**ENGINEER**  
(WISCONSINENSIS)

**Robert T. Blake, Class of '49**

speaks from experience when he says,

**“At U.S. Steel, the opportunities are unlimited.”**

Bob Blake had his first experience in steel mills working there during summer vacations from college. After receiving his B.S. degree in Electrical Engineering, he became an operating trainee in U.S. Steel's Irvin Works. During his training program, his background and versatility were used by the Training Division to develop a training program for Electrical Maintenance employees. By the end of 1951, Mr. Blake had become a Foreman with experience in both Cold Reduction Maintenance and the Galvanizing Department.

Effort is made to have young engineers obtain varied experience before devoting themselves to one field. Mr. Blake feels that, "An engineering graduate has practically no ceil-

ing provided he has the right attitude and is willing."

Promoted again in 1954, Mr. Blake is now Foreman—Electric Shop in Central Maintenance. Supervising a crew of 40 men, he is responsible for electrical construction work, maintenance and crane wiring. Mr. Blake feels he is in "an interesting and challenging field of work." He has found that "U.S. Steel is a highly desirable employer in this most basic

of all industries."

If you are interested in a challenging and rewarding career with United States Steel and feel you are qualified, further information is available from your college placement director. Or, we will gladly send you our informative booklet, "Paths of Opportunity." Just write to United States Steel Corporation, Personnel Division, Room 1622, 525 William Penn Place, Pittsburgh 30, Pa.

**SEE THE UNITED STATES STEEL HOUR.** It's a full-hour TV program presented every other week by United States Steel. Consult your local newspaper for time and station.

**"ELECTRIC BLANKET"  
DEICES  
ARCTIC AIRCRAFT**

AKRON, OHIO — Now available to aircraft on the northernmost frontier of our air defense network is new protection from severe in-flight icing dangers. The secret is a revolutionary electrothermal deicing system conceived by The National Research Council of Canada and developed for aircraft by Goodyear.

Goodyear engineers produced rubber-covered heating units flexible enough to be easily applied to the compound contours of modern jet aircraft. Known as the Iceguard, this rubber "electric blanket" defies biting rain, hail and ice.

By combining the Iceguard with the new electromechanical ice detector and Control System of PSC Applied Research, Ltd., operation is fully automatic. The pilot is completely freed from icing worries. Another tribute to the teamwork for which Goodyear engineers have become famous.

Significant developments like this are "par for the course" at Goodyear.

Here, engineers are given the freedom of thought and expression they need for the practical application of their new ideas. This imaginative approach, encouraged by Goodyear Management and supervised by many of industry's leading technical men, has been an important factor in establishing Goodyear as "the greatest name in rubber."

Today's greater dependence upon technology means that now, more than ever, Goodyear offers a world of opportunity to young engineers. The Goodyear Management Training Program for Technical Gradu-

ates will give you a solid foundation upon which to select a challenging career in research and development, design and production, sales and service. For, with 27 plants in the United States and 26 plants in 19 foreign countries, Goodyear offers you the know-how, experience and security of the largest rubber company in the world.

For further information on *your* career opportunities at Goodyear, contact your Placement Officer or write: Technical Personnel, Dept. 806-W, The Goodyear Tire & Rubber Company, Akron 16, Ohio.

**Recreation a Major Activity at Goodyear**

"All work and no play makes Jack a dull boy." Here at Goodyear employees have the finest in gymnasium, bowling, theatre and other hobby space and equipment. Just one example, the Goodyear basketball team, provides players and spectators alike with an exciting season in one of the fastest circuits in the country. With so many varied leisure time activities, Goodyear people have no difficulty in finding adequate and interesting recreation with friends having similar interests.

*There's a world of opportunity at*

Iceguard—T.M. The Goodyear Tire & Rubber Company, Akron, Ohio

**THE GREATEST NAME IN RUBBER**

## ENGINEERS

Aviation leadership is not an overnight achievement. It's the result of a long series of outstanding engineering ideas.

Republic engineers have been producing these top ideas for over a quarter of a century—and turning them into great planes: The first American all-metal plane; the trail-blazing P-35; the famous P-47 Thunderbolt fighters; the matchless F-84 Thunderjets and F-84F Thunderstreaks, and now the super-secret, supersonic F-105. And, our Guided Missiles Division is pioneering in upper atmosphere research and missiles technology.

Republic has always been an engineer's organization...and the achievements of our engineers speak for themselves.

## If you're still on the fence—

FOR THE BENEFIT of the young engineer who is puzzling over his future—hasn't yet decided on a job—we'd like to mention some facts about General Motors.

GM gives young engineers a great chance to follow their natural bent—because GM makes a wide variety of products including cars, trucks, Diesel engines, Prop-Jet aircraft engines, road-building machines, home appliances, military equipment.

GM gives young engineers an opportunity to work with small, friendly groups of more experienced men, in a choice of locations. For GM is decentralized into 34 manufacturing divisions with 122 plants in 67 U. S. cities.

At GM, the young engineer finds prestige, security, the support of vast technical resources, including the research facilities of a multimillion-dollar Technical Center.

He is encouraged in his professional growth through training programs, publication of reports, material incentives, and assignment of additional responsibilities as rapidly as he is able to handle them.

Fact is, the way things are going now, 40% of GM executive posts will be filled by men with engineering backgrounds.

Think you can take the measure of a job with the world's largest and most successful industrial company—dedicated to producing “more and better things for more people”?

Then your very next step is a chat with your Placement Officer. Or else, write us directly—the sooner, the better.

WITH THE

# EDITOR

This being the first issue put out by the new staff I would like to take this opportunity to meet all our readers. In doing so I have two requests that I would like to have you fulfill.

First, the only way that I can find out what you want in this magazine is for you to tell me.

Please criticize this magazine at any time whether it be what students of speech call constructive criticism or just plain old fashioned gripes. The staff will welcome all comments and give due consideration to any new ideas you would like us to incorporate in the magazine.

Second, if any of you would like to put some of your wasted spare time to good use, the staff would very much like to have you join us. A simple telephone call to anyone on the present staff will give you all the information you want. Whether it be just the desire to see your name in print or the chance of providing a service for your department we would be glad to have you with us. Remember, the best way to use your ideas for this magazine is for you to put them in effect yourself.

\* \* \*

We of the *Engineer* would like to tip our hats to the Wisconsin Engineering Exposition Committee and especially to John Bollinger the chairman for the top notch job they did in handling the exposition. With the help of the weather man this was by far one of the most successful expositions in their history. The University can certainly be proud of The College of Engineering. —R.F.S.

P. S. Do you have any comments on the new registration procedures? Let's hear them!

# No one gets lost in Norton City

**N**ORTON CITY, the largest single industry in Worcester, Mass. and the world capital of the abrasives industry, is a big bustling community of thousands of skilled workers.

It is still growing. Yet one thing is certain. Norton City will never be too big for the men and women who compose it — never so large that they will feel lost among so many others.

Because the Norton success story is made up of countless individual success stories, in which opportunity for all is the ever-present theme.

## Your Own Success Story

can have no more favorable or congenial background than you'll find at Norton City. For Norton, as the largest manufacturer of abrasives and related products, serves not only every manufacturing field but supplies materials for the great, modern developments of nuclear science and jet and rocket propulsion.

That is one reason why your opportunities are practically unlimited at

Norton — with training, facilities and surroundings planned to give all possible encouragement to individual progress.

## Engineering At Norton

offers many inviting opportunities — particularly in the mechanical, chemical, ceramic and industrial fields. Research and development offer constant challenges to Norton scientists, and this company's long record of "firsts" in technical advancement is proof of how successfully these challenges have been met.

Other attractive openings here are in technical sales, finance and administration. In planning your own future — technical, business or a combination of the two — you will do well to consider the established leadership and far-ranging scope of the Norton world-wide organization.

## Let's Get Acquainted

The new illustrated brochure "*Your Future With Norton*" tells you a good deal about Norton City. It describes the

products made there and what they're used for. It charts the Norton organization on the world map. But best of all, it gives you an insight into the lives of Norton folks, at work and at play. Write for your free copy to Director of Personnel, NORTON COMPANY, Worcester 6, Massachusetts.

## to the well too often

There are easier ways to get a drink.

And engineering graduates will be called upon to develop them. They'll have to help supply and distribute the billions of gallons of water needed daily by homes and industry. Water that will be increasingly hard to find.

But when they find it, they can rely on cast iron pipe to carry it. Practically every city in America—large or small—uses it for water and gas mains. In over 70 public utilities cast iron pipe has served for a century or more. No other pipe can point to such a long and useful record of service to the nation.

1916 SPERRY "AERIAL TORPEDO," FORERUNNER OF TODAY'S GUIDED MISSILES

*For Graduate Engineers, the Sky is the Limit in*

## **Missile Careers with Sperry**

Study the list above and you'll find that here at Sperry we are engaged in every phase of engineering necessary for missile development. Since 1916 when Sperry developed the first pilotless aerial torpedo for the Navy, we have specialized in all the arts required for the missiles of today — and tomorrow. Currently Sperry is putting its capabilities to work in six major missile systems—of all types—ranging from complete systems' cognizance to major sub-system responsibility.

If you are interested in getting into missile engineering or want to specialize in any of the phases of engineering listed above — see the Sperry representative when he visits your school—or write now to J. W. Dwyer, Sperry Gyroscope Company, Section 1B5.

# MOTION WITHOUT MOTORS

by Peter J. Barrett, m'57

## Theory of Sailing

Most people find it easy enough to understand why a sailboat can move with the wind pushing it, but often have difficulty seeing how a yacht can move upwind against the force which is giving it motion. A boat moves downwind because the wind is pushing it, just as a chip of wood will be blown across a puddle on a windy day. See Fig. 1, where the sail is arranged perpendicular to the wind to present the greatest area and consequently the greatest driving force.

Fig. 1

Fig. 2.

Fig. 3.

In Fig. 2 the boat is moving upwind, against the wind, at an angle of  $45^\circ$ . This is as close as any sailboat can sail to the direction the wind is blowing from. Thus, to reach a point directly upwind, a sailboat is forced to sail a series of zig-zags, each  $45^\circ$  from the wind direction, and with each corner a  $90^\circ$  turn. See Fig. 3.

The force that is driving the boat upwind is the same force that keeps an airplane in the air. Picture an airplane wing with the air flowing over it (Fig. 4). Particle A, moving over the top of the wing, has further

Fig. 4.

to go than particle B which moves underneath the wing. If both particles start across the wing at the same instant, they must both arrive at the trailing edge of

the wing at the same instant. Since A had farther to go, we may assume that it traveled faster than B, which had a shorter distance to cover. This means a current of air traveling over the wing with a higher velocity than the current passing under the wing. Bernoulli's Theorem, from high school physics, states that fluid pressure is inversely proportional to velocity. Translated, this means that the higher velocity air stream above the wing exerts less pressure on the wing than the air beneath . . . and the wing will rise.

Fig. 5.

All this can be directly translated to a sailboat. Instead of the wing, we have a sail with an air stream flowing over it, and a low pressure area on the side away from the wind. Thus a force is exerted which tends to move the boat sideways and ahead, and because a boat is long and narrow it moves ahead much more easily than sideways. See Fig. 5. It is this low pressure area, or vacuum, which pulls the boat forward against the wind.

## How Sails Are Made

Most landlubbers, after seeing white sails flitting about on a lake, would assume that all that is necessary to make a sail is to know the three dimensions of the triangle, make a big piece of cloth and cut it to the correct size, and put it on the boat and sail. This is far from the truth, in that sailmaking is one of the eldest, most secret, and most highly skilled trades (or perhaps it should be called an art) in the world. Going back to the analogy of an airplane wing, it is easy to see that a flat piece of cloth could hardly be expected to assume the shape of an aerodynamic surface automatically when hoisted on the mast and pulled out along

(Continued on next page)

the boom. The art of the sailmaker is to cut a piece of cloth so that when two of its edges are securely fastened to straight, rigid spars the cloth will take the shape of an aerodynamic surface. In order for this to happen, the edges of the sail must be curved in their natural form, so a sail laid out on a flat surface, say the floor of a sail loft, will look like a straight-sided triangle but like a spherical triangle. See Fig. 6.

Fig. 6.

A great deal of effort is spent in making sails in order to arrive at the correct curves for sides AB and AC (Fig. 6), so that the sail will assume the proper shape when AB is fastened to the mast and AC to the boom. What makes it even more of a challenge is the fact that nobody knows exactly what is the best shape. The draft of a sail is the depth of the belly in it, the extent to which it curves away from the plane of the mast and boom. The amount of this draft and the location of the point of maximum draft are two important variables which even the most experienced sailmakers and yacht racers cannot control perfectly. Not only because the

Downwind beauty.

Watch out for that puff coming across the lake.

means of control are imperfect (no two sailcloths will react the same, no length of rope which is sewn on the edge of the sail will stretch or shrink exactly evenly, no two spars will bend the same), but more important because the correct solution is itself an unknown.

However, there are some generalities that are pretty well agreed upon. A flat sail (little draft) is better in a strong wind, and as the wind decreases, the amount of draft should increase proportionally so that a light wind requires a rather full sail (one with a large amount of draft). Since the number of sails which a yachtsman may own is limited by the size of his budget (and at \$1 plus per square foot may find their budget quite limited), it becomes important to be able to control the draft of a sail by means which enable the same sail to be utilized over a variety of wind conditions.

### Spars

Before going into the actual methods of sail control, a brief description of spars might be useful. We are only concerned with two for the present; the mast, or vertical spar, along which the sail is hoisted; and the boom, or horizontal spar, which holds the bottom of the sail taut and provides a means for adjusting the angle between the sail and the centerline of the boat.

There are two popular ways of fastening the sails to the spars. The most widely used today is the channel, or boltrope, method where a small channel in the mast (or boom) is connected with the outside by a smaller opening, and a rope sewn on the edge of the sail runs in this channel while the sail extends through the smaller opening. See Fig. 8.

The other method is track and slides, where slides are sewn onto the sail and slide freely on a track which is screwed to the spar. See Fig. 9.

Fig. 7.

Fig. 8.

The shape of the mast is quite important, because it is the leading edge of the sail and very important in establishing smooth, non-turbulent flow over the surface of the sail. Masts may either be rigidly fastened at their base or may be mounted upon a swiveling device, so they can turn freely. In the first case a round mast is superior, because at no angle will there be any eddies caused by the flow of fluids around a corner. In the second case, that of a pivoting mast, it is possible to design a teardrop cross-section for the mast, because, while the boat is going against the wind and streamlining is important, the mast will always be pointing into the wind. In fact, some designers have gone to extremes and designed a long tapering teardrop which faces into the wind during upwind sailing and doesn't act as a resistance, and which turns perpendicular to the wind while sailing downwind and greatly increases the effective sail area of the boat.

The shape of booms is not as important as that of masts. However, one can design a high, narrow boom which will also add to the effective sail area, or a perfectly round boom which will reduce turbulent flow around the lower edge of the sail.

In the next section the bending of masts and booms is going to become important, and this is also an important factor in designing the cross-section of a mast or boom. Naturally the spar will bend easier in the direction of least cross-sectional width, and the designer should decide whether he is going to want fore and aft bending or lateral bending, or rigidity, and should keep this in mind as well as the other factors mentioned.

### Controlling Sail Draft

Something that few inexperienced and intermediate yacht racers realize is that just because they have only one sail, or perhaps two, they are not limited in the number of different wind conditions they can rig their boat for. The draft and shape of a sail can be greatly controlled by the proper adjustment of the mast and rigging of the boom.

Let us suppose that we have a sail which is cut for moderate winds (that is, with a medium amount of draft and the point of maximum draft approximately one third of the distance back along the boom). Suppose we come down to the shore on Saturday, eager for the big race, only to find it blowing a gale with whitecaps racing across the gray water. Before we turn homeward in disgust because our sail simply isn't flat enough to drive us to windward under these conditions, let's try a few adjustments.

Normally our mast is straight. What we want to accomplish is to pull out some of the bag or belly in our sail. Now if we can get the mast to bend concave backwards, with the top going back and the middle moving forward, we can in effect pull out that belly in the center of the sail and have a flatter setting sail. This we can do by slacking off on any stays running to the top of the mast, leaving the top limber and free to bend backwards when the sail is trimmed in flat. And of course, when the conditions are opposite (light wind) we want the mast to bend concave frontwards, with the top forward; so we tighten up on any stays running to the top of the mast and pull the top forward. This has the effect of moving the center of the mast backward, thus adding to the looseness of the sail and the draft or belly. Thus the mast may be caused to curve in either direction and the amount of this curvature closely controlled. There are numerous staying variations possible, depending upon the length and rigidity of the mast and the amount of control desired. Some scow sailors prefer such a limber mast that they can actually see it bend as a wave hits the hull or a gust of wind strike the sail—this is probably going to extremes.

Once we have seen how one can control the amount of curvature, it is easy to imagine how one can control the shape of the curvature by causing the mast to curve

**A WHIRLPOOL SPIRALS** into the inlet of a model pump. This unique picture shows how air, a common cause of pumping trouble, was carried into the pump in . . .

## The Case of the Baffled Whirlpool

Some time ago, the report reached us that two Worthington vertical turbine pumps installed by one of our customers weren't working right. They delivered plenty of water, but vibrated badly and burned out bearings.

The customer asked us to find the trouble fast. After checking we knew the pumps were okay, so Worthington Research had to answer him.

First thing we did was build a one-tenth scale model of the customer's installation. The photo shows what happened when we started pumping.

A whirlpool immediately formed between the water surface and the pump inlet. Air, trapped in the whirlpool and carried into the pump, was the villain in the case.

The solution came with experimentation. A simple baffle arrangement in a side channel eliminated the whirlpool—and the trouble-making air.

Chasing the gremlins from pump installations like this, boosting the efficiency of heat transfer in air conditioners, developing better seals for pumps and compressors—these are all in the day's work for Worthington's busy research engineers. At Worthington, research ranks right alongside engineering, production, and sales to develop better products for all industry.

For the complete story of how you can fit into the Worthington picture, write F. F. Thompson, Mgr., Personnel & Training, Worthington Corporation, Harrison, New Jersey.

RALPH PFISTER'S FAST RISE in only four years at Dow exemplifies the opportunities that exist with the "fastest-growing chemical company."

*"Expansion is so rapid  
at Dow, you have to  
keep moving up,  
growing, learning,  
just to keep pace."*

THIS COMMUNITY CENTER in a Dow city is typical of the excellent recreational facilities available to Ralph Pfister and other Dow employees.

**Thus, this 27-year-old production engineer explains his new position as Superintendent of a multimillion dollar warehouse with a work force of 100 men.**

In June, 1951, Ralph Pfister graduated from Northwestern University's Technological Institute. His studies, experience and natural inclination pointed to a future in production engineering. Pointed right to a position as process engineer in the Dow saran plant.

Within three years, Ralph moved to Ass't. Superintendent of a production train in a wing of the Styron® plant, to Ass't. Superintendent of the entire wing and two months ago to Superintendent of the 500,000 sq. ft. warehouse serving all wings of the plant.

"Always something new to learn . . . upper management not only allows but encourages our making the important decisions . . . the people are interesting, stimulating both at work and socially."

These excerpts from a conversation with Ralph Pfister give a quick profile of employment at Dow. Here is the fastest-growing company in the nation's fastest-growing industry. Dow communities provide some of America's most pleasant living surroundings and educational and recreational facilities.

*Whether your interest be production, research or technical sales, for more information on a career at Dow write for the 16-page booklet "Opportunities with The Dow Chemical Company." Address your request to Technical Employment Department, THE DOW CHEMICAL COMPANY, Midland, Michigan, or Freeport, Texas.*

you can depend on DOW

*no matter how many offers you've had*

## THE FACTS HAVEN'T CHANGED

It still takes good money, security, interesting work and good working conditions to make a man happy in his job. You needn't settle for less.

We'd like to tell you our five different versions of the story: *airplanes* (Air Force and Navy), *missiles*, *peaceful atomic energy*, *rocket engines*, and *electronics*.

**NORTH AMERICAN AVIATION, INC.** 

Herschel Loomis asks:

**What are my chances for advancement in a large company like Du Pont?**

**Herschel H. Loomis, Jr.**, will receive his B.S. degree in electrical engineering from Cornell University June 1957. Herschel is a member of the freshman and varsity rifle teams, an associate member of Octagon, a dramatic group, and belongs to Theta Chi Fraternity. Like many other students, he's making employment plans early.

**Peter J. Meshkoff** joined Du Pont at the Jackson Laboratory in 1941, after obtaining a B.S.Ch.E. from the University of Detroit and an M.S. from the University of Michigan. He has had a wide range of Du Pont experience, from chemist in the Dye Works to chief supervisor and works engineer at several plants, with many opportunities to observe Du Pont personnel policies. Today Pete Meshkoff is works engineer at Du Pont's new Film Plant at Circleville, Ohio.

Peter Meshkoff answers:

Your question is a natural one, Herschel—one we hear quite often. Du Pont is unquestionably a large company in total number of employees and in all its operations. But, actually, Du Pont is made up of ten independent departments, almost as if it were ten companies under one management. And it is a fundamental policy at Du Pont to promote from within and on merit only.

That produces many opportunities for new men, but in addition there are proportionately more promotions at Du Pont each year—by reason of expansion and retirement—than you would find in most smaller companies. I say “proportionately more” because Du Pont has grown at an average rate of seven per cent a year for the past 153 years—a record that few companies can match.

And Du Pont is still growing rapidly. Take your field, electrical engineering. A host of novel and challenging problems have to be faced, both in new construction and in maintenance. There are plants to design with features that have never been applied before; there are new equipment-control problems to work out, and new engineering processes to pioneer. So, to answer your question in a word, Herschel, I'd say your chances of promotion on merit are extremely good at Du Pont!

**WANT TO KNOW MORE** about the opportunities for growth touched on by Pete Meshkoff? Send for a free copy of “The Du Pont Company and the College Graduate,” which discusses many of the employment policies and activities of Du Pont in detail. Write to E. I. du Pont de Nemours & Co. (Inc.), 2521 Nemours Building, Wilmington 98, Delaware.

# DIE CASTING

by Robert Wesolowski, m'57

The process of die casting has come to be recognized as one of the leading modern high speed production methods for converting raw materials into finished products. No one other fabricating technique has contributed more to the economic and quantity production of metal parts.

Wherever one may look, in the office, store, factory, on the street, or in the home, he is confronted with numerous products in which die castings are an integral part. Aircraft, precision instruments, hardware, industrial machinery, internal combustion engines, and thousands of other items depend on die casting for their component parts. From an obscure beginning, die casting has grown into a mighty industry.

One of the oldest methods of casting molten metal is by gravity pouring it into sand molds. That method, with some refinements, is still practiced in our sand foundries today. In the course of time, the jewelry trade by its requirements for sharper outlines and smoother castings developed a process utilizing plaster or gypsum molds.

This method resulted in parts having a finer surface than sand castings. The disadvantage was that, as in sand casting, the mold had to be destroyed to remove the cast part.

The search for a permanent mold or form which could be used to produce parts in quantity from the same mold seemed to be a natural development. In the Middle Ages the pewterware manufacturers perfected a casting process using iron molds to produce plates, cups, pitchers and other household utensils.

The next step was the production of toy soldiers, or "tin soldiers" which appeared in the 1800's. They were made by gravity pouring molten metal into iron molds constructed in two halves which were hinged together and mechanically opened and closed. The mold was filled with molten metal, and after a suitable interval of time had elapsed, the bulk of still liquid metal was poured out. A thin walled casting was produced with a minimum metal consumption. This technique is termed "slush" casting and is still used today.

In the light of those established practices of using iron molds for quantity production to produce sharper, better, and smoother cast parts, in contrast to the centuries-old method of using sand forms, the next logical step was to improve accuracy and appearance of cast parts. This was accomplished by applying pressure to force the molten metal into strong steel molds, instead of merely relying on gravity pressure.

The casting of type about a century ago is believed to have been the first article cast by applying pressure to force the molten metal into the mold. A machine for die casting type was patented in 1849, but it was not until some twenty years later that a machine for making miscellaneous castings appeared.

By 1904 bearings for automobile connecting rods were die cast. This was the beginning of the rapid progress of die casting which has more or less paralleled that of the automobile industry.

Today some die casting machines are almost, if not quite, completely automatic and nearly all have the major parts actuated by power.

The production of castings by die casting is one of the more notable developments in modern manufacturing practice. Die casting provides a means of producing unlimited quantities of castings of such uniformity and accuracy that machining costs are either reduced greatly or eliminated entirely. Die casting is generally considered a "one step" process because the molten metal is converted in a matter of seconds from

—Courtesy Doehler-Jarvis Corporation

Aluminum engine blocks such as these are typical of the wide range in both materials and products possible with die casting.

a fluid formless mass, into a finished or semi-finished product.

The actual production of a die casting involves three basic requirements: a properly designed die, a smooth working casting mechanism properly designed to hold and operate a die under pressure, and a suitable alloy.

The die casting die, which consists of two steel blocks into which an impression of the casting is cut, must be split in two sections so that the casting can be removed after it is formed. The two sections are called the cover die and the ejector die. The cover die is fastened to the casting machine and does not move during the casting cycle.

The ejector half is mounted on the movable table of the machine. The die halves are fastened to opposing plates which are operated as the machine opens and closes. When the machine is closed, the two halves of the die are locked tightly together, after which the molten metal is injected at high pressures, which may vary from 100 to 100,000 pounds per square inch, into the die cavity.

Within a fraction of a second, the fluid alloy fills each minute detail and section of the die. Because of the low temperature of the die, the casting cools quickly permitting the die halves to be separated and the casting ejected from the cavity in a few seconds.

The function of the die casting machine is to hold the two halves of the die tightly together, to inject molten metal under pressure into the die cavity, and to close and open the die halves to permit removal of the finished castings.

Essentially any die casting machine consists of a frame on which the die is mounted, an actuating device which opens and closes the die, and the injection part of the machine which forces the molten metal into the die under pressure. The injection part of the machine is basically a plunger which when moved forward, propels the molten metal into the die cavity. The plunger for metal injection is arranged for operation either by hand, compressed air, or hydraulic pressure.

The sharpest restriction on the use of die casting comes about through the limited range of die castable metals. However, through research and close quality control during production of castings, maximum physical properties are being secured. Furthermore, current work is being done to increase the life of die casting dies for high temperature die casting alloys, which may permit more extensive use of brass and bronze.

The usual non-ferrous metals for die casting in approximate order of commercial use are: zinc, aluminum, copper, magnesium, lead and tin.

Zinc alloys account for about three-fourths of the total tonnage of die castings produced, because they present the most favorable combination of low cost per casting, good physical properties, and ease of casting and finishing. The average melting point of zinc

—Courtesy Doehler-Jarvis Corporation

This die casting machine contains a 30 ton die that stamps out 6-cylinder engine blocks under 4,000,000 pounds of pressure.

alloys is 716°F. Casting is commonly done at temperatures of 750 to 800° F. at which temperature the metal is quite fluid and is easily injected into the die.

At this comparatively low casting temperature, dies will last almost indefinitely because they will not be subject to attack by the alloy. For short runs, the steel dies can even be used without hardening, although for long runs at least surface hardening is recommended. There is little tendency for the zinc alloy to solder to the die, hence little or no die lubrication is needed. In many instances speeds up to 500 die casting cycles per hour can be obtained.

Castings of extreme smoothness are produced with zinc alloys and if the die cavities are properly polished, castings can be plated with little or no polishing. This fact, together with the ease and speed in the plating of brass, nickel or chromium, is the primary reason for using zinc die castings for hardware and decorative applications, especially in automobiles and other consumer merchandise.

Aluminum alloys rank second in die casting use. In some cases they cost no more or even slightly less per casting, than zinc castings of the same dimensions. About 20% of all die castings are of aluminum alloys. The primary advantage is light weight. Dimensional stability is rated as high. Where low weight and the savings therefrom are desired, aluminum is favored unless magnesium alloys can be used. Die casting rates for aluminum are lower than for zinc but commonly range from 80 to 200 die fillings per hour.

Copper alloys, usually referred to as "brass", have the highest physical properties of any die casting alloy. Because of the high melting point of such materials,

## 1956 Engineering Exposition

Vastness and versatility were the keynotes of the University of Wisconsin's 1956 Engineering Exposition. The main purpose of the Exposition was to open the doors of engineering to the public and reveal to them the many advancements that have been made in industry. All desires of attendance were fulfilled for along with perfect weekend weather came thousands of people eager to see the many innovations to the fields of engineering.

Escorted tours took viewers through the various engineering buildings. Housed in these buildings were over thirty industrial exhibits representing companies located throughout the United States, and over seventy student exhibits. Much time and effort were put into the student exhibits, the incentive being three trophy awards and \$400 in cash awards. The awards were presented to the students near the close of Saturday's activities.

The complete success of the Exposition can be attributed to the students whose combined efforts made it the best exposition this campus has ever seen.

## **OPPORTUNITY KNOCKS for engineering careers at this magnificent new jet aircraft equipment plant**

Make the *right* choice when you begin to invest your hard-won skill and knowledge in engineering. Hamilton Standard offers a plant where initiative and responsibility are encouraged . . . where young men are in top management posts . . . an engineering staff which has been continuously expanding for 35 years . . . a plant which has been judged one of the top 10 in the nation. You don't just fill a position at H-S . . . you commence a career! Some of Hamilton's present projects include jet fuel controls, jet turbine starters, hydraulic pumps, air cycle and vapor refrigeration systems, controls and accessories for nuclear engines, propellers for turbine and piston engines.

GRADUATE PROGRAM . . . while at Hamilton Standard you will be encouraged to take advantage of the company's liberal tuition assistance plan and to pursue postgraduate studies at nearby Hartford Graduate Center of Rensselaer Polytechnic Institute.

**HAMILTON STANDARD**

**Send for "YOU AND YOUR FUTURE"**

. . . a colorful brochure picturing and describing all of the activities and opportunities at H-S . . . plus information on the graduate engineering program. Write Mr. T. K. Bye, (key no.) Bradley Field Road, Windsor Locks, Connecticut.

WESLEY J. HELLEN

## "I'm glad that I chose WISCONSIN ELECTRIC POWER COMPANY"

After receiving a BS degree in mechanical engineering from the University of Wisconsin in 1949, Wesley J. Hellen decided to follow in the footsteps of his father who has been at Wisconsin Electric Power Company for more than 30 years. Starting as a Cadet Engineer in the Testing division, Wesley has advanced through several steps to his present position of Senior Test Engineer in the Company's newest and most modern power plant at Oak Creek.

### THERE'S A PLACE FOR YOU IN OUR FUTURE!

Many engineering graduates choose Wisconsin Electric Power Company because of its reputation for sound and steady progress . . . for its modern and pioneering policies. For example, our power plants have established world records for efficiency. They were the first to develop and use the

process of burning pulverized fuel, the first to introduce radiant superheaters into their furnaces. Engineering talents are needed in the varied fields of our operations. Recognition of ability is assured through an unique "management inventory" system which has received industry-wide attention.

**PLANNING** — Engineers are needed to help plan and design the generating, transmission and distribution facilities which serve the needs of more than half a million electric customers in Wisconsin and upper Michigan.

**CONSTRUCTION** — Engineers are needed to supervise the details of a continuing construction program. The 1955 construction budget for the Wisconsin Electric Power Company system amounted to more than 41 million dollars.

**SALES** — Engineers are needed for many phases of the Company's sales program. Openings are available in the field of industrial sales . . . in the activities of lighting, heating, air conditioning and commercial groups.

**ADMINISTRATION** — Engineers are needed for many activities which provide an excellent training for advancement into administrative fields. Many of our executive positions are now held by engineering graduates.

Write to our **PERSONNEL SERVICES DEPT.** for a copy of our Annual Report and other information

NOTHING ROLLS LIKE A BALL

# WOOD ARCHES

by Jim Schilling, e'58

*West Palm Beach*—Florida's fourth Jai Alai fronton, also the fourth in the nation, will open here tonight with a seating capacity of 3,500—AP release.

Fronton, the word means court, and this new building will be just that, a mammoth sports center where spectators will be able to watch Jai Alai—the national Spanish game now growing popular in the United States. This game, which originated in the Basque country of Spain in the seventeenth century, requires a large indoor playing area unencumbered by posts. And such an area was provided by the use of the largest glued laminated wood arches ever manufactured.

There are only twelve arches in all, but they are the sole structural support for the entire building. Each arch has an arc measurement of 340 feet, and a clear span of 247 feet. At the crown, they are 80 feet above the ground—the equivalent of an eight-story building.

This span is more than 50 feet greater than that of any that have been built before. But it is not only this great span that makes the Jai Alai fronton of significance to architects and builders. These arches also lack the constant cross-section that is so common and they taper from 11 inches by 20 inches at the crown, and 11 inches by 25 inches at the base, to 11 inches by 46 inches at the middle third of the arches, which is the point of maximum stress. These twelve arches, spaced 16 feet apart, give the fronton a length of 195 feet, making it the largest of all the Jai Alai courts in the United States.

These monstrous arches seem to rise from the

ground itself on each side of the building and are so large that each arch contains approximately 17,000 board feet of Southern Pine lumber weighing over 15 tons.

No wood structural members of this size could ever have been cut from the largest tree grown, and each arch is of glued laminated lumber, glued and shaped through the use of specially engineered presses. The entire structure is covered with 4 inch by 5 inch solid wood decking that eliminates the need of purlins, joists and other bracing. Only four rows of struts are required for lateral support because of this extensive decking.

With this combination of arch and decking, this new Jai Alai court will afford a stage as dramatic as the game being played in it. Beside being entirely post free and affording an excellent view for all of its 3,500 spectators, the ceiling will be painted a midnight blue and the lighting arrangement is to be installed in such a manner that the ceiling will resemble the open sky.

Because the designers wanted to achieve an impressive appearance for both the interior and exterior of the court, a complete wood construction was chosen for the sports arena. Noise reduction must also be considered in this type of building and wood has a natural sound absorbing quality that keeps the noise at a lesser minimum that is possible with any other exposed material. Coupled with this is the high degree of fire resistance that is inherent in heavy timber construction.

Now completed, this new Jai Alai court possesses a

simplicity of design that does not reveal the problem that had to be solved before the structure could be built. While still in the planning stage, it became evident that the large size of the arches requires special study. Theoretically, there is no limit to the size of the glued, laminated wooden arch, but in practice, the handling and shipping of the arches impose certain limitations.

Even before the arches for the court were fabricated, an airport runway was needed to lay out and build the plywood template needed to align the jigs that formed the finished arches. So important were the shipping restrictions on such a large span, that even before bidding for the job a special shipping plan was formulated. This called for specific cars and carriers and it indicated the sufficiency of tunnel and bridge clearances between the fabricator's plant and the job site.

Once the shipping plan was established, the handling restrictions were studied. Because the requirements for quality control in glued laminations are so demanding, lamination at the job site was out.

The laminating process was carried on completely in plants especially controlled and equipped for the process. Because of the huge span of the arches, it was also decided to ship the arches in four sections, the longest having a length of 88 feet. Ordinarily, wood structural members of this type would have only two, or at the most, three sections. This departure from customary procedure, the use of four arch sections, was possible because of a special splice joint used at the quarter joints of the arch.

This splice was accomplished by using one-half inch thick steel plates, 12 feet long on the top of the arch and 6 feet long on the bottom. These plates were joined to the arch by 100 shear plates at each splice. The base and the crown connections of each arch had hinges instead of a splice. At the base, these hinges are fastened to buttresses.

—Courtesy Unit Structures, Inc.

While still in the fabrication stage, the quarter arch sections were prepared for future splicing at the job site.

—Courtesy Unit Structures, Inc.

This special splice joint of 1/2 inch thick steel plate was fastened to the quarter joint of each arch.

In the actual manufacturing of the arches, long laminations were formed using 2 by 12 inch pieces of Southern Pine joined end to end by means of scarf joints. The longest such lamina contained six such scarf joints. Following this, the laminae pieces were planed on each wide face in order to have a smooth surface for the gluing process. After the surfacing was completed, the lamina were run through a mechanical glue spreader and then were placed on the forming jigs in the proper position.

The eleven interior arches were fabricated with casein glue (a mixture of milk curds and alkali), but the single exposed arch was laminated with a water-proof glue. After all the lamina were assembled in the jigs, screw clamps and calibrated impulse wrenches pulled each piece into place, applying a uniform pressure of 150 psi on all glue lines. The entire process of gluing and clamping for each arch section took about 30 minutes, and then the glue was allowed to dry for 24 hours.

Once the gluing process was completed, all clamps were removed and each section was taken to a finishing table where a portable planer surfaced the sides of the arch to its 11 inch width. Then each arch segment was precision trimmed to fit its plywood template, sanded, and equipped with its clear plate connectors.

After two coats of clear sealer were applied, the arches were loaded on rail cars and shipped over 1,000 miles to the job site. When the arch sections reached the job site, concrete piers embedded in the ground were prepared to hold the arch bases. Three 1 1/2 inch diameter steel rods set in each pier carried the horizontal component of each arch.

Each half arch was assembled on the ground at the site of the construction. After installing the splice plates and crown and base hinge connections, each half arch was attached to the buttress connections while still on

(Continued on page 54)

# TO SEE OR NOT TO SEE

## The Importance of Plant Lighting

by Paul M. Karcher, m'57

Artificial lighting is one of the most necessary and universally employed artificial aids to modern life. During the hours when natural light is not available, or in places where it cannot sufficiently penetrate, it is only with the aid of artificial lighting that one can enjoy the nature of his surroundings or perform the tasks which require vision. However beautiful the design and decoration of a room may be, it can be appreciated best only when there is light to see it; however well laid out a factory may be, it will be idle if there is no light.

But the problem of good lighting is not just a question of light or no light, of seeing or not seeing; it is a question of how much the amount and kind of light we use affect our efficiency and comfort. Sufficient and suitable lighting reveals and enhances beauty of form, line, and detail, creates a pleasing atmosphere, makes one feel cheerful and fit, helps one to work faster without feeling tired, helps to avoid dangers and accident, promotes cleanliness, and in many other ways affects favorably our mental and physical health, our appreciation of our surroundings, and our working efficiency. The wrong type of lighting may have exactly the opposite effects.

Adequate and appropriate plant lighting is important no matter what type of building a company occupies. And although there has been great improvement throughout industry during the past thirty years, so far as the adequacy of lighting is concerned, it would be too optimistic to say that all plants are up to date in this respect. Thus the subject is one that is worthy of attention.

Although this discussion will remain nontechnical, there are several definitions required for an understanding of the subject. *Candlepower* refers to the illuminating capacity or luminous intensity of a standard candle. A *foot-candle* is the amount of direct illumination given by a standard candle when it is placed one foot from the object illuminated. A *luminaire* is the lighting engineer's name for a complete lighting fixture including the reflector, housing, globe or fluorescent tube, and any auxiliary equipment.

However highly technical the subject of plant lighting may be, it is important that everyone in a position of responsibility be aware of the general nature of the problem of lighting so that one can recognize when steps should be taken to improve situations which for one reason or another have become unsatisfactory.

Good lighting is not simply the packing of the maxi-

imum number of foot-candles into the smallest area at the lowest possible cost. On the contrary, it is a matter of providing adequate intensity with proper diffusion.

*Intensity* refers to the amount of light supplied at the workplace measured in foot-candles. The intensity required for the various jobs around a plant varies according to the nature of the work. It is noteworthy that over the years there has been a considerable upward revision of the intensity considered desirable for certain types of work. For example, in cases where 35 to 40 foot-candles were adequate a few years ago, lighting engineers are now recommending 50 to 60-foot candles.

Lighting intensities of over 100 foot-candles are recommended only for the most exacting factory jobs. As little as 5 to 10 foot-candles is sufficient for aisles, service areas, and the like. General area lighting is usually the best way to produce low intensities, but it is uneconomical to produce high intensities. It is cheaper and just as effective to use to moderate amount of general lighting supplemented by additional lighting at points where more is needed. It is rarely economical to produce intensities as high as 50 foot-candles by general lighting alone. Many companies maintain a general intensity of 25 foot-candles and use supplementary lighting wherever greater intensities are needed.

*Proper diffusion* means that there is a more or less even spread of the light over the working area with freedom from sharp contrasts of light and shade. Differences in brightness up to ten to one are generally regarded as satisfactory for industry, but much higher ratios are often found. If such contrasts are eliminated, there will be a reduction in the amount of eye-strain and eye-fatigue caused by the necessity of the eye to adjust itself to varying intensities of light. Proper diffusion, however, does not call for complete elimination of shadows since seeing can actually be aided in the right places and at the right angles.

In the case of artificial lighting, proper diffusion is largely a matter of selecting the right type of luminaire and placing it correctly in relation to the working area. A luminaire serves to direct the light to the area where it is desired and to reduce the brightness which causes glare. Thus in selecting a luminaire one should consider such things as the efficiency with which it directs the light, the amount of glare which it causes, the ease with which it can be maintained, and its general appearance.

Closely related to the question of proper diffusion is

—Courtesy Pittsburgh Reflector Co.

An air products plant artificially lit with both mercury and incandescent lighting.

that of glare. *Glare* itself is any brightness within the field of vision which causes discomfort, fatigue of the eyes, annoyance, or interference with vision. Excessive glare in the field of vision can cut visual acuity by as much as 90%. It is harmful to the nervous system, it decreases the efficiency of the worker, and it may be a cause of accidents.

A well-conceived system of artificial illumination will have one other feature in addition to adequate intensity and proper diffusion, namely flexibility. It is important always to provide for future changes of plant design. Certainly it would be naive to assume that lighting problems would be exempt from this consideration. Inevitably, changes in product or process will call for a lighting system using different intensities, different light patterns or concentrations, or special types of ceiling diffusions. Such changes can be achieved but they will be more expensive if the fixtures are semi-permanent, the number of outlets inadequate, and the ceiling unadaptable to change.

Achieving good lighting is complicated by the type of building a company occupies, the physical characteristics of the building, and the nature of the work carried on within it. Most plants have windows admitting light from the outside. As a matter of fact, many industrial buildings are designed to make maximum use of natural illumination. In spite of the vagaries of natural lighting, it is free, and most companies use as

much of it as possible, particularly for general lighting.

Supplemental lighting for local areas is used both to produce greater intensities where they are needed and to make always available certain minimum intensities. Diffusing glass or painted glass can be used to reduce a good portion of glare from direct sunlight.

There are many plants which use ordinary filament light bulbs of varying wattages placed in appropriate reflectors. The reflectors can be simple and inexpensive. In many cases these lights are used for supplementary lighting or in areas which occasionally require lighting. They find their best use in those areas where the air contains smoke, dirt, or chemical fumes. Thus in boiler rooms, foundries, heat treating rooms, steel mills, railroad shops, and the like, it is usually economical to use reflector lamps.

In order to eliminate or minimize glare, some attention must be given to the question of locating these lamps. Generally speaking, the best results have been obtained by using the lamps in pairs or in clusters with each lamp of fairly low wattage rather than a few quite powerful lamps scattered here and there. The larger lamps cost more and require more power; hence it may be wise to avoid their use.

Mercury lamps have many industrial uses, although they are seldom used as a sole source of light. They are efficient, provide a maximum amount of light per out-

Now — put your years of college training to work, in the finest professional atmosphere . . . gain experience that brings added recognition and continually increasing earnings.

Before you make a decision, investigate CONVAIR-Fort Worth. Here you'll work on the nation's most challenging engineering projects. At Convair, the opportunity for rapid advancement is unlimited.

You'll like living in Fort Worth, home of the great Southwestern Exposition and Fat Stock Show, the internationally famous Colonial Invitational Golf Tournament, acres of spacious parks and conveniently accessible lakes. These and many other attractions and recreational facilities make leisure time in Fort Worth wonderfully relaxing and entertaining. Living conditions are ideal and the cost of living is low — no state income tax, no sales tax!

**Whatever your major, you'll find a place at Convair. Check the list of engineering fields below, then confirm YOUR future . . . at CONVAIR-Fort Worth.**

## A Campus-to-Career Case History

### **“One open door after another”**

“When I joined the telephone company,” says Walter D. Walker, B.E.E., University of Minnesota, '51. “I felt I could go in any direction. And that’s the way it has been.

“For the first six months I was given on-the-job training in the fundamentals of the telephone business—how lines are put up and equipment installed. Learning those fundamentals has paid off for me.

“Then I had the opportunity to go to the Bell Laboratories in New Jersey. I worked on memory crystals—ferro-electric crystals—for use in digital computers. I learned how important research is to the telephone business.

“After two years I came back to Minnesota, to St. Cloud, to work in the District Plant Engineer’s

Office. There I made field studies of proposed construction projects and drew up plans to guide the construction crews. This combination of inside and outside work gave me invaluable experience.

“In July, 1955, I came to Minneapolis as an Engineer in the Exchange Plant Extension Engineer’s Office. We do forecasting—not of the weather, but of future service needs. Using estimates of growth and economic studies, we make our plans for the years ahead. We figure out where and when new facilities will be needed to meet future growth.

“All this has been preparing me for a real future. You see, the telephone company is expanding by leaps and bounds. That’s why it offers a young man so many open doors.”

**Wally Walker’s career is with Northwestern Bell Telephone Company. Many interesting career opportunities exist in other Bell Telephone Companies, Bell Telephone Laboratories, Western Electric and Sandia Corporation. Your placement officer has more information regarding Bell System companies.**

**Bell Telephone System**

## YOUR FUTURE—Chemistry and Koppers?

**I**N an age when most frontiers are shrinking, there is one that is constantly growing—the frontier of the chemist.

This frontier has been pushed slowly back ever since the days of the pioneer 18th and 19th Century chemists. Their theories, proved in laboratories, were made useful by the mechanical genius of engineers such as Heinrich Koppers, designer of the modern chemical recovery coke oven. These early scientists laid the foundation for the diversified chemical industry that has grown so rapidly in the 20th Century.

And what are the results? An industry that has helped mankind by developing entirely new and better products for more pleasant living; an industry that has extended the life of man by developing new or improved medicines; an industry that has extended the life of many materials, conserving our natural resources.

Your future? It's going to be touched by chemistry to an extent never dreamed of by earlier college classes. That's why a future in the chemical industry can be such a rewarding one for those who are not afraid of the challenge of responsibility, the new and the difficult.

In addition to chemicals and plastics, Koppers produces tar products, metal products, pressure-treated wood. It designs and builds coke, steel and chemical plants.

If you would like to know more about

a future in chemistry or engineering with Koppers, contact your College Placement Director. Or write Industrial Relations Manager, Koppers Company, Inc., Koppers Building, Pittsburgh 19, Pennsylvania.

SEND FOR free 24-page brochure entitled "Your Career at Koppers." Just address your letter to Industrial Relations Manager, Koppers Company Inc., Koppers Building Pittsburgh 19, Pa.

*Consider a Career with Koppers*

THE WISCONSIN ENGINEER

This is just one of the many fields in which Union Carbide offers CAREERS WITH OPPORTUNITY

## To save a life

Portable packages of electricity help make our lives safer and more enjoyable

THE BRIGHT BEAM of a flashlight in the hands of an airman down at sea . . . the untold comfort of an almost invisible hearing aid . . . the pleasure of listening to your favorite music over a portable radio.

**THESE INGENIOUS DEVICES** have one thing in common—they all get their electric power from dry-cell batteries. Each day millions of us depend on these portable packages of power for greater safety, comfort, and pleasure.

**LARGE BATTERIES** furnish power for signalling and communications systems. Hearing aid batteries are now so tiny that they can hide under a dime. Other dry-cells supply power to everything from toys to Geiger counters.

**OVER 60 YEARS AGO**, the people of Union Carbide produced the first commercial dry-cell. From this be-

ginning, they developed the great variety of EVEREADY batteries that now serve dependably in so many applications.

**SCIENTISTS** of Union Carbide are constantly working on new, improved methods of producing packaged power. Their goal is to make dry-cell batteries do even more work for all of us.

**STUDENTS AND STUDENT ADVISERS:** Learn more about career opportunities with Union Carbide in ALLOYS, CARBONS, CHEMICALS, GASES, and PLASTICS. Write for "Products and Processes" booklet.

## ON TO SPACE

The U. S. Navy released photographs of an artist's conception of the Vanguard three-stage rocket vehicle being designed and built to place the world's first man-made satellite in its orbit. Also released is a drawing depicting the trajectory (flight path) of the vehicle from its launching point to its orbit established some 300 miles above the earth.

In physical appearance, the satellite launching vehicle will resemble a giant rifle shell complete with bullet. It will be the first liquid fuel rocket designed to be controlled without the use of fins.

The first-stage rocket, approximately 45 feet in length, resembles the Navy Martin Viking research rocket which attained an altitude of 158.4 miles, a world's record for a single stage rocket.

The second stage rocket, mounted above the first stage, has a cone shaped nose section. It also uses liquid propellants. The third stage rocket, with the satellite attached to its nose, will be carried completely enclosed within the second

Artist's conception of the Navy Martin Vanguard research vehicle.

A drawing of the trajectory (flight path) of the Navy Vanguard research vehicle.

stage rocket. The third stage uses a solid propellant because of its simplicity.

The first stage, which launches the entire assembly, will burn out its fuel at an altitude of between 30 and 40 miles. Then it will separate and drop off.

The second stage will start firing, and at a certain time during the second stage burning will jettison its nose streamlining, leaving the third stage and the satellite exposed.

The second stage rocket will tilt in the direction of the satellite's pre-determined flight path. After its burnout, the second stage will continue to coast upward until it

attains the satellite's intended orbital altitude.

There a spinning movement will be imparted to the third stage rocket to insure directional stability. By that time, the third stage will be set on its course; the second stage will drop off; and the third stage will start firing.

The third stage rocket carrying the sphere has no guidance system, no electronic brain to direct its flight. It's job is to boost the satellite's speed to approximately 18,000 miles per hour. This high speed, necessary to counteract the earth's gravitational pull, will be attained at the rocket's burnout.

At burnout, the satellite may be nudged ahead by means of a releasing device in the nose of the rocket. Therefore its speed will be slightly greater than that of the rocket shell, which will not drop to the earth, but will trail the satellite until atmospheric drag causes both gradually to slow down and spiral toward a lower atmosphere.

Through friction induced by passing into this denser atmosphere, both satellite and rocket will burn briefly and disintegrate after the manner of meteors.

#### COATING CHECK

A thickness gage, the size of a child's top which operates on a magnetic principle and requires no power, has been developed.

The new Permanent-Magnet (PM) Thickness Gage is designed for quick, accurate, non-destructive measurement of the thickness of non-magnetic materials bonded to smooth iron or steel. The gage will also measure the thickness of nonmagnetic materials which can be placed over a magnetic reference plate.

Typical materials which can be measured are paint coatings, platings, enamels and sheet materials such as plastics, paper and mica.

The small, portable gage consists of a double range scale (high scale from 0.001 to 0.060 inch and low scale from 0.000 to 0.007 inch), range changing slider, calibration

adjuster, adjustable limit pointers, and reference thickness standards.

The instrument uses an internal alnico magnet which provides flux to the contact feet. A variable air-gap in the magnetic circuit—introduced by the variable thickness of the film on the backing material—causes flux changes in the circuit. The thicker the film the more flux will leak between two iron legs located between the magnet and the contact feet. A gaussmeter-type movement measures this internal leakage flux.

Accuracy of the PM Thickness Gage is 5 to 10 per cent within 50 per cent of the calibration point, and is capable of taking readings in any position, making it ideal for spot checks on a production line.

#### TRANSISTORS IN POWER SYSTEMS

The first application of transistors in protective relays for electric power systems has been made.

A newly developed alarm relay controlled by transistors is three and one-half times more sensitive than previous designs.

In the alarm unit of the negative-phase-sequence overcurrent relay where transistors are now applied, the relay becomes more sensitive in protecting generators. When the relay was first introduced in 1953 with an alarm unit of conventional design, the alarm would function if the negative-phase-sequence current exceeded 25 per cent of full load positive-phase-sequence current. With the transistor, the alarm unit can now detect 7 to 15 per cent of this quantity.

Further application of transistors is expected to result in improved performance, smaller sizes, and reduced maintenance for relays, and wider use of transistors in relays is being studied.

#### TESTING AT 2,300 MPH

A \$20,000,000 test facility capable of simulating supersonic flight conditions for jet engines three times more powerful than any currently in production will be constructed.

The construction plans were announced today at an introduction of the division's present development facilities to top military and aviation officials.

The supersonic test facility will be the most advanced of its type in the world. It will be able to simulate the same conditions a large jet engine would encounter flying at 2300 miles per hour, or three and a half times the speed of sound at 60,000 feet.

Main part of the test facility will be two altitude test cells, each having a diameter of 18 feet in which engines under test will be housed. Vast amounts of air, flowing at supersonic speeds, will be forced through the test cells to simulate engine flight conditions.

*(Continued on page 58)*

Bug Man—He's not a Martian about to blast through the floor, but a General Electric employee at the Hanford plutonium plant using head antennas and throat microphone to report by radio the radiation intensity in a "hot" zone. Mask and clothing protect from contamination.

The J-57, in the 10,000-pound thrust class, is the most powerful turbojet engine now in production. A new generation of U.S. air power has been designed around this mighty new Pratt & Whitney Aircraft engine.

North American's F-100 Super Sabre, fastest Air Force jet fighter, is powered by Pratt & Whitney Aircraft's J-57 engine.

First all-jet heavy U. S. Air Force bombers are the huge Boeing B-52s, powered by eight J-57s mounted in pairs.

The Douglas F4D Skyray, fastest Navy jet fighter, will be powered with the big J-57 engine.

The Douglas A3D, the Navy's most powerful carrier-based attack airplane, has two J-57 engines.

# Blazing the Way for a New Generation of Air Power

The most powerful turbojet engine in production is blazing the way for a whole new generation of American aircraft.

That engine is Pratt & Whitney Aircraft's J-57, the first turbojet to achieve an official rating in the 10,000-pound thrust class.

But the J-57 provides far more than extreme high thrust. Its unique Pratt & Whitney Aircraft design, achieved after years of intensive research and engineering, offers as well the low specific fuel consumption so vital to jet-powered bombers and future transports, plus the additional important factor of fast acceleration.

The importance of the J-57 in America's air power program is clearly shown by the fact that it is the power plant for three of the new "century series" fighters for the U. S. Air Force—North American's F-100, McDonnell's F-101 and Convair's F-102—as well as Boeing's B-52 heavy bomber. The Navy, too, has chosen the J-57 for its most powerful attack aircraft, the Douglas A3D, the Douglas F4D fighter and for the Chance Vought F8U day fighter. And the J-57 will power the Boeing 707 jet transport.

The J-57 is fully justifying the long years and intensive effort required for its development, providing pace-setting performance for a new generation of American aircraft.

Engineering graduates who can see the challenge in this new generation, might well consider a career with the world's foremost designer and builder of aircraft engines.

## TECHNICAL INSTITUTE DIVISION, AMERICAN SOCIETY FOR ENGINEERING EDUCATION, REPORT ON GENERAL STUDIES

By KARL O. WERWATH

Among the 18 standing committees of the Technical Institute Division of the American Society for Engineering Education, ten are charged with some phase of curriculum development of the technical institute type of higher education. Some of these standing committees are engaged in broad studies, as applied to curriculum development, such as Student Selection and Guidance, Teacher Training, Completion Credentials, Relations with Industry, Manpower Studies and Enrollment and Graduate Surveys. From the projects accomplished by these groups indirectly comes valuable information for the development of course content. Other committees are engaged in the examination and development of new programs, such as the groups working on Metals Technology and Nucleonics. A third type of committee activity is devoted directly to the study of quantitative and qualitative analyses of courses now being offered. Two major published studies have resulted from such work. One is the five year study "Quantitative Analysis of Subject Matter in Technical Institute Type Curricula as Accredited by the Engineers' Council for Professional Development on November 1, 1949 and Related Qualitative Study of Subject Content in Mathematics, Drawing, Industrial Electricity, Physics, English and Electronics by the Curriculum Development Committee, Technical Institute Division, American Society for Engineering Education, from October, 1951 to June, 1955" and a second is the recent one year study "Report of the Com-

mittee on the Place of General Studies in the Technical Institute Program as a Result of the Survey to Discover Techniques Used to Accomplish General Education Objectives Through Both Curricular and Extracurricular Activities."

## WISCONSIN SOCIETY OF PROFESSIONAL ENGINEERS 13th ANNUAL MEETING

Schroeder Hotel, Milwaukee, Wisconsin

#### EDUCATIONAL GROUP

John Gammell, Presiding

Mr. John Gammell, the presiding officer, opened the meeting with a brief statement of the topics to be discussed, namely, "What is being done and what should we do about Nuclear Energy Education in Engineering Colleges?" and "Teaching high school mathematics for college."

He then introduced Dean K. Wendt, College of Engineering, University of Wisconsin, who led the discussion on "WHAT IS BEING DONE AND WHAT SHOULD WE DO ABOUT NUCLEAR ENERGY EDUCATION IN ENGINEERING?"

Dean Wendt stated that the ASEE appointed a committee in 1950 to study Nuclear Engineering Education. The work of this committee was closely associated with the AEC. The activities of the committee resulted in the establishment of seminars, meetings, and in the publication of reports. In 1955, a survey was made by the deans of the engineering schools and in their report, they pointed out that the engineering schools faced four broad problems, namely:

1. To determine the immediate needs for engineers in the nuclear field and the probable long-term requirements.

(Continued on page 42)

# Meet the President

**L. W. LEMBCKE**

**Wisconsin Valley Chapter President**

This month the "Meet the President" series features L. W. Lembcke, president of the Wisconsin Valley Chapter. Mr. Lembcke is a graduate of the University of Wisconsin having received his Bachelor of Science degree in Civil Engineering in 1927. Also in 1927 he was married to Lucille Haddy. They now have two daughters, Lois and Florence.

Mr. Lembcke was born on April 22, 1887 in Township Center, Outagamie County, Wisconsin. He is employed by the Wisconsin Conservation Department as Chief Mechanical Engineer.

2. To present information relative to undergraduate, graduate, and special programs which colleges and universities might be in a position to offer to aid in the over-all education in engineers for this field.
3. To determine the part colleges and universities should play in the education of foreign engineers in the field of nuclear engineering.
4. To study the long-term role of government sponsored training programs.

The best study in answering these questions was made by Professor Myers. This study presents the following alternatives:

1. The minimum offering that could be regarded as significant in an undergraduate engineering program is 6 credits.
2. An undergraduate option in nuclear engineering would increase the offering to 15 credits. The cost of equipment for this program according to Professor Myers would be \$13,000.
3. A third alternative is to offer a major in nuclear engineering of 27 credits. In order to equip an engineering school to offer an undergraduate program would cost approximately \$430,000.
4. To expand this minimum program of an undergraduate level to a graduate program of 30 credits would increase the cost by another \$300,000.
5. For an adequate PH.D program the cost of the facilities and equipment would be approximately \$1,000,000.

This indicates that for a school of engineering to set up an engineering program in nuclear energy would entail a considerable outlay of money. Is the need so great for nuclear engineers to warrant

this outlay? To clarify the thinking on this problem, Dean Wendt raised two questions:

1. What is the need for trained engineers in nuclear engineering?
2. What kind of training is needed?

Dean Wendt stated that there is no way of getting the information from industry as to the number of nuclear engineers needed today. From studies made, the present need would indicate that we need from 500 to 1000. It perhaps is possible Dean Wendt continued, that

(Continued on page 44)

# To the engineer who likes to blaze new trails...

AiResearch is looking for your kind of engineer.

AiResearch is a key company in the industrial future of America. We are playing a vital part in the great engineering advances now taking place.

The field of heat transfer is an example. The advent of high-speed, high-altitude aircraft has made heat control one of the most pressing present-day problems. This promises to be even more acute when atomic energy becomes an industrial fact. AiResearch is constantly developing new methods of heat transfer. But this is only one aspect of our operation. We pioneered the field of small turbomachinery, pioneered aircraft air-conditioning and pressurization systems, developed many different types of pneumatic and electronic equipment, now manufacture more than 1000 different products. We develop new solutions for industry as required.

That's why we need creative engineers... and appreciate them. You who qualify for an AiResearch position will receive stimulating assignments, utilize some of the finest research facilities in the country and be well rewarded financially.

**BUMPY ROAD FOR HOT MOLECULES,**  
*an AiResearch development, helps lick heat problem in modern engineering. Dimples interrupt the smooth flow of air in thin walled tubes, permit more rapid exchange of hot and cold molecules and step up cooling efficiency 26%.*

Premium positions are now open for mechanical engineers...electrical engineers...physicists...specialists in engineering mechanics...specialists in aerodynamics...electronics engineers...aeronautical engineers.

Write to Mr. Wayne Clifford, AiResearch Manufacturing Company, 9851 S. Sepulveda Blvd., Los Angeles 45, California. Indicate your preference as to location either in Los Angeles or Phoenix.

CABIN AIR COMPRESSORS • TURBINE MOTORS • GAS TURBINE ENGINES • CABIN PRESSURE CONTROLS • HEAT TRANSFER EQUIPMENT • ELECTRO-MECHANICAL EQUIPMENT • ELECTRONIC COMPUTERS AND CONTROLS

## W.S.P.E.

(Continued from page 42)

the school of engineering can do a good job in a few basic courses in nuclear engineering on the undergraduate level and then give them the broader training after graduation in a graduate school.

He pointed out that a cooperative program by the schools of engineering has been suggested. Last fall, the deans of the midwest engineering schools met and discussed such a program. They determined that the cost of a cooperative graduate school would be as follows:

1. Facilities and equipment—\$3,000,000
2. Ground and buildings—\$5,000,000
3. Facilities for staff and students—\$4,000,000

The total cost of such a separate nuclear engineering school would be \$12,000,000.

In conclusion, Dean Wendt pointed out the biggest problem faced by schools in the field of nuclear engineering is where to get the teachers. Already some steps are taken to help solve this problem. The ASEE, the National Science Foundation, AEC, and Northwestern University are sponsoring an 8 week institute during the summer of 1956 at the Argonne Laboratory. The purpose of the institute is to provide engineering college faculty members with information which will help them to incorporate nuclear engineering material into their courses of instruction.

### RECRUITING, RETENTION AND USE OF ENGINEERS BY THE STATE HIGHWAY COMMISSION OF WISCONSIN

By R. F. MILHAUPT  
Personnel Officer

Probably the most critical shortage of engineers today is the shortage in government service. There are many reasons for this; governmental agencies are usually thought of as organizations where low pay and limited opportunity

abound and graduating seniors, with this distorted picture in mind, do not normally seek employment in government service. Another factor which bears mentioning is the use of engineers in non-engineering work and conversely, the admittance of non-engineers to the engineering classifications. The former is a breach of good management practice for which private enterprise can be found as guilty as government service.

The State Highway Commission pays regular visits to twelve midwestern colleges and universities twice each year. In addition to this, the department sends informational materials to about 140 accredited schools throughout the country. As part of its recruiting program it also gathers and maintains data on current salaries being offered by competing agencies and in this way has succeeded rather well in keeping abreast of competition. Furthermore supplementary data thus obtained have indicated that a high initial salary offer is not the final answer to the problem of devising and maintaining a successful engineer recruiting program. Government agencies have been too prone to wring their hands over salary discrepancies and overlook the fact that the successful recruiting program cannot base its appeal on this factor alone.

In conclusion, it must be stated the previously mentioned innovations in employment of engineers by the State Highway Commission are not expected to solve the engineer shortage, completely. The engineer who places salary above such considerations as public service, job satisfaction and creative opportunity will never be attracted to the State Highway Commission or any other organization with a fixed salary structure. On the other hand salary adjustments are a necessary counterpart of an effective production or service program in any organization. Once an engineer has been employed however, he must be shown that his engineering training will be effectively utilized, that he will not be sad-

dled with tasks which can be satisfactorily performed by less well-trained personnel, that his job will be both creative and professional. If these aims are accomplished demands for more engineers will be tempered by actual needs and supply should eventually meet demand.

(Continued on page 46)

The diagram, with a minimum number of reactors, illustrates cyclic regeneration. Piping arrangement permits the swing reactor to substitute for any other reactor in the system. High activity of catalyst is maintained—without interrupting production—in the ULTRAFORMING process.

## HOW TO KEEP \$1,000,000 WORTH OF CATALYST ON THE JOB

When you have a million dollars' worth of platinum catalyst in a single refinery unit, you hope you can keep it steadily on the job. That's too much money to be standing around idle. Also, you'd like to keep the catalyst working at high efficiency.

Most catalysts lose activity with use. The platinum that "reforms" 40-octane gasoline to 100-octane gasoline is no exception. And the higher the octane number, the faster the catalyst loses activity.

For years activity could be restored only by taking the catalyst out of the unit and sending it away for special treatment. To keep from having too many of these shutdowns, refiners had to operate at relatively low octane numbers.

Standard Oil research scientists came up

with a better answer. They developed a new type of platinum catalyst, and they learned how to regenerate it repeatedly—while it is still in the unit. When a swing reactor is provided, the unit need not even be shut down. The new process is called ULTRAFORMING.

During a year of ULTRAFORMING at Texas City, one reactor was regenerated 53 times. The unit is still producing 100-octane gasoline.

ULTRAFORMING also gives high yields of by-product hydrogen. The hydrogen can be used in upgrading other oil products. Or, it can be reacted with nitrogen from the air to make ammonia.

ULTRAFORMING is only one of the many major achievements credited to the scientists who have made careers at Standard Oil.

# WHEN YOU ARE CHIEF ENGINEER ...WHICH DESIGN WILL YOU OK?

**welded steel  
or cast iron**

**T**HE first question you'd ask is . . . does the design do the best job at lowest cost? If not—*why* not.

Industry constantly asks why things are done the way they are . . . to see if there is a better, less costly way.

One question is why shouldn't all machinery be designed for welded steel . . . when steel designs are stronger, more rigid, more rugged . . . yet cost less to build.

By knowing how to use welded steel, you hold the answers to many designing problems. Here for example is how one machine part is made for 43% less cost by a simple change from cast iron to steel.

**Former Design  
Cost \$664.33**

**Welded Steel  
Design  
Cost \$378.34**

Latest ideas for developing welded steel designs are available to engineering students by writing for *Elements of Machine Design*.

## Chapter News

### SOUTHWEST CHAPTER

"How to Attract and Hold Engineering Talent" was the subject of great interest presented by Arthur M. G. Moody, Chief Engineer, Trane Company of La Crosse, to the Southwest Chapter at their dinner meeting held at the Cuba Club on Tuesday, March 20.

About 50 members and guests

attended and, although this is considered a normal turnout, T. K. Jordan, program chairman, offered a plan whereby each member present at this meeting will assume responsibility to call three other members assigned to him prior to the next meeting to remind them and urge attendance. It is hoped that a substantial increase will be gained thereby.

Paul J. Grogan of the program committee introduced the speaker who gave an excellent presentation of a subject so vitally important to employers of engineers as well as to engineers themselves.

"The greatest secret in holding engineers is to have a growing company or organization," Mr. Moody said. "The work must be challenging and grow with the man." Some of the more important factors in attracting and holding engineering talent are: a good training program, creative interesting work, a good prospective future, job security, and beneficial retirement program.

He cautioned that employers take greater "interest and acquaint themselves with the problem of holding men in the 4 to 8 years experience category in addition to their interest in recruiting young graduates."

He pointed out that companies and management are becoming aware of professionalism in engineering and should encourage young engineers toward registration and participation in professional societies. All of which will tend to elevate the engineering profession towards universal recognition and with it better compensation.

### SOUTHEAST CHAPTER NEWS

DONALD C. BENGS

Wesley Burmeister P.E. district engineer for the Wisconsin Highway Commission spoke on "The Engineer in the Highway Program" at the quarterly dinner meeting in the Hotel Racine on March 7th.

The Chapter voted to extend an invitation to the WSPE to hold

(Continued on page 50)

## B-52 jack screw—a typical Boeing design challenge

On Boeing B-52 bombers, the horizontal tail surface has more area than the wing of a standard twin-engine airliner. Yet it can be moved in flight, up or down, to trim the aircraft.

The device that performs this function is a jack screw, which, though it weighs only 255 pounds, can exert a force of approximately 225 tons!

Many kinds of engineering skills went into designing and developing a jack screw so precise that it automatically compensates for stretch and compression under load. Civil, electrical, mechanical and aeronautical engineers, and mathematicians and physicists—all find challenging work on Boeing design projects for the B-52 global jet bomber, and for the 707 jet tanker-transport, the BO-

MARC IM-99 pilotless interceptor, and aircraft of the future.

Because of Boeing's steady expansion, there is continuing need for additional engineers. There are more than twice as many engineers with the company now as at the peak of World War II. Because Boeing is an "engineers' company," and promotes from within, these men find unusual opportunities for advancement.

Design engineers at Boeing work with other topnotch engineers in close-knit project teams. They obtain broad experience with outstanding men in many fields, and have full scope for creative expression, professional growth and individual recognition. And they find satisfaction in the high engineering integrity that is a Boeing byword.

In addition to design engineering, there are openings on other Boeing teams in research and production. Engineers like the life in the "just-right" size communities of Seattle and Wichita. They may pursue advanced studies with company assistance in tuition and participate in a most liberal retirement plan. There may be a place for *you* at Boeing-Seattle or Boeing-Wichita.

For further Boeing career information consult your Placement Office or write to either:

# The Importance of Electrical Conductors

In the ability to transmit electricity, all forms of matter may be divided into two general classes, namely, conductors and insulators. Conductors permit electric current to flow readily; that is, they offer little resistance to its flow, whereas, insulators offer relatively great resistance to the flow of electricity. All substances at normal temperatures offer some resistance to the flow of electric current. In general, the metals are good conductors, while glass, oil and most organic substances are classed as insulators. Although silver offers the lowest resistance to the flow of electricity of the common metals, its cost is such that it is not widely used as a conductor. The conductors most generally used in the cable industry are made of copper or aluminum.

The manner in which electricity flows through elementary material may be readily visualized from the modern concepts of the structure of matter. According to these concepts all elements are made up of minute indivisible particles called atoms. These in turn are composed of a positively charged nucleus around which one or more very small negatively charged particles, called electrons, rotate at high velocity. In conductors, some of these electrons

are free to move when only a small difference of potential is applied to the ends of the conductor and, since they are negatively charged, they flow to the positively charged end. This movement of electrons is electric current.

*In passing through conductors, the electrons must pass through the electron fields of many atoms. They thus collide with the atomic nuclei and other electrons. These collisions obstruct the flow of electrons and result in electrical resistance.*

The resistance of a homogeneous conductor of uniform cross-sectional area varies directly as its length and inversely as its cross-section, the length being in the direction of current flow. That is,  $R = \rho L / A$  where, R is the resistance in ohms, L is the length in the direction of current flow, A is the area perpendicular to the length and  $\rho$  is a constant of the particular material known as its specific resistivity. When the length and area are expressed in the same units such as L = one inch and A = one square inch,  $R = \rho \times 1/1$  or  $R = \rho$ , the specific resistance of the material in ohms per inch cube.

The length and area of a conductor are generally expressed in other units

Stranding

than inches. The most commonly used unit of cross-sectional area in the cable industry is the circular mil, usually designated as cir. mil or CM. This is the area of a circle whose diameter is one mil, 0.001 inch. The area of a circular mil is  $\pi/4$  or 0.7854 of a square mil. The unit of length usually associated with this unit is the foot and the resistance becomes ohms per CM-foot. The resistance of annealed copper and aluminum per circular mil-foot at 20C are 10.371 and 17.011 ohms respectively. The resistance of a copper conductor 64 mils in diameter and one foot long thus becomes  $10.371 \div 64^2$  or 0.00253 ohms.

The sizes of electrical conductors are expressed in the United States in terms of the American Wire Gauge. This was originally set up on the basis of a geometrical progression of 39 steps or sizes between a wire 460 mils in diameter (Size 4/0) and a wire 5 mils in diameter (Size 36). The ratio of the diameter of a wire to that of the next larger size in this series is  $\sqrt[39]{460/5} = 1.12293$ . This ratio has since been used to extend the American Wire Gauge (AWG) to sizes smaller than 36 AWG (5 mils). The sizes of conductors larger than 4/0 are expressed in circular mil area. The size of a conductor made up of a number of wires is determined from the sum of the circular mil areas of the individual wires.

When current flows through a conductor there is, according to Ohm's law, a voltage drop of  $E = IR$ , where E is in volts, I is in amperes and R is in ohms, and power equal to EI watts is converted to heat. Since  $E = IR$ , this power converted to heat becomes  $I^2R$  watts.

These two factors, voltage drop and conductor heating, are of prime importance in the design of conductors. Conductors must be of sufficiently low resistance that the voltage drop does not become excessive. In good design this voltage drop should not exceed 3 per cent for power circuits or 1 per cent for lighting circuits. The conductors should also be large enough that, when carrying their current, their temperature does not exceed that for which their insulation is designed. This rated current is referred to as the current carrying capacity. The current carrying capacities of the various sizes of conductors and installation conditions have been established. It should be noted that the temperature attained by a conductor depends not only on the amount of heat generated but also on the thermal resistance of its surroundings.

In addition to providing satisfactory voltage drop and current carrying capacity, conductors must be designed to provide adequate flexibility during installation and service. This is accomplished by building up the conductor from one or more adequately small wires, depending on the flexibility required. For example, the conductor for heater cord or welding cable, which is subject to repeated flexing in service, is usually made up of copper strands having a diameter of .005" or .0063", while the conductor for overhead weather-proof cable may be a single wire.

the summer conference for 1956 in the Southeast area. The location and program will be announced in the News-Letter.

A resolution sponsoring the formation of a Waukesha County Chapter was approved for transmitting to the Board of Directors of the State Society with the petition of the Waukesha members.

The next meeting of the Southeast Chapter will be Ladies Night on Friday, May 25th at the Kenosha Elks Club. The officers to be installed that evening are:

President—Leo Jeselun  
Vice-President—Charles B. Lee  
Secretary—Treasurer—Walter E. Dick  
Directors—Rudy Gocht, John Mielke  
Past-President—Donald C. Bengs

Members are requested to have the application blanks of new members approved by the membership chairman or by the President of the Chapter before sending the applications to the State Secretary.

### WESTERN CHAPTER

M. L. HOGLUND

The Western Chapter held their April Meeting on Tuesday April 3, 1956. Jose B. Calva, president and technical director of the J. B. Calva & Co., consulting and research engineers, was the principal speaker. The topic of the talk was "Engineering as a Profession." Mr. Calva pointed out that the engineer is not recognized on the same professional level as the medical and legal professions largely be-

cause they have not shown a strong degree of unity in their profession. The Minnesota Society of Professional Engineers of which Mr. Calva is president-elect has taken some definite steps to improve this situation. First is the encouragement of all graduating seniors to take the "Engineer in Training" examinations. Second was the formation of an "Engineer in Industry" committee to further the standing of the professional engineer.

E. T. Neubauer reported on activities during Engineer's week and a business meeting was conducted by the chapter president, R. B. Brindley.

R. E. Lucey, Trane Vice President and manager of engineering, has announced the promotion of three senior development engineers in the Company's Products Engineering Department to positions of Chief Engineer.

"The men, R. G. Miner, Jr., E. T. Neubauer and A. M. G. Moody, are all registered professional engineers in the State of Wisconsin and are members of the Western Chapter WSPE. They will assume added responsibilities in their respective fields by heading the Controls and Electrical, Reciprocating Compressor, and Centrifugal Compressor phases of the Trane Company product development program.

### FOX RIVER VALLEY CHAPTER

Berry E. Brevik, field engineer for the Portland Cement Association, retires from that position on

April 1, 1956, after nearly 30 years of service. (Retirement at age 65 is compulsory).

Mr. Brevik started with the Association July 1, 1926, in the General Office in Chicago, transferring to the Milwaukee office in 1927. Here in Wisconsin he covered the Milwaukee metropolitan area for 16 years, and for the past 13 years whole Fox River Valley as his territory.

Brevik was graduated from Iowa State College in 1918, was awarded a C.E. degree in 1919, and won his Master's degree in Civil Engineering at the University of Michigan in 1922. After spending a few years with the Michigan and Iowa highway departments, he taught two years at Iowa State and one year at the University of Minnesota before joining the Portland Cement Association staff.

Throughout his career, Brevik has been active in engineering societies, serving as President of the Wisconsin Section of the American Society of Civil Engineers in 1942, and on many committees of the Fox River Valley Chapter of the Wisconsin Society of Professional Engineers. He is also active in Masonic circles, and is a member of the Appleton Rotary Club. He and Mrs. Brevik are both active church workers.

The Breviks had two children. The son, Richard, lost his life in the Aleutians during World War II. Their daughter, Jean, is married and living in Chicago.

(Continued on page 52)

R. G. Miner Jr.

E. T. Neubauer

A. M. G. Moody

Today at Martin, one of the finest engineering teams in the world is at work on tomorrow's development and design problems in the fields of AERODYNAMICS, ELECTRONICS, STRUCTURES, PROPULSION AND NUCLEAR POWER.

If you're on the way up – and going far... if you are willing to apply your ability to the toughest engineering challenge... you'd do well to look into the Martin story.

No matter *how limited* or extensive your background, there will always be openings on the Martin team for the engineer who has what it takes to go *higher*.

Contact your placement officer or J. M. Hollyday, The Martin Company, Baltimore 3, Maryland.

---

**MARTIN**  
BALTIMORE

## W.S.P.E.

(Continued from page 50)

Brevik will be sorely missed by his many friends throughout the state, by architects and engineers, and by public officials whom he regularly contacted.

His very effective promotional, educational and service activities will also be missed by the Portland Cement Association.

### WISCONSIN VALLEY CHAPTER

J. E. HAEFT

The next chapter meeting will be held at the Hotel Tomahawk. Members and wives are invited and dinner will be served at the hotel after the business meeting.

E. J. Carrington, W.S.P.E. member from Marshfield spoke at the Medford High School "Career Day" on the Engineering profession.

### NORTHWEST CHAPTER

E. J. POLASEK

A special meeting of the Northwest Chapter was held in Superior

on April 12, 1956. The purpose of the meeting was the formation of a new chapter, consisting of the present members of the Northwest Chapter who reside in the counties of Ashland, Bayfield, Douglas, Sawyer, and Washburn, and a number of new members (exact number unknown at this time, estimated at 7). The prime purpose of dividing the Northwest Chapter was to reduce the distance which the members of the new chapter had to travel to meetings. At this meeting, the members of the proposed new chapter voted to form such a chapter, and selected the name 'Lake Superior Chapter'. The following officers were selected:

*Directors*—H. Sargent, W. Berg, M. McGauley

*President*—Gene Potter

*Vice-President*—Wm. Forsythe

*Secretary-Treasurer*—M. Olsen

The formation of the chapter will become official upon approval by the State Board of Directors.

Paul Grogan, Executive Administrator of the Extension Program of the University of Wisconsin, spoke at the meeting on the advantages of Society memberships.

### MILWAUKEE CHAPTER

R. M. LYALL

National Engineers Week is set aside each year to give special emphasis to the contributions of engineers in developing a bright future. Your local chapter sponsors many public relations activities during Engineers Week including programs on television and radio. Special displays have been arranged in store windows and the occasion of Engineers Week is used to promote Engineering interest in high school students.

Carl Matheis ably directed our activities for the Engineers Week just past and we tender him a vote of thanks for a job well done.

President Wes Lallier wrote following letter which appeared in the March 17 Milwaukee Journal:

#### NONPOLITICAL ENGINEERS

"To The Journal: From time to time organizations, with political

interests and a few registered professional engineers among them, purport to speak for all the professional engineers.

"For the record, the Wisconsin Society of Professional Engineers, which represents only registered professional engineers, is a nonpolitical organization and does not endorse political candidates or political issues. In this regard, the WSPE (with over 500 members in the Milwaukee chapter alone) expresses the same altitude consistently taken by all professional engineering societies.

"In this state, a 'registered professional engineer' is one who is registered by the Wisconsin registration board of architects and engineers. Such registration is based on his proven ability, academic prerequisites, experience and his moral responsibility to professional standards for 'the preservation of health, safety and the general welfare of the public.'

"This is the attitude of service rather than one of more attempted influence.—WESLEY LALLIER, *President*, Milwaukee Chapter, W.S.-P.E., 431 N. 49th St., Milwaukee."

The letter had reference to an article in the Journal relative to the Technical Engineers Assn. The article erroneously stated that the Professional Engineers had endorsed Mayor Zeidler for reelection. Lallier's letter put the record straight.

The next general meeting will give us all an opportunity to ask questions and express opinions on matters relating to the profession.

The discussion will be led by a team consisting of Art Behling, Karl Werwath, Kurt Roth and Bob Claypool.

Among the subjects to be discussed are the following:

Legislative Liaison  
Professional versus Unions for Engineers  
The Large Consulting Office  
Questions from the Members Present

The meeting will be preceded by Dinner at 6:30 P. M. **END**

## Die Casting

(Continued from page 19)

ranging up to 1700° F, die life is short depending upon the die steels used and the mass or volume of the casting sections.

Most of the heat from the molten metal, deposited in the die, must be transferred from the casting through the walls of the die cavity before the casting can be ejected. Therefore, castings of relatively thin wall sections can be die cast most economically. Copper alloys have high specific gravity and cost per castings is higher than for aluminum or zinc castings. Brass die casting is commonly done at pressures of 9000 to 25,000 pounds per square inch, and up to 150 die casting cycles per hour can be obtained.

Since cost per casting is the highest of any produced by die casting, copper alloys are employed for die castings only where their strength, high hardness, and good corrosion resistance are essential.

Die casting of magnesium has greatly increased within the past few years primarily because of the extreme lightness of the finished parts. Magnesium is less than one-fourth the weight of steel and about two-thirds the weight of aluminum. Besides ultra lightness, magnesium has relatively high thermal conductivity and good energy absorption qualities. It also has relatively good corrosion resistance. Parts of bare magnesium have been exposed to various outdoor conditions for as long as 15 years, the only effect being the formation of a gray, adherent oxide film.

Commercial production of sound magnesium die castings, free of cracks, has been more difficult than with aluminum. The cost per casting is higher than for aluminum with the result that applications are usually confined to those in which minimum weight is the main consideration. The speed of die casting magnesium is about the same as for aluminum, ranging from 80 to 200 die fillings per hour.

Die casting has many applications, but the biggest single industrial usage of die castings is in the building of automobiles. Die castings go into many parts of the modern car, such as: decorative trim, fuel system, ignition system, functional hardware, chassis, grille, cooling system, window operating mechanisms, trunk hardware, the brake system and so forth.

In home appliances, sewing machines, washing machines, vacuum cleaners, refrigerators, fans, freezers, air-conditioners, driers, and waste disposal units, have many die cast parts in them.

The aircraft industry finds use for a large assortment of die cast parts, principally aluminum and magnesium, because of the weight factor. Electrical fittings, hydraulic housings and components, instrument housings, chair seat hardware, and pilot ejector mechanisms are a small part of the many applications found in this field.

Industrially, die castings find their way into every

conceivable type of special machine. Those intended to knit or weave cloth, evacuate radio tubes, blow glass, manufacture shoes, drill holes, roll cigarettes, package foods, produce printing, process chemicals, form pottery, measure gasoline, saw wood, or fill milk bottles are a few examples.

Business and vending machines, likewise, use millions of die cast pieces each year for housings and frames, working parts of type writers, calculating machines, time clocks, music players, drink dispensers, and cigarette machines.

Among other industries, too numerous to list completely, are: radio and electronics, agricultural equipment, builders hardware, textile findings, lighting fixtures, outboard motors and small gasoline engines, photographic and scientific instruments, and toys.

The advantages of die castings are cumulative; that is, the features which favor the use of a die casting will usually give more than one advantage. For example, a die casting is preferred over a rough sand casting because fewer and less expensive machining operations are required. At the same time, the product designer gains lighter weight, better surface finish, and improved detail and accuracy that helps in assembly.

Probably the greatest single advantage of die casting is the cost factor. The end cost of a finished die casting is relatively low because of the high speed of operation and the low amount of labor involved. Initial tooling costs are high because of the intricate dies made of special tool steel and the large amount of skilled labor required to design and build such dies. However, where production runs are long and appreciable degree of complexity or precision are indicated, die casting is the most economical.

Compared with a completely machined component, the die casting is very often less expensive, consumes very little production time or equipment, results in no scrap loss in chips, is likely to be lighter, and has many other features which would be impractical by conventional machine shop methods.

Die castings are inherently smooth on both internal and external surfaces because they are formed against finished metallic surfaces of the die. In sand castings, sand inclusions commonly occur with the result that tools used for machining die castings have a short life between grinds.

Compared with molded plastics, die castings have the advantage of greater strength and stability, provide more secure anchorage for screws and other fasteners, and are generally superior in durability.

Inserts of other materials can readily be placed in the die cavity and permanently assembled into the casting when the molten metal flows around it. These types of insertions are used to incorporate stiffening materials such as brass, non-metallic materials such as magnets, electrical materials such as core laminations,

(Continued on page 57)

Each half arch is attached to the buttress connections while still on the ground, then truck-mounted cranes rotate them about their base until the two-halves meet at the crown.

## Wood Arches

(Continued from page 27)

the ground. Then two truck-mounted cranes lifted the two opposite halves and rotated them about the base hinges until the crown hinges were lined up.

The crown hinge pin was then inserted to complete the erection. As each arch was rotated and aligned, it was tied to the adjacent arch with four 7 by 12 inch struts. Following this, the 4 by 5 inch wood decking was applied to the arches by nailing each piece with a special 7 inch grooved spike. In addition, bolt fasteners were inserted every 4 feet along the roof surface. These fasteners were found to be more than

enough to resist any uplift forces which might be caused by wind.

The ease of this type of erection was a big economy factor in the building of the Jai Alai fronton. It was erected very quickly, and thus provided a covered space in which to carry out the rest of the construction. Furthermore, the arch shell of the building could be built entirely separate from the seating and other interior construction. This allowed work to proceed on various parts of the structure without interference.

A second big economy factor was in the fabrication of the arches. Because of their laminated construction, it was possible to build them to the desired thickness at the point of maximum stress simply by adding a few laminates. If steel had been used, extensive welding would have been required at these points.

When the fronton was opened in January of this year for its first game of Jai Alai, it presented a completed structure that is a study in simplicity. The twelve arches, the struts, and the wood roof deck provide the large indoor playing area, unencumbered by posts, and the high clearance at the center of the building that the game requires.

This \$1,250,000 building gives ample room to the old Spanish sport so popular in Cuba and other Latin American countries. As the players use their basket-like "Cestas" to receive and toss the Jai Alai balls against the end walls of the court, and as the spectators watch and bet under a roof that looks like the open sky, they will be playing and watching in a Jai Alai fronton that boasts the largest arch span of any building in the United States.

END

## Plant Lighting

(Continued from page 29)

let, and are long-lived. Their main drawbacks are their need for auxiliary ballast equipment and the greenish-blue light which they emit. The last consideration dictates that they be used with the ordinary filament lamp since the combination of the two gives a cool white light.

A combination of mercury lamps and filament bulbs has the further advantage of insuring that there will be light immediately after a power interruption, since the filament lamps relight at once while the mercury lamps require up to seven minutes to reach full brilliance.

Since the introduction of fluorescent lighting into industrial plants in 1938, it has enjoyed wide acceptance. Fluorescent lamps are about three times as efficient as the usual filament lamp, and although their initial and maintenance costs are high, they give more light per dollar of total cost than the filament bulbs. One characteristic of the fluorescent lamp is the large area giving off light and its low brightness. This results in more uniform lighting, less glare, and fewer harsh shadows. Another important consideration is the fact that they are cool, and this means additional savings where air-conditioning is used and greater comfort when the source of light must be placed near the worker.

Filament lamps and their fixtures cost only two-thirds as much to install as fluorescent or mercury vapor lamps and fixtures. But filament lamps last only about 1,000 hours while fluorescent lamps burn 3,000 to 7,500 hours and mercury vapor lamps from 2,000 to 4,000 hours. Frequent turning off and on has little effect on the life of incandescent lamps, but it reduces materially the life of other types. A 40-watt fluorescent lamp should last 7,500 hours if it burns an average of three hours per start, but its life may be halved when it is turned off and on frequently. Both mercury vapor and fluorescent lamps require auxiliary equipment in the form of starters. The starters may burn out and add to the expense caused by the burning out of the lamp itself. Maintenance and cleaning of reflectors are cheapest when incandescent lamps are used.

Nearly burned-out fluorescent lamps flicker and are annoying to the worker, but incandescent lamps go out suddenly, leaving no light at all. Mercury vapor lamps are deficient in red rays and give off a bluish light which is not suitable for work calling for color discrimination. Workers seen under a mercury vapor lamp sometimes appear to have a sickly pallor, to which female employees in particular may object.

Fluorescent and mercury vapor lamps give a more diffused and softer light than incandescent lamps. Fluorescent lamps give a cool light, and their light output is roughly three times that of incandescent lamps for the same amount of electricity. They also maintain their light output throughout their life, whereas incandescent lamps give progressively less as they age. Fluorescent

lamps giving white light the color of daylight are available and are superior to all other types where color discrimination is important. Altogether, if lights are not turned off and on too often, fluorescent lighting will save one-quarter and mercury vapor one-sixth the cost of lighting by incandescents.

If the problems of plant lighting are broadened to include everything that has to do with better vision within the plant, then one phase of the question is that which deals with colors used on floors, walls, ceilings, machines and equipment. It has been proved time and again that seeing can be aided or hindered by the colors used throughout the building.

Generally speaking, ceilings should be painted white in order to reflect light downward on to the workplaces. Walls should not be painted white since they would reflect too much light, causing glare. Thus the preferred colors for the walls are various soft tints. In some cases where it is desirable to reflect light from the floors to the work being done, floors can be painted white.

Various experiments have proved that the passage of time is generally over-estimated in rooms painted red and underestimated in rooms predominantly blue. Moreover, it has been found that it is unwise to use red paint in rooms where the temperature is high or green paint where the temperature is low.

As is the case with a lighting system, whenever a color combination is used in order to aid seeing and to add to the general attractiveness of the plant, it is necessary to maintain it properly if the maximum results are to be achieved. If this is not done, dust and grime will soak much of the light which should be reflected to the workplaces. Thus walls and ceilings should be painted periodically.

It is not enough for a company merely to install a lighting system that achieves the goals of adequate intensity and proper diffusion. It is equally important to see that the system is properly maintained so that these benefits can be enjoyed.

Proper maintenance of all windowed areas is very important. A study made in England revealed that systematic cleaning of 16,000 square feet of skylight increased output by 6%, reduced errors by 5%, and cut accidents by 10%.

The luminaires must also be kept clean so that the amount of light coming from them will not be unduly reduced. One study has shown that the loss of light from dirty lamps and reflectors may run as high as 32%. The frequency of cleaning will be determined by the amount of dust in the atmosphere and by the type of lighting fixture used. Illumination increases are definitely obtained by removing dirt from luminaires.

Many companies have found that it pays to replace lamps periodically on a group basis. Group replacement is the policy whereby all of the lamps in a given area are replaced after they have burned a certain percentage of their rated life, usually around 75 to 80%.

This means that roughly 20 to 25% more lamps will be used than would be the case were bulbs allowed to burn out. However, the savings from group replacement more than offset the additional sum invested in lamps.

In addition to savings on the cost of replacement, there are certain other benefits that come from the use of this plan. Where fluorescent lighting is used, it has been found that old tubes tend to increase costs in that they do not deliver the desired amount of light while continuing to use the same amount of current. Old tubes also cause excessive wear on starters and other auxiliary equipment.

Group replacement has the further advantage, no matter what type of lighting is used, of permitting the installation of new lamps at a time when there is no work going on in the department, thereby eliminating interference with the workers at the machines. Also it is possible to combine ordinary maintenance and cleaning of the fixtures with replacement and thus further reduce costs.

A company should always work out a replacement policy to fit its particular needs. A number of factors should be considered: the net cost of the lamps, the average time required to change them individually compared to the time per lamp to change the group, the percentage of the rated life of the lamps used at the time when the group is replaced, the percentage of failures between the regular replacement periods, the wages paid the maintenance workers who do the job, and so forth. Since these factors vary from plant to plant, it is important that a proper plan be used if the maximum benefits are to be gained. And since improvements are constantly being made in the lamps themselves, it is desirable to examine any given plan from time to time to see if it is still appropriate.

From the above discussion it is clear that plant lighting is a subject of great importance in the successful operation of a plant. But at the same time it is obvious that achieving and maintaining a good system of lighting is neither a simple matter nor inexpensive. Consequently, one is entitled to ask whether the benefits more than offset the effort and expense required to bring the lighting up to modern standards.

Every study of plant lighting indicates that where the proper system is used there has been an increase in the accuracy of the work produced and a reduction in the number of rejects and the amount of spoilage. That this means a great saving is evident when one recalls the enormous cost to industry of material that is spoiled during the process of manufacturing. And although good plant lighting does not eliminate spoilage, it reduces it significantly.

Apart from lowering the amount of rejected work, a good system of lighting increases production. It seems to be a general rule that the more light at the workplace, the more production there will be. To be sure, there is an upper limit beyond which this rule does not apply, for it cannot be assumed that increased pro-

duction is merely a matter of increased lighting. However, it has been noticed that an improvement in the lighting system is generally followed by an increase in the rate of production.

Employee morale also tends to improve where improvements have been made in the lighting system. There may be many reasons for this. The workers may feel that management is interested in giving them the best possible working conditions, or the cheerfulness of a well-lighted room may make for better feeling on the part of the workers. Or a reduction in the amount of eye-strain and eye-fatigue may result in a better attitude on the part of the workers. In any event there is every reason to believe that where the lighting is good, the morale of the workers will be high. And where this is the case, labor relations will probably be friendly.

It is also a general rule that a well-lighted plant is a clean plant. Where this is true, the task of the maintenance department is made easier. Where all corners of the room are lighted, workers may hesitate to throw refuse and dirty waste away but will place them in the receptacles provided. On the other hand, dark corners seem to invite carelessness in this respect on the part of the workers.

Finally, there can be no doubt of the connection between the accident rate in a plant and lighting. Wherever lighting has been improved, the accident rate has gone down, often by unbelievably large percentages. One company reported a reduction of 60% in its accident frequency rate after a new lighting system was installed. This seems to be a general experience. The savings in terms of higher production and lower insurance rates are, of course, significant. But most significant are the savings in terms of human suffering and misery. These alone would justify the cost and inconvenience of installing and maintaining good systems of plant lighting. END

## Die Casting

*(Continued from page 53)*

or conduits such as copper tubing. The metallic parts of zippers are die cast around the cloth that supports them.

Die castings permit very economical fastening methods: self tapping screws, spring type fasteners, screw thread inserts, drive pins, and self-riveting and so forth.

One of the greatest features die casting has to offer, from the view point of the product stylist, is the freedom of shape permissible and the unlimited range of surface ornamentation that can be introduced at a very small increase in tooling or finishing costs.

Ease of surface finish is another factor that favors die casting. The castings are received with smooth surfaces and substantially all flash trimmed off. Following a light sanding at the parting line, the casting is ready for painting.

## A Tower of Opportunity

**for America's young engineers with capacity for continuing achievements in radio and electronics**

Today, engineers and physicists are looking at tomorrow from the top of this tower . . . the famed Microwave Tower of Federal Telecommunication Laboratories . . . a great development unit of the world-wide, American-owned International Telephone and Telegraph Corporation.

Here, too, is opportunity for the young graduate engineers of America . . . opportunity to be associated with leaders in the electronic field . . . to work with the finest facilities . . . to win recognition . . . to achieve advancement commensurate with capacity.

Learn more about this noted Tower of Opportunity . . . its long-range program and generous employee benefits. See your Placement Officer today for further information about FTL.

## Science High Lights

(Continued from page 35)

Before entering the test cells the air will be cooled or heated, as required. Two air flows of different temperatures will be mixed close to the cells to obtain the required test conditions.

The test facility will have its own power distribution station, water supply system, and steam plant for heating.

A crew of about 100 men will be needed to operate the new facility, which will use more than 80,000 kilowatts of electric power during operation. This is approximately enough electricity to supply the needs of a city with a population of over 100,000.

Included in the plans for the new facility is a means of noise level control.

Already under consideration are future extensions which will allow testing of engines under all possible conditions, even restarting an engine after it has ceased operating at high altitude owing to equipment failure or improper handling. Duplicating this condition and finding the required correction may save many airmen's lives and valuable aircraft.

### 'COPTERMATIC

An "automatic transmission" similar to the type found in some automobiles will be used on helicopters of the future.

The fluid, in the case of the T58, will be air rather than a liquid as in an automobile's transmission. After the air passes through the turbine wheel connected to the compressor, it comes in contact with a

second, unconnected turbine, causing it to spin at a very high speed. It is from the revolving action of this second (or "free") turbine that horsepower is produced to turn the helicopter's rotors.

Rated in the "1000 horsepower class," the T58 is also expected to provide superiority in endurance, range, durability and reliability over a comparable piston engine-powered aircraft.

The T58 is a turboshaft engine. With modifications, it could be converted into a small turboprop (jet engine with propeller) or turbojet.

### COLD FABRICATING LAMINATE

A new plastic laminate with properties particularly suited for automatic production of electronic equipment utilizing printed circuits has been introduced recently.

Called Textolite cold punch 11570, the new material is a high insulation-resistance XXXP phenolic, paper-base laminate which permits close registration punching at normal room temperatures.

The cold fabricating quality is reported to eliminate dimensional changes in the material which result from the combination of heat and punching stresses.

It allows precision punching of printed circuits, facilitating the use of automatic assembly equipment in mounting components. The translucency of the laminate permits a visual check for accuracy of circuit registration.

Other significant features include high flexural strength, very low factor, high heat resistance, and optimum uniformity. **END**

## A.S.M.E.

The Wisconsin Student Branch of the American Society of Mechanical Engineers concluded an active and commendable year at their final meeting on May 9th. The evening was highlighted by a speaker from E. W. Bliss Co. of Ohio who spoke on the topic of mechanical and hydraulic presses.

Joe Murray, president of the student branch, was the proud winner of first place in the speech contest at the annual regional conference held this year in Fargo, North Dakota. Wisconsin has been chosen to be host to the ASME Student Regional Conference next year.

Elections were held for ASME officers for the coming year and the following slate was chosen: President—John Bollinger, Vice President—Robert Gehr, Treasurer—Robert L. Roberts, Polygon Representatives—Peter Reichelsdorfer and Dave Rex, Secretary—Robert Wesolowski, Corresponding Secretary—Bob Kruse.

## POLYGON BOARD

At the May 10th meeting of Polygon unanimous acclamation was given to Milo Swanson for his very fine record as Chairman of the Board. Elections were held and the following people were chosen as officers for the fall semester.

*Chairman*—Ken Stahl  
*Secretary*—Dave Hartman  
*Treasurer*—Carl Jaeck

Points for Polygon profits distribution were submitted and approved as follows:

ME	4926
EE	4197
CHE	2981
CE	2564
M&ME	2280

The profits distribution for the entire year will be based on a percentage of total points earned by each school.

## 1956 TAU BETA PI SPRING INITIATES

**Seniors**—William J. Cattoi, Henry Goehring, Ronald H. Schenck, Duane A. Williams, Wayne H. Jorgenson and Charles C. Zanzig.

**Juniors**—Robert E. Suelflow, Kenneth L. Stahl, Paul Raab, William J. Salkowsky, Donald E. Tormey, Donald E. Baldouin, Gerald L. Carlson, Charles L. Soukup, Phillip F. Noth, Charles W. Spalding, Thomas A. Kanneman, Ronald G. Fenske, Alfred Hubbel, Donald M. Tacke, William E. Botcher, Richard G. Kott and James P. Murphy.

## ENGINEER'S DAY

Six widely-known engineers and industrialists, all of them graduates of the University of Wisconsin College of Engineering, were cited for outstanding accomplishments in their fields at the annual Wisconsin Engineers Day celebration held on the UW campus May 4.

The outstanding graduates were recommended for distinguished service citations by the UW College of Engineering faculty and Pres. E. B. Fred, and the recommendations were approved by the University Board of Regents.

The six are:

J. Gordon Baker, president of the Baker Manufacturing Co., Evansville, Wis.;

Arthur W. Consoer, consulting engineer, of Chicago and Pittsburgh;

Malvin J. Evans, head of a management engineering consulting firm in Chicago;

Charles A. Halbert, retired Chief State Engineer of Wisconsin, Madison;

T. Delbert Jones, executive of the American Smelting and Refining Co., of Barber, N.J.; and

Keith S. McHugh, president of the New York Telephone Co., New York City.

The citations were presented at the eighth annual Engineers Day dinner held in Great Hall of Wisconsin's Memorial Union at 6:30

p.m. on May 4. More than 400 engineers and industrialists from all parts of the state and nation attended the dinner at which the UW College of Engineering annually honors some of the state's and the nation's leading engineers and industrialists.

The Benjamin Smith Reynolds Award was presented by Mr. Charles D. Gelatt, President of the Board of Regents, to Professor Raymond Jefferson Roark of the Department of Mechanics.

This award is a Living Memorial established in 1954 at the University of Wisconsin in honor of the Wisconsin-born, Wisconsin-educated Benjamin S. Reynolds. It is awarded as a symbol of excellence in teaching of future engineers.

Professor Roark, who has been teaching in the College of Engineering for nearly forty years is a highly respected figure in the engineering world. In addition to his devotion to the education of young engineers, he is recognized as an outstanding consultant for indus-

tries throughout the state and nation.

#### ALUMNI

**Anthony J. Woods** has been appointed assistant manager of Dow Corning's Cleveland office.

Woods, a technical sales representative with Dow Corning since 1946, received his Bachelor of Science degree in electrical engineering from the University of Wisconsin in 1940. After graduation, he joined the Wisconsin Power and Light Company as customer representative.

From 1941 to 1945, he served as a chief electrical inspector in the U. S. Navy Department. Married to the former Catherine M. Ziebell of Milwaukee, Woods has one son, James and one daughter, Mary.

Woods is a member of the American Institute of Electrical Engineers and the Sales Executive Club of Cleveland. He lives at 3866 Strandhill Road, Cleveland, Ohio.

Fifteen outstanding college students working for their doctor's degrees were named today to receive the 1956 Bell Telephone Laboratories Graduate Fellowships.

The fellowships, awarded for the first time this year, were established to encourage study and research in engineering and science related to communications technology. Each fellowship is for one year and carries a grant of \$2,000 for the fellow and another \$2,000 for tuition, fees and other costs of the academic institution he selects for his study.

Donald L. Dietmeyer, 23, of 1341 Prospect Ave., Wausau, Wis., received his B. S. degree in electrical engineering in 1954 and his M. S. in 1955, both from the University of Wisconsin. He plans to do his Ph. D. work there on the design and construction of digital computers. He expects to work on the analysis and synthesis of sequential switching circuits.

Harold R. Leland, 24, of 1426 Grand Ave., Wausau, Wis., received his B. S. and M. S. degrees in electrical engineering from the University of Wisconsin in 1954.

After his release from the Air Force in September, 1956, Mr. Leland plans to return to that university to begin his Ph. D. work on non-linear control problems, applying techniques of digital and analog computing.

**Lindon E. Saline** has been named manager of headquarters recruiting in the General Electric Company's Engineering Services.

Saline will have responsibility for engineering relations with many of the technical colleges in the upstate New York area and supervisory responsibilities in the engineering recruiting headquarters here.

A native of Minneapolis, Minn., Saline served in the Navy from 1942 to 1946. He received a bachelor of electrical engineering degree from Marquette University in 1945 while still in service. He completed his work for his M. S. degree at the University of Wisconsin and obtained his Ph. D. from the same university in 1950.

Joining General Electric in 1948, Saline devoted his efforts until 1953 primarily to the field of power-systems engineering. In 1953 he was assigned to operations research in the analytical-engineering section of the company's Apparatus Sales Division and from November 15, 1954 until September 1, 1955 was analyst with the Project Analysis section of G-E's Research Laboratory.

**Charles R. Dunfee** was appointed as Manager of the New York office, Jack and Heintz, Inc., one of the nation's leading designers and manufacturers of electric and hydraulic accessories for aircraft.

Mr. Dunfee will be responsible for sales and service functions at all aircraft customers in the Company's Northeastern District. END

A recently patented device for the rescue of downed aviators, or others, at sea consists of a spherical "capsule" which can be dropped from a rescue plane and into which the man in the water can crawl. Provision is made for hooking the capsule from a rescuing plane.

# "A new era is beginning..."

"As I review the progress in aeronautics within so short a span, and marvel at the complex aircraft of today, I call it an achievement little short of miraculous.

"Today, electronically-guided planes take off and land without human touch. Lethal sky missiles seek and destroy invisible targets with uncanny precision. And still other fantastic achievements in both man-controlled and pilotless flight are now in the offing.

"When men go to the moon and planets, electronically-controlled skycraft will take them there. Aviation maps will be studded with stars as well as with cities. New developments in aeronautics will go on and on. Success opportunities and careers will continue to develop for ambitious young men in this exciting field where a new era is beginning."\*

LEE De FOREST

Appropriately qualified to speak for aeronautics and other fields in which his own scientific achievements play an important part, Dr. Lee de Forest gives helpful counsel to young graduates headed for successful, rewarding careers.

His expression, "a new era is beginning," has particular significance at Northrop, world leader in the design, development and production of all-weather and pilotless aircraft.

At Northrop, permanent positions are available that offer full play for individual talent and ambition. Here the graduate engineer will find interesting assignments for which he is best fitted. Surroundings are attractive, co-workers congenial, opportunities for advancement unceasing, the compensation good.

*For detailed information regarding specific openings in your field of specialization, write Manager of Engineering Industrial Relations, Northrop Aircraft, Inc., 1001 East Broadway, Hawthorne, California.*

Barrett General Chemical  
Mutual Chemical National Aniline  
Nitrogen Semet-Solvay  
Solvay Process • International  
**Allied to serve you better**

Maybe you can't see the connection between paper and handsome chrome plating—but it's there. Like so many things, both products begin with chemistry—and alkalis are indispensable to both.

Allied Chemical's Solvay Process Division is a leading producer of alkalis—like caustic soda and soda ash used in papermaking. Another Allied Division, Mutual Chemical, uses soda ash in the making of chromium chemicals, such as chromic acid for plating.

Because Allied's seven divisions are foremost producers of chemicals, there are scores of cases where two or more divisions team up to contribute to a finished product or to serve a particular industry.

Allied Chemical altogether turns out more than 3,000 products. Seen or unseen, they're helping everyone who makes, grows or uses things—that is, *you*.

# YOUR BEARING NOTEBOOK

## How to get longer roller and belt life in a conveyor system

Engineers had to find a way to reduce costly friction and wear on rollers and idlers in designing this big conveyor system. It handles up to 3,300 tons of ore per hour on each of two 54" belts traveling at more than 500 feet per minute. Their solution: Mounting the idlers on Timken® tapered roller bearings. Result: reduced friction, less sliding and scuffing between idlers and belts, longer roller and belt life.

## True rolling motion, high precision practically eliminate friction

All lines drawn coincident with the working surfaces of the rollers and races of Timken bearings meet at a common point on the bearing axis. This means Timken bearings are designed by geometrical law to have true rolling motion. And they're manufactured with great accuracy to live up to their design. Result: Timken bearings practically eliminate friction, give longer bearing life, keep conveyors rolling smoothly.

## Want to learn more about bearings or job opportunities?

Many of the engineering problems you'll face after graduation will involve bearing applications. For help in learning more about bearings, write for the 270-page General Information Manual on

Timken bearings. And for information about the excellent job opportunities at the Timken Company, write for a copy of "This Is Timken". The Timken Roller Bearing Company, Canton 6, O.

# Sailing

(Continued from page 13)

with varying degrees of sharpness at various heights. There are an infinite number of possibilities, and to even begin to discuss them would lengthen this article to an impractical degree. However, we can apply this principle to the boom, where it is even more important to control the shape of the sail (because the curvature is essentially fore and aft, rather than vertical, due to the horizontal nature of the wind flow).

One can still control the draft of the sail at the boom by using the same principles: A curvature concave upwards, with the center of the boom down, results in a flatter sail; and of course reversing the curvature adds to the draft of the sail. This can be accomplished by putting jumper stays on the boom (as is done in some Star boats), but an easier way is to vary the lead of the mainsheet. For normal sailing have a heavy, rigid boom that will remain straight. When the wind is heavy, use a limber boom and lead your sheet from the central part of the spar. The pull of the sail will then cause the outer end to move upwards, resulting in the desired curvature (at the expense of leverage for the sheet.) In light airs, use a very limber boom with a single sheet leading from the extreme outer end. The sail will pull up on the center of the boom and the sheet will pull down on the end, causing it to take the desired concave downward curvature. See Fig. 9.

Fig. 9.—All side views.

Another and more revolutionary means of controlling draft with the boom is to control the horizontal variance of the bottom of the sail. This was first done with the famous Park Avenue boom, which had a long fore and aft track resting on numerous cross-tracks. By putting stops on the cross-tracks, the bottom of the sail could be made to assume any desired curvature. See Fig. 10. Other means of accomplishing the same thing are to have the sail fastened to a wire running the length of the boom. The wire can be tightened or slackened, flattening or bellying the sail, and small adjustable wires spaced along the boom and attached to the fore and aft wire would give the same control found

in the Park Avenue boom. Or a series of diamond stays on the side of the boom could provide a means of causing the boom to assume an infinite number of different curvatures. The only trouble with this system is that it would require all the stays to be re-adjusted each time the boat came about. See Fig. 10 for all methods.

Park Avenue boom—long center track slides on cross-tracks.

Boom with wire—small adjustable wires control long wire.

Series of diamond stays make various curvatures possible.

Fig. 10—All top views.

One of the most useful auxiliary racing lines is a vang. A vang is a line attached to the center of the boom (or slightly forward of center) and used to pull downward and flatten the sail when sailing downwind or on a reach. Another functional but seldom thought of use would be to trim down hard while sailing to windward in a heavy breeze, thus pulling down the center of the boom and preventing the sail from becoming too full.

Another useful line is the topping lift, running from the truck of the mast to the outer end of the boom. It can be used to hoist the boom a little in very light airs, thus taking the weight of the boom off of the sail and letting the sail hang fuller.

Still another method of controlling draft is found on some class C scows. The last 2 feet of sail track are not fastened firmly to the boom, but are mounted on a vertical screw thread which allows them to be cranked up. See Fig. 11. This loosens the after edge of the sail and allows the boom to drop, pulling out the pocket or draft and flattening the sail.

Fig. 11.

There are other, more unconventional ideas on the subject of controlling sail draft, but these are the more widely used methods.

END

# PIONEERING NEVER ENDS AT ALLISON

Today's powerful turbo-jet and turbo-prop engines are a far cry from the aircraft engines of a mere 10 years ago.

But we've hardly scratched the surface. We're still pioneering.

Sure, the sound barrier's been cracked. But, who knows, perhaps in the next 10 years we'll be flying at speeds 2 or 3 times the speed of sound. Newer, more complex, more powerful engines ARE in the offing. There'll be new fields to conquer. For instance, the thermal barrier!

Allison, a pioneer in the design, development and production of aircraft engines, now is working on advanced design turbine engines to meet future requirements . . . whatever they might be. Proven features of engines like the Allison J71 and T56 may be adapted to the engines of tomorrow. Allison engines of the future will be backed up with worlds of experience gained in the development and production of its first 100,000 aircraft engines.

Now, Allison is in the midst of a \$75 million expansion program in engineering research and development facilities. Completion of the program will give Allison one of the world's most complete, best-equipped, centers for the development of new, high performance turbo-prop and turbo-jet aircraft engines. This opens new and unlimited opportunities for young graduate engineers, for the program—financed by General Motors—creates an immediate need for a 40% increase in engineers.

Want to know more about YOUR career opportunities at Allison? Why not arrange now for an interview with our representative on your campus. Or, write for information about the challenging work awaiting you at Allison: Engineering College Contact, Allison Division, General Motors Corporation, Indianapolis 6, Indiana.

# So You Think You're SMART!

by Sneedly, bs'60

Due to circumstances beyond his control (this sounds like last month), namely, the Engineering Exposition, Sneedly is unable to present the solutions to last month's problems. However, the solutions to the following problems will definitely appear in the May issue of the *The Wisconsin Engineer*. (Sneedly swears to this fact with his right hand over his slide rule).

Sneedly's first problem this month was solved by him while he was doing research work on the problem of birth control in house flies at Westnorthern State.

There are a number of house flies lying side by side in straight line long the bottom of a hog trough. There were half as many yesterday. There will be twice as many tomorrow; for, owing to the force of circumstances, the number of house flies doubles every day.

At this rate the entire hog trough will be full of horse flies in just 57 days. But what Sneedly was asked to solve was this: In how many days will the hog trough be just exactly half-full of house flies? Sneedly solved it. Can you?

Ole, Pierre, Juan, and Fred are four engineers that are working part-time as cab drivers to try to earn a living. They are going fare-hunting tomorrow on one of the Madison streets. The street has no traffic lights and they estimate that equal numbers of pedestrians walk in each direction, at an average of four miles an hour.

Ole says: "You boys are crazy to use up gas cruising around all the time. I'm going to park beside the curb until a fare comes along."

Pierre says: "I'm going to cruise up and down at four miles an hour, and I'll have twice your chance of picking up a fare."

Juan says: "Eight miles an hour for me, up and down the street; and I'll have twice the chance of either of you."

Fred says: "I'm going to average twelve miles an hour and I'll have twice as much chance as Juan of getting a fare."

Think about this and figure out the true facts, deciding who was right and who was wrong. What would happen if twice as many people were walking one way as there were walking the other? What would happen if those walking South averaged three miles an hour and the others averaged four miles an hour?

In his physics class the other day Sneedly was asked by his instructor to give four different ways of turning a glass of water upside down without spilling the water. Sneedly mystified his instructor by giving six different ways, each based on a different natural law. How many can you give?

Sneedly's girl friend, Gertrude, has disappeared. Can you help the University police find her? They have nothing to go on except a few torn scraps of paper which they've succeeded in pasting together, and some facts gathered from Sneedly.

The facts: Gertrude never had more than two dresses at a time. Actually, she seldom had more than one, as she was in the habit of selling her old dress shortly after she bought a new one. Her new dress was always a different color from the old.

The notes (in Gertrude's own handwriting). I sold my old dress today before running away. B. The dress I bought before the one I got yesterday was blue. C. The dress I sold before buying the dress I got yesterday was brown. D. The dress I sold before I bought the dress I got before buying the one yesterday was green. E. The dress I bought yesterday is the same color as the one I sold after buying the brown one. What color dress was Gertrude wearing when she ran away? What color dress did she buy yesterday? What color was the oldest dress referred to in the notes that she left? What was the color of the first dress she mentioned buying?

## a combination... for game!

*laminated plastics... a combination of properties for trouble-shy designers*

When a man goes a-hunting for a combination material for a specific application, he wants a material that satisfies the property requirements . . . and is easy to machine. Synthane laminated plastic is just the material—plenty of good mechanical, electrical, electronic and chemical properties...combined with excellent machining and fabricating characteristics.

Synthane terminal insulators must meet high property and machining standards. They must have high dielectric strength in a machinable insulator, good moisture resistance, excellent arc resistance, good heat resistance and mechanical strength. This insulator and similar parts can be fabricated at the Synthane plant with no waste, no problems to the purchaser.

... send for complete catalog and fabricating data.

Getting a joke column is fun, but it's no picnic.

If we don't print jokes, we are too serious.

If we print jokes, we are silly.

If we take from other magazines, we are too lazy to write them ourselves.

If we don't print contributions, we don't appreciate true genius.

If we do print them, the pages are full of junk.

And now, like as not, someone will say we stole these from some other magazine.

We did.

\*\*\*

A professor sought admission to the pearly gates.

"Who are you?" Saint Peter asked.

"I am a college professor."

"What do you want?"

"I want to get in."

"What have you done that entitles you to admission?"

"Well, I saw a decrepit old senior on campus the other day and I gave him two cents."

"Gabriel, is that on the records?"

"Yes, Saint Peter."

"What else have you done?"

"Well, the other night I gave a starving freshman a penny."

"Gabriel, is that on the records?"

"Yes, Saint Peter."

"Well, Gabriel, what do you think we ought to do with this guy?"

"Give him back his three cents and tell him to go to hell."

Kissing is just so much chemistry, according to Douglas Walkington, a chemist for Canadian Industries. It has to do with a craving for salt.

The cave man found that salt helped him cool off in the summer heat. He found, too, that he could get salt by licking his neighbor's cheek. Also that it was more interesting if the neighbor was of the opposite sex.

Then everybody forgot about salt.

\*\*\*

The girl was through with her bath and was just stepping onto the scales to weigh herself. Her husband happened to return home at this time and entered through the back door. Seeing what his wife was doing as he passed the bathroom door, he exclaimed, "Well, dear, how many pounds today?" Without turning her head, she replied, "I'll take 50 pounds today, and don't you dare pinch me with those tongs."

\*\*\*

Life is like that. You usually hear about the man who hits the jackpot, but the fellows who built up the pot are unknown.

\*\*\*

A farmer had ten employees on his farm, and as none of them were as energetic as the farmer thought they should be, he hit upon a plan which he believed would cure them of their lazy habits.

"Men," he said one morning, "I have a nice, easy job for the laziest man on the farm. Will the laziest man step forward?"

"Why don't you step to the front with the rest," inquired the farmer of the remaining one.

"Too much trouble," came the reply.

# HOW **HERCULES** HELPS...

...IMPROVE TOOTHPASTE

**CONSISTENCY, FIRMNESS AND STABILITY**, important characteristics not only for toothpaste but for many pharmaceuticals, cosmetics, and other preparations, can be obtained with purified Hercules® cellulose gum. An unusually effective water-binder, Hercules cellulose gum has exceptionally high purity (99.5+%) and meets the specifications of the Toilet Goods Association.

...CREATE BETTER PACKAGING

**FROM SHIPPING CONTAINERS** to individual packages, Hercules paper making chemicals play an important role in improving performance. Kymene® wet-strength resin, for example, can "weather-proof" corrugated boxes while Aquapel® or one of Hercules' many grades of rosin size provide water resistance and an improved printing surface. Solving difficult paper sizing problems has been a Hercules specialty for more than forty years.

...IMPROVE WIRE INSULATION

**PLASTIC-COATED DUPLEX WIRE** is used in this type of electric blasting cap assembly. The insulation has to be particularly tough since the wire assembly is used to lower charges of explosives into blast holes 100 feet or more in depth. The plastic coating on these wires is Hercules Hercocel® E, providing excellent insulating properties, good flexibility, and other physical characteristics to meet rugged field requirements.

# ENGINEERS... LOOK TEN YEARS AHEAD!

A Douglas engineer lives here

Will your income and location  
allow you to live in a home  
like this...spend your  
leisure time like this?

*They can...if you start your  
career now at Douglas!*

Take that ten year ahead look. There's a fine career opportunity in the engineering field you like best waiting for you at Douglas.

And what about the Douglas Aircraft Company? It's the biggest, most successful, most stable unit in one of the fastest growing industries in the world. It has giant military contracts involving some of the most exciting projects ever conceived...yet its commercial business is greater than that of any other aviation company.

The Douglas Company's size and variety mean that you'll be in the work you like best — side by side with

the men who have engineered the finest aircraft and missiles on the American scene today. And you'll have every prospect that ten years from now you'll be where you want to be career-wise, money-wise and location-wise.

Brochures and employment applications are available at your college placement office

For further information about opportunities with Douglas at Santa Monica, El Segundo and Long Beach, California and Tulsa, Oklahoma, write today to:

**DOUGLAS AIRCRAFT COMPANY, INC.**  
C. C. LaVene, 3000 Ocean Park Blvd.  
Santa Monica, California

INDUSTRIES THAT MAKE AMERICA GREAT

**TEXTILES . . .**

**SPINNING FABULOUS YARNS**

The textile industry—through its variety of processes and products—plays one of the most significant roles in the everyday lives and activities of all Americans. Today, efficient men, methods and machines produce yarns and fabrics for an almost endless list of products of which clothing, carpets, drapes, tires, belting, shoes and furniture are but a sample. With heartening regularity, textile manufacturing advances are being made, new fibers and blends created, and new applications developed.

Pacing textile industry progress is an intensive research program. Synthetics now are as familiar and serviceable as cotton, wool and other natural fibers, and have

freed us from any dependence upon imports such as silk. Concentrated development of the industry's manufacturing processes has brought new techniques and methods to improve and speed up the transformation of raw fiber into finished material.

But not content with the dynamic progress already made, the textile industry is continuing to reinvest earnings to insure further advances. It is enlisted—with its suppliers and processors—in a never-ending effort to improve machines and methods.

An important requirement in this second largest industry in America is steam, used in textile plants for power, processing and heating. The Babcock & Wilcox Company,

whose experience with steam extends over nearly a century, has long been a contributor to textile industry progress. B&W boilers and associated equipment are being improved constantly as B&W's research and engineering facilities devote time, effort and money to help make better boilers for all industry. The Babcock & Wilcox Company, Boiler Division, 161 East 42nd Street, New York 17, N. Y.

N-205

THE WISCONSIN ENGINEER

In the Arma Visual Computer, a single control selects the desired chart from as many as 700 photo slides. Each slide contains punched code holes which automatically tune in the corresponding Omni Bearing Distance station. The image of the plane is governed by a combination of the radio signals and the plane's gyro instruments.

## Photography teams with electronics and adds new certainty to flight

Now a visual computer pictures a plane's precise position and heading on projected photos of aeronautical maps.

Arma Division, American Bosch Arma Corp., working with the Air Navigation Development Board and C.A.A., has developed a valuable new aid in air navigation using photography.

With it the pilot, high above the weather, flicks a switch and before him appears a map of the area he's over. On the screen a tiny shadow of a plane moves and shows exactly where he is, where he's heading and whether he's on course.

This spells added certainty. Even more! It can mean savings in time and money, too. For the flight can proceed by plan rather than by dog-legs on the beams.

So again we see photography at work helping to improve operations—doing it for commercial aviation just as it does for manufacturing and distribution.

Photography works in many ways for all kinds of business, large and small. It is saving time, saving money, bettering methods.

This is why graduates in the physical sciences and in engineering find photography an important tool in their new occupations. Its expanding use has also created many challenging opportunities at Kodak, especially in the development of large-scale chemical processes and the design of complex precision mechanical-electronic equipment. If you are interested in these opportunities, write to Business and Technical Personnel Department, Eastman Kodak Company, Rochester 4, N. Y.

**Eastman Kodak Company, Rochester 4, N. Y.**

# Use your engineering know-how in dealing with customers\*

For a professional career with business responsibility, investigate G.E.'s Apparatus Sales Training Program. You're trained in the branch of industrial selling most suited to your interests and aptitudes, to be a *Sales Engineer, Application Engineer, Product Specialist, or Field Supervisor.*

As a G-E representative in one of the Company's 147 Apparatus Sales Offices in key cities, you work with customers to determine what design, new development or system will best serve their needs. The program offers—in addition to exciting district work—career opportunities in the Company's headquarters marketing and sales operations. 956-7
