the body are of two very different kinds, but are mingled regularly and intimately with one another. Some of theſe hairs are long, the others ſhort and downy; the long ones are about an inch and half in length, and of a ſort of reddiſh black colour, very bright and gloſſy, and

and theſe are very firm and ſolid: the ſhort ones are not of half the length of theſe, and are not indeed regularly of the ſame length one with another, and differ accordingly in fineneſs, the long being ſomewhat harſh, the ſhort perfectly ſoft and fine, and no other than a moſt ſmooth down. Theſe are what make the fur uſed by the hatters; and this diverſity of hair on the animal is no way ſingular, ſeveral creatures having the ſame; a long hair for a ſort of ornament, and a downy fur for warmth and for defence.

The tail has no hairs, but is black and ſcaly, ſomewhat in the manner of the skin of fiſhes; the ſcales are as thin as parchment, and are joined to and by a firm cuticle; the tail is ten or eleven inches long, and four or five broad, ſmall at its inſertion, then ſwelling out toward the middle, and becoming again a little ſmaller juſt at the extremity, ſo that it is of a ſort of oval figure. The anus and paſſage for the urine are contained in one common aperture; the penis in the male lies in the upper part of this aperture, and is boney, and under this aperture is by means of a membrane divided into two parts, each of which terminates in a lateral ſinus. For the ſtructure of the bags which contain the caſtor. See CASTOR.

We have not the beaver now wild with us in England, but there is great room to believe, that it once was ſo, from what our own authors have ſaid of it.

FIBRARIÆ, in natural hiſtory, the name of a claſs of foſſil bodies, the greateſt part of which have been very improperly called by the writers of foſſils, fibroſe talcs, they being of a very different ſubſtance and ſtructure of parts from the talcs, and having none of their diſtinguiſhing characters.

The word is derived from the latin fibra, a fibre, or filament, theſe bodies being all compoſed of arrangements of parallel filaments or fibres. See Tab. of Foſſils, Claſs 1.

The *Fibrariæ* in general are foſſils compoſed of parallel filaments uſually remaining ſo diſtinct as to preſerve in the whole maſſes a thread like texture; but ſometimes uniting ſo as to form plates or flakes, reſembling thoſe of the talcs in external figure. They are bright, and in ſome degree tranſparent; not giving fire with ſteel, nor fermenting with, or ſoluble in acid menſtrua. *Hill*'s Hiſt. of Foſſ. p. 88.

Of this claſs of bodies there are two diſtinct orders, and under thoſe four genera. The firſt order is of thoſe which are compoſed of filaments ranged perpendicularly in the maſs, not flexile nor elaſtic, and readily calcining in the fire. Theſe are the bodies which have been called the fibroſe talcs.

The ſecond order is of thoſe which are compoſed of filaments ranged horrizontally in the maſſes, and are flexile and elaſtic in ſome degree, and not calcining in the fire. The firſt genus of the firſt order, is of thoſe fibroſe bodies which are not elaſtic, and are compoſed of ſtrait and continuous filaments called tricheriæ. The ſecond is of thoſe which are not elaſtic, and are compoſed of ſhort and abrupt filaments, the lachnides. The firſt genus of the ſecond order is of thoſe fibroſe bodies which are flexile and elaſtic, and are compoſed of ſtrait and continous filaments, as the asbeſti. The ſecond is of thoſe fibroſe bodies which are flexile and elaſtic, and are compoſed of ſhort and abrupt filaments, the amianthi.

FIBROSE *roots*, thoſe which conſiſt wholly of ſmall fibres, ſuch as the roots of the meadow-graſs, pinks, and ſeveral other flowers. When a *fibroſe* root penetrates ſtrait into the ground, it is called *perpendicular*; when it creeps under the ſurface, *horizontal*; when ſomewhat thick, it is called *fleſhy*; when very thin, *capillary*; when it runs all the way undivided, *ſimple*; when divided, or when it ſends off ſmaller roots, *branched*; when its ſurface is covered with extremely ſhort and fine fibres, *hairy*. See ROOT.

FIBULA, in natural hiſtory, a name given to a claſs of the echinodermata, which have their mouth in the middle of the baſe, and the aperture of the anus on one edge. Theſe are found principally among the foſſil kinds, and ſeem to have had their ſhells of the aſſulated kind, or compoſed of ſmall plates joined tranſverſely to one another. Of this claſs, there are two genera, the conulus and diſcoides. *Kleine*'s Echinod. See CONULUS and DISCOIDES.

FIBULA, in anatomy (*Cycl.*) — The upper extremity of this bone is a kind of tuberoſity or head, obliquely flatted by a ſmall cartilaginous plane, by which it is articulated with the cartilaginous ſurface, at the lower part of the external condyle of the tibia. It terminates backward by a kind of ſhort blunt point directed upward. The lower extremity is broader, flatter, and more oblong than the upper; it is partly a continuation of the body of the bones, and partly an epiphyſis in children; the marks of which are quite loſt in a more advanced age. It has in a manner three ſides, one rounded like a tuberoſity, one flat, and the third narrow; when it is placed in the lateral cavity of the baſis of the tibia, it makes the outer ankle oppoſite to the inner ankle.

In its natural ſituation, it reaches much lower down than the baſis of the tibia, and ends in a point turned a little backward. The flat ſide is cartilaginous, and turned toward the cartilaginous ſide of the inner ankle, with which, and with the inferior ſide of the baſis of the tibia, it completely forms the cavity by which the leg is articulated with the foot. The narrow ſide is turned backward, and near its lower part is a ſmall, oblong, unequal foſſula, formerly believed to be for the paſſage of a tendon, in which a ſmall mucilaginous gland is lodg'd. The point by which the baſis of the *fibula* ends, has a ſmall ſmooth ſurface immediately below the narrow ſide, for the inſertion of an annular ligament.

The body of this bone is long and ſmall, more or leſs contorted, and irregularly triangular. Near the two extremities it contracts into a kind of neck, and a little below the middle it is often bent inward; but this curvature ſeems chiefly owing to the method of dreſſing children, for we ſometimes meet with the bone very ſtrait. It is diſtinguiſhed in an irregular manner into three ſides, and three angles, principally towards its lower part. The outſide is the moſt conſiderable: the upper part of it is more or leſs hollowed; afterwards it grows round, and altering its direction, becomes almoſt poſterior in the lower half. The poſterior ſide is more or leſs convex toward the upper part, thence it grows flat, and turning in the ſame manner as the former, it becomes nearly internal toward the lower part. The inner ſide has likewiſe a turn near its middle, and becomes anterior from thence downward; and this turn is marked by an oblique line, which runs down on this ſide, from behind, forwards, and divides it into two. Theſe ſides ſerve partly for muſcles to lie upon, and partly for their inſertions. The internal angle of the fibula anſwers to the external poſterior angle of the tibia, and both ſerve for the inſertion of the interoſſeous ligament of the leg; the other two angles are more or leſs acute, eſpecially the anterior, which is ſometimes like a kind of criſta, and terminates below in a ſmall triangular ſurface.

The internal ſtructure of the fibula, though a very ſmall bone, is like that of the other long bones; it is articulated by its upper extremity, with the inferior ſurface of the external condyle of the tibia; this articulation is an arthrodia, with a very ſmall degree of motion. The inferior extremity is articulated by its cartilaginous ſide, partly with the lateral depreſſion in the baſis of the tibia, and partly with the firſt bone of the foot, completing the ginglymus between the leg and that bone. *Winſlow*'s Anatomy, p. 95.

Cartilages of the FIBULA. The *fibula* has two cartilages, one lying on the upper extremity of that bone, for its articulation with the ſmall cartilaginous ſurface in the head of the tibia; the other cartilage covers the inſide of the inferior extremity, or the outer ankle, near the point of which poſteriorly, there is a ſuperficial cartilaginous incruſtation for the paſſage of the tendons of the muſculi peronæi. The cartilage at the upper extremity ſeems thicker, than that at the lower. *Winſlow's* Anatomy, p. 128.

Ligaments of the FIBULA. This bone is joined to the tibia by nine ligaments, four at each end, and one in the middle, called the interoſſeous ligament. The four at the upper extremity are ſhort, very ſtrong, more or leſs oblique and compound; two of them are anterior and two poſterior, and they lie on each other; the ſuperior ligaments ſurrounding the articulation more cloſely then the inferior, which have a ſmall void ſpace, and are weaker than the former; they are all faſtned to the capſular ligament, which runs in between them and the articulation, and they are inſerted round the edges of the cartilaginous ſurfaces in each bone.

The ligaments of the lower extremity of the *fibula* which runs below the tibia, and forms the outer ankle, are much ſtronger, thicker, more complex, broader, longer, and more oblique, than thoſe of the ſuperior extremity; and are like thoſe diſpoſed, two before, and two behind. They are fixed to the anterior and poſterior edge of the lateral depreſſion at the inferior extremity of the tibia, and from thence they run down on the lower end of the *fibula*.

The two inferior ligaments are longeſt, and they are fixed anteriorly and poſteriorly at the lower end of the outer ankle; the two ſuperior are fixed more cloſely, and nearer each other, but there is ſtill a ſmall ſpace between them, which is filled with fat. As the two bones touch each other only by the upper part of the cartilaginous ſurface of the outer ankle, and the ſmall cartilaginous border in the lower edge of the depreſſion of the tibia, the middle ſpace between them is filled by a capſular ligament, which lines each ſide of the bones, and is continued down to the true articulation of the external ankle, with the inferior edge of the baſis of the tibia.

The middle or interoſſeous ligament of the two bones of the leg, ſo called becauſe it fills up all the ſpace left between them, being ſtretched from one to the other, is fixed along the poſterior external angle of the tibia, and the neighbouring angle of the *fibula*. It is made up chiefly of two planes of very oblique ligamentary fibres, which croſs each other, and at different intervals ſeem to be multiplied. It is perforated both above and below, and ſometimes in ſeveral places beſide, for the paſſage of the blood-veſſels and nerves. It is not a ligament intended for the tying theſe two bones together, but is rather a ligamentary ſeptum for the inſertion of muſcles, ſupplying in this reſpect the place of a bone, and ſeeming indeed to be partly a continuation of the perioſteum of the tibia and *fibula*. At the lower part of each ankle, there are common-

ly three ſtrong ligaments for the connection of the bones of the tarſus with thoſe of the leg; one of theſe runs downward, one backward, and one forward. *Winſlow*'s Anat. p. 130.

Luxation of the FIBULA. Sometimes the *fibula* is ſeparated by external violence from the thigh bone, and is then diſtorted either upwards or downwards: this generally happens, when the foot has been luxated outwards. Whenever this happens the bone is to be firſt reſtored to its natural place, and then properly bound up, and left to the aſſiſtance of nature and reſt, till it be grown firm again to the tibia and leg. The patient in this and the like caſes, muſt be always ſtrictly cautioned not to uſe or bear any ſtreſs upon the diſordered leg too ſoon; the conſequence of which may be worſe than the firſt misfortune. *Heiſter*'s Surg. p. 172.

FIBULÆUS, in anatomy, a name given by Spigelius and ſome other authors to a muſcle of the leg, called by Albinus and other writers the *peronæus poſticus*, and *peronæus longus*, in diſtinction from the *peronæus anticus* or *brevis*.

FICARIA, in botany, a name uſed by ſome authors for the ſmall celandine, pilewort or figwort. *Dill.* Cat. Giſs. p. 39.

FICEDULA *cannabina*, in zoology, a name by which ſome authors have called the cannevarola, a leſſer reed ſparrow. *Ray*'s Ornitholog. p. 99. See the article CANNEVAROLA.

FICOIDES, a name uſed by different authors in botany for different plants; many underſtanding by it, the opuntia or Indian fig, as it is vulgarly called; and ſome, as Herman and others, making, it the name of the muſa or plantain tree. *Herm.* Cat. Hort. L. B. p. 256.

FICUS, *the fig-tree*, in botany, the name of a genus of trees, the characters of which are theſe. The flower is produced within the body of the fruit, and is compoſed of a number of ſtamina, proceeding from a ſort of caſe, which incloſes the embryo or ſeed. The ſeed is roundiſh, and the whole fruit is of a turbinated figure, though ſometimes alſo round or oval, and is fleſhy, ſoft, and placed cloſe upon the branches, with either none or a very ſhort ſtalk. The ſpecies of *fig* enumerated by Mr. Tournefort are theſe.

1. The cultivated *fig*, with fruit early ripe, of a greeniſh colour on the outſide, and red within. 2. The cultivated *fig* with a roundiſh early ripe fruit, whitiſh and ſtriated on the outſide, and roſe coloured within. 3. The cultivated *fig* with an oblong white and very ſweet fruit, called by many the uttata *fig*. 4. The cultivated *fig* with a round, white and very ſweet fruit. 5. The cultivated *fig* with an early ripe and ſoon periſhing white fruit. 6. The cultivated *fig* with a ſmall white, late ripe fruit, of a ſweet taſte, and a torn kind, looking of a pale red within; this is called by ſome the Marſeilles *fig*. 7. The cultivated *fig* with an extremely ſmall white round fruit. 8. The cultivated *fig* with a green fruit, ſtanding on a long pedicle. 9. The cultivated *fig* with fruit yellowiſh on the outſide, and red within. 10. The cultivated *fig* with fruit yellow both on the outſide and within. 11. The cultivated *fig* with a ſmall fruit, brown on the outſide, and red within. 12. The cultivated *fig* with a great oblong violet coloured fruit, with a broken skin. 13. The cultivated *fig* with a long ſhaped violet couloured fruit, red within. 14. The cultivated *fig* with a blackiſh red fruit, covered with a bluiſh duſt. 15. The cultivated *fig* with a round blackiſh red fruit, purple within, and covered with a firm tough skin. 16. The late ripening *fig*, with a long and large fruit, black without, and white within. 17. The cultivated *fig* with a large and long fruit, black on the outſide, and purple within. 18. The dwarf *fig*. 19. The wild *fig*. 20. The wild *fig*, with a ſmall round whitiſh fruit. 21. The wild *fig*, with a ſmall oblong bluiſh black fruit. 22. The wild mulberry leaved Portugal *fig*. 23. The Goa *fig*, or Eaſt Indian *fig*, with leaves like the quince-tree. 24. The cheſnut leaved American *fig*, with a round ſpotted fruit. 25. The great American *fig* with roundiſh citron like leaves and umbilicated fruit. 26. The American *fig* with ſharp pointed citron-like leaves, and green fruit. 27. The American *fig* with obtuſe citron-like leaves, and blood-red fruit. 28. The bay leaved American *fig* with very large fruit. 29. The leſſer American *fig*, with leaves of a ſilvery white underneath. *Tourn.* Inſt. p. 662. See FIG.

FICUS, in conchyliology, a name given by authors to a peculiar ſpecies of ſea-ſhell. It is of the genus of the dolium, and has a remarkably depreſſed clavicle.

FIDD, an iron pin uſed at ſea to ſplice or faſten ropes together; it is made tapering and ſharp at one end.

There are alſo *fidds* of wood, which are much larger than the iron ones.

The pin alſo in the heel of the topmaſt, which bears it upon the cheſs-trees, is called a *fidd*.

FIDD-*hammer*, is uſed for a hammer, the handle of which is a *fidd*, or made tapering into that form.

FIDICULÆ, in antiquity, is often uſed to ſignify the ſame with *equuleus*, a kind of puniſhment uſed among the antients. See EQUULEUS, *Cycl.*

FIDICULÆ, in a more proper ſenſe, denotes the cords wherewith the criminals limbs were diſtended on the *equuleus*. *Pitiſc.* Lex. Ant. in voc.

FIDE JUSSORES *aſſidui*. See ASSIDUUS.

FIELD (*Cycl.*) — In order to find the contents of a *field*, it is moſt convenient to meaſure the lines by chains; that of 22 yards for computing the Engliſh acres, and that of 24 Scotch ells for the acres in Scotland. The chain is divided into 100 links, and the ſquare of the chain is 10000 ſquare links; ten ſquares of the chain, or 100000 ſquare links, give an acre. Therefore, if the area be expreſſed by ſquare links, divide by 100000, or cut off five decimal places, and the quotient ſhall give the area in acres and decimals of an acre. Write the entire acres apart, but multiply the decimals of an acre by 4, and the product will give the remainder of the area in roods and decimals of a rood. Let the entire roods be noted apart, after the acres, then multiply the decimals of a rood by 40, and the product will give the remainder of the area in falls or poles. Let the entire falls or poles be then writ after the roods, and multiply the decimals of a fall by 36, if the area is required in the meaſures of Scotland, or by $30\frac{1}{4}$ if in thoſe of England, and the product will give the remainder of the area in ſquare ells in the former caſe, but in ſquare yards in the latter. If in the former caſe you would reduce the decimals of the ſquare ell to ſquare feet, multiply them by 9.50694; but in the latter caſe the decimals of the Engliſh ſquare yard are reduced to ſquare feet, by multiplying them by 9. Treat. Pract. Geom. p. 82.

FIELD-*ale*, or FILCTALE, in our antient cuſtoms, a kind of drinking in the field, by bailiffs of hundreds; for which they gathered money of the inhabitants of the hundred to which they belonged. But this cuſtom has been long ſince prohibited. *Bract.* ap. *Coke*, 4 Inſt. 307.

FIELD-*book*, in ſurveying, a book uſed for ſetting down angles, diſtances and other things remarkable in taking ſurveys.

The pages of the *field-book* may be conveniently divided into five columns. In the middle column the angles at the ſeveral ſtations taken by the theodolite are to be entred, with the diſtances from the ſtations. The diſtances taken by the off-ſet-ſtaff, on either ſide of the ſtation line, are to be entred into the columns on either ſide of the middle column, according to their poſition with reſpect to that line. The names or characters of the objects, with proper remarks, may be enter'd in the columns on either ſide of theſe laſt mentioned. Treat. Pract. Geom. p. 74.

FIELDFARE, in zoology, the Engliſh name of a bird of the thruſh kind, called by authors turdus pilaris. It is larger than the common thruſh, and is of a bluiſh grey colour on the neck; the head is ſpotted with black, and the ſhoulders and back are of a yellowiſh brown, variegated with black; the the throat is variegated with black and yellow, the lower part of the belly is white and but a little ſpotted; and on each ſide of the neck, and near each eye it has a large black ſpot; thoſe on the neck are on its lower part near the inſertions of the wings; its wing feathers are variegated with black, white, and a yellowiſh brown, and the tail is of a bluiſh black, with ſome variegations of black and white.

It is a bird of paſſage, and viſits us in England toward the end of autumn in vaſt flocks, and leave us in ſpring; it is not certainly known where they breed. They feed on berries, particularly thoſe of the holly, and are a well taſted bird. *Ray*'s Ornith. p. 138. This bird is eaſily taken with water-bird-lime in the following manner; take out a gun and kill two or three *fieldfares* with it; by that time the gun has been diſcharged two or three times, the reſt of theſe birds will be ſo ſhy, that there will be no coming near them; then tie one or two of thoſe that were ſhot, to the upper branches of ſome buſhy tree, in ſuch manner, that they may ſeem alive and ſitting there. Then prepare two or three hundred twigs, covering them well with the water-bird-lime, made warm for that purpoſe; take a good birchen bough, and in that place all the twigs; tie this faſt to the tree, juſt underneath where the other *fieldfares* are tied, and let this be in a place where they come in a morning to feed, for they always uſe one haunt for feeding ſo long as there is any food left there. By this means the *fieldfares* will ſettle in whole flocks, near thoſe which they ſee tied to the buſh, and two or three dozen may be in this manner taken at a time. See the articles BIRD and LIME.

FIELD *fort*, in fortification. See FORTIN, *Cycl.*

FIELD-*officers*. See OFFICER, *Cycl.*

FIFE-*rails*, in a ſhip, are thoſe that are placed on baniſters on each ſide of the top of the poop, and ſo along with *hances* or falls; they reach down to the quarter-deck, and to the ſtair of the gangway.

FIFTH (*Cycl.*)--*Diminiſhed* FIFTH, in muſic. See DIMINISHED *fifth*.

FIGS, The Greeks in ſome of the iſlands of the Archipelago, have a peculiar method of ripening the fruit of the domeſtic *fig*-trees, called *caprification*. See CAPRIFICATION.

The common dried *figs* afford two very curious phænomena; the one is, that within thoſe which are ſomewhat decayed, and indeed often in thoſe which appear moſt ſound, there are a peculiar ſort of mites, which live on the pulp of the fruit, and we eat millions of theſe unknowingly in this fruit.

Theſe are different from the common mites, in that they are rounder bodied and more tranſparent, and are a very beautiful little creature when examined.

The other object is the seed in which the plantula seminalis is very elegantly to be seen. To this purpose however, the largest *figs* must be chosen, for the smaller are commonly such as are pulled off from the tree before they are ripe. Out of one of these large and ripe *figs*, a fair seed is to be picked, and on cutting this carefully, the whole pulpy part may be separated from the hard husk, and on examining it, there will be found lodged in it, a very perfect and beautiful little plant consisting of two leaves, and of a part which is to be the root, and another which is to be the stalk, and in fine the trunk of the tree. The pulpy matter of this seed is covered with a delicate thin membrane, and this must be carefully taken off before the plantule can be seen; after this, all the rest is only a sort of pith destined to give place and nourishment to the young shoot, before it is committed loose to the earth.

FIGS, in antiquity, were used in divination. See SYCOMANTIA.

FIG, in the manege, is a sort of wart on the frush, and sometimes all over the body of a horse. The *figs* that appear in the frush or sole, make an evacuation of stinking malignant humours, that are very hard to cure.

FIG *insect*, in natural history, a name given by the English to the creature called by the French after Mr. Reamur, the faux puceron, or false puceron, from its very much resembling the puceron in external appearance, but being extremely different from it when nearly examined. These insects are when at their full growth of the bigness of the head of a pin of the largest size, but there are usually found among them several that are smaller, down to such as are scarce perceivable to the naked eye. They are found in great plenty on the back, or underside of the leaves of the *fig*-tree, but they never are seen in clusters like the pucerons; twenty or thirty being the greatest number usually found on one leaf, and these scattered in different parts of it. These animals tho' of the same general figure with the pucerons, yet are of so very different a nature, that they are all of them to become at length wing'd insects, none remaining naked, as great part of the pucerons do; and they are not in a condition to multiply or bring forth young in this state, but must pass thro' their transformation first into the fly, like that to whose eggs they owed their origin.

The cases under which the wings are placed in this state are very large, and take up a great deal of room on the animal; they extend themselves also as far as the extremity of the head, so that they give the creature a very singular figure, it being much thicker and broader before than behind, and its head looking at the extremity square, as if cut off evenly from some other body.

The body and breast of this insect are green, and the cases of the wings are white and beset with hairs. This creature has two antennæ or horns, which it can exert and shew at pleasure; but they usually are lodg'd under the furrows of the wings, and are not to be seen, unless the animal be turned belly upwards; the head also is bent downwards, and the eyes seem directed to look at objects only placed under them. *Reaumur*'s Hist. Inf. v. 6. p. 98.

It has six legs, and a fine small trunk issuing from the extremity of the head; this is but short, and is of a lively green; it is terminated by a sharp point, and has a fine brown filament like a hair, which it thrusts out of the body of the trunk at pleasure, and which seems a sort of engine or organ destined to convey into the body the juices extravasated by the wound and suction of the trunk. The creature usually remains in perfect quietness on the leaf on which it is found, but has this peculiarity in its position, that it is always found with its head resting upon one of the ribs of the leaf, and its body on the plain part; by this means the anterior part of the head is raised above the surface of the plain part of the leaf, and the creature can by that advantage move his trunk about at pleasure, and fix it into different parts of the leaf, while his body is perfectly still all the time.

These creatures throw off their skins many times in their growth, the furrows marking the places where their wings are, and the protuberances made by their cases, are always seen, however young they are examined. When they are about to throw off the skin, it opens by a slight crack in the middle of the breast, and the creature first enlarges this slit by various motions, and there thrusts out its head at it; this is followed by the anterior pair of legs, and the motions of these parts soon disengage the remainder of the body. The skins which they thus cast off, have usually some cottony matter on their hinder part, as the exuviæ of the pucerons of many kinds have. The resemblance of the puceron kind, is also kept up in the excrements, for this animal voids no other than a clear and limpid fluid like water; this is however very viscous, and by that means often forms itself into a large drop, before it is thrown off from the body of the animal. If the creature be at any time squeezed, it immediately voids such a drop, and the efforts used by it in quiting its exuviæ, seem also to have the same effect, for there is always a drop seen on the old skin. Though the leaves of the *fig*-tree are the usual residence of these animals, they are sometimes found on the young fruit. In some seasons when they are very plentiful, every green *fig* will be found surrounded by twenty or more of them, but it does not appear that they do any harm.

In the months of May and June, these insects all become wing'd, and afford a peculiar species of a four-wing'd fly, which is remarkable for hopping, but as its hinder legs are not greatly larger than the rest, it leaps but a little way at a time. The body of this fly is green, its wings are bordered with yellow, and its legs are white; it has a trunk of the same nature with that of the creature before its wing'd state, and with this it continues to seek the juices of the leaves of the *fig*-tree as it did before.

It continues also in the same manner to void a clear viscous fluid by way of excrements, and this is done in a very singular manner: the end of the body is terminated by a short pipe or tube, which in its common posture runs parallel with the rest of the body, and is placed in an horrizontal direction; but when it is to be used in voiding the excrement, the creature turns it up in a very remarkable manner, so that it stands perpendicularly to the body. The wings are folded up so as scarce to appear distinct when the creature is first delivered from its last exuviæ; but they soon begin to unfold themselves, and by degrees arrive at their full extent, and are placed over the body so as to make an angle, and form a sort of covering or tent for the body. The manner in which these animals propagate their species, is not yet known. The pucerons, to which they more approach in figure than to any other animals, have always young ones found within them; but these if examined in whatever state, never have any such appearance, not even so much as eggs being found in them; it should seem that their eggs are too minute for our inspection, but that they are oviparous, not viviparous animals. *Reaumur*'s Hist. vol. 6. p. 98.

FIG-*tree*. There are some different species of this tree cultivated in the gardens of England, but many more in those of France and Italy, where the fruit is in very high esteem, as it is also with the nicer palates here; though so much out of favour with the vulgar, that it stands safe on trees planted in places so exposed, that every other species of fruit would be stripped by robbers.

One great discouragement to their more frequent propagation in England, is the unskilfulness of the generality of our gardeners in their culture and management. To obviate which, it may not be amiss to say somewhat at large here, of the proper management of all the species of this tree.

The common method has been to propagate these trees by suckers from the roots of the old ones, but they are much more successfully raised from cuttings. The branches may be laid down in February, and by the February of the following year, they will be fit to remove. This is the proper season to transplant them; and the best soil is such as has a gravelly, chalkey, or stony bottom, with a light surface; the tree will seem to flourish indeed more in a better soil, but in this poor one it will produce the finest and most plentiful fruit. They should always be planted in a free open situation, not shaded by trees or buildings, and will never ripen their fruit well unless against a good south, south-east or south-west wall. They should be planted at twenty feet distance, and the height for the wall they stand against, is about fourteen feet; the middle spaces between the trees, may be planted with vines to fill up the vacant part of the wall till the *figs* are grown, and then these should be taken up. In the summer, as the branches shoot, they must be trained horizontally against the walls, and no foreright shoots should be suffered to come, but the buds of such should be rubbed off as fast as they appear. At Michaelmas they should be always prun'd and nailed up. The great care to be had in pruning the old trees, is always to have a supply of young branches, for it is those only which produce fruit. None of the shoots of the former autumn pruning must be shortened, for it is on the two year old wood, that the fruit is produced; the young branches must be always brought very close to the wall, and this will screen them from injuries by frosts, and much forward the early ripening of their fruit. The old branches should never be laid in too thick, which is a great fault among most gardeners; the distance ought to be at least a foot between branch and branch, and as the young ones grow strong, the old ones should be always cut away. In April or the beginning of May, several of the leading shoots, should be stopped, which makes them throw out side branches. In very hard weather the trees should be covered with straw, peas,halm or the like; and that not to be removed till the weather is milder, and then not all at once, but only by a little at a time. The higher the wood runs up the wall, usually so much the better tasted is the fruit; and no trees succeed better in fruiting, than those which are nailed up against chimnies, where beside the height, they have some advantage from the heat. *Miller*'s Gardener's Dict. See FICUS.

FIGWORT *worm*, in natural history, the name of an insect, which feeds on the leaves of the scrophularia or *figwort*, and which is usually esteemed a caterpillar, but is one of those insects called by the French fausse chenilles. Its head is spherical, and it has twenty-two legs, and by these characters and the changing its colour after the parting with its last skin, it may be distinguished from the caterpillars, without waiting for its last

laſt change, on which it produces a four winged fly, not a butterfly.

This beautiful inſect is of the ſize of a middling caterpillar; it is of a fine pearly white, variegated with a great number of round and large ſpots, of a deep blackiſh brown, which run down its back in two regular rows, and form two even ſtreaks or lines; beſide theſe, there are ſeveral other ſmaller ſpots of a deep black, in ſeveral parts of the body, and from every one of theſe, there grows a long black hair.

All theſe dark colours on the pearly ground, make a very beautiful appearance. The creature changes its skin four or five times in the courſe of its life; and in this ſtate, and on the laſt change before its entering on the nymph ſtate, it is ſo altered, that there would be no diſtinguiſhing it for the ſame animal, if the change were not made under the eye of the obſerver; the pearly skin with all its elegant variegations is thrown off, and the creature appears of a plain green colour, without the leaſt ſpot or variegation. In this ſtate it eats for ſeveral days, at the end of which time, it becomes a nymph or chryſalis, and from this iſſues in form of a large fly. *Reaumurs's* Hiſt. Inſ. v. 9. p. 117.

FIGWORT, in botany. See SCROPHULARIA.

FIGHTING-*ſails*, at ſea. See SAILS.

FIGHTS, in a ſhip, are the waſte cloths which hang round about her in a fight, to hinder the men from being ſeen by the enemy.

Cloſe FIGHTS, is uſed for thoſe bulkheads afore or abaft the ſhip, which are put up for men to ſtand ſecure behind, and fire on the enemy, in caſe of boarding.

Running FIGHTS, at ſea, thoſe where the enemy does not ſtand the battle, but are continually chaſed.

FIGHTWITE, *Fihthwita*, in the Saxon times, ſignified a mulct for making a quarrel, to the diſturbance of the peace. — *Mulcta ob commiſſam pugnam in* [a] *perturbationem pacis, quæ in exercitu regis* 10 *ſolidorum erat.* Blount and Jacob in tranſcribing this paſſage, have inſerted 120 ſols. [[a] *Du Cange*, Gloſs. Lat. in voc. *fihtwita.*]

FIGURAL, or FIGURATE *numbers*, ſuch as do or may repreſent ſome geometrical figure, in relation to which they are always conſidered; as triangular, pentagonal, pyramidal, &c. numbers. See NUMBER, *Cycl.*

FIGURATIVE *Deſcant*. See DESCANT, *Cycl.*

FIGURE (*Cycl.*)—*Apparent* FIGURE, in optics. See APPARENT.

Plain FIGURES, in geometry, ſuch as are terminated and bounded by right lines only.

Brimſtone FIGURES. See BRIMSTONE.

FIGURES *on China ware*. There are ſeveral very different ways of making the *figures* we ſee on the China ware, and according to the method uſed, they have a very different appearance; but none of them are difficult. The common *figures* which we ſee, are traced on with a pencil dipp'd in the colours prepared of ſtones and earths, waſhed to fineneſs by water, and afterwards dried, and then blended with gum-water to uſe in the common way. The common blue is our ſmalt, and the finer blue a ſtone they call *leao*; the reddiſh is calcined copperas; and the green, a preparation of the ſcoriæ of copper. Theſe will all mix with gum-water, and ſpread from the pencil, and the only care to be taken in regard to them is, to make the powders very fine. The miniature paintings as they are called, on the blue china, are thus done; the veſſel is plunged all over into the common blue, made into a ſoft paſte or varniſh with water; this gives the whole veſſel a coat of blue, and the workman takes a fine needle fitted into a proper handle, and with the point of this, he pricks out his *figure*, every touch leaving behind it a ſmall white ſpot, which is owing to the taking off the blue where the point touched it; after this is finiſhed, and the whole is dry, the veſſel is varniſhed over, and the *figures* appear painted in miniature under the ſurface.

The elevated or emboſſed *figures* of beaſts and flowers which we ſee on china, are done in a much eaſier manner, than would naturally be imagined. The artiſts carves theſe firſt with a *burin* on the ſurface of the veſſel while yet ſoft, after this he cuts away the ſubſtance about the *figures*, and they appear elevated in any degree that he pleaſes. Theſe are painted by the common hands employed in this work, and when dry are varniſhed over, and the effect is very elegant, while the means are not at all to be diſcovered.

The moſt beautiful of all china in the judgment of many, is that which is all white, but has *figures* within the ſurface; theſe appear very neat and diſtinct, though the ſurface is perfectly ſmooth. They are made of a whiter matter than the reſt, called *hoache* (which ſee); and when theſe are laid on in this white, and covered with the common varniſh, they are ſeen through it, and are of a different white both from the varniſh and the ſubſtance of the china. Obſervations ſur les Coutumes de l'Aſie. p. 325.

FIGURE, *figura*, σχημα, in the antient muſic, is uſed for the different diſpoſitions of the tones and ſemitones in a conſonance.

Caſting of FIGURES — To make a figure that ſhall truly repreſent any face. See PLASTER.

FIGURED (*Cycl.*) — FIGURED *ſtones*, in natural hiſtory, a name given by ſome writers to thoſe foſſil bodies which are found in the ſhape of ſhells and other parts of animals. Diſputes among the learned have never run higher on any ſubject, than on the origin of theſe ſtones; ſome have declared them to be all of marine origin at firſt, and that they were brought to the places where we find them in this foſſil ſtate, at the time of the univerſal deluge, and have been ſince altered into the nature of ſtones, by long lying in the earth in the way of waters impregnated with ſtony particles, which they have depoſited in them, after entering their ſubſtance in their paſſage through the earth.

Others are of opinion, that theſe bodies tho' reſembling ever ſo exactly the ſea fiſhes, yet never were in the ſea at all: but that the firſt ſemina of the ſea ſhells, corals, and other ſubſtances, being carried by the ſea water through the ſubterranean paſſages into all parts of the earth, even into the higheſt mountains, have been there left in vaſt numbers, and growing there among ſtony matter, have arrived at their true bulk and figure, but in a ſtony ſubſtance. Langius in a treatiſe expreſsly written on this ſubject, has accurately enquired into the ſubject, and examined the ſtrength of the arguments on both ſides the queſtion, with great ſagacity and candour.

Thoſe who argue for the origin of theſe foſſil ſhells being from the deluge, he obſerves, aſſert, that in the time of that fatal cataſtrophe, the ſea ſhells, corals, and other marine bodies, in company with the ſands from its ſhores and bottom, were by the violent agitation of the waters, toſſed out of their natural places, and carried far on land, as it was afterwards to be, where they were ſcattered over the whole ſurface, and toſſed into holes and caverns in immenſe quantities together; and in other places that the mud and ſand, together with theſe ſhells, all were heaped up in immenſe piles, where after the going off of the waters, they all hardened by degrees and became ſtones of ſeveral kinds: and that the ſhells among them remained in the places to which they were brought in this manner, and became petrified together with the earth or mud and ſand, and hence they ſay were formed mountains of different ſorts of ſtone, as different earths or ſands concurr'd in the formation of their ſeveral parts; and that hence it is, that the foſſil ſhells are found petrified in them, while the ſcattering them over the ſurface of the yet ſoft earth, into which they penetrated to different depths according to their own gravity and its ſoftneſs, accounts for their being met with in the different ſtrata now hard, and the amaſſing of them in ſubterranean caverns at that time, exiſting together with mud, ſand, &c. with which they became afterwards petrified, gives occaſion to the immenſe heaps of ſhells, which we find in ſome places, with very little ſtony or earthy matter interſperſed among them.

The *figured* ſtones repreſenting ſhells in mountains, &c. are found in two forms; the one exhibiting a ſurface much reſembling the colour and ſubſtance of the ſhell in its natural ſtate, and being filled with abſolute ſtony matter of another kind and colour within this cruſt, which does not exceed the natural thickneſs of the ſhell. The others only repreſenting the ſhape of the ſhell, but all of the ſame ſubſtance, and without any cruſt, and that ſubſtance being in different inſtances, of very different kinds; ſome of theſe being compoſed of abſolute flints, ſome of pure ſpar, ſome of coarſe ſtone, and ſome of the matter of the agate, while others are of the ſubſtance of the common pyritæ. The firſt kind are ſuppoſed to be compoſed of the very ſhell itſelf yet remaining, though altered into the nature of ſtone, and forming a cruſt to the other ſtoney matter petrified in the ſame manner within it, though doubtleſs received into it, in the form of ſoft mud. The others they ſuppoſe only to be the caſts in theſe ſhells, or the mud, or other matter originally received into thoſe ſhells, hardened into ſtone with the loſs of the ſhell, which having been waſhed away and carried wholly off from it, has now left it naked; though that not having happened till after the matter was petrified within it, could not alter or injure that form which the contained ſubſtance had formed itſelf into.

Thoſe who aſcribe the origin of theſe foſſils to the deluge, ſay, 1. That it is wholly impoſſible, that the figured ſtones ſhould be form'd in the other way; ſince the various meanders in the ſubterranean paſſages from the ſea to the places where we find many of theſe bodies, are too intricate for the ſeminia ever to be brought through; and are compoſed of ſo many different ſubſtances, through the pores of which they muſt paſs, that ſuch ſeminia as are ſuppoſed to be carried through them could never paſs, were it poſſible to allow all the reſt, in a condition to grow into their proper ſhape, ſince they muſt have been mutilated by the hard bodies they paſſed through, and impregnated by the ſaline and other penetrating ſubſtances in their way, ſo as not to leave it poſſible that they ſhould afterwards grow, had they all the other requiſites.

2. That even ſuppoſing it poſſible that the ſeminia of ſhells and corals, could be thus conveyed uninjur'd from the ſea to the places where we find them in their foſſil ſtate, even then it is wholly impoſſible for them to grow; becauſe they want

both

both the grand requiſites for the growth of plants and animals, that is a proper matrix, and proper nouriſhment. *Lang.* Hiſt. Lapid. Figurat.

3. That if ſuch a generation of theſe bodies could be allowed, their growth up to the ſtate in which we find them, muſt have been from their ſmall ſeminia, either inſtantaneouſly or ſucceſſively, as in other plants and animals; but it is eaſily proved from their ſtate, and the ſtate of the bodies in which we find them, that neither of theſe can poſſibly have been the caſe. Their growing inſtantaneouſly to their full ſize from a ſmall ſeminium, is neither poſſible from the nature of the place, that being uſually a hard ſtone, which cannot poſſibly give way to ſo quick an expanſion; nor natural, as all other animal and vegetable bodies grow from their ſeminia to their full ſize, by ſlow and regular degrees; and this ſort of growth can never be allowed to theſe bodies, were it only that the ſeminia themſelves would be alſo petrified, and their ſubſtance would then reſiſt any expanſive fall within. If they were then formed from ſeminia brought from the ſea through ſubterranean paſſages, they muſt alſo have been found in all ſorts of places among all ſorts of bodies, and that ſingly; whereas on the contrary, we find them uſually in cluſters together, and that much more frequently in ſome bodies than in others, and in ſome never.

4. Another unanſwerable objection to the ſuppoſition of their ariſing from ſeminia of the animal or vegetable they repreſent is this; that if they did ſo, they muſt needs grow into the whole animal, or the whole plant, and not form a part of it only. Thus why ſhould we ſuppoſe, that the ſeminium of an oiſter being conveyed thro' ſubterranean paſſages to the place where we find the foſſil body, ſhould have grown not into a complete fiſh, but only into a ſingle ſhell; for it is much more common to find both this and the other bivalve foſſils ſingle, than in the pair, even when buried in ſtone, and wholly out of the way of being ſeparated by accidents. And in the other caſe of vegetables, if the foſſils of that claſs are owing to ſeminia of the plants themſelves, why ſhould ſuch a ſeminium produce only the cone of a fir, the catkin of a hazel, or the fragment of a leaf of a fern inſtead of the whole plant or tree? and to what ſort of ſeminia are we to ſuppoſe we owe the bufonitæ and gloſſopetræ, and ſiliquaſtra, with a number of parts of animals beſide? Are we to think, that the ſeminium of a fiſh when in the earth produces only a tooth, or a part of its palate; or that the ſeminium of an echinus marinus, or ſea hedge-hog, produces only one of that creatures ſpines, or the bare impreſſion of them on a flint.

5. It ſeems an inſuperable difficulty, to ſuppoſe that the form of an animal or a plant, or a part of one or the other could any way be delineated in the body of a hard ſtone, or that a part of that ſtone could any way be moulded or faſhioned into the ſhape of ſuch an animal or vegetable, unleſs ſome certain body of that kind and bigneſs, were actually received into the body of the ſtone to determine its particles in that part to aſſume that figure; and it is plain to reaſon, that nothing but the very ſhell or plant itſelf, could have done in this caſe, from the nice traces and delineations that are exhibited, even of its moſt minute parts.

6. The error of thoſe who ſuppoſe all theſe figures of foſſils owing to the ſhooting of various ſalts, is evident from this, that they are always regular in their ſhape in all places where they are found; whereas ſalts of all kinds, though they have a natural determinate figure, yet are liable to ſo many accidents in their concretions, that they are often mutilated, imperfect and conjoined; three or four of their cryſtals often being embodied in one regular one. But this is never the caſe in our foſſil ſhells, or in the parts of animals or plants; they are always perfect, unleſs by accidents of breaking, as ſtones may be broken, always ſingle, always alike, even in the minuteſt ſhapes; and it is evident from a mere inſpection of them, that they owe their formation not to a ſhooting of ſome ſolid body out of a fluid, but to regular organizations of parts and veſſels.

7. If theſe ſtones were form'd from their ſeminia received from the ſea into the beds where we now find them, ſome of them muſt be of long ſtanding, and others newly form'd there; and we ſhould be able to diſtinguiſh theſe by the different appearances their different ages would give them; but this is by no means the caſe, all that we find ſeem to be of the ſame age, and all ſeem evidently to have been placed at one time, where we find them.

That the foſſil ſhells are really the ſame with the marine ſhells ab origine, appears indiſputably, from their being perfectly of the ſame ſhape, even to the moſt minute particular. All the conchitæ of the earth agree with the ſhells they repreſent at ſea not only in their general figure, but even in their number of ſpines, in the figure of their mouth, and even in the number and ſituation of the tubercles. The ſpines of echini, as well as their ſhells, perfectly agree with thoſe now living at ſea; and there is not any one genus of ſea ſhells that is not found alſo in ſome part or other of the world, and that perfectly agreeing with the recent kind, nay even crabs and lobſters are found foſſil, though that but rarely. Thoſe foſſils which repreſent the parts of ſea fiſhes, agree alſo as perfectly with the ſame parts of the living fiſhes, as the foſſil ſhells with the recent ones; and the bufonitæ originally called gems, and the gloſſopetræ called ſerpent's tongues are refered to their proper claſs, by being compared with the teeth of the recent wolf fiſh and the ſhark, with which they perfectly agree; alſo the corals found on the tops of the higheſt mountains, though buried in ſtone, yet in all reſpects perfectly reſemble the corals at this time growing in the ſea.

But if reaſon thus proves to us, that the foſſils, now abſolute ſtones, only repreſenting the figures of ſhells and parts of animals, were once the real thing they repreſent; our ſenſes in other inſtances prove to us, that real ſea ſhells, unqueſtionably ſuch, at this time are found buried at equal depths in the earth. According to the matter ſhells have been depoſited among in the earth, they are found at this time more or leſs altered; when lodged in ſtone they are frequently turned to abſolute ſtone themſelves, but when bedded in earth, they often are found very little altered from their native ſtate. The ſhells of this kind not only repreſent the figure of certain ſea ſhells which we know, but their very ſubſtance is the ſame, and they are form'd of laminæ laid together in the ſame manner; and their whole external and internal make, is found both by the microſcope and by the naked eye, wholly the ſame with that of the ſea ſhells recent on the ſhores. Their ſubſtance and gravity are the ſame, and they anſwer in the ſame manner in the ſeveral chymical trials. An echinites of this ſhelly kind being macerated in water, ſhews all the regular ſtructure of the cortical part of the ſame ſpecies of echinus when recent; and internally all the nice lineaments and traces of the ſhell neceſſary to the living animal within, are perfect and complete in it.

The oiſter ſhells found foſſil are always compoſed of plates or laminæ, laid one on another, as in the recent ſhells; and the pinna marina which when recent is of the ſtrongeſt texture of any ſhell in the world, being formed of tranſverſe ſtriæ, as appears on breaking it, is of the ſame texture when foſſil. The tubuli marini have been found foſſil with the very body of the fiſh in them; and the teeth of ſharks ſo frequent among us, under the name of gloſſopetræ, are ſo far from being native foſſils, that they are often only petrified on the ſurface, their internal part being of the very ſame bony ſtructure as in the recent teeth.

The ſituation of theſe bodies in the earth, is alſo another great argument of their having been brought thither in their perfect ſtate, as they almoſt always lie in a regular horizontal poſition, among the tender kinds particularly, tho' not much altered. The echinitæ, which do not lie thus, are uſually found cruſhed and broken. The foſſil ſhells are alſo uſually found together in great quantities, as it was natural they ſhould be, if brought to the places where they now lie by the waters of the deluge, which would naturally roll great numbers of the ſame ſort of bodies to the ſame place; whereas if they were form'd from ſeminia, they might the more naturally expected to be found ſingly and diſperſed in all places equally; but neither is this the caſe, ſince there are many large tracts of land wholly without them. Upon the whole, the fact ſeems plain, that they are the remains of a deluge, by which every part of the earth was drowned; and by what we ſee of the places where they now lie, it ſhould ſeem that the whole ſurface was at that time diſſolved upon the globe, and that it afterwards ſubſided from the waters in form of a ſoft mud, which petrified again when the waters went off.

As clear as this proof appears on the diluvian ſide of the queſtion, the author, to whom the world is obliged for collecting theſe arguments, is not however influenced by them, in favour of it, but rather approves the other ſyſtem of their ariſing from ſeminia. His giving theſe their full force, is a great proof of his integrity as an author; and as the opinion of all the world is for this ſide of the queſtion now, this may be eſteemed the proper account of theſe things. The Author's reaſons for judging otherwiſe, See under the article SEMINIUM. *Langii* Hiſt. Lapid. figurat.

FILACIUM. See FILE, *Cycl.* and *Suppl.*

FILAGO, *cudweed*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the floſculous kind, and is compoſed of ſeveral floſcules which are divided into many ſegments, and formed like a ſtar at the ends; theſe are placed upon the embryo fruit, and are contained in a general cup, which is of a ſcaly or ſquamoſe ſtructure, but is not at all bright or ſhining.

The ſpecies of *cudweed* enumerated by Mr. Tournefort, are theſe: 1. The common *cudweed*, called herb impious. 2. The larger *cudweed*, with longer and narrower leaves. 3. The ſmall *cudweed*. 4. The alpine ſmall *cudweed*, with foliaceous heads. 5. The ſea *cudweed*, with foliaceous heads. 6. The foliaceous headed ſea *cudweed*, cultivated in gardens, and called the roſe headed *cudweed*. 7. The Portugal *cudweed* with foliaceous heads, and 8. The common, ſmall erect *cudweed*, with very narrow leaves.

FILAMENTS, among botaniſts. See STAMINA.

FILATERIUS, a name given by the writers of the middle ages to a ſtone which they have greatly celebrated for its imagina-

ry

ry virtues; they ſay it diſpelled fear, gave chearfulneſs, and had many other ſuch effects; and deſcribe it as being of the colour of the chryſolite. But neither this nor its virtues can determine what ſtone they meant.

FILAWS, among the modern Ægyptians, villages inhabited by the original natives of the country. *Pocock*'s Egypt. p. 177.

FILE (*Cycl.*) — FILE, *filacium*, in law proceedings, is uſed for a thread, ſtring, or wire, by which writs and other exhibits in courts and offices are faſtened or filed, for the more ſafe keeping and ready turning to the ſame.

A *file* is a record of the court, and the filing of the proceſs of a court makes a record of it. 1 *Lill.* Abr. 112.

FILE-*leaders*, in the military art, the foremoſt men in each file. See FILE, *Cycl.*

Half FILE *leaders*, are the men of the fourth rank; the fourth, fifth and ſixth ranks being called the *rear half files*, as the firſt, ſecond and third are the *front half files*.

FILICULA, *dwarf fern*, in botany, the name of a genus of plants, the characters of which are theſe: the flowers are not diſcovered; the ſeeds grow in cluſters on the backs of the leaves, and the whole plant reſembles the larger or common ferns.

The ſpecies of *filicula* enumerated by Tournefort are theſe: 1. The ſmall water *fern*, called dryopteris, or *fern* leaved white maidenhair. 2. The large water *fern*, called the dryopteris, and *fern* leaved white maidenhair. 3. The obtuſe leaved *filicula*, called the black maidenhair with obtuſe pinnules. 4. The ſharper leaved *filicula*, called the black maidenhair with acute pinnules. 5. The larger Scotch *filicula*, with the appearance of black maidenhair. 6. The mountain *filicula*, with various and finely divided leaves. 7. The polypody rooted Portugal *filicula*. 8. The ſea rock *filicula*, with round ſegments. 9. The Portugal, branched *filicula*, with leaves like the ceterach. 10. The rock *filicula*, with thick ſet ſharp pointed pinnules. 11. The capillaceous *filicula*. 12. The fingered *filicula*. 13. The cup bearing *filicula*. 14. The black *filicula*, with pointed jaggs. 15. The ſmalleſt beautiful ſtone *filicula*. 16. The ſtone horned *filicula*, called *filis ſaxatilis corniculata*. 17. The ſmalleſt African *filicula*, with finely divided pinnules. 18. The great African *filicula*, divided into ſharp ſegments. 19. The Virginian *filicula*, with baſtard hemlock leaves. 20. The larger *filicula*, covered with a ſilvery powder. 21. The American *filicula*, covered with a gold coloured powder. 22. The American *filicula* with obtuſe pinnules. 23. The ſmall American *filicula*, with the appearance of black maidenhair. 24. The Chineſe *filicula*, with obtuſe and uſually bifid pinnules.

FILIPENDULA, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, being compoſed of ſeveral petals which are arranged in a circular form. The flower cup is one leaved, but divided into many points; from this there ariſes a piſtil, which finally becomes a roundiſh fruit compoſed of ſeeds arranged together in the ſhape of a little barrel.

The ſpecies of *filipendula* enumerated by Mr. Tournefort are theſe: 1. The common *filipendula*, ſuppoſed by many to be the molon of Pliny. 2. The common *filipendula*, with variegated leaves. 3. The ſmaller *filipendula*. *Tournefort* Inſt. p. 293.

FILIX, *fern*, in botany, the name of a genus of plants, the characters of which are theſe. The leaves are compoſed of other leaves affixed on each ſide of their middle rib, and thoſe are ſubdivided almoſt to their rib, into other pinnulæ, or little leaves. The flowers have not been diſcovered, and the ſeeds grow in cluſters on the under part of the leaves. To this it is to be added, that there is alſo a peculiar face in the *ferns*, which diſtinguiſhes them at firſt ſight from the other plants of this kind.

The ſpecies of *fern* enumerated by Mr. Tournefort are theſe: 1. The great branched *fern*, with obtuſe and not dentated leaves, called the female *fern*. 2. The great branched or female *fern*, with undulated leaves. 3. The great branched *fern*, with very acute, not dentated leaves. 4. The ſmaller branched *fern*, with dentated pinnules. 5. The ſmall Pyrenæan branched *fern*, with polypody leaves. 6. The indented, not branched *fern*, commonly called the male *fern*. 7. The broad leaved dentated, not branched *fern*. 8. The unbranched, dentated *fern*, with leaves growing together, into the figure of a birds-neſt. 9. The unbranched *fern*, with very narrow and finely dentated leaves. 10. The ſmooth ſoft *fern*, reſembling the common male *fern*. 11. The finely divided *fern* of mount Ballon. 12. The finely dentated rhætic *fern*. 13. The little marſh unbranched *fern*. 14. The berry-bearing *fern*. 15. The ſpleenwort leaved unbranched Portugal *fern*. 16. The great branched African *fern*, with dentated leaves. 17. The ſpleenwort like dentated African *fern*. 18. The branched African *fern*, with lonchites leaves. 19. The tree *fern*, with dentated leaves. 20. The prickly tree *fern* with pinnules ſerrated at the ends. 21. The broad leaved prickly tree *fern*. 22. The low, prickly-tree *fern*. 23. The climbing *fern*, with elegantly ſerrated pinnules. 24. The great tall lobular *fern*. 25. The broad band prickly *fern*, with ſmooth and black pinnules. 26. The broad jagged leaved *fern*, lightly prickly at the jaggs. 27. The broad leaved branched *fern*, with black and prickly ſtalks. 28. The broad leaved tailed *fern*, with leaves like the lonchitis. 29. The broad leaved dentated *fern*, with pointed pinnules. 30. The hemlock leaved branched *fern*. 31. The dentated *fern*, with bifid tops to the pinnules. 32. The greater yew-leaved *fern*. 33. The leſſer yew-leaved *fern*. 34. The hairy *fern*, with oak like pinnules. 35. The ſmall hairy *fern*, with deeply indented pinnules. 36. The great branched hairy *fern*, with pinnules dented into round crenæ. 37. The hairy *fern*, duſted with yellowiſh powder. 38. The branched golden *fern*, with round crenæ. 39. The duſty *fern*, with very deeply but obtuſely dentated pinnules. 40. The prickly creeping *fern*. 41. The prickly tailed *fern*. 42. The great *fern*, with broad dentated pinnules. 43. The ſmaller *fern*, with broad dentated pinnules. 44. The *fern* with leaves at the alæ. 45. The branched *fern*, with roſtrated pinnules. 46. The *fern* with cruſted pinnules. 47. The polypody rooted broad dented *fern*. 48. The *fern* with pinnules, ſhaped like the lonchitis, not dentated, and duſty at the edges. 49. The ſmall broad dentated unbranched *fern*. 50. The forked *fern* with long, not dentated pinnules. 51. The branched *fern*, with long, and in part auriculated pinnules. 52. The *fern* with undulated pinnules and ſquammoſe pedicles. 53. The greater unbranched *fern*, with round not dentated pinnules. 54. The leſſer unbranched *fern* with round not dentated pinnules. 55. The unbranched *fern* divided into obtuſe pinnules. 56. The great adiantum-like tree *fern*. 57. The ſmall adiantum-like tree *fern*, and 58. The *fern* with oblong pinnules, ſerrated at their tops. *Tourn.* Inſt. p. 137.

The root of the *male-fern* is greatly recommended by medical writers, as a cure for the rickets in children. Some alſo give it in powder, againſt worms; and it has the ſame virtues againſt the ſtone and gravel, with the reſt of the genus of capillary plants, aſcribed to it. *Lemery* Dict. des Droug. See FERN.

FILTER, *or* FILTRE (*Cycl.*) — Beſide the common *filtre*, which is only a piece of ſpungy paper, there is uſed on many occaſions another made of a ſkain of cotton or other the like matter twiſted together; this is only to be conſidered as a compound capillary ſiphon; for the threads or filaments of which it conſiſts, lying very near together, make a number of long and ſlender vacuities or interſtices, which repreſent ſo many capillary ſiphons; theſe attract, raiſe, and decant off the fluid, in a conſiderable quantity, which is proportional to their number or to the largeneſs of the *filtre*.

After the ſame manner, it is, without doubt, that the humidity of the earth is drawn up into the ſubſtance of the roots of vegetables, which we know conſiſts of long and very minute fibres, ſo diſpoſed as to form a great number of tubular interſtices; theſe act in the nature of this ſort of *filter*, and attract the juices and moiſture appointed for the nutriment and increaſe of the plant.

FILTRUM, in natural hiſtory, the name of a ſtone much in uſe in the eaſtern parts of the world, and ſometimes with us, for the filtrating water intended for drinking. The Japoneſe are extremely fond of this ſtone, and impute their uninterrupted health, and particularly their being always free from the ſtone and gravel, to their drinking the water thus cleared of all its heterogeneous, and miſchievous particles. The people of this and many other places thereabout, have a ſettled opinion, that moſt diſeaſes ariſe from impurities of water, and are well aſſured, that theſe impurities are all lodged in the ſtone filtre, and left behind by the water in its paſſage.

The manner of uſing the ſtone is this; they form a ſort of mortars with very thick bottoms, out of the largeſt pieces of it, and the water is poured into theſe, and the ſtone being of a very lax and ſpungy texture, it ſoon make its way through, and is received into a veſſel placed underneath for that purpoſe. Some ſay that the ſtone itſelf is a kind of marine fungus, that it is ſoft while in the water, and grows to the ſides of rocks in ſome part of the gulf of Mexico, at the depth of a hundred ells, from whence it is with the utmoſt difficulty got up, and that it hardens into a ſtone as ſoon as it comes into the air.

This ſeems a fabulous account, however, only propagated to countenance the high price the ſtone bears. Whatever be its origin in Mexico, we are well aſſured that there are other places where it is to be had on much eaſier terms, than by fetching it from the deep bottoms of the ſea. We are at preſent acquainted with two kinds of it: the one black, reſembling the common black ſlate, with which we cover houſes, and the other grey and of a tophous ſtructure. We have alſo ſtones which may be applied to this purpoſe, in many parts of Europe; and in all probality, every ſpecies of thoſe which are porous, and of the tophus kind, will do. The oſteocolla uſed in the ſhops as a medicine, will perfectly well anſwer that purpoſe; and if one of the tubes of this be ſtopped at the bottom and then filled with water, it will be ſeen immediately making its way thro' it on all ſides. The incruſtations on vegetable and other ſubſtances in ſprings, are all form'd of a matter very analogous to the oſteocolla, that is, of a coarſe terrene ſpar. And if a piece of any of theſe be hollowed at the

top, and water put into it, it will be ſeen to fall out at the bottom in form of a little ſhower of rain; this might give ſome countenance to the Mexican ſtory of their filtrum being formed under water. As the ſpar contained in all water, ſo that of the ſea, as well as of rivers and ſprings, may form itſelf into a ſort of fungous maſſes, againſt the ſides and edges of the rocks; but it is not probable that it ſhould be found at ſuch depths. On obſerving the great denſity and firmneſs of the ſparry concretions in ſprings, which yet ſuffer water to pervade their texture ſo very readily, Dr. Vater, to whom we owe this account, was induced to try the common coarſe ſtone uſed in building houſes to this purpoſe; and a mortar being made of this, was found to let the water thro', as well as the Mexican ſtone. The water firſt paſſed thro' this mortar had an earthy taſte from ſome of the looſe matter of the ſtone, which it diſloged in its paſſing thro', but this is alſo the caſe in the Mexican, and all other kinds of filtering ſtones, and it goes off in all, after a few times uſing.

It being found therefore an eaſy thing for us to have our water filtered in the ſame manner that the Japoneſe have, it remains to try, whether it will have all thoſe ſalutary effects, which the people of that part of the world give it; and this ſeems not to be imagined from reaſon and analogy. We very well know that water is frequently impregnated with ſaline particles, and that it alſo frequently diſſolves by this means earthy and other matters, which it otherwiſe could not do. But we alſo know, that ſalts diſſolved in water, are not to be ſeparated by filtration; and it is equally certain, that earthy ſparry or other matter that is ſuſpended in water when clear, will in like manner paſs thro' the filter with it. We daily ſee that the ſolid bodies of metals when perfectly diſſolved in proper menſtruums, paſs through the filter of paper with thoſe menſtruums; and if afterwards ſomething be added to the ſolution to weaken the force of the menſtruum, ſo that it can no longer ſuſpend ſo much of thoſe heavy bodies; then the liquors become turbid, and the diſunited particles of the metal will on a ſecond filtration, be left in the paper. It ſeems evident from this, that it is not the fineneſs of the filtre, but the ſtate in which heterogene ſubſtances are ſuſpended in fluids, which is the occaſion of their paſſing thro' with them, or ſeparating from and remaining behind them. It is in vain to ſay, that filtres of ſtone can ſtop the earthy and ſparry particles of water, though filtres of paper cannot; ſince we every day ſee in caverns in the earth, that the water which oozes through the hardeſt rocks, forms ſtony icicles or ſtalaclitæ, before it falls to the bottom. Upon the whole, we are happy enough to have no occaſion for filtering ſtones, ſince our ſprings and rivers afford us waters already pure enough to our hands; and in places where this is not the caſe, it is always poſſible to ſave rain water, which will keep a long time with proper management, and is much purer than all the art in the world can make ſuch as has once been foul. *Valentini* Muſæum Muſæorum, L. 1. C. 22.

The only inſtance in which a filtering ſtone can be of real uſe is, when there is no water to be had, but that of ſome muddy river; in this caſe the mud being a foreign body not diſſolved in, but only floating among the water, it will be left behind in its paſſing the cloſe ſtructure in the filtre; but this is always to be as well obtained by letting it ſtand a while to ſubſide. Ephem. Germ. Cent. 3. p. 76.

FIN, in ichthyology. See the article PINNA.

FINDERS, in our old ſtatutes, are ſuppoſed to be the ſame with thoſe we now call ſearchers; who are employed for the diſcovery of goods imported or exported, without paying cuſtom. Stat. 18 Ed. 3. 14 Ric. 2. 17 Ric. 2. &c.

FINE (*Cycl.*) — FINE *adnullando levato de tenemento quod fuit de antiquo dominico*, in law, a writ directed to the juſtices for diſannulling a fine levied of lands in antient demeſne, to the prejudice of the lord. Reg. Orig. 15.

FINE *capiendo pro terris*, &c. a writ lying where a perſon upon conviction of any offence by jury, hath his lands and goods taken into the king's hands, and his body is committed to priſon, to be remitted his impriſonment, and have his lands and goods redelivered him, on obtaining favour, for a ſum of money. Reg. Orig. 142.

FINE *levando de tenementis tentis de rege in capite*, &c. a writ directed to the juſtices of the common pleas to admit of a fine for the ſale of land holden of the king in capite. Reg. Orig. 167.

FINE *non capiendo pro pulchre placitando*, a writ to inhibit officers of courts to take fines for fair pleading. Reg. Orig. 179.

FINE *pro rediſſeiſina capienda*, &c. a writ lying for the releaſe of one impriſoned for a rediſſeiſin, on payment of a reaſonable fine. Reg. Orig. 222.

FINES *le roy*, in law, are all *fines* to the king. Under this head are included fines for original writs.

FINE *ſtiller*, in the diſtillery. That branch of the art which is employed on the diſtilling the ſpirit from treacle of other preparations or recrements of ſugar, is called *fine* ſtilling, by way of diſtinction from malt ſtilling; and the perſon who exerciſes this part of the trade is called a *fine* ſtiller.

The operation in procuring the ſpirit from ſugar is the ſame with that uſed in making the malt ſpirit; a waſh of the ſaccharine matter being made with water from treacle, &c. and fermented with yeaſt. It is uſual to add in this caſe, however, a conſiderable portion of malt and ſometimes powdered jalap to the fermentiug backs. The malt accelerates the fermentation, and makes the ſpirit come out the cheaper, and the jalap prevents the riſe of any muſty head on the ſurface of the fermenting liquor, ſo as to leave a greater opportunity, for the free acceſs of the air, and thus to ſhorten the work, by turning the foamy into a hiſſing fermentation. *Shaw*'s Lect. p. 220.

FINERY, in the iron works, is one of the two forges, at which they hammer the ſow iron. In order to make the wrought iron, they firſt hammer a piece of a proper ſize gently at this forge, and by degrees bring it after it has been hammer'd into a ſquare bar or bloom, into what they call an ancory; which is the ſame maſs hammer'd ſmaller in the middle, and there reduced to the ſhape the whole is to be brought to, at the chofery or other forges. *Ray*'s Engliſh Words, p. 127.

FINGART, in the manege, ſignifies a horſe that kicks againſt the ſpurs.

FINGERS (*Cycl.*) — *Bones of the* FINGERS. The phalanges of the bones of the four *fingers* are all of nearly the ſame ſtructure, differing only in ſize. The firſt phalanges are made nearly in the ſame manner with the ſecond of the thumb, only that they are flatter in proportion on their concave ſides, and more rounded at their convex ſides. They are alſo larger in proportion; and the edges of the flat ſides, have the ſame rough line as the ſecond phalanx of the thumb. Their bones are more hollow for their articulations with the metacarpal bones, and their heads are formed like pullies. The ſecond phalanges are ſhorter, narrower and thinner, than the firſt; both phalanges are gently incurvated, and reſemble each other in ſtructure, except that the ſecond contract by degrees from their baſes, to the heads which are very ſmall, and that their bones have a double cavity for their articulation by ginglymus, with the heads of the firſt phalanges. Their flat ſides have all the beforementioned rough lines. The third phalanges are in every thing like that of the thumb (which ſee) but that they are ſmaller, each of them being proportioned to the fingers they belong to. It is to be obſerved of all the phalanges, that their baſes have ſmall tuberoſities, and their heads, except thoſe of the laſt phalanges, have on each ſide a ſort of roundiſh foſſula, bordered with ſmall eminences. *Winſlow*'s anatomy, p. 88.

Mr. Hunauld has given us obſervations on the ſtructure and action of ſome muſcles of the *fingers* in the Mem. Acad. Sciences for 1729.

Superfluous FINGERS. Infants are often born with ſuperfluous, or ſupra numerary *fingers*, which are uſually miſhapen and miſplaced: ſome of theſe are found to have nails and bones like the other *fingers*; others have nothing of this, but are mere maſſes of fleſh.

Theſe ſhould always be amputated in the infancy of the child, but if they are many in number, and the child but weakly, it may be better not to take them all off at one time, but to ſtay ſome time between each amputation, that one may be near well, before another is taken off. They are to be cut off with the ſcalpel, or ſciſſars, and the hæmorrhage ſtopped either with dry lint, or with the ſame dipped in ſpirit of wine, and afterwards healed as common wounds, with vulnerary balſams. *Heiſter*'s Surgery, p. 330.

Carious FINGERS. The *fingers* when carious or affected by a ſpina ventoſa, are to be amputated three ways. 1. By a pair of ſtrong ſciſſars or ſharp edged pincers. 2. By a chizzel ſtruck by a leaden mallet, by which they are ſeparated at one blow, or laſtly by dividing the next ſound joint with a ſcalpel, and drawing back a part of the skin to wrap over the ſtump, that it may heal the ſooner; and this is the beſt method of all, as by this you are in no fear about any ſplinters of the bone being left. *Heiſter*'s Surgery, p. 331.

Fractur'd FINGERS. When one or more of the bones in the *fingers* are broke, the ſurgeon's buſineſs is carefully to replace what has been removed, and to roll up the *finger* a little way with a narrow bandage, and then to bind it firmly to the next ſound *finger*. But it is much more proper, when the *finger* is maſhed, ſo as to give no hope of a good cure, to take it off at once. *Heiſter*'s Surg. p. 129.

Luxated FINGERS. The bones of the *fingers* and thumbs are liable to luxations of each of their articulations, and that in ſeveral directions; but theſe are accidents not only eaſily diſcovered, but very eaſily remedied alſo; for the ligaments being not very robuſt, the fat and muſcles thin, and the ſinuſes of the articulations ſhallow, the extenſion is very eaſy, and the reduction of them into their former places not leſs ſo. The beſt method is to extend ſufficiently the *finger* with one hand, and to replace the luxated bone at the ſame time with the other, and to retain it ſo by a proper bandage. *Heiſt.* Sur. p. 166.

FINGITES, a name given by ſome of the barbarous writers of the middle ages to the phengites, a very tranſparent ſort of marble uſed by the Romans in building.

FINING (*Cycl.*) — FINING of wines. The uſual method of *fining* down wines, ſo as to render them expeditiouſly bright, clear, and fit for uſe, is this. Take an ounce of iſinglaſs, beat it into thin ſhreads with a hammer, and diſſolve it by boiling, in a

pint

pint of water; this when cold becomes a ſtiff jelly. Whisk up ſome of this jelly into a froth with a little of the wine intended to be fined, then ſtir it well among the reſt in the cask, and bung it down tight; by this means the wine will become bright in eight or ten days. *Shaw*'s Lectures, p. 208. This method however is found to be beſt ſuited to the white wines; for the red ones the wine coopers commonly uſe the whites of eggs beat up to a froth, and mixed in the ſame manner with their wines. The method by which theſe viſcous bodies act in the operation is this; they entangle themſelves among the flying lee or light fæculencies, that float in the wine, and thus forming a maſs ſpecifically heavier than the wine, they ſink thro' the body thereof like a net; carrying down all the foulneſs it meets in the way to the bottom; but when the wine is extremely rich, ſo that its ſpecific gravity is greater than that of the maſs formed by the ingredients uſed in fining and the dregs or lee, this maſs then riſes upward, and floats at the ſurface of the wine, which will in this caſe alſo draw off fine.

FINIRE, in law, was uſed to fine, or pay a fine upon compoſition and making ſatisfaction. It is the ſame with *finem facere*, mentioned in Leg. Hen. 1. c. 53.

FINITO, in the Italian muſic, a canon or fugue is ſaid to be *finito*, when 'tis not perpetual; but when at ſome certain places all the parts join or unite, after having followed one another for ſome time. *Broſs.* Muſic. Dict. in voc. See CANON, *Cycl.* and *Suppl.*

FINNIKIN, the name of a particular ſpecies of pigeon called by Moore the *columba in gyrum flectens*. It is of the ſhape and ſize of the common pigeon. The crown of its head has ſomething of the reſemblance of a ſnake's head, and it is gravel eyed, and has a tuft of feathers on the hinder part of its crown, which runs down its neck, not unlike a horſes main. It is not feather leg'd, and is in colour always either a black or blue pied. *Moore*'s Columb. p. 49.

They have their name from their ſingular manner of courting the female, which is always by riſing over her, and making three or four turns, flapping the wings, and then turning as many times round the other way.

Were a gentleman in the country to ſtock a pigeon houſe with this ſpecies alone, their antic geſtures would make people believe he kept an inchanted caſtle. Some people diſapprove theſe pigeons, as apt to ſpoil the hens, by making them ſquat with theſe antic geſtures. But this is a groundleſs fear.

FINOCHIA, in gardening, the name of a plant which has of late years been introduced into the Engliſh gardens, and cultivated as a ſallad herb. It is a ſpecies of fennel, and is called by authors *Fæniculum dulce azoricum*. The ſweet fennel of the Azores iſlands. It is a high delicacy with ſome in England, though in general it is not liked; it ſeems however to be gaining more and more ground among us, and probably will in a little more time be a commonly eſteemed herb. The culture of it is this.

Good ſeeds muſt be firſt procured from Italy, for thoſe of Engliſh ripening are very apt to degenerate. In February ſome of theſe ſhould be ſowed for the firſt crop, on a light dry ſoil, and in a warm ſituation. The manner of ſowing theſe ſeeds is firſt to rake the bed very ſmooth, then draw a ſmall rill along it, and in this ſcatter them pretty thin; for the plants are not to ſtand nearer than ſix inches to one another; cover this with half an inch of earth, and at the diſtance of ſixteen inches, make another rill, and ſo on throughout the bed. In about a month the plants will come up, and they muſt be then cleared of weeds, and cut up to four inches diſtance; a month after this, they muſt be thin'd to ſix or ſeven inches diſtance; the ſtalks will now begin to ſwell to a large bulk juſt above the ground, this part muſt be earthed up in the manner of celeri, about a fortnight before it is uſed, which will make it eat very tender and criſp.

A ſecond crop ſhould be ſown three weeks after the firſt; and in that manner till July; every three weeks or month a new crop ſhould be ſown, to keep a conſtant ſupply for the table. The crops ſown in the hotter weather ſhould be water'd and ſhaded from the great heats. *Miller*'s Gardener's Dict.

FINSCALE, an Engliſh name for the river fiſh, more uſually called the rudd, the *rutilus latior*, or *rubellio fluviatilis* of authors. *Willoughby*'s Hiſt. Piſc. p. 252. See RUBELLIO.

FINTO, in the Italian muſic, ſignifies a feint, or an attempt to do ſomething, and not to do it; as *cadenza finta*, is when having done every thing proper for a true cadence, inſtead of falling on the right final, another note, either higher or lower, is taken, or perhaps a pauſe brought in. *Broſs.* Muſ. Dict. in Voc.

FIR-*tree*, *abies*, in botany the name of a genus of trees, the characters of which are theſe. The flower is of the amentaceous kind, being compoſed of a number of ſtamina; this is only a male or barren flower however, the embryos being ſituated between the leaves of a ſpike, placed in ſome other part of the tree. Theſe finally become foliated ſeeds, which are hid under a ſeries of ſcales affixed to a central axis, which together conſtitute the fruit or cone, as it is called of the *fir*; for this is no other in reality than the ſpike of embrios grown thicker and larger. To this it is to be added, that the leaves grow ſingly, not more than one out of the ſame theca as thoſe of the pine.

The ſpecies of *fir* enumerated by Mr. Tournefort are theſe: 1. The yew-leav'd *fir*, with the fruit pointing upwards. 2. The narrower leaved *fir*, with the fruit pointing downward. 3. The long leaved *fir*, called by ſome the pinaſter like *fir*. 4. The ſmall Virginian *fir*, with pectinated leaves, and ſmall roundiſh fruit. *Tourn.* Inſt. p. 585.

The manner of propagating *fir*, pines, and other trees of that kind from ſeeds is this. The ripe cones of theſe trees are to be either expoſed to a gentle heat, or ſoaked for twelve hours in warm water; after which the ſeveral cells will open, and the ſeeds fall out.

Theſe ſeeds ſhould never be taken out till the time of ſowing them, which is March. The ground they are to be ſown in, muſt be carefully turned ſeveral times to deſtroy the roots of weeds. For a large plantation, this is beſt done by ploughing ſeveral times; after this, the earth is to be levelled with a ſpade in ſmall ſpots at every ſix feet ſquare; in each of which ſpots, ten or twelve ſeeds are to be ſown, and covered with ſome of the ſame mould broken fine but not ſifted; then they are to be covered with a furze buſh or other ſuch covering; and this is to remain for ſome time after the plants are come up, but they muſt not be covered too cloſe by it; when this covering is taken off, a little looſe earth is to be drawn about the ſtems of the plants, and a little furze ſtuck about them, to keep off the too great heat of the ſun. Uſually from twelve ſeeds there are eight plants or thereabout, and theſe may be left ſtanding together, till the third year. In March or April the third year after ſowing, the plants are to be removed to the place where they are to ſtand, and planted at eight foot ſquare diſtance, or greater, if deſired. Two plants ſhould however be left in the plantation in each cluſter, and great care taken not to injure the roots of theſe. The others alſo muſt be taken up with as much earth about their roots as poſſible. When they are ſet in the new plantation, there muſt be ſtakes fixt near them to tie them to, that the wind does not blow them down, and the roots muſt be covered with litter, and they muſt have a gentle watering to ſettle the earth to their roots. If the weather prove very dry, this may be repeated two or three times, but a little at a time; over watering kills all new ſet trees, and the cutting any of the heads or branches of theſe of the reſinous kind is a very dangerous thing.

The Scotch pine delights in a chalky ſoil on the ſide of a hill, but will alſo grow in gravel, and in any ground that is not too wet.

The common *fir* loves a loamy ſtrong ſoil, and is a native of low flat grounds; and moſt of the American *firs* and pines, love a looſe moiſt ſoil. The ſilver *fir*, and the manured pine, love a dry ſituation, but muſt have a deeper ſoil than the Scotch pine, and muſt be ſhelter'd from the north winds. The two trees left in each ſpot of the place where they were ſown, may be left together ſeven years, then the leaſt flouriſhing tree is to be carefully removed. *Miller*'s Gard. Dict.

FIRDFARE. See FERDFARE.

FIRDWITE. See FERD-WIT, *Cycl.*

FIRE (*Cycl.*) — By the general name of *fire*, men ſeem to underſtand a certain ſenſation or complex notion of light, heat, burning, melting, &c. but this notion ſhould be reſolved, to ſee what parts of it are eſſential, what arbitrary. We frequently find the effects of *fire* produced where no *fire* is viſible; thus the fingers may be burnt by an iron much leſs than red hot; therefore the eye is no judge of fire; nor is the touch, for that give us no ſenſation of heat below the natural warmth of the body, nor of any ſo great as to deſtroy the organ. If this method of rejection be purſued to the utmoſt, we ſhall perhaps find no criterion of *fire*, but that of a general motion ſtruggling among the ſmall parts of bodies, and tending to throw them off at the ſurface; and in this caſe motion is the form or eſſence of *fire*. But we have more light into this, by finding that all bodies are expanded by *fire*; that the inflammable matter of ſuch is oil: that no fuel will conſume without the admiſſion of freſh air, and that flame exiſts only in the ſurface of fuel. *Shaw*'s Lectures, p. 26. See the articles EXPANSION, OIL and FUEL.

The chemiſts in all ages have been uſed to talk of the degrees of *fire*, they uſually divided them into four; but very little certainty was to be found on this head, till the way was found of applying the excellent thermometer of Farenheit to meaſure the progreſs of heat by certain and invariable rules. On this baſis Boerhaave has eſtabliſhed the chemiſts doctrine of the power of *fire* of different ſtrength, and divided it into ſix degrees, and theſe are the degrees of *fire* which our chemiſts allude to, when they now mention the force of *fire* in their operations. The firſt degree of heat, is that whereby nature performs the office of vegetation in plants, and by which chemiſtry imitates and does the like. This commences from the higheſt degree of cold, which in Farenheit's thermometer is marked by 1, and ends at eighty degrees; ſince in this

whole

whole interval we find certain plants give indication of life and growth.

Thus in the ſevereſt winters cold, we find the moſſes growing on the barks of trees, and what is more remarkable, they only grow and produce the rudiments of their ſeeds at ſuch times. The fir, juniper, larix, cedar, pine, ſavin, yew, arbor vitæ, and other evergreens, maintain their verdure in ſevere froſts; the like holds true alſo of the corellines, earth moſſes, black hellebore, the winter aconite and many other plants, which will ſhoot, bloſſom, generate, conceive and bring forth their ſeeds under the ſevereſt colds, which are unable to check their conjugal heat; in fine, were we to riſe from the loweſt to the higheſt pitch of theſe degrees of heat, and then recount all the known plants, we ſhould find ſome growing and flouriſhing in the extreameſt limits of it, and in every intermediate point.

Hence it appears probable, that a chemiſt by duly conducting this degree of heat in an artificial ſtove might imitate the various heats of nature, ſo as to cheriſh all plants, not to deſtroy them; and in the offices of chemiſtry for the raiſing this degree of heat a furnace might be made, and on this a veſſel full of water ſet, and to this a thermometer applied, which by its riſing and falling would indicate the degree of heat required. Then placing glaſs veſſels in the water thus tempered, the ſubſtances are to be put into them, which are to undergo this degree of *fire*. This degree of heat ſeems calculated to be the moſt proper for impregnating oils with any excellent precious vegetable ſpirit without waſting. Thus to communicate the fragrant ſcent of roſes to a given oil, the beſt method ſhould ſeem, to take pure inodorous and inſipid oil of olives, and putting it into a tall clean chymical glaſs, digeſt it in a heat of fifty-ſix degrees, with the moſt fragrant roſes gathered juſt as they are opening in a morning; by this means the heat will unite the ſpirit of the flowers with the viſcidity of the oil, in the moſt intimate manner, and exhibit a highly odorous balſam. The application of a ſimilar degree of heat would impregnate alcohol with the pureſt ſpirit of ſaffron; a leſſer heat ſcarce ſerving to extract this ſpirit from the body, while a greater will diſſipate and evaporate it, or at leaſt the more volatile and fine parts of it.

The ſecond degree of heat may be commodiouſly taken from that which obtains in animals, and which may be ſuppoſed to commence at the fortieth degree of the thermometer, and end about the ninety fourth; within this compaſs, animals may live and ſubſiſt, that is, if their juices be of any degree of heat within theſe bounds. Some inſects ſeem to have ſo little heat in their juices, that it is wonderful to conceive how their eggs can ſubſiſt unhurt, during hard winters; as the eggs of caterpillars and the like; but yet they do, and hatch in the ſucceeding ſpring.

Fiſhes as well of the ſea as of rivers, live in a watery medium, which is only thirty-four degrees hot, and conſequently their blood and juices are of the ſame temperature, yet they can bear any heat from thence to the ſixtieth, and live in that and a ſomewhat farther heat: but fiſhes that have lungs, and all breathing animals, conceive a greater degree of heat in their juices, which when healthy, are found to riſe to ninety-two degrees hot; therefore the limits of this degree are fixed at thirty-three and ninety-four; within which compaſs all the vital functions of all animals, the fermentations of all vegetables, and the putrefactions of animals and vegetables, as alſo their generations, geſtations, incubations, births, nutritions, are performed. *Boerh.* Chym. pt. 1. p. 374.

This degree is uſed by the beſt chymiſts for making elixirs, and volatile alkaline ſalts, both ſimple and oily, alſo tinctures, and the digeſtion of the philoſophic mercury for the ſtone.

The third degree of heat, is that which extends from the ninety-fourth degree on the thermometer, to the two hundred and twelfth, at which laſt, water uſually boils; in this whole degree the water and native ſpirits are ſeparated from all vegetables and animals, and the remainder drying, becomes durable and almoſt immutable. The eſſential oils of plants thus become volatile; but the ſalts and oils obtainable from the recent juices of animals, ſcarce riſe within this degree, but rather dry into a thick, hard, brittle, inſipid, inodorous matter, which remains unchanged for many years; by which appears the falſehood of that common opinion, that volatile alkaline and oily ſalts are generated and found in the healthy bodies of men in this degree of heat. All diſtilled oils are prepared, and all the medicated waters of ſimples are diſtilled in this degree; and the ſanguineous and ſerous humours of animals coagulate by boiling water, into ſciſſile maſſes; all their ſolid parts are deſtroyed and turned into a thick tenacious liquid; and conſequently all animals deſtroy'd therein.

The fourth degree of heat may be taken from 212 to 600 degrees on the thermometer, within which compaſs the diſtillation of all oils, ſaline lixiviums, quickſilver and oil of vitriol is performable; within this degree alſo, lead and tin will melt and mix together. Oils, ſalts and ſapos, both of animals and vegetables, become volatile and acrimonious in this degree, tending more or leſs to an alkaline nature; their ſolid parts drying up, and burning into a black coal. In fine, all theſe matters are utterly deſtroyed, and have their nature chang'd, and loſe their powers in this degree of heat; and foſſile ſulphur, and ſal armoniac are ſublimed in the ſame. The fifth degree of heat, is that wherein the other metals melt, and which commences from 600 degrees, and ends at that heat by which iron is kept in fuſion; in this degree moſt bodies are deſtroy'd: glaſs, gold, ſilver, copper and iron remain long unchanged in it, all other fixed bodies grow red hot in this degree; the fixed ſalts of vegetables and foſſils melt, are deprived of moſt of their oils, and are raiſed further and further toward an alkaline acrimony, and thus with ſand or flint turn to glaſs. In this heat limeſtones calcine, and all other bodies, either vitrify or become volatile, and are diſſipated in the air.

The ſixth and higheſt degree of *fire*, is that made either by a lens or a burning ſpeculum; this ſcarce any ſubſtance is able to withſtand, and gold and the diamond are conſiderably altered by it. The almoſt univerſal effect of this degree of fire is the turning all fixed bodies into glaſs, whence it is laid down as a rule, that the utmoſt effect of *fire* is the vitrification of fixed bodies; and this the antient ſages of Aſia ſeem to have been appriſed of, as they ſay in all their predictions, that the whole world ſhall at length periſh by *fire*, and be turned into tranſparent glaſs. Having thus regulated what are the degrees of *fire*, it remains to ſay in what manner a *fire* may be raiſed and maintained in any given degree. *Boerh.* Chem. part 1. p. 376.

Alcohol or ſpirit of wine affords a very feeble but equable heat; and this may be managed and directed to ſeveral regular degrees by lighting up more or fewer wicks at a time, under the veſſel to be heated.

After alcohol follow other light ſpungy and porous fuels, ſuch as hay, ſtraw, ruſhes, dried leaves, hair, feathers, ſawduſt, barks, chaff, bran, &c. After theſe come oils, tallow, wax, camphor, pitch, reſin, ſulphur, and other inflammable ſubſtances prepared from theſe; then follow the thick, hard and heavy woods, not over dry, and the coals made from theſe; and laſtly pit-coal, and red hot metals. And tho' the materials or fuel be the ſame, a different degree of heat may be given by uſing a ſmall or a large quantity at a time. The heat produced differs alſo according to the object to be chang'd and its diſtance from the fuel; as all heat decreaſes in proportion to the diſtance from it, and laſtly the degree of *fire* may be modified by ſhaking, ſtiring, or compreſſing the fuel, or the airy vault ſurrounding it; hence bellows become of prodigious uſe in raiſing the power of *fire* from the ſame fuel or materials; to all this it is to be added, that the degree of *fire* is to be greatly regulated by the figure of the furnace, that being conſtructed with an arch'd top, may be ſo diſpoſed to reflect the *fire* and collect its power to ſome one place; and if all theſe aſſiſtances be applied at once, we have the higheſt poſſible degree of vulgar *fire*.

The dread that wild beaſts have of *fire*, is very ſurpriſing. The natives of the Cape of Good Hope, chaſe away the lions from their cattle by means of *fire*; and the Ceyloneſe drive tigers, &c. from their plantations in the ſame manner. By means of *fire* deer, elks, &c. may be caught in this manner; two men go out into the woods in the night, one of theſe takes an earthen veſſel on his head, with *fire* in it made of ſticks and reſin, and in one hand he carries a ſtaff with eight bells on it, and the other goes cloſe behind with a ſpear in his hand; when the deer, &c. ſee the light and hear the bells, they come up, ſtand, and gaze, while the ſpear man kills them. The men are in no danger from tigers, &c. for they run away from the *fire*. Phil. Tranſ. p. 1094.

FIRE *from cold liquors*. It is poſſible to produce *fire* and flame by the bare mixture of two cold liquors in the following manner; take two drams of ſtrong and freſh ſpirit of nitre prepared with oil of vitriol, and putting it into a clean and dry gallipot, ſet it under a chimney, then pour to it at once of the oil of cloves one dram, there will be immediately produced a loud noiſe, and a conſiderable flame, and when that is gone, a dry reſin is formed in the pot. *Shaw*'s Lect. p. 399.

Lambent FIRES. Among the number of theſe lambent or innocent flames, is the ſhining of meat at certain times. It has been uſually ſuppoſed, that this was owing only to the putrefaction of the meat, and that it never ſhone till ſtinking or nearly ſo, but experience proves the contrary. We have in the Philoſophical Tranſactions an account of a piece of veal which was obſerved to ſhine the night after it was killed, and yet when eaten the day afterwards was perfectly ſweet, and a part of it that was kept by way of experiment continued good many days after. This is not of the nature of common *fire* or flame, and not only differs in not burning, but in this alſo, that it is not extinguiſhable in water. A perſon ſtriking this piece of veal, had the flame covering his whole hand, and that continuing, even when he had put it under water, but the wiping it with a towel, carried it all off and deſtroyed it. It is not uncommon to find the guts of hogs when dreſſed by the good women for the making what they call chitterlings, and put into the pickle, ſhine in this manner. Some of the pieces while under this management uſually ſwim on the water and others ſink in it. Thoſe which ſwim, are the only

only ones that ſhine. The light upon them is as bright as the ſtrongeſt moonſhine, and may be communicated to a perſon's hand, by rubbing the pieces on it; where it will continue to be bright a long time, without any ſenſible heat. The face and hands of a perſon being rubbed over with one of theſe ſhining pieces of the chitterling, not only appear bright and flaming, but are made to look conſiderably larger than they really are; and a perſon who had a mind to raiſe ſtories of ghoſts and apparitions, might eaſily do it by covering the whole body of a man with this flame, and making him appear a fiery giant to all that ſaw him.

Mackrel in pickle will uſually become luminous in ſome degree, a little before they ſtink, but it is rarely, that the light is great; and when it has once happened ſo, it is not eaſy to hit the ſame again on a ſecond trial, tho' all the ingredients of the pickle are kept the ſame in the niceſt manner. Worms are often found luminous on their ſurfaces in oiſter ſhells, yet the ſame worms are not always ſo; and what Pliny reports of the pholas, and Reaumur has ſince found to be true, perhaps may not always hold ſo in future experiments. Philoſoph. Tranſ. N°. 124. See PHOLAS.

One of the moſt ſingular kinds of lambent *fire*, is that diſcovered at certain times on the ſea water, and on other water in which there are fiſh, or other ſea productions kept. We have in the Philoſophical Tranſactions, an account of ſome water in which mackrel were boiled and afterwards kept, which became blackiſh and thick after two or three days, and then would ſparkle on the touch of a finger. The fiſh alſo were luminous, eſpecially about the gills, and the water when ſtirr'd about with the hand, would appear ſo bright over the whole ſurface, that the appearance was like that of water in motion, on which the moon ſhines very ſtrongly.

In the ſame manner, the ſea water in many places will ſparkle and ſhine on the breaking its ſurface. Where a ſhip makes a good way in the night, in many ſeas, the whole breaking of the water will appear behind it, as if on fire, ſparkling and ſhining all the way that it moves from the diſturbance of the paſſages of the ſhip. Phil. Tranſ. N°. 37.

It is in this part as bright and glittering as if the moon ſhone upon it; but as this happens moſt of all, when there is no moon up, it is plainly to be attributed to another cauſe. Some have ſuppoſed the ſtars to brighten the water, or the lanthorns of the ſhip to ſhine upon it as the veſſel moves; but it is always found to be brighteſt and ſtrongeſt when there is no other light any where, when the ſtars are clouded, and there is no light in the lanthorns. This light is not equal at all times; ſome nights, in the ſame places, it is ſcarce perceivable at all; ſometimes it is very vivid and bright, ſometimes it covers only the way that it is juſt in motion behind the ſhip, and ſometimes extends itſelf a great way on each ſide it. Thirty or forty foot is a common extent for it from the ſtern of the ſhip, but it is much more faint at a diſtance than where the water is juſt broken; and it is at the ſtern of the ſhip often ſo bright, that a perſon on the deck may ſee to read by it, tho' ſo high above it. The luminous water that follows the road of the ſhip, is ſometimes very diſtinct from the reſt of the ſurface. Sometimes they are blended with it, and the luminous matter blending itſelf at the ſides with the adjacent water, the appearance is confuſed: in the firſt caſe it is very agreeable to ſee a luminous river follow as it were the road of the ſhip. The luminous matter of the water appears generally compoſed of ſmall ſparkles, but ſometimes theſe form themſelves into the figure of a ſtar, as we ſee it repreſented, and in ſome places it forms globules without any radiations from them. Theſe are of different ſize, from that of a large pin's head, to a foot in diameter; and ſometimes the luminous matter is ſeen in form of oblong ſquares of three or four inches each. Theſe are at times diſtinct, and at times confuſed and ſeen all together. When the ſhip goes very ſwiftly, theſe figures all combine to form a ſort of luminous whirlpools, but when it goes more ſlowly, the ſingle ſquares and globules appear and diſappear momentarily like lightnings. It is not particular to a ſhip to make this appearance on the water by putting it in motion, and breaking its ſurface, but any thing that moves in it does the ſame thing. The large fiſh as they ſwim along near the ſurface, leave the ſame ſort of luminous road behind them, and that ſo bright, that a perſon may often diſtinguiſh by it, what fiſh it is that paſſed along there. A number of fiſh playing thus on, or near the ſurface, as is very common in ſome ſeas, break the water in a great many different directions, and make a ſort of artificial fires, which afford an agreeable ſight.

Sometimes the throwing out a rope or any thing that breaks the ſurface of the water will render it luminous in the ſame manner in that part. If ſea water be taken up and ſet on the the deck in a veſſel of any kind, as ſoon as it is ſtirr'd it will ſparkle and give more or leſs of the like luminous appearance according to the darkneſs of the night and other accidents; and if a piece of linen rag be wetted in the ſea water and hung up to dry, when it is thoroughly dried it will appear luminous on being rubbed in the dark; and when half dry it need only be ſhook to ſhew a great number of ſparkles. When theſe ſparkles of light are once form'd they will laſt a conſiderable time; often many hours, if they chance to fall upon any ſolid body on the ſides of the veſſel, otherwiſe, if they remain on the water, they ſoon go out.

There does not always need the motion of a foreign body in the ſea to occaſion this ſort of phoſphorus, but the waves beating againſt one another, will often occaſion it in great plenty, and ſometimes the waves waſhing againſt the rocks or againſt the ſhore, will yield a long courſe of light the whole night. This is no where ſo remarkable as at the Braſils: the ſhores there are often all on fire to appearance, from the vaſt effuſion of this luminous matter, as the waves waſh and break upon the ſhore.

This flaming and ſparkling of the ſurface of the ſea is wholly owing to the peculiar quality of the water; and in general, the thicker and fouler the ſea is, the more light it affords on being ſtirred in the night. A cloth dipped in the ſea water will ſometimes be ſtickey as if dipt in a ſolution of glue; in this caſe it will afford much brighter, and more luminous ſparks in the drying, and this fat water will give much more *fire* from the motion of the ſhip than any other. In many places the ſurface of the ſea is found covered with fiery matter of a reddiſh or yellowiſh colour, looking like ſaw-duſt, and ſeeming to be the ordure or recrement of ſome ſea animals. This matter always is of a viſcous nature, and the ſea water is viſcous and gluey wherever this is found, and gives more light on the moving, than any other water. In the Northern ſeas there are ſometimes ſeen whole banks as it were of this matter, the ſurface of the ſea appearing wholly covered with it for ſeveral leagues; and this is often luminous all over in the night, tho' not ſtirred by any ſhip, or even by the motion of any fiſh. Many of the ſea fiſh have a viſcous matter about their gills, eſpecially when they have been ſome time dead. Theſe when kept in ſea water, have ſo much of this luminous property, that all that part appears as ſoon as taken up, of the brightneſs of a flaming coal, and gives a light which it is eaſy to read by. A piece of ſtick rubbed on the gills of theſe fiſh, will become luminous wherever it has touched them, and will continue ſo, as long as it retains any of the moiſture, but as that dries, the light will fade and go off; and it may be revived again, on touching the fiſh a ſecond time. Obſerv. ſur l'Aſie, p. 289.

Subterraneous FIRE, that *fire* which manifeſts itſelf upon the earth in fiery eruptions from beneath, in vulcanos or burning mountains, and in other parts of the earth. The effects of this ſeem wholly the ſame with thoſe of the common culinary *fires:* for burnt coals, cinders and melted minerals are thrown out by the burning mountains; and hot ſprings, ſteams, vapours, &c. are found in ſeveral parts of the globe, riſing nearly in the ſame manner, as if they were produced by the heat of a common furnace. Whence there is little room to doubt but that the ſubterranean *fires* are not like the celeſtial or ſolar, but the culinary. *Shaw*'s Lectures, p. 29.

Martin in his Atlas, tells us, that there are pits of natural *fire* in China, which are capable of dreſſing meat, but will not conſume wood; but we have no authentic teſtimony of any eye witneſs to this ſtrange fact.

Extinguiſhing of FIRE. See the article EXTINGUISHING.

FIRE, in the manege. To give the *fire* to a horſe, is to apply the firing iron red hot to ſome preternatural ſwelling, in order to diſcuſs it; which is oftentimes done, by clapping the firing iron upon the skin, without piercing through. We give the *fire* to farcy knots by running a pointed burning-iron into the ulcers. We likewiſe give the *fire* for wrenches of the paſterns. See FIRING-*iron*.

FIRE-*ball*, a compoſition of meal-powder, ſulphur, ſalt-petre, pitch, &c. about the bigneſs of a hand granade, coated over with flax, and primed with the ſlow compoſition of a fuze. This is to be thrown into the enemies works in the night time, to diſcover where they are; or to fire houſes, galleries, or blinds of the beſiegers; but they are then armed with ſpikes or hooks of iron, that they may not roll off, but ſtick or hang where they are deſired to have any effect.

FIRE *Bare*, in our old writers, is uſed for a beacon. *Quod ſine dilatione levari & reparari fac. ſigna* & firebares, *ſuper montes altiores in quolibet hundredo, ita quod tota patria, per illa ſigna, quotieſcunque neceſſe fuerit, præmunire poteſt.* Ordin. Obſervand. Temp. Edw. 2.

Bone-FIRE. M. Mahudel has a diſſertation on the origin of *bone-fires*, wherein he endeavours to make it appear, that they were unknown to the antients, and conſequently muſt be a modern invention.

He does not deny that the antients had rejoicings on occaſion of the concluſion of a peace or alliance, or the news of a victory's being obtained againſt their enemies, on the birth-day, proclamation, or marriage of their prince; as alſo when they recovered from a dangerous ſickneſs; but, according to him, the *fire* on all theſe occaſions ſerved only to burn the victims or the incenſe; and as theſe ſacrifices were moſtly offered in the night time, the illuminations were only intended to give light to perform the ceremonies. Hiſt. Acad. Inſcirp. T. 2. p. 430. ſeqq.

FIRE-*cocks*.—Church-wardens in London, and within the bills of mortality, are to fix *fire-cocks* at proper diſtances in ſtreets, and keep a large engine and hand-engine for extinguiſhing *fire*, under the penalty of 10 l. Stat. 6. An. c. 31.

FIRE-*damp*, in natural hiſtory. See DAMP, *Cycl.*
It is otherwiſe called *fulminating Damp*.

FIRE-*flaire*, in ichthyology, a name given by us to a ſpecies of the raja or ray-fiſh, called by the generality of authors *paſtinacha marina*. It is diſtinguiſhed by Artedi from the other ſpecies of the raja by the name of the ſmooth bodied ray with no fins to the tail, but with a long bony ſpine in it, ſerrated on one ſide. This is the trygum and tragum of the old ichthyologiſts, and is called by the modern Italians, bancho. See PASTINACHA *Marina*.

FIRE-*lock*, or FUSIL, a ſmall gun which fires with a flint. It is diſtinguiſhed from an old muſket or match-lock, which was fir'd with a match. The *firelock* is now in common uſe in the European armies.

FIRE-*pots*, are ſmall earthen pots, into which is put a grenade filled with fine powder till the grenade be covered; and then the pot is covered with a piece of parchment, and two pieces of match laid acroſs and lighted. This pot being thrown where it is deſigned to do execution, breaks and fires the powder, and thereby fires the powder in the grenade, which ought to have no fuze, that its operation may be the quicker.

FIRE-*ſhips*, in the navy, veſſels charged with artificial fire-works; which having the wind of an enemies ſhip, grapples her, and ſets her on *fire*.

FIRE-*water*, a name given to alkaheſt. See IGNIS *Aqua*.

FIRE-*works*. The invention of *fireworks* is by M. Mahudel attributed to the Florentines and people of Siena; who found out likewiſe the method of adding decorations to them of ſtatues, with *fire* iſſuing from their eyes and mouths. Hiſt. Acad. Inſcript. T. 2. p. 435.

FIRING-*iron*, in the manege, is a piece of copper or iron, about a foot long, one end of which is made flat, and forged like a knife; the back of it being half an inch thick, and the fore edge about the fifth or ſixth part of this. When the farrier has made his *firing*-iron red hot in his forge, he applies the thinneſt part to the horſes skin, and ſo gives the *fire* to the hams, or ſuch places as ſtand in need of it.

FIRLOT, a dry meaſure uſed in Scotland. The oat *firlot*, which contains 21 $\frac{1}{4}$ pints of that country, is 19 $\frac{1}{2}$ inches in diameter both at top and bottom, being of a perfect cylindrical form, and in depth 7 $\frac{1}{3}$ inches. The wheat *firlot* contains about 2211 cubical inches, and the barley *firlot* 31 ſtandard pints. Whereby it appears that the Scotch wheat *firlot* exceeds the Engliſh buſhel by 33 cubical inches. Tr. Pract. Geom. p. 115, 117.

FIRM-*ore*, a kind of lead ore. See LEAD-*ore*.

FIRST *mover*, in the antient aſtronomy. See PRIMUM *Mobile*, *Cycl.*

FIRUZINUS *color*, a term that frequently occurs in ſome of the old writers on gems, and has been miſtaken by many to mean a ruſty brown; and by others, black: but theſe are not colours to be ſought after among the gums, and yet it is to thoſe that this epithet is uſually applied. We find it uſed for a blue kind of jaſper by ſome authors, the ſame with the jaſpis boreas of Pliny and Dioſcorides, and by others for the ſapphire, which ſome of the antients, particularly Theophraſtus, having called μελανα, that is, black in its deepeſt colour, authors have been led to ſuppoſe this word ſtood for black; but as there are not, nor ever were any black ſapphires, it is certain from this as well as many other inſtances, that the ancients uſed this word μελας, for a deep blue, and in that ſenſe *firuzinus color* does ſignify the ſame thing. It being the aerinus color of the antients, or what we call sky-colour, or a fine blue; ſuch as the colour of the fineſt ſapphires.

FISANELLE, in zoology, a name given by the Venetians to a water fowl of the colymbus kind, called by authors the colymbus major, or great diver. Its general weight is about a pound, its beak is two fingers breadth long, and all its feathers are downy, ſoft, and very thick ſet together; its head and neck are brown, and its back is blackiſh; its ſides and belly brown, and its breaſt of a ſilver white. It has no tail, and its wing feathers are black and white. Its feet are not webb'd, but the toes are all widened by membranes. It is very common in the markets of Italy. *Ray*'s Ornith. p. 256.

FISCHERLIN, in zoology, a name given by many of the northern nations to a ſmall ſpecies of the larus or gull, called by Mr. Ray, larus piſcator; and in Engliſh, the leſſer ſea ſwallow. It is ſmaller than the common black-bird. Its wings are long and grey, its feet ſhort and yellow, its breaſt and belly are white, the crown of its head black, and its back grey. It is very common on the German coaſts, and feeds on ſmall fiſh. *Ray*'s Ornithology, p. 269.

FISGUM, a name uſed by ſome, for the fiſh commonly called miſgum. *Willoughby*'s Hiſt. piſc. p. 129.

FISHES, (*Cycl.*) in natural hiſtory, make one of the diſtinct claſſes of animals, the characters of which are, that they have either a naked or ſcaly body, that they have no feet, and always have fins. *Linnæi*, Syſt. Nat. p. 33.

It is ſaid, that all *fiſh* regulate their times of eating and abſtinence, by the temperature of the air, and the quarter from whence the wind blows. Hence if thoſe who are lovers of angling, would take the pains to keep a few ſmall fiſh in glaſſes, they might at any time eaſily foretel, from their taking or refuſing food, what ſport is to be expected, and thus ſave themſelves many a weary ſtep. Phil. Tranſ. N°. 482. Sect. 15.

It is reported by many people, who have written accounts of China, that there are certain fiſh of a ſaffron colour in the ſeas thereabout, which in the ſpring caſt off their ſcales and get feathers and wings, and fly to the woods, where they build their neſts, and live all ſummer, but in winter return to their watery habitation with their young ones, and become fiſhes again. This is too abſurd to be believed, tho' very ſeriouſly related by grave authors. If the famous gold fiſh be meant by it, as ſome ſay, the whole is proved to be fabulous, by theſe fiſh being often found with ſpawn or roes in them. *Redi*'s Eſperienze.

The northern countries abound in large and delicate fiſh even to the extremeſt degrees of cold. Scheffer in his hiſtory of Lapland, gives us a wonderful account of the abundance, and large ſize of the fiſh there.

The ſalmons grow to a larger ſize than we ever ſee them of, and are caught in ſuch abundance, that the natives who pickle them, ſometimes export not leſs than thirteen thouſand tuns in a year: pikes are very common, and grow to the length of ſix or ſeven foot, and a proportionable thickneſs.

The carp grow to an ell long and often conſiderably more; and trout, barble, gudgeons and pearch grow to a proportionable ſize and fatneſs. The laſt of theſe fiſh have one very peculiar among them. They ſoak the skins in water, and then ſtripping off the ſcales, they add freſh water and boil the skins down till wholly diſſolved, of this they make a very pure and beautiful ſort of glue, which is not inferior in ſtrength to our coarſe and ſtinking kind. *Scheffer*'s Hiſt. Lapland.

The coming of certain kinds of fiſh in ſhoals and infinite multitudes, to certain coaſts at certain times of the year, is a thing of great advantage to mankind, as it gives opportunities of taking them with great eaſe, and in vaſt quantities; but the reaſon of theſe periodical returns of the ſeveral kinds, does not ſeem much underſtood, tho' a little obſervation would probably clear it up. There is a ſmall inſect common in many ſeas, but peculiary plentiful on the coaſts of Normandy in the months of June, July and Auguſt. This is well deſcribed by Rondeletius, under the name of the ſea caterpillar; and at this time of the year it is ſo frequent in the place before mentioned, that the whole ſurface of the water is covered with it as with a ſcum. This is the ſeaſon of the year when the herrings come alſo in ſuch prodigious ſhoals to thoſe coaſts. The fiſhermen complain much of theſe naſty vermin which diſturb their fiſheries, but they do not conſider that it is to theſe alone, that their fiſheries are owing; for it is evident, that the herrings feed on theſe creatures greedily, by the vaſt quantity found in all their ſtomachs; and it is highly probable, nay ſcarce to be doubted, that the reaſon of thoſe fiſh coming up in ſuch numbers is to feed on them; probably if obſervation was made, the ſame would be found to be the caſe in all the other places where the herrings come in the ſame ſort of plenty. The mackrel come down in the ſame numbers regularly at certain times of the year, and for the ſame ſort of reaſon. This fiſh is an herb eater, and is particularly fond of that ſea-plant called by naturaliſts, the narrow leaved purple palmated ſea wrack; this grows in great abundance on the coaſts of England, and many other places, and is in its greateſt perfection in the beginning of the ſummer, tho' ſometimes later than others according to the ſeverity or mildneſs of the winter.

The whole occaſion of theſe fiſh coming in ſuch quantities is to feed on this plant; and thoſe who would attend to its growing up, would know when to expect the mackrel better than thoſe who liſten for thunder for the ſignal of them. The tunnys come at certain ſeaſons to the coaſts of Provence and Languedoc, in the ſame ſhoals that herrings and mackrel do to other places. This ſeems to be on another occaſion. The fiſh called by the French the emperor, and by the ſame confounded with the ſword-fiſh, is the great enemy of theſe fiſh, and in ſummer is ſo plentyful in thoſe ſeas, that they find no way of ſaving themſelves, but by flying to the ſhallow waters, where the other cannot eaſily follow them, hence they frequent the ſhores. The pilchards caught upon the coaſts of Bretany, and making a conſiderable article of commerce for that province, are yet a ſtronger proof of the natural means that bring *fiſh* in ſhoals to certain places, than any other. Theſe *fiſh* evidently come for food, and that not natural to the place, but prepared for them by the inhabitants.

The people of Bretany purchaſe from Norway, the offal and entrails of all the large *fiſh* caught in the Northern ſeas; this is of late years become a regular and conſiderable article of trade; they cut theſe to pieces, and ſtrew them in vaſt quantities over the whole ſurface of the ſea along their coaſts, at times when the winds do not ſit ſo as to blow it off.

This always brings together the pilchards in as vaſt ſhoals as the herrings or mackrel come in other places; and the fiſher-

men

men catch them in ſuch quantities, as to be able to ſupply all the maritime places in the neighbourhood with them at a ſmall price. The ſalmon, a *fiſh* bred in rivers, yet going at certain times to the ſea, is another of thoſe *fiſh* which come up at times in vaſt ſhoals. The ſeaſon of their coming is as well known as that of other *fiſhes*, and the cauſe of it is, the other great principle of nature, beſide the preſervation of the individual, that is, the propagation of the ſpecies. The ſalmons always depoſit their ſpawn in ſhallow freſh waters. For this purpoſe they go up into rivers at certain proper ſeaſons, the females firſt, the males following; and when they have done this neceſſary office, they go back into the ſea in the ſame order. Theſe are the plain cauſes of the appearance of ſhoals of certain *fiſh* at certain times in theſe places, and in all probability, the ſame ſort of cauſes would appear to influence all the reſt, were they ſufficiently enquired into.

The ſalmons when they are going up a river out of the ſea, are always obſerved to ſwim as deep or as near the bottom as they can; and on the contrary, when they are going down the ſame river into the ſea, they are always ſeen ſwimming near the ſurface. The reaſon of this is, that in going up, they are to ſwim againſt the current, which always runs much ſwifter at the ſurface than deeper; and when they are going down, they get to the ſurface, when the force of the current alone is ſufficient to carry them, and they have little or no trouble in puſhing themſelves on.

Small fiſh may very well be kept in glaſs jars with freſh water; and thoſe of prey are very fit to be tamed by this means.

Some of theſe creatures often have no other ſuſtenance, than the animalcula of the water they are put in. Phil. Tranſ. N°. 478. p. 26. See DAC and RUFF.

Mr. Boyle ſpeaks of a kind of fiſh in the coaſt of Ireland, the hearts of which are found inverted. Works Abridg. vol. 1. p. 27.

In the Philoſophical Tranſactions N°. 463, Sect. 1. we have a method of preparing ſpecimens of fiſh, by drying their ſkins, as practiſed by Dr. Gronovius.

Generation of FISHES. The general opinion of the world as to the generation of *fiſhes*, is, that the female depoſits her ſpawn or eggs, and that the male after this ejects the ſperm or male ſemen upon it in the water. The want of the organs of generation in *fiſhes*, gives an apparent probability to this; but Linnæus is greatly againſt it. He affirms that there can be no poſſibility of the impregnation of the eggs of any animal out of its body.

To confirm this, the general courſe of nature not only in birds, quadrupeds and inſects, but even the vegetable world has been called in to his aſſiſtance, as proving, that all impregnation is performed, whilſt the ova are in the body of the parent; and he ſupplies the want of the organs of generation by a very ſtrange proceſs, affirming that the males eject their ſemen always ſome days before the females depoſit their ova or ſpawn, and that the females ſwallow this, and have their eggs by that means impregnated by it. *Artedi*'s Ichthyogr.

He ſays, that he has often ſeen three or four females at this time frequently gathered about the male, and greedily ſnatching up into their mouths, the ſemen he ejects: he mentions ſome of the eſoces, ſome pearch, and ſome of the cyprini, in which he had ſeen this proceſs. It is worthy farther enquiry.

Hearing of FISHES. When the lapilli or bones in the heads of fiſhes, which are truly their organs of hearing, are examined in the heads of the ſeveral kinds; it appears, that they differ from one another both in their ſtructure and ſubſtance. For in the cetaceous fiſhes whoſe ſkeletons are truly bony, and which in certain reſpects may be compared to truly ligneous trees, both the os petroſum, and the auditory organs are in theſe as in other animals perfectly oſſeous or bony; whereas the cartilaginous fiſh, whoſe ſkeletons are elaſtic, and are cartilaginous rather than bony, may be compared to the keratophyta, or tough horny ſea plants: and theſe fiſh, inſtead of an os petroſum, have ſomething analogous; but it is cartilaginous not bony, and the auditory bones are of a tartareous kind of ſubſtance, being friable and eaſily crumbled to pieces. *Klein*'s Hiſt. Piſc. See EAR.

It has been a diſputed point among the naturaliſts of many ages, whether *fiſhes* hear or not; it is plain that the cetaceous *fiſhes* have all of them auditory paſſages or ear holes, but it has not been found, that any other *fiſhes* have any appearance of them. Many authors have been fond of believing that all *fiſhes* have hearing, but their arguments in general are inconcluſive.

Among the antients, many authors appear to have been poſitive in the opinion, that *fiſhes* had hearing, tho' they were by no means ſatisfied about the ways or paſſages by which they heard. Placentini afterwards diſcovered ſome bones in the head of the pike, which had very much the appearance of being organs of hearing, but he could never diſcover any external paſſages to them. Klein ſeems to be the only author who has improved upon this hint to any purpoſe; and he affirms and proves from experiments and obſervations, that all *fiſhes* have the organs of hearing and have alſo paſſages from without to thoſe organs, tho' in many ſpecies they are difficult to be ſeen, and that even the moſt minute and obſcure of theſe, are capable of communicating a tremulous motion to thoſe organs from ſounds iſſuing from without; nor does the water appear on ſerious conſideration to be any impediment, but rather a proper medium for the conveying the ſounds to ſuch organs; and it appears no way more ſtrange, that they ſhould hear thro' the water, than that a man ſhould hear in one room, the words pronounced in another, tho' there is a partition between them.

The organs of hearing in *fiſhes* are indiſputably theſe little bones commonly called lapilli, and found in the heads of all *fiſh*; theſe are conſtituent and eſſential parts in the heads of *fiſhes*, and are generated with the brain itſelf; not an accidental thing as ſome have believed them to be. They are always found to differ in magnitude, according to the ſize of the *fiſh* they belong to; and they are more eaſily diſtinguiſhed in the heads of the ſpinoſe *fiſhes*, than in any other kind. There are in all kinds of *fiſh* three pair of them; the firſt are the two largeſt bones, and are eaſily enough found; but the greateſt difficulty lies in diſcovering the other two pair, which are ſmall, and lie enveloped in diſtinct little bags compoſed of a fine membrane. Theſe ſeem to be the auditory organs, and to anſwer to the incus, malleus, and ſtapes in other animals; and by a diligent and careful inſpection, the age of a *fiſh* may be determined by the number and thickneſs of the laminæ and fibres of theſe bones, in the ſame manner as the age of a tree is known by the number of circles of the wood. The paſſages by which a tremulous motion is conveyed from without to theſe internal organs are to be diſcovered with care in moſt *fiſhes*, and in particular in the pike; tho' Placentini could not diſcover them there. A cloſe examination of the head of this *fiſh*, will ſhew ſeveral holes into which hog's briſtles may be thruſt, and theſe will be found to go directly into the internal auditory organs; and in diſſecting the head of a ſturgeon, the auditory duct is eaſily traced as far as the membranous body, in which the three pair of little bones are placed. Curious figures of theſe auditory ducts, and of the great variety of theſe officula or lapilli, are exhibited in Klein's hiſtory of *fiſhes*, to which we refer as greatly more expreſſive than any form of words can be. *Klein*'s Hiſt. Piſc.

Iſland FISH. See ISLAND *fiſh*.

Iſinglaſs FISH. See ACCIPENSER.

Shell-FISH. See SHELL.

Melt of FISHES. See MELT.

Teeth of FISH. See TEETH.

Feeding of FISH. See the article FEEDING.

Eyes of FISH. See the article EYE.

Noſtrils of FISH. See NARES *piſcium*.

Swimming of FISHES. See the articles SWIMMING *of Fiſhes* and AIR-*bladder*.

FISHES, aboard a ſhip, are pieces of timber uſed to ſtrengthen the maſts and yards, when they begin to fail in a ſtreſs of weather. They both nail the *fiſhes* on with iron ſpikes, and alſo *would* them, as they call it, that is, wind ropes hard round about them. There is alſo a tackle called the *fiſh*, which hangs at the end of the *davit* by the ſtrap of the block, in which is the runner of the *fiſh*-hook; by which means the fluke of the anchor is haled up to the ſhip's bow or *chainwaile*. Perhaps this tackle was called a *fiſh*, from that which the antients called a *dolphin*, which was a pointed and vaſtly heavy piece of iron, which they uſed to heave up by a tackle to a good height, and then, when they came near enough to the enemies ſhip, let it fall at once, to break or pierce a hole through the bottom of the enemies veſſel, and ſink her.

FISH-*block*, in a ſhip, is the block which is hung in a notch at the end of the davit, and ſerves to hale up the fluke of the anchor to the ſhip's bow.

FISH-*ponds*, are not only a thing of convenience to great families, but may be made a very profitable article with the farmer under due management. Watery and boggy lands are often fit for no other uſe, and theſe are then a great improvement on them. Ponds made in dry grounds in the flat bottoms between hills, will alſo ſerve not only to ſupply the cattle with water, but the profit of the *fiſh* that may be bred in them, is greater than many are aware of, and comes without any labour or expence. The head of a pond muſt be placed at the loweſt part of the ground, and the trench of the flood-gate or ſluice, muſt have a good fall, that it may not be too long in emptying. The beſt way of making the head, is by driving three or four rows of ſtakes about ſix foot long, and at about four foot diſtance from one another, the whole length of the pond-head; the firſt row of theſe is to be driven in four foot deep, that they may be very firm and ſecure, and if the bottom be not good but be of a looſe ſand, ſome lime is to be added, which will harden into a ſort of ſtone. The earth dug out of the pond is to be laid between theſe ſtakes and rammed hard down. Other rows of ſtakes muſt be added behind and over theſe, and the ſpaces filled up till the whole is as high and as thick as is neceſſary. The face of it muſt be made even and ſlanting, and there muſt be a waſh left to carry off the ſuperflous water in floods, &c. *Mortimer*'s Husb. p. 291.

The

The deepeſt part of the pond ſhould be about ſix foot, but the ſides ſhould be ſhallower, that the *fiſh* may have a place to ſun themſelves, and lay their ſpawn.

Carp and tench will live and thrive very well together in the ſame pond. Where pike are kept, there ſhould be roach or ſome other quick breeding fiſh to ſupply them with food.

Some think pike and tench may be kept in the ſame pond. They imagine that pike will not feed upon tench, but they are miſtaken, for the pike is fonder of this, than of almoſt any other *fiſh*. Ponds with clear gravelly and ſandy bottoms are uſually the beſt for breeding of *fiſh*, and foul water with muddy bottoms, are the beſt for them to fatten in. Carp have been known to grow in one year from five to eighteen inches long, in ponds where the water of the common ſewers of any town have run into it.

The ordinary growth of a carp is not above two or three inches in that time, ſo that all the exceſs is to be attributed to the fatneſs of the water of the ſewers.

All *fiſh* ponds ſhould be drawn once in three or four years, and the *fiſh* ſorted; if it be a breeding pond, the ſmaller *fiſh* ſhould be taken out to ſtore other ponds with; and in feeding ponds, all the *fiſh* ſhould be kept as nearly as may be of a ſize, for the larger and ſmaller never all thrive well together.

Flounders will both thrive and breed in any pond, eſpecially in a clay pond, and will be much larger than in rivers.

Bitterns, herons, otters, water-rats and ſea-gulls are all great deſtroyers of *fiſh*, and the ponds ſhould be kept as clear as poſſible of them; but the greateſt of all deſtruction in *fiſh*-ponds is occaſioned by froſts.

To remedy this, ſome propoſe to break the ice and lay in pipes, ſtraw and other things, to give air to the *fiſh*, but all theſe fail when the ponds are foul; but when they are clean, the *fiſh* ſeldom ſuffer any harm, be the froſt ever ſo long, and that tho' no holes be broken in the ice. The ſtench of foul water ſeems to be the occaſion of the death of the *fiſh*, in this caſe of its being lock'd up by froſts, and not the want of air.

The cleaning of ponds frequently is of great uſe as well on this as on many other occaſions; and it is done at no expence, becauſe the mud ſerving as manure to the lands, more than pays the expence of taking it out.

When the ground is boggy and carts cannot come up to take the mud, it is beſt to cut the ponds long and narrow in form of moats, that it may be thrown out at one toſs by the labourers in the clearing them, for if it require two toſſes, the difference will be juſt the double price of labour.

In fiſhing for carp and tench, the morning and evening hours are the only ones for ſucceſs. From four to eight in the morning is the beſt time of all; afterwards from four in the afternoon, till ſun-ſet. In the middle of ſummer, carp will riſe to the ſurface of the water among the reeds, and may be caught with baits of large acorns, which they will readily take on the ſurface.

In March, April and September, the warmeſt days are the beſt for fiſhing, and the bait muſt be deep; for the *fiſh* in theſe cool months lie near the bottom. In fly-fiſhing it is always obſerved, that the *fiſh* will riſe beſt after a ſmall ſhower of rain, that has juſt beat down the flies upon the water without muddying it. March, April, May and June are the beſt months for fly-fiſhing, and the beſt hours are about nine in the morning, and three or four in the afternoon; in a ſtill warm evening, they will bite as long as the day-light laſts, at thoſe ſeaſons when the gnats are ſeen moſt plentyfully about in the air.

In the extremity of heat when the earth is parched with drought there is but little ſport to be expected in fiſhing, in whatſoever water. In cold weather when there is a white hoary froſt in the morning, the *fiſh* will not bite kindly all day except in the evening, if that ſhould prove ſerene and warm.

Too much wind is never convenient for fiſhing, tho' a little is rather advantageous than otherwiſe. It is bad fiſhing about ſheep-ſhearing time, in waters where the ſheep are waſhed, for the *fiſh* glut themſelves in ſuch a manner, with what is waſh'd from theſe creatures, that they will not take any bait till that ſeaſon is over.

North and eaſt winds are enemies to fiſhing, and it is not right to fiſh ſoon after the time of the *fiſhes* ſpawning, for they are then ſick and have no great appetite, ſo that they do not bite readily. All *fiſh* have a natural fore-knowledge of a ſhower of rain, and when clouds are coming on, that will fall in rain, they will not bite: the expert angler who is uſed to this, often eſcapes being wet to the skin by it.

The ſubterranean or underground fiſhing of the lake Ribeskajamnia, has been much talked of by thoſe who have written of the Zirchnitzer ſea, of which it is a part; but on the whole it amounts to no more than this. The waters of this lake emptying themſelves thro' ſubterranean paſſages into another lake below, the whole body of the water, with the *fiſh* in it, is firſt received into a large opening, which conveys it into a ſort of ſubterranean baſon, in the bottom of which there are many holes, and thro' theſe the water is let out, but the *fiſh* left behind. The people of the place who know this, deſcend thro' the large hole into this ſubterranean baſon with torches in their hands, and as the waters run off they ſieze upon the *fiſh* wherever they can catch them. This ſort of fiſhing is attended with one inconvenience, for the people being obliged to ſtand up to the middle more or leſs in the water, the horſe-leeches, which are extremely plentiful there, ſieze upon their legs and other parts, and are only to be got off by ſome perſons making water upon the part; the heat and nauſeous taſte of the urine always making them let go their hold. Phil. Tranſ. N°. 91.

FISSURES, in the hiſtory of the earth, certain interruptions, that horrizontally or parallely divide the ſeveral ſtrata, of which the body of our terreſtrial globe is compoſed.

FISTUCA, in antiquity, an inſtrument of wood uſed in driving piles, and fitted with two handles. It was either raiſed with pullies fixed at the head of large beams, and then let fall again directly on the piles, or was wrought by the hand only. *Pitiſc.* Lex. Ant. in voc.

FISTULA *lachrymalis* (*Cycl.*) — Dr. Hunauld has communicated ſome thoughts on the operation of the *fiſtula lachrymalis*, and propoſes, that no tent ſhould be put into the perforation of the os unguis, becauſe the tears will of themſelves keep it open. Phil. Tranſ. N°. 437. Sect. 5.

Mr. Lamorier propoſes to abridge the operation of the *fiſtula lachrymalis*, and to ſecure a paſſage for the tears into the noſe. The os unguis is to be laid bare at the firſt inciſion, and pierced with a pair of ſtrong, ſharp-pointed and crooked forceps, and then the perforation dilated by opening the forceps. After the inflammation is over, a piece of ſmall wax-candle, ſhaped like a tent, is to be introduced by the wound into the noſe, and ſecured by the other dreſſings. He continues the uſe of this bougie, till the paſſage is made callous, and out of hazard of reuniting. After which he allows the external wound to cure. Medic. Eſſ. Edinb.

Mr. Petit, conſiders the canals for the tears from the *puncta lachrymalia* as a ſyphon, the longer leg of which is the naſal duct, and therefore thinks, that a ſhorter paſſage made thro' the os unguis, would not convey away the tears; for which reaſon he would always have the natural paſſage forced open in the *fiſtula lachrymalis*, and a ſmall bougie kept in it till it heals. Mem. Acad. Sciences, 1734.

FISTULA *pulmonis*, in anatomy, a term uſed by ſome writers for the *aſpera arteria*.

FISTULA *ſacra*, in anatomy, is that part of the back bone which is perforated. *Blancard.*

FISTULA *urinaria*, in anatomy, the ſame with the *urethra*.

FITCHES, a name given by our farmers to a ſort of pulſe which they ſow in their fields. Many ſuppoſe it the ſame with the tare, but erroneouſly: it is the chich or chich pea of authors. There are two principal kinds of this in uſe among us, the winter and the ſummer *fitch*. The one is ſown before winter and abides the extremity of it; the other is ſown in ſpring. They are propagated in the ſame manner as peaſe, and they make a very good and nouriſhing food for cattle, whether given in the ſtraw, or threſh'd out. They are ſometimes ſown only to improve the land. In this caſe, they are to be plow'd in, juſt as they are beginning to bloſſom, and in this manner they finely enrich a tough ſtiff clay. *Mortimer*'s Husbandry.

FITCHET, a name uſed in ſome places for the weaſel; called alſo the fitchel, and the foumart. See MUSTELA.

FITS (*Cycl.*) — Dr. Cheyne is of opinion that *fits* of all kinds, whether epileptic, hyſteric, or apoplectic, may be cured ſolely by a milk diet, of about two quarts of cow-milk a day, without any other food. *Cheyne*, Nat. Meth. of curing, p. 265. See CONVULSIONS.

FIXED *line of defence*, a line drawn along the face of the baſtion, and terminating in the curtain. See DEFENCE. *Cycl.*

FLAG (*Cycl.*) — The *flag* or ſlate ſtone common in Northumberland, and ſome of the neighbouring counties, is called by ſome Carliſle *flag*. It is a white fiſſil ſtone, eaſily ſplitting into thin plates, and is full of ſmall ſpangles of a fine glittering talc. It is alſo common in Yorkſhire and the neighbouring places; it varies a little in colour, being ſometimes grey, ſometimes browniſh, and ſometimes merely whitiſh. Its ſtrata are very thick, but they eaſily ſeparate into lamina of about half an inch thick, and the workmen ſeldom attempt to ſplit it any thinner; the uppermoſt ſtrata however grow gradually thinner, and the bottom ones are ſo thick as not to be uſed for ſlates. Theſe they raiſe however, and uſe for tanners fats, the pavements of floors, and ciſterns for water.

FLAGS, in the military art, are ſmall banners of diſtinction ſtuck in the baggage waggons of the army, to diſtinguiſh the baggage of one brigade from another; and of one battallion from another; that they may be marſhalled by the *waggon maſter general* according to the rank of their brigades, to avoid the confuſion that otherwiſe might ariſe. *Guillet.*

FLAG-*flower*, in botany. See IRIS.

FLAIR, aboard a ſhip. The ſeamen ſay that the work doth *flair-over*, when a ſhip being houſed in near the water, a little above that the work hangs over a little too much, and ſo is let out broader aloft than the due proportion will allow.

FLAIRS, in ichthyology, a name given by ſome to the skaite. See SKAITE and RAJA.

The

The antient Greeks called this batos, when they ſpoke of the male, and when of the female, batis.

FLAKE, in gardening, a name given by the floriſts to a ſort of carnations, which are of two colours only, and have very large ſtripes, all of them going quite thro' the leaves. *Millar*'s Gardener's Dict.

FLAMBO, in natural hiſtory, a name given by ſome to a long anguilliform fiſh, a ſpecies of the tænia, called Cavagiro. *Rondelet*, de Piſc. v. 1. p. 96. See CAVAGIRO.

FLAME *(Cycl.)* — It is evident to every curious obſerver, that *flame* dwells and plays only about the ſurface of fuel, having nothing to do with its interior parts. If a lamp glaſs be filled with ſpirit of wine, another with oil of turpentine, and others with other liquors, and each ſet on fire, it will be eaſily diſtinguiſhable thro' the ſides of the glaſs, that they all burn and *flame* only on their ſurface, the *flame* continually ſinking lower and lower in the glaſſes as the liquors conſume. The ſame obſervation holds good in ſolid as well as liquid fuel, and appears to be univerſal; and hence we are directed to the choice of proper fuel on the different occaſions we want it for. *Shaw*'s Lect. p. 33.

Flames of burning ſubſtances are of different colours, according to the ſubſtances which produce them. Thus the *flame* of burning camphor is white, like the focus of a burning glaſs. The *flames* of ſulphur, and of ſpirit of wine, are blue; the *flame* of white wax, is white, inclining to blue; and that of tallow is white, a little inclining to yellow.

From this difference of the colours of the *flames*, proceeds the difference of the colours of bodies as viewed by day-light, candle-light, or any one of theſe *flames*; and for making curious experiments of this kind, oil may be impregnated with copper, &c. *Shaw*'s Lect. p. 176.

FLAME *from cold liquors*. See the article FIRE.

FLAME *heat*, the ſame with white heat. See IRON, *Cycl.*

FLAMEN *(Cycl.)* — FLAMEN *dialis*, the ſovereign prieſt of Jupiter, among the old Romans. He revived an antient pretenſion to a ſeat in the ſenate, in right of his office; which by the indolence of his predeceſſors, had not been claimed or enjoyed for many generations. The prætor rejected his claim, nor would ſuffer him to ſit in that aſſembly: but upon his appeal to the tribunes of the people, that is, to the people, his right was confirmed, and he was allowed to take his place as a ſenator. *Liv.* 27. 8. *Middlet.* of Rom. Sen. p. 49.

FLAMETTE, in zoology, a name given by the French writers to a ſpecies of chama or ſhell-fiſh of the bivalve kind, with its ſhells always more or leſs open; this ſpecies is as hot as pepper to the taſte.

FLAMINGO, in zoology, the name of a very beautyful and very remarkable bird; it has long legs, and a long neck, yet has webb'd feet, and is remarkable for the fine bright red of its wings. *Ray*'s Ornitholog. p. 240. See the article PHOENICOPTEROS.

FLAMMA *Jovis*, a name given by many writers to a plant of the clematitis or virgin's bower kind, called by the greek writers phlogium or phlogus. See CLEMATITIS.

Pliny very improperly ranks it among the violets, the only reaſon for doing which, ſeems to have been the meeting with this plant and the violets in the ſame part of the writings of Theophraſtus, from whom he has tranſlated the greateſt part of his account of plants. This author however is not to be accuſed of mixing them together, as if of the ſame nature, for they only follow one another in his works, as they both flower in the ſpring ſeaſon of the year. There is alſo another miſtake in Pliny in this place, to which the plant owes its name *flamma* or *flammula jovis*; for the Greek name expreſſes only *flamma*, but Theophraſtus having in the ſame place, named another plant under the name of jovis flos, dioſanthos; Pliny ſeems to have confounded the two plants together in his memory; and to have formed this name for one of them out of the ſeparate names of both, and has wholly dropped the dioſanthos.

FLAMMULA, in botany, a name given by ſome authors to a particular ſpecies of the crowfoot, commonly called the ranunculus flammeus. *Chabræus*, p. 470.

FLAMMULÆ *auri*, in natural hiſtory, a name given by Dr. Woodward, and others to thoſe ſmall pieces of gold found among the ſands of rivers in ſome places. They are ſometimes found in roundiſh pieces, but more uſually in their ſhining flakes, whence the name *flammula* ſeems to have been given them, as being very bright and gloſſy. This ſort of gold is pure and malleable, and loſes ſcarce any part of its weight in fuſion.

The gold duſt as it is called, which is brought from Guinea, is much of this kind; its particles are uſually very ſmall, though ſometimes lumps of the ſize of a pea or horſe-bean are found, and ſometimes maſſes of an irregular figure of three or four ounces weight; but theſe looſe the name of *flammulæ* when they become ſo thick and ſolid, and ſo large, and are called by the merchants rock-gold.

All the *flammulæ* of gold found among the ſands in the beds of rivers, are doubtleſs parts of a rich ore, lodged in ſome neighbouring hills, and waſhed away by the impetuous rains, which carry them down in the currents they form, and afterwards drop them in the places where the waters of the river they mix themſelves with, run more ſlowly. This appears plainly from theſe particles of gold being always found toward the the heads of the rivers; or near the mountainous countries where the torrents cauſed by ſudden rains, diſcharge themſelves into them near their entrances into the ſea; and alſo by this, that the people always find the gold moſt plentifully after great rains. *Woodw.* Cat. Foſſ. v. 2. p. 30.

FLANEL *(Cycl.)* — It has been obſerved that new *flanel*, after ſome time wearing, acquires the property of ſhining in the dark, but loſes it on being waſhed. *Vid.* Phil. Tranſ. N°. 483. Sect. 7.

FLANKED *line of defence*, in fortification. See ANGLE, *Cycl.*

FLANKING *angle*, in fortification. See ANGLE, *Cycl.*

FLASK, in the artillery. See POWDER-*flask*.

FLAT *baſtion*, in fortification. See BASTION, *Cycl.*

FLAT-*bottomed moat*, in fortification. See MOAT, *Cycl.*

FLAT-*crown*, in architecture. See CORONA, *Cycl.*

FLAT *third*, in muſic, the third minor. See INTERVAL.

FLATTING *courſe*, among brick makers. See BRICK.

FLATTING, aboard a ſhip. To hale in the fore-ſail by the ſheet as near to the ſhip's ſides as may be, is called *flatting in the fore-ſail*. This is done when a ſhip will not fall off from a wind without it, though the fore-ſheet was haled aft.

FLATULENCY, a word uſed by medical writers to expreſs a diſtempered ſtate of the body, in which there is an uncommon and unnatural generation of flatuſes or halituous and elaſtic matter of the nature of air, ariſing from the humidity of the abdomen, and attended with ſeveral very bad ſymptoms.

Some authors mention flatuſes of the uterus and of the bladder, but theſe are very rare caſes, tho' they do ſometimes happen; and what is uſually underſtood by the word *flatulency*, are ſuch flatuſes in the ſtomach and bowels. Theſe are either torpid or impetuous. The torpid *flatulencies* of the bowels give the patient very little uneaſineſs; people of phlegmatic habits are much ſubject to them, and generally very little regard them. But the impetuous kind very often occaſion the utmoſt diſorders, on the ſlighteſt accidental occaſions irritating them; people of a ſanguine and melancholic habit, are moſt ſubject to them. *Flatulencies* differ alſo greatly in regard to their cauſes; for ſome are only occaſioned by a ſimple languor, or ſmall loſs of tone in the inteſtines, in which caſe the flatuſes are generally diſcharged upwards in eructations, or downward without trouble. Other *flatulencies* have their origin from a tough viſcid matter, which deſtroys the intent of the periſtaltic motion to this purpoſe; and in this caſe the patient is ſometimes troubled with ſpaſtic conſtrictions of the inteſtines, ſometimes with troubleſome relaxations of them; and finally ſome *flatulencies* take their origin from a turbulent commotion of the blood about the vena portæ, from the ramifications of this veſſel having connections with the inteſtines.

Signs of flatulencies. The moſt obvious of theſe are the rumblings that are felt in the bowels, with noiſes in them; and in the place of theſe rumblings, there are ſometimes plainly perceived fixed diſtenſions of them in particular parts, with tenſion and ſtraitneſs of the abdomen. From the continuance of theſe ſymtoms ariſe pains which ſometimes change place, and ſometimes remain fixed, and ſeem to ſwell the inteſtines in ſuch manner as to endanger burſting: and when commotions of the blood are the cauſe of theſe, there are uſually pains felt attending them on the left ſide, and about the region of the heart, and the patient complains of the uſual ſymptoms of hypocondriacal people.

An obſtinate coſtiveneſs alſo uſually attends this diſtemper, which always makes it more violent; and a ſtraitneſs of the breaſt attended with anxieties and diffiulties of breathing are uſually the attendant ſymptoms on it, when violent. The more the *flatulency* has been owing to crudities in the primæ viæ, the more will the patient be affected with vertiginous complaints, and other diſorders of the head; and when the cauſe is a commotion of blood about the vena portæ, the pains are always very violent, and are often attended with bad conſequences.

Perſons ſubject to it. *Flatulencies* attack perſons of all ages, ſexes and conſtitutions, but eſpecially the phlegmatic, whoſe parts are of a weaker tone, and naturally more ſubject to expanſion; after theſe, perſons of a ſanguine habit are moſt ſubject to them, and thoſe of choleric and melancholy habits, tho' naturally leſs ſubject to them, yet often fall into them after illneſſes.

People who are particularly ſenſible of the changes of the air from warmer to colder, are alſo more ſubject to them, than thoſe of a more robuſt and leſs delicate frame; hence women are more ſubject to them than men, and thoſe eſpecially in the times of the menſes and lochia.

Cauſes of them. Theſe are in general a relaxation of the periſtaltic motion of the guts; but this not extending to the whole canal, but only to ſome one part, the tranſpiration of the halituous matter being chiefly into this flacid part, which it diſtends in a manner that it could not do by a part that had its natural tone and motions. And the defect in one part is always attended with

with an exceſs of the periſtaltic motion in another, in order to the driving off the cauſe; hence proceed alternate conſtrictions and relaxations, to which, in a great meaſure, the pain is owing; and in caſes of the commotions of the blood about the vena portæ, the ſame conſtrictions and relaxations always happen. The material cauſes of *flatulencies*, are thoſe ſubſtances ſwallowed in food, which are of a mucous and tenacious conſiſtence, and by their obſtinately adhering to the bowels are capable of giving great trouble. Of this kind are the herbs in uſe in food, which are of a thick tough juice; or the leguminous tribe, as peas, beans and the like; alſo dried ſea fiſh, and all animal fats, as that of ſheep and calves, eſpecially if the perſon drink immediately after eating heartily of them. The drinking fæculent liquors will alſo occaſion them very violently, as new malt liquors, or the ſame when the veſſels are almoſt out; the ſummer fruits alſo are to be accuſed in this ſenſe, and above all things honey. To all theſe cauſes, the habit of the patient greatly concurs, and a general coolneſs of the body, and dryneſs of the bowels are a frequent occaſion of them.

Prognoſtics in them. *Flatulencies* often prove an extremely troubleſome complaint, and people of an idle ſedentary life, eſpecialy women, owe a great many uneaſy hours to them; and when they grow into a habit, they are always attended with colic pains, cardialgias, anxieties, and ſuffocatory emotions. It is always to be obſerved, that the forcible ſuppreſſion of flatuſes, brings on much worſe complaints, eſpecially in plethoric and ſanguine habits; for ſpaſtic tormina of the bowels, and vibrative convulſions with faintings, are often the conſequences of it; and the phyſician is apt to accuſe foulneſſes or ſcorbutic habits of the blood, for the ſymptoms he ſees, which, in truth, are only owing to ſuch a ſuppreſſion. The free diſcharging of *flatulencies*, on the other hand, is attended with its ill conſequence, it naturally degenerating into a habit.

The ſuppreſſion of habitual *flatulencies*, brings on tumours, indurations of the abdomen, hectics, and a tympanites, and particularly the anterior flatuſes: theſe, which might be avoided by eructations, when ſuppreſſed, bring on cardialgious and vertiginous diſorders of the head.

Method of cure. In this it is firſt to be conſidered, whether the flatuſſes have their origin in the bowels, or whether they affect them only by conſent, as is often the caſe in diſeaſes of the neighbouring parts in hypocondriac and hyſteric patients, and in perſons afflicted with hæmorrhoidal and nephritic complaints, and in caſes where women have been ill managed in lyings-in, or in miſcarriages: in all theſe caſes the original cauſe is to be conſidered and treated with its proper remedies. But in caſes of direct and ſimple *flatulencies*, the following method will be uſually found effectual. The bowels muſt be carefully kept gently open, for in caſes of coſtiveneſs, *flatulencies* will always be increaſed. To this purpoſe, the common clyſters muſt be given at repeated times, and to theſe by way of increaſing the ſtimulus, ſome of the leſſer centaury is to be added, and ſome common ſalt. After theſe the laxative medicines of the gentler kind are to be given, and in the intermediate days, the digeſtive ſalts to attenuate the viſcous matter in the bowels; to theſe nitre and a little cinnabar may be added, and theſe always have a much better effect than all the hot carminatives uſually given. After theſe, thoſe things are to be given which reſtore the tone of the part; ſuch are the bitter and aromatic extracts, with ſpirit of ſalt of tartar, ſpirit of nitre dulcified, and the volatile urinous ſalts aromatiſed. Externally ſtomachic plaiſters may be applied to the pit of the ſtomach, as may alſo the ſtomachic balſams, ſuch as the oils of nutmeg, carui, fennel, and the like.

The general method of treating *flatulencies*, is by the hot aromatics, but theſe are to be given with great caution; for when the commotions of the blood about the vena portæ are in fault, theſe things always irritate, rather than do good; but beyond all things, the too common methods of giving a vomit in theſe caſes is to be avoided, for the diſcharge of the *flatulencies* upwards is inverted by this means, and then uſually follow exquiſite pains and tenſions of the parts, difficulty of breathing and vertiginous complaints in the head, with noiſes in the ears, and many other complaints which are continually increaſing, till they are a little eaſed for the preſent by an eructation. The happy way of getting rid of theſe anterior flatuſes, is by driving the cauſe of them downwards, and the reſtoring the loſt tone of the parts. Continued exerciſe is alſo of the utmoſt ſervice. *Junker*'s Conſp. Med. p. 600.

FLAUTINO, in the Italian muſic, the name of a ſmall flute or flajeolet. *Broſſ.* Dict. Muſ. in voc. See FLAJEOLET, *Cycl.*

FLAUTO, in the Italian muſic, is uſed to denote a flute, or the part to be played by that inſtrument. *Broſſ.* Dict. Muſ.

FLAUTO *traſverſo*, in the Italian muſic, a German flute. *Broſſ.* ibid. See FLUTE, *Cycl.*

FLAW, at ſea, ſignifies a ſudden guſt of wind, otherwiſe called *ſquale.*

FLAX, *linum* (*Cycl.*) —This is a plant that will grow in any kind of good ſound land, but that does beſt for it, which has lain ſometime unplowed. The beſt land yields the beſt *flax*, and makes the greateſt improvement; and upon the whole, it is an excellent commodity, and the tilling and ordering it is ſo good a piece of husbandry, that it well deſerves to be more frequently practiſed among us. It is a plant that exhauſts the land very much, on which account it is beſt to ſow it on very rank ground, and not often on the ſame piece. The time of ſowing is in March; the land ſhould be well prepared and laid even, and the drieſt ſeaſon that can be, ſhould be choſen for the ſowing it. The ſeed procured by our own crops, is not ſo good as that imported from the Levant; this is dearer indeed, but it yields greatly the largeſt crops, and will hold good to the third crop with us, but then it ſhould be renewed. Two buſhels of good ſeed are ſufficient for an acre: it muſt not ſtand till too ripe, but muſt be pulled as ſoon as the ſeed grows brown, and bends down the heads. If the flax is pulled while in flower, the produce will be whiter and ſtronger, but then the ſeed will be loſt.

They have a very good way of beating their hemp and flax in Derbyſhire, which is this; they make the axletree of the main wheel of their corn-mills longer than ordinary, and place pins in it to raiſe large hammers, like thoſe uſed in the paper and fulling mills, and with theſe they beat the ſtalks, and ſave a great deal of labour. *Mortimer*'s Husbandry, p. 154.

Purging FLAX, *Linum catharticum.* See LINUM *catharticum.*

Toad FLAX, in botany. See LINARIA.

FLEA (*Cycl.*) — The *flea* when examined by the microſcope affords a very pleaſing object. It is covered all over with black, hard and ſhelly ſcales or plates, which are curiouſly jointed, and folded over one another in ſuch a manner, as to comply with all the nimble motions of the creature. Theſe ſcales are all curiouſly poliſhed, and are beſet about the edges with ſhort ſpikes in a very beautiful and regular order. Its neck is finely arched, and much reſembles the tail of a lobſter; the head alſo is very extraordinary, for from the ſnout part of it there proceed the two fore legs, and between theſe is placed the piercer or ſucker, with which it penetrates the skin to get its food. *Baker*'s Microſcope, p. 191.

Its eyes are very large and beautiful, and it has two ſhort horns or feelers. It has four other legs joined all at the breaſt. Theſe when it leaps fold ſhort one within another, and then exerting their ſpring all at the ſame inſtant, they carry the creature to a ſurpriſing diſtance. The legs have ſeveral joints, and are very hairy, and terminate in two long and hooked ſharp claws.

The piercer or ſucker of the *flea* is lodged between its fore-legs, and includes a couple of darts or lancets, which after the piercer has made an entrance, are thruſt farther into the fleſh, to make the blood flow from the adjacent parts.

This piercer, its ſheath opening ſideways, the two lancets within it are very difficult to be ſeen, unleſs the two fore-legs, between which they are hid, be cut off cloſe to the head; for the *flea* rarely puts out its piercer, except at the time of feeding, but keeps it folded inwards; and the beſt way of ſeeing it is by cutting off firſt the head, and then the fore-legs, and then it is uſually ſeen thruſt out in convulſions.

By keeping *fleas* in a glaſs tube corked up at both ends, but ſo as to admit freſh air, their ſeveral actions may be obſerved, and particularly their way of coupling, which is performed tail to tail; the female which is much the larger, ſtanding over the male: they may alſo be thus ſeen to lay their eggs, not all at once, but ten or twelve in a day, for ſeveral days ſucceſſively, which eggs will be afterwards found to hatch ſucceſſively in the ſame order. The *flea* may eaſily be diſſected in a drop of water, and by this means the ſtomach and bowels with their periſtaltic motion may be diſcovered very plainly, as alſo their teſtes and penis with the veins and arteries, tho' minute beyond all conception. Mr. Leiwenhoek affirms alſo, that he has ſeen innumerable animalcules ſhaped like ſerpents, in the ſemen maſculinum of a *flea*. *Baker*'s Microſ. p. 192.

FLEA, in the hiſtory of inſects. See PULEX.

FLEA *Bane*, *conyza*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the floſculous kind, being compoſed of a number of ſmall floſcules, divided into many ſegments at their ends, ſtanding each upon an embryo ſeed, and all contained in a ſort of cylindric, foliaceous husk. The embryo finally becomes a ſeed wing'd with down.

The ſpecies of *conyza* enumerated by Mr. Tournefort are theſe. 1. The common great *conyza*, called Plowman's ſpikenard. 2. The *conyza*, with red ſlender ſtalks and naked yellow flowers. 3. The *conyza*, with toad-flax leaves. 4. The broad leaved viſcous *conyza*, with yellow flowers, and a ſweet ſmell. 5. The white flowered, nettle leaved American *conyza*. 6. The American *conyza*, with dead nettle leaves. 7. The white flower'd, ſallow leaved American *conyza*. 8. The ſea purſelain leav'd Virginian *conyza*. 9. The quince leaved ſhrubby American *conyza*. 10. The yellow flowered American tree *conyza*, with trifid leaves. 11. The purple flowered American tree *conyza*, with dentated mullein like leaves. 12. The purple flowered American tree *conyza*, with undulated mullein like leaves. 13. The ſhrubby American *conyza*, with roundiſh nervous leaves, and ſpikated flowers. 14. The dwarf African *conyza*, with roundiſh nervous leaves and umbellated flowers.

ers. 15. The ſhrubby African *conyza*, with ſage like leaves, and the ſmell of camphor. 16. The ſhrubby African *conyza*, with hoary, hooked, rocket like leaves. 17. The Roſemary leaved ſhrubby African *conyza*. 18. The blunt leav'd African *conyza*, with groundſel flowers. 19. The purple flowered figwort leaved Indian *conyza*; and 20. The *conyza*, with ſerrated mullein like leaves. *Tourn.* Inſt. p. 454, ſeq.

The common *fleabane* ſtands recommended by the old authors as a remedy for many cutaneous diſorders. They had an opinion alſo, that the ſmoke of it when burnt in a room deſtroyed fleas, and other inſects.

FLEA *Wort*. See PSYLIUM.

FLEAM (*Cycl.*) — There are many ſurgeons in Germany who bleed, or perform the operation of phlebotomy with this inſtrument, which they uſe in this manner: they hold one finger upon the end of it, which ſerves as a handle, and applying the point to the vein they are to open, ſtrike upon the back over the point with one of the fingers of the other hand, opening the vein much as farriers bleed horſes. Others uſe a ſpring *fleam*, ſomething like a ſingle point of the ſcarifying inſtrument uſed in cupping; and others employ a ſort of inſtrument in form of a dart; but as the poſition and ſize of the veins is different, in different ſubjects, no inſtrument will ever be found ſo uſeful as the common lancet of a proper ſize. *Heiſter*'s Surgery, p. 274.

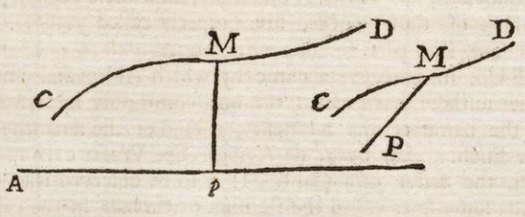
FLEECE (*Cycl.*)—*Golden* FLEECE. See the article GOLDEN.

FLEMENEFRIT, FLEMENESFRINTHE, or FLYMENAFRYNTHE, in our old writers, ſignifies the receiving or relieving of a fugitive or outlaw. Leg. Inæ, cap. 29. 47. LL. H. 1. c. 10, 12.

FLEMESWITE. *Fleta*, who writes of this word, interprets it *habere catalla fugitivorum*. Flet. Lib. 1. c. 4.

FLESUS, in zoology, a name uſed by ſome authors, for the common flounder; the paſſer fluviatilis of moſt writers. *Bellonius*, p. 113.

FLESHY *roots*. See FIBROSE *roots*.



FLEXION, (*Cycl.*) in geometry. See FLEXURE.

FLEXOR (*Cycl.*) — FLEXOR *digitorum pedis acceſſorius*, a flat and pretty long fleſhy muſcle, ſituated obliquely under the ſole of the foot, and from its ſituation and figure, formerly called *caro plantæ pedis quadrata*.

It is fixed poſteriorly by one fleſhy portion, in the lower ſide of the os calcis, and in the anterior tuberoſity on that ſide, and by the other in the ligament which joins this bone to the aſtragalus. From thence the two other portions run obliquely to the middle of the ſole of the foot, and there unite in a flat, long, and irregularly ſquare muſcular maſs, which is fixed to the outer edge of the faſciculus of tendons of the *flexor longus*, to which it ſerves as a frænum in that place. *Winſlow*'s Anatomy, p. 224.

FLEXOR *profundus*, in anatomy, a name given by Cowper and ſome other writers to the muſcle of the foot called alſo the perforans pedis, and the perodactylæus by Riolan, and ſome others. See PERFORANS.

FLEXURE, or FLEXION, in geometry, is uſed to ſignify that a curve is both concave and convex, with reſpect to a given right line, A *p*, or a fixed point, P. Thus the curve

CMD, having the part CM concave towards A*p*, or P, and the part MD convex to the ſame, is ſaid to have a flexure. And the point M, which limits the concavity and convexity, is called the point of contrary *flexure*. See POINT *of contrary flexure*, *Cycl.* and *Suppl.*

This is to be underſtood, when the point ſuppoſed to deſcribe the curve, coming to M, continues its courſe towards the ſame ſide; but if it turn backwards, as in the figures annexed, tho' the curve may either have a continued curvature, as in

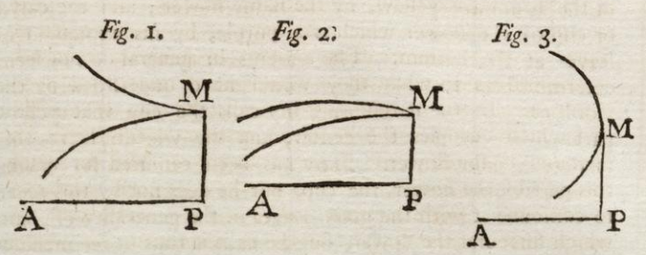


fig. 3. or have a cuſpis point of reflexion, or of retrogradation, as in *fig.* 1. and *fig.* 2.

As to the method of finding the points of contrary *flexure*, ſee *L'Hoſpital*'s Anal. Inf. Petits, Sect. 4. See alſo the head POINT *of contrary flexure*, where ſome neceſſary corrections of L'Hoſpital's rule are given.

FLIDETHRIFT, or more truly SLIDETHRIFT, is the game we now call *ſhovel-board*. It is otherwiſe called *ſhove-groat*, and is mentioned in the ſtatute. 33 H. 8. c. 9.

FLING, in the manege, is the fiery and obſtinate action of an unruly horſe.

To fling like a cow, is to raiſe only one leg, and give a blow with it. See YERK.

To *fling* or kick with the hind legs. See YERKING, *Cycl.*

FLINGING, among bowlers. See BOWLING.

FLINT (*Cycl.*) — The ſparks of fire which are produced by ſtriking *flint* againſt ſteel, are of the number of thoſe things which cuſtom has made familiar to us, but which we might find much matter of inquiry, if we would give way to reaſon on the ſubject.

The ſtriking fire in this manner has probably been as old as the knowledge of ſteel; and ſince the microſcope has been familiar among us, it has been diſcovered, that theſe ſparks are ſo many ſpherical balls of iron detached by the blow from the maſs, and rendered by the heat a ſort of ſcoriæ. Kemp de Kenvyck, a very ingenious chemiſt, propoſed it as a problem worthy the attempts of the curious to ſolve, and propoſed the whole in theſe words; when a flint and ſteel are ſtruck together, if the ſparks are received upon a white paper, they are found to be round maſſes, which examined by the microſcope, are found to be melted and ſcorified or vitrified iron, which will no longer anſwer to the magnet. It is therefore demanded, 1. Which of the two inſtruments contributes moſt to this change in the iron? 2. What ſubſtance it is, that is employed to this purpoſe? 3. In what manner the operation is performed; and 4. Why if iron be uſed inſtead of ſteel, the ſparks are very few or none, when with ſteel they are ſo many? Theſe queſtions have appeared almoſt unanſwerable, becauſe people ſcarce knew how to conceive, that iron which requires ſo long continued, and ſo violent a fire to put it in fuſion, could by means only of a ſlight blow, be not only melted, but deſtroyed as it were. The moſt eminent perſons of the time declined engaging in the attempt, and Mr. Muſchenbrok, from whom a ſolution was expected by many, at length referred the whole to Mr. de Reaumur, who had ſome time before publiſhed a treatiſe on iron and ſteel, and was therefore judged to have moſt conſidered the metal in both thoſe ſtates.

This gentleman accepted the task, and attempted the ſolution of the problem by reſolving theſe queſtion. 1. By what means the iron is in this act converted into ſcoriæ? 2. By what methods it can be ſo deſtroyed? 3. How it comes not only to be reduced to ſcoriæ, but to be in a ſtate of fuſion, and truly rendered liquid, and 4. Why iron gives leſs as well as fewer ſparks on colliſion with flint than ſteel does? The nature of iron is well enough known for us to be aſſured that it contains a large portion of inflammable matter, and that it is never ductile, but while it has a quantity of that inflammable matter in it; and that when that is wholly taken from it, it becomes friable, and is reduced to a ſort of ſcoriæ, analogous to common vitrified matters.

What much conduces to the explication of the given problem, is, that this inflammable matter contained in iron is very eaſily ſeparated when iron is heated in an open fire; which is evidently ſeen, in that it is impoſſible to heat a bar of iron in a ſmith's forge, ſo much as to make it ready for working or joining with another bar, without reducing its whole ſurface to ſcoriæ, or a friable matter which is all thrown off from the bar by the blows of the hammer.

The ſmaller and thinner a piece of iron is, the more eaſily is it reduced to ſcoriæ, and it is eaſy to conceive from hence, that in pieces extremely ſmall, there requires no more than the once thoroughly heating them to reduce the whole to ſcoriæ; and it is eaſily proved by experiment, that the flame of a candle being applied to a fine ſmall piece of filings of ſteel, will ſoon make it red hot, and that if it be then ſuffered to cool and laid on a white paper, it will be found much to reſemble the ſparks thrown off by *flint* and ſteel, and will be reduced to ſcoriæ and be friable under the nail, like a piece of charcoal.

It appears then, that there requires but an inſtant of time to give a red heat to a ſmall particle of iron; and alſo that when that heat has been given, the particle muſt have loſt that inflammable matter which cauſed its ductility, and conſequently muſt be reduced to ſcoriæ; and hence it appears not wonderful, that the very ſmall piece or particle of ſteel which is ſtruck off by the flint, ſhould be diveſted of its inflammable matter, and with it of its ductility, by being kept red hot in the open air, only ſo long as it was in falling from the ſteel to the paper that is placed to receive it. The extreme ſmallneſs of the particle gives power to ſo ſhort a heat to deſtroy its inflammable matter, in which its ductility conſiſts; and therefore to reduce it to a matter no longer ductile, that is, into ſcoriæ; and we find that if a parcel of fine ſteel filings be dropt thro' the flame of a lamp driven into an horizontal direction by the blaſt of a blow-pipe, they will in the inſtant of their

paſſing

paſſing thro' that flame, ſparkle and become ignited, and if they are received on a white paper placed underneath, the ſmaleſt particles will be found round and friable, reduced to ſcoriæ, no way differing from the little globules of ſcorified ſteel, which are ſtruck off from the *flint* and ſteel in giving fire by their colliſion.

When we have occaſion to melt larger parcels of ſteel or iron, we are obliged to have recourſe to ſuch ſubſtances to mix with them as will replace with increaſe that inflammable matter which the fire drives off: the ſubſtances of this kind are common ſulphur, orpiment, arſenic, and the like; and by means of theſe, it is ſoon made to run like lead. Memoires Acad. Scien. Par. 1736.

Mr. Reanmur having given theſe hints for the underſtanding the occaſion of iron's being found ſcorified by the ſhort heat it receives from the colliſion of *flint* and ſteel, proceeds to account for the reaſon why iron yields fewer ſparks with *flint* than it does with ſteel.

On this occaſion he obſerves, that he accidentally had diſcovered a new phoſphorus of iron, in giving the proceſs of which, great light would be thrown into this ſubject: the method of making it was this, having melted ſome antimony in a crucible, he threw in at ſeveral times, twice the quantity of iron reduced into thin ſcales; the whole ſoon melted together, and became one fluid maſs; when this had been caſt into a mould and was become cold, it afforded a long train of ſparks on being filed with a common coarſe file. The ſparks were much larger than thoſe produced by a colliſion of *flint* and ſteel, and the larger of them ſet fire to the paper placed to receive them; but upon examination, theſe were all found to be melted in the manner of the ſparkling particles ſtruck off from ſteel, not only burnt, but melted, and that more perfectly than the others from the common colliſion with *flint*. If after all this, it be ask'd, why ſteel yields greatly more numerous ſparkles than iron? the anſwer is plain, that the difference of hardneſs alone is ſufficient to occaſion it; but granting even that ſteel and iron were of equal hardneſs, ſteel has the ſame advantage of iron in this reſpect, that the before mentioned mixture of iron with antimony has over plain iron, in that it contains greatly more of the inflammable matter than the iron does, and this inflammable matter is alſo more equally diſtributed thro' all its ſurface.

It may alſo be judged, that the *flint* not only contributes by its hardneſs to the ſending off the ſparks, but alſo by its ſulphur; what the blow diſlodges from it of this kind, and puts in violent motion, probably having no ſmall effect both in the fuſion and ſcorification of the metal. That all *flints* contain a large quantity of ſulphur is plain, from the ſulphureous ſmell they afford on being ſtruck together; and the ſparks which are produced by ſtriking iron againſt iron are probably affected in the ſame manner, by the ſulphur of the metal diſlodged from the adjoining parts by the blow.

One great proof of the ſparks being melted and rendered globular by means of the ſulphur of the *flint* is, that ſparks may be ſtruck from ſteel, in the ſame manner by glaſs as by *flint*, but in leſs quantity; theſe having been received on a paper, were examined by Mr. Reaumur, and were found to be ſcoriæ, of an irregular figure, having never been melted, and therefore never reduced to the globular ſhape of the others. In regard to the great change wrought in iron by this operation, or its being according to the words of Kemp deſtroyed, no longer retaining its great character of being attracted by the loadſtone, Mr. Reaumur willing to try the experiment before he reaſoned upon it, found this aſſertion not to be a fact, or at leaſt not a general one.

All the ſeveral kinds of ſparks which he mentions, thoſe produced by the common colliſion of *flint* and ſteel, thoſe by dropping ſteel filings thro' the flame of a lamp, and even thoſe from the filing of the antimoniated iron, all as readily anſwering to the loadſtone as common filings of iron; ſo that if this caſe ſometimes happen, and iron be liable thus to be deſtroyed, it is however no general fact, but a very rare and extraordinary one. Memoris Acad. Par. 1736.

FLINTS, *in the glaſs trade.* The way of preparing *flints* for the niceſt operations in the glaſs trade is this. Chuſe the hardeſt *flints*, ſuch as are black and will reſiſt the file, and will grow white when calcined in the fire. Cleanſe theſe of the white cruſt that adheres to them, then calcine them in a ſtrong fire, and throw them while red hot into cold water; waſh off the aſhes that may adhere to them, and powder them in an iron mortar, and ſift them through a very fine ſieve; pour upon this powder ſome weak aqua fortis, or the phlegm of aqua fortis, to diſſolve and take up any particles of iron it may have got from the mortar; ſtir this mixture ſeveral times, then let it reſt, and in the morning pour off the liquor, and waſh the powder ſeveral times with hot water, and afterwards dry it for uſe. You will thus have a powder for making the pureſt glaſs as perfectly fine and faultleſs, as if you had uſed rock cryſtal itſelf. *Cramer*'s Art of aſſaying metals, p. 438.

The waſhing off the ferrugineous particles with aqua fortis is not neceſſary, when the glaſs intended to be made is to be tinged with iron afterwards; but when meant to be a pure white, this is the method to be ſure of ſucceeding.

Breaking of FLINT. — The art of cutting or rather breaking *flint* ſtones into uniform figures, was by ſome ſuppoſed to be one of the arts now loſt. That it was known formerly appears from the antient Bridewell at Norwich, from the gate of the Auſtin-friars at Canterbury, that of St. John's abbey at Colcheſter, and the gate near Whitehall Weſtminſter. But that the art is not loſt, and that the French know it, appears from the platform on the top of the royal obſervatory at Paris, which inſtead of being leaded, is paved with *flint*, in the manner here mentioned. But we know not that this art is any where deſcribed. Phil. Tranſ. N°. 477. p. 521, and Note ibid.

Oil of FLINTS, a name given by ſome to a preparation made of four ounces of *flints* calcined and powdered and mixed with twelve ounces of ſalt of tartar; theſe being melted together by a ſtrong fire, run into a glaſs, which being afterwards powdered and ſet in a cellar, runs into an oil per deliquium; with this and the calx of any metal is prepared, one of the metallic vegetations. See VEGETATIONS *metallic.*

FLOATING (*Cycl.*)—FLOATING-*bridge*, a bridge conſiſting of ſeveral boats covered with planks; which ought to be ſo ſolidly framed, as to bear both horſes and cannon. See BRIDGE, *Cycl.* and *Suppl.*

FLOATING *iſlands.* See ISLANDS.

FLOOD (*Cycl.*) — FLOOD-*mark*, the mark which the ſea makes on the ſhoar, at flowing water, and the higheſt tide: it is alſo call'd *high-water mark.*

Sand FLOOD. See SAND.

FLOOKING, a term uſed in mining to expreſs a peculiarity in the load of a mine. The load or quantity of ore is frequently intercepted in its courſe, by the croſſing of a vein of earth or ſtone, or ſome different metallic ſubſtance; in which caſe the load is moved to one ſide, and this tranſient part of the land is called a *flooking*. See MINE.

FLOOR (*Cycl.*) — FLOOR-*timber*, in a ſhip. See TIMBER.

FLORAL *leaf*, among botaniſts. See LEAF.

FLORES *argenti*, in natural Hiſtory, a name given by ſome to the earth, called by the generality of authors, lac lunæ. It has both theſe names from its being ſuppoſed to partake of the nature of ſilver. See the article LAC *lunæ*, *Cycl.* and *Suppl.*

FLORES *Martiales*, a name given to a preparation of the nature of what was formerly called ens veneris. Theſe flowers are thus prepared; take of waſhed colcothar or green vitriol, or of iron filings one pound; of ſal armoniac, two pounds; mix them, and ſublime them in a retort, and mixing again the bottom with the flowers, renew the ſublimation till the flowers acquire a beautiful yellow colour. To the reſidue may be added half a pound of freſh ſal armoniac, and the ſublimation repeated, and the ſame proceſs may be continued as long as the flowers ariſe duly coloured. *Pemberton*'s Lond. Diſp. p. 215.

FLORIST, *Floriſta*, in botany, an author who writes what is called the flora of any particular place, that is, a catalogue of the plants and trees which are found ſpontaneouſly growing there. The flora laponica of Linnæus, and flora virginiea of Gronovious, are works of this kind; and theſe authors, as the authors of thoſe works, are properly called *floriſtæ*. *Linn.* Fundam. Bot. p. 1.

FLORUS, in zoology, a name by which Aldrovand and ſome other authors have called the bird commonly known with us by the name of the whinchat, a kind of the ænanthe or fallow-finch. *Aldrovand*, de Avibus. See WHINCHAT.

FLOS, the *flower* of a plant. It is to be obſerved that the antients ſometimes called the ſtamina or threads in the center of flowers, the *flos*, and not the petals which we uſually call ſo. Without underſtanding this, it is not poſſible to underſtand many paſſages in their writings. We find in Aurelian, the roſe called a yellow flower ſtanding in a purple husk; it is plain by this, that he meant the threads in the middle of that flower, which are of a fine yellow, and are very numerous, by the word flower; and calls the fine purple petals which we eſteem the flower, only the husk of the flower; in this ſenſe Virgil is explained to mean the common baum by the name amello; he ſays it has a yellow flower and purple leaves at the bottom, and they ſuppoſe that he meant the ſtamina or threads which in the baum are yellow, by the name flower; and the calyx or cup of the flower which is a purple, by his expreſſion of leaves at the bottom. The antients in general do not ſeem determined as to what they would have underſtood by the word *flos*. In the narciſſus, Pliny calls the cup that yellow part which occupies the center, and the whitiſh leaves that ſurround it the flower. Pliny has been cenſured for calling this part of the flower the cup, but he does not by this mean to confound it with the green leaves in the generality of plants which ſurround the flower, but he calls it thus in reſemblance to the cups out of which they drank, in their feſtivals.

FLOS *æris.* See the article ÆS.

FLOS *ambarvalis*, in botany, a name given by ſome to the polygala or milkwort. *Herm.* Cat. p. 450.

FLOS *Asiæ*, in natural hiſtory, a name given by Swenkfield and ſome other writers to that ſalt which is found on the ſurface of the earth in ſome parts of Aſia in form of an efflorescence, and is called the *Smyrna ſoap earth*.

This ſalt is evidently the ſame with the nitre of the antients. It will ferment with any acid, in the manner of our potaſh or other fixed ſalts made by fire; and with oil or any fatty ſubſtance, boils into a ſoap. Euclius gives us a great many different places for its production, from which he diſtinguiſhes it into ſeveral kinds: all theſe lie in the eaſtern parts of the world, but to theſe Wormius adds, that it is found in New Spain. It is always eaſy to be known, however, in whatſoever place it is found, being a native alcali ſalt, perforated like a ſpunge, and of a lixivial taſte. Pliny, Mathiolus, and Agricola agree in the deſcribing it in this manner, and all that is found native of it confirms their being in the right. Its principles ſeem to be two, a marine ſalt, and an urinous ſalt. That it contains a marine ſalt ſeems manifeſt from this, that it has the ſame taſte in ſolution, or nearly ſo, with marine ſalt; that the particles of it when coagulating in the evaporated water in which they were diſſolved, firſt riſe to the top or ſurface, as thoſe of common ſalt do, and that it is always of a ſpungy texture, or full of holes, which is always the caſe with thoſe things in which the common ſalt makes a part. Its natural concretions being hollow pyramids. Its containing an urinous ſalt is plain from its producing with ſalt of tartar, the ſame ſort of ſpirit that ſal armoniac does, when mixed with that fixed ſalt.

FLOS *cæli*, the *flower* of the heavens, a name given by the alchemiſts to the noſtoch, which often appearing after rain, was ſuppoſed to fall from heaven. See FLOS *terræ* and NOSTOCH.

FLOS *terræ*, *flower* of the earth, a name given by ſome of the chemical authors to the noſtoch, a remarkable plant which reſembles the common green oiſter weed, but that it is thicker and more like a jelly. It ſuddenly appears on gravel walks in gardens after rain; and the alchemiſts who knew not what to think of its origin, ſuppoſed it to contain an univerſal ſpirit, capable of turning metals into gold. It is a very ſingular plant, being no way fixed to the ground, nor having any roots, but imbibing its nutritious juices from the humidity of the air, as the ſea plants do theirs from the ſea water. See NOSTOCH.

FLOS *tinctorius*, in botany, a name given by Fuchſius and many others, to the geniſtella tinctoria, or dyer's weed, called alſo lutea herba, and lutum by the Latins, and alcomenium, cymene and thapſos by the Greeks.

FLOS *argenti*. See FLORES *argenti*.

FLOS *martialis*. See FLORES *martiales*.

FLOSCULOUS, in botany, a term uſed by Mr. Tourneſort, and others, to expreſs ſuch flowers of plants as are compoſed each of a great number of other ſmaller flowers placed cloſe to one another, and encloſed in the ſame common cup; each of theſe ſmaller flowers, conſiſts of one petal, which is ſlender and hollow and wider than the bottom, and uſually divided into many ſegments, which ſometimes are diſpoſed in the form of a ſtar. Each of theſe flowers ſtand upon an embryo, or young fruit, from which there grows a capillament which reaches beyond the flowers. Theſe embryos are lodged in the bottom of the cup, which is called by authors the thalamus of the flower, and finally become ſeeds winged with down, or ſometimes without that, and ſometimes are armed with prickles. Of this ſort are the flowers of thiſtles, kapweed, &c. See Tab. 1. of Botany, Claſs 1. *Tourn.* Inſt. p. 438.

FLOUNDER, in icthyology, the Engliſh name of the fiſh called by the generality of authors paſſer fluviatilis, and fleſus. According to the new ſyſtem of Artedi, this is a ſpecies of the pleuronectes. See the articles PASSER and PLEURONECTES.

FLOUR. The grain itſelf is not only ſubject to be eaten by inſects in that ſtate, but when ground into *flour*, it gives birth to another race of deſtroyers, who eat it unmercifully, and increaſe ſo faſt in it, that it is not long before they wholly deſtroy the ſubſtance. The fineſt *flour* is moſt liable to breed theſe, eſpecially when ſtale or ill prepared; in this caſe if it be examined in a good light it will be perceived to be in a continual motion, and on a nicer inſpection, there will be found in it a great number of little animals of the colour of the *flour*, and very nimble. If a little of this *flour* be laid on the plate of the double microſcope, the inſects are very diſtinctly ſeen in great numbers, very brisk and lively, continually crawling over one another's backs, and playing a thouſand antic tricks together; whether for diverſion or ſearch of food, is not to be eaſily determined. Theſe animals are of an oblong and ſlender form, their heads are furniſhed with a kind of trunk or oblong hollow tube, by means of which they take in their food, and their body is compoſed of ſeveral rings. They do vaſt miſchief among the magazines of *flour* laid up for armies and other public uſes; when they have once taken poſſeſſion of a parcel of this valuable commodity, it is impoſſible to drive them out; and they increaſe ſo faſt, that the only method of preventing the total loſs of the parcel, is to make it up into bread as ſoon as can be. The way to prevent their breeding in the *flour* is to preſerve it from damp; nothing gets more injury by being put up damp than *flour*, and yet nothing is ſo often put up ſo. It ſhould be always carefully and thoroughly dried before it is put up, and the barrels alſo dried into which it is to be put; then if they are kept in a room tolerably warm and dry, they will keep it well. Too dry a place never does *flour* any hurt, tho' one too moiſt always ſpoils it. See MEAL.

FLOWER (*Cycl.*) — Tho' no part of plants are more known than their *flowers*, yet the diſtinction given by different authors of the word are extremely various, and are very neceſſary to be explained, in order to the underſtanding their works. Jungius defines it to be the moſt tender part of a plant, remarkable for its colour or form, or for both, and cohering with the fruit. Yet this author himſelf, acknowledges his definition to be too confined, as he very well knew there were ſeveral plants, whoſe *flowers* were produced remote from the fruit.

Mr. Ray ſays the *flowers* coheres for the moſt part with the rudiments of the fruit, but ſuch phraſeology is by no means to be admitted into definitions. Tourneſort defines it to be a part of a plant very often remarkable for its peculiar colours, for the moſt part adhering to the young fruit, to which it ſeems to afford the firſt nouriſhment, in order to explicate its moſt tender parts; but this is a more indeterminate definition, than the former, from its looſe mode of expreſſion.

Pontedera defines it to be a part of a plant unlike the reſt in form and nature. If the *flower* has a tube, it adheres to, or is fixed very near to the embryo, to the uſe of which it is ſubſervient; but if the *flower* has no tube, then its baſe does not adhere to the embryo. This is ſcarce intelligible, except to the expert botaniſt, and may be made to take in ſome parts of plants by no means to be underſtood by the name *flowers*.

Juſſieu defines it to be compoſed of chives and a piſtillum, and to be of uſe in the generation of the plant; but this is too imperfect, as there are very many plants in which the piſtillum is found at a great diſtance from the chives, and many *flowers* which have no piſtillum, and many others which have no chives.

Valliant however, has been happier in his definition; he ſays, that *flowers* are the organs which conſtitute the different ſexes of plants, which are ſometimes found naked and without any covering; and that the petals which moſt of them have are no way eſſential to their uſe, but ſerve and are intended merely as covers for them; but yet as theſe coats or coverings are the moſt conſpicuous, and moſt beautiful part of the *flower*, theſe are to be called *flowers*, be they of what ever form or ſtructure, or colour; and whether they contain only the organs of both ſexes in each individual, or only of one, or even but of ſome part of one, provided that they are not of the ſame figure and colour with the leaves of the plant. The ſhorteſt and moſt expreſs definition however, ſeems to be Martyn's; which is, that *flowers* are the organs of generation of both ſexes, adhering to a common placenta, together with their common covering; or of either ſex ſeparately with its proper coverings, if it have any.

The parts of *flowers* are, 1. The ovary which is the rudiment of the fruit, and is therefore properly the female organ of generation. 2. The ſtyle which is a body accompanying the ovary, either ariſing from the middle of it, or ſtanding as an axis in the middle, with the embryos of the ſeeds round it. 3. The ſummits, called alſo apices and antheræ, which are thoſe bodies that contain the prolific powder, analogous to the male ſperm in animals, and generally hung upon ſlender threads which are called the chives. 4. The petals, commonly called the *flower* leaves, which are thoſe tender fine colour'd leaves which are generally the moſt conſpicuous parts of a *flower*. 5. The impalement or calyx, which is formed of thoſe tender leaves which cover the outer parts of the *flower*. Theſe *flowers* according to the number of their leaves or petals are called monopetalous, or one leaved, dipetalous or two leaved, and ſo on.

The ſtructure of the different *flowers* is very various; but Dr. Grew has obſerved, that the far greater number of them have the empalement, the foliation, and the attire or chives, &c. Mr. Ray accounts that every perfect *flower* has the petals, ſtamina or chives, apices or ſummits, and the ſtyle or piſtil, and ſuch as want any of theſe parts he calls imperfect *flowers*. The greater number of plants have a *flower* cup which is of a firmer ſtructure than their leaves, and ſerves for their ſupport.

Flowers are diſtinguiſhed into three kinds, the male, the female, and the hermaphrodite. The male *flowers* are thoſe which have the ſtamina and apices, but bear no fruit; the female are ſuch as contain the piſtillum, and not the apices and ſtamina; this piſtil is ſucceeded by the fruit, and theſe are therefore called the fruitful or kniting *flowers*; and the hermophrodite are ſuch as have in them the organs of both ſexes in each individual, and of this ſort are the generality of *flowers*, particularly the lilly, tulip, daffodil, roſemary, ſage, &c. *Miller*'s Gardiner's Dict.

Colours of FLOWERS. It is generally agreed among the chemiſts, that all colours ariſe from ſulphurs, and that they differ according to the different admixture of ſalts, with theſe ſulphurs. Perhaps on theſe principles, it may be poſſible to form ſome rational conjectures in regard to the origin of co-

lours in the *flowers* of plants. We know very well that the *flowers* of all plants abound in an eſſential oil or ſulphur, to which according to this doctrine their colours may be rationally ſuppoſed to be owing; and tho' this oil ſhould be prov'd to be the very ſame ſubſtance in all, yet their variety of colours may be accounted for from it, ſince we find that one and the ſame oil, the eſſential oil of thyme, according to Mr. Geoffroy's experiments, may be turned to all the colours that we find in the different *flowers* of plants, from white to deep black, with all the ſhades of red, yellow, purple, blue and green, by mixing it with different ſubſtances; and by the ſame laws, the eſſential oils of plants while contained in their *flowers* may by the different mixtures they meet with give them all their beautiful variety of colours. See the article *Eſſential* OILS.

We know that the infuſions of *flowers*, and of other parts of plants become red on being mixed with acids, and green on being mixt with alkalis; and there is no reaſon to doubt, but that it is the ſulphureous part of the vegetable in theſe infuſions which thus changes colour on theſe mixtures. This however, ought to be proved poſſible, before it is allowed in argument.

This proof is given in the change of colours before mentioned, which are produced in oils merely by the admixture of different ſalts; and as all the colours in theſe, are the regular reſult of certain combinations, there is great reaſon to believe, that in thoſe plants whoſe *flowers* give the ſame colours, there may be the ſame combinations. The principal colours of plants, and their ſeveral parts are green, yellow, red, purple, blue, white, black, and tranſparent whitiſhneſs; all the others are produced by different combinations of theſe. The green which is the common colour of the leaves of plants is probably the effect of an oil rarified in that part of the plant, and there mixed with the fixed and volatile ſalts of the ſap, which remain intangled by the earthy particles after moſt of the aqueous humidity is evaporated, and by that means become in a ſtate to act upon the oil. A clear proof of this is, that if the leaves are covered up in ſuch a manner, that the aqueous humidity of the ſap cannot evaporate itſelf, the oil and ſalts cannot act upon one another as they naturally would, but becoming diffuſed among ſo great a quantity of water, loſe the colour they would otherwiſe have obtained together, and become whitiſh or tranſparent. This is ſeen in the obvious inſtance of ſuccory and celeri, the leaves of both which plants, tho' naturally green, become white by being covered up with earth by the gardiner. Mem. Acad. Par. 1707.

The leaves both of plants and trees uſually turn red in autumn, or on the attack of the firſt froſts; the reaſon of which is, that the ſeveral canals of the ſap being conſtringed by the cold, the juices are detained in the veſſels of the leaves, or at leaſt its circulation is greatly interrupted, and being detained there, it naturally grows ſour, the acidity of this alter'd juice deſtroying the green colour produced by the alkaline ſalts. The ſap brings on a red colour, in the very ſame manner that an eſſential oil made green by a mixture of oil of tartar, is again changed to red, by adding to it a proper quantity of diſtilled vinegar. Where we find in our common experiments the acids of the mineral kingdom turning the infuſions of *flowers* red; it ſeems by the analogy of theſe experiments, to be only owing to their deſtroying the blue, brown, or other colour, which the alkaline ſalts of the plant had made with its eſſential oil.

All the ſhades and degrees of yellow and ſaffron colour in the *flowers* of plants, ſeem wholly owing to a mixture of an acid in their juices, with their eſſential oil; as the oil of thyme, which itſelf has very little colour, is made to paſs thro' all theſe ſhades of colours, only by digeſting it with diſtilled vinegar. From the digeſting the volatile alkalis, ſuch as ſpirit of ſal armoniac and urine, with the ſame oil, it appears that all the ſhades of red, from the paleſt fleſh colour, to purple, and even to the violet blue, are only owing to the different admixtures of an alkaline volatile ſalt of the urinous kind, mixed in different manners with their eſſential oil.

Black, which is a very uncommon colour in *flowers*, and which in them ought to be regarded only as a very deep violet, ſeems the effect of an addition of an acid juice to their oil, already turned purple or violet colour by a volatile alkali.

All the ſhades of blue and purple ſeem alſo, by the analogy of the ſame experiments, to be only the effects of mixtures of alkalis of the fixed and volatile kind, with the oils of plants; ſince theſe colours are all produced in thoſe experiments, by mixing the ſpirit of ſal armoniac, and the oil of tartar with oil of thyme.

The bright green of ſome *flowers* ſeems alſo to be produced by the ſame ſalts, only acting on oils more rarified. For the oil of thyme, of a purple violet colour, diluted with rectified ſpirit of wine, being united with oil of tartar, becomes green. Mem. Acad. Par. 1707.

Boccone is of opinion, that in many plants the colour of the *flower* is wholly owing to the colour of the juices of the root. This he inſtances in the greater celandine, whoſe roots and *flowers* are of the ſame yellow colour. The barberry in like manner he obſerves, has both its roots and its *flowers* yellow. The dentillaria has its roots and *flowers* both of a pale red, and the acacia indica Aldini, and many other plants, he ſays are inſtances of this.

The reaſon that he aſſigns for this is, that the more fixed parts wherein this colour conſiſts, preſerve the ſame tincture, without being at all alter'd by ſo long a circulation as that from the root to the *flower*; and he adds another very remarkable obſervation, which is, that in all theſe plants and trees, whoſe roots and *flowers* are of the ſame colour, the juices are more fixed; and therefore, that theſe are more fit for dying than any other coloured woods or plants. Vid. *Boccone* Muſ. de Piant.

Preſervation of FLOWERS. The method of preſerving *flowers* in their beauty thro' the whole year, has been diligently ſought after by many people; ſome have attempted it, by gathering them when dry, and not too much opened, and burying them in dry ſand; but this tho' it preſerves their figure well, yet takes off from the livelineſs of their colour. Muntingius gives a method which he ſays is preferable to all others; this is as follows: gather roſes or other *flowers* when they are not yet thoroughly open, in the middle of a dry day; put them into a good earthen veſſel glazed within; fill the veſſel up to the top with them; and when full, ſprinkle them over with ſome good French wine with a little ſalt in it; then ſet them by in a cellar, tying the mouth of the pot carefully down. After this, they may be taken out at pleaſure, and on ſetting them in the ſun, or within the reach of the fire, they will open as if on the tree, and not only the colour, but the ſmell will be preſerved.

The *flowers* of plants are by much the moſt difficult part of them to preſerve in any tolerable degree of perfection; of this we have inſtances in all the collections of dried plants or *horti ſicci*. In theſe the leaves and ſtalks and the roots and ſeeds of the plants appear very well preſerved, the ſtrong texture of theſe parts making them always retain their natural form, and the colours in many ſpecies naturally remaining; but where thoſe fade, the plant is little the worſe for uſe, as to the knowing the ſpecies by it. But it is very much otherwiſe in regard to *flowers*: theſe are naturally by much the moſt beautiful part of the plant to which they belong; but they are ſo injured in the common way of drying, that they not only loſe, but change their colours one into another, by which means they give a handle to many errors; and they uſually alſo wither up, ſo as to looſe their very form and natural ſhape. The primroſe and cowſlip kind are very eminent inſtances of the change of colours in the *flowers* of dried ſpecimens; for thoſe of this claſs of plants eaſily dry in their natural ſhape, but they not only loſe their yellow, which might be expected naturally enough, but they acquire a fine deep green, much ſuperior to that of the leaves in their moſt perfect ſtate. The *flowers* of all the violet kind, loſe their noble blue, and become of a dead white, ſo that in dried ſpecimens, there is no difference between the blue flowered violet and the white flowered kinds.

Sir Robert Southwell has communicated to the world a method of doing the buſineſs of drying plants, by which this inconvenience is propoſed to be in a great meaſure remedied, and all *flowers* to be preſerved in their natural ſhape, and many in their proper colours. To this purpoſe two plates of iron are to be prepared of the ſize of a large half ſheet of paper or larger for particular occaſions; theſe plates muſt be made ſo thick as not to have any power of bending, and there muſt be a hole made near every corner for the receiving a ſcrew to faſten them cloſe together.

When theſe plates are prepared, lay in readineſs ſeveral ſheets of paper, and then gather the plants with their *flowers*, when they are quite perfect; let this always be done in the middle of a dry day, and then lay the plant and its *flower* on one of the ſheets of paper doubled in half, ſpreading out all the leaves and petals as nicely as can be. If the ſtalk be thick, it muſt be pared or cut in half, ſo that it may lie flat, and if it be woody, it may be peel'd and only the bark left; when the plant is thus expanded, lay round about it, ſome looſe leaves and petals of the *flower*, which may ſerve to compleat any part that may prove deficient; when all is thus prepared lay ſeveral ſheets of paper over the plant, and as many under it; then put the whole into the iron plates, laying the papers ſmoothly on one, and laying the other evenly over them; then ſcrew them cloſe and put them into an oven after the bread is drawn, and let them lie there two hours; after this make a mixture of equal parts of aqua fortis and common brandy; ſhake theſe well together, and when the *flowers* are taken out of the preſſure of the plates, rub them lightly over with a camel's hair pencil dipped in this liquor; then lay them upon freſh brown paper, and covering them with ſome other ſheets, preſs them between this and other papers with a handkerchief, till the wet of theſe liquors is dried wholly away. When the plant is thus far prepared, take the quantity of a nutmeg of gum dragon, put this into a pint of fair water cold, and let it ſtand four and twenty-hours; it will in this time be wholly diſſolved;

diſſolved; then dip a fine hair pencil in this liquor, and with it daub over the backſides of the leaves, and lay them carefully down on a half ſheet of white paper fairly expanded, and preſs them with ſome more papers over theſe. When the gum water is fixed, let the preſſure and papers be removed, and the whole work is finiſhed. The leaves retain their verdure in this caſe, and the *flowers* uſually keep their natural colours. Some care muſt be taken, that the heat of the oven be not too great. When the *flowers* are thick and bulky, ſome art may be uſed to pare off their backs and diſpoſe the petals in a due order; and after this, if any of them are wanting, their places may be ſupplied with ſome of the ſupra numerary ones dried on purpoſe; and if any of them are only faded, it will be prudent to take them away, and lay down others in their ſtead: the leaves may be alſo diſpoſed and mended in the ſame manner. Another way of keeping both *flowers* and fruit the whole year without ſpoiling, is delivered by the ſame author in the following manner: take ſalt petre, one pound; bole armeniac, two pounds; clean common ſand three pounds; mix all well together, then gather fruit of any kind, that is not fully ripe, with the ſtalk to each; put theſe in one by one into a wide mouth'd glaſs, laying them in good order; tie over the top with an oil cloth, and carry the glaſs into a dry cellar, and ſet the whole upon a bed of this prepared matter of four inches thick in a box; fill up the remainder of the box, with the ſame preparation, and let it be four inches thick over the top of the glaſs and round all its ſides. *Flowers* are to be preſerved in the ſame ſort of glaſſes in the ſame manner, and they may be taken up after a whole year as plump and as fair as when buried.

FLOWERS, in antiquity. We find *flowers* in great requeſt at the entertainments of the antients, being provided by the maſter of the feaſt, and brought in before the ſecond courſe; or as ſome are of opinion, at the beginning of the entertainment. They not only adorned their heads, necks, and breaſts with *flowers*, but often beſtrewed the beds whereon they lay, and all parts of the room with them. But the head was chiefly regarded. *Potter*, Archæol. Græc. T. 2. p. 383. See GARLAND, *Cycl.* *Flowers* were likewiſe uſed in the bedecking of tombs. *Potter* Archæol. Græc. l. 4. c. 7. T. 2. p. 232. ſeqq. See BURIAL and BURYING.

Labiated FLOWERS. See LABIATED *Flowers.*

FLOWER *de luce*, in botany. See IRIS.

Trumpet FLOWER. See TRUMPET.

Wind FLOWER. See WIND *Flower.*

FLOWER *of oſteocolla*, a name given by the people employed in finding the oſteocolla to a ſort of white marley matter, which they uſually find on the ſurface of the ground in the places where the oſteocolla lies underneath. It ſeems very nearly allied to the nature of the oſteocolla itſelf, and uſually has under it ſome of that blackiſh matter reſembling rotten wood, which the oſteocolla itſelf is formed upon, and which fills up thoſe hollows we find in moſt of the pieces, while the whole is in the ground. This rotten vegetable matter has much the reſemblance of the roots or branches of trees, and is called by the common people the root of the oſteocolla or hammoſtei radix. Phil. Tranſ. N°. 39.

FLOWER-*root worm*, in natural hiſtory, a peculiar ſpecies of fly-worm, which makes its habitation only in the bulbous roots of *flowers*. The roots of the narciſſus at the time they are taken up out of the earth toward the end of autumn, very frequently are found to contain each a ſingle worm, which eats and deſtroys them. Sometimes one root is found to contain two of them; but this is but rarely the caſe. The roots which have them may eaſily be known, by having each a round hole in ſome part, at which the deſtroyer has entered while it was ſmall, and which probably ſerves it now in its larger ſtate for reſpiration of the freer air. The interior part of theſe bulbs is always found rotted and deſtroyed, and the worm is found in theſe, lying in a brown ſort of dirt made by its own liquid excrements, mixed among the fragments of the coats of the root which it has deſtroyed. *Reaumur*'s Hiſt. Inſect. vol. 4. p. 499.

When theſe worms are firſt taken out of the roots, it is not eaſy to know which end is the head, which the tail; for both appear almoſt equally pointed. The intermediate ſpace is cylindric, and made up of vaſt number of circular or annular fibres. It is not long, however, before the worm begins to change place, and one may then ſee him extend his head, and diſcover, that it is furniſhed, as in the reſt of theſe kind of inſects, with two hooks. The way to ſee theſe hooks diſtinctly is to preſs the worm between the fingers, it then throws them out as far as poſſible, and one ſees that they are thick, and whitiſh at their baſes, and pointed and brown at their extremities, and are hook'd inward toward the belly. At a little diſtance above each of theſe hooks, the creature has a pair of fleſhy horns which are forked at the ends; and a little below the inſertion of the horns, it has two brown ſpots which are probably its anterior ſtigmata. In order to ſee the poſterior ſtigmata of this worm, it is neceſſary to preſs a little the hinder part of the body, and it will then throw out a ſort of ſmall tube of a blackiſh brown, which is uſually hid among the commiſſures of the poſterior rings. On the upper part of this little tube are two apertures, which are the two poſterior ſtigmata. Theſe are of a round circumference, and in the center of each there is a ſmall black eminence, which ſeems the half of a little round ball. This is the place where the poſterior ſtigmata are ſituated, and this larger ſingle protuberance, anſwers all the purpoſes of the two tubes placed cloſe together, which are ſo common in the other fly-worms of this ſort.

A little below this there are two fleſhy appendages, between which, is the anus of the worm. When viewed with the microſcope, the whole body of the creature appears ſomewhat rough and wrinkled, and has a few ſhort hairs thinly ſcattered about it. *Reaumur*'s Hiſt. Inſ. v. 4. p. 502.

Theſe worms undergo all their changes in a ſhell made of their own skin, which is of the ſame egg faſhioned ſhape with that of the blue fleſh fly, but conſiderably larger, and of a greyiſh colour. But this is not all its difference from thoſe ſhells; for on its anterior and ſuperior part, it has two horns of the ſame kind with the four of the ſhells of the rat tailed worms, and ſeeming to ſerve to the ſame purpoſes, and ſerve to convey the air neceſſary for the life of the creature, into its corcelet; the old ſtigmata which ſerved the creature in its worm ſtate being now obliterated, and ſomething neceſſarily wanted in their place. After having undergone all the neceſſary changes, the ſhells are burſt open, in the month of April, and let out the fly they contained.

This has ſo much the appearance of an humble bee, that at firſt ſight, it is ſcarce to be diſtinguiſhed from it. It is covered with black, yellow, and reddiſh hairs, as the ſmaller kinds of the common humble bees are; but its antennæ, which are of the battledoor faſhion, prove plain enough, that it is really no bee, even before one can determine with certainty, that it has only two wings.

FLOWERING *of bulbous plants.* Theſe plants will grow and *flower* in water alone without any earth, and make a very elegant appearance. We daily ſee this practiſed in ſingle roots, but there is a method of doing it with ſeveral together, as follows: take a common ſmall garden pot, ſtop the hole at the bottom with a cork, and lute in the cork with putty that no water can get through; then fit a board to the top of the pot, and bore ſix or ſeven holes in it, at equal diſtances, to place the bulbs in, and as many ſmaller holes near them to receive ſticks, which will ſerve to tie up the *flowers*. Then fill up the pot with water to the board, and place tulips, jonquiles, narciſſus's and the like plants in the root upon the holes, ſo that the bottom of the roots may touch the water; thus will they all *flower* early in the ſeaſon, and be much more beautiful than any pot of gathered *flowers*, and will laſt many weeks in their full perfection. After the ſeaſon of *flowering* is over, the roots will gradually ſhrink thro' the holes of the board, and get looſe into the water, but inſtead of becoming ſpoiled there, they will ſoon increaſe in ſize, ſo as not to be capable of coming back, and will produce ſeveral off-ſets. It is natural to try from this, the conſequence of keeping the roots under water during the whole time of their blowing, and in this manner they have been found to ſucceed very well, and *flower* even ſtronger and more beautifully, then when in the ground. They may thus alſo with proper care in the degree of heat in the room, be kept *flowering* from before Chriſtmas, till March or April. It is not eaſy in this laſt manner to manage the keeping the boards under water, for which reaſon it is better to procure ſome ſheet lead of about four pounds to the foot, and cut this to the ſize of the mouth of the pot; in this there ſhould be bored holes for the bulbs, and other holes for the ſticks; and in order to keep the ſticks quite firm, it is proper to have another plate of lead ſhaped to the bottom of the pot, with holes in it, anſwering thoſe in the upper plate made for the ſticks. The ſticks will by this means be kept always perfectly ſteady, and the roots being kept under water by the upper plate of lead, will *flower* in the moſt vigorous and beautiful manner imaginable.

Some have thought of adding to the virtues of the water by putting in nitre in ſmall quantities, and others have added earth and ſand at the bottom, but it has been always found to ſucceed better without any addition.

It may be more agreeable to ſome to uſe glaſs jarrs, in this laſt method with the leads, inſtead of earthen pots. The bulbs ſucceed full as well in theſe; and there is this advantage, that the progreſs of the roots is ſeen all the while, and they are managed better as to the ſupply of water.

By repeated experiments in this way on dried bulbs, and on thoſe taken freſh out of the ground, the former have been found to ſucceed the beſt; for thoſe taken freſh out of the ground being full of moiſture, will not ſo ſoon upon changing their element be nouriſhed fully by a new one; and the fibres which they had ſtruck in the ground always rot when put into the water, and new ones muſt be formed in their places, ſo that it requires more time for them to come to *flowering*. The bulbs themſelves will not rot in this manner, but they will never be ſo ſtrong as thoſe which were put into the water dry, which gradually fill themſelves with moiſture from it, and regularly plump up. The beſt method of managing

the whole proceſs is this: place the bulbs at firſt only on the ſurface of the water; for thus they will ſtrike out their fibres moſt ſtrongly. When they have ſtood thus ſix weeks, pour in the water ſo high as to cover them intirely, and keep them at this ſtandard till they have done *flowering*.

Sometimes the roots will become mouldy in ſeveral parts while they ſtand above the water, and the cleaning them of it is to no purpoſe, for it will eat and ſpread the farther, and frequently eat thro' two or three of their coats. In this caſe, they muſt be immediately covered with water, and the mould will be ſtopp'd and they will become ſound, and *flower* as well as thoſe which never had any ſuch diſtemperature. If the roots are ſuffered to remain in water all the year, they will not decay, but will *flower* again at their proper ſeaſon, and that as vigorouſly as thoſe which are taken out and dried. The old fibres of theſe roots never rot till they are ready to puſh out new ones. It is found by experience, that the hyacinth, and many other plants, grow to a greater perfection thus in water, than when in the ground. There is a peculiar ſpecies of hyacinth, called Keyſer's jewel; this never, or however very rarely, produces ſeed veſſels in the common way of *flowering* in the ground, but it often will produce ſome pods when blown in water.

Mr. Miller has intimated in the Philoſophical Tranſactions, that bulbs ſet in glaſſes, grow weaker, and ſhould be renewed with freſh ones every other year, but it is found that when they are managed in this manner, and kept under water, at the time of taking them up, they are as large, and ſome of them larger and ſtronger than when planted, and if theſe be dried at a proper ſeaſon, they will *flower* year after year as well as freſh ones.

Ranunculus and anemone roots have been found to ſhoot up their ſtalks very well in this way, but the flowers are uſually blaſted, which ſeems to ariſe from want of free air. Pinks will *flower* very well in this manner, and auriculas thrive very well, and may with care be brought to *flower*, but not ſtrongly. Roſes, jeſſamines and honey-ſuckles, may alſo be made to *flower*, this way, and will thrive and ſend out ſuckers; the beſt pieces to plant are ſuckers cut off about three inches under ground, without any fibres.

The ſucculent plants may alſo be raiſed this way, for inſtance, an opuntia or Indian fig. If a fragment of a leaf of this plant be cut and laid by to dry for a month, till it is an abſolute skin, as ſoon as it is put in this manner into water, it begins to plump up, and ſoon ſends out fibrous roots, and produces new leaves, at leaſt as quickly as it would do in the ground. Philoſ. Tranſ. N°. 432. p. 274.

This is the more ſingular in theſe ſort of plants, becauſe in their natural ſtate in the ground, they cannot bear much water. This method of growing of plants is not particular to the bulbous rooted ones, but others may even be raiſed from ſeed by it; a bean or pea ſet in this manner, will grow up to its proper ſtandard, and will *flower* and produce pods, which will ripen their ſeed.

The ſmaller ſeeds may alſo be raiſed in this manner, by the help of wool to ſupport them. See the article SEEDS.

No plant tranſplanted out of earth into water, will thrive kindly; but any plant, whether raiſed from the root or ſeed in water, may be tranſplanted to the earth, and will ſucceed very well. It may be poſſible therefore, from this method of raiſing plants in water, to come at a better way than is uſualy practis'd of raiſing ſome roots in the earth which are ſubject to rot there; ſuch as anemonies, ranunculus's and hyancinths. A bulb dropped by chance upon the ground, will ſtrike out both ſtronger and more numerous fibres, than thoſe which are planted in the uſual way in the ground. On this principle it may be proper to take out the earth of the bed where the bulbs are to ſtand at the time of planting them, to ſuch a depth as they are to be placed under it, when ſet for *flowering*. The bulbs are then to be ſet in their places on the ſurface of this low ground, and to ſtand there till they have ſhot out their fibres and their head, then the earth is to be added over them by degrees, till they are covered as high above the head as they are in the uſual way of planting them; thus they would be preſerved from the danger of rotting, and their fibres would be much ſtronger, and conſequently they would draw more nouriſhment, and *flower* better than in the common way. The common way of planting theſe roots, renders them liable to be deſtroyed by either extreme of a wet or a dry ſeaſon; in the firſt caſe they immediately rot by the abundant moiſture they receive; and in the other, they become dry as a ſtick, and mouldy, ſo that they are infallibly rotted the firſt rain that falls afterwards.

The directions neceſſary to the ſucceſs of the bulbs planted in water are theſe; when the leaden falſe bottoms are fixed down tight within two or three inches of the bottom of the veſſel, (which is only deſigned to hold the ſticks ſteady which are to ſupport the leaves and ſtalks) then lay on the lead which is to ſupport the bulbs, placing the notched part oppoſite to that in the falſe bottom, as near as the ſticks when placed, will ſuffer it; then place the bulbs one in each hole, and fill up with water to the upper lead. The bottom of the bulb will then touch the water; and as the water diminiſhes in quantity, keep it ſupplied with more up to the ſame height for a month or ſix weeks, in which time the bulbs will have ſhot ſtrong fibres; then fill up water about half an inch above the ſurface of the lead, and by degrees as the fibres ſtrengthen, and the plume ſhoots from the head, keep the water higher and higher, till at length the whole bulb be covered. And the water is to be kept at this ſtandard till the ſeaſon for drying them returns.

At the time of planting the bulbs, they muſt be carefully cleaned from any foulneſs at the bottom, by ſcraping them clean with the point of a knife, till the ſound part of the bulb appears; clear them likewiſe from any looſe skins, and even take off their brown skin, till they appear white; otherwiſe this brown skin will tinge the water, and the growth will not ſucceed ſo well.

The notches in the ſide of each lead, are intended to give eaſy paſſage to the water, that if there ſhould be any foulneſs or ſediment in it, on ſhaking it a little, it may all run thro', and freſh water be put in its place; but this ſhifting the water need not be done more than once or twice in a winter, as there may be occaſion from the foulneſs; and when this is done, the ſides of the veſſel ſhould be cleaned with a painter's bruſh, and rinſed out again, and the bulbs themſelves waſhed, by pouring water on them at a little diſtance.

At any time when the outer skins of the bulbs dry, they are to be peeled off, that they may not occaſion foulneſs in the water, and if any duſt or foul matter be at any time obſerved ſwiming on the ſurface, the method is to fill up the pot or veſſel to the rim, and let it run over: this will carry off that light foulneſs, and the water may afterwards be poured away to the proper ſtandard.

Bulbs of equal bigneſs ſhould be planted together in the ſame pot, that they may all have the ſame benefit of the water. Narciſſus's and hyancinths do well together; as alſo tulips and jonquils, and crocus's and ſnow-drops. Phil. Tranſ. N°. 431. p. 278.

The method of cauſing *flower* roots of the bulbous kind to ſend forth their *flowers* early, by placing them over or in veſſels of water, has been already delivered; but there is yet another way of cauſing them to blow early in pots of earth in this manner. Diſſolve crude ſal armoniac in water, in ſuch proportion, as that a piece of the bigneſs of a walnut may be diſſolved in every quart; then prepare ſome pots of a proper ſize filled with good garden mould. Sow the annual *flowers*, and ſet the roots of the perennial ones, ſuch as tulips, &c. in theſe pots at Michaelmaſs; continue the enſuing ſeaſon to water them with this ſolution of the ſalt, and keep them in a warm room; by this means they will be in full *flower* about Chriſtmas, and will continue thro' January and February.

FLOWN *ſheets*, at ſea. The ſeamen ſay a ſhip ſails with *flown ſheets*, when her ſheets are not *haled home*, or cloſe to the blocks: they ſay alſo, *let fly the ſheet!* when in a great guſt of wind, for fear the ſhip ſhould overſet, or *ſpend* her top-maſts, they would have the ſheet go *amain*, or as far as it will run, becauſe then the ſail will hold no wind; and when the ſheets are thus let go, they ſay her ſheets are *flown*.

FLOX, in the colour trade, a very well cleaned wool uſed to abſorb the colours of cochineal, &c. It is prepared in this manner; infuſe a pound of the fineſt ſheerings of woollen cloth in cold water for one day, then take them up, and preſs them well together to waſh off the unctuoſity the wool naturally has. This is the ſimple *flox*, which when impregnated with a ſolution of alum, is called alumed *flox*; this is done in the following manner. Take four ounces of roach alum, and two ounces of crude tartar, both in fine powder; put them into an earthen veſſel with three quarts of water, ſet it over the fire, and when it begins to boil, then put in the *flox*; let the liquor now boil half an hour over a gentle fire, then take it off, and when all is perfectly cooled, waſh the *flox* with fair water, leting them ſtand in it two hours, then preſs them in the hand and let them dry. *Neri*'s Art of Glaſs. p. 172.

FLUDER, or *Sea* FLUDDER, in zoology, the name of a water fowl of the colymbus or diver kind, deſcribed by Geſner, and ſome other authors, under the name of the colymbus maximus, or largeſt diver. It is nearly of the ſize of a gooſe, and moves but very ſlowly on the water, and much worſe either on land, or in the air, being but little able, either to walk or fly. Its beak is long, and its legs very ſhort; it makes a very ſhrill noiſe, and is remarkable for diving to vaſt depths. Its feet are webbed, its back is of a greyiſh colour, and its belly white. It ſeems much to approach to the northern colymbus, called the lumme, and perhaps differs only in colour, which may be an accidental variety, as is common in birds. *Ray*'s Ornithol. p. 260.

FLUELLIN, *elatine*, in medicine. See ELATINE.

FLUENT, or *flowing quantity*, in the doctrine of fluxions, that quantity (whether line, ſurface, ſolid, &c.) which is continually increaſing, or decreaſing. See the article FLUXION, *Cycl.* and *Suppl.*

Mr. Maclaurin, in his treatiſe of fluxions, has made ſeveral inquiries into *fluents*, reducible to the rectification of the ellip-

ſis, and hyperbola. Mr. D'Alembert has purſued the ſame ſubject and carried it farther, in Mem. de L'Acad. de Berlin. Tom. 2. p. 200. ſeqq.

FLUIDS (*Cycl.*) — Animalcules obſerved in *fluids* are of divers kinds; ſome are flat, others eel like, but the greater part of an oval figure. Leewenhoeck gives a deſcription of a very unuſual ſhaped creature, fixed in a little ſcabbard or ſheath; which was faſtned to ſome of the ſmall green weeds found in ditches full of water. Phil. Tranſ. N°. 337. p. 160.

Waters of all kinds that have ſtood a while expoſed to the air, till they have grown a little putrid, or where putrefaction has been promoted by the admixture of other matters, abound in variety of animalcules, having each their peculiar characters, ſizes, figures, œconomy, and method of life, not to ſay uſes. In a ſmall drop of the diſcoloured ſurface of rain water, which had ſtood two months in a window, Dr. Harris obſerved four ſorts of animalcules: the clear part of the drop preſented two kinds, both very ſmall; the firſt of the figure of ants eggs: theſe were in a continual briſk motion. The ſecond more oblong, three times as long as broad, were exceedingly numerous, but their motion ſlow.

In the thick part of the drop there were alſo two ſorts of animalcules. The firſt of the eel kind, reſembling thoſe in vinegar, but much ſmaller, and with their extremes more ſharp. Theſe would wriggle out into the clear part, and then ſuddenly betake themſelves back again, and hide in the thick and muddy part of the drop, much like common eels in the water. The ſecond ſort reſembled a large maggot, which would contract themſelves into a ſpherical figure, and then ſtretch out again. The end of the tail appeared with a forceps, like that of an ear-wig. They might be plainly perceived to open and ſhut their mouths, from whence air bubbles were frequently diſcharged. The number of theſe was not above four or five. The ſame four kinds of animalcules he alſo found in many other drops of the ſame corrupted water.

Animalcules in *Fluids*, are generally found at the top. In the lower parts of the water, Mr. Harris aſſures us he could never find any, unleſs when the liquor had been diſturbed, and the ſurface ſhaken down, and mingled with the lower parts. Mr. Harris examined ſome rain water that had ſtood uncovered a pretty while, but had not contracted any thick or diſcoloured ſcum.

And here where the water was clear, he could not find any animals at all; but a little thin white ſcum, that like greaſe began to appear in its ſurface, he found to be a congeries of exceeding ſmall animals of different ſhapes and ſizes, much like thoſe produced by ſteeping barley in water.

Viewing a ſmall drop of the green ſurface of ſome puddle water, he found it altogether compoſed of animalcules of ſeveral ſhapes and magnitudes; the moſt remarkable, were thoſe which gave the water that green colour, and were oval creatures, whoſe middle parts were of a graſs green, but each end clear and tranſparent. They would contract and dilate themſelves, tumble over and over many times together, and then ſhoot away like fiſhes. Phil. Tranſ. N°. 220. p. 255.

Mr. Harris looked on the ſurface of ſome mineral chalybeate water, which had ſtood in a vial unſtopt for about three weeks. In it he ſaw two kinds of animals. One exceeding ſmall, and the other very large, which latter ſort had on the tail, ſomething that look'd like fins. There were but very few of either ſort. Phil. Tranſ. N°. 220. p. 257. ſeqq.

Animalcules in *Fluids* are eaſily deſtroyed by only ſeparating them a while from their element. Naturaliſts have even found ſhorter ways. A needle point dipped in ſpirit of vitriol and then immerſed into a drop of pepper water, readily kills all the animalcules, which tho' before friſking about with great livelineſs and activity, no ſooner come within the influence of the acid particles, then they ſpread themſelves and tumble down to all appearance dead. The like may be done by a ſolution of ſalt, only with this difference; that by the application of this latter, they ſeem to grow vertiginous, turning round and round, till they fall down. Tincture of ſalt of tartar uſed in the ſame manner kills them ſtill more readily; yet not ſo, but there will be apparent marks of their being ſick firſt and convulſed. Inks deſtroy them as faſt as ſpirit of vitriol, and human blood by virtue of the ſalt contained in it, produces the ſame effect. Urine, ſack, and ſugar, do all deſtroy them, tho' not ſo faſt; beſides, that there is ſome diverſity in their figures and appearances, as they receive their deaths from this poiſon, or that [a]; the point of a pin dipped in ſpittle preſently killed all the kinds of animalcules in puddle water, as Mr. Harris ſuppoſes it will other animalcules of this kind [b]. [[a] Phil. Tranſ. N°. 203. p. 863. ſeq. [b] Phil. Tranſ. N°. 220. p. 256.]

We find in the waters of our ditches many ſpecies of ſmall animalcules, both of the cruſtaceous and teſtaceous kinds. The legs of the creatures are ſhort, they reſemble thoſe of crabs and lobſters, but are of a much more curious ſtructure; they are leſs than a ſmall flea, but they ſeem all breeders, carrying ſpawn at their tails, or in two ſmall bags, one hanging from each ſide. Theſe bags are often ſeen broken, and the ſpawn is then found to conſiſt of globules very large in proportion to the ſize of the creature. There is another ſort beſide theſe as beautiful but much ſmaller than they; this in ſhape more reſembles the ſhrimp, and carries its ſpawn as the ſhrimp does. Theſe kinds both ſeem to have only one eye and that placed exactly in the middle of their forehead, without the leaſt trace of a dividing line; and they are often ſo tranſparent that the motion of their bowels, and pulſation of their heart may be ſeen. *Baker's* Microſcope, p. 93.

All who are acquainted with the microſcope, know very well, that in water, in which the beſt glaſſes can diſcover no animated particle of matter, after a few grains of pepper, or a ſmall fragment of a plant of almoſt any kind has been ſome time in it; animals full of life and motion are produced, and thoſe ſo numerous as to equal the fluid itſelf in quantity.

When we ſee a numerous brood of young fiſhes in a pond, we make no doubt of their having owed their origin to the ſpawn that is, the eggs of their parents of the ſame ſpecies. What are we then to think of theſe? if we will conſider the progreſs of nature in the inſect tribes in general, and eſpecially in ſuch of them as are moſt of all analogous to theſe, we ſhall find it leſs difficult to give an account of their origin, than might have been imagined.

A ſmall quantity of water taken from any ditch in the ſummer months, is found to be full of little worms, ſeeming in nothing ſo much as ſize, to differ from theſe microſcopic animalcules. Nay water without theſe expoſed in open veſſels in the ſummer months will be always found after a few days to abound with multitudes of them, viſible to the naked eye, and full of life and motion.

Theſe we know by their future changes are the fly worms of the different ſpecies of gnats, tipulæ, and multitudes of the other fly-ſpecies; and we can eaſily determine, that they have owed their origin only to the eggs of the parent fly there depoſited. Nay a cloſer obſervation will at any time give ocular proof of this; as the flies may be ſeen laying their eggs there, and thoſe eggs may be followed in all their changes to the fly again. Why then are we to doubt but that the air abounds with other flies and animalcules, as minute as the worms in theſe *fluids?* and that theſe laſt are only the fly-worms of the former, which after a proper time ſpent in that ſtate will ſuffer changes like thoſe of the larger kinds, and become flies like thoſe to whoſe eggs they owed their origin? Vid. *Reaumur*, Hiſt. Inſect. vol. 4. p. 431.

The differently medicated liquors made by the infuſions of different plants, afford a proper matter for the worms of different ſpecies of theſe ſmall flies; and there is no reaſon to doubt but that among theſe ſome are viviparous, others oviparous, and to this may be in a great meaſure owing the different time taken up for the production of the inſects in different *fluids*. Thoſe which are a proper matter for the worms of the viviparous fly, may be ſooneſt found full of them, as probably the liquor is no ſooner in a ſtate to afford them a proper nouriſhment, than their parents place them there: whereas thoſe produced from the eggs of the little oviparous flies muſt after the liquor is in a proper ſtate, and they are depoſited in it in form of eggs, have a proper time to be hatched before they can appear alive.

It is eaſy to prove that the animals we find in theſe vegetable infuſions were brought thither from elſewhere. It is not leſs eaſy to prove that they could not be in the matter infuſed, any more than in the *Fluid* it is infuſed in.

Notwithſtanding the fabulous accounts of ſalamanders, it is now well known, that no animal large or ſmall, can bear the force of fire for any conſiderable time; and by parity of reaſon we are not to believe, that any inſect or embryo inſect, in any ſtate can bear the heat of boiling water for many minutes. To proceed to inquiries on this foundation, if ſeveral tubes filled with water with a ſmall quantity of vegetable matter, ſuch as pepper, oak bark, truffles, &c. in which after a time, inſects will be diſcovered by the microſcope; and other like tubes be filled with ſimple water boiled, with water and pepper, boiled together, and with water with the two other ingredients, all ſeparately boiled in it; when all theſe liquors come to a proper time for the obſervation of the microſcope, all, as well thoſe which have been boiled, as thoſe which have not, will be found equally to abound with inſects, and thoſe of the ſame kind in the infuſions of the ſame kind, whether boiled or not boiled.

Thoſe in the infuſions which had ſuſtained a heat capable of deſtroying animal life, muſt therefore not have ſubſiſted either in the water, or in the matters put into it, but muſt have been brought thither, after the boiling, and it ſeems by no way ſo probably, as by means of ſome little winged inhabitants of the air depoſiting their eggs or worms in thoſe *Fluids*.

It is a natural queſtion on this to ask, why it is, that while we ſee myriads of the progeny of theſe winged inſects, in water we never ſee themſelves. The anſwer is equally eaſy, viz. becauſe we can always place a drop of this water immediately before the focus of the microſcope, and keep it there while we at leiſure examine its contents; but that is not the caſe with regard to the air inhabited by the parent flies of theſe our worms, which is of immenſe extent in proportion to the water proper

to nouriſh theſe worms, and conſequently, while the latter are cluſtered together in heaps, the former may be diſperſed and ſcattered. Nor do we want inſtances of this even in the inſects of a larger kind. In many of our gardens we frequently find veſſels of water filled with the gnat worms, as plentifully in proportion to their ſize, as theſe our *Fluids* with animalcules. Every cubic inch of water in theſe veſſels contains many hundreds of theſe animals; yet we ſee many cubic inches of the air in the garden not affording any one of the parent flies. Id. ibid.

But neither are we to declare poſitively that the parent flies of theſe our animalcules are in all ſtates wholly inviſible to us, if not ſingly to be ſeen; there are ſome ſtrong reaſons to imagine, that they may in great cluſters. Every one has ſeen in a clear day, when looking ſtedfaſtly at the ſky, that the air is in many places diſturbed by motions and convolutions in certain determinate ſpots. Theſe cannot be the effect of imagination, or of faults in our eyes, becauſe they appear the ſame to all; and if we conſider, what would be the caſe to an eye, formed ſo as to ſee nothing ſmaller than an ox, on viewing the air on a marſh fully peopled with gnats, we muſt be ſenſible that the clouds of theſe inſects, tho' to us diſtinctly enough viſible, would appear to ſuch an eye, merely as the moving parcels of air in the former inſtance, do to us; and ſurely it is thence no raſh concluſion to infer, that the caſe may be the ſame, and that the myriads of flying inſects too ſmall to be ſingly the objects of our view, yet are to us, what the clouds of gnats would be in the former caſe. See the articles EEL, VINEGAR and PEPPER *water*.

Cauſtic FLUID. See CAUSTIC *Fluid*.

Senſitive FLUID. See SENSITIVE *Fluid*.

FLUKE, in ichthyology, a word uſed in ſome parts of England as a name for the flounder.

FLUKE *of an anchor*, that part of it which faſtens in the ground. See ANCHOR, *Cycl.* and *Suppl.*

FLUKEN, in natural hiſtory, a name given by the miners in Cornwall, and ſome other places, to a ſort of greyiſh ſoft earth, in which there are a great number of ſmall white ſtones of a ſparry nature. They uſually find this mixt ſubſtance near the places where the loads or veins of ore lie, and it ſeems evidently to have been waſhed from among the broken parts of the ſtrata near where the metals lie. It is itſelf a coarſe and often foul earth, and the white ſtones which it contains, are ſometimes ſmall cryſtalline, but opake pebbles, of the nature of thoſe which we find in various ſizes in our ſand and gravel pits; but more uſually they are ſmall fragments of common ſpar, and are of a plated figure when broken, and ſeem only rounded by the motion of the water, like many ſmall ſtones which are found in the beds of rivers, and on the ſea-ſhores. The ſoft nature of the ſubſtance of which theſe are compoſed makes them eaſily liable to be thus rubbed into roundneſs.

FLUOR *albus* (*Cycl.*) — Authors diſtinguiſh this diſeaſe in two kinds, the benign and the malignant; the firſt is ſimple, the other complicated with the venereal diſeaſe. The ſimple *Fluor albus*, tho' called benign in compariſon of the other, is yet very difficult to cure, and is always the more ſo, the longer it has continued upon the perſon; and very often the common methods by medicine fail, unleſs the cauſe and manner of life be changed. But tho' it is thus difficult of cure, it is of leſs danger than many other diſeaſes, for many women have had it many years, nay a great part of their lives even to old age, and that without any great hurt. Indeed it very rarely grows to that height as to injure the ſtrength or health, farther than by a paleneſs of the face, and a tumid look, and a laſſitude of the limbs: but if this diſcharge when it has been many years habitual to a perſon, be ſtopped by any improper methods, it often brings on very terrible complaints. The worſt effect of the *Fluor albus*, is that when of long ſtanding it uſually renders women barren; and its principal difficulty of cure is this, that it will often ſeem to give way to medicines, but return afterwards with all its former violence; nay when people ſeem ever ſo perfectly cured of it, it often returns, and the whole method is to be gone thro' again. The *Fluor albus* while it only attends the flowing of the menſtrual diſcharges, is a thing of no great moment, but when thoſe diſcharges ſtop, and this matter becomes more acrid, and is voided in larger quantities, it then becomes a diſeaſe that calls for all the art of the phyſician to remedy it; for in ſome perſons it brings on finally hectics and waſting of the fleſh, and in others cachexies, œdemas and dropſies.

Method of cure. When this diſeaſe happens to a perſon of a plethoric habit, the firſt ſtep toward a cure is bleeding in the foot to diſcharge part of the load of blood, leſt nature ſhould make that an occaſion of converting a great part of it into ſerum, and throwing it upon the uterus for its diſcharge. After bleeding, an abſterſion of the matter of the diſeaſe, and a ſucceſſive evaucation of it are to be attempted, by the more temperate uterine medicines, the gentle emmenagogues and cleanſers; ſuch are amber, myrrh and turpentine. The ſecond of theſe is to be given, but in moderate doſes, and the laſt ſucceeds beſt after boiling, or when mixt with maſtic. The digeſtive ſalts are alſo to be given, and nitre in this caſe often proves a very beneficial medicine. The aperient roots, ſuch as lovage, pimpernel, and the like, are to be given in decoction, and the leaves of baum and ſouthernwood are no idle remedies; and finally the gums are to be added, ſuch as galbanum, ammoniacum and ſagapenum. After theſe abſtergents and preparatory medicines, gentle purges are to be given, and finally ſuch medicines as reſtore the due tone of the parts; of this nature are the milder chalybeates, and decoctions of the nervous and aromatic herbs, ſuch as roſemary, origanum, ſerpyllum and the like. *Junker's* Conſp. Med. p. 472.

Dr. Morgan thinks the *Fluor albus* is the lymph corrupted, and aſſures us, that the tincture of cantharides, given in a pretty ſtrong decoction of guaicum, has good effects when the diſtemper is recent, but when it is of long ſtanding and inveterate, recourſe muſt be had to mercurials. Vid. *Morg.* Mechan. Pract. Phyſ.

FLUSH-*deck*, one that lies even in a right line, fore and aft, from ſtem to ſtern.

FLUSHER, in zoology, the common name of the leſſer butcher-bird called by authors the lanius minor, and the lanius tertius of Aldrovand. It is of the hawk kind, but very ſmall, not exceeding the common lark in ſize. Its beak is black, long, very ſtrong, and a little hooked at the end, but ſtrait all the way to that. The mouth is yellow within, and the tongue is jagged. It has ſeveral ſhort briſtles at the top of the beak. The middle of its back and the ſmaller feathers of its wings, are of a reddiſh brown; its head and rump grey; it has a broad black line on each ſide of the head, running from the angle of the beak: its belly is white, its throat and breaſt whitiſh with a caſt of red. Its wing feathers are brown and black, and its legs and feet of a deep bluiſh black. It builds in holly buſhes and the like places, its neſt is made of graſs and feathers, and it lays ſix eggs which are oblong, white at the ſmaller end and ornamented with a circle and reddiſh ſpots at the other. It is common in Germany and in the northern parts of England. *Ray's* Ornith. p. 54.

FLUTA, in ichthyology, a name given by Gaza and ſome authors to the common ſparus, diſtinguiſhed by Artedi, by the name of the plain yellowiſh ſparus, with a large annular black ſpot near the tail. See the article SPARUS.

FLUTA is alſo a name given by Columella to the muræna of Ariſtotle and the antient authors in general, as well Greek as Roman. It makes only one ſpecies of the muræna, according to Artedi; but being with him a generical name which comprehends all the eel kind, the ſerpens marinus and the like, among theſe. This which was antiently called ſimply the muræna, is diſtinguiſhed by that author under the name of the muræna having no pectoral fins. This as it is peculiar to this ſpecies, evidently and obviouſly diſtinguiſhes it at firſt ſight from all the reſt.

FLUTINGS—*Cabled* FLUTINGS. See CABLING.

FLUVIALIS, in botany, the name given by Vaillant and Micheli to a genus of plants called by Linnæus najos. *Vaillant*, A. G. 1719. See NAIOS.

FLUVIATILES *cochleæ*, freſh water *ſhell-fiſh*, a term uſed by naturaliſts, to expreſs thoſe kinds of ſhell-fiſh which never inhabit the ſea, but are found in our ponds, rivers and ditches. Theſe tho' greatly leſs numerous than the ſpecies of ſea ſhells, are yet of greater variety and beauty, than is uſually ſuppoſed. What are known at preſent, may be arranged under their proper heads in the following manner.

Of the univalve kinds we have two ſpecies of patellæ: the one having a beak at the ſummit of the ſhell; the other wanting it, and being ſmooth as the common patellæ or limpets of the ſea.

Of the *limaces* or ſnails we have five ſpecies, 1. The white water ſnail. 2. The umbilicated water ſnail. 3. The water ſnail, commonly called St. Hubert's horn. 4. The yellow water ſnail, and 5. The high and faſciated water ſnail.

Of the freſh water *neritæ*, we have three kinds. 1. The variegated grey nerita. 2. The notched nerita, and 3. The variegated reddiſh nerita.

We have alſo one ſpecies of *trochus*, commonly called and known by the name of trochilus aquæ dulcis, or the little freſh water trochus.

Of the *turbo* we have three ſpecies. 1. The depreſſed vittated turbo. 2. The prominent turbo, and 3. The ſimple turbo, or ſcrew-ſhell.

Of the freſh water *buccina*, we have ſeven ſpecies. 1. The greeniſh buccinum, with four ſpires. 2. The reddiſh buccinum. 3. The ſlightly furrowed buccinum. 4. The white buccinum with five ſpires. 5. The brown buccinum, with an operculum. 6. The contabulated and tuberous buccinum, and 7. The freſh water buccinum with its mouth turned the contrary way to that of other ſhells. Hiſt. Nat. Eclairc. p. 367.

Of the dolia or conchæ globoſæ, we have the following ſpecies. 1. The grey dolium. 2. The yellowiſh dolium. 3. The blunt pointed dolium. 4. The milk-white dolium.

Of the freſh water *cornu ammonis*, we have four ſpecies. 1. The brown common cornu ammonis. 2. The metalline cornu ammonis. 3. The grey cornu ammonis, and 4. The agate coloured cornu ammonis.

Of

Of the bivalve freſh water ſhells, we have the following ſpecies. Of the *chama* kind we have five. 1. The white chama. 2. The red ſpotted chama. 3. The blackiſh brown chama. 4. The grey chama, and 5. The common dwarf chama.

Of the *muſcle* kind we have ſix ſpecies. 1. The brown ſpotted muſcle. 2. The blackiſh brown muſcle. 3. The oblong muſcle. 4. The large light muſcle. 5. The long prickly muſcle, and 6. The white muſcle.

Of the *pecten* kind we have only one ſpecies, that is, the white pecten.

Of the multivalve claſs, there is not one known ſpecies.

The reducing the ſeveral ſpecies to their proper genera is eaſy from a remembrance of the characters of each genus of the marine ſhells. The limpet is a flat ſhell elevated into a ſort of cone at the ſummit. Of the ſnail kind, if the mouth be round, the ſhell is a true limax; when it is ſemicircular, the ſhell is a nerita; and when it is oval or depreſſed, and the clavicle is long, it is then a trochus. The turbo or ſcrew-ſhell, is known by its long and ſlender figure. The buccina are long ſhaped, and have a tail, and their mouth is narrow; and the dolia are of a ſomewhat globoſe figure. The cornu ammonis, and the umbilicated ſnail are often confounded together by thoſe who obſerve their external reſemblance among the freſh water ſhells; but they are in reality ſufficiently different, the cornu ammonis being marked on the outſide with circular ridges, and divided on the inſide into ſeveral ſeparate cells like the common foſſil kinds; whereas the umbilicated ſnail is of an even external ſurface, and has only one cavity within. The ſnail alſo has its mouth placed toward one ſide, the cornu ammonis in the middle: there are other differences, but theſe are ſufficient for the diſtinction. The chamæ are known by their roundiſh figure; the muſcles by being oblong; and the pecten is known by its ears and its ſtriæ. Hiſt. Nat. Eclair. p. 372.

FLUX, (*Cycl.*) in medicine. The Biſhop of Cloyne in his reflections on tar-water, ſays he has known a *bloody-Flux* of long continuance, after divers medicines had been tried in vain, cured by tar-water. But what he takes to be the moſt ſpeedy and effectual remedy in a *bloody-Flux*, is a clyſter of an ounce of common brown roſin, diſſolved over a fire in two ounces of oil, and added to a pint of broth, which not long ſince he had frequent occaſion of trying, when that diſtemper was epidemical. Nor can he ſay, that any to whom he adviſed it, miſcarried. See TAR *water*, &c.

FLUXES, in metallurgy, are whatever can cauſe a body otherwiſe not at all, or hardly fuſible by fire, to melt.

The moſt powerful of theſe, are glaſs of lead, and the alkaline and neutral ſalts. Theſe are principally uſed by aſſayers, when they would work minerals in a ſmall quantity; but when large quantities of minerals are to be wrought on, it is ſeldom poſſible to uſe *Fluxes* of this kind to any advantage, becauſe of their prices. In theſe caſes, inſtead of theſe expenſive *Fluxes*, they uſe ſuch ſtones as are vitrified by a gentle fire, or the ſcoriæ made of the ſame ſtones when melted, which always ſerves their purpoſes much better; for the oftner theſe ſtones have been expoſed to the fire, the more eaſily are they put in fuſion: the reaſon of which ſeems to be, that the alkaline ſalt proceeding from the fuel of the fire, adheres to the ſcoriæ; and theſe added in large quantities to the reſt of the metals in great operations, cauſe the ſaid ores to melt, which are otherwiſe made refractory by the calcarious and incombuſtible ſtones and earths mixed with them.

The melting of gold and ſilver, and of their calxes is greatly promoted by glaſs of lead, alkaline ſalts, &c. but when gold and ſilver in the fuſion itſelf, are to be purged from other metals and ſemimetals, it is proper to uſe nitre only; or if not ſo, nitre muſt be always mixed with the other ſalts; for the ſemimetals and the four leſs perfect metals are deſtroyed by nitre.

In this operation, nitre by its detonation with their ſulphurs is in part alkaliſed, and by the help of a gentle fire, turns their calxes into a vitrious and much attenuated ſcoriæ.

From hence, the reaſon is plain, why gold and ſilver, when made brittle, are readily reſtored to their malleability by nitre: for the ſemimetals, and among the metals, lead, and tin, moſt of all communicate this fault to gold and ſilver; but theſe being changed as before obſerved by nitre, are then rejected by gold, and ſilver in a ſimple fuſion, ſo that they can no longer mix with theſe metals, unleſs they are themſelves firſt again reduced to their metallic ſtate; and there is beſide theſe, no other body that can be mixed with ſilver and gold to render them brittle, unleſs crude charcoal happening to fall into the veſſel, wherein thoſe metals are melted, ſhould impregnate them with ſomething arſenical, there being ſome arſenic contained in coals of this kind; as has been demonſtrated by Stahl and Hoffman.

The leſs perfect metals, and the ſemimetals melt more eaſily by adding ſalts to them, than of themſelves; they always however, loſe a great deal of their ſubſtance by this means, and this is more particularly the caſe, in regard to copper and iron. To amend this, it is neceſſary to add ſome kind of fat body, which prevents the deſtruction, and even reduces the metals already deſtroyed; and this is the more neceſſary, when the calxes prepared either by burning, or by a detonation with nitre, are to be reduced.

The moſt proper *Flux* on theſe occaſions is, that uſually known among metallurgiſts, under the name of the *black Flux powder*, and is thus prepared.

Take of common nitre one part, of crude tartar thoroughly dried, two or three parts; make them ſeparately into very fine powder, then grind them well together, and afterwards put them into an earthen pot, narrow at the orifice, not glazed within, and of capacity three times larger than the powder will take up; put this into a gentle fire, and as ſoon as the maſs begins to flame with ſome noiſe, ſhut the orifice of the veſſel with a tile; after the detonation is over, you will find in the veſſel a black oily alkaline ſalt, which is very eaſily fuſible in the fire, and is called the *black flux*; keep it in a dry warm place, and in a veſſel cloſely ſhut, to prevent its growing moiſt.

Tartar being burnt either alone in veſſels cloſely ſhut, or detonated with nitre, is very readily alkalized; and thus retains a conſiderable quantity of the oil which it contains in great abundance, and which is fixed enough to remain with it, after this operation; and for this reaſon it very eaſily becomes a reducing *Flux*, which on account of its alkaline ſalts, diſſolves earths and ſtones, and changes them into an imperfect kind of glaſs by a moderate melting fire; but the oil being of a more fixed nature, ſtill remains concealed therein, and is of great uſe both to preſerve metals from being deſtroyed, and to reduce ſuch as have been deſtroyed already.

If the pot in which this *Flux* powder is made be glaz'd within, and part of the glazing comes off, and mixes with the *Flux*, and melts with it, it is again reduced to lead, and may thus diſappoint the artificer; for this cruſt of glazing is given to earthen veſſels by lead or litharge.

Another caution is alſo neceſſary; which is, that all *Fluxes* muſt be kept and uſed very dry, for moiſt ſalts foam very much; and when the operations are made in cloſe veſſels, if the fire is quickly increaſed, not being able to get rid of the moiſture, the veſſels will ſplit and break.

Beſide the black, aſſayers are alſo very fond of a white *Flux* powder, which is prepared only of equal parts of nitre and tartar detonated in the ſame manner. For in this caſe the oil of the tartar is almoſt entirely conſumed by the abundance of the nitre, and the remaining maſs becomes a whitiſh or aſh coloured ſalt; which is alſo more powerfully alkaline, and ſharp than the foregoing. This *Flux* is very efficacious in the diſſolving of ſtones, and earths; but for want of its oil is of a leſs reductive virtue, and deſtroys the metal, when the fire is continued a little longer than is required.

Flux powders are of great ſervice alſo to reduce metals out of their reſpective calxes, and to free them from the ſtones in which they are embodied; but when the refractory calx of iron is to be reduced by a great and long laſting fire, theſe *Fluxes* being greatly attenuated, tho' confined in cloſe veſſels, part from their oily principle, and their alkaline ſalt remaining, begin to corrode and conſume the veſſels of what matter ſoever they are made, and finally make their way thro' them and get out. The firſt of theſe accidents is prevented by adding coal duſt, which will never part with its oil, without the help of a free air; and the others by an admixture of common glaſs, made of a due mixture of flints and fixed alkali. For this is ſufficiently fuſible, and readily melts with the *fluxes*, and by its viſcidity, in ſome ſort coagulates, and holds the ſalt of the *Flux* together, and prevents it from ſo eaſily corroding the veſſels.

Many artificers affect to compoſe a great variety of *Fluxes* with the different proportions and combinations of the alkaline and neutral ſalts; nay ſome are for having as many *Fluxes*, as there are ores of metals; but theſe ſimples ores will be found on trial more uſeful, as well as more eaſily prepared, than many of the laboured compoſitions, which increaſe the number, not the virtue of the things employed. The ſkilful will eaſily make from theſe the ſlight neceſſary variations. *Cramer*, Art. Aſſ. p. 48, 52.

The great ſecret in making and improving *Fluxes* for the ores of metals, is not only to find ſuch ingredients as will be of efficacy to ſeparate the metal already ripened in the ore, but even to mature and ripen the yet immature part of it in the fire; and ſomething of this kind we apprehend might be effected, as there is great reaſon to believe, that certain *Fluxes* will obtain a much larger yield of metals from certain ores than other *Fluxes* in common uſe, tho' eſteemed of the beſt, and perhaps of the deareſt kind: thus clean iron filings will often do more than borax; but as the ſcales and ruſt of iron have commonly been uſed under the name of iron in *Fluxes*, few operators know the value of pure iron in that intention, and many advantages are now obtained by mixing one ore with another of the ſame denomination, and with the ſlags or recrements of metals in the way of a *Flux*.

The *Fluxes* for the ores of metals ſeem in general reducible to

two kinds, the vitreous and the ſaline. The vitreous are thoſe which either naturally have a gloſſy form, or readily aſſume one in the fire; the principal of theſe are glaſs of lead, glaſs of antimony and borax.

By the ſaline *fluxes*, authors generally mean thoſe which are compoſed of ſalts, whether tartar, nitre, fixed alkali or the like, as the black *flux*, ſandiver, pot aſhes, and the like. The vitreous *fluxes* ſeem deſtined more immediately to act upon the ſtony or vitreſcible matter, wherewith the ſtubborn ores are frequently mixed, and the ſaline kind to act more immediately upon the matter of the ore itſelf, for the due excluſion or ſeparation of the metal.

The more kindly ores require no *Fluxes* at all, and often they contain in themſelves, the neceſſary matter for that *flux*; thus there are copper ores, which being only ground to powder, and put into a common wind furnace, will yield as much pure metal at the firſt operation, as can be procured from them, by all the *fluxes*. *Shaw*'s Lectures, p. 256.

FLUXION (*Cycl.*)—The elements of the doctrine of *fluxions*, have been delivered by its great author, in ſo conciſe a manner, as to give occaſion to one of the moſt ingenious writers of this age, to repreſent it, as founded on inconceivable principles, and full of falſe reaſonings. This author in a letter, under the title of *the Analyſt*, publiſhed in the year 1734, has been at great pains to convince his readers, that the object, principles, and inferences of the modern analyſis by *fluxions*, are not more diſtinctly conceived, or more evidently deduced, than religious myſteries and points of faith. He ſays he does not controvert the truth of the concluſions, but only the logic and method of mathematicians. He asks how they demonſtrate, what objects they are converſant with, and whether they conceive them clearly; what principles they proceed upon, how ſound they may be, and how they apply them; declaring himſelf not concerned about the truth of the theorems, but only about the way of coming at them, whether it be legitimate or illegitimate, clear or obſcure, ſcientific or tentative. He conſiders the concluſions not in themſelves, but in their premiſes; not as true or falſe, uſeful or inſignificant, but as derived from ſuch principles, and by ſuch inferences. And for as much as it may ſeem an unaccountable paradox, that mathematicians ſhould deduce true propoſitions from falſe principles, be right in the concluſion, and yet err in the premiſes, he endeavours particularly to explain, how this may come to paſs, and ſhew how error may bring forth truth, tho' it cannot bring forth ſcience. His ſolution of the paradox is, that in the application of the method of infiniteſimals and *Fluxions*, two errors are committed which being equal and contrary, deſtroy each other. We cannot enter into a detail of all he ſays on theſe and many other heads, nor of all that has been ſaid on the other ſide, in defence of the method of *Fluxions*, and of its inventor Sir Iſaac Newton. An Anſwer to the Analyſt, appeared very early under the name of *Philalethes Cantabrigienſis*, ſuppoſed to be Dr. Jurin; a ſecond by the ſame hand, in defence of the firſt; a diſcourſe of *Fluxions* by Mr. Robins; a treatiſe of Sir Iſaac Newton's, with a commentary by Mr. Colſon; and ſeveral other pieces were publiſhed on this ſubject; particularly a very full and excellent treatiſe of *Fluxions*, by Mr. Maclaurin, late profeſſor of mathematics in the univerſity of Edinburgh, containing not only a moſt diſtinct account of the principles of *Fluxions*, but alſo of the chief diſcoveries in geometry, and mathematical philoſophy of this age. The curious may find an elegant account of this treatiſe in the Philoſophical Tranſactions, N°. 468, 469.

We preſume that Mr. Maclaurin's demonſtrations are ſufficient to ſatisfy the moſt ſcrupulous; it would exceed the bounds of our deſign to inſert them at length here; but we cannot omit mentioning what ſeems neceſſary to explain and illuſtrate the notion of *Fluxions*; and the principles on which this method of computation is founded.

In the doctrine of *Fluxions*, magnitudes are conceived to be generated by motion, and the velocity of the generating motion is the *Fluxion* of the magnitude. Lines are ſuppoſed to be generated by the motion of points. The velocity of the point that deſcribes the line, is its *Fluxion*, and meaſures the rate of its increaſe or decreaſe. When the motion of a point is uniform, its velocity is conſtant, and is meaſured by the ſpace deſcribed by it in a given time. When the motion varies, the velocity at any term of the time is meaſured by the ſpace which would be deſcribed in a given time, if the motion was to be continued uniformly, from that term, without any variation. And this is analogous to the general doctrine of powers, or may be conſidered as a particular application of it. As a power which acts continually and uniformly is meaſured by the effect that is produced by it in a given time, ſo the velocity of an uniform motion, is meaſured by the ſpace that is deſcribed in a given time. If the action of the power vary, then its exertion at any term of the time is not meaſured by the effect that is produced after that term in a given time, but by the effect that would have been produced if its action had continued uniform from that term; and in the ſame manner, the velocity of a variable motion at any given term of time, is not to be meaſured by the ſpace that is actually deſcribed after that term in a given time, but by the ſpace that would have been deſcribed, if the motion had continued uniformly from that term. If the action of a variable power, or the velocity of a variable motion, may not be meaſured in this manner, they muſt not be ſuſceptible of any menſuration at all. When it is ſuppoſed that a body has ſome velocity or other at any term of the time, during which it moves; it is not therefore ſuppoſed, that there can be any motion in a term, limit or moment of time, or in an indiviſible point of ſpace; and as velocity is always meaſured by the ſpace that would be deſcribed by it, continued uniformly for ſome given finite time, it cannot ſurely be ſaid, that geometers pretend to conceive motion or velocity without regard to ſpace or time, as the author of the Analyſt often ſuggeſts. This is a ſhort view of the nature and tendency of the doctrine of *Fluxions*, which we ſhall now proceed to explain more particularly.

We have already ſaid that lines may be conceived as generated by the motion of points; in like manner ſurfaces may be conceived as generated by the motion of lines; ſolids by the motion of ſurfaces; angles, by the rotation of their ſides; the *flux* of time being ſuppoſed to be always uniform. The velocity with which a line flows, is the ſame as that of the point which is ſuppoſed to deſcribe or generate it. The velocity with which a ſurface flows, is the ſame as the velocity of a given right line; that, by moving parallel to itſelf, is ſuppoſed to generate a rectangle which is always equal to the ſurface. The velocity with which a ſolid flows, is the ſame as the velocity of a given plain ſurface, that, by moving parallel to itſelf, is ſuppoſed to generate an erect priſm or cylinder that is always equal to the ſolid. The velocity with which an angle flows, is meaſured by the velocity of a point, that is ſuppoſed to deſcribe the arch of a given circle, which always ſubtends the angle, and meaſures it. In general, all quantities of the ſame kind (when we conſider their magnitude only, and abſtract from their poſition, figure, and other affections) may be repreſented by right lines, that are ſuppoſed to be always in the ſame proportion to each other as theſe quantities. They are repreſented by right lines in this manner in Euclid's Elements, in the general doctrine of proportion, and by right lines and figures in the data of that accurate geometer. In this method likewiſe, quantities of the ſame kind may be repreſented by right lines, and the velocities of the motions by which they are ſuppoſed to be generated, by the velocities of points moving in right lines. All the velocities we have mentioned are meaſured, at any term of the time of the motion, by the ſpaces which would be deſcribed in a given time, by theſe points, lines or ſurfaces, with their motions continued uniformly from that term.

A *Fluxion* being the velocity with which a quantity flows, at any term of the time while it is ſuppoſed to be generated, is therefore always meaſured by the increment or decrement that would be generated in a given time by this motion, if it was continued uniformly from that term without any acceleration or retardation: or it may be meaſured by the quantity that is generated in a given time by an uniform motion, which is equal to the generating motion at that term.

Time is repreſented by a right line that flows uniformly, or is deſcribed by an uniform motion; and a moment or termination of time repreſented by a point or termination of that line. A given velocity is repreſented by a given line, the ſame which would be deſcribed by it in a given time. A velocity that is accelerated or retarded, is repreſented by a line that increaſes or decreaſes in the ſame proportion. The time of any motion being repreſented by the baſe of a figure, and any part of the time by the correſponding part of the baſe; if the ordinate at any point of the baſe be equal to the ſpace that would be deſcribed, in a given time, by the velocity at the correſponding term of the time continued uniformly, then any velocity will be repreſented by the correſponding ordinate. The *Fluxions* of quantities are repreſented by the increments or decrements, deſcribed in the foregoing paragraph, which meaſure them; and inſtead of the proportion of the *Fluxions* themſelves, we may always ſubſtitute the proportion of their meaſures.

When a motion is uniform, the ſpaces that are deſcribed by it in any equal times are always equal. When a motion is perpetually accelerated, the ſpaces aſcribed by it in any equal times that ſucceed after one another, perpetually increaſe. When a motion is perpetually retarded, the ſpaces that are deſcribed by it in any equal times that ſucceed after one another, perpetually decreaſe.

It is manifeſt, converſely, that if the ſpaces deſcribed in any equal times are always equal, then the motion is uniform. If the ſpaces deſcribed in any equal times that ſucceed after one another perpetually increaſe, the motion is perpetually accelerated: For it is plain, that if the motion was uniform for any time, the ſpaces deſcribed in any equal parts of this time would be equal; and if it was retarded for any time, the ſpaces deſcribed in equal parts of this time that ſucceed after one another would decreaſe: both of which are againſt the ſuppoſition. In like manner it is evident, that a motion is perpetually retarded, when the ſpaces that are deſcribed in any equal times that ſucceed after one another perpetually decreaſe. The

following

following axioms are as evident, as that a greater or leſs ſpace is deſcribed in a given time, according as the velocity of the motion is greater or leſs.

Axiom 1. The ſpace deſcribed by an accelerated motion is greater than the ſpace which would have been deſcribed in the ſame time, if the motion had not been accelerated, but had continued uniform from the beginning of the time.

Axiom 2. The ſpace deſcribed by a motion while it is accelerated, is leſs than the ſpace which is deſcribed in an equal time by the motion that is acquired by that acceleration continued uniformly.

Axiom 3. The ſpace deſcribed by a retarded motion is leſs than the ſpace which would have been deſcribed in the ſame time, if the motion had not been retarded, but had continued uniform from the beginning of the time.

Axiom 4. The ſpace deſcribed by a motion while it is retarded, is greater than the ſpace which is deſcribed in an equal time by the motion that remains after that retardation, continued uniformly.

From theſe axioms general theorems concerning motion, of uſe in the doctrine of *Fluxions*, may be demonſtrated. Thus when the ſpaces deſcribed by two variable motions are always equal, or in a given ratio, the velocities are always equal, or in the ſame given ratio; and converſely, when the velocities of two motions are always equal to each other, or in a given ratio, the ſpaces deſcribed by thoſe motions in the ſame time are always equal, or in that given ratio: that when a ſpace is always equal to the ſum or difference of the ſpaces deſcribed by two other motions, the velocity of the firſt motion is always equal to the ſum or difference of the velocities of the other motions; and converſely, that when a velocity is always equal to the ſum or difference of two other velocities, the ſpace deſcribed by the firſt motion is always equal to the ſum or difference of the ſpaces deſcribed by theſe two other motions. See Mr. *Maclaurin*'s Treatiſe of Fluxions, Book I. chap. 1.

The main point in the method of *Fluxions*, is to obtain the *Fluxion* of the rectangle, or product of two indeterminate quantities, ſince from thence may be derived rules of all other products and powers be the coefficients, or the indices what they will, integers or fractions, rational or ſurd; according to the manner of Sir Iſaac Newton in the ſecond lemma of his ſecond book of principles.

Mr. Maclaurin has therefore been very full in eſtabliſhing this point; and after what he has ſaid, we preſume that no reaſonable objection can lie either againſt the clearneſs and diſtinctneſs of the notion of *Fluxions*, or againſt the truth of the principles, or accuracy of the demonſtrations by which their meaſures are determined. We cannot here inſert his demonſtrations at length; but as many readers may, perhaps, be deſirous of ſeeing the argument contracted into a narrow compaſs, we ſhall here give a ſummary of it, from the Philoſ. Tranſ. N°. 468. p. 331.

A triangle that has two of its ſides given in poſition, is ſuppoſed to be generated by an ordinate moving parallel to itſelf along the baſe. When the baſe increaſes uniformly, the triangle increaſes with an accelerated motion, becauſe its ſucceſſive increments are *trapezia*, that continually increaſe; therefore if the motion with which the triangle flows, was continued uniformly from any term for a given time, a leſs ſpace would be deſcribed by it, than the increment of the triangle, which is actually generated in that time by axiom 1; but a greater ſpace than the increment which was actually generated in an equal time preceeding that term, by axiom 2. And hence it is demonſtrated, that the *Fluxion* of the triangle is accurately meaſured by the rectangle contained by the correſponding ordinate of the triangle, and the right line which meaſures the *Fluxion* of the baſe. The increment which the triangle acquires in any time, is reſolved into two parts; that which is generated in conſequence of the motion with which the triangle flows at the beginning of the time, and that which is generated in conſequence of the acceleration of this motion for the ſame time. The latter is juſtly neglected in meaſuring that motion (or the *Fluxion* of the triangle at that term) but may ſerve for meaſuring its acceleration, or the ſecond *Fluxion* of the triangle. The motion with which the triangle flows, is ſimilar to that of a body deſcending in free ſpaces by an uniform gravity, the velocity of which, at any term of the time, is not to be meaſured by the ſpace deſcribed by the body in a given time, either before or after that term, becauſe the motion continually increaſes, but by a mean between theſe ſpaces.

When the ſides of a rectangle increaſe or decreaſe with uniform motions, it may be always conſidered as the ſum or difference of a triangle, and trapezium; and its *Fluxion* is derived from the laſt propoſition. If the ſides increaſe with uniform motions, the rectangle increaſes with an accelerated motion; and in meaſuring this motion at any term of the time, a part of the increment of the rectangle that may be determined [a], is rejected, as generated in conſequence of the acceleration of that motion. [[a] See *Maclaur.* l. c. art. 102.]

Thoſe who have well underſtood what precedes, will not be at a loſs to conceive, that the *Fluxions* of a curvilineal area, whether generated by an ordinate moving parallel to itſelf, or by a radius revolving round a given center, may be determined by demonſtrations of the ſame kind. When the ordinates of the figure increaſe, the increment of the area may be reſolved in like manner into two parts, one of which only is to be retained in meaſuring the *Fluxion* of the area, the other being rejected as generated in conſequence of the acceleration of the motion with which the figure flows.

What has been hitherto ſaid will ſet the difference between the notions of *Fluxions* and that of infiniteſimals, in a clear light. *Fluxions* may always be repreſented by finite quantities. The ſuppoſition of an infinitely little magnitude is too bold a poſtulatum for ſuch a ſcience as geometry. Nor have authors accounted explicitely for the truth and perfect accuracy of the concluſions derived from this conſideration. When they determine what is called the *difference*, but more accurately the *Fluxion* of a quantity, they tell us, they reject certain parts of the element, becauſe they become infinitely leſs than the other parts. But this is no proper reaſon, not only becauſe a proof of this nature may leave ſome doubt as to the accuracy of the concluſion; but becauſe it may be demonſtrated that theſe parts ought to be neglected by them at any rate, or that it would be an error to retain them. If an accountant, that pretends to a ſcrupulous exactneſs, ſhould tell us, he had neglected certain articles, becauſe he found them to be of ſmall importance; and it ſhould appear that they ought not to have been taken into conſideration by him on that occaſion, but belong to a different account, we ſhould approve his concluſions as accurate, but not his reaſons. See *Maclaurin*'s Treatiſe of *Fluxions* in the Preface, and book I. ch. 12. where the method of infiniteſimals is expreſsly treated of. See alſo the article INFINITESIMAL.

Mr. Maclaurin in the firſt part of his treatiſe conſiders *Fluxions* in a merely geometrical form, and has demonſtrated the rules of the method with all poſſible accuracy and rigour; but as the great improvements made by this doctrine are chiefly to be aſcribed to the facility, conciſeneſs, and great extent of the methods of computation, or the algebraic part, it is neceſſary to add ſome account of theſe methods alſo.

Any quantities produced from each other by an algebraic operation, or whoſe relation is expreſſed by any algebraic form, being ſuppoſed to increaſe or decreaſe together, ſome will be found to increaſe or decreaſe by greater differences, or at a greater rate, others by leſs differences or at a leſs rate; and while ſome are ſuppoſed to increaſe or decreaſe at one conſtant rate by equal ſucceſſive differences, others increaſe or decreaſe by differences that are always varying. Theſe rates of increaſe or decreaſe may be determined by comparing the velocities of points that always deſcribe lines proportional to the quantities as before mentioned, but they may alſo be determined without having recourſe to ſuch ſuppoſitions, by a juſt reaſoning from the ſimultaneous increments or decrements themſelves.

When a quantity A increaſes by differences equal to a, 2A increaſes by differences equal to $2a$, and manifeſtly increaſes or decreaſes at a greater rate than A in the proportion of $2a$ to a or 2 to 1; and if m and n be invariable $\frac{m\,A}{n}$ increaſes or decreaſes by differences equal to $\frac{m\,a}{n}$, and therefore at a greater or leſs rate than A in proportion as $\frac{m\,a}{n}$ is greater or leſs than a, or m is greater or leſs than n. This ſeems to be eaſily conceived, without having recourſe to any other conſiderations, than the relation of the differences by which the quantities increaſe or decreaſe. In order therefore to avoid figurative expreſſions in the algebraic part, it will be proper to ſubſtitute in the place of the definition and axioms before mentioned, others that are rather of a more general import, but are perfectly conſiſtent with them. Thus,

Fluxions *of quantities are any meaſures of their reſpective rates of increaſe, or decreaſe, while they vary or flow together.*

There can be no difficulty in determining thoſe meaſures when the quantities increaſe or decreaſe by ſucceſſive differences that are always in the ſame invariable proportion to each other, while A by increaſing becomes equal to $A + a$, or by decreaſing equal to $A - a$, 2 A becomes equal to $2A + 2a$, or to $2A - 2a$; and as 2 A increaſes or decreaſes at a greater rate than A in the proportion of $2a$ to a; ſo the *Fluxion* of A being ſuppoſed equal to a, the *Fluxion* of 2A muſt be equal to $2a$. In the ſame manner the *Fluxion* of $\frac{m}{n} \times A$ (or of $\frac{m}{n} \times A \mp e$ ſuppoſing m, n and e to be invariable) is $\frac{m}{n} \times a$; and ſince m may be to n in any aſſignable ratio, a quantity may be always aſſigned that ſhall increaſe or decreaſe, at a greater or leſs rate than A in any proportion, or that ſhall have its *Fluxion* greater or leſs than the *Fluxion* of A in any ratio. In ſuch caſes the ratio of the *Fluxions* and that of the differences by which the quantities increaſe or decreaſe are the ſame.

But while A is ſuppoſed to increaſe at a conſtant rate by any equal ſucceſſive differences, if B increaſe or decreaſe by diffe-

rences that are always varying, B cannot be said to increase or decrease at any one constant rate; and it is not so obvious how the *Fluxion* of A being supposed equal to its increment a, the variable *Fluxion* of B is to be determined. It cannot be supposed that the *Fluxions* and differences are always in the same proportion in this case; but it is evident, that if B increase by differences that are always greater than the equal successive differences by which $\frac{m}{n} \times A$ increases, it cannot increase at a less rate than $\frac{m}{n} \times A$; and it cannot increase at a greater rate than $\frac{m}{n} \times A$, while its successive differences are always less than those of $\frac{m}{n} \times A$. The *Fluxion* of A, being still represented by a, the *Fluxion* of B therefore cannot be less than $\frac{m}{n} \times a$ in the former case, or greater then $\frac{m}{n} \times a$ in the latter.

The following propositions are consequences of this, and will enable us to determine at what rate B increases, when its relation to A is known.

The successive values of the root A being represented by $A - a$, A, $A + a$ &c. which increase by any constant difference a, let the corresponding values of any quantity produced from A, by any algebraic operation (or that has a dependance upon it so as to vary with it) be $B - b$, B, $B + b$, &c. Then if the successive differences b, b &c. of the latter quantity always increase, how small soever a may be, then B cannot be said to increase at so great a rate as a quantity that increases uniformly by equal successive differences greater than b, or at so small a rate as any quantity that increases uniformly by equal successive differences less than b. In like manner, if the relation of the quantities is such, that the successive differences b, b &c. continually decrease; then B cannot be said to increase at the same rate as a quantity that increases uniformly by equal successive differences greater than b, or less than b.

Therefore the *Fluxion* of A being supposed equal to the increment a, the *Fluxion* of B cannot be greater than b or less than b, when the successive differences b, b &c. continully increase; and cannot be greater than b or less than b, when these successive differences always decrease.

In the same manner, if the latter quantity decrease while the former increases, and its successive values be $B + b$, B, $B - b$, &c. then if the decrements b, b &c. continually increase, B cannot be said to decrease at so great a rate as a quantity that decreases uniformly by equal successive differences greater than b, or at so small a rate as a quantity that decreases uniformly by equal successive differences less than b. Therefore in this case the *Fluxion* of A being supposed equal to a, the *Fluxion* of B cannot be greater than b or less than b. And in the same manner if the successive decrements b, b &c. always decrease, the *Fluxion* of B, cannot be greater than b, or less than b. Vid. *Maclaurin*'s Flux. B. 2. c. 1. T. 2. p. 579, seq.

As the *Fluxions* of quantities are any measures of the respective rates, according to which they increase or decrease; so it is of no importance how great or small those measures are, if they be in the just proportion or relation to each other. Therefore if the *Fluxions* of A and B may be supposed equal to a and b respectively, they may be likewise supposed equal to $\frac{1}{2} a$ and $\frac{1}{2} b$, or to $\frac{m a}{n}$ and $\frac{m b}{n}$.

The Fluxion of the root A being supposed equal to a, the Fluxion of the square A A will be equal to $2 A \times a$.

To demonstrate this, let the successive values of the root be $A - u$, A, $A + u$, and the corresponding values of the square will be $A A - 2 A u + u u$, A A, $A A + 2 A u + u u$, which increase by the differences $2 A u - u u$, $2 A u + u u$, &c. and because those differences increase, it follows from what has been said, that if the *Fluxion* of A be represented by u, the *Fluxion* of A A cannot be represented by a quantity that is greater than $2 A u + u u$, or less than $2 A u - u u$. This being premised, suppose, as in the proposition, that the *Fluxion* of A is equal to a; and if the *Fluxion* of A A be not equal to $2 A a$, let it first be greater than $2 A a$ in any ratio, as that of $2 A + o$ to 2 A, and consequently equal to $2 A a + o a$. Suppose now that u is any increment of A less than o; and because a is to u as $2 A a + o a$ is to $2 A u + o u$, it follows, that if the *Fluxion* of A should be represented by u, the *Fluxion* of A A would be represented by $2 A u + o u$, which is greater than $2 A u + u u$. But it has been shewn, that if the *Fluxion* of A be represented by u, the *Fluxion* of A A cannot be represented by a quantity greater than $2 A u + u u$. And these being contradictory, it follows that the *Fluxion* of A being equal to a, the *Fluxion* of A A cannot be greater than $2 A a$. If the *Fluxion* of A A can be less than $2 A a$, when the *Fluxion* of A is supposed equal to a, let it be less in any ratio of $2 A - o$ to 2 A, and therefore equal to $2 A a - o a$. Then because a is to u as $2 A a - o a$ is to $2 A u - o u$, which is less than $2 A u - u u$, (u being supposed less than o, as before) it follows, that if the *Fluxion* of A was represented by u, the *Fluxion* of A A would be represented by a quantity less than $2 A u - u u$, against what has been shewn. Therefore the *Fluxion* of A being supposed equal to a, the *Fluxion* of A A must be equal to $2 A a$.

The *Fluxions* of A and B being supposed equal to a and b, respectively, the *Fluxion* of $A + B$ will be $a + b$, the *Fluxion* of $\overline{A + B}^2$, or of $A A + 2 A B + B B$, will be $2 \times \overline{A + B} \times \overline{a + b}$, or $2 A a + 2 B b + 2 B a + 2 A b$, by the last article. The *Fluxion* of $A A + B B$ is $2 A a + 2 B b$, by the same; consequently the *Fluxion* of $2 A B$ is $2 B a + 2 A b$; and the *Fluxion* of $A B$ is $B a + A b$. Hence if P be equal to A B, and the *Fluxion* of P be p, then p will be equal to $B a + A b$, and dividing by P, or A B, we find $\frac{p}{P} = \frac{a}{A} + \frac{b}{B}$. If $Q = \frac{A}{B}$, and q be the *Fluxion* of Q, then $Q B = A$, $\frac{q}{Q} + \frac{b}{B} = \frac{a}{A}$, or $\frac{q}{Q} = \frac{a}{A} - \frac{b}{B}$, and consequently $q = \frac{Q a}{A} - \frac{Q b}{B} = \frac{a}{B} - \frac{A b}{B B}$ or $\frac{a B - A b}{B B}$.

When any of the quantities decrease, its *Fluxion* is to be considered as a negative.

The rule for finding the *Fluxion* of a power is usually deduced from the binomial theorem of Sir Isaac Newton. But as this theorem, though easily found by induction, is not so easy to demonstrate; it is proper to proceed upon a principle, the truth of which may be shewn from the first algebraic elements, with more facility and perspicuity.

This principle is, that if n be any integer number, and the sum of the terms E^{n-1}, $E^{n-2} F$, $E^{n-3} F^2$, $E^{n-4} F^3$, &c. continued till their number be equal to n, be multiplied by $E - F$, the product will be $E^n - F^n$. For the terms being formed by subducting continually unity from the index of E, and adding it to the index of F, the last term will be F^{n-1}. The product of the sum of the terms multiplied by E will be $E^n + E^{n-1} F + E^{n-2} F^2 \ldots\ldots + E F^{n-1}$; their sum multiplied by $-F$ gives $-E^{n-1} F - E^{n-2} F^2 \ldots\ldots - E F^{n-1} - F^n$; and the sum of these two products is $E^n - F^n$. Supposing E to be greater than F, $E^n - F^n$ will be less than $n E^{n-1} \times \overline{E - F}$, but greater than $n F^{n-1} \times \overline{E - F}$. For each of the terms E^{n-1}, $E^{n-2} F$, $E^{n-3} F^2$, &c. is greater than the subsequent term in the same ratio that E is greater than F, and E^{n-1} is the greatest term; consequently the number of terms being equal to n, $n E^{n-1}$ is greater than their sum; and $n E^{n-1} \times \overline{E - F}$ is greater than their sum multiplied by $\overline{E - F}$, or (by the last paragraph) greater than $E^n - F^n$. Because the last term F^{n-1} is less than any preceding term, $n F^{n-1} \times \overline{E - F}$ is less than the sum of the terms multiplied by $\overline{E - F}$, or less than $E^n - F^n$.

When n is any integer positive number, the root A being supposed to increase by any equal successive differences, the successive differences of the power A^n will continually increase. For let $A - a$, A, $A + a$ be any successive values of the root, and $\overline{A - a}^n$, A^n, $\overline{A + a}^n$ will be the corresponding values of the power. But $\overline{A + a}^n - A^n$ is greater than $n A^{n-1} a$; as appears by substituting in the last paragraph $A + a$ for E, A for F, and a for $E - F$. In like manner $n A^{n-1} a$ is greater than $A^n - \overline{A - a}^n$. Therefore $\overline{A + a}^n - A^n$ is greater than $A^n - \overline{A - a}^n$, and the successive differences of the power continually increase.

The Fluxion of the root A being supposed equal to a, the Fluxion of the power A^n *will be* $n a A^{n-1}$.

For if the *Fluxion* of A^n can be greater than $n a A^{n-1}$, let the excess be equal to any quantity r; suppose o equal to the excess of $\sqrt[n-1]{A^{n-1} + \frac{r}{n a}}$ above A, and consequently $\overline{A + o}^{n-1} = A^{n-1} + \frac{r}{n a}$. Then $n a \times \overline{A + o}^{n-1}$ will be equal to $n a A^{n-1} + r$, the *Fluxion* of A^n. Let u be any increment of A less than o; and because a is to u as $n a \times \overline{A + o}^{n-1}$ to $n u \times \overline{A + o}^{n-1}$, it follows (from what has been said) that if the *Fluxion* of A be now represented by the increment u, the *Fluxion* of A^n will be represented by $n u \times \overline{A + o}^{n-1}$, which is greater than $n u \times \overline{A + u}^{n-1}$, and this last is itself greater than $\overline{A + u}^n - A^n$. But when the successive values of the root are $A - u$, A, $A + u$, those of the power are $\overline{A - u}^n$, A^n, $\overline{A + u}^n$, the successive differences of which continually increase; consequently if the *Fluxion* of A be represented by u, the *Fluxion* of A^n cannot be represented by a quantity greater than $\overline{A + u}^n - A^n$, or less than $A^n - \overline{A - u}^n$. And these being contradictory, it follows that when the *Fluxion* of A is supposed equal to a, the *Fluxion* of A^n cannot be greater than $n a A^{n-1}$. If it can be less than $n a A^{n-1}$, let it be equal to $n a A^n - r$, or (by supposing $o = A - \sqrt[n-1]{A^{n-1} - \frac{r}{n a}}$) to $n a \times \overline{A - o}^{n-1}$. Then u being supposed less than o, if the

the *Fluxion* of A was repreſented by u, the *Fluxion* of A^n would be repreſented by $n u \times \overline{A - o}^{n-1}$, which is leſs than $n u \times \overline{A - u}^{n-1}$ (becauſe we ſuppoſe u to be leſs than o) and therefore leſs than $A^n - \overline{A - u}^n$. But this is repugnant to what has been demonſtrated. Therefore the *Fluxion* of A being ſuppoſed equal to a, the *Fluxion* of A^n muſt be equal to $n a A^{n-1}$.

The Fluxion *of A being ſuppoſed equal to a, the* Fluxion *of* $\dot{A}^{\frac{m}{n}}$ *will be* $\frac{m}{n} \times \dot{A}^{\frac{m}{n}-1}$.

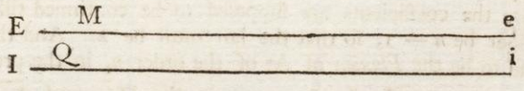
Firſt, let the exponent $\frac{m}{n}$ be any poſitive fraction whatſoever, ſuppoſe $A^{\frac{m}{n}} = K$; conſequently $A^m = K^n$; and the *Fluxion* of K being ſuppoſed equal to k, $m a A^{m-1} = n k K^{n-1}$, and k or the *Fluxion* of $A^{\frac{m}{n}}$ will be equal to $\frac{m a A^{m-1}}{n K^{n-1}} = \frac{m a K}{n A} = \frac{m}{n} \times a A^{\frac{m}{n}-1}$. When $\frac{m}{n}$ is negative, let it be equal to $-r$; and ſuppoſe $A^{-r} = K$, or $1 = A^r K$, then taking the *fluxions*, $r A^{r-1} a K + k A^r = o$, and $k = \frac{r A^{r-1} a K}{A^r} = -r A^{-r-1} a = \frac{m}{n} \times a A^{\frac{m}{n}-1}$.

Suppoſing P to be the product of any factors A, B, C, D, E, &c. *and the* Fluxions *of P, A, B, C,* &c. *reſpectively equal to p, a, b, c,* &c. *then will* $\frac{p}{P} = \frac{a}{A} + \frac{b}{B} + \frac{c}{C} + \frac{d}{D}$, &c.

Let Q be equal to the product of all the Factors of P, the firſt A excepted, that is, ſuppoſe $P = A Q$. Suppoſe R equal to the product of all the factors, the firſt two, A and B, excepted; that is, let $P = A B R$, or $Q = B R$. In the ſame manner let $R = C S$, $S = D T$, and ſo on. Then the *fluxions* of Q, R, S, T, *&c.* being ſuppoſed reſpectively equal to q, r, s, t, *&c.* it follows that $\frac{p}{P} = \frac{a}{A} + \frac{q}{Q} =$ (becauſe $\frac{q}{Q} = \frac{b}{B} + \frac{r}{R}$) $\frac{a}{A} + \frac{b}{B} + \frac{r}{R} =$ (becauſe $\frac{r}{R} = \frac{c}{C} + \frac{s}{S}$) $\frac{a}{A} + \frac{b}{B} + \frac{c}{C} + \frac{s}{S} =$ (becauſe $\frac{s}{S} = \frac{d}{D} + \frac{t}{T}$) $\frac{a}{A} + \frac{b}{B} + \frac{c}{C} + \frac{d}{D} + \frac{t}{T}$, and ſo on. Therefore $\frac{p}{P}$ is equal to the ſum of the quotients, when the *fluxion* of each factor is divided by the factor itſelf.

If the factors be ſuppoſed equal to each other, and their number be equal to n, then $P = A^n$, and by the laſt propoſition $\frac{p}{P} = \frac{n a}{A}$; conſequently $p = \frac{n P a}{A} = n a A^{n-1}$ as was before demonſtrated.

If $P = \frac{A B C,}{K L M,}$ &c. *and the* Fluxions *of the reſpective quantities be expreſſed by the ſmall letters p, a, b, c,* &c. *as before, then* $\frac{p}{P} = \frac{a}{A} + \frac{b}{B} + \frac{c}{C} - \frac{k}{K} - \frac{l}{L} - \frac{m}{M}$, &c.



For P K L M, &c. $= A B C,$ *&c.* and $\frac{p}{P} + \frac{k}{K} + \frac{l}{L} + \frac{m}{M}$, *&c.* $= \frac{a}{A} + \frac{b}{B} + \frac{c}{C}$, *&c.* whence by tranſpoſition $\frac{p}{P} = \frac{a}{A} + \frac{b}{B} + \frac{c}{C} - \frac{k}{K} - \frac{l}{L}$, *&c. Maclaurin,* ibid.

The notation we have hitherto uſed is the ſame as Sir Iſaac Newton's in the 2d lemma of the 2d book of his principles. But it is generally more convenient to diſtinguiſh *Fluxions* from other algebraic expreſſions, and in ſuch manner, that the ſecond and higher *Fluxions* may be repreſented ſo as to preſerve the original fluent in view. Hence Sir Iſaac in his laſt method, repreſented variable or flowing quantities by the final letters of the alphabet as x, y, z, their firſt, ſecond, &c. *Fluxions*, reſpectively by $\dot{x}$, $\dot{y}$, $\dot{z}$, and $\ddot{x}$, $\ddot{y}$, $\ddot{z}$, &c. as is mentioned in the Cyclopædia, under the head FLUXION, where the rules of the algorithm are alſo delivered; but as this doctrine has been conteſted and repreſented by the author of the analyſt, as inconceivable and ſophiſtical, we thought it proper more fully to explain and demonſtrate the principles thereof, from Mr. Maclaurin's excellent treatiſe on this ſubject.

It is to be obſerved, that the *Fluxions* of powers are commonly delivered in an algebraic form; but this is not neceſſary. The ſame may be done geometrically by ſuppoſing a ſeries of lines in geometric progreſſion, the firſt term of which is invariable. Then if the ſecond term be ſuppoſed to increaſe uniformly all the ſubſequent terms will increaſe with an accelerated motion. The velocities of the points that deſcribe thoſe lines being compared, it may be demonſtrated from common geometry, that the *Fluxions* of any two terms, are in a ratio compounded of the ratio of thoſe terms, and of the ratio of the numbers that expreſs how many terms precede them reſpectively, in the progreſſion. Thus if A, B, C, D, E, &c. repreſent any lines in geometric progreſſion, the firſt term (A) of which is invariable, then will the *Fluxion*, for inſtance, of E be to the *Fluxion* of D as 4 E is to 3 D, and the *Fluxion* of E will be to the *Fluxion* of B, as 4 E to B. The analogy between powers in algebra and lines in geometric progreſſion, is ſufficiently known. Thus A being invariable may be called unity or 1; let $B = x$, then will $C = x x$, $D = x^3$, $E = x^4$, &c. and conſequently, the *Fluxion* of E or x^4, will be to the *Fluxion* of B or x, as $4 x^4$ is to x, or as $4 x^3$, is to 1. Therefore if the *Fluxion* of x be expreſſed by $\dot{x}$, the *Fluxion* of x^4 will be expreſſed by $4 x^3 \dot{x}$, agreeably to the common algebraic method of expreſſion. Vid. Mr. *Maclaurin*'s Flux. B. 1. Ch. 6. See alſo the Preſent State of the Rep. of Let. Oct. 1735, pag. 248, 249, &c.

If the *Fluxion* of B or the ſecond term of the progreſſion be invariable, every term of the progreſſion will have *Fluxions* of as many degrees, as there are terms that precede it in the progreſſion. And the increment of any term generated in a given time may be reſolved into as many parts, as it has *Fluxions* of different orders; and each part may be conceived to be generated, in conſequence of its reſpective *Fluxion*. Hence *Fluxions* of all orders may be illuſtrated and meaſured. See Mr. *Maclaurin*'s Treat. of Flux. B. 1. c. 5, and 6.

As to the higher orders of *Fluxions*, it is to be obſerved, that when a motion is accelerated or retarded continually, the velocity may itſelf be conſidered as a variable or flowing quantity, and may be repreſented by a line that increaſes or decreaſes continually. When a velocity increaſes uniformly ſo as to acquire equal increments in equal times, its *Fluxion* is meaſured by the increment which is generated in any given time. In this caſe, the velocity is repreſented by a line that is deſcribed by an uniform motion; and its *Fluxions*, by the conſtant velocity of the point that deſcribes the line, or by the ſpace which this point deſcribes in a given time. When a velocity is not accelerated uniformly, but acquires increments in equal times, that continually increaſe or decreaſe, then its *Fluxion* at any term of the time is not meaſured by the increment, which it actually acquires, but by that which it would have acquired, if its acceleration had been continued uniformly, from that term for a given time. And in the ſame manner, when a motion is retarded continually, the quantity by which it would be diminiſhed in a given time, if its retardation was continued uniformly from any term, meaſures its *Fluxion* at that term. While the point M deſcribes the line E *e*, let the point Q deſcribe the line I *i*, ſo that I Q may be always equal to the ſpace that would be deſcribed by the motion of M, if it was continued uniformly for a given time. Then I Q ſhall always repreſent the velocity of M, and the velocity of the

point Q ſhall repreſent the *Fluxion* of the velocity of M; which therefore is meaſured, at any term of the time, by the ſpace which would be deſcribed by Q, with its motion at that term continued uniformly for a given time. The velocity of M is the *Fluxion* of E M; and therefore the velocity of Q repreſents the *Fluxion* of the *Fluxion* of E M. Thus, when a *Fluxion* of a quantity is variable, it may be conſidered itſelf as a fluent, and may have its *Fluxion*, which is called the *ſecond Fluxion* of that quantity. This may alſo have its *Fluxion*, which is called the *third Fluxion* of the firſt fluent: and motions may be eaſily conceived to vary in ſuch a manner, as to give ground for admitting ſecond *Fluxions*, and thoſe of any higher order. And as the firſt *Fluxion* of a variable quantity, at any term of the time, is meaſured by the increment, or decrement, which would be produced, if the generating motion was continued uniformly from that term, for a given time; ſo its ſecond *Fluxion* may be meaſured by twice the difference betwixt this increment, or decrement, and that which would be produced, if the acceleration, or retardation of the generating motion was continued uniformly from that term for the ſame time. *Maclaurin*, lib. cit. Sect. 70. Ibid. Sect. 75. in fin.

See a farther illuſtration of ſecond and third *Fluxions*, in the ſame author, (Chap. 3. and 4.) deduced from the conſideration of the *Fluxions* of ſolids.

The author of the analyſt has repreſented the notions of ſecond and third *Fluxions*, as inextricable myſteries; and indeed, when ſome ſpeak of the velocities of velocities, &c. it is not eaſy to ſay what they mean. But it is to be obſerved, that the firſt *Fluxion* of any fluent, is not the velocity of that fluent, but the velocity of the motion by which the fluent

is conceived to be generated. And in like manner, the ſecond *Fluxion* of that fluent is not the velocity of the velocity of this fluent, but the velocity of the motion by which the quantity is generated that always repreſents its firſt *Fluxion*, and ſo of the reſt. See *Maclaurin*, Lib. cit. Sect. 164.

When the *Fluxion* of a quantity is variable it may be conſidered as a fluent; and its *Fluxion* which is the ſecond *Fluxion* of the propoſed quantity may be determined by the preceeding propoſitions. Thus the *Fluxion* of A being ſuppoſed equal to *a* the *Fluxion* of A A is $2\,A\,a$; and if A be ſuppoſed to increaſe at an uniform rate, or its *Fluxion* *a* to be invariable, $2\,A\,a$ will increaſe by equal ſucceſſive differences; conſequently its *Fluxion*, or the ſecond *Fluxion* of A A, will be equal to any of theſe differences, as to $2a \times \overline{A + a} - 2\,A\,a$, or $2\,a\,a$. If *a* be variable, let its *Fluxion* be equal to *z*, and the *Fluxion* of $2\,A\,a$ (or ſecond *Fluxion* of A A) will be $2\,a\,a + 2\,A\,z$. In the ſame manner the *Fluxion* of A being conſtant, the *Fluxion* of $n\,A^{n-1}\,a$, or the ſecond *Fluxion* of A^n is $na \times \overline{n-1} \times A^{n-2}\,a$, or $n \times \overline{n-1} \times a\,a\,A^{n-2}$; the *Fluxion* of this, or third *Fluxion* of A^n, is $n \times n-1 \times \overline{n-2} \times a^3 A^{n-3}$. And the *Fluxion* of A^n of any order denoted by *m*, is $n \times \overline{n-1} \times \overline{n-2} \times \overline{n-3}$, &c. $\times a^m\,A^{n-m}$, where the factors in the coefficient are to be continued till their number be equal to *m*. When *n* is any integer poſitive number, the *Fluxion* A^n, of the order *n*, is invariable and equal to $n \times \overline{n-1} \times \overline{n-2} \times \overline{n-3}$, &c. $\times a^n$. The quantities that repreſent thoſe *Fluxions* of A^n depend on *a*, which repreſents the *Fluxion* of A. When A remains of the ſame value, the firſt *Fluxion* of A^n is greater or leſs in the ſame proportion, as *a* is ſuppoſed to be greater or leſs; the ſecond *Fluxion* of A^n, is in the duplicate ratio of *a*; and its *Fluxion* of the order *m*, is as a^m. If *a* be variable, but *z* the *Fluxion* of *a*, or the ſecond *Fluxion* of A, be conſtant, then the fourth *Fluxion* of A A will be conſtant and equal to $6\,z\,z$; for we found, that the ſecond *Fluxion* of A A was $2\,a\,a + 2\,A\,z$; the *Fluxion* of which is $4\,a\,z + 2\,a\,z$, or $6\,a\,z$; and the *Fluxion* of this is $6\,z\,z$. In like manner the ſixth *Fluxion* of A^3 will be conſtant in this caſe and equal to $9\,0\,z^3$.

The ſecond differences of any quantity B are the ſucceſſive differences of its firſt differences; and as the *Fluxion* of B increaſes when its ſucceſſive differences increaſe; ſo its ſecond *Fluxion*, or its *Fluxions* of any higher order increaſe when its ſecond or higher differences increaſe. If we arrive at differences of any order that are conſtant, the *Fluxion* of the ſame order is conſtant and is expreſſed by that difference. Thus when A is ſuppoſed to increaſe by conſtant differences equal to *a*, and its *Fluxion* is ſuppoſed equal to *a*, the ſecond difference of A A (or $\overline{A + a}^2 - 2\,A\,A + \overline{A - a}^2$) is $2\,a\,a$, which is likewiſe its ſecond *Fluxion*; and the third difference of A^3 is $6\,a^3$, which is its third *Fluxion*. When *n* is any integer and poſitive number, the *Fluxion* of A_n of the order *n* is equal to the *Fluxion* of any of its firſt differences of the order $n-2$, and ſo on. For the *Fluxion* of $\overline{A + a}^n - A^n$ (one of the firſt differences of A^n) of the order $n-1$ is $n \times \overline{n-1} \times \overline{n-2}$, &c. $\times \overline{A + a}^{n-n+1} - A \times a^{n-1} = n \times \overline{n-1} \times \overline{n-2}$, &c. $\times a^n$ where the coefficients are ſuppoſed to be continned till their number be $n-1$, ſo that the laſt muſt be 2. And this we found to be the *Fluxion* of A^n of the order *n*, in the preceeding paragraph. In the ſame manner the *Fluxion* of $\overline{A + a}^n - 2\,A^n + \overline{A - a}^n$ (the ſecond difference of A^n) of the order $n-2$, is equal to the *Fluxion* of $\overline{A + a}^n - A$ of the order $n-1$; and conſequently equal to the *Fluxion* of A^n of the order *n*. Theſe *Fluxions* are invariable and equal to the laſt or invariable differences. But in other caſes the *Fluxions* of A^n of any order are leſs than its ſubſequent differences of the ſame order, but greater than the preceeding differences, as before mentioned. *Maclaurin*'s Flux. art. 720, ſeq.

By ſuppoſing one of the variable quantities to flow uniformly it will have no ſecond or higher *Fluxions*, and the higher *Fluxions* depending on it will be expreſſed in a more ſimple manner. Thus the *Fluxion* of *x* being ſuppoſed conſtant, the firſt *Fluxion* of x^n being $n\,x^{n-1}\,\dot{x}$, its ſecond *Fluxion* will be $n \times \overline{n-1} \times \dot{x}^2\,x^{n-2}$, and its *Fluxion* of any order m will be $n \times \overline{n-1} \times \overline{n-2} \times \overline{n-3}$, &c. $\times \dot{x}^m\,x^{n-m}$, where the factors in the coefficient are to be continued till their number be equal to *m*.

The ſecond or higher *Fluxions* of quantities may be found by particular theorems (without computing thoſe of the preceeding orders) as may be ſeen by the laſt example. See farther in *Maclaurin*'s Fluxions, Art. 734.

Inverſe method of FLUXIONS. By this method the fluent is found when the *Fluxion* is given; and the rules are derived from thoſe of the direct method; as the rules in diviſion and evolution in algebra are deduced from thoſe of multiplication and involution. As when a fluent conſiſts of a variable, and invariable part, the latter does not appear in the *Fluxion*; ſo when any *Fluxion* is propoſed, it is only the variable part of the fluent that can be derived from it. If $\dot{x}$ repreſent any *Fluxion* that may be propoſed, the variable part of the fluent will be equal to x: for ſuppoſing y to be any variable quantity, if $x + y$ could repreſent the fluent of $\dot{x}$, then $\dot{x} + \dot{y}$ would be equal to $\dot{x}$, and $\dot{y} = o$, or y would be invariable, againſt the ſuppoſition. But ſuppoſing K, to repreſent any invariable quantity, than $x + K$ may generally repreſent the fluent of $\dot{x}$. If it be required to find ſuch a fluent of $\dot{x}$ as ſhall vaniſh when x is ſuppoſed to vaniſh, it can be no other than x; and if it be required that the fluent ſhould vaniſh when x is equal to any given quantity *a*, then by ſuppoſing $x + K$ to vaniſh when x becomes equal to *a*; we ſhall have $a + K = o$, or $K = -a$; whence the fluent is $x - a$. In the ſame manner, the fluent of $-\dot{x}$ may be generally repreſented by $K - x$.

When a *Fluxion* that is propoſed, coincides with any of thoſe which were deduced from their fluents in the preceeding articles, the variable part of the fluent required, muſt coincide with that which was there propoſed. As diviſion in algebra leads us to fractions, and evolution to ſurds; ſo the inverſe method of *Fluxions* leads us often to quantities, that are not known in common algebra, and that cannot be expreſſed by common algebraic ſymbols. *Maclaurin*'s Flux. art. 735.

We cannot here pretend to enter into a detail of the rules of the inverſe method of *Fluxions*. We ſhall only obſerve in general, that a *Fluxion* being propoſed, its fluent may ſometimes be found accurately in algebraic terms; but this is far from being always poſſible; and recourſe muſt ſometimes be had to a converging ſeries. Thus, if $nx^{n-1}\dot{x}$ were propoſed, the variable part of the fluent is found by adding unity to the exponent of the power, dividing by the exponent thus increaſed, and by the *Fluxion* of the root. That is, the variable part of the fluent of $n\,x^{n-1}\,\dot{x}$ will be $\frac{n\,x^{n-1}\,\dot{x}}{\overline{n-1+1} \times \dot{x}} = x^n$. But if the propoſed *Fluxion* were $\frac{a\,\dot{x}}{a-x}$, we cannot find its fluent by this rule, but we may throw the *Fluxion* into an infinite ſeries by dividing *a* by $a - x$ in the uſual method, and we ſhall find the quotient or $\frac{a}{a-x} = 1 + \frac{x}{a} + \frac{x^2}{a^2} + \frac{x^3}{a^3} +$ &c. Hence $\frac{a\,\dot{x}}{a-x} = \dot{x} + \frac{x\,\dot{x}}{a} + \frac{x^2\,\dot{x}}{a^2} + \frac{x^3\,\dot{x}}{a^3} +$ &c. Now the fluent of each term of this ſeries may be found by the foregoing rule; and therefore the fluent of $\frac{a\,\dot{x}}{a-x}$ will be expreſſed by the ſeries $x + \frac{x^2}{2\,a} + \frac{x^3}{3\,a\,a} + \frac{x^4}{4\,a^3} +$ &c. which may be of uſe for determining the fluent when x is very ſmall in reſpect of *a*; becauſe in that caſe, a few terms at the beginning of the ſeries will be nearly equal to the value of the whole. But it often happens that the ſeries deduced in this method converges ſo ſlowly, as to be of little or no uſe. See *Maclaurin*'s Treat. of Flux. Art. 737, 744, 827. *Stirling*, de Summat. Serier. p. 28.

Mathematicians therefore do not always immediatly recur to infinite ſeries, when it does not appear that a fluent can be aſſigned in a finite number of algebraic terms. The arches of a circle, and hyperbolic areas or logarithms, cannot be aſſigned in algebraic terms, but have been computed with great exactneſs by ſeveral methods. By theſe with algebraic quantities, any ſegments of conic ſections, and the arches of a parabola are eaſily meaſured; and when a fluent can be aſſigned by them, this is conſidered as the ſecond degree of reſolution. When it does not appear that a fluent can be meaſured by the areas of conic ſections, it may however be meaſured in ſome caſes by their arcs; and this may be conſidered as the third degree of reſolution. If it does not appear that a fluent can be aſſigned by the arcs of any conic ſections (the circle included) it may however be of ſome uſe to aſſign the fluent by an area, or arc of ſome other figure, that is eaſily conſtructed or deſcribed; and it is often important, that the propoſed *Fluxion* be reduced to a proper form, in order that the ſeries for the fluent may not be too complex, and that it may not converge at too ſlow a rate. See *Maclaurin*'s Treatiſe of Fluxions, Book II. ch. 3.

We may therefore conſtitute three orders or claſſes of fluents. Firſt, ſuch as can be accurately aſſigned in finite terms by common algebraic expreſſions. Secondly, thoſe which can be reduced to the areas of conic ſections, or to circular arcs and logarithms. Thirdly, ſuch as can be aſſigned by hyperbolic or elliptic arcs. The firſt two claſſes (conſidering triangles and circles as conic ſections) may therefore be meaſured by the areas of conic ſections; and the third claſs by their perimeters, or lines that bound them. *Maclaurin*, ibid. art. 798.

The fluent of $\frac{\dot{x}}{\sqrt{1 \pm x}}$ is of the firſt claſs; that of $\frac{\dot{x}}{\sqrt{x} \times \sqrt{1 \pm x}}$ or of $\frac{\dot{x}}{\sqrt{1 \pm x\,x}}$ is of the ſecond; but the fluents of $\frac{\dot{x}\sqrt{x}}{\sqrt{1 \pm x\,x}}$, $\frac{\dot{x}}{\sqrt{x} \times \sqrt{1 \pm x\,x}}$, $\frac{\dot{x}}{1 \pm x\,x}^{\frac{1}{4}}$ and

$\frac{\dot{x}}{\overline{1 \pm xx}^{\frac{3}{4}}}$ are of the third claſs, and as far as has appeared hitherto, cannot be reduced to the former. See *Maclaurin*, Flux. B. II. Ch. 3. Art. 798, &c.

It is to be obſerved, as to the fluent of $\frac{\dot{x}}{\sqrt{x} \times \sqrt{1 \pm xx}}$, or of $\frac{\dot{x}}{\overline{1 \pm xx}^{\frac{3}{4}}}$ that it does not appear poſſible to repreſent them by any hyperbolic arc and algebraic quantities. But by aſſuming an elliptic arc likewiſe, they may be conſtructed. See *Maclaurin*, Lib. cit. Art. 802.

So likewiſe to repreſent the fluent of $\frac{\dot{z}}{\sqrt{z} \times \sqrt{b^2 \pm 2ez - zz}}$ or of $\frac{\dot{p}}{\sqrt{a^2 b^2 \pm 2aep^2 - p^4}}$, we muſt have recourſe to both the hyperbolic and elliptic arcs. *Maclaurin*, L. c. Art. 805.

The fluent of $\frac{z^{\frac{rn}{4} - 1} \dot{z}}{\sqrt{e + fz^n}}$ is aſſignable by the arcs of conic ſections, when r is an integer number; that is, by right lines, when r is equal to 4 or to any multiple of 4; by circular and parabolic arcs (reducible to logarithms) with right lines, when r is any other even number; by arcs of an equilateral hyperbola with right lines, when r is any number of the ſeries 3, 7, 11, 15, &c. and by arcs of the ſame hyperbola and right lines, with arcs of an ellipſis, that has its excentricity equal to the ſecond axis, when r is any of the numbers 1, 5, 9, 13, &c. See *Maclaurin*, ibid. Art. 809.

We preſume, upon the whole, that few will be ſo ſcrupulous as to deny the Newtonian doctrine of *Fluxions* to be intelligible, and accurately demonſtrated. But on the other hand it muſt be confeſſed, that the introduction of the notions of motion and velocity, which are mechanical, ſeems not to have thrown any light on this part of geometry. The conſideration of the limiting ratios of variable quantities, and that of the limiting polygons of curves, as it requires no other knowledge but what depends on the common properties of number and magnitude, ſo it ſeems, in all reſpects, the moſt clear and unexceptionable manner of conſidering the ſubjects treated of in the higher geometry. An eminent mathematician ſeems to declare himſelf of this opinion, when he ſays, that quadratures by limiting polygons is one of that kind which requires no other knowledge but what depends on the common properties of number and magnitude; and ſo may ſerve as an inſtance to ſhew, that no other is requiſite for the eſtabliſhment of principles for arithmetic and geometry. A truth, which, though certain in itſelf, may perhaps ſeem doubtful from the nature and tendency of the preſent inquiries in mathematics. For among the moderns ſome have thought it neceſſary, for the inveſtigation of the relations of quantities, to have recourſe to very hard hypotheſes; ſuch as that of number infinite, and indeterminate; and that of magnitudes in *ſtatu fieri*, exiſting in a potential manner, which are actually of no bigneſs. And others, whoſe names are truly to be reverenced on account of their great and ſingular inventions, have thought it requiſite to have recourſe even to principles foreign to mathematics, and have introduced the conſideration of efficient cauſes and phyſical powers, for the production of mathematical quantities; and have ſpoken of them, and uſed them, as if they were a ſpecies of quantities by themſelves. Vide *Machin*, in Phil. Tranſ. N°. 447.

FLY. The account of the ſeveral ſpecies, genera and claſſes of *flies*, is no ſmall part of the natural hiſtory of inſects. The number of the ſpecies of *flies* exceeds perhaps even that of the butterfly; but the *flies* are in general ſmall, tho' there are ſome, as the libellæ, whoſe bodies are longer and larger, than thoſe of the largeſt butterflies. The cicadæ alſo belong to the *fly* claſs, and there are ſome of thoſe, whoſe ſize exceeds that of the largeſt butterflies in the thickneſs of their bodies. The generality of *flies* however are much ſmaller than the butterfly claſs, and many of them are indeed ſo very ſmall, as not eaſily to be diſtinguiſhed.

Many of the *flies* are in their prior ſtate hid from us, or detained among very diſpleaſing matters; it is in their winged ſtate, that they become an agreeable object of our reſearches, and it may be moſt proper therefore, to begin their hiſtory in that ſtate, occaſionally deſcending to the others. *Reaumur*'s Hiſt. Inſ. Vol. 4. p. 124.

It is a common error to imagine, that the ſmall *flies* one ſees in the ſpring, will become larger in ſummer. This is wholly without foundation, ſince all the *flies*, like other inſects which undergo a metamorphoſis, become of their full bigneſs, as ſoon as they arrive at the *fly* ſtate, and never grow afterwards.

The general and obvious character of *flies*, by which they are diſtinguiſhed from other winged inſects, is their having tranſparent wings, made as it were of gawze, and never having on them any of that powder which duſts the fingers in touching the wings of butterflies, and having no caſes or covers for them. They are by this plain character of their tranſparent and naked wings, diſtinguiſhed from the butterfly, the beetle, the graſshopper, and other claſſes of winged inſects.

The parts of *flies* are the head, the corcelet, and the body. The corcelet many authors have called the breaſt, becauſe it is placed as the breaſt in us; but as that name might naturally lead us to believe, that the lungs and tracheæ had their place there, it is very neceſſary to change the term, when ſpeaking of animals whoſe tracheæ are diſtributed all over their bodies.

To the corcelet the wings are affixed, and in the body are contained the ſtomach, inteſtines, the parts of generation, and a great many of the tracheæ. The head in *flies* is uſually joined to the corcelet by a very ſhort neck, and can often turn on it as on a pivot. Some *flies* there are which have as it were two corcelets, one ſeparated from the other; the firſt in this caſe is uſually very ſmall, and the wings are affixed to the ſecond. The corcelet is the moſt prominent and rounded part of the inſect, it is always the ſtrongeſt part, and is frequently the thickeſt. The formica leo and ſome water inſects, are transformed into *flies* which have double corcelets, or corcelets divided into two.

The moſt obvious diſtinctions for the arrangement of *flies* into claſſes, is the number of their wings; ſome having only two, others four. And this is ſo plain and obvious a diviſion, that it is wonderful, that the writers of natural hiſtory have not long ſince fallen into it, nay, many of them have often omitted to tell us the number of wings of the ſpecies they deſcribe.

The firſt general diviſion of *flies* is therefore into that of the two winged, and four winged kinds. A very ſlight obſervation is generally ſufficient to determine to which of theſe diviſions, a *fly* belongs; but if we afterwards examine a *fly* with more attention, and take into conſideration, the organs by which it takes its nouriſhment; one may obſerve, that ſome of them are able to thruſt out that organ to a conſiderable diſtance from their head; and that this organ, which while in a ſtate of reſt is folded up or ſhortened, or turned about, or laid cloſely down, when the creature wants to uſe it, is unfolded, lengthened, extended or raiſed. This organ, is what naturaliſts call the trunk of an inſect, but there are many other *flies* which have no trunk; theſe have no other than an opening, ſerving for a mouth, ſurrounded with lips and with ſome other parts. This ſort of opening from its ſituation and figure, may very properly be called a mouth.

Some of theſe mouths have nothing analogous to teeth about them; but there are others which have teeth, ſaws, or grinders, placed on the outſide of the mouth, and moveable as in the caterpillars, with which the *flies* tear and deſtroy leaves, fruits and fleſh; finally there are alſo ſome *flies* to which nature has allotted both a trunk, and theſe organs.

Theſe characters give us very naturally the diſtinctions of four ſubordinate claſſes under the two former general ones.

The firſt contains thoſe *flies* which have a trunk and no teeth or ſaws. The ſecond contains thoſe which have a mouth without any ſenſible teeth. The third, thoſe which have a mouth furniſhed with teeth; and the fourth, thoſe which have both trunks and teeth. Among the *flies* which have mouths furniſhed with teeth, ſome have them not only without, but within their mouths alſo.

All the two winged *flies* belong to the firſt or ſecond of theſe claſſes; the great blue fleſh *fly*, the ſmall *flies* that are ſo troubleſome about our houſes, and the gnats are all of the firſt claſs, and have trunks and no teeth. The ſpring *fly* ſo common in gardens, and a ſort of *fly* reſembling the gnat kind, but much larger, are of the ſecond claſs, and have mouths, but no ſenſible teeth.

The four winged *flies* furniſh us with great numbers to fill up the other two claſſes, left vacant by the former. All the bee kind have a trunk and two teeth; all the waſp kind have a mouth furniſhed with two teeth; and there are beſide theſe ſeveral of the four winged *flies* which belong to the ſecond claſs; all the papilionaceous *flies* produced of water tæniæ, are of this ſort, as having a mouth without teeth. Several ſmall four winged *flies* are alſo of the firſt claſs; as the flying pucerons, and falſe pucerons, which have all trunks and no teeth: neither are the ſmaller ſpecies only of this claſs, ſince the cicadæ alſo belong to it.

A fifth claſs may however be alſo eſtabliſhed, tho' the ſpecies of it are only few, there being only two kinds of *flies* of it, this is of thoſe which have their head ſerving the office, or made in the form of a trunk. The *flies* of this kind have very long heads, which like thoſe of birds terminate in a ſort of beak: this however in the *fly* kind is never opened except at the end, or in other words, theſe *flies* have heads, which are lengthned out into the reſemblance of a bill, or figure of a trunk, but which is ſtiff and cannot change its figure, nor alter its poſition otherwiſe than by the altering that of the whole head. At the end of this ſort of trunk are placed the

teeth or other organs, by which the creature gets its food. The firſt example of theſe heads is in the ſcorpion *fly*; and a very beautiful *fly* that is frequently ſeen skipping and leaping about flowers is the other.

Under theſe general claſſes, ſubordinate ones are to be formed, from whatever beſides is the moſt obvious and eſſential diſtinction among theſe little animals. The form of the body may very well afford us theſe.

Some *flies* have bodies ſhort and of an oval figure, reſembling an ellipſoide or a truncated ellipſoide figure, more or leſs flatted. Of this figure is the body of the common great blue fleſh *fly*, ſuch is alſo the form of the body of the bee kind, and of multitudes of other *flies* both of the two and four winged kinds, whoſe bodies are as broad as thick.

Among the ellipſoide bodied *flies*, ſome have a rounder, others a more oblong body, others a thicker, and others again a thinner or flatter, and others have the hinder part of it bent underneath like a hook. Of this kind are the *flies* common about excrements, and a little grey *fly* common about the bloſſoms of the pear-tree.

Some *flies* there are however, which are longer and rounder than theſe, and deſerve to have a peculiar claſs alloted for them. Of this kind are the libellæ, commonly called with us dragon-*flies* and demoiſelles by the French. Others have their bodies ſhorter but cylindric, as the gnats; and others have them conic, as the common corn-*fly*, which reſembles the ſcorpion-*fly*, and is found in the harveſt-time among the corn. Others finally have bodies in the form of a ſpindle; that is, long, and thicker in ſome part between the ends, than at the ends. Theſe might be arranged in a peculiar claſs, and called the large bodied *flies*, that is to ſay, *flies* whoſe bodies are long in proportion to their thickneſs.

The *flies* whoſe bodies are of this ſpindle ſhape, may very properly be taken from the other claſſes, and made to eſtabliſh a new one, for this reaſon, that as the whole anterior part of the body is in other *flies* joined to the corcelet, in ſuch manner, that they ſeem united in their whole ſurfaces; theſe on the contrary are not joined body and corcelets together, neither indeed do theſe parts touch, but are united by means of a ſlender filament, as may be obſerved in the hornets, and others of the waſp claſs. In ſome *flies* this filament is very long, and in others, as remarkably ſhort; and in ſome, after it has been extended to ſome length, from the corcelet, very thin and fine, thickens by degrees as it approaches the body of the *fly*, as in the greater part of the ichneumon *flies*. There is great difference among the different ſpecies of the ichneumons, ſome inſtead of the common long body have a ſhort and thick one faſtened to the corcelet by a very ſlender thread; ſuch are the ichneumons of the oak galls.

Under the five former claſſes we have therefore three other ſubordinate ones; the firſt of thoſe *flies* whoſe bodies are ſhort and broader than they are thick; the ſecond of thoſe with long bodies; and the third of bodies faſtened to the corcelet only by a fine filament. And under all theſe, the ſeveral genera are to be eſtabliſhed from other leſſer but conſtant and invariable differences; ſuch as the differences of the manner of their carrying their wings, the figures of their antennæ, the poſition of their trunks, and other the like differences. *Reaumur*'s Hiſt, Inſ. tom. 4. p. 124. ſeq. See Tab. of Inſects, and the articles WINGS, TRUNKS, &c.

Bodies of FLIES. The bodies of theſe inſects are extremely different one from another, and even thoſe whoſe general form makes them properly ranged in the ſame claſs, are not without their diſtinctions, by which they alone may be made to eſtabliſh ſubordinate genera.

Among the *flies* which have ſhort or ellipſoide bodies, ſome have the body extremely flat and thin; ſuch are thoſe of the *flies* produced from the worms which devour the pucerons; and others have the hinder part of the body bent downward in form of a hook.

The extremity of the body in theſe animals is uſually ſmaller than the adjoining parts. Yet there is a *fly* found in the neſts of ſwallows, the extremity of whoſe body is larger than any other part of it; and not only the form of the body, but the differences of the filament, by which in many genera, it is connected to the corcelet, may furniſh great matter for the diſtinction of the ſubordinate genera.

The hinder part or extremity of the body alone may alſo afford great matter of diſtinction. Thoſe *flies* which carry ſtings in their tails, have in that alone a ſufficient diſtinction. *Reaumur*'s Hiſt. Inſ. tom. 4. p. 144.

Others there are which have organs placed there, which tho' we need not fear them, offer ſubject enough for our admiration; 'tis indeed the females alone, who have occaſion for theſe, and therefore the females alone are furniſhed with them.

Several of theſe inſtruments are a kind of auger or borer, carried in a caſe or ſheath. This ſometimes has the form of a long tail to the inſect, and its uſe is to pierce and bore the body, in which the creature is to depoſit its eggs. Several of the female ichneumons have this ſort of long tail; and there are other inſects which have a long and ſtrong piercer, which however does not make a tail to their body, but is partly lodg'd either under their belly, or in their body; of this kind are the cicadæ and others.

Other inſects of this kind have a ſingular inſtrument lodged in this part of their body, which may properly be called a ſaw. They never ſhew this on examination unleſs their bodies be preſſed, and then we cannot but greatly admire the inſtrument itſelf, and the powers by which the creature moves it.

Other inſects of this claſs carry behind one or more long ſlender filaments, which in their form and ſtructure, have ſome ſort of reſemblance to the antennæ; and the uſes of which, are as little known to us, as thoſe of the antennæ. The genera of *flies* may very properly be diſtinguiſhed by means of theſe: among the four winged *flies*, the ephemerons, and many other ſpecies, have them; and among the two winged kinds, the ſmall *fly*, which is the male gall-inſect, furniſhes us with an inſtance of them. See Tab. of Inſects.

FLIES *of water worms*. Theſe according to their ſeveral ſpecies, have ſome varities in their manner of egreſs from their ſhell at their leaving the nymph ſtate, for that of the perfect *fly*.

The long water worms compoſed of many rings, and with funnel faſhioned tails made with an aperture for the admiſſion of the air, ſurrounded with a multitude of hairs, retain, in their ſhell ſtate, ſo much of the ſame form they were of while living, that the one is not eaſy to be diſtinguiſhed from the other. The nymph in each of theſe fills up only a ſmall part of the cavity, and the *fly* in many of them is produced perfect in five or ſix days. At this time the parts of the nymph being thorougly ſtrengthened, it begins to ſhew the firſt ſigns of life in its attempt to open its priſon.

To effect this, nature has ſo provided for the incloſed *fly*, that the head is but ſlightly joined to the ſecond ring of the body; but the creature in this ſtate, not being lodged in that part of the worm, can make no efforts againſt it; all its endeavours are bent to force a ſlit or opening in the ſecond ring, like that in the back of the skin of a caterpillar, that is going to change its skin, or like that of the butterfly cryſalis's. The means the incloſed *fly* uſes to this purpoſe, are the inflating and ſwelling its head, and then thruſting out the bladder from its anterior part, with which theſe *flies* are provided by nature in this ſtage of their lives, and for this only purpoſe.

When this ſlit or crack is effected, the head of the worm is in ſome meaſure ſeparated from the body, and the efforts of the *fly* to puſh itſelf forward, finiſh that ſeparation, and leave an aperture of a proper ſize, for the egreſs of the *fly*.

But the water, on the ſurface of which this change is effected, is a thing much to be dreaded, and indeed is often of fatal conſequences to the new born *fly*, ſince the *flies* produced of water worms, are as much afraid of this element, and are as eaſily drowned as thoſe produced from worms who ſpend their lives on dry land.

The *flies* produced from this long water worm, are however in leſs danger and leſs afraid of the water than many others; they advance ſlowly out of their ſhells in an horizontal direction, and as ſoon as their fore-feet are at liberty, they boldly place them upon the water, as if upon dry land, and it ſerves as well for their ſupport; and as their other parts get at liberty, they are gradually ſet upon the water too, and the creature there reſts till his wings are unfolded, and all its parts have their proper form, and then takes its flight into its new element.

The *fly* produced from this long worm is of the ſhort bodied kind, and much of kin to the common great blue fleſh *fly*. It has a fleſhy trunk furniſhed with lips, and has no teeth; but tho' this *fly* is ſo far of the ſame claſs with that common ſpecies, it has enough to amply diſtinguiſh it in theſe ſeparate characters. The firſt is, that this has its antennæ formed of granulated filaments, whereas the other has them of the battledore kind: the wings of the fleſh *fly* are not croſſed upon the body, whereas, thoſe of this water *fly* are; but what more than theſe diſtinguiſhes it from this, and indeed from all the other ſpecies of *flies* is, that it has two oblong and ſlender bodies formed like pins, and pointed as thoſe, which are a little crooked, of a cruſtaceous ſtructure, and are inſerted in the upper part of the corcelet of the *fly*, and directed toward its hinder part. See Tab. of Inſects, N° 40, ſeq.

Theſe prickles are hard, rigid and immoveable.

St. Mark FLY, in natural hiſtory, the name of a ſpecies of *fly*, which makes its firſt appearance every year, about St. Mark's day, and is then ſeen in vaſt numbers; it is ſomewhat ſmaller than the large blue fleſh *fly*, and has no trunk, but a mouth without teeth: notwithſtanding this ſeemingly innocent organization, the creature does great miſchief, and every gardiner knows the effects of it at one time or other. Theſe *flies* are found about fruit trees, and are always ſeen ſitting upon the buttons of the leaves, and the flower buds; and they do great miſchief to many kinds of trees, by ſucking the juices of thoſe tender parts, and either deſtroying them before they open, or at leaſt rendering them very weak. Some tell us that theſe *flies* had originally a ſting, but that the miſchief they did, being very great, St. Mark deprived them of that

that offenſive weapon for all generations: this is a ſtory much believed by the country people, in many of the Roman catholic kingdoms. The mouth is of the ſame figure with that of the tipula, or long-legs, being compoſed of two membranous lateral lips, like the two valves of a ſhell-fiſh, which defend and cover two other fleſhy lips within.

The aperture of the mouth is occaſionally covered in the ſame manner with that of the tipula, by two beards which ſtand near it; and the antennæ are ſhort, of the granulated kind, but have nothing ſingular in them.

The male is eaſily diſtinguiſhed from the female, by having a much larger head, and his reticular eyes much larger than hers; they in a manner cover the whole head, and fall over it behind, ſo that the creature ſees every way at once.

Beſide theſe, it has alſo a cluſter of three bright ſingle eyes placed in a triangle on the upper part of the head, and reſembling the eyes of ſpiders.

The wings of this *fly* are a little longer than its body, and in their uſual poſition. They are croſſed in ſuch a manner, that one of them intirely covers the other, and even the body. When the wings are opened and the body examined, the male and female are found to be very different in figure; the male would naturally be called one of the long bodied kind, his body being ſlender and compoſed of ſeveral rings; the thickeſt of which adheres to the breaſt, and the reſt grow gradually ſmaller all the way; the ſurface is rough and uneven, and the whole of no great beauty. The body of the female is uſually diſtended with eggs, and thence appears very thick, and much ſhorter than the other, and is of a ſmooth and poliſhed ſurface. Both the male and female fly in a very ſingular and awkard manner; they ſeem as if hanging in the air, their legs always hanging ſtrait down from their body, and theſe being very long appear very oddly. The common *flies* of this kind are of two ſpecies, there is a black one, and one whoſe breaſt is of a dusky red; but according to this deſcription of their ſeveral parts, there are ſeveral other ſpecies of them, which are ſo ſmall as not to appear diſtinctly without the aſſiſtance of a microſcope.

All the ſpecies of the St. Mark *fly*, are produced from worms which are hatched from the eggs of the parent *fly*, depoſited under the ſurface of the earth. Theſe worms are ſmall and have ſcaly heads and no legs; they ſomewhat reſemble caterpillars in ſhape, and are hairy, as many of the ſpecies of caterpillars are. It is a very common thing to find thouſands of theſe worms in the dung of cows lying on the paſtures, where they feed. There is vaſt plenty of them thus found in the months of September and October; and as this is a ſeaſon when their parent *flies* have been long dead, and the dung they are found in but freſh or a few days old, it is very evident that the eggs of of which they were hatched were not originally depoſited there, but that they have crawled up out of the earth, into a ſubſtance which is more agreeable to them by way of food, than any thing they find under ground.

This is not ſingular in this inſect, for the ſeveral worms of the beetle kind, ſo frequently found in dung, are not produced there, but under the ſurface of the earth, and only crawl up into the dung for the ſake of food and moiſture, when it happens to fall upon the place where they are.

If a piece of cow-dung in which the worms of this St. Mark *fly* are, be preſerved in a box, it will keep them alive the whole winter, and they will be found in the beginning of March, to be grown much larger than before, and to be leſs hairy, their hairs being longer, and ſtanding about nine on every ring. In order to ſee the transformation of theſe into the *Fly* ſtate, the dung muſt be at this time laid on ſome common earth; the worms ſoon quit the dung, and crawl into the ground, where they transform themſelves almoſt immediately into the nymph ſtate, and from thence they iſſue out in the form of *Flies* a few days after the middle of April. They do not all quit the ſhell of the nymph at the ſame time, but the young *Flies* may be ſeen crawling up out of the ground at times, during ſix or ſeven days, from the appearance of the firſt.

The manner of theſe *Flies* leaving their worm ſtate to enter into that of the chryſalis or nymph, is worthy obſervation. The worm ſeems in great diſorder, and twiſts itſelf about ſeveral ways, till at length the skin cracks on the ſurface of the back, immediately upon this there appears the anterior part of the nymph at the aperture, and this forces its way out by degrees, the head becomes of no farther uſe, and is left with the skin; and the nymph by diſtending and contracting itſelf, at length makes its way wholly out of it, and then remains at reſt till the *Fly* iſſues out of it. The laſt transformation of this inſect, or the appearance of the *Fly* from the nymph, has nothing ſingular in it, but is performed in the ſame manner, with the ſame change in other animals of this kind As ſoon as the *Flies* are produced they take wing, and ſettle upon the fruit trees, or other plants. The male and female ſoon meet and engage in the work of propagating the ſpecies; in this the male remains fixed to the female for an hour or longer, and the female often in this ſtate flies away with him, and carries him to a great diſtance. If they are ſeen ſitting in this condition, they may be caught and even killed without their parting from one another. The male on this occaſion does not ſit upon the back of the female, but they are joined tail to tail, and the wings of the female cover ſo large a part of the body of the male, that the two animals look like one, with a head at each end of the body. After the buſineſs of the impregnation of the eggs in this manner is once over, the creatures have no buſineſs for any long life. The male has done his part, and the female has no farther buſineſs in the world, than the depoſiting her eggs in the earth, or in the dung of cows and horſes; which as ſoon as ſhe has done, ſhe dies. The male being uſually dead before her. The miſchief theſe creatures do to the fruit trees therefore tho' very great is not very laſting, for their duration in the winged ſtate is but ſhort, they only appear about the middle of April, and they are all gone before May is over. The eggs they depoſite ſoon hatch into worms, which live till the ſeaſon of their appearing in the *fly* ſtate again.

Flower FLY, in natural hiſtory, the name of a ſmall but very beautiful *fly*, deſcribed by Cluſius. It is black, and has two ſilvery wings, two white eyes, ſeven yellow ſpots on the back, and a black one in the middle.

Eyes of FLIES. See the article EYE.

Legs of FLIES. See LEG.

Rings of FLIES. See RINGS.

Harveſt FLY. See HARVEST.

Lanthorn FLY. See LANTHORN *fly*.

Roſe FLY. See ROSE.

FLY *catcher*, in zoology. See MUSCICAPA.

FLY *tree*, in natural hiſtory, a name given by the common people of America to a tree, whoſe leaves they ſay, at a certain time of the year, produce *Flies*. On examining theſe leaves about the middle of ſummer, the time at which the *Flies* uſe to be produced, there are found on them a ſort of bags of a tough matter, of about the ſize of a filbert, and of a dusky greeniſh colour; on opening one of theſe bags with a knife, there is uſually found a ſingle full grown *fly* of the gnat kind, and a number of ſmall worms, which in a day or two more have wings and fly away in the form of their parent. The tree is of the mulberry kind, and its leaves are uſually very largely ſtocked with theſe inſect bags, and the generality of them are found to contain the inſects in the worm ſtate; when they become winged, they ſoon make their way out. The bags begin to appear when the leaves are young, and afterwards grow with them, but they never rumple the leaf, or injure its ſhape. They are of the kind of leaf galls, and partake in all reſpects, except ſize, of a ſpecies we have frequent on the large maple, or, as it is called, the ſycamore. Philoſ. Tranſ. N°. 431.

The *Fly* tree is found in many parts of France, where it grows in great abundance, and is there ſaid to bear fruit, which give origin to vaſt numbers of *Flies*. The truth of the matter is this; the tree is a ſpecies of turpentine tree, and frequently produces or gives origin to certain tubercles, which in the common turpentine tree are called its horns. Theſe are a ſort of long bladders of the length and thickneſs of a finger, which ariſe not from the ſtalks as fruits do, but from the ſurface of the leaves, and are only a kind of leaf galls formed of an elongation of its outer membranes, occaſioned by the punctures of a number of inſects contained within it, which occaſions a derivation of freſh juices to the part. Theſe inſects are not *Flies* of the common kind, but are the pucerons ſo well known for feeding on the leaves and tender ſtalks of trees, and ſome few of theſe only are winged, the others being deſtitute of them. The origin of theſe tubercles or bladders is this, the female puceron as ſoon as produced from the parent, makes a way under the membrane that covers the leaf by means of a hole bored in it with her trunk. This hole ſoon heals up after ſhe is in, and the young ones which ſhe afterwards produces, by their wounding and ſucking the ſides of the lodgment in which they find themſelves placed, occaſion all the ſwelling and growth of the tubercle. *Reaumur*'s Hiſt. v. 6. p. 34. See the article PUCERON.

FLY, in the ſea language, that part of the mariner's compaſs on which the 32 winds are drawn, and to which the needle is faſtened underneath. See COMPASS, *Cycl.* and *Suppl.*

Let FLY *the ſheets*, at ſea, a word of command, in caſe of a guſt of wind, leſt the ſhip ſhould overſet, or ſpend her top-ſails and maſts, to have the ſheet go a-main, and then the ſail will hold no wind.

FLY *the heels*, in the manege. A horſe is ſad to *fly* the heels, when he obeys the ſpurs. See SPUR and HEEL, *Cycl.*

FLYING *fiſh*, a name given by the Engliſh writers to ſeveral ſpecies of fiſh, which by means of their long fins have a method of keeping themſelves out of water for ſome time. The *flying* fiſh moſt properly ſo called is the exocætus of the antient authors, and of Artedi. See Tab. of Fiſhes, N° 41. It is called alſo the *adonis*, *hirundo*, and *mugil alatus* or winged mullet, by authors; but they uſe theſe words indeterminately for this, and the other kinds. See the articles MUGIL *Alatus*, and EXOCÆTUS.

FLYING *fiſh* is alſo the name of a fiſh of the cuculus or gurnard kind

kind, with very large gill fins, called by the writers on theſe ſubjects, *milvus*. It ſometimes uſes theſe fins inſtead of wings for flying. *Ray*'s Ichthyol. p. 283. See MILVUS.

FODDER, (*Cycl.*) in mining, is a meaſure containing twenty-two hundred and an half weight, though in London but twenty hundred weight. *Houghton*'s compl. Miner, in the explan. of the terms.

FOECIALES, among the Romans, a college of prieſts, firſt inſtituted by Numa, whoſe office it was to declare war, and proclaim peace. No war could be undertaken till they had examined and found the cauſes for it juſt, and neceſſary, and till ſatisfaction had been refuſed. *Hofm.* Lex. in voc. See CLARIGATIO and WAR.

FOENICULUM, *fennel*, in botany, the name of a genus of umbelliferous plants, the characters of which are theſe; the flower is of the roſaceous kind, or compoſed of ſeveral petals arranged in a circular form; theſe ſtand on a cup, which afterwards becomes a fruit compoſed of two long and thick ſeeds which are gibboſe and ſtriated on one ſide, and flat and plain on the other. To this it is to be added, that the leaves are very finely divided, and ſtand on complex ſtalks.

The ſpecies of *fennel* enumerated by Mr. Tournefort are theſe. 1. The common *fennel* with blackiſh acrid ſeeds. 2. The common German *fennel*. 3. The blackiſh leaved *fennel*. 4. The ſweet *fennel* with large pale coloured ſeeds. 5. The ſweet fennel of the azores iſlands. 6. The white flowered *fennel* with ſmall roundiſh ſeeds. 7. The crooked *fennel*, called by authors ſeſeli of Marſeilles. 8. The perennial wild *fennel*, with ſhort leaves, called by ſome the broad leaved ſpignel. 9. The tall wild *fennel*, with longer leaves. 10. The dwarf wild *fennel*, with peucedanum leaves. 11. The wild *fennel*, with bluiſh green leaves. 12. The annual *fennel*, with long and narrow umbels, called by authors gingidium, and viſnaga. 13. The tall globular headed *fennel*, called by authors, the hippomarathrum. 14. The oriental *fennel*, called by authors cummin. 15. The oriental *fennel*, called cummin with hairy ſeeds. 16. The annual *fennel*, with the ſmell of origanum, called by authors, the leſſer ammi. 17. The little annual Portugal *fennel*, with the ſmell of dill, called by ſome wild dill. 18. The little acrid Portugal *fennel*, called the dwarf ammi. 19. The ſmall *fennel* with wide umbels, called mountain daucus, and ſelinum, by ſome authors. 20. The ſmalleſt water *fennel*, called by authors the leaſt water *ſium*. *Tourn* Inſt. p. 311.

FOENUM *græcum*, *fœnugreek*, in botany, the name of a genus of plants, the characters of which are theſe; the flower is of the papilionaceus kind, and its piſtil which ariſes from the cup, finally becomes a flat and hornlike pod, containing a number of ſeeds approaching to a rhomboidal or reniform ſhape. The leaves ſtand three on every ſtalk.

The ſpecies of *fœnugreek*, enumerated by Mr. Tournefort, are theſe; 1. The common cultivated *fœnugreek*. 2. The common wild *fœnugreek*. 3. The ſmaller Arabian wild *fœnugreek*. 4. The many podded wild *fœnugreek*. 5. The wild *fœnugreek* with numerous long pods. 6. The Sicilian *fœnugreek*, with birdsfoot pods. *Tourn.* Inſt. p. 409.

FOETOR (*Cycl.*) — FOETOR *oris*, a term uſed by medical writers to expreſs that ill ſmell in the mouth, uſually, tho' often improperly, called by us a ſtinking breath. This is a malady ariſing in different caſes from very different cauſes; as from the ſcurvy, and particularly that ſpecies of it which affects the mouth, and is therefore called *ſtomacace*; from the french pox; from an ulceration whether ſimple or fiſtulous in the lungs, which is the caſe in conſumptions; from ulcers in the mouth; from caries or rottenneſs of the teeth, or from any other impurity of them; from crudities in the ſtomach ariſing from a bad digeſtion, and in particular, from a weakneſs about the left orifice of the ſtomach, from which part the fœtid vapours will often ariſe in very great abundance. *Juncker*'s Conſp. Med. p. 607.

Method of cure. According to the different cauſes of this diſorder, it requires a very different method of cure in caſes where it depends on the ſcurvy, pox, or other diſeaſes. Thoſe diſeaſes are to be attacked by the proper medicines, in order to its cure; when it ariſes from a carious tooth, there is no cure for it, but the drawing the tooth; when the impurities of the teeth occaſion it, the cleaning them proves a cure. *Juncker*'s Conſp. Med. p. 607.

FOETUS (*Cycl.*) — The formation of the bones in a *fœtus* is very gradual and regularly performed. In the firſt two months there is nothing of a bony nature in the whole; after this, the hardneſs of the parts where the principal bones are to be ſituated becomes by degrees perceptible. Dr. Kerkring deſcribes the progreſs of the oſſification from ſceletons which he had prepared from *fœtus*'s of two months, and thence up to nine. In the firſt two months, or till the end of that time, there appears not any thing bony; after this in the third and fourth months, and ſo on, the ſeveral parts one after another, acquire their bony nature. In the firſt ſtages every thing is membranous, where the bones are to be; theſe by degrees tranſmigrate into cartilages; and from theſe by the ſame ſort of change continued, the bones themſelves are by degrees formed. All this is done by nature, by ſuch ſlow, tho' ſuch certain progreſſions, that the niceſt eye can never ſee it doing, tho' it eaſily ſees it when done.

While *fœtus*'s continue in the womb, their muſcles commonly act only by their natural contraction, or the *fœtus* is ſaid to be in a ſleeping ſtate; but ſometimes, when its eaſe or preſervation requires a change of ſituation, it ſeems to perform ſome voluntary motions, which are called its *ſtirrings*. The poſture of the child in the womb, is owing to the muſcles being left to their natural contractions, the ſtronger always prevailing, till their antagoniſts exert ſuch a reſiſtance by being ſtretched, as brings them to an equilibrium. See *Monro*, in Medic. Eſſ. Edinb. vol. 1. p. 152.

Fœtuſes increaſe proportionally leſs, the longer they continue in the womb. Mauriceau pretends, that the increaſe of a child, is ſixty-four times its own weight in triple the time. Thus he ſays, that at the birth, a child weighs twelve pounds, of ſixteen ounces each; at the three months, it weighs three ounces; at one month $\frac{3}{4}$ of a drachm; and at ten days, leſs than half a grain. *Monro*, ibid. p. 153.

Nutrition of the FOETUS. How the nutrition of the *fœtus* is performed, is diſputed among the learned. Mr. Monro is of opinion, that the *fœtus* in viviparous animals is nouriſhed by the navel alone. He has given a curious diſſertation on this ſubject in the Medical Eſſays [a]. Where he obſerves, 1. That the *fœtus* is capable of receiving its whole nouriſhment by the umbilical vein alone, whereas no *fœtus* can ſubſiſt without the umbilical veſſels. 2. That the liquor of the amnios is ill calculated, in its natural ſtate, for the food of a *fœtus*; and becomes altogether unfit food in morbid caſes. 3. That it is highly improbable that a creature ſhould furniſh its ſubſiſtence out of its own body, which muſt be the caſe, if the *fœtus* feeds on the liquor of the amnios. 4. That it cannot be inferred from any reſemblance of the liquor of the ſtomach and amnios, nor from any other appearances, that the liquor of the amnios is ever ſent down into the ſtomach. 5. That no direct proof can be had of the liquor of the amnios, being preſſed or ſwallowed down; but on the contrary, all circumſtances make it probable, that it does not go down. 6. That all the phænomena of a *fœtus*, can moſt reaſonably be accounted for, without ſuppoſing the liquor of the amnios to be any part of its food; hence he thinks it reaſonable to exclude the mouth from the office of conveying the aliment of the *fœtuſes* of viviparous animals, and to believe that all their nouriſhment is conveyed by the umbilical veſſels. [[a] Ib. Vol. 2. Art. 9.] Hippocrates among the antients was of opinion, that the *fœtus* was nouriſhed both by the mouth, and by the umbilical veſſels. He maintains, that the child in the womb with its lips compreſſed together attracts nouriſhment; for which he aſſigns this reaſon; that unleſs the child had ſucked in utero, it neither could depoſit excrement, nor know how to ſuck ſo ſoon as it is born. Mr. Gibſon, in the Medical Eſſays of Edinburgh [a], has lately adopted this opinion; that the *fœtus* is nouriſhed by the mouth and by the navel alſo, as moſt probable. Mr. Monro, has anſwered him loc. cit. [[a] Vol. 1. Art. 13.]

Mr. Monro has given us ſeveral curious obſervations relating to the queſtion about the nutrition of the *fœtuſes* of oviparous animals. See Med. Eſſ. Edinb. Art. 10. or its Abridgment, vol. 1. p. 323, ſeqq.

He has alſo there conſidered the nouriſhment of plants in a *fœtus* ſtate. And he ſhews the analogy there is between theſe and animal *fœtuſes*. To fix the analogy between animals and plants, he obſerves, that the former may be ſaid to remain in the ſtate of a *fœtus*, ſo long as the young creature is ſolely nouriſhed by liquors furniſhed by the uterus of the parent; and plants are to be conſidered as *fœtuſes* only, while the ſeed is ripening, and before the earth, water, moiſture of the air, &c. have communicated immediately any matter for its increaſe.

The ſame author has given us ſome practical corollaries, from his eſſay on the nutrition of *fœtuſes* of viviparous animals, where he makes ſeveral very juſt obſervations relating to abortion, its cauſes, and the method of preventing it in many caſes. See Medic. Eſſ. Edinb. Vol. 2. Art. 11.

The liquors ſent into the *fœtus* by the umbilical vein, not having their propelling force communicated from the mother, the ſtate of the mother's pulſe cannot affect the child otherwiſe than by occaſioning abortion, or vitiating the fluids. Hence the impreſſions ſaid to be made on children by the imaginations of the mother, cannot be accounted for phyſically. Hence alſo children may be infected with the diſeaſed juices of the mother; but it is poſſible for them to eſcape catching their mother's diſeaſes, if either theſe be only topical, without affecting the whole maſs of the fluids; or even when the mother's blood is ſpoiled, the child may be free of her diſeaſe, if the morbid particles be ſuch as the placentary veſſels cannot abſorb. See Medic. Eſſ. Edinb. Vol. 2. p. 238.

The mother ſupplies liquors to the *fœtus*, which returns others to the mother, by means of the uterine and umbilical veſſels. This ſeems proved from obſervations; *fœtuſes* whoſe placenta were not in the leaſt ſeparated from the uterus, having been

been quite exhauſted of blood by the mother's dying of an hæmorrhage; and Mr. Monro acquaints us, that he has ſeen children pale and weak by violent floodings in the time of labour. See Medic. Eſſ. Edinb. vol. 2. art. 9.

The liquors are not carried from the mother to the *fœtus*, or from the *fœtus* to the mother by continued canals. That is, The uterine arteries and veins do not anaſtomoſe with the veins and arteries of the ſecundines; but the extremities of the umbilical vein take up the liquors by abſorption, in the ſame way as the lacteal veſſels do in the guts; and the umbilical arteries pour their liquors into the large cavities of the ſinuſes, or other cavities analogous to them. Vid. *Monro*, in Med. Eſſ. Edinb. vol. 2. p. 133, ſeq.

It is a queſtion, whence the *fœtus* has its red blood. Mr. Monro anſwers, that *fœtuſes* in viviparous animals have their red blood, from the ſame ſource that chickens in ovo have theirs; which can be no other than the action of their heart and of the veſſels in their body and ſecundines. See Medic. Eſſ. Edinb. vol. 2. p. 144.

A liquor is found in the thorax of *fœtuſes*, which Mr. Petit inclines to believe is furniſhed by the thymus. See Mem. de l'Acad. des Sciences, 1733.

Reſpiration ſeems to be the great act by which the change is made in animals, from the ſtate of *fœtus*, to that of motion, ſenſation, and the other qualities of animal life in their larger degree. Mr. Duverney obſerved this in the *fœtus* of a common ſnake: he broke the egg of one of theſe animals, at a time when it was juſt ready for hatching, and the young ſnake fell out rolled in a ſpiral, at firſt quite ſtiff and motionleſs; but it had no ſooner breathed three or four times, than it began to perform all the motions of animal life, in the moſt nimble and active manner.

We have a very ſurpriſing account in the Philoſophical Tranſactions of an extraneous body lodged in the bladder of an infant, which was born with many imperfections, and could not be expected to live any long time; on the opening the body after the death, there was found in the bladder a tough ſubſtance of the bigneſs of a ſmall fig, in the center of which was a pin with the head on, and grown very black. The child was opened in preſence of ſeveral perſons, who all ſaw this; but the moſt probable account of its coming there ſeems however not to have been in the *fœtus* ſtate, but by ſome accident after the birth. Philoſ. Tranſ. N°. 479, p. 365.

The *fœtus* often dies in the womb. This is diſcovered to be the caſe by the following ſymptoms. The mother becomes languid and weak, and is ſubject to frequent faintings. She complains alſo of flying heats and chilneſſes, ſucceding one another at ſhort intervals, and of ſtraitneſs of the præcordia, anxieties of mind, and vertiginous dizzineſs of the head. The breaſts tho' before diſtended and hard, grow flaccid on this, and have an abundance of a thin watery ſerum in them. The *fœtus* is not perceived to move, and the belly hangs upon the thighs with an uncommon dead weight; and is affected with a remarkable coldneſs. *Junker*' Conſp. Med. p. 710.

The death of the *fœtus* is often owing to a remarkably plethoric ſtate of the mother; and yet more frequently to her violent paſſions, whether of grief, anger, fear, or any other kind. The morbid conſtitution of the mother may alſo occaſion it, be it almoſt of any kind whatever, as will habitual diarrhœas. But the death of the *fœtus* is moſt frequently of all occaſioned by the bad ſucceſs of labour pains, or bad aſſiſtance in them, and by its being left conſtricted by the womb.

The expulſion of the dead child is to be attempted by all the forcing medicines, ſuch as borax, and the like; and the ſpirits and ſtrength are to be kept up during the attempt, by giving analeptics in the intermediate time; but if theſe medicines have not the deſired effect, the manual operation of the man-midwife, muſt be called in; and when the *fœtus* is taken out, the woman is to be treated with the utmoſt care in the common way of lying in women. *Junker*'s Conſp. Med. p. 711.

The accidents which attend a dead *fœtus* of conſiderable growth are well known, but the conſequence of its dying, while very young, is leſs underſtood. There is an account in the memoirs of the Paris academy, of a caſe of this kind, where all the circumſtances are very accurately delivered. A lady of Genoa, who found that ſhe was breeding, accidentally got a fall, but without perceiving that ſhe had received any great hurt. After the fall, her belly continued to grow big till the end of the fifth month, but after that time, it began to decreaſe inſtead of enlarging in ſize, and ſhe began to entertain ſome doubt, whether ſhe had been really with child or not; no motion of the *fœtus* had ever been perceived, nor had the lady ever the leaſt appearance of milk in her breaſts; about a month after this, that is, in her ſixth month of pregnancy, ſhe was delivered of a ſhapeleſs maſs of the bigneſs of a man's fiſt.

Mr. Anell who attended her, found that this was a kind of bag, formed by the chorion and amnios, and faſtened to a placenta of about two finger's thick, and filled with a fluid much reſembling milk, both in colour and conſiſtence. Near the middle of the placenta, there was an appendage of about two fingers long, which was the remainder of the umbilical cord, but there appeared no *fœtus*; and indeed a leſs curious obſerver than Mr. Anell might very eaſily have concluded, that there was none. This gentleman, however perſiſting in his ſearch, at length diſcovered it. It was very well formed, but not longer than a kidney bean, yet the head was very perfect, and there were rudiments of arms and legs, and the navel was cloſed. The principal things to be remarked in this extraordinary caſe are; 1. That the *fœtus* and the placenta had a very different age, the firſt being not above a month old, and the placenta and its membranes being of ſix months growth, and being of the ſize that thoſe parts uſually are, ſix months after pregnancy. 2. That the *fœtus* was entirely ſeparated from the navel ſtring; and 3. That it had been ſo well preſerved for ſo many months after its death, it not being at all corrupted. The *fœtus* naturally died by the injury received in the fall, the navel ſtring no longer conveying nouriſhment to it. After this the umbilical cord being unhurt, might continue to receive by the vein the blood drived to it from the placenta, and from the mother; but the dead *fœtus* could no more return that blood by the umbilical arteries; and this impoſſibility of any farther circulation, muſt make the cord ceaſe to grow any larger. On the other hand, the continual tranſpiration decreaſing its ſubſtance, it could not but diminiſh; and this is the more probable, as the *fœtus* when taken out of the bag, and put into ſpirits, diminiſhed in a little time to half its original ſize; which proves that the ſofter and leſs conſiſtent parts of theſe bodies eaſily evaporate. There muſt however have been a circulation in the placenta, as it grew larger to the time of the delivery.

The fall of the mother was plainly the cauſe of the breaking of the umbilical cord, and from hence followed all the other circumſtances; but it is not eaſy to explain how the *fœtus* became preſerved ſo long a time in a peculiar liquor furniſhed to the ſack. See DELIVERY.

FOAL, or *Colt*, the young of the horſe kind. The word *Colt* ſimply ſpoken, is among the dealers underſtood to mean the male kind; the female or mare *colt* being called a *Filly*.

Colts are uſually foaled in the beginning of ſummer, and it is the cuſtom to let them run with the mare till Michaelmas; when they are to be weaned. This is to be done ſooner or later according as the cold whether comes in. Some are for not having them weaned till the middle of November, and that three days before the full of the moon, if it happen near that time. And ſome of the beſt writers on this ſubject, are of opinion, that we do not let the *foals* ſuck long enough, and that this is the reaſon, why they are ſo very long before they are fit for uſe. Theſe authors are of opinion, that a *colt* ought always to ſuck the whole winter, and that this would make them fit for ſervice a great deal ſooner than they are at preſent.

When firſt weaned, they muſt be kept in a convenient houſe with a low rack and manger for hay and oats, that they may eat freely and eaſily, and the hay muſt be very ſweet and fine, eſpecially at firſt; a little wheat bran ſhould be mixed with the oats in order to keep their bodies open, and make them eat freely and drink freely.

It has been obſerved, that the eating too much oats has rendered *colts* blind; but the cauſe has been wrongly attributed to the heating quality of the oats. If the oats are bruiſed in a mill before they are given them, tho' they eat ever ſo much of them, there never happens any miſchief of this kind; but endeavouring with their teeth to break and chew them when whole, they are apt to ſtretch and ſwell the veſſels of the head, and occaſion a fullneſs of blood about the eyes, which often terminates in inflammations, and in blindneſs.

The difficulty of chewing oats, and not their heating nature, is therefore the true reaſon of this miſchief; and if this be obviated by the firſt bruiſing the grain, the *colt* always grows the better for eating it. His legs do not grow thick, but he becomes broader and better knit, and as he grows up, will beat fatigue much better than if he had been fed only with bran and hay. Above all things, theſe creatures are to be kept from wet and cold while they are young, for nothing is more tender than a *colt*, and the miſchiefs he gets at this time are not ſo eaſily got over. Experience ſhews the great advantage of houſing and taking care of *colts:* for if the ſame ſtallion cover two mares, both alike in age, beauty and all other particulars, and theſe bring both *foals* of the ſame ſex, ſo that there is no room to expect the leaſt difference between them; let one of theſe *colts* be houſed every winter, and let the other always run abroad, it will be found as they grow up, that the *colt* which has been kept abroad, ſhall have large fleſhy ſhoulders, flabby and gouty legs, weak paſterns, and bad hoofs, and ſhall be a dull heavy creature; and that the other which has been houſed and taken care of, ſhall have a fine forehand, be well ſhaped, have good legs and good hoofs, and be of good ſtrength and ſpirit. From this it may be learned, that it is of no conſequence to have a good ſtallion, and a good mare, if the *colts* are ſpoiled in the breeding up.

It is obſerved that ſome *colts* under the age of ſix months, tho' the mare yields plenty of good milk, yet decay and waſte daily. They are in this caſe always troubled with a cough. The breeders

breeders have a great many fantaſtic remedies in ſuch caſes, as the bag wherein the creature was foaled, the lungs of a fox and the like; but a little liquorice and elecampane powder mixed with honey and milk, is a remedy greatly to be preferred to all theſe.

When the *colts* are kept up in the winter, they are not to be continually immured in the ſtable, but in the middle of the day when the ſun ſhines warm, they ſhould always be let out to play about for an hour or two; and when the winter is ſpent, they ſhould be turned into ſome dry ground, where the graſs is ſweet and ſhort, and where there is good water, that they may drink at pleaſure. The winter after this, they may be kept in the ſtable without any farther care than that which is taken of other horſes; but after the firſt year the mare *colts* and the horſe *colts* are not to be kept together.

This may be the method every ſummer and winter till they are broke for uſe; which may be when they are three years old, and they will take the breaking much more eaſily, after this ſort of breeding, than if they had been all the time running about wild: for ordering them the ſecond year as the other horſes are ordered, they will be tame and gentle like them, and will not flounce and plunge about on the firſt mounting, as they otherwiſe would, but will take the ſaddle quietly. The common way of breaking a *colt* by beating him and tiring him by trotting over plowed fields, however neceſſary it may be to a *colt* that has always run wild, is not to be choſen when it can be avoided; for it is breaking and ſpoiling the creature's ſpirit. Uſing him to other horſes, and winning him by gentleneſs is a vaſtly preferable way. It is proper to wear no ſpurs for ſome time with a newly backed horſe.

In order to make him endure the ſaddle well, the way is to make it familiar to him, by clapping it with the hands as it lies on his back; then ſwaying upon it, and dangling the ſtirrups by his ſides, rubbing his ſides with them, and bringing him thus to be uſed to every thing about him. Then the crupper ſhould be often ſtrained, the girths looſened and tightened, and the ſtirrups taken up and let down at times, all the while making much of him. This will make every thing eaſy to him, and will make him gentle without breaking his ſpirit.

As ſoon as he will trot with the ſaddle obediently, the mouthing of him is to be conſidered. In order to this, put a trench of a full mouth into his mouth, and throw the reins over the fore part of the ſaddle, ſo that he may have a full feeling of it, then put on a martingale, buckled at ſuch a length that he may juſtly feel it when he jerks up his head. A broad piece of leather is then to be put round his neck, and the ends made faſt by plating it, or ſome other way at the withers, or before the wind-pipe, about two handfuls below the throppple, betwixt the leather and his neck; let the martingale paſs ſo that at any time when he offers to duck or throw down his head, the caveſſon being placed upon the tender griſtle of his noſe, may correct and puniſh him. This will make him bring his head to, and form him to the rein.

FOLDING *of ſheep*, a term uſed by our farmers to expreſs the keeping theſe creatures on their arable lands, within folds made of hurdles, which they remove about, ſo that when the ſheep have dunged one place they are ſet upon another.

This is a very great advantage to the land; the dung of theſe creatures being a very rich manure. It ought only to be done in ſummer time and in good weather, for the *folding* them in bad weather is apt to give them the rot. Care muſt be taken that they are only driven into theſe folds over night, and let out again in the morning, half an hour after ſun-riſe, into places where there is good food; for being hungry at this time they will eat whatever comes next them. Many ſheep are ruined by this practice in moiſt ground, and ſome farmers who think all *folding* very bad for ſheep, only ſtick up ſloping ſtakes in ſuch parts of the lands, as they would have dunged and never fold the ſheep at all, but truſt to their coming to theſe ſtakes to rub themſelves for the dunging the ground, as they conſtantly void their dung and urine at that time. *Mortimer*'s Husbandry.

FOLD-*foca*, in law. See FALDAGE, *Cycl.*

FOLDAGE and FOLD-COURSE. See FALDAGE, *Cycl.*

FOLIATE, in the higher geometry, a name given by ſome to a curve of the ſecond order expreſſed by the equation $x^3 + y^3 = axy$, being one ſpecies of defective hyperbolas, with one aſymptote, and conſiſting of two infinite legs croſſing one another, and forming a ſort of leaf.

FOLIATING (*Cycl.*) — The method of *foliating* globular looking glaſſes, delivered by Mr. Boyle, is ſomewhat different from that given by Sir Robert Southwell, in the Philoſophical Tranſactions and tranſcribed in the Cyclopædia.

Mr. Boyle's method, which he prefers to any he ever met with in print, is this: take tin and lead, of each one part, melt them together, and immediately add of good tin glaſs, or biſmuth, two parts; carefully skim off the droſs; then take the crucible from the fire, and, before the mixture grows cold, add thereto ten parts of clean quickſilver, and having ſtirred them well all together, keep the fluid in a new clean glaſs. When you go to uſe it, firſt purge it, by ſtraining it thro' linnen, and gently pour ſome ounces into the glaſs to be *foliated*, thro' a narrow paper funnel, reaching almoſt to the glaſs to prevent the liquor from flying to the ſides. After this, by dextrouſly inclining the glaſs every way, endeavour to faſten it to the internal ſurface; which done, let it reſt for ſome hours; then repeat the ſame operation, and ſo continue, at times, till the liquor is ſlowly paſſed over, and equally fixed to the whole ſuperficies; which may be diſcerned by expoſing the glaſs to the eye between that and the light. *Boyle*'s Works Abr. Vol. 1. p. 129.

FOLIS or FOLLIS, a ſmall coin in uſe among the Greeks and Romans; it was firſt made of braſs, and afterwards of ſilver. Authors are not agreed as to the value of this coin. Vid. *Pitiſc.* Lex. Ant. in voc.

FOLIUM *branchiarum*, *the leaf of the gills*, a term uſed by ſome of the ichthyologiſts, to expreſs that part of the *gills* which looks red and fringed. The *gills* of fiſh are compoſed of certain bony circles which are formed on the convex ſide with a great number of laminæ; theſe ſerve to receive the ramifications of the arteries, and are called the *folium* or leaf of the gills. The aorta or great artery reaches no farther than this part in fiſh. It has no deſcending trunk, but every part of the body is ſupplied by a large venal trunk, formed by the joining of the ſeveral ſmaller trunks of the ſeveral circles of the gills. *Artedi*, Ichthyol.

FONCEAU, in the manege, is the bottom or end of a canon-bitt-mouth; that is, the part of the bitt that joins it to the banquet. See CHAPERON.

FONGITES, a name given by the writers of the middle ages to a ſtone famous for its imaginary virtues. Authors are very vague in their deſcriptions of it; ſome deſcribing it as pellucid and colourleſs, like cryſtal; others, as opake and of a flame colour; and ſome ſay, that it was partly of the one and partly of the other of theſe colours. It is ſaid to mitigate pain, on being held for ſome time in the hand.

FONTINALIS, in botany, the name of a genus of moſſes the characters of which are theſe. The capſules are ſeſſile, or have either no pedicles, or extremely ſhort ones; they are not naked as in the ſphagna, but are covered with calyptræ, and are included beſides in a membranous huſk, by which laſt particular, they are diſtinguiſhed from the hypnums, bryums and other moſſes which produce capſules. See Tab. of Moſſes, N° 9. There are only five known ſpecies of this genus. 1. The common large triangular *fontinalis*: this floats in the water and is compoſed of ſtalks of five, ſix, or even twelve inches long; the the ſtalks are ſlender and black, and the leaves pellucid and of a fine green. The heads in this ſpecies are uſually produced in the lower part of the plant. 2. The leſſer triangular *fontinalis*. The ſtalks in this ſpecies are ſhorter and leſs branched, and the capſules are produced from the tops of the branches. 3. The fine leaved ſhining black *fontinalis*, the leaves of this are pellucid, very thin and blackiſh: it is found in rivers in mountainous countries. 4. The ſmall lancet leaved *fontinalis*. This is produced in Patagonia. 5. The fine leaved *fontinalis*, with pointed ſheaths, this is found in Penſylvania. *Dillen.* Hiſt. moſc. p. 256.

FOOD (*Cycl.*) — Phyſicians have attempted to determine the healthful quantity of *food* for a human body. Some ſay, that in winter, where the perſpiration of an unexerciſed perſon is only equal to the urine, the diet for twenty-fours, ought not to exceed four pounds, or four pounds and an half. In ſummer the diet may be ſix pounds and an half, which may be carrid off without the help of exerciſe, when the air is hot and dry.

Dr. Bryan Robinſon [a], thinks, that if the quantity of *food* be ſuch as to make the perſpiration and urine of a natural day always nearly equal, and the morning weight of the body always nearly the ſame, that quantity is the truly healthful quantity of *food* for grown bodies, who uſe but little exerciſe. [a Of the food and diſcharge of human bodies, p. 93.]

The quantity of *food* neceſſary to keep a grown body in health, will be better and more eaſily digeſted, when it is ſo divided, as to make the meals equal, than when they are very unequal. The diſtance between one meal and another, ſhould bear ſome proportion to the largeneſs of the preceeding meal. *Robinſon*, ibid. p. 94.

The ſame author thinks, that good and conſtant health, conſiſts in a juſt quantity of *food*, and a juſt proportion of the meat to the drink; and that to be freed from chronical diſorders contracted by intemperance, the quantity of *food* ought to be leſſened, and the proportion of the meat to the drink increaſed more or leſs, according to the greatneſs of the diſorders; and that both the quantity of *food*, and the proportion of meat to drink ought to be ſuch as ſhall make perſpiration and urine nearly equal at all ſeaſons of the year. See his Diſſer. on the food and diſcharge of human bodies, p. 6.

FOOD *of plants*. — What is generally underſtood by this term, is ſuch matter of whatever kind, as being added and united to the firſt ſtamina of plants or plantulæ, at their ſowing, or to their roots, and thence to their trunks and other parts afterwards, gives them their increaſe, or in other words, is itſelf the matter of that increaſe. The great art of the husbandman is the giving this *food* to plants, in the beſt manner, and to the

the greateſt advantage. But before he can expect to arrive at any true knowledge in this article, it is neceſſary that he ſhould know what this *food* or matter of nouriſhment is. There are five things generally allowed to contribute to the growth and increaſe of plants; theſe are nitre, water, air, fire and earth; but it has been much diſputed which of all theſe it is that increaſes, or is properly the *food* of the plant. Many people ſay much of the acid ſpirit reſiding in the air, but as this is ſharp enough to corrode iron bars it is too ſharp to be fit for nouriſhing tender plants. As to nitre, it is ſaid to nouriſh them; but its true office is not actualy nouriſhing, but preparing other things to nouriſh them. Nitre applied to the root of a plant will kill it; but at a diſtance, ſo attenuates, cuts and divides the viſcous matters found in the earth, that after this they are fit to nouriſh plants, tho' they were not ſo before. Water has been thought by ſome the only *food* of plants, but Van Helmont's famous experiment, uſually brought to prove this is nothing, for the water contains earth, and therefore is never given to a plant as water alone.

Air becauſe of its elaſticity, is neceſſary to the increaſe of plants, but it is not that increaſe, tho' Bradley and others have taken great pains to prove, that it is ſo. As to fire, we are very well aſſured indeed, that no plant can live without heat; but tho' different degrees of it, are neceſſary to different plants, yet none can live in actual fire, nor has fire ever been thought the food of plants except by Mr. Lawrence, and ſome of the metaphyſicians. This author indeed, ſays, plants are true fire-eaters, and others explain away the meaning of the phraſe, by defining that fire to be only the minuteſt particles of earth put in motion; if this be the caſe, probably enough the doctrine may be true. But in plain fact, earth alone is the true food and matter of increaſe of plants. Every plant is earth, and the growth and increaſe of that plant, is only the addition of more earth to it, in the ſame form. Nitre and other ſalts, as thoſe of dung, &c. prepare, attenuate, and divide the earth, deſtined for the increaſe of vegetables; water and air move it by conveying, and fermenting it in the juices; but earth itſelf ſtill is the *food*. When the additional earth is once aſſimilated to the plant, it becomes a part of it, and remains for ever with it; but let water, air and heat, be taken away, and the plant remains a plant ſtill, tho' a dead one. *Tull*'s Horſehoeing Husbandry, p. 13.

The exceſs of the other things, proves, that they are not the proper *food* of the plant, by deſtroying not nouriſhing it. Too much nitre or other ſalts corrode and kill the plant, too much water drowns it, too much air dries the roots of it, too much heat burns it: but too much earth a plant never can have, unleſs wholly buried under it, ſo as to exclude the neceſſary action of the reſt of the aſſiſtant articles. Too much or too fine earth can never be given to the roots of a plant, for they never take up ſo much of it, as to ſurfeit the plant, unleſs it be deprived of leaves which ſhould purify it. Nay earth is ſo ſurely and ſo eſſentially the *food* of all plants, that with the proper ſhare of the other acceſſary elements, any earth, no matter of what kind, will ſerve for the nouriſhment of any plant.

FOOT (*Cycl.*) — *Bleeding in the* FOOT. Bleeding in the *foot*, is an operation of very old ſtanding, and has been uſed by the oldeſt phyſicians, for diſorders of the head and breaſt, and for obſtructions of the menſtrual, and habitual diſcharges by the hæmorrhoidal veins. It has been of old ſuppoſed, that the bleeding from the ſaphæna was more particularly ſerviceable in ſome caſes, and from the cephalica in others; but this is now known to be highly erroneous, and the ſurgeon is always to take that which lies faireſt and moſt conſpicuous. If the veins on the metatarſus or inſtep, do not appear ſo fairly as might be wiſhed, it is common to take one of thoſe about the ankle, or the calf of the leg or ham.

The patient to be blooded in the *foot*, muſt firſt keep both *feet* ſome time in warm water, that the veins may become turgid, and the ſurgeon have his choice, which he will take. Having fixed upon the proper *foot*, the ligature muſt be made about two fingers breadth above the ankle, and the patient muſt then return the *foot* into water. The ſurgeon is to kneel on one knee, and having wiped the *foot* dry, to put it either againſt his other knee, or upon a board placed over the veſſel of hot water, and the vein muſt be held ſecure from ſlipping away, with the left hand, while the orifice is made with the other. If the blood does not flow freely, the *foot* muſt be returned into the warm water, till by the colour of the water, ſtrength of the patient, &c. it is found to have bled enough. *Heiſter*'s Surgery, p. 280.

Cartilages of the FOOT. The aſtragalus is covered by three cartilages; the firſt covers the ſurfaces which make the convex part and ſides of the pully; the ſecond the concave ſurface of its inferior part, and the third the convex ſurface of its anterior part, being continued over the inferior part, ſo far as to form three other ſmall ſurfaces; one of which is not articular in a ſtrict ſenſe. The firſt of theſe cartilages is for the articulation of this bone with the tibia and fibula, the ſecond for the os calcis, and the third for the os ſcaphoides; two of the inferior ſurfaces formed by the continuation of the third cartilage, are for the articulation of this bone with the os calcis; and the third contributes to the formation of a channel for the paſſage of a tendon.

The os calcis has four cartilages, of which three are ſuperior, one large and two ſmall for its triple articulation with the aſtragalus; the fourth is anterior for the os cuboides. And to theſe muſt be added a ſmall thin cartilage of a kind of ligamentary ſubſtance, under the tubercle on the outſide of this bone. The os ſcaphoides has two cartilages; one poſterior for its articulation with the aſtragalus, and one anterior, divided into three parts, for the three oſſa cuneiformia.

The os cuboides has two remarkable cartilages, one poſterior for its articulation with the os calcis, the other anterior lying in two planes, for its articulation with the two laſt metatarſal bones, it has likewiſe a cartilage on the inſide for the os cuneiforme which is next to it, and one on the lower part, covering an oblique eminence ſituated there.

The three oſſa cuneiformia have each of them a poſterior cartilage for their articulation with the os ſcaphoides, and one anterior for the three firſt metatarſal bones; they have likewiſe ſmall cartilaginous ſurfaces on their lateral ſides for their articulations with each other; and beſide, the firſt and third bones are joined thereby, to the lateral parts of the baſis of the ſecond metatarſal bone, and the third to the os cuboides. The baſes and heads of the metatarſal bones are covered with cartilages. The phalanges alſo have, in the ſame manner, cartilages at their baſes and heads, except at the heads or extremities of the laſt. The ſeſamoide bones are covered with cartilages on that ſide, by which they ſlide on other bones; but great caution is required not to confound the remains of tendons, ligaments, and aponeuroſes with the true cartilages, particularly on the poſterior part of the os calcis. *Winſlow*'s Anatomy, p. 132.

Ligaments of the FOOT. The *foot* being made up of many bones, muſt neceſſarily beſide thoſe ligaments, by which it is tied to the bones of the leg, have ſeveral others to connect not only the three parts of which it is compoſed, but alſo the particular bones of each part to one another. In each ankle there are three ligaments for their articulations with the *foot*. One anterior, one middle, and one poſterior. The ligaments of the inner ankle are all fixed with the inſide of the aſtragalus; the anterior and middle ligaments of the outer ankle, are more or leſs broad and are fixed in the outſide of the aſtragalus, the poſterior which is the narroweſt and pretty thick is chiefly fixed in the outſide of the great portion of the os calcis. All theſe ligaments lie on the outſide of the capſula, which ſurrounds the articulation of the aſtragalus with the bones of the leg. The ligaments by which the bones of the tarſus are connected to one another, are ſhort, flat, of different breadths, and run from one bone to another, in different directions. Some of theſe are common to ſeveral bones, and others belong only to two. The aſtragalus is tied to the other bones of the tarſus by ſeveral true ligaments; to the inſide of the os calcis, by one which comes from the lateral apophyſis of the os calcis, in an inequality on its hinder part, and is fixed again to the poſterior internal tuberoſity of the body of the aſtragalus, to the outſide of the ſame bone, by two ligaments which come from the edge of the oblique inferior depreſſion of the aſtragalus, and afterwards ſeparating a little, are fixed in the outſide of the great apophyſis of the os calcis, one forward which ſeems to ſend off a ſmall portion to the os cuboides, and the other backward of different breadths; to the os ſcaphoides ſuperiorly by a ligament, which goes from the neck of the aſtragalus, to the upper part of that bone, and from thence is extended to the middle of the os cuneiforme, to the ſame bone internally by two ligaments, one of which is a continuation of that which goes from the lateral apophyſis of the os calcis to the cartilaginous production of the aſtragalus; the other is near the ſame production, being partly covered by the former, and fixed in the tuberoſity of the os ſcaphoides, to the os calcis, by a ligament which comes from the oblique inferior depreſſion of the aſtragalus, and is fixed in the oblique ſuperior depreſſion of the os calcis; and to theſe the principal ligaments of the aſtragalus, ſeveral ſmaller may be added which are uſually ſeen and increaſe the number very greatly.

The capſular ligaments go very little farther than the edges of the articulations of this bone with the reſt; they adhere very cloſely to the true ligaments, and are covered and hid by them.

The os calcis is connected to the os ſcaphoides, by a continuation of the ligament that goes from its lateral internal apophyſis to the cartilaginous production of the aſtragalus, by a ligamentary plane, which goes from its great apophyſis, to the inferior part of the ſcaphoides, and by a narrower ligament which goes from the ſuperior internal part of its great apophyſis, and ends in the neareſt part of the circumference of the ſcaphoides. It is connected to the os cuboides, by ſeveral ligamentary faſciculi, which go from its extremity in its ſuperior oblique depreſſion, to the contiguous angle of the os cuboides, by one from near the lateral external tuberoſity of the os calcis, to a part of the cuboides near the former; by one fixed to the exterior and inferior part of the great tuberoſity of the os calcis, to the contiguous part of the cuboides; by a pretty broad plane, which covers the inferior part of the os calcis, and ends in the oblique eminence of the cuboides; and by a broader plane which

filling

filling the lower part of the lateral concavity in the os calcis, is chiefly inſerted in the contiguous angle of the os cuboides. The capſular ligaments agree with thoſe of the aſtragalus.

The os ſcaphoides is tied to the os cuboides on its outſide by one ligament, which connects it to the contiguous angle of that bone: on its upper part two go from it to the ſecond and third oſſa cuneiformia; on its anterior ſide it is joined to the convex ſide of the great os cuneiforme by two ligaments, and on its lower, it has four; the firſt appears double, and goes from the tuberoſity of this bone to the baſis of the firſt os cuneiforme, the ſecond and third go obliquely to the ſecond and third os cuneiforme, and the fourth is a little tranſverſe, being fixed in the inferior internal angle of the os cuboides.

The os cuboides, beſide thoſe already deſcribed, has ligaments which tie it above, below, and on the outſide with the third os cuneiforme, and the two laſt bones of the metatarſus; the ſuperior ligaments are almoſt equally flat, the inferior irregularly thick and ſtronger than the ſuperior. The three oſſa cuneiformia are connected together on their upper part by particular ligamentary planes, which go more or leſs tranſverſely, from one bone to another, being all joined to one common ligamentary plane which covers theſe three bones; and alſo to the os cuboides, they are alſo connected by ligaments to the three firſt bones of the metatarſus.

The bones of the metatarſus are connected together by their baſes, and heads, the ligaments which go between the baſes are ſuperior and inferior. The ſuperior ſmall and flat, the inferior, ſtrong and thick; thoſe between their heads have nearly the ſame diſpoſition, but the inferior have this peculiar to them, that by filling up the ſpaces between the heads, they keep them at ſome diſtance from one another; the inferior portions are fixed in the angles at the lower part of each head, and are ſtrengthned by their union and intexture with the aponeuroſis plantaris. *Winſlow*'s Anatomy, p. 134.

Bathing of the FEET. See PEDILUVIUM.

Fractures of the FEET. The bones of the *foot* which compoſe the tarſus, the metatarſus and toes, are equally liable to fractures with the other bones, but by reaſon of the great complication of nerves, tendons, ligaments and membranes, fractures in this part are uſually attended with very bad ſymptoms. The bones are carefully to be replaced and ſecured by bandage; but fractures of the *feet*, like thoſe of the hands can ſeldom be ſo perfectly cured, as not to leave a ſtiffneſs or want of motion behind; if the patient ſhould be ſo happy as to eſcape ulcers, caries, or incurable fiſtulæ. Theſe bad ſymptoms when they appear in the courſe of the cure, are no way to be remedied, but by the amputation of the limb, nor will that indeed always ſecure the patient from death. *Heiſter*, p. 138.

Dr. Waltherus has given a minute deſcription of the muſcles and ligaments of the ſole of the foot, in the Nova Act. Erudit. Lipſ. April 1732.

FOOT, in meaſuring — In Scotland, this meaſure of length, tho' conſiſting of twelve inches, exceeds the Engliſh *foot*, ſo that 185 of the former is equal to 186 of the latter. Treat. Pract. Geom. p. 4. See MEASURE, *Cycl.*

FOOT, in the manege, is the extremity of a horſe's leg, from the cronet to the lower part of the hoof. The four *feet* are diſtinguiſhed by four different names: the two fore *feet* are by ſome called the hands of a horſe; but that term is in diſuſe, the common expreſſion being the *far fore foot*, to denote the right *foot* before; and the *near fore foot*, the *ſtirrup foot*, and the *bridle-hand foot*, to denote the left foot before.

Of the two hinder *feet*, the right is called the *far hinder foot*; and when ſpears were uſe, 'twas called the *ſpear foot*, becauſe in reſting the ſpear, the ſocket of it anſwered the right hinder *foot*. The left-hind-*foot*, is called the *near foot behind*.

FOOT-*derobé*, in the manege. A horſe's *foot* has this appellation when it is worn and waſted by going without ſhoes, ſo that for want of hoof, it is a hard matter to ſhoe him.

A horſe's *foot* is ſaid to be worn and waſted, called in French *uſé*, when he has but little hoof, and not enough for ſhoeing.

To gallop upon a good FOOT, or put a horſe upon a good *foot*, called in French *ſur le bon pied*. See *falſe* GALLOP.

Fat FOOT, in the manege. A horſe is ſaid to have a *fat foot*, when the hoof is ſo thin and weak, that unleſs the nails be driven very ſhort, he runs the riſque of being pricked in ſhoeing. The Engliſh horſes are very ſubject to this diſorder.

FOOT is alſo uſed for the *foot* ſoldiers, or the infantry of an army. See BATTLE.

FOOT-*hooks*, in a ſhip, ſee FUTTOCKS.

FORAMEN (*Cycl.*) — FORAMEN *auditorium internum*, in anatomy, is ſituate in the backſide of the apophyſis petroſa, in ſome meaſure behind the veſtibulum and baſis of the cochlea. It is a kind of blind hole divided into two foſſulæ, one large, the other ſmall; the large one lies loweſt, and ſerves for the portio mollis of the auditory nerve, or ſeventh pair; the ſmall one is uppermoſt, and is the opening of a ſmall duct, thro' which the portio dura of the ſame nerve paſſes. The inferior foſſula is full of little holes, which in the natural ſtate are filled with nervous filaments of the portio mollis, which go to the ſpindle, to the ſemicircular canals, and to thoſe of the cochlea. It is this foſſula which forms that ſhallow cavity at the baſis of the ſpindle of the cochlea. The paſſage of the portio dura of the auditory nerve runs behind the tympanum, and its orifice is the ſtylomaſtoide hole. Fallopius gave this duct the name of the aqueduct, from its reſemblance to the aqueducts in Italy. It begins by the ſmall foſſula, and pierces from within outwards, the upper part of the apophyſis petroſa, making there an angle or curvature; from thence it is inclined backward behind the ſmall pyramid of the tympanum, and runs down to the ſtylomaſtoide hole, thro' which it goes out. It communicates likewiſe by a ſmall hole with the ſinus of the pyramid, and lower down by another hole with the barrel of the ear. In ſome ſculls this aqueduct of Fallopius is open on the upper part of the apophyſis petroſa, a kind of break appearing in it, formed by a double hole. It is at this place that it makes the angle already mentioned, but it is commonly covered with a bony lamina. *Winſlow*'s Anat. p. 52.

FORAMEN *ovale*. — The anatomical diſcoveries of the ſeveral parts and their conſtructions, does not always bring with them the certain knowledge of the uſes of thoſe parts. The heart, the arteries, and the veins of the human body, have been known for many ages; yet the uſes of theſe ſeveral parts for the circulation of the blood was reſerved for a later diſcovery. The circulation of the blood in the fœtus is a thing yet not perfectly underſtood, nor are we well aſſured, whether it paſſes in the heart from right to left, or from left to right, or whether by means of the *foramen ovale*, it may not paſs at once in both thoſe directions.

The different method of the circulation of the blood in adults, and in the fœtus in the uterus, is owing to the different conſtruction of certain parts. We very well know that in adults, the blood going out from the right ventricle of the heart, is carried by the great artery and the two pulmonary branches, throughout the whole extent of the lungs, and thence by the pulmonary veins is returned into the auricles, and left ventricle of the heart, from whence it is diſtributed throughout every part of the body, thro' other arteries, and is returned thence to the heart again by other veins, into the right ventricle, to continue this certain courſe, during the life of the animal.

The courſe of the blood thro' the heart ſuppoſes therefore two circulations, the one a ſmaller and ſhorter courſe of all the maſs of blood from the heart to the lungs, and thence to the heart back again. The other a much greater, and by a much longer courſe, by which the whole maſs of blood parting out of the left ventricle of the heart is diſtributed by numbers of veſſels into every part of the body for the nouriſhment and increaſe of the parts, without excepting any part of the human frame, and returns thence into the right ventricle, to be thence ſent into the lungs again. Memoirs Acad. Scien. Par. 1739. See CIRCULATION.

Tho' this is however the caſe in adults, it is far otherwiſe in regard to the circulation in the fœtus; for beſide the placenta, the umbilical veſſels and the venal canal, which are peculiar to the animal in that ſtate, the ſeptum which divides the two auricles of the heart, is at this time perforated by an aperture which is called the *foramen ovale*; and the trunk of the pulmonary artery a little after it has paſſed out of the heart, gives riſe to a canal called the arterial canal, or canal of communication, which terminates in and diſcharges the blood which paſſes into it into the deſcendant aorta.

As ſoon as the fœtus is born, the *foramen* begins to ſhut, and by degrees becomes wholly cloſed, and the arterial canal dries up and degenerates into a mere ligament.

Anatomy informs us, that in adults, the blood which paſſes thro' the pulmonary artery, in order to its being diſtributed thro' the lungs, does not make that circuit on account of the lungs, but merely on its own account, that is to ſay, to be itſelf altered by the change the air we reſpire is capable of making in it; for the lungs themſelves are in reality nouriſhed by that blood which is derived into them by means of the bronchial artery.

As the fœtus therefore while it remains in the womb does not reſpire, it would be a wholly uſeleſs circuit for the blood in that ſtate of the body, to make this ſhorter paſſage of the whole maſs thro' the lungs, as it does in adults, before it arrives at the left ventricle, and is thence diſtributed throughout the whole body; and as the blood would in this ſtate of the the animal, make a needleſs and a uſeleſs paſſage thro' the lungs, ſo would it alſo, while making that circuit, be wanted in thoſe parts, to whoſe nouriſhment and growth it is extremely wanted; and what afterwards determines the blood to take the circuit of theſe parts and to drive itſelf into them with all poſſible ſpeed, is a ſeries of neceſſary conſequences which happen at that time.

When we conſider what it is that happens to a fœtus at its coming forth from the womb, and that it at that time firſt reſpires, it is eaſy to conceive that this new action of reſpiration, cannot but neceſſarily hurry the blood toward the lungs, and that the extenſion which the inſpired aerial particles make in the lungs, gives place to a much larger quantity of blood than before, to fill the veſſels there; and conſequently in that inactive ſtate in which the lungs in the fœtus are continually placed, before it has ever yet reſpired, we may conclude, that the

the blood passes thro' their substance with difficulty, and in but very small quantity, since the lowness of the sides of the lungs, the largeness of the thymus, and the arch formed by the diaphragm cannot but keep them in a continual state of compression. This compression of the lungs does that to the pulmonary arteries, that a ligature would do, which should prevent a part of the blood passing thro' those arteries at every systole of the heart, and cannot suffer them to become depressed, or to part at every such systole in the time required for it, with more than perhaps, a fourth, a third, or the half of that blood, which they use to receive at every pulsation. It is easy to conceive, that the blood thus left behind in the vessels of the lungs from one pulsation to another, and mixed with the new blood of still succeeding pulsations, must, in thus accumulating itself by degrees, more and more separate and distend the sides of the vessels, and more augment their diameters, than would have been the case, if from the beginning the ramifications of the arterial vessels of the lungs had been more perfectly empty: for tho' at every pulsation, there passes certainly from the trunk of the artery, but a small quantity of blood into the ramifications of the vessels of the lungs, yet this small quantity added to the excess of the former pulsations, and mixed with them, must in process of time, form a little mass, and produce an extension and considerable bulk in the vessels.

It is not difficult to conceive that the compression of the pulmonary vessels will make its effects sensible at greater distances than barely the extent of those vessels, and that indeed not only to the *foramen ovale*, but also to the left ventricle of the heart and to the aorta; that the blood which is carried back by the reflux toward the *foramen ovale*, must naturally become less and less, as the new born infant enjoys the benefit of respiration, and the blood of the two pulmonary arteries, finds its access as easy as it was before difficult; and finally, that of all the blood which arrives every instant at the heart, there will be only a small part that will make its way thro' the lungs; the greater quantity, while the *foramen ovale* remains yet open, finding itself a much shorter passage, by means of that aperture, and of the yet open arterial canal.

It is evident therefore, from all that has been observed, that the *foramen ovale*, and the canal of communication in the fœtus are in reality, no other than a sort of subsidiary parts to the lungs, formed only for a certain time, and to become useless, and disappear when the act of respiration has given the turn to the circulation of the blood, which it is to retain thro' the whole life of the animal. Memoirs Acad. Scien. Par. 1739.

Dr. Trew does not agree with Monsieur Mery's hypothesis, which he has minutely examined, and affirms, that the membrane of the *foramen ovale* is so placed as to permit the blood to pass freely from the right auricle to the left, during the diastole of the auricles, but never from the left auricle to the right. Phil. Trans. N°. 457. Sect. 7.

The *foramen ovale* has sometimes been found open in adults. See Phil. Trans. N°. 460. Sect. 5.

FORCE, in mechanics. See the *Appendix*.

FORCEPS (*Cycl.*) — Mr. Monro describes and gives a figure of a *forceps*, the mouth of which has on each side two small sharp teeth, which apply close to one another, when it is shut. This *forceps* when shut may be safely introduced into a gun-shot wound, and the blades being immediately opened behind the bullet, the teeth will pierce into the lead, and hold it fast enough to bring it out, tho' they are not advanced so far as the largest part of it. Med. Ess. Edinb. vol. 5. art. 41.

FORCING, in the wine trade, a term used by the wine-coopers for the fining down wines, and rendering them fit for immediate draught. See FINING.

The principal inconvenience of the common way of fining down the white wines by isinglass, and the red by whites of eggs, is the slowness of the operation; these ingredients not performing their office in less than a week, or sometimes a fortnight, according as the weather proves favourable, cloudy, or clear, windy or calm: this appears to be matter of constant observation. But the wine merchant frequently requires a method that shall, with certainty, make the wines fit for tasting in a few hours. A method of this kind there is, but it is kept in few hands a valuable secret. Perhaps it depends upon a prudent use of a tartarized spirit of wine, and the common *forcing*, as occasion is, along with gypsum, as the principal; all which are to be well stirred about in the wine, for half an hour before it is suffered to rest. *Shaw*'s Lectures, p. 208.

FORCING, among gardiners, is used for producing ripe fruits from trees before their natural season. The method of doing it is this; a wall should be erected ten foot high; a border must be marked out on the south side of it, of about four foot wide, and some stakes must be fastened into the ground all along the edge of the border; these should be four inches thick. They are intended to rest the glass lights upon, which are to slope backwards to the wall, to shelter the fruit as there shall be occasion; and there must be at each end a door to open either way according as the wind blows. The frame should be made moveable along the wall, that when a tree has been *forced* one year the frame may be removed to another, and so on, that the trees may be each of them *forced* only once in three years, at which rate they will last a long time. They must be always well grown trees that are chosen for *forcing*, for young ones are soon destroyed, and the fruit that is produced from them, is never so well tasted. The fruits most proper for this management are the avant, or small white nutmeg, the albermarle, the early Newington, and the brown nutmeg peaches; Mr. Fairchild's early, and the elrugo and Newington nectarins; the masculine apricot, and the may-duke and may-cherry. For grapes, the white and black sweet-water, are the propereſt; and of gooseberries, the Dutch-white, the Dutch early-green, and the walnut-gooseberry; and the large large Dutch white, and large Dutch red currants.

The dung before it is laid to the wall should be laid together on a heap for five or six days, that it may heat uniformly thro', and when thus prepared, it must be laid four foot thick at the base of the wall, and go sloping up, till it is two foot thick at the top. It must be laid at least within three or four inches of the top of the wall, and when it sinks, as it will sink two or three feet, fresh dung must be laid; for the first heat will do little more, than just swell the blossom buds. The covering the trees with glasses is of great service, but they should be taken off to admit the benefit of gentle showers to the trees, and the doors at the ends should be either left intirely open, or one or both of them opened, and a mat hung before them, at once to let the air circulate and to keep out the frosts.

The dung is never to be applied till toward the end of November, and three changes of it will be sufficient to ripen the cherries, which will be very fine in February. As to the apricots, grapes, nectarines, peaches and plumbs, if the weather be milder, the glasses are to be opened to let in sunshine or gentle showers.

If a row or two of scarlet strawberries be planted at the back of the frame, they will ripen in February, or the beginning of March; the vines will blossom in April, and the grapes will be ripe in June.

It should be carefully observed not to place early and late ripening fruits together, because the heat necessary to force the late ones will be of great injury to the early ones, after they have fruited.

The masculine apricot will be ripe in the beginning of April, the early nectarines will be ripe about the same time, and the forward sort of plumbs by the latter end of that month. Gooseberries will have fruits fit for tarts in January or February, and will ripen in March, and currants will have ripe fruit in April.

The trees need not be planted so distant at these walls as at others, for they do not shoot so freely as in the open air: nine feet asunder is sufficient. They should be pruned about three weeks before the heat is applied. *Miller*'s Gard. Dict.

FOREFANG, or FOREFENG, in our old writers, is the taking of provision from any one in fairs or markets, before the king's purveyors are served with necessaries for him.

The word is Saxon, compounded of *fore*, ante, and *fangen*, prendere.

FOREGAVEL, *forgabulum*, in our old writers, is used for a small reserved rent in money, or quit-rent.

FOREGOERS, in our old writers. The king's surveyors were thus called from their *going before*, to provide for his household. 36 Ed. III. 5.

FOREHEAD. *Wounds of the* FOREHEAD. After a wound in this part is cleansed from grumous blood and extraneous bodies, if any were left there, it should be dressed with balsam of Peru, or some other vulnerary balsam; the lips of the wound are then to be kept together by long slips of sticking plaister, and over this a vulnerary plaister is to be laid. Where the wound is large, these plaisters will not be sufficient to bring on an even cicatrix; therefore to forward this end, the wound should be sprinkled with a compound powder of comfrey root and gum tragacanth and arabic, and with gum sarcocolla in powder; and then the plaisters, compresses, and proper bandages are to be applied. The bloody suture is never to be used in any wound of the face if it can be avoided, because the stitches increase the number of the scars. If a wound of the *forehead* is made in a strait line, the uniting bandage will be of great service in forming a fine cicatrix: but if the *forehead* is wounded transversely, and the fibres of the frontal muscle are divided, it occasions a great deformity; for the power of lifting up the eye-brows, and of contracting the skin of the *forehead* ceases. In this case after cleaning the wound, it is best to unite it with a stitch or two, dressing it with a vulnerary balsam and laying on sticking plaisters, securing all with a proper bandage, and enjoining the patient to keep himself still. In young and healthy persons, the fibres of the muscles join and unite when this method is used, without coming to a suppuration. *Heister*'s Surg. 78.

FORE-JEER-*bits*, in a ſhip. See BITS.

FOREIGN (*Cycl.*) — *Foreign* ſeamen ſerving two years on board Britiſh ſhips, whether of war, trade, or privateers, during the time of war, ſhall be deemed natural born ſubjects [a]. But the perſons ſo naturalized are not capable of being of the privy council, or members of parliament, or of taking any place of truſt, civil, or military, or to have any grant from the crown of lands [b]. [[a] Stat. 13 Geo. 2. c. 3. Sect. 2. [b] Ibid Sect. 3.]

Foreigners reſiding ſeven years in the Britiſh plantations without any longer abſence than two months at one time, and taking the oaths, are to be deemed natural born ſubjects [a]. But excepting Quakers and Jews, all other perſons muſt receive the ſacrament in ſome proteſtant or reformed congregation in Great Britain, or the colonies; a certificate whereof muſt be produced at the time of taking the oaths [b]. [[a] 13 Geo. 2. c. 7. Sect. 2. [b] Ibid. Sect. 3.] See NATURALIZATION.

FORELLA, in ichthyology, a name given by Figulus and others to the trout.

FORE-MAST-MEN, in a man of war, thoſe on board that take in the top-ſails, ſling the yards, furl the ſails, browſe, triſe, and take their turn at the helm, &c.

FORE-REACH, at ſea. The ſeamen ſay one ſhip *fore-reaches* upon another, when both ſailing together, ſhe ſails better, or outgoes the other.

FOREST (*Cycl.*) — FOREST *trees*. Many are wholly averſe to pruning *foreſt trees*; but tho' it is to be done with care, and under proper regulations; (See LOPPING.) yet it is by no means to be wholly omitted. It may be obſerved in *foreſts* and large woods, that for one tree which thrives well, there are twenty that grow faulty, and all this is owing to the want of pruning or lopping in a proper manner; for this when wiſely executed, is a renewal of their age, and of their growth too; the want of it being what occaſions trees to run out into ſuckers, and to load themſelves with uſeleſs boughs, which draw away the ſap from the upper part, and make it grow knotty and diſtempered, and uſually covered with moſs.

If a tree grow crooked, the buſineſs of the owner is to cut it off ſloping at the crooked place, and nurſe up ſome young bough that grows upright from that part, and it will make it a ſtrait body. This is not to be done when trees are very large, but the careful owner will not ſuffer them to grow very large without doing it. *Mortimer*'s Husbandry, vol. 2.p. 84. There is alſo another caution, which is, that ſoft woods do not bear this heading ſo well as the harder, and the beech in particular is leſs able to bear it, than any other. If young trees grow but a little crooked, they may be cured by only ſhreding up the branches while young, all the way up the body, till paſt the crooked part. When cattle have cropped any of the ſhoots of young trees, they ſhould be cut off cloſe to the body, for they not only never grow well after it, but the cattle uſually leave a drivel where they have bitten, which ſometimes begins a rot of the branch, and endangers the whole tree. The beſt time for pruning young *foreſt* trees is in February; and it ſhould be done where there is occaſion every year, or at the utmoſt every ſecond year, ſo that the tree may be able to overgrow the knot, and the place not liable to put out ſuckers becauſe the ſap has had no great recourſe to it. When it is neceſſary to cut off a bough of any bigneſs, there muſt always be given a chop or two underneath, oppoſite to the part where it is cut above, otherwiſe the weight of the bough in its fall, is apt to ſtrip off the bark from the remaining ſtump, to the great detriment of the tree. When trees are kept for pollards, they muſt be regularly lopped every two years; for if the branches are ſuffered to grow longer than that, they are apt to be faulty at the wound when cut off, and to let in water, the conſequence of which will be the decay of the tree, and it can no more bear any great quantity of branches or lop. *Mortimer*'s Huſ. v. 2. p. 85.

The general growth of trees in thickneſs of the body, is from one inch to two inches a year. The large and ſmall, increaſe much in the ſame proportion in this reſpect, if they are in a like thriving condition. The goodneſs of ſoil will make a great difference in this growth,as has been experienced by Mortimer, who obſerved, that the common increaſe of the oak is about an inch and a quarter in thickneſs in the body in a year; but a large oak that grew in one of his own plowed fields, where the earth was tilled and manured every year, and that often had cattle lying under it, and dunging about its roots, grew annually no leſs than four inches in thickneſs. This ſhews the great advantage of digging about the roots of trees, and dunging them, and may ſerve as a hint for a very practicable method of increaſing the growth of trees on occaſion. The killing of weeds that grow about the roots of trees is one great method of haſtening their growth, but there is an error which ſome have run into on this principle, that is to be careſully avoided. Theſe people obſerving the great damage that weeds do the trees, have ſuppoſed that ſhrubs and underwood in hedges and coppices do the ſame; but this is a miſtake. Experience ſhews, that *foreſt* trees thrive better and grow faſter in coppices, than when they ſtand ſingle, and it is certain that next to digging and dunging about the roots, the growth of underwood about the tree is the beſt method of promoting its increaſe; theſe ſhrubs keeping the earth moiſt about the roots of the tree, and manuring all the earth about, with their falling leaves and rotten branches, which break off at times, and which are the richeſt of all manure. A little rotten wood blended among even a bad ſoil converting it into the nature of garden mould. *Mortimer*'s Husbandry, v. 2. p. 86.

FORESTID *ore*, in mining, is ore got out of earth and dirt that has been waſhed, and ore taken from it before. *Houghton*'s Compl. Miner in the Explan. of the Terms.

FORFICULA *marina*, the *ſea earwig*, a name given by authors to an inſect frequently found about the ſea-ſhores, and having ſome ſort of external reſemblance to the common *earwig*. It is of the ſize of the common *earwig*, and is of a mixed colour, of a deep black and a ſilvery white. The ſhoulders are ſomewhat gibboſe, the eyes ſtand cloſe to one another on the ſummit of the head, the antennæ are long and very ſlender. It has eight pair of legs on the anterior part of the body, and eight pair more at the hinder part, and there are three or four briſtles at the tail. It moves about very ſwiftly and lives on rocks and among ſtones.

FORFIELD, in mining, is the fartheſt place that a man has wrought in his ground; or the end of a meer above ground. *Houghton*'s Compl. Miner in the Explan. of the terms.

FORKTAIL, among the fiſhermen of England, a name given to the ſalmon, while in the fourth years growth, and not yet come to be what they call a ſalmon. *Willughby*'s Hiſt. Piſc. p. 189. See SALMON.

FORLANA, in the Italian muſic, a ſort of dance much in uſe among the Venetians. *Broſſ.* Dict. Muſ. in voc. See SALTARELLA.

FORLORN, or FORLORN-*hope*. See ENFANS *perdus*, *Cycl.*

FORMATION *of ſtones*. See the article STONE.

FORMELLA, a certain weight of about ſeventy pounds, mentioned in the ſtatute of weights and meaſures. 51 H. 3.

FORMER, in gunnery, a round piece of wood fitted to the diameter of the bore of a gun, on which the paper, parchment or cotton which is to make the cartridge, is rolled before it be ſewed.

FORMICA, the *ant*, an inſect famous in natural hiſtory, of which we have five ſpecies common in England. 1. A ſmall blackiſh *ant*. 2. A ſmall reddiſh brown *ant*. 3. A middle ſized black *ant*. 4. A middle ſized reddiſh *ant*, and 5. The common great hippomyrmex, or horſe-*ant*.

The *ant* lays eggs in the manner of the common flies, and from theſe eggs are hatched a ſort of ſmall maggots or worms without legs; theſe are ſharp at one end and blunt at the other; and are white, but ſo tranſparent, that the inteſtines are ſeen thro' the skin. Theſe after a ſhort time, change into large white aureliæ, which are what are uſually called *ant*'s eggs, thoſe who call them by that name, not conſidering that they are larger than the body of the creature ſuppoſed to have laid them in this aurelia ſtate. That end which is to be the tail, is the largeſt, and that which is the head, is ſomewhat tranſparent.

The *ants* move theſe about at pleaſure with their forceps. It is well known that when a neſt of theſe creatures is diſturbed and the aureliæ ſcattered about, the *ants* are at infinite pains to get together all that are unhurt, and make a neſt for them again: nay any *ants* will do this, and thoſe of one neſt will often take care of the aureliæ of another.

Swammerdam obſerves, that the affection of the *ant* for its offſpring is amazing. He ſays, that they carry the young worms about in thir mouths, that nothing may injure them; and when the earth of the neſt is dry, they carry them down to a greater depth, but when wet they bring them to the ſurface, that they may not be injured by the damps.

Thoſe which are called horſe-*ants*, are much larger, ſtronger, and ſwifter in their motion than the common *ants*, and the middle part of their body is yellow. This is not connected to the hinder part by ſo thin a filament as in the common *ant*; and the belly is yellowiſh and leſs gloſſy than in that ſpecies. Theſe make their neſts of large quantities of ſticks, ſtraws, and fragments of leaves of trees, and uſually build in woods, and on the ſurface of the earth. *Swammerd.* Bibl. Natur.

The common *ant* builds only with ſmall pieces of dry earth, and there is always found a vaſt quantity either of eggs, worms, or aureliæ at the bottom of the neſt. The aureliæ are covered only with a thin skin, and when carefully opened, they ſhew the worm perfect, and in its ſeveral ſtages of perfection. *Ray*'s Hiſt. Inſect. p. 70.

Swammerdam ſays, that in every neſt of *ants*, as in every hive of bees, there are three kinds of the inſect. Theſe he diſtinguiſhes as in the bees, by the names of males, females, and working *ants* or labourers. Theſe laſt are neither male nor female, nor have any other buſineſs, than the taking care of the young brood.

The male *ant* has four wings, and its eyes are larger than thoſe of the labourers or females, and there are three lucid

points

points on its head, which this author thinks to be wanting in the labouring *ant*. Theſe males are not found in the neſts in all ſeaſons, but only at particular times, and it ſeems as if their fate was the ſame with that of the male bees, which are always killed as ſoon as the ſeaſon of their impregnating the females is over.

The female *ant* is larger than the male, and working *ants*, and her body is much fuller and thicker. This creature alſo has the three lucid ſpots on her head as the male has, and her body may very eaſily be opened, and then ſhews a great number of eggs in regular lines.

The labouring *ants* are very eaſily diſtinguiſhed by their not having thoſe lucid ſpecks on the head, that the male and female have. *Ray*'s Hiſt. Inſect. p. 70.

Theſe lucid ſpecks deſcribed by Swammerdam, ſeem to be three eyes of the ſame ſtructure with thoſe of the ſpider. It is not peculiar to the *ant* to have theſe beſide the reticulated kind; all the common flies have beſide their large reticulated eyes, three of theſe ſmall and ſhining ones, which uſually ſtand in a triangle on the back part of the head. What ſeems moſt remarkable, is, that they ſhould not be common to all the kinds of *ants*, but that the labourers ſhould be without them.

Naturaliſts relate wonders of the policy and œconomy of *ants*, the contrivance of their houſes, their granaries, &c.

We are told of cities, ſocieties of *ants*, commerce between *ants*, &c.

Dr. Hook gives us the figure of an *ant* as repreſented by a microſcope. Microſ. Obſ. 49. *Power*, Exper. Phil. Obſ. 22.

Some writers on the materia medica, pretend to find extraordinary medicinal virtues in *ants*.

Mercury is a mortal poiſon to them, and the moſt effectual way of deſtroying theſe inſects. Vid. Mem. of Liter. T. 3. p. 215.

The chemiſts draw a ſpirit of *ants*. Act. Phyſ. Med. Acad. N. C. Vol. 2. Obſ. 136.

Mr. Newman has alſo procured an ætherial oil from *ants*.

Ants make the principal food of young patridges and pheaſants; beſides ſeveral other kinds of creatures, which prey on this inſect. Phil. Tranſ. N°. 28. p. 428.

Zoographers ſpeak of an *ant* bear, called *tamandua*, in Braſil; which feeds wholly on *ants* [a]. It has a long ſharp ſnout, a ſlender tongue, extenſible to a great length. It catches *ants* by ſcratching open their ſubterraneous hives, and then thruſting its tongue into them, after a while it draws it back into its mouth loaden with prey. [a *Grew*, Muſ. Reg. Societ. p. 1. Sect. 2. c. 1.]

The antients had an opinion that *ants* were a ſpecific or antidote made uſe of by bears, which they had always recourſe to, when poiſoned with *mandragoras*, &c. *Buxtorf.* Not. in Anatolii Fragm. ap. Fabric. Bibl. Græc. l. 4. c. 29. p. 317. v. 8. *Plin.* viii. 27. and *Solin.* c. 26.

The tarantula or malmignatto of Corſica, by ſome called a poiſonous ſpider, is really of the *ant* kind. Phil. Tranſ. N°. 249. p. 57.

It is alſo a ſort of winged *ants* that compoſe the gum lacca. *Lemeri*, Tr. des Drog.

The French academy ſpeaks of a ſort of *ants* in Surinam, which come viſiting in troops once in two or three years, enter the houſes, and are readily admitted into all their cheſts, &c. [a]. They exterminate rats, mice and other vermin. But this account is contradicted by M. de Robaix, who, however, relates wonders of the military diſcipline, the marches, guards, ſentinels, fortifications, roads, ſlaves, priſoners, &c. of theſe *ants* of viſitation [b]. [a Hiſt. Acad. Scien. 1701, p. 19. b Jour. Liter. T. 6. p. 185. ſeqq.]

Ants are in poſſeſſion of certain ſecrets for the preſervation of their proviſions, preventing their corn either from ſprouting, or from rotting under ground, which they practiſe with great dexterity, and are not unworthy the attention of the greateſt philoſophers. The activity is no leſs remarkable, with which they ranſack the neighbourhood around; than the labour and toil they undergo to bring home the proviſion, they have found.

Some ſuggeſt, that to prevent the ſprouting of the corn, the *ants* cut off all the buds before they lay it up. So that the corn which has lain in their neſts will produce nothing. 'Tis eaſy to make the experiment, and plainly diſcover, that there is no germ or principle of germination in their corn. Yet tho' the bud were cut off, there remains another difficulty, for the corn under ground would ſwell and rot, and thus become unfit for their nouriſhment. To prevent this, they have a peculiar expedient, by which corn is kept as dry in their neſts as in our granaries. This is done by ſunning it every day. They bring it out of their magazines towards the middle of the day, and ſpread it in little heaps on a kind of dry earth provided for that purpoſe, about the mouth of their neſt. At night they carry it back again to the magazine. It is obſervable they never venture their corn out, unleſs in a day that promiſes fair weather; in the prognoſtics of which, they ſhew great ſagacity. In ſome occaſions, where it has been dangerous for them to expoſe their riches in the day time, on account of the birds, particularly in the neighbourhood of ſome pidgeon-houſe, they have been found to vary their rule, and bring it forth in the night, ſpread it in the moon ſhine, and lock it carefully up in the morning. Vid. Mem. of Liter. T. 3. p. 206, and 208.

They ſcout round the country in queſt of corn; ſometimes they are diſappointed, and find none after long and painful rambles, at other times they do not like the corn they meet with; but notwithſtanding none of them come home without ſomething: one brings a grain of wheat, another a grain of rye or oats, a third, if it can meet with nothing elſe, a particle of dry earth, for beds to lay the corn on. Id. Ib. p. 209.

The forecaſt of *ants* in providing againſt the winter is a miſtake. Leewenhoeck is of opinion they do not eat in the winter, but ſpend that ſeaſon like dormice, and many other ſorts of animals, in a ſtate of ſleep. What confirms this is, that they have been obſerved as the cold draws on in autumn, to move very heavily, and in the vintage time, they can hardly ſtir at all; ſo that the proviſion they make, ſeems intended not for themſelves, but for their young.

Ants frame their habitations differently; ſome have their neſts in banks, or hillocks, called *ant-hills*, others build in houſes, others higher in trees, &c. Some curious obſervers diſtinguiſh divers apartments for different uſes, in the neſts of *ants*. They take ſpecial care to guard their neſts againſt the wet. Whatever community of goods there be between the *ants* of the ſame neſt, they exclude all foreigners belonging to other colonies from any intercourſe.

In ſome parts of Siam, which lie open to great inundations, the *ants* make their ſettlements in trees. No neſts are to be ſeen any where elſe. Id. Ib. p. 212.

Ligon mentions a large ſort of *ants* in Barbados, which build their neſts with clay and loam againſt a wall or tree, as big as bee-hives, and divided into ſeveral cells. Hiſt. of Barbados, p. 64.

The white *ants* in Maduras, called by the Indians *carreian*, being the ordinary prey of ſquirrels, lizards, and ſeveral other creatures, raiſe their houſe the height of a man from the ground, which they form of a durable ſort of ſtuff, or mortar, put ſo well together, that it is almoſt impenetrable. The fields are full of theſe banks; which the countrymen do not demoliſh, partly on account of their extreme hardneſs, and partly becauſe they would be repaired again in a few days. Lett. Edif. T. 12. p. 102.

There is a ſtrait hole in every *ant*'s neſt, about half an inch deep, after which it goes down ſloping into a place where they have their magazine, which ſeems to be a different place from that where they reſt and eat, they being too neat to lie among their proviſions. Mem. of Liter. T. 3. p. 206. Guard. N°. 156.

Over the hole of their neſt they lay ſome flat ſtone, tile, piece of plaiſter, or the like, to cover it from the rain, &c. which is their great enemy. In a fair day the hole is open; but when they foreſee it will rain, and almoſt every night, the cover is drawn over the entrance, with great ingenuity as well as labour, Fifty of theſe little animals, eſpecially thoſe of the ſtronger ſort, ſurround the ſtone, and draw and ſhove in concert: the like operation is renewed in the morning, to thruſt it back again. Mem. Liter. p. 211.

An *ant* never goes into any other neſt but her own; and if ſhe ſhould venture to do it, ſhe would be turned out, and ſeverely puniſhed; if ſhe proved refractory, and returned again after this warning, the other *ants* would tear her to pieces. Even when purſued, they will never fly into another hole for ſhelter, except in the laſt extremity; and will even ſometimes rather ſuffer themſelves to be taken.—They ſeem not to know what hoſpitality is. Mem. of Liter. l. c. p. 213. ſeqq.

Each kind of *ant*, Dr. King aſſures us, inhabit by themſelves in their ſeveral banks, or hillocks: if a red *ant*, ex. gr. be put into a black *ant*'s bank, war immediately ariſes, the black ſeize their gueſts, and never leave pinching him on the head with their forceps, or claws, till they have killed him on the ſpot. After which they drag his dead body out of the verge of the bank. If a black *ant* be put into a red *ant*'s bank, he ſeems ſtartled at the ſtrangeneſs of the thing, and preſently ſeeks for ſafety by flight. Phil. Tranſ. N°. 23. p. 425. ſeqq.

It has been a vulgar error, that *ants*, bite; they have not ſtrength enough in their jaws and teeth to penetrate the cuticula. But the red ſort have a ſting in the poſterior part of their bodies, which they thruſt out, and plunge into any thing that offends them, by a kind of vibratory motion, which expreſſes an acrid, corroſive ſort of liquor, which paſſing thro' the canal of the ſting raiſes an inflammation. The black *ants* have no ſting. Bibl. Univ. T. 11. p. 156.

It is ſaid that there is a white ſort frequent in India, which when they have taken poſſeſſion of a houſe, or a room, there is no getting rid of them, but by means of a black kind, which hunt them out. They eat their way thro' every thing, will even gnaw iron, ſilver, &c. unleſs the ruſt they raiſe be rather the effect of their ſaliva, which is of a diſſolving nature, and acts almoſt like aqua fortis. Vid. *Lemer.* des Drog.

On opening the *ant*-hills a great quantity of their eggs are uſually found. Theſe are extremely ſmall and white, and look like the ſcatterings of fine ſalt or ſugar. They may be taken up in cluſters, but are too minute ſingly, to be diſtinctly ſeen by the eye. Examined by the microſcope, they have very much the appearance of the eggs of ſmall birds, and are as clear as the air-bladders of fiſhes.

The ſame eggs are found in the bodies of the female *ants* on opening them at a proper ſeaſon. Theſe lie in cluſters together under cover of ſome light earth or other looſe matter, and when this is removed and they are uncovered, the *ants* are very induſtrious, and cover them again as quick as poſſible. The *ants* themſelves ſeem to brood over this ſpawn, and in a little time every granule of it is hatched into a ſmall worm or maggot not larger than a mite. Theſe can ſcarce be perceived to move at firſt, but afterwards they begin to twiſt their bodies about. They then grow yellowiſh and hairy, and in this ſtate arrive very nearly at the ſize of the *ants*; each of theſe has a black ſpot on its head. When they are arrived at this ſize, they get a film over them of a whitiſh colour, and in this caſe, wrapt up into an oval form, are called *ant*'s eggs, tho' very improperly. If theſe ſuppoſed eggs be opened, there will always be found in them, either the maggot as at firſt it went in, or nearer and nearer its change into the *ant* ſtate. In ſome, the lineaments of the *ant* may be compleatly traced, tho' the whole is tranſparent, except the eyes, which are two dark ſpecks. A little time after this, the *ant* is perfectly found and obtains its natural colour. If the egg be then opened, it is found ready for the light and crawls about, and ſoon gets the uſe of its limbs and ſtrength for all its motions.

The care theſe creatures take of their offſpring is amazing. When ever a hill is diſturbed, all the *ants* are found buſied in conſulting the ſafety, not of themſelves, but of the eggs or theſe larger bodies encloſing the maggot or young *ant*; they carry theſe down any way ſo as to get them out of ſight, and will do this over and over as often as they are diſturbed.

They carry away the eggs and verrmicles together in their confuſion, but as ſoon as the danger is over, they carefully ſeparate them, and place each ſort in parcels by themſelves under ſhelter of different kinds, and at various depths, according to the different degree of warmth and coverture the different ſtates require.

In the warm ſeaſon of the year, they every morning bring up the eggs, as they are uſually called, to the ſurface or nearly ſo; and from ten in the forenoon to five in the afternoon or thereabouts, all theſe will be found juſt under the ſurface; and if the hills be examined toward eight in the evening they will be found to have carried them all down; and if rainy weather be coming on, it will be neceſſary to dig a foot deep or more, in order to find them.

Theſe little inſects are the great food of young pheaſants and partidges in their wild ſtate, and the reaſon why people ſeldom ſucceed well in the bringing up thoſe birds, is their not giving them a proper ſupply of that ſort of food, as often as they require it. Theſe birds in their wild ſtate run to the *ant*-hills as ſoon as the day breaks in the morning, and feed heartily. We give them not only improper food, but at improper times; for a repaſt of *ants* at ſuch a time of day, when the birds are faint with faſting, will not recover them, unleſs they are very hardy. Phil. Tranſ. No. 23.

The *ant* examined by the microſcope, appears a very beautiful creature. Its head is large, and adorned with two very pretty horns, each having twelve joints. Its eyes are protuberant, and pearled; its jaws are ſerrated or indented with ſeven little teeth, which exactly tally; they open ſideways, and are able to gape very far aſunder, and by this means the *ant* is often ſeen graſping and carrying away bodies of three times its own bulk and weight. It is naturally divided into the head, the breaſt, and the belly or tail, each of theſe parts being joined to the other by a very ſlender ligament. From the breaſt, three legs come forth on each ſide, and the tail is armed with a ſting; but this the creature only uſes, when provoked; but a poiſonous liquor is then convey'd by it, into the wound it makes, occaſioning much pain and ſwelling.

The whole body is caſed over with a ſort of armour, ſo hard as ſcarce to be penetrated by a lancet, and is thick ſet with ſhining whitiſh briſtles. The legs alſo are covered with hairs, but they are ſhort, and of a darker colour. *Baker*'s Microſ. p. 271.

Theſe little creatures are very troubleſome in gardens, and in paſture lands,; as well by feeding on the fruit, as by making up hills for their habitation. In the hotter countries, as Italy, Spain, and the Weſt-Indies, *ants* are the great peſt of the fields. Trees may be preſerved from them by incompaſſing the ſtem for four fingers breadth, with a roll of wool, newly pulled from the ſheep's belly; or by laying ſaw-duſt all round the ſtump of it. Some anoint the tree with tar, which has the ſame effect; but then the tar is prejudicial to the tree.

We have an account of Engliſh *ants* by Mr. Gould, in 12mo. London, 1747.

The five ſpecies of this inſect, which have occurred to the author, are, 1. The hill-*ant*, or horſe-*ant*. 2. The jet-*ant*. 3. The red-*ant*. 4. The common yellow-*ant*. 5. The ſmall black-*ant*.

He obſerves, that there is in the body of *ants*, a bag of corroding liquor, which they can throw out to ſome diſtance. The red *ants* have a ſting like bees; others bite, and make a ſmall inciſion with their ſaws, ejecting ſome of their corroding liquor.

As to the cells, government, propagation, &c. of *ants*, we refer to the book itſelf; or to Phil. Tranſ. N°. 482. Sect. 4. where there is an abſtract of his book. We muſt not omit, that Mr. Gould contradicts the vulgar notion of the foreſight of *ants*, and their laying up proviſions for winter; in which he agrees with Swammerdam as, before mentioned.

FORMICA, or ANT, in medicine, denotes a ſpecies of warts, called alſo *myrmecia*.

The name *ant*, *formica*, is alſo given to thoſe minute varicous intumeceſences of the ſmalleſt blood-veſſels, obſerved either in the anus, or the glans of the penis *Caſt.* in voc. *formica*.

Some alſo give the appellation *ant* or *formica* to the milliary *herpes*.

FORMICA *leo*, the *ant-eater*, in natural hiſtory, the name given by authors to a very remarkable ſpecies of inſect, which is in its perfect ſtate, a winged creature, approaching to the nature of the libellæ; but in its prior ſtate of a creeping animal, has a wonderful art and addreſs in the catching its prey. It is in this ſtate, that it is known by the name of *formica leo*, as it chiefly feeds upon *ants*.

It is ſomewhat of the nature of the ſpider in its way of taking its prey, its manner of ſpinning, and in the figure and ſoftneſs of its body; and has in its general figure, ſomewhat of the appearance of the millepes, or wood-louſe; ſo that ſome have miſtaken it at firſt ſight for that animal. It is of a dirty greyiſh colour marked with ſome black ſpots, and theſe are alſo many points, which when it is viewed with the microſcope, make it reſemble a hedge-hog or porcupine. Its body is compoſed of ſeveral rings, and has thence a wrinkled look. It has ſix legs, four are joined to the breaſt, and the other two to a long part which may be taken for its neck; its head is ſmall and flat, and it has two remarkable horns; theſe are about a ſixth of an inch long, and as thick as a hair, and are hard, hollow, and hooked at the end, like the claws of a cat; at the origin of each of theſe horns, it has a clear and bright black eye, which ſees very diſtinctly, and gives the creature notice to eſcape on ſight of the ſmalleſt object. Mem. Acad. Par. 1704.

Of all food the *ant* affords the propereſt to this animal; it is not able to hunt after prey, nor to deſtroy large inſects, it can only draw into its ſnares, ſuch as come by its habitation, and of theſe very few are ſuch as he can manage; all the winged tribe are able to eſcape by flight, and the beetle kinds, and others that have hard ſhells upon their bodies, are of no uſe to him, as his horns cannot pierce them. The ſmallneſs of the *ant*, and its want of wings, make it the deſtined prey of this devourer. The manner in which he catches his prey is this.

He uſually encamps under an old wall, that he may be ſheltered from the injuries of the weather, and he always chooſes a place where the ſoil is compoſed of a fine dry ſand; in this he makes a pit of the ſhape of a funnel, or an inverted hollow cone; he executes this in the following manner.

If he intends the pit to be but ſmall, he thruſts down his hinder part into the ſand, and by degrees plunges himſelf backward into it, and when he has got to a certain depth, he toſſes out the looſe ſand which has run down with his head, artfully throwing it off beyond the edges of his pit; thus he lies at the bottom of a ſmall hollow, which is wideſt at the top, and comes ſloping down to his body.

But if he is to make a larger pit, more pains is required to bring it to perfection. He firſt traces in the ſurface of the ſand, a large circle, which is the erected baſe or mouth of the pit he is to make in form of an inverted cone; he then buries himſelf in the ſand near the edge of this circle, and carefully throws up the ſand above him, with his head toſſing it out beyond the circumference of the circle. Thus he continues his work running down backwards in a ſpiral line all the way, and carefully throwing off the ſand from above him, till he is come to the place of his reſt, which is the point or reverted apex of the hollow cone, he has formed by his paſſage. The length of his neck and the flatneſs of his head, gives him a power of uſing the whole as a ſpade, and throwing off the ſand with great eaſe, and his ſtrength in this part is ſo great that he is able to throw off a quantity of it, to ſix inches diſtance. This is a power he oftener exerts however, in the throwing away the remains of the animals he has fed upon, that his den may not become frightful to other creatures of the ſame ſpecies, the ſeeing their fellow carcaſſes about it.

When he has finiſhed his pit, he buries himſelf at the bottom of it in the ſand, leaving no part above ground, but the tips of his two horns, which he expands to the two ſides of the pit. In this condition he lies and waits for his prey, and never comes up after it. When an *ant* or any other ſuch creature chances to walk over the edges of his pit, his ſteps throw

throw down a little of the ſand, which naturally running down to the bottom of the pit, gives the enemy notice of his prey; he then toſſes up the ſand which covers his head, to bury the *ant*, and bring him down with its returning force to the bottom; and as one ſuch attempt cannot be ſufficient to prevent the *ant*'s eſcape, he throws more and more ſand upon him, till he by degrees brings him down to the bottom. All the endeavours of the *ant* to eſcape when once it is within the verge of the pit are in vain, for as it attempts to climb, the ſand runs away from under its feet, and it ſinks the lower for every attempt. This motion of the ſand alſo informs the enemy where it is, and directs him to throw up more ſand in the right place, which it does till the poor *ant* falls to the bottom between its horns. It then plunges their points deep into the *ant*'s body; and having ſucked out all the juices of the prey, it throws out the empty skin, as far from the hole as it can. This done it mounts up the edges of its pit, and if they have ſuffered any injury, repairs them with great care, and immediately buries itſelf again in the center to wait for an other meal.

The horns of this creature are its only organs for receiving nouriſhment; it never brings any animal that it has ſeized near to its head, but always holds it at the tip of the horns, they therefore plainly ſerve as ſyringes to draw into its ſtomach the juices of the bodies of the inſects it feeds on, neither is there any mouth or trunk, or any other organ to be diſcovered about its head, which could ſerve to the purpoſe of eating; the head ſeeming only intended to throw away the ſand in forming the pit. The horns of this animal being ſo neceſſary to its life, nature has provided for the reſtoring them in caſe of accidents, and if cut off they are found to grow again.

The food this creatures procures by its pit, can be but little; and as it has no power of catching its prey any other way, its motion being only backwards, and that ſlowly, and by ſmall ſpaces at a time, ſome people have believed this catching now and then an *ant*, by this means was rather for diverſion than hunger; but tho' the *formica leo* will live a long time without food, and even paſs thro' all its changes when ſhut up in a box, yet it is always ready to eat if food is offered it; it always appears ſtarved and ſmall when kept thus, and if a fly be given it in this hungry ſtate, it will ſo ſuck out all its juices that the ſhell remaining may be rubbed to powder between the fingers, while the body of the creature that has ſucked it, appears remarkably ſwelled and diſtended, ſo that it is plain that the juices of the prey are conveyed into the body of the creature, tho' it is not eaſy to ſee by what means, the horns not appearing to have any perforation.

When the *formica leo* has lived a proper time in this ſtate, it leaves its pit, and is only ſeen drawing lines and traces on the ſurface of the ſand; after this it buries itſelf under the ſurface, and there incloſes itſelf in a fine web to paſs its transformation into the wing'd ſtate in. This caſe is made of a ſort of ſilk which the creature ſpins in the manner of the ſpider, and of a quantity of the grains of ſand cemented together by a glutinous humour which flows from its pores. This caſe however would be too harſh and coarſe for the body of the creature, and therefore it ſerves only for the outer covering to defend it from injuries; the creature ſpinning one of pure and incomparably fine ſilk, of a beautiful pearl colour within it, which covers its whole body.

When the creature has lain ſome time in this caſe, it throws off its outer skin, with the eyes, the horns, and every other part neceſſary to its life before, and becomes an oblong nymph, in which a careful eye may trace the form of the fly it is to become. There may be ſeen thro' its tranſparent covering, new eyes, new horns, wings, and all the other parts of the animal in its perfect ſtate. This nymph makes its way about half out of the ſhell and remains in this condition, but without farther life or motion, till the perfect fly makes its way out at a ſlit in the back; in this ſtate it much reſembles the libellæ or dragon-flies, common about our waters. The male couples with the female in this ſtate only, and Mr. Poupart, to whom the world is indebted for this curious deſcription, is of opinion that the females lay only one egg; but this is very different from the courſe of nature, in the other animals of the ſame claſs. Mem. Acad. Par. 1704.

When this inſect forms its pit in a bed of pure ſand, it is made and repaired with great eaſe, but where it meets with other ſubſtances among the ſand, the labour becomes greatly the more embaraſſing. If for inſtance, when the creature has half formed its pit, and then comes to a ſtone of ſome moderate ſize, it does not deſert the work for this, but goes on, intending to remove that impediment at laſt. When the pit is finiſhed, the creature crawls backward up the ſide of the place where the ſtone is, and getting its backſide under it takes great pains and time to get it on a true poiſe, and then begins to crawl backward with it up the edge, to the top of the pit, to get it out of the way.

It is a very common thing to ſee a *formica leo* in this manner labouring at a ſtone four times as big as its own body; and as it can only move backward, and the poiſe is hard to keep, eſpecially up a ſlope of ſuch crumbly matter as ſand which moulders away from under its feet, and neceſſarily alters the poſition of its body, the ſtone very frequently falls down when near the verge, and then it is ſure to roll to the bottom; in this caſe, the creature attacks it again in the ſame way, and often is not diſcouraged by five or ſix miſcarriages of this kind, but after all, attempts again, and at length gets it over the verge of the place. When it has done this, it does not leave it there leſt it ſhould roll in again, but is always at the pains of puſhing it farther on till it has removed it to a neceſſary diſtance from the edge of the pit.

The common *formica leo* moves only backward, but Mr. Rouet, has obſerved a ſpecies which moves forward in the common way of other animals, and makes no pit of this kind to intrap its prey, but ſeizes other inſects by force. Philoſ. Tranſ. N°. 469. p. 466.

FORNA, in ichthyology, a name given by Hildegard, and others, to the trout.

FORNAGE, *Fornagium*, in our old writers, ſignifies the fee taken by a lord from his tenants, bound to bake in the lord's oven, or for a permiſſion to uſe their own; this was uſual in the Northern parts of England. Plac. Parl. 18 Ed. 1. The word comes from the French *fournage*, which ſignifies the ſame.

FORRAGE (*Cycl.*) — FORRAGE-*guard*, in military affairs, a detachment ſent out to ſecure the *forragers*. The *forrage* guard is poſted at all places, where the enemies parties may come to diſturb the *forragers*. This guard is likewiſe called the *covering party*, and marches generally the night before the *forraging*, that they may be poſted in the morning before the *forragers* come. The guard conſiſts both of horſe and foot, and muſt ſtay at their poſt till the *forragers* be all come off the ground.

FORSES, *catadupæ*, a term uſed in Weſtmoreland, for waterfalls. *Camb.* Britan.

FORTAMENTE, in the Italian muſic, the ſame with *forte*. See FORTE.

FORTE, in the Italian muſic, directs to play ſtrong and loud.

FORTE FORTE, or F. F. ſignifies a degree louder or ſtronger than *forte*. *Broſſ.* Dict. Muſ. in voc.

PIU FORTE, the ſame as *forte forte*. Id. Ibid.

FORTIS *aqua*. See the article AQUA *fortis*.

FORTISSIMO, in the Italian muſic, is uſed to ſignify *very ſtrong*. It is ſometimes denoted by F F F, or *fff*, and intimates that the performers are to play or ſing very loud or ſtrong, to expreſs ſome paſſion, &c. *Broſſ.* Dict. Muſ. voc. See FORTE.

FORTUNE-*tellers* — Pretenders to tell *fortunes*, and to any crafty ſcience for the diſcovery of ſtolen goods, are puniſhable by impriſonment, pillory, and binding to the good behaviour [a], and ſhall be deemed vagabonds [b]. [[a] Stat. 9 Geo. 2. c. 5. Sect. 4. [b] Stat. 17 Geo. 2. c. 5. Sect. 2.]

FORTY *Shilling-land*, is uſed in *Scotland*, for a certain portion of arable land. The *forty ſhilling-land* of old extent contains eight oxgang, or 104 acres. Tr. Pract. Geom. p. 89. See OXGANG.

FOSSIL (*Cycl.*) —FOSSILS are defined to be native ſubſtances, found either buried in the earth, or lying on its ſurface, of a plain ſimple ſtructure, and ſhewing no ſigns of containing veſſels, or circulating juices. *Hill*'s Hiſtory of Foſſils, p. 1.

Foſſils are the ſeveral natural ſubſtances, of what is uſually called the mineral kingdom, as plants are of the vegetable, and living creatures of the animal.

FOSSIL *plant*. See the article PLANT.

Marine FOSSILS. See MARINE.

FOSSILE *Ivory*. See IVORY.

FOSSORES, in natural hiſtory, a name given to a ſpecies of ſmall worms hatched from the eggs of a fly, which feeds on the parenchymatous ſubſtance of the leaves of plants, burying themſelves between the two membranes. Theſe animals in general are called by Reaumur, *aſcarides*; but as they greatly differ in their ſize, and in their manner of eating and deſtroying leaves, the ſmall ones which eat but ſlowly, and gnaw their way in crooked furrows, are called by him *foſſores parvi*; and on the contrary, thoſe which eat away all that lies before them, and are of a ſomewhat larger ſize, are called *foſſores magni*. See ASCARIDES.

FOSTER-*land*, in our old writers, is land given or allotted for the finding of food or victuals; as for monks in monaſteries, &c.

FOTHER or FODDER, is a weight of lead, containing eight pigs, and every pig one and twenty-ſtone and a half; ſo that it is about a tun or common cart-load. Among the plumbers in London, it is ninteen hundred and an half; and at the mines it is two and twenty hundred and an half. *Skene*.

The word is of Teutonic origin from *fuder*.

FOUL, (*Cycl.*) a ſea term, importing the runnnig of one ſhip againſt another. This happens ſometimes by the ungovernable violence of the wind, and ſometimes by the careleſſneſs of the people on board; and ſometimes happens to ſhips of the ſame convoy; ſometimes to ſuch as meet accidentally; and ſometimes to ſuch as are in port by means of others coming in.

The damages occaſioned by running *foul*, are of the nature of thoſe in which both parties muſt bear a part; they are uſually made half to fall upon the ſufferer, and half upon the veſſel which did the injury: but in caſes where it is evidently the fault of the maſter of the veſſel, he alone is to bear the damage. *Savary*, Dict. Comm.

FOULNESS *in wounds*. When what the ſurgeons call uncleanneſs or *foulneſs* is perceived in a wound, that is, when the fleſh in it, looks fungous, black, putrid or livid, it muſt be well cleanſed before any attempts are made to heal it. Different methods of effecting this, have been in uſe at different times among the ſurgeons: the antients uſed honey, but the moſt uſual practice now is, to apply a digeſtive ointment made of turpentine diſſolved in the yolk of an egg, and afterwards mixed with honey of roſes; but where this is not found ſtrong enough for the purpoſe, the Egyptian ointment is to be uſed, mixed either with ſpirit of wine, or with the common digeſtive. To theſe digeſtive ointments, a ſmall quantity of aloes and myrrh may alſo very properly be added, and where more ſtrength is required in them a ſmall quantity of red precipitate is to be added. The uſe of lime water as a detergent is alſo very great, and yet more ſo, if there be added to every pint of it twenty or thirty grains of ſublimate; this makes what is called the *phagedenic* water. Applications of this kind, are to be continued till the wound is entirely clean, and then it is to be healed with the common digeſtives, &c. *Heiſter*'s Surg. p. 42.

FOUMART, a name uſed in ſome parts of England for the weaſel, called alſo in ſome places, the *fitchett*. See MUSTELA.

FOUNDAY, in metallurgy, a term uſed by the workers at the iron mines, in many counties of England, for the ſpace of ſix days, in which time, they contrive to make a determinate quantity of iron, ſo that they count their work by theſe *foundays* or weeks. *Ray*'s Engliſh Words, p. 126.

FOUNDER, (*Cycl.*) in glaſs-making, is a term appropriated to the green-glaſs-houſes, and is the perſon there, who in the ſame office in the white-glaſs-making is called the *conciator*. He weighs and proportions the ſeveral ingredients for glaſs, and calcines them into fire, from which ſtate they are to be run into glaſs. *Neri* of Glaſs, p. 240.

FOUR-*corners*, in the manege, or to work upon the *four-corners*, is to divide in imagination the volt or round into four quarters; ſo that upon each of theſe quarters, the horſe makes a round or two at trot or gallop; and when he has done ſo upon each quarter, he has made the *four corners*.

FOURTH (*Cycl.*) — Some modern muſicians have doubted whether the *fourth* ſhould be received among the number of concords, or not[a]. The antients expreſsly admitted it as ſuch; and Andreas Papius wrote a treatiſe againſt thoſe moderns who reject it[b]. [[a] *Merſen.* Harm. l. 4. prop. 8. [b] *Wallis* Append. Ptolem. Harm. p. 182.]

Diminiſhed FOURTH, in muſic. See DIMINISHED *fourth*.

FOWL (*Cycl.*) — The ſea *fowls* which come on ſhore in immenſe numbers to rooſt, in the north iſlands of Scotland, ſet their watches and centinels at diſtant poſts, to give them notice of any danger; on the leaſt alarm from theſe, the whole body riſes, but without ſuch notice they are not to be alarmed by almoſt any thing. The people of the country know this, and when they go out to take them, they employ all their art to take the centinels without noiſe; this they ſometimes ſucceed in, and when they do, they often afterwards catch three hundred of the others, or more, in one night. Philoſ. Tranſ. N°. 233.

The laying of theſe ſea birds is leſs certain as to time than might be imagined. They can occaſionally defer it; and as they uſually lay in a rainy ſeaſon, if the rain does not come on at the uſual time, they will defer it ſome weeks; and if the April moon goes far in May, that alſo has been obſerved to hinder them from laying ten or twelve days longer than ordinary. See BIRD.

The belly of a living *fowl* being ript up, the creature is thus applied to a part bit by a rattle-ſnake, to draw out ſome of the poiſon. It ſeems to have ſome effect this way. We find an inſtance in the Philoſophical Tranſactions [a], where a *fowl* thus applied to a hand bit by that moſt venomous ſnake, immediately ſwelled, grew black and ſtunk. [[a] N°. 479. p. 144.]

Water FOWL. The Ceiloneſe have great plenty of water *fowl* wild on their iſland, and have a very remarkable way of catching them, which is this; the fowler enters a lake or other water which has a good bottom, and is not very deep, he puts an earthen pot upon his head, in which there are bored holes, thro' which he can ſee; he keeps himſelf ſo bent down in the water, that only the pot is above the ſurface; in this manner he enters the place where the wild *fowl* are in cluſters, and they think it is only ſome floating block. He then takes ſome one by the legs and gently draws it under water, and wrings its neck till he has killed it; then putting it into his bag which is faſtened about his middle, he takes hold of another in the ſame manner, and ſo on, till he has got as many as he can carry off, and then he goes back in the ſame manner in which he came, not diſturbing the reſt of the birds who never miſs their companions, but only ſuppoſe that they dive down for their diverſion, when the fowler pulls them under. In places where this has been practiſed ſo long or ſo careleſsly that the birds are ſhy, the fowler uſes a gun; but this he does in the following manner. He makes a ſcreen of about five foot high, and three foot wide, which he carries in one hand ſtrait between himſelf and his game, and in the other hand his gun. The birds are not alarmed at what appears only a buſh; for this ſcreen is always covered with branches of trees freſh cut down, and full of leaves, ſo that the ſportſman behind advances as near as he pleaſes, and then putting the gun thro' ſome crevice of the ſcreen he fires. See WATER *Fowl*.

FOXGLOVE, *Digitalis*, in botany. See DIGITALIS.

There are ſeveral ſpecies of this flower propagated in gardens, to which they are a very great ornament. They are to be ſown in March in a freſh ſoil, that is not too ſtiff, and when the plants come up, they ſhould be tranſplanted into beds at ſix inches diſtance, where they may remain till the Michaelmas following, obſerving to keep them clear from weeds; they are then to be tranſplanted into large borders, and in the May following they will produce their flowers. Theſe will continue a month or more in their beauty, and the ſeeds will ripen in Auguſt, which if let alone, will ſow themſelves, and ſufficiently ſtock a garden; but ſome of the ſpecies, as the iron coloured one, if the ſtalks be cut down as ſoon as it has flowered, will ſhoot again from the root and continue; theſe may be afterwards propagated by parting the roots. *Millar*'s Gard. Dict.

FOXGLOVE, in medicine, is eſteemed deterſive and laxative, but ſeldom preſcribed inwardly. It is alſo a noted vulnerary, the ungentum digitale, taking its name from it. Vid. *Lemery* and *James*, in voc. *Digitalis*.

FOYNA, in zoology, a name given by many to the martin or martes, an animal of the weaſel kind, common with us. See the article MARTES.

FRACHES, in the glaſs trade, are the flat iron pans into which the glaſs veſſels already formed are put, when in the tower over the working furnace, and by means of which, they are drawn out thro' the leers, that they may be taken gradually from the fire, and cool by degrees. *Neri* of Glaſs, p. 244.

FRACTURES (*Cycl.*)—Theſe may be diſtinguiſhed into ſeveral claſſes or ſpecies. Firſt every *fracture* is either *ſimple*, that is, when no other parts beſide the bone are injured; or *compound*, that is, when you have at the ſame time a wound, a diſlocation, hæmorrhage, inflammation, fever, caries or contuſion of the bone; or where the bone is fractured in ſeveral places at the ſame time. Other differences ariſe with regard to the ſituation of the *fracture*, and from its poſition: ſome are tranſverſe, others oblique; in which caſe it frequently happens, that the points of the bones wound or puſh themſelves thro' the neighbouring parts. Violent contuſions alſo may be claſſed under the head of *fractures*; for in theſe the bones are frequently broken into ſplinters, by the falling of any heavy body upon the part, or other ſuch accidents. When the ſituation of the bone is not altered by a *fracture*, or the broken parts ſtart very little from their proper ſituation, they are much eaſier replaced than when they are entirely ſeparated from one another, and a great ſpace intervenes between them. Tranſverſe *fractures* admit of an eaſier cure than oblique ones. When two bones of the ſame limb are fractured, the cure is uſually much more difficult, than when only one is. When the bone is broken into ſeveral pieces, the patient ſeldom eſcapes a gangrene, at leaſt the cure in theſe caſes requires a longer time, and the limb ſeldom recovers its true ſhape.

When the broken bones are inſtantly reduced, the cure will be much ſooner performed, than when they have been ſome time ſeparated. *Fractures* in the neighbourhood of parts of great conſequence to the animal œconomy, are always attended with great danger; ſuch are *fractures* of the cranium from the vicinity of the brain; of the vertebræ, from the medulla ſpinalis; and of the ribs, or ſternum, or the oſſa ilei and pubis, from the ſituation of the viſcera of the thorax and abdomen. *Fractures* of the bones to which the larger arteries are connected, are alſo very dangerous; more particularly, when one ſplinter or point of the bone vellicates or wounds large veſſels, or when the bone is broken into ſeveral fragments, the conſequences are generally inflammations, ſuppurations, or fiſtulæ, which will admit of no remedy, till the ſplinter of the bone is removed. *Fractures* proceeding from internal diſorders or caries of the bones, as ſuch ſometimes happen, are cured with much more difficulty, than thoſe ariſing from external injuries; nay this indeed, is frequently an incurable caſe, unleſs the internal cauſe be firſt removed. This is uſually either a ſcorbutic habit of body, or a venereal taint. When a large piece of the bone is driven away by a piſtol or muſket ball, the limb muſt be taken off, for the two ends of the bone are never likely to unite, unleſs it be a very ſmall piece that is thus taken away, for in that caſe the bone will ſometimes join, but then the limb always becomes ſomething ſhorter than it was before. When the blood inſinuates itſelf by a

fiſſure

fiſſure into the internal part of the bone, by corrupting there it produces a caries, a ſpina ventoſa, or elſe incurable fiſtulæ, tabes and a ſphacelus, which always require amputation of the limb, and frequently deſtroy the patient. The ſame accidents will happen in *fractures* of any kind, when the extravaſated blood mixes with the marrow and corrodes it. *Heiſter*'s Surg. p. 103.

Inſtances have been known of the *fracture* of the patella in perſons thoroughly ſound, where the part itſelf has received no hurt. The cauſe of this is aſcribed to the action of the muſcles only. And many inſtances might be given of *fractures* in the neck of the os femoris, in the middle of the humerus, tibia and perone, by the power of the muſcles only, or ſuch power at leaſt as ſhewed they have as great a ſhare in ſeveral *fractures* aſcribed to outward cauſes, as they are frequently known to have in the *fracture* of the tendo Achillis. We have an obſervation of a *fracture* of the os humerus, by the power of the muſcles only, in the Philoſophical Tranſactions, N°. 475. Sect. 15.

FRACTURE *of the thigh*. See THIGH.

FRACTURED, in a general ſenſe, denotes ſomething broken. See FRACTURE.

Extenſion of FRACTURED *limbs*. See EXTENSION.

FRÆNA, a word uſed by ſome anatomical writers, as a name for the ſockets of the teeth.

FRAGA, *ſtrawberries*. The antient Greeks uſed the word *comari* indifferently for the ſtrawberries produced on the common creeping plant, and for thoſe which are the fruit of the arbutus or ſtrawberry tree; they alſo evidently called the tree, and the plant which produced them both, by the ſame name. For Theophraſtus ſpeaks of the wood of the comarus, and Theocritus tells us, of the oxen eating the comarus, and the goats lying all day in it. The Latin writers have copied this from the Greeks; and they alſo call indiſcriminately the fruit of the arbutus, and that of the common ſtrawberry plant, by the name *fraga*. All the Roman authors have called the common garden ſtrawberries *fraga*; and Juvenal in his ninth ſatire, where he is deſcribing the antient ruſtics gathering their food from the wild trees of the wood, calls the fruit of the arbutus, *fraga*; and Varro in the deſcription of the manner of life of the ſame people, has in the very manner of this poet, coupled acorns, and the fruit of the arbutus.

Pliny has run into an error, in ſuppoſing, that the common cinquefoil was the plant which produced the ſtrawberries in their native wild ſtate; whereas, it is a peculiar plant that produces them in the woods, and this not a cinquefoil or five leaved, but a three leaved one. Errors ſeldom fail to be propagated, and accordingly we find Marcellus Empiricus to the beſt of his pains, continuing the error of Pliny to poſterity; he tells his reader, to gather the leaves of the common cinquefoil, on which the ſtrawberries grow, and ſteep them in ſea-water for the preparing ſome medicines.

FRAGARIA, *ſtrawberry*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, being compoſed of ſeveral petals arranged in a circular form. The piſtil ariſes from the cup of the flower, and finally becomes a roundiſh or oval fruit, to the placenta of which, which is in ſome ſpecies ſoft and fleſhy, in others hard and dry, there adhere a great number of ſeeds. To this it may be added, that the leaves always ſtand three on a ſtalk.

The ſpecies of *ſtrawberry*, enumerated by Mr. Tournefort, are theſe: 1. The common *ſtrawberry*. 2. The *ſtrawberry* with variegated leaves. 3. The white fruited *ſtrawberry*. 4. The *ſtrawberry*, with fruit of the ſize of a plumb. 5. The rough leaved *ſtrawberry*. 6. The *ſtrawberry*, which produces fruit twice in the year. 7. The little yellow flowered *ſtrawberry*. 8. The *ſtrawberry* with double white flowers, and a ſmall round and very ſweet fruit. 9. The hairy *ſtrawberry*, with red ſweet ſcented fruit. 10. The ſcarlet Virginian *ſtrawberry*. 11. The green flowered ſhrubby *ſtrawberry*. 12. The wild barren *ſtrawberry*. 13. The double flowered wild barren *ſtrawberry*. 14. The barren *ſtrawberry* with double botryoide flowers. 15. The hoary and ſilky leaved wild barren *ſtrawberry*. 16. The hoary barren *ſtrawbery*. 17. The large upright alpine barren *ſtrawberry*. 18. The narrow leaved and alpine barren *ſtrawberry*. 19. The great alpine *ſtrawberry* with ſilky ſharp pointed leaves, and roſe coloured flowers. 20. The great alpine *ſtrawberry* with ſilky obtuſe leaves, and roſe coloured flowers. 21. The leſſer alpine *ſtrawberry*, with obtuſe ſilvery leaves, and roſe coloured flowers. *Tourn.* Inſt. p. 295. See STRAWBERRY.

FRANCA, in botany, the name given by Micheli to a genus of plants, ſince called by Linnæus *Frankenia*. *Micheli*, Nov. Gen. 22. See FRANKENIA.

FRANCOLINO, in zoology, the name given by the Italians, and from them by others to the attagen of Aldrovand, a bird of the gallinaceous kind, in ſize and ſhape much reſembling the pheaſant. It is a very beautifully variegated bird. Its Head is ornamented with a very elegant creſt of feathers of a yellowiſh hue, variegated with black and white ſpots. Its eyelids are ſmooth, and of a fine ſcarlet, it has a ſort of beard of fine ſlender feathers hanging down from its chin; its neck is long and ſlender, and is of a greyiſh colour, variegated with black and white ſpots; the breaſt is of the ſame colours, but has alſo ſome ſtreaks of a ruſty brown among them. Its belly and tail are of a lead colour, as are alſo its legs.

It is called *francolino* by the Italians, becauſe it is forbidden to the common people to deſtroy it. It extremely reſembles our red-game or lagopus. It is eſteemed a very delicate fowl and ſells at a large price. It is common in the mountains of Italy, Germany, and many other countries. Authors ſeem to diſagree a little in their deſcriptions of it, ſome figuring it without its creſt. *Ray*'s Ornitholog. p. 128.

FRANGULA, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, being compoſed of a number of leaves arranged in a circular form between the ſegments of a one leaved cup. From the bottom of this cup there ariſes a piſtil, which finally becomes a round ſoft fruit, a berry uſually containing two flatted and roundiſh ſeeds.

The ſpecies of *frangula* enumerated by Mr. Tournefort, are theſe. 1. The common *frangula*, called the black alder, or berry-bearing alder. 2. The *frangula*, with larger and rougher leaves. 3. The roundiſh leaved dwarf rock or mountain *frangula*, and 4. The dwarf rock or mountain *frangula*, with oblong leaves, called the long leaved berry-bearing alder. *Tourn.* Inſt. p. 612.

FRANKENIA, in botany, the name given by Linnæus to a genus of plants, called by Micheli, *Franca*. The characters are theſe. The perianthium is permanent and is compoſed of one leaf of an oblong tubular form, divided into five ſegments at the edge. The flower conſiſts of five petals, the ungues of which are narrow and of the length of the cup, and the tops roundiſh and expanded. The ſtamina are ten filaments longer than the tube, the apices are ſimple. The germen of the piſtil is roundiſh, the ſtyle is capillary, and of the length of the ſtamina; the ſtigma is divided into three parts; the fruit is an oval capſule covered with the cup, and formed of three valves, but containing only one cell, in which are a great number of ſmall ſeeds of an oval figure. *Linnæi* Gen. Plant. p. 187. *Micheli*, Nov. Gen. 22.

FRASSETUM, in our old writers, is taken for a wood, or woody ground, where aſh grows. 1 Inſt. 4.

The word is a corruption of the Latin *fraxinetum*, which ſignifies the ſame.

FRATERCULA, in zoology, a name by which Geſner and Aldrovand have called the *anas arctica cluſii*. See the article DUCK.

FRATRES *gaudentes*, a deſignation given to the knights of the order of the *virgin Mary*, inſtituted about the year 1261. *Hofm.* Lex. in voc.

FRAXINELLA, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the polypetalous anomalous kind, uſually conſiſting of five petals. From the cup of the flower, there ariſe a vaſt number of crooked ſtamina ſurrounding a piſtil, which afterwards becomes a fruit compoſed of ſeveral capſules of an elaſtic nature, and ſplitting when ripe into two parts, and bending into the ſhape of a rams horn; theſe capſules uſually contain many turbinated ſeeds. *Tourn.* Inſt. p. 430.

The ſpecies of *fraxinella* enumerated by Mr. Tournefort are theſe: 1. The common *fraxinella*. 2. The large purple many flowered *fraxinella*. 3. The leſſer purple *fraxinella*. 4. The *fraxinella*, with ſnow white flowers.

The *fraxinella* or white dittany of authors, is cultivated in gardens with us, and grows wild in France and Italy. It generally grows about two foot high. The leaves much reſemble thoſe of the common aſh-tree, whence it has its name; the flowers are produced in long ſpikes, and are of a whitiſh red, mixed with purple. The fruit is compoſed of five capſules, in which are contained black ſhining oval ſeeds, pointed at the ends. *Pomet*'s Hiſt. of Druggs, p. 45.

This root ſhould be choſen plump and full, white within and without, little burdened with ſmall fibres, and clean. It is alexipharmic, diuretic and uterine, and is ſaid to deſtroy worms. *Hill*'s Hiſt. Mat. Med. p. 588.

FRAXINUS, the *aſh*, in botany, the name of a genus of trees; the characters of which are theſe: the flower is of the apetalous kind, and its ſtamina have uſually double heads. The piſtil finally becomes a fruit of the figure of a tongue, flatted and membranaceous, and containing a ſeed of the ſame figure. There is alſo a ſpecies of *aſh*, which has a petaloide flower; but as this flower is always barren, Mr. Tournefort did not judge it proper to ſeparate it from the reſt. *Tourn.* Inſt. p. 577.

The ſpecies of the *aſh*, enumerated by Mr. Tournefort, are theſe. 1. The common tall *aſh*. 2. The lower *aſh*, with ſmaller and narrower leaves. 3. The round leaved *aſh*. 4. The botryoide flowering *aſh*.

The ſpecies of *aſh* when not in flower or fruit are known by their leaves being of the pinnated kind, and the ſmall ones growing on pairs on the ribs. *Tourn.* Inſt. p. 577.

FREE (*Cycl.*)—FREE, aboard a ſhip. The ſeamen ſay the pump *frees* the ſhip, when it throws out more water than leaks into her; but, on the contrary, when it cannot throw out the water as faſt as it leaks in, they ſay the pump cannot *free* her: alſo bailing or lading out water out of a boat, is called *freeing* the boat.

FREE-*hord*, *Franchordus*, is ground claimed in ſome places, more or leſs, beyond, or without the fence: it is ſaid to contain two foot and a half. Mon. Angl. Tom. 2. p. 241.

FREE-*ſtone*. The qualities of the ſeveral kinds of *free-ſtone* in common uſe in the ſeveral parts of Europe are very different. They all agree in this general property indeed, that they are ſofter while in the quarry, than when they have been ſome time expoſed to the air: but even this general property differs greatly in degree. They have a ſort of grey *free-ſtone* in uſe at Paris, of which we do not ſeem yet to have met with any quarries in England, though probably enough there are ſuch, which has this property in ſo eminent a degree, that the expence of working it is in a great meaſure ſaved.

This ſtone lies every-where on the ſouth ſide of the river Seine, and is of a coarſe and large grit. It is ſo ſoft when newly taken out of the ſtrata, that they cut it very conveniently with a ſort of broad axe, and faſhion as many ſtones for building in this manner in an hour, as an equal number of our people do in a day or two. Though this ſtone is as ſoft as dry clay when firſt taken up, it is found to harden ſo conſiderably in the air, that it becomes more than equal to our ordinary *free-ſtone*.

Our Portland ſtone of the fineſt kind, which is white, and of a cloſe grit, is very fit for hewing or carving; but it will neither reſiſt water nor fire, which is a very ſingular circumſtance in ſo denſe a ſtone; while the *free-ſtone* of Kent, which is leſs beautiful to the eye, and is of a greyiſh colour, and conſiderably cloſe, tho' of a larger grain, reſiſts the air and water very well.

The *free-ſtone* of Derbyſhire, on the other hand, is ſo brittle as to be unfit for any fine working, and ſo coarſe and open in its texture that it lets water through; yet it bears the fire extremely well, and is fit for ovens, hearths, &c. Phil. Tranſ. N° 93.

FREEZING (*Cycl.*) — A degree of cold ſufficient for this may be procured in all climates, and at all ſeaſons of the year, by this means. Let a quantity of dry powder'd ſal armoniac be ſeparately included in one glaſs, and a proper quantity of common water in another. Let both theſe glaſſes be placed in a ſolution of other ſal armoniac in water while the ſalt is diſſolving; both the confined ſalt and the water will by this means be brought to the ſame ſtate of cold with the ſolution; and being then mixed together, they will form a ſecond ſolution much colder than the firſt. And this may be made the liquor for another quantity of ſal armoniac and of water to be placed in, which being afterwards mixed, and the ſame proceſs repeated, the cold may be brought to a degree proper for *freezing* in any climate or ſeaſon. *Shaw*'s Lectures, p. 78.

Nothing is more commonly known than the method of congealing liquors into ice by an artificial froſt even in the warmeſt ſeaſon; but it does not ſeem to be yet known what are the ſalts moſt efficacious of all on this occaſion, or, in other words, what ſalt is capable of producing the greateſt degree of artificial cold, or in what manner it may be beſt uſed, and what proportion it ought to bear with the powder'd ice or ſnow that is uſed on the occaſion. The common proceſſes are known, but few have enquired ſo curiouſly into the whole as ſo nice a ſubject ſeems to deſerve.

Mr. Reaumur at length took the whole into conſideration, and examined the various degrees of cold by a nice thermometer, which being placed in the liquor to be *frozen*, ſhewed very exactly the degree of cold by the deſcent of the ſpirit.

Salt petre uſually paſſes for a ſalt that may be very ſerviceable in theſe artificial congelations; but the experiments of this gentleman prove, that this is an erroneous opinion. The moſt perfectly refined ſalt petre employed in the operation ſunk the ſpirit in the thermometer but three degrees and a half below the fixed point.

Of the ſalt petre he uſed, the unrefined makes the ſpirit ſink conſiderably lower; the cauſe of which is, that the rough ſalt petre contains a large quantity of common, or ſea ſalt; and this being able to cauſe a greater degree of cold than the ſalt it is mixed with, exerts itſelf with it, and carries it to a greater degree of coldneſs: whereas in the refining ſalt petre, this ſea ſalt is thrown out, and conſequently the nitre becoming purer, acts only on its own principle, and cauſes a leſs degree of cold, ſuch as is its appropriated one.

Two parts of common ſalt being mixed with three parts of powder'd ice in very hot weather, the ſpirit in the thermometer immediately deſcended fifteen degrees, which is half a degree lower than it would have deſcended in the ſevereſt cold of the year 1709. Mr. Reaumur after this experimented the ſalts all round, and tried with great regularity and exactneſs, what was the degree of cold occaſioned by each in a given doſe. Among the neutral ſalts, none produced a greater degree of cold than the common ſea ſalt. Among the alkalies, ſal armoniac, though generally eſteemed ſo very powerful a one on theſe occaſions, ſunk the thermometer only to thirteen degrees. Pot aſhes ſunk it juſt as low as well refined ſalt petre. Thus by trials of the ſeveral ſalts, the proper degree of cold producible from each is eaſily aſcertained, and tables may be made of the numbers. After which, in the deſcribing any degree of cold in a particular ſeaſon, it will be a much better way of expreſſing it, to ſay it was equal to that produced by ſuch or ſuch a ſalt, than to name it by the degrees of a thermometer.

For the common uſes of the table, the ice required is not expected to be very hard, or ſuch as is produced by long continuance of violent cold: it is rather deſired to be like ſnow. Salt petre, which is no very powerful *freezer*, is therefore more fit for the purpoſe than a more potent ſalt. It is not required that the congelations ſhould be very ſuddenly made; but its retaining its form as long as may be when made, is a thing of great importance to the dealer in theſe things; nor is the price of the ſalts, which are to be uſed for this purpoſe, a matter of indifference.

If it be deſired to have ices very hard and firm, and very ſuddenly prepared, then ſea ſalt is of all others moſt to be choſen for the operation. The ices thus made will be very hard, but they will keep only a very little time without running. Pot aſhes afford an ice of about the hardneſs that is uſually required. This forms indeed very ſlowly, but then it will preſerve itſelf a long time. And there is another ſubſtance which performs the buſineſs very nearly in the ſame manner with the pot aſhes, and that on the ſame principle: this is a very cheap and ſimple one, being no other than common wood aſhes; but for this purpoſe the wood, which is burnt, ought to be freſh.

The ſtrong acid ſpirits of the neutral ſalts act much more powerfully in theſe congelations than the ſalts themſelves, or indeed than any ſimple ſalt can do. Thus ſpirit of nitre mixed with twice its quantity of powder'd ice, immediately ſinks the ſpirit in the thermometer to nineteen degrees; that is, it produced a cold of four degrees greater than that obtained by means of ſea ſalt, the moſt powerful of all the ſalts in making artificial cold. A much greater degree of cold may be given to this mixture by piling it round with more ice mixed with ſea ſalt. This gives a redoubled cold, and on the trial the thermometer was found to ſink to twenty-four degrees; that is, a degree of cold was thus artificially produced, which was to the greateſt known natural cold, that of the ſevere winter in 1709, as twelve to ſeven, or thereabouts. If this whole matter be covered with a freſh mixture of ſpirit of nitre and ice, a yet greater degree of cold is produced, and ſo on; the cold being by this method of freſh additions to be increaſed almoſt without bounds: but every addition, it is obſerved, gives a ſmaller increaſe than the former.

It is very remarkable in the acid ſpirits, that though ſea ſalt is ſo greatly more powerful than nitre in ſubſtance in creating cold, yet the ſpirit of nitre is greatly ſtronger than that of ſea ſalt; and another not leſs wonderful phænomenon is that of ſpirit of wine, a liquor which is little other than a liquid fire, has as powerful an effect in congelations, or very nearly ſo, as the ſpirit of nitre itſelf. What but experiment could have brought people to imagine, that theſe two ſo very different liquors could have this property as it were in common.

The mixture of any other matter with powder'd ice does not create a new cold by any other means than that of melting the ice it is mixed with. The moment of that melting is therefore the points of time in which the cold is ſtrongeſt of all, as after that the warmth of the external air cannot but be continually taking off from the new engender'd cold. It is plain from hence, that the quicker this melting is performed, the harder the ice muſt be, or the greater the degree of cold. It were much to be wiſhed therefore, that the melting could be inſtantaneous, as in that caſe the particles of ice would all act at one and the ſame time on the matter to be congealed: and in order to this, it is neceſſary that every particle of ice ſhould have a particle of ſalt ready to act upon it. This requires that the ice and the ſalt ſhould be both powder'd to a certain fineneſs. Hence may be deduced a rule, which though not quite preciſe, yet may be ſufficiently ſo for the determining the proper proportion of the ſalt to be mixed with any determinate quantity of ice. We well know from experiment, how large a quantity of water is neceſſary to melt a certain quantity of ſalt of any kind, and repeated experiments might bring the knowledge of the other ſolution to nearly as great a certainty. It would be well to try the whole carefully with ſea ſalt; and when the proportions of this were known, it would be no difficult matter from theſe to deduce the proper quantities of other ſalts, according to their known differences, in regard to the quantities of water neceſſary to diſſolve them.

The ſeveral liquid ſubſtances which create a cold, in the ſame manner as the dry ſalts on being mixed with ice, are much more ſpeedy in their action than the ſalts; becauſe they immediately and much more intimately come into contact with the particles of the ice, than the ſalts can. Of this nature are ſpirit of nitre, ſpirit of wine, &c. to produce the expected

pected degree of cold, it is always neceſſary that the ice and the added matter, whatever it be, ſhould both run together and intimately uniting form one clear fluid; 'tis hence that no new cold is produced with oil, which tho' it melts the ice, yet cannot mix itſelf into a homogene liquor with it, but muſt always remain floating on the ſurface of the water, produced by the melting of the ice. Mem. Acad. Scienc. Par. 1734.

In the *freezing* of wines and the like liquors, the aqueous parts *freeze* firſt, and are by this means ſeparated from the truly vinous; an obſervation which may be made of great uſe, in the wine trade. The experiment may be made by art, at any time: take a quart of common red port, put it into a Florence wine flask, and bury it in a mixture of one part common ſalt, and two parts ſnow or beaten ice, the conſequence will be, that the aqueous part of the wine ſoon turns to ice, and the rich thick remainder of the true vinous parts, may be poured off by inclination. Natural cold, however, in *freezing* wines, performs this experiment much better. By this means, wines, vinegars and malt liquors, may be all reduced to a fourth part of their quantity for exportation, without any conſiderable loſs of their eſſential parts, little more then the mere water *freezing*, and the eſſential part of the wine remaining thus admirably cured, and capable of keeping ſeveral years.

It is eaſy to ſee, that a great uſe may be made of this in the wine trade, as large quantities of the pooreſt wines might thus be converted into rich ones, and the quinteſſence of the richer wines might be procured for the amending the poor ones; and vaſt advantages might be reaped from this in wine countries.

Wines and vinegars concentrated by *freezing*, tho' they keep unaltered for ſeveral years, yet are liable to ſome accidents in proceſs of time.

Thus wines on being concentrated ſeem to acquire a more auſtere taſte than they had originally; and this is not wonderful, as the condenſation brings the ſaline and rough matter into a third or a fourth part of the compaſs that it originally lay in; ſo that this is properly no addition or increaſe of the rough taſte, but probably on the contrary, ſome mitigation of it in regard to the cloſeneſs to which this rough matter is brought, which of itſelf ought rather to multiply the effect in a greater proportion.

The change may be conceived owing to this, that all wines are obſerved to grow mild and ſoft by lying long, which effect is greatly promoted in them by a ſucceſſive ſeparation of their tartar, and a gentle evaporation of ſome part of their water occaſioning that neceſſity which is frequently found in the ſummer months of filling up the casks; but in our concentrated wine, tho' the ſame tartar be ſucceſſively ſeparated, yet there is found no concurrent ſlow evaporation, for the concentrated wine grows ſoft and mellow in a well ſtopped glaſs, where no diminution of the quantity is perceived; the effect in this caſe proceeds principally from a cloſer and more intimate combination of the ſpirituous, with the groſſer and more terreſtial part. *Stahl*, de Concentrat.

Beſide this, there ſeems another remarkable change incident to the concentrated wine, not only in the taſte, but more abundantly in the ſmell. For if an auſtere and rough wine, and of the uſual ſmell of ſuch wines, be put up in bottles, its taſte after two or three years not only becomes more mellow and ſmooth, but its ſmell at this time, perfectly reſembles that of ſack or canary. This is a high degree of melioration, and will give a poor auſtere German wine, for ſuch were thoſe on which Stahl made the experiments, the flavour of ſo rich a wine as canary, and that ſo perfectly, that very good judges may not find out the difference by their ſmell, tho' the taſte is abundantly different. Whatever advantage the dealer in wines may foreſee from the ſucceſs of theſe experiments, there is this farther inducement to his bringing them into practice in the large way, that every thing will anſwer better, and not worſe, than the experiments in the ſmaller quantities. All theſe experiments have been made with little portions, which are very well known not to keep ſo well as larger; and it is evident both from reaſon and experience, that great bulks of liquor are much leſs ſubject to changes and alterations from the external effects of air and heat, which are the two great incentives to fermentative motions; and that if ſuch ſmall parcels ſuffered no change for the worſe, much leſs need it be apprehended, that any larger would. *Shaw*'s Chem. Eſſay.

FREEZING *rains*. Our own annals give us many accounts of the damage done to our trees by rains *freezing* as they fall, and conſequently forming cakes of ice about all the branches, which by degrees increaſe to a weight that the branch is unable to ſupport. In the year 1672, there fell ſuch a rain as this at Briſtol, and over all the country thereabouts. Moſt of the orchards expoſed to the north-eaſt, were deſtroyed by it, and had it continued longer, and been attended with guſts of wind, ſcarce any thing could have ſtood before it. A piece of an aſh tree of juſt three quarters of a pound weight was weighed, with its coat of ice upon it occaſioned by this rain; the ice weighed ſixteen pounds, beſide what was melted off by the perſons hands who brought it. The ſtalks of graſs were ſurrounded with coats of ice, ſome of which were five inches round by meaſure. All the time that the orchards and hedges were thus breaking under the loads of the ice, the waters were all free, and not ſo much as a puddle frozen over. The roads were rendered impaſſable by the parts of trees every where fallen acroſs them, and the noiſe of the icy boughs rattling againſt one another, as ſhook by the wind, was very terrible. Where this rain fell upon the ſnow, it immediately became ice as on the trees.

It is remarkable, that men who were out on the road, complained of the moſt exceſſive colds, and were in agonies on coming into a warm room; though all the while in ſome places, there only fell a kind of ſleet, which was wet under the feet, and gave no appearance of froſt upon the ground.

This ſort of temper in the air preceeded alſo the *freezing* rains, in the very places where they happened. Tho' this ſevere weather happened in December, as ſoon as it was over, which was in a few days, there was a ſudden change, into not only a mild, but a hot ſeaſon. People complained of exceſſive ſweating, both by night and day, and the trees and hedge-buſhes put forth their buds for leaves and bloſſoms, as if it had been April; ſome of the apple-trees flowered before Chriſtmas, and had the young fruit before New-years day. Dr. *Beal* in Phil. Tranſ. N° 90.

FREGAROLA, in zoology, a name given by many, to a ſmall river fiſh, well known in England by the name of the *minow*. *Willughby*'s Hiſt. piſc. p. 268. See the article PHOXINUS.

FREGGIA, in zoology, the name of a long anguilliform fiſh of the tænia kind, more commonly called *cavagiro*. *Willughby*'s Hiſt. piſc. p. 117. See the article CAVAGIRO.

FREISER, a name uſed by ſome for the ſtrawberry plant. *Ger.* Emac. Ind. 4.

FRENCH *bole*. See the article BOLUS.

FRENCH *graſs*, a name given by our farmers to a plant raiſed for the food of cattle, and more properly called ſaint foin. It had its name *French graſs*, from its coming originally to us from France, and from its uſe in ſerving both freſh and dried for the food of cattle; the common clover is called graſs alſo by the farmers, tho' neither this nor the other, are properly graſſes. Some of our farmers alſo call it everlaſting graſs, from its long continuance, a ſtrong crop often yielding a plentiful annual produce for forty years without any renewing. See the article SAINT *Foin*.

FRESH (*Cycl.*) — FRESH *the hawſe*, on board a ſhip. See HAWSE, *Cycl.*

FRESH-*water ſhell-fiſh*, See FLUVIATILES *cochleæ*.

FRETTS, in mineralogy, a term uſed by our miners to expreſs the worn ſide of the banks of the rivers in mine countries, where they ſearch for the ſhoad ſtones, or grewts, waſhed down from the hills in order from them to trace out the running of the ſhoad up to the mine. Philoſ. Tranſact. N° 69. See SHOAD.

FRETUM, *ſtraight*, or *ſtreight*, in geography. See the article STRAIGHT, *Cycl.*

There are three kinds of *ſtreights*: 1. Such as join one ocean to another. Of this kind are the *ſtreights* of Magellan and Le Maire. 2. Thoſe which join the ocean to a gulph. The *ſtreights* of Gibraltar and Babelmandel are of this kind, the Mediterranean and Red ſea being only large gulphs. 3. Thoſe which join one gulph to another; as the *ſtreight* of Caffa, which joins the Palus Mæotis to the Euxine or Black ſea.

The paſſage of *ſtreights* is commonly dangerous, on account of the rapidity and oppoſite motion of currents.

FRICIUM, in pharmacy, a name given to ſuch medicines as are intended to be rubbed into the ſeveral parts of the body. The antients had three kinds of *fricia*, the dry, the ſoft, and the liquid, the firſt was uſed in the way of fumigation, the ſecond was bound on the part with cloths, and the laſt was uſed by way of embrocation.

FRIESLAND *horſe*. See CHEVAL *de friſe*, *Cycl.*

FRIGAT, in ſea affairs, a ſhip of war, uſually of two decks, light built, and deſigned for ſwift ſailing. When it hath but one deck, and conſequently is of a ſmaller ſize, they call her a light *frigat*.

FRIGHT. This paſſion has been known not only to cauſe, but to cure diſeaſes. Mr. Boyle mentions agues, gout and ſciatica, cured by this means. See Works abr. p. 82, &c.

It is a commonly known cure for the hiccough, to put the patient in a ſudden *fright*.

FRINGILLA, in the Linnæan ſyſtem of zoology, the name of a large genus of birds of the general order of the paſſeres. The diſtinguiſhing characters of this genus are theſe: the tongue is whole and even, the beak is of a conic ſhape, and one mandible receives the other into the ſinus of its baſis. Of this genus are the ſparrow, linnet, greenfinch, and the like. *Linnæi* Syſtema Naturæ, p. 48.

FRINGILLAGO, in zoology, a name by which ſome have called

called the whole genus of the titmouſes; but others have reſtrained it only to one ſpecies of them, which is the common larger kind. called by us the ox-eye. This is much larger than any of the other titmouſes, weighing near an ounce, whereas they ſeldom exceed three drams. Its head and the upper part of its throat are black, and from the angle of the mouth there runs a broad white ſtreak. Its back, ſhoulders and neck are of a greeniſh yellow; its breaſt, belly and thighs yellow, but the farther part of the belly toward the tail, is white. The tail is moderately long, and variegated with blue, black and grey. *Ray*'s Ornithol. p. 174.

FRINGILLAGO *Americana cærulea*, in zoology, a name given by Mr. Ray to the American titmouſe, otherwiſe known by its Braſilian name *guiracenoia*.

FRINGILLARIUS *accipiter*, in zoology, the name of a ſpecies of hawk, of the ſhort-winged kind, called by ſome *niſus*, and in Engliſh the ſparrow hawk. It is nearly of the ſize of the common pigeon. Its beak is ſhort and crooked, blue at the end, and blackiſh at the point; near the head it is covered with a greeniſh yellow membrane. Its tongue is thick and black, and is a little bifid. Its head is of a browniſh colour, but over the eyes and behind, variegated with white feathers. The neck, back and wings are all of the ſame brown, but ſome few of the wing-feathers which are near the back, are ſpotted with white; its breaſt and belly are variegated with brown and white; its chin and thighs are white; its wings are ſo ſhort, that when folded they do not reach more than to the middle of the tail; its legs are long, ſlender and yellow. It lays five eggs, which are white, but have at their larger end a circle of red ſpots. It is a very bold and lively bird, and will not, as many other ſpecies do, eat beetles, worms, &c. but feeds only on birds. *Ray*'s Ornithol. p. 51.

FRISONE, in zoology, a name by which many call the coccothrauſtes or groſs beak, called alſo in Engliſh, the hawfinch. *Ray*'s Ornithol. p. 178. See COCCOTHRAUSTES.

FRIST, a term among merchants for ſelling goods upon credit.

FRIT, in glaſs making, the calcined matter to be run into glaſs. To make this for cryſtal glaſs, take of the fineſt tarſo, powdered fine and ſifted, two hundred pound, of the ſalt of polvorine an hundred and thirty pound, mix them well together, and put them into the calcar, or calcining furnace, which muſt be thoroughly heated firſt, otherwiſe the operation will be very difficult; a moderate fire is to be kept up for an hour, and the matter continually ſtirred together with a rake, and then the fire muſt be made very violent, and kept up for five hours. After this, take it out and cover it from duſt, it will be white as ſnow. It muſt be kept in this ſtate, three or four months, and is then ready to make the fineſt cryſtal glaſs. *Neri*'s Art of glaſs, p. 8.

FRITH. See FRYTH, *Cycl.*

FRITILLARIA, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the liliaceous kind, and is bell faſhioned and pendulous. It is compoſed of ſix leaves, and has in the middle a piſtil, which finally becomes a fruit divided into three cells, and containing many flat ſeeds, lying in double rows on one another. To this it is to be added, that the root is compoſed of two bulbs, the one of which lies by the ſide of the other, theſe are uſually of a globular form, and the ſtalk ariſes from between them.

The ſpecies of *fritillary*, enumerated by Mr. Tournefort, are theſe. 1. The early purple variegated *fritillary*. 2. The great purple Italian *fritillary*. 3. The great yellow Italian *fritillary*. 4. The purple branched *fritillary*. 5. The greeniſh yellow many flowered *fritillary*. 6. The umbelliferous *fritillary*. 7. The great *fritillary*, with dusky purple flowers. 8. The branched *fritillary*, called the leſſer Perſian lilly. 9. The white many flowered *fritillary*. 10. The bright yellow flowered *fritillary*. 11. The late double *fritillary*, with greeniſh yellow flowers. 12. The tall Spaniſh *fritillary*, with pale red flowers. 13. The black flowered *fritillary*, 14. The Iſabella *fritillary*, with greeniſh red flowers. 15. The *fritillary*, with a dusky purple ſulcated angular flower. 16. The *fritillary*, with very large double flowers. 17. The white variegated teſſellated *fritillary*. 18. The early white *fritillary*. 19. The late *fritillary*, with blackiſh purple flowers. 20. The late *fritillary*, with yellowiſh green flowers. 21. The yellow *fritillary*, with red ſpots. 22. The narrow leaved yellow variegated *fritillary*, with large flowers. 23. The narrow leaved yellow variegated *fritillary*, with ſmall flowers. 24. The Pyrenean ſmall flowered *fritillary*, and 25. The ſmalleſt many leaved *fritillary*. *Tourn.* Inſt. p. 377.

Beſides the many diſtinct ſpecies of this beautiful plant; there are vaſt varieties in the colours of the flower, in the plants carefully propagated from ſeeds. They are by ſome propagated by roots, but the method by ſeeds is greatly preferable, as it produces much the greater number of roots, as well as the better flowers.

The ſeeds for this ſhould be ſaved from the fineſt flowers, and ſown on ſome light freſh earth in flat ſhallow pans, or boxes with holes at the bottom, kept open by tile-ſhreds to let out the moiſture. The ſeeds muſt be ſown pretty thick, and covered with a quarter of an inch of earth: this is to be done in the beginning of Auguſt. The pans or boxes are then to be ſet in a place where they may have the morning's ſun, till about eleven o'clock, and if the ſeaſon proves dry, they muſt be watered, and always carefully kept clear of weeds. *Miller*'s Gard. Dict.

Toward the latter end of September the boxes muſt be removed into a warmer ſituation, and placed under ſhelter of a hedge or under a ſouth wall, and they are here to remain till the middle of March, by which time the plants will be come up an inch high. They are now to be removed into a ſhady ſituation, and are to remain there the whole ſummer. About the beginning of Auguſt, a bed of freſh earth is to be prepared, on which the earth of the pans and boxes containing the roots of the plants is to be ſtrewed, after their leaves are all dead: this is to be covered half an inch thick with fine freſh earth evenly ſifted on, and in this ſtate they are to remain till they flower, which is generally the third year from the ſowing. When they are in flower, the fineſt kinds ſhould be marked with ſticks, and their roots planted out into ſeparate beds. *Millar*'s Gard. Dict.

As ſoon as the leaves are decayed they ſhould be carefully weeded, and thin offsets taken up and tranſplanted.

FROG, in zoology. See RANA.

Generation of FROGS. This was very nicely inquired into, by the ſagacious Lewenhoek. He found by repeated obſervations, that the male in copulation only ſits upon the female, not being joined to her, nor having any apparent penis. At the time that the female *frog* drops her ſpawn, the male alſo throws out his ſemen, which is to be placed under the eggs, as the ſemen of fiſhes that want the penis is caſt under the eggs or ſpawn of their females, that the animalcules in it, may impregnate the eggs. The animalcule in the male ſeed, has its way to make into a certain point of the egg of the female, elſe that egg is unfruitful; and this is the reaſon why the animalcules in the male ſemen are ſo prodigiouſly more numerous, than the eggs in the female, becauſe vaſt multitudes of them muſt neceſſarily be loſt. The teſticles and vaſa deferentia of *frogs*, are very evident to any one uſed to anatomical inquiries on opening the creature; and theſe contain vaſt numbers of very vigorous animalcules at the time when the creature is to produce its young, which is in April, but at other times, they are not ſo numerous or lively.

This creature bears the experiments of the air pump, better than moſt other animals. It will breathe ſome time after the extraction of the air, but at length the viſible motion of the throat will ceaſe, and the body ſwell a little. After three hours lying in this condition, when no farther ſign of life appears, if the animal be placed in the open air, a few hours will recover it to its former life and vigour. The ſame animal put into a receiver exhauſted of the air, but nearly filled with water, will live many hours under the water, and ſeem to reſpire, but in five or ſix hours it will die. The larger and luſtier *frogs* live longer than the young ones in the receiver. Phil. Tranſ. N°. 62.

FROG *microſcopically examined.* — The *frog* affords the curious in microſcopic obſervations, a very beautiful view of the circulation of the blood; but the method of examining it to advantage was never hit upon, till the contrivance of the late ingenious Dr. Stuart for that purpoſe. This he did by the ſolar microſcope in the following manner. The looking glaſs, tube, and convex lens are the ſame in this, as in the common ſolar microſcope, but inſtead of the little pocket microſcope of Wilſon, he uſed the belly part of the common large reflecting one, fixed horizontally on a pedeſtal, juſt at an equal height with the tube. This ſtands on a little ſhelf made to ſupport it; and to its ſnout, which lies on a level with the tube, the magnifiers are ſcrewed; the object being extended and faſtend with ſtrings and pins on a frame contrived for that purpoſe, is applied between the tube and the magnifier, whereby the ſun's rays reflected from the looking glaſs, thro' the tube, upon the object, paſs on thro' the magnifier, and exhibit upon the ſcreen an image of the object moſt prodigiouſly enlarged. *Baker*'s Microſ. p. 132.

To view a *frog* with this apparatus, the skin of the belly is to be opened from near the anus to the throat, and then giving it a little ſnip ſide ways both at the top and bottom, and ſticking a fiſh-hook into each corner of the skin, it was eaſily extended before the microſcope, and ſhewed on the ſcreen the moſt beautiful view imaginable of the veins and arteries of the skin, with the blood circulating thro' them. In the arteries thus viewed, the blood is ſeen to ſtop, and recede a little at every pulſation by the dilatation, and ruſh forcibly on again, by the contraction of the heart; while in the veins it ever kept the ſame equable and uniform current, with a ſurpriſing rapidity; and when the ſcreen was removed farther back, and the object by that means more enlarged; the alternate expanſion and contraction of the ſides of the arteries was very viſible. After this, the abdomen of the *frog* being opened, and the

muſcles

muſcles of it extended before the microſcope in the ſame manner as the skin was, the ſtructure of theſe muſcles is beautifully ſeen, they being all made up of bundles of tranſparent ſtrings or fibres, all lying parallel to one another, and are joined by a common membrane.

Theſe ſtrings or fibres appeared alſo thro' their whole length made up of roundiſh veſicles, and reſembled ruſhes divided longitudinally; but there is no certainty of any circulation being ſeen in theſe.

When this has been ſufficiently examined, a part of the creature's gut being pulled out and extended with the meſentery, there is ſeen the fineſt of all views of the circulation of the blood. Words are not able to deſcribe this wonderful ſcene. The blood is ſeen paſſing through numberleſs veſſels at one and the ſame inſtant, in ſome one way, and in others directly the contrary. Several of the veſſels are thus magnified to more than an inch in diameter, and the globules of the blood rolling through them appear near as large as pepper-corns; while in many of the minuteſt veſſels only ſingle globules were able to find their paſſage, and that too by changing their ſhape into an oblong ſpheroide. The pulſation and acceleration of the blood in the arteries is thus alſo very beautifully ſeen. As the animal under examination grows languid and near expiring, the blood in the arteries will often ſtop on a ſudden, and ſeem as if it were coagulating, and will then run back for ſome time; after which it will again recover its natural courſe with a great deal of rapidity. A due conſideration of theſe particulars may poſſibly account for the intermiſſions, ſtarts and irregularities in the pulſe of perſons near death. *Baker*'s Microſcope, p. 136.

FROG *fiſh*, in ichthyology, an Engliſh name for the rana piſcatrix or lophius. See RANA *Piſcatrix*.

FRONDES, among botaniſts. See LEAF.

FRONT *half files*, in the military art. See FILE *Leaders*.

FRONTATED, in botany, a term uſed to expreſs the leaf of a flower, which grows broader and broader, and uſually terminates in a right line. It is uſed in oppoſition to cuſpidated or ſpear-pointed, the common term for the petals of flowers which end in a point. *Miller*'s Gard. Dict. See LEAF.

FRONTIS *Os*. See Os *frontis*.

FROST (*Cycl.*)—In very cold countries meat may be preſerved by the *froſt* for ſix or ſeven months, and prove tolerable good eating. See Captain *Middleton*'s Obſervations made in Hudſon's Bay, in the Phil. Tranſ. N° 465. Sect. 2.

In that climate the *froſt* ſeems never out of the ground, it having been found hard frozen in the two ſummer months.

Brandy and ſpirits of wine, ſet out in the open air, freeze to ſolid ice in three or four hours. Lakes and ſtanding waters, not above ten or twelve feet deep, are frozen to the ground in winter, and all the fiſh therein periſh.

But in rivers, where the current of the tide is ſtrong, the ice does not reach ſo deep, and the fiſh are preſerved.

Springs have never yet been found free from freezing, though lying ever ſo deep; ſo that the water uſed is melted ſnow and ice. Id. ibid. See FREEZING.

FROST, in gardening, husbandry, *&c.* —Our old authors have given many idle admonitions about preſerving the fruit-trees from the injuries of *froſts*, ſome of which are religiouſly believed and practiſed by ſome to this day. One is the placing a veſſel of water on ſome part of the tree, that the *froſt* may ſeize upon that, and ſo let the tree eſcape. Others uſe a pernicious method inſtead of this idle one, which is the digging a trench about the roots of their trees, and keeping it ſupplied with water during the whole ſeaſon of the ſpring *froſts*. This has hurt many good trees.

The great power of *froſt* on vegetables is a thing ſufficiently known; but the differences between the *froſts* of a ſevere winter, and thoſe which happen in the ſpring mornings, in their effects on plants and trees, were never perfectly explained, till by Meſſ. Du Hamel and De Buffon, in the Memoirs of the Paris Academy.

The accurate knowledge of vegetables, which is ſo material a part of agriculture, as to deſerve the attention of all who wiſh well to their country, is however a thing only to be arrived at in length of time, and by a great number of experiments, ſuch as no one man's life can give him opportunities of making; and even thoſe which have been made ſeemingly with the greateſt care and caution in one place, and have ſerved for the eſtabliſhment of rules with one author, have been found to ſucceed very differently, and to give very different ideas in another place, and to another perſon.

The *froſts* of ſome winters have been ſo ſevere, as to deſtroy almoſt all the tender vegetables; and that ſevere one of 1709, gave the world proofs of more than was before ſuppoſed could be done by them. The corn that was ſown, and moſt other ſeeds in the ground, periſhed entirely. The hazels and filbert trees periſhed almoſt without exception; and many of the more hardy fruit trees periſhed to the ground, but ſhot out afterwards new branches from the root or ſtock, while ſome of the larger trees, which were very vigorous and ſtrong, threw out leaves in the ſpring on almoſt all their branches, and ſeemed to have ſuffered very little; though in reality they had ſuſtained many irreparable injuries, which did not then appear.

The *froſts* of ſevere winters are thus able to injure all the vegetable world. Thoſe of the ſpring however are much leſs terrible. Theſe ſometimes injure the young ſeedling plants; but they never are able to affect the ſolid parts of trees, or hurt their trunks or larger branches, tho' they too often deſtroy their buds, and take off the embryo fruits of the growing year; and are not much leſs detrimental to the foreſt than to the fruit trees, as they ſtop the growth of thoſe buds which would grow into branches.

The *froſts* of ſevere winters are greatly more terrible than thoſe of the ſpring, as they bring on a privation of all the products of the tenderer part of the vegetable world; but then they are not frequent, ſuch winters happening but once perhaps in an age, and the *froſts* of the ſpring are in reality greater injuries to us than theſe, as they do us great injuries, though not ſo terrible as the others, and theſe are every year repeated.

In regard to trees the great difference is this, that the *froſts* of ſevere winters affect even their wood, their trunks and large branches; whereas thoſe of the ſpring are only of power to hurt the buds. Theſe two ſeaſons of *froſts* act in very different circumſtances, and thoſe ſituations and expoſures where the vegetables have ſuffered moſt in the winter's *froſts*, are often found to be leaſt affected by thoſe of the ſpring. This is a truth that can only be found out by frequent obſervations, which however are not to be regarded as mere matter of ſpeculation, but may have their uſe in the teaching us to guard againſt the miſchiefs they warn us of. The winter *froſts* happening at a time when moſt of the trees in our woods and gardens have neither leaves, flowers, nor fruits upon them, and have their buds ſo hard as to be proof againſt ſlight injuries of weather, eſpecially if the preceding ſummer has not been too wet; in this ſtate, if there are no unlucky circumſtances attending, the generality of trees bear moderate winters very well; but hard *froſts*, which happen late in the winter, cauſe very great injuries even to thoſe trees which they do not utterly deſtroy. Theſe are, 1. Long cracks following the direction of the fibres. 2. Parcels of dead wood incloſed round with wood yet in a living ſtate. And, 3. That diſtemperature which the foreſters call the double blea, which is a perfect circle of blea, or ſoft white wood, which, when the tree is afterwards felled, is found covered by a circle of hard and ſolid wood. The blea is in its natural ſtate an outer circle of white and imperfect wood ſurrounding the hard and more perfect wood of the tree, and ſurrounded by the bark, and is eaſily diſtinguiſhed in moſt ſpecies from the hard wood or heart of the tree by its different colour and want of hardneſs.

The ſound or perfect wood in trees, in their natural ſtate, is all of one colour and hardneſs from its circumference to its center; but in theſe injured trees the blea ſurrounds the heart, and more of the heart ſurrounds the blea, which appears again in an outer circle round that, and covered by the bark. This is the ſtate of a tree before and after being injured by *froſt*; and in this ſtate are trees found on the felling in different degrees, according to the different ſoils and ſituations in which they ſtand. In ſtrong ſoils, and in the covert of foreſts, where the trees are well rooted, and well ſhelter'd and defended, this diſtemperature is found leſs frequent, and in leſs degree, than in thoſe trees which ſtand expoſed, and are rooted in a laxer earth. The ſole inſpection of theſe circles of falſe blea, as the inner circle of white wood may very properly be called, ſhews them to be very poor and weak; and experiment abundantly proves the truth of the opinion. Beams cut of the ſame ſize out of the true blea and this falſe blea, by the weights required to break them, ſhewed the difference very plainly; the natural blea bearing twice the weight, or being of double the ſtrength of this in its unnatural ſtate. Though the blea at beſt is of no great ſtrength, compared with that of the perfect wood of the tree.

The ſpecific gravity of the true blea is alſo much greater than that of this falſe kind; but the outer circle of ſound wood ſurrounding this falſe blea is found to be of equal weight and hardneſs with the heart or central wood; ſo that whatever perfect wood is found in the tree, appears to be all of the ſame quality. Notwithſtanding that, there is this great difference between the two bleas, the inner being ever lighter and weaker, even though it have been formed twenty or thirty years before, as may be known by the annual circles which appear on the outſide of it.

The number of obſervations which Mr. Reaumur made of this blea in trees of different parts of France, all ſhewed him the falſe blea under the ſame number of annual circles of the after-growth of the tree; and theſe being counted, proved juſt as many as the number of years ſince 1709; whence he very juſtly concluded, that all the falſe blea he found throughout the kingdom was the effect of the ſeverity of this one hard winter. And it is very evident, that this falſe blea is that part of the tree, which in the year 1709 was the true and natural blea, and which the ſeverity of the *froſts* of that winter prevented from ever becoming the ſound and ſolid wood,

but

but left it to become more weak and defective for a ſucceſſion of years; during which the ſeveral annual circles of ſupervening blea all became ſound and perfect wood in their natural courſe.

It appears very plain, that the blea muſt be that part of the wood which ſuffers moſt, becauſe it is the outer wood of all, and itſelf makes a covering for the inner part: and add to this, that it is of itſelf of a much leſs compact texture, and contains more juices for the *froſt* to act upon. It was obſerved in France the year after this ſevere *froſt*, that the young trees had ſuffered much leſs by it than the old ones. But it it is not improbable, that the reaſon of this might be, that the ſap-veſſels being very tender and flexile in theſe, and hard and rigid in the old trees, the ſame force which only dilated them in the young ones, might burſt them to pieces in the old ones. It was ſuppoſed by ſome, that the blea of all the old trees was abſolutely killed in this ſevere winter. But that ſeems not to have been the caſe. Experiments made it appear, that it ſtill maintained a courſe of ſap for the ſervice of the remaining part of the tree, though it had ſuffered ſuch a rupture in its veſſels, as not to be convertible, according to the due courſe of nature, into ſolid wood; and, in fine, that it got an incurable diſeaſe, though not abſolute death.

In the accurate examinations made after the year 1709, the falſe blea was not found in the ſame ſtate in all the trees that were examined, but appeared to have ſuffered by the *froſt* in very different degrees. Some trees afforded much thicker on one ſide than on the other, which is a ſtate wholly unnatural to it; and others had it ſo thin all round, as plainly to prove that the whole blea had not ſuffered, but that the inner part of it had eſcaped, and had abſolutely been ſince turned into wood according to the due courſe of nature, while only the outer parts had ſuffered the diſtemperature, and remained, though much damaged, yet not at all changed into wood.

The falſe bleas of the ſeveral trees were not at all alike in colour, nor had ſuffered the diſtemperature in an equal degree; and in thoſe which had ſuffered it in ever ſo great a degree, on digging down towards their roots, that part of the blea which was under ground was found to have eſcaped unhurt, and to have been ſince regularly converted into hard wood; the cover of earth having proved an abſolute defence againſt the *froſt*.

The injuries done by ſevere *froſts* to old trees are therefore very great, and it is not one or two particular ſpecies that are ſubject to them; but it is hard to name any one that is exempt from them. Timber may always be diſcovered to have this defect by the eye, when viewed in the whole tree; and where there is ſeen a bed of falſe blea in it, its ſtrength is accordingly to be accounted the leſs, in proportion to the thickneſs and unſoundneſs of this blea.
