Plain *parterres* are moſt valuable in England, becauſe of the firmneſs of the Engliſh graſs turf, which is ſuperior to that of any other part of the world; and the *parterres* of embroidery are cut into ſhell and ſcroll work, with alleys between them. An oblong, or long ſquare, is accounted the moſt proper figure for a *parterre*; and a *parterre* ſhould, indeed, be always twice as long as it is broad, becauſe, according to the known laws of perſpective, a long ſquare always ſinks to a ſquare; and an exact ſquare always appears leſs than it really is. As to the breadth of a *parterre*, it is to be proportionable to the front of the houſe; but leſs than a hundred feet in breadth is too little.

There ſhould be on each ſide the *parterre* a terras walk raiſed for a view, and the flat of the *parterre* between the terraſes ſhould never be more than three hundred feet, at the utmoſt, in breadth; and about a hundred and forty feet in width, with twice and a half that in length, is eſteemed a very good ſize and proportion. *Miller*'s Gard. Dict.

PARTHENIUM, in botany, the name given by Linnæus to a large genus of plants, comprehending, beſide the *parthenia* commonly ſo called, the partheniaſtrum of Niſſole and Dillenius, and the hyſterophorus and tarchonanthus of the ſame author, and of Vaillant. The characters of the genus are theſe: the common cup is very ſimple, being five leaved and expanded; the leaves of it are roundiſh, plane and equal; the corolla is compound and convex; the corollulæ or ſemifloſcules are very numerous; and the hermaphrodite ones are placed in the center. The female ones are only five in number; they are placed in the verge or radius, and ſcarce exceed the others in length. The hermaphrodite flowers are monopetalous, tubuloſe, and erect; the rim divided into five ſegments, and of the length of the cup. The female ones are monopetalous and tubuloſe, but they are flatted at the end, obtuſe, and roundiſh, and of the ſame length with the hermaphrodite ones. In the hermaphrodite flowers there are five capillary filaments ſerving as ſtamina; theſe are of the length of the flower, and the antheræ are thick and almoſt looſe. In the hermaphrodite flowers the piſtil has a germen placed under the cup, and ſo ſmall as to be ſcarce viſible; the ſtyle is very ſlender, and ſhorter than the ſtamina, and it has no ſtigma. In the female flowers the germen of the piſtil is turbinated and cordated at the end, and is naked and of a compreſſed figure; the ſtyle is capillary and of the flower's length; there are on this two capillary ſtigmata of the ſame kind, and opening at their tops. There is no other fruit but the cup, which remains upon the plant unaltered. The ſeed in the hemaphrodite flowers is abortive, and in the female, remains in the cup and is ſingle, of a turbinated form, cordated at the extremity, and compreſſed. The flowers are ſo diſpoſed in the head, that every female has two hermaphrodite ones at its back. *Linnæi* Gen. Pl. p. 455. *Niſſole*, A. G. 1711. *Dillen.* Gen. 13. Hort. Elth. 22. *Vaillant*, A. G. 1720. p. 1719.

Some of the Greek writers have called the *parthenium* by the name of the ſweet marjoram, *amaracus*; and this has often occaſioned great doubts, as to which of the two plants was meant. Dioſcorides ſays, that the *parthenium* was by ſome called *Leucanthemum*; and by others, *amaracus*. Pliny ſays, that ſome called it *tamnacus*; but this is evidently only a falſe print, for he has trrnſlated the before mentioned words of Dioſcorides in the very order in which they ſtand in that author, and the word *tamnacus* ſhould be *amaracus*. But this is not the only perplexity Pliny has occaſioned about this plant: he has tranſlated the account of it in a Greek author, which plainly ſhews, that the plant was the ſame that we now call by the name *parthenium*. Pliny has miſtaken his original when he ſays, that it has a white flower, ſwelling like an apple; whereas the original ſays, that the exterior border of the flower was white, and the central part a diſcus yellow.

The antients had another *parthenium*, which they diſtinguiſhed by the name *murale*. This is our *parietaria*.

PARTISAN, in the military art, the commander of a *partiſan* party.

PARTISAN-*party*, a ſmall body of infantry given to a *partiſan*, to make an incurſion upon the enemy, to lurk about their camp, to diſturb their foragers, and to intercept their convoys.

PARTITION (*Cycl.*)—PARTITION, in huſbandry. The *partitions* in land ſown with wheat by the drill, for the horſe-hoing huſbandry, are different according as the wheat is ſown, in double, treble, or quadruple rows. The double row has but one *partition*, and this is beſt to be uſed in caſes where the land is ſuſpected to be full of the ſeed of weeds, which muſt be taken out with the hand hoe. This *partition* ſhould be twelve or fourteen inches wide. Whole fields drilled in theſe rows may be hand-hoed at the expence of four ſhillings an acre; and when there is but one foot in ſix, the price of that work ought to be proportionable.

The common width of the two *partitions*, when the wheat is ſown in treble rows, is ſix or eight inches. Care is to be taken in this particular; for, if they are planted cloſer, they will ſtarve one another before the intervals are hoed to give them a freſh ſupply of nouriſhment; and if they are planted too far aſunder, the two outer rows will thrive well, but the middle row will be ſtarved, and look worſe and weaker, becauſe of its being at ſo great a diſtance from the hoed intervals. In quadruple rows the *partitions* are beſt to be ſeven inches wide each: at this diſtance the plants will thrive ſufficiently, and if they are ſet nearer, the whole will be worſe; and if farther off, the two outer rows will thrive, but the two inner ones will be ſtarved, by reaſon of their diſtance from the plowed intervals.

PARTITION, *partitio*, in rhetoric, the ſame with diviſion. See the article DIVISION.

PARTITIONE *facienda*, in law, a writ which lies for thoſe who hold lands or tenements *pro indiviſo*, and would ſever to every one his part, againſt them that refuſe to join in partition, as copartners, &c. F. N. B. 61, 31 H. 8. c. 1. *Cowel.*

PARTITURA, in the Italian muſic, the ſame as *partition*. See PARTITION, *Cycl.*

PARTNER (*Cycl.*)—PARTNERS, in a ſhip, are ſtrong pieces of timber bolted to the beams incircling the maſts, to keep them ſteady in their ſteps, and alſo keep them from rolling, that is, falling over the ſhip's ſides. There are alſo of theſe *partners* at the ſecond deck, to the ſame end; only the miſſen-maſt hath but one pair of *partners*, in which that maſt is wedged ſo firm that it cannot move. Some ſhips do not ſail well unleſs their maſts are looſe, and have leave to play in the *partners*; but in a ſtorm this is dangerous, leſt the *partners* ſhould be wronged, (as they ſay) *i. e.* forced out of their places; for then there is no help but to cut the maſt by the board.

PARTRIDGE, *perdix*, in ornithology. See PERDIX.

The *partridge* is a timorous and ſimple bird, and is ſo valuable at the table, that there are a great many ways of taking it invented by ſportſmen, all of which ſucceed from the folly and fear of the animal.

The places that *partridges* moſt delight in, are corn-fields, eſpecially while the corn grows; for that is a ſafe retreat, where they remain undiſturbed, and under which they uſually breed. They frequent the ſame fields after the corn is cut down, and that with another intent; for they then feed on the corn that has fallen from the ears, and find a ſufficient ſhelter for them under the covert of the ſtalks, eſpecially thoſe of wheat ſtubble. When the wheat ſtubble is much trodden by men or beaſts, they retire to the barley ſtubble, and will there hide themſelves in coveys of twenty or thirty. When the winter comes on, and the ſtubble fields are trodden down or ploughed up, they then retire to the upland meadows, where they lodge in the high graſs and among the ruſhes; ſometimes they reſort to the low coppice woods, eſpecially if there be corn lands near them.

In the harveſt time, when the corn fields are full of men, they are found in the fallow fields next to the corn fields, where they lie lurking among the weeds till evening, and then they get over into the corn, and feed late and early on the corn in the ſheaves. When the proper haunts are known, the next thing is to find the birds in them: this is done variouſly, ſome will do it by the eye only; and this art can never be taught, but can be had only from long obſervation: the colour of the birds being ſo like that of the earth at a diſtance, that no eye but a very converſant one could diſtinguiſh them. When they are once ſeen, the buſineſs is to keep the eye upon them, and then to keep in continual motion. They are a very lazy bird, and by this means will let a perſon almoſt tread upon them; tho' if the perſon ſtands ſtill to eye them, they will riſe immediately, tho' they are at a conſiderable diſtance.

Another method of obſerving them is by going to their haunts very early in the morning, or at the cloſe of the evening, which is called jucking time. The noiſe of the cock *partridge* is to be attended to at this time, and is very loud and earneſt. The hen will ſoon come up to the cock after her making the noiſe, which ſhe does by way of anſwer; and when they are got together, their chattering will diſcover them. Thus they may always be found at theſe times: but there is a yet better method of finding this bird, which is by the call. The buſineſs, in order to have ſucceſs in this way, is carefully to learn the notes of the *partridge*, and be able to imitate all the ſeveral ſounds. When perfect in this, the perſon is to go to the haunts morning and evening, and placing himſelf in ſome place where he can ſee the birds without being ſeen by them, he is to liſten to their calling; and when they are heard, he is to anſwer in the ſame notes, doubling again as they do: by continuing this, they may be brought ſo near, that the perſon lying down on his back may count their whole number. Having in this manner found where the birds are, the next care is to catch them.

They are ſo fooliſh, that it is extremely eaſy to take them in nets. In order to this, there needs no more than the going out, provided with two or three nets, with meſhes ſomewhat ſmaller than thoſe of the pheaſant nets, and walking round about the covey, a net is to be fixed ſo as to draw over them, on pulling a line at a diſtance. All this may be eaſily done; for ſo long as the ſportſman continues moving about, and does not fix his eyes too intently upon them, they will let him come near enough to fix the nets, without moving. If they lie ſo ſtraggling, that one net will not cover them, then two or three muſt be fixed in the ſame manner. The ſportſman may then draw the nets over them, and they will often lie ſtill with the nets upon them till he comes up to fright them, then they will riſe and be entangled in the net.

A ſecond method of taking them is with bird-lime: this is done by means of wheat ſtraws. Theſe muſt be large, and cut off between knot and knot; they muſt be well limed with the beſt and ſtrongeſt bird-lime, and the ſportſman muſt carry a great number of them out with him. Having found a field where there are *partridges*, he is to call; and if they anſwer, he is then to ſtick up the limed ſtraws in rows acroſs two or three lands, and going backward, call again to them, leading them on in the road where the ſtraws are: they will follow one another like a flock of chickens, and come out to the call; and will in their way run upon the ſtraws, and liming themſelves, they will daub one another by crowding together, ſo that very few of them will be able to eſcape.

But there is yet a pleaſanter way of taking them than this, that is, by driving of them: in order to this, an engine is to be made of canvas ſtuffed with ſtraw, to repreſent a horſe; this horſe and nets are to be taken to the haunts of the *partridges*, and the nets being placed ſlanting or ſlopewiſe in the lower part of the field, the ſportſman is to take the wind in his back and get above them, driving them downwards; his face is to be covered with ſomething green or blue, and placing the horſe before him, he is to go towards them ſlowly and gently; and by this means they will be raiſed on their legs, but not on their wings, and will run before the horſe into the nets. If in the way they go into a wrong path, the horſe is to be moved to face them; and they will be thus turned back again, and driven every way the ſportſman pleaſes.

Indian PARTRIDGE, *coturnix Indica*, the name given by the Spaniards to a bird of the Weſt Indies, of which there are three or four ſpecies; all which, Nieremberg ſays, are properly of the *partridge* kind. See the articles COLIN, and QUAUHTZONECOLIM.

Red-legged PARTRIDGE, a very delicate and valuable bird, called *cutumo* by the Italians.

It is diſtinguiſhed from the common *partridge* by the redneſs of its beak and legs. It is of a greyiſh aſh colour on the back; its throat is white near the head, but has a ſmall black ſpot on each ſide at the angle of the bill, and this white ſpace is ſurrounded by a black line; its breaſt is of a yellowiſh brown, and its wings are variegated with black, yellowiſh, and white. It is not found in England, but is ſometimes ſhot in the iſlands of Guernſey and Jerſey. *Ray*'s ornithology, p. 122.

PARTY (*Cycl.*)—PARTY-*bleu*, in the military art, a name given to a party of robbers who infeſted the roads in the Netherlands. They belonged to neither army, but robbed both ſides, without any regard to paſſes.

PARTY-*china*, a name given by the Engliſh merchants and others to a ſort of porcelain or china-ware, which is elegantly painted on the outſide with ſome bright colour, and blotted or variegated with round or ſquare ſpots of a different tinge. The manner in which the Chineſe do this is a very ſimple and eaſy one, and may be imitated in our own potteries with great eaſe. They prepare as many pieces of paper as they intend to have ſpots on the veſſel, and cut them exactly into the ſhape of thoſe ſpots: they wet theſe, and then ſpread them ſmoothly on the places where the ſpots are to be. When this is done, they cover the veſſel with the brown and gold, or any other varniſh, and then take off the papers: in the places which they covered no varniſh has come, ſo that they are ſo many regular white ſpaces. Theſe they cover with ſome other colour, laying it on carefully with a pencil: when this is done, they varniſh over the whole veſſel with the common varniſh, and bake it. In ſome veſſels they lay on only plain blue, or plain black in the ſpaces deſtined for ſpots; and after the firſt baking they cover theſe with gold, and make them ſo many figures of ſquares, triangles, or globes in pure gold. Obſerv. ſur les Coutumes de l'Aſie.

PARU, in natural hiſtory, the name of a very ſingular American fiſh.

It is broad, flat, and roundiſh; of no great thickneſs, and is uſually of about five or ſix inches long, and more than four broad. It has ſix fins, one large and long, one on the back, and another on the belly, behind the anus. Each of theſe reaches to the tail, and has, toward the end, a long ſtring or cord, made of a ſingle filament; that, on the back fin, being longer than that on the belly. Behind the gills it has alſo two fins of two fingers breadth long, and one broad; and two others on t e belly, which are very narrow. Its head is ſmall, and its mouth elevated and ſmall, and furniſhed with ſmall teeth. Its ſcales are of a moderate ſize, and are half black and half yellow; ſo that the fiſh appears of a black colour, variegated with yellow half moons. Its gills, and the beginning of its fins, are alſo yellow; and it has, on each ſide near the head, a yellow ſpot; it is an eatable fiſh. *Marggrave*'s Hiſt. of Braſil.

PARULIDES, in ſurgery. See GUM-*boils*.

PARUS, the *titmouſe*, in zoology, the name of a genus of ſmall birds, of which there are ſeveral ſpecies; ſome very common with us, the others of foreign origin. The Engliſh kinds are, 1. The *fringillago*, or great *titmouſe*. See FRINGILLAGO. 2. The *parus ater*, or *co'emouſe*, which has a black head, white ſpot on the back part of it, a greyiſh green back, and a green rump. This is the ſmalleſt of all the kind, not weighing above two drams. 3. The *parus paluſtris*, or *marſh titmouſe*, commonly called the *black cap*. This is ſomething larger than the colemouſe, and weighs three drams; its head is black, but its jaws white; its back greeniſh, and its feet of a lead colour. It has a larger tail alſo than the colemouſe, and wants the white ſpot at the back of its head, which is its diſtinguiſhing character. 4. The *parus cæruleus*, or *blue titmouſe*, or *nun*. This is of the ſame ſize with the black cap, but its head is blue, with a circle of white drawn round it; and round that white circle there is another of different colours, which ſurrounds the back part of the head and throat; there runs on each ſide a black line, from the beak to the hinder part of the head, and the jaws are white; the back is of a greeniſh yellow, its ſides, breaſt, and belly, yellow; but there runs a white line longitudinally down the middle of its breaſt 5. The *parus caudatus*, or *long-tailed titmouſe*. The head of this ſpecies is white, the neck black, and ſeveral black lines of the ſame colour, run from the beak to the back of the head; the breaſt is white, variegated with ſmall ſpots of brown; the belly and ſides are of a pale cheſnut colour. Its tail is extremely long, and is variegated with black and white. It is found in gardens and orchards, and builds its neſt with great art and nicety. *Marggrave*'s Hiſt. of Braſil.

The kinds not known to be found in England, are the blue American one called *guiracenoia*. See GUIRACENOIA. The *parus criſtatus*, or *creſted titmouſe*, known by its black head being fimbriated with white feathers, and its creſt, which it can at pleaſure raiſe to a fingers breadth high: and the *parus ſylvaticus*, or *wood titmouſe*, of Geſner and Aldrovand, which is very ſmall, and is diſtinguiſhed from all others by a red ſpot on its head. *Aldrovand.* de Avib.

The *titmouſe*, in the Linnæan ſyſtem of zoology, makes a diſtinct genus of birds, of the order of the paſſeres; the diſtinguiſhing characters of which are theſe: The extremity of the tongue is truncated, or as it were cut off, and terminated by four briſtles, and the beak is pointed. *Linnæi* Syſtema Naturæ, p 49.

The general characters of the *parus* kind, according to Mr. Ray, are, that they are all very ſmall, and are fond of climbing about trees, where they feed on the ſmall inſects they find in their bark; tho' ſome of them will alſo eat ſeeds. They are always reſtleſs; their beaks are ſhort, and their tails long; they make a conſiderably loud noiſe, ſome of them ſinging very agreeably; and all lay a great number of eggs. *Ray*'s Ornithology, p. 174.

PARVUS *naſi muſcu'us*, in anatomy, a name given by Caſſerius, and ſome others, to a ſmall muſcle of the noſe, called by Albinus *comprefſor naris*; by Winſlow, *tranſverſalis*, or *inferior naſi*; and by Cowper, *elevator alæ naſi*.

PARVUS *et tenuis palpebræ*, in anatomy, a name given by Fallopius to one of the muſcles of the face, called by Cowper and Douglaſs, *aperiens palpebram rectus*; and by Albinus, the *levator palpebræ ſuperioris*. See APERIENS, *Cycl.* and *Suppl.*

PARYPATE, in the antient muſic, was the name of that note or chord of a tetrachord which lay next to the hypate. As the hypate was the *principalis*, the firſt or principal ſound, according to Martianus Capello's tranſlation; ſo the *parypate* was, according to him, the *ſub principalis*. See the article TETRACHORD.

The name *parypate* was given to this ſecond note when a tetrachord was conſidered ſeparately from others; but when combined, this chord ſometimes took the name *trite*. See the articles DIAGRAM and TRITE.

PARYPATE *hypaton*, in the antient Greek ſcale of muſic, was the ſecond note of the hypaton tetrachord, and anſwers to C-ſa-ut of Guido's ſcale. *Wallis*, Append. ad Ptolem. Harm. p. 157. See DIAGRAM and PARYPATE.

PARYPATE *meſon*, in the Greek muſic, was the ſecond note of the *meſon* tetrachord, and anſwers to F-fa-ut of the Guidonian ſcale. *Wallis*, Append. Ptolem. Harm. p. 157. See DIAGRAM.

PAS *de ſouris*, in the military art, the ſame with *liziere*. See the article LIZIERE, *Cycl.*

PASHA, an office of dignity under the Grand Seignior, otherwiſe called *baſhaw*. See BASHAW, *Cycl.*

All Egypt is, on the part of the Grand Seignior, governed by a *paſha*, who has in reality but little power; but ſeems principally to be meant for the means of communicating to his divan of beys, and to the divans of the ſeveral military ogiacs, that is, their bodies, the orders of the Grand Seignior, and to ſee that they be executed by the proper officers.

If he farms the country of the Grand Seignior, the fines that are paid when any life drops upon the lands belong to him; for originally all the lands of Egypt belonged to the Grand Seignior; and the porte ſtill looks on them as its own: but the Grand Seignior's power being now loſt, they all go to the next heir; who muſt, however, be inveſted by the *paſha*, and is glad to compound for a ſmall ſum.

The nature of the *paſha*'s office requires him to be ever attempting means to cut off ſuch as are too aſpiring, or engaged in deſigns that may be any way prejudicial to the porte. This often occaſions his own depoſition; but he is in no care about that, as his perſon is always ſacred; and his loſing this poſt is only a ſtep to higher preferment. *Pecock*'s Egypt, Vol. 1. p. 162.

PASHAUNA *beady*, in natural hiſtory, a name given by the people of the Eaſt Indies to a kind of fibroſe talc, found in the ſides of the mountains, and uſed in medicine with them. They calcine it, and then powder and boil it in milk, and give half a dram for a doſe mixed in milk, for the gravel and ſtone.

PASS *(Cycl.)*—PASS, among miners, a frame of boards conſiſting of two or three bottom boards and two ſide ones, ſet ſlope-wiſe; thro' which the ore ſlides down into the coffer of the ſtamping mill.

PASQUE-*flower*, in botany. See PULSATILLA.

PASSACAGLIO, in the Italian muſic, is properly no more than a chacone. See CHACONE.

The only difference then, is, that the movement of the *paſſacaglio* is ſomewhat graver, the tune ſofter, and the expreſſion leſs lively: they are for the moſt part in the minor modes, or flat keys.

PASSADE, *(Cycl.)* in the manege. This cannot be performed without changing the hand, or turning and making a demi-tour at each of the extremities of the ground. Hence it is, that there are ſeveral ſorts of *paſſades*, according to the different ways of turning, in order to part or put again, and return upon the ſame piſte, or tread; which we call cloſing the *paſſade*. See CLOSE and SERRER.

A paſſade of five times, or a demivolt of five times, is a demi-tour made at the end of the ſtraight line, one hip in, in five times of a gallop upon the haunches; and at the fifth time ought to have cloſed the demivolt, and to preſent upon the *paſſade*-line ſtraight and ready to return. The demivolts of five times or periods, are the moſt common airs of changing the hand or turning, that are now practiſed.

Furious paſſades, thoſe performed upon a full career, being moſtly uſed in duels. To make theſe *paſſades*, you put your horſe ſtraight forwards, and towards the extremity of the line make a half ſtop, keeping the horſe ſtraight without traverſing; then you make the demivolt at three times, in ſuch a manner, that the third time the horſe preſents ſtraight upon the *paſſade*-line ready to ſet out again upon a ſhort gallop. You continue this ſhort gallop half the length of the *paſſade*, then you put on furiouſly at full ſpeed; and at the end of the *paſſade* mark a half ſtop, and then a demivolt of three times. This you continue to do as long as the horſe's wind and ſtrength will hold. This *paſſade* at full ſpeed, ſuppoſes that the horſe has an excellent mouth, and requires ſtrength and agility both in the horſe and horſeman. There are but few horſes that are capable of it.

Paſſade of one time, is a demivolt or turn, made by the horſe, in one time, of his ſhoulders and haunches. To make this *paſſade*, which is the moſt perfect of all, the horſe ſhould ſtand ſtraight upon the *paſſade*-line; and then putting forwards, he forms a half ſtop, making falcades two or three times in ſuch a manner, that he is ſtill ſtraight upon the line; and at the laſt time he prepares to turn nimbly, and retain to fix his haunches as a center; ſo that the demivolt is performed in only one time of the ſhoulders: and tho' the haunches make likewiſe a time, they make it in the center, or upon the ſame ſpot, and *de ferme a ferme*, as the French call it.

Raiſed or high paſſades, are thoſe in which the demivolts are made in corvets.

In all *paſſades* the horſe ſhould, in making the demivolt, gather and bring in his body, making his haunches accompany his ſhoulders, without falling back, or not going forward enough each time: and he ſhould go in a ſtraight line, without traverſing or turning his croupe out of the line.

PASSAGE *(Cycl.)*—*Birds of* PASSAGE, a name given to thoſe birds which at certain ſtated ſeaſons of the year remove from certain countries, and at other ſtated times return to them again, as our ſwallows, and many other ſpecies.

The places to which theſe birds retire on their leaving the countries in which they have made their abode, for a certain

ſeaſon,

ſeaſon, not having been ever perfectly known, ſome have formed idle conjectures of their not going away, but remaining torpid in hollow trees, in caverns, and under waters; but theſe are too abſurd to gain credit with the thinking part of the world; and their whole journey ſeems directed by inſtinct toward ſuch parts of the world as will afford them food, when that whence they depart will no longer do ſo: this want of food ſeems in all the ſpecies to be the chief reaſon of their departure; and the plenty of it in an after-ſeaſon, that of their return from a place which then, perhaps, affords it no more.

The generality of birds that remain the winter with us, have ſtrong bills, or are enabled to feed on what they can find at that ſeaſon; thoſe which leave us, have uſually very ſlender bills, and their food is the inſects of the fly kind; which diſappearing toward the approach of winter, compel them to ſeek them in regions where they may be found; and the length of the wings of the generality of theſe birds, enables them to prey flying, if there be food for them in their way, and to continue a long time on the wing without reſt.

The various conjectures about the places to which they retire, are owing to want of ocular teſtimony; but if we conſider the vaſt tracts of land yet unknown to us, we cannot doubt but there may be many places for them, in which we can have had no opportunities of finding them. But the moſt probable conjecture ſeems, that the places to which they retire lie probably in the ſame latitude in the ſouthern hemiſphere, as the places from whence they depart; where the ſeaſons reverting, they may enjoy the like agreeable temperature of the air. And if theſe places are ſuppoſed to be divided from them by too large ſeas, why may not ſome other parts of the ſouthern hemiſphere, which are leſs diſtant, ſerve their turn?

This, certainly, ſeems much more reaſonable than that they ſhould remain on our ſide of the northern tropic, within a few degrees of which, at the winter ſolſtice, it is ſo cold as frequently to produce ſnow; which, by diſperſing ſuch inſects as birds that feed upon the wing ſubſiſt on, muſt make them periſh, were they not to remove to thoſe warmer climates where they may ſtill find food.

The ſwallows, as they cannot ſubſiſt ſo long in cold ſeaſons as ſome other birds of *paſſage*, which feed after the diſappearance of flies in the air, on what inſects they find in their receſſes, viſit us later, and depart from us ſooner, than the reſt. The nightingales, and ſome other birds, which leave us for the winter, are ſeen, ſometimes, a month after the ſwallows: and from the whole it ſeems natural to infer, that the ſwallows paſs the tropic of Cancer, tho' it is not yet known to what place they at length retire.

The manner of the birds of *paſſage*, journeying to their ſouthern abode, may vary, according to the different ſtructure of their bodies, and their power of ſupporting themſelves in the air. Thoſe birds with ſhort wings, ſuch as the redſtart, blackcap, *&c.* tho' they are incapable of ſuch long flights as the ſwallow, or of flying with ſo much celerity, yet may paſs to leſs diſtant places, and by ſlower movements. Swallows and cuckows, may perform their paſſage in a very ſhort time; but there is for them no neceſſity for ſpeed, ſince every day's paſſage affords them an increaſe of warmth, and a continuance of food.

Providence, which has guided the defenceleſs animals in many other inſtances to the ſafeſt methods of performing their neceſſary works, may have inſtructed many of theſe birds which have ſhorter paſſages to make, or places to ſtop at by the way, to fly only in the night, that they may be ſecure from the birds of prey: and Mr. Cateſby gives a proof that ſome ſpecies do ſo, from his own obſervation; for lying on the deck of a ſloop on the north ſide of Cuba, himſelf and the whole company, heard ſucceſſively, for three nights, flights of rice birds, which are eaſily diſtinguiſhed from all others birds by their notes, and which were paſſing over their heads northerly; which is their direct way from Cuba, and the ſouthern continent of America, from whence they got to Carolina, annually about the time that rice begins to ripen, and from whence they return ſouthward again, when it is gathered, and they are become fat.

The ſhort winged birds are ſuppoſed little qualified for long flights, particularly the quail, which is a bird never ſeen long together on the wing, or making any long flights: its not doing this frequently, is, however, no proof that it is not able to do it; nor does the ſtructure of its body at all beſpeak its inability: and Bellonius affirms, that he ſaw them in great flights paſſing over, and repaſſing, the Mediterranean ſea, at the very ſeaſons when they leave us, and return to us again. The ſame inſtinct that directs theſe birds to depart to diſtant countries, doubtleſs, alſo directs them to the ſhorteſt way, and ſends them to the narroweſt cuts, not the wider ſeas to croſs.

Among the birds of *paſſage*, we have ſome alſo which come to us in the autumn, at the time when the ſummer birds are leaving us; and go from us again in the ſpring at the times when theſe return: theſe, however, are only four kinds; the fieldfare, the redwing, the woodcock, and the ſnipe; and of theſe, the two laſt often continue with us thro' the ſummer, and breed; ſo that the two firſt ſeem the only kinds that certainly leave us at the approach of ſpring, retiring to more northern parts of the continent, where they live the ſummer and breed; and at the return of winter, are driven ſoutherly from thoſe frigid climes, in ſearch of food, which there the ice and ſnow muſt deprive them of. There are many others alſo, particularly of the duck or wading kind, that bre d and make their ſummer abode in the deſolate fenny parts of our iſland; and when the ſeverity of our winters deprives them of their food, neceſſity forces them to retire toward the ſea in numerous flights; where they find water unfrozen, and where they remain till the return of ſummer; but theſe cannot properly be called birds of *paſſage*.

It ſeems pretty evident from the whole, that the ſummer birds of *paſſage* leave us only in ſearch of a more warm climate, and a greater plenty of food; both which advantages they procure to themſelves by their alternate change of climate; but the migration of the winter birds of *paſſage* is not ſo eaſily accounted for, ſince there is no ſuch apparent neceſſity of their leaving us either on the ſcore of food, or climate. The place of the ſummer retirement of theſe birds is Sweden, and ſome other countries in that latitude; but as they would find thoſe places too cold and deſtitute of proviſion, were they to haſten immediately to them on their departure from us, they journey along gradually, and prolong their paſſage thro' the more moderate countries of Germany and Poland; by which means they do not arrive at their northern habitations, where they are to paſs their ſummer, and where they breed till the ſeverity of the cold is ſo far abated as to render it pleaſing to them, and there is proper food there for them: and when they reviſit us the following winter, thier journey is performed in the ſame leiſurely manner.

Sweden, and the other countries whence they come to us, ſeem the proper home of theſe birds; ſince there they were bred; and the journey they take to us being only for a warmer climate, and a plenty of food, it is no wonder that when theſe benefits are to be expected again in their native place, they return to it.

The principal food of theſe birds, while with us, is the fruit of the white thorn, or haws; which hang on our hedges, in winter, in prodigious plenty; but where they breed, and ſeem to live moſt at eaſe, as in Sweden, *&c.* there are no haws, nor indeed in many of the countries thro' which they journey in their way; ſo that it is evident they change their food in their paſſage. And upon the whole it appears, that Providence has created birds, *&c.* with conſtitutions and inclinations adapted to their different degrees of heat and cold; which, to them, are moſt agreeable, and to which they will travel from places which to other animals might ſeem more agreeable: by this means no part of the globe is without its inhabitants.

Beſide the migratory birds, which live in different countries a whole winter, or a whole ſummer, there are ſome others which annually appear in particular places, at the time of the ripening of particular kinds of grain which their own country is deſtitute of; and theſe depart after a ſhort ſtay, and are no more ſeen till that time the following year. Of this kind are the rice-bird, and bluewing of Carolina. Birds like men, purſue their ſearches after food, or whatever elſe is neceſſary and agreeable, thro' diſtant climes; and when they diſcover ſome new grain, or pleaſing food, they return and acquaint their community of the good fortune, and then joining in numerous flights, make annual excurſions to ſolace themſelves on this exotic food.

Since the diſcovery of America, there have been introduced from Europe ſeveral ſorts of grain which were before unknown there, and which, not before ſome length of time, were found out, and coveted by birds of this migratory kind. Of this ſort there is a very beautiful ſpecies, which has very lately made its firſt appearance in Virginia: theſe arrive annually at the time that the wheat is ripe, or nearly ſo; and conſtantly ſince they found it out, have appeared in great droves every year, at the ſeaſon of its ripening; the inhabitants call them, for this reaſon, *wheat-birds*. Phil. Tranſ. N° 483.

PASSAGE, in the manege. To *paſſage* a horſe upon his own length. See LENGTH.

PASSAGIO, in the Italian muſic. See PASSAGE, *Cycl.*

PASSAGO, in the glaſs trade, the inſtrument with which the workman makes the bowl of the drinking glaſſes, or other the like veſſels. *Neri's* Art of Glaſs, p. 247.

PASSARADO, in a ſhip, is a rope whereby all the ſheet-blocks of the main and fore ſails are haled down; the clew of the main ſail to the cubbridge-head of the main maſt, and the clew of the fore ſail to the cat-head. This is to be done when the ſhip goes large; and they are alſo kept firm down, and hindered from flying up, by this *paſſarado* rope.

PASSEPIED, in the French muſic, an air in all reſpects like a minuet, except that it is more briſk and lively. See the article MINUET.

PASSER, the *ſparrow*, in zoology, the name of a large genus of birds, the diſtinguiſhing characters of which are theſe: they feed on corn and worms; their beak is thick, ſhort, and ſomewhat bent; their colour commonly a duſky brown.

There

There are many known ſpecies of this bird. 1. The common houſe *ſparrow*. 2. The *paſſer ſtultus*, or fooliſh *ſparrow*, which is of a yellowiſh brown, with duſky ſtreaks. 3. The baſtard *ſparrow*, *paſſer congener*, of Aldrovand, which is of a reddiſh brown, and has no black ſpot under its throat. 4. The *paſſer tricolor*, or three coloured *ſparrow*; this is variegated with an equal proportion of black, white, and yellow. 5. The *paſſer albicilla*, or white-tailed *ſparrow*, diſtinguiſhed by its greyiſh white tail. 6. The *paſſer Illyricus*, or Illyrian *ſparrow*, which is larger than the common kind, and has a very white belly. 7. The *paſſer torquatus*, or ring *ſparrow*, which is very ſmall, and has a white ring about its eyes: the ſpot under the throat, which is black in the common *ſparrow*, is yellow in this ſpecies. 8. The *paſſer Indicus caudatus porphyromelas*, or long tailed black and red Indian *ſparrow*. 9. The *paſſer Indicus*, called *tijepiranga*. See TIJEPIRANGA. 10. The *paſſer Indicus macrouros roſtro miniaceo*, or long-tailed Indian *ſparrow*, with a red beak. 11. The *paſſer Indicus macrouros alius* of Aldrovand, or the other long-tailed Indian *ſparrow*; a very beautiful bird, with a blue beak and a black head; the body being moſtly of a fine ſcarlet. 12. The *paſſer Indicus brachyuros*, or ſhort-tailed Indian *ſparrow*, which is ſmall, and all over of a bluiſh black. 13. The *paſſerculus brachyuros Europæanus*, or European ſmall ſhort-tailed *ſparrow*: this is common in Italy, and is very ſmall, and all over of a pale yellow. 14. *Paſſer erythromelas Indicus, ſine uropygio*, the red and black Indian *ſparrow*, with no tail. 15. *Paſſer Indicus cyanerythromelas, ſine uropygio*; the blue, black and red Indian *ſparrow*, without a tail. Theſe are deſcribed by Marggrave; but he only ſaw the figures of them, ſo that the painter, not nature, perhaps, denied them tails. 16. The *paſſer montanus*, or mountain *ſparrow*: this is common in Carinthia, and is variegated with a browniſh red and black. 17. The *paſſer ſylveſtris*, or field *ſparrow* of Aldrovand: this is of the ſize of the common *ſparrow*, and is of a duſky ruſt-coloured brown, and has a broad ſtreak running from the angle of its beak to its tail. And laſtly, 18. The Braſilian *ſparrow*, called *Guiranheemgatu*. See GUIRANHEEMGATU. *Ray*'s Ornithology, p. 184. *Aldrovand.* de Avibus, l. 15 c. 33. *Ray*'s Ornithology, p. 182, to 186. *Aldrovand.* Hiſt. l. 15. c. 16.

In the Linnæan ſyſtem of zoology, the *paſſer* is one of the orders of the bird kind; the diſtinguiſhing mark of which is, that the beak is of a conic form, and tapers to a point. *Linnæi* Syſtem. Natur. p. 48. See Tab. of Birds, N°. 29 and 38.

PASSER, in the hiſtory of fiſhes, the name of the common plaiſe, a flat fiſh, of a duſky olive-colour, ſpotted with red on the back, and white on the belly, called in Latin alſo, *quadratulus* and *plateſſa*. *Willughby*'s Hiſt. Piſc. p. 96.

PASSER-*aquaticus*, the water *ſparrow*, the name of a bird deſcribed by Nieremberg, which he ſays the Indians call *acototle-quichitl*. It ſings all day long without ceaſing, but with no very pleaſing note: it is, however, a well taſted bird; it lives among ſedge and buſhes, and is of the ſize and ſhape of a ſwallow, but has a black bill and yellow legs; its breaſt and belly are white, and its back is of a browniſh yellow, variegated with ſpots of black and white. This bird much reſembles our reed *ſparrow*. *Ray*'s Ornithol. p. 300.

PASSER-*arundinaceus*, the reed *ſparrow*, a bird of which there are two ſpecies, a greater and a ſmaller, both living among reeds and in watery places, and both ſinging very ſweetly: the greater is known among authors by the name of *junco*, and the leſſer by that of *cannevarola*. *Ray*'s Ornithology, p. 99. See JUNCO and CANNEVAROLA.

PASSER *arundinaceus torquatus*, the ringed reed *ſparrow*, the name of a ſmall bird, ſcarce exceeding the linnet in ſize, found among reeds, and always building its neſt among them. Its head is black; its neck has a very beautiful ring of white, reaching to the angle of the beak on each ſide; its throat is black, and its breaſt and belly white; its back and wings are of a browniſh black, and its rump bluiſh or greyiſh, with an admixture of brown. In the female the ring ſcarce appears, and the colours on the throat are reddiſh, brown, black, and grey. *Ray*'s Ornithol. p 197.

PASSER *aſper*, in ichthyology, the rough or ſcaly *plaiſe*, called in Engliſh the *dab*; a flat fiſh, ſomething thicker than the common *plaiſe*, and of the ſame general ſize, covered with conſiderably large ſcales, rough at their extremities, and edged as it were with teeth: the eyes are on the left ſide, and are placed very cloſe together: its back is of a reddiſh grey, ſpotted with yellow, and the mouth moderately large. It is caught in the Mediterranean and Engliſh ſeas. *Rondelet.* de Piſc. p. 352.

PASSER *Britannicus*, in ichthyology, a name given by Charleton to the ſoal fiſh, and by ſome others to the turbut. See the articles HIPPOGLOSSUS, and PLEURONECTES.

PASSER *canarius*, and *canarienſis*, in zoology, the common name for what we call ſimply in Engliſh, the *canary bird*.

The *canary bird* may be bred with us, and if treated with proper care, they will become as vigorous and healthful as in the country from whence they have their name. The cages in which theſe birds are kept are to be made of either walnut-tree or oak, with bars of wire; becauſe theſe being woods of ſtrength, do not require to be uſed in large pieces; and the more freedom they have of looking about them, the leſs will they be ſtartled at people going up to them. The common ſhape of cages, which is cylindric, is very improper for theſe birds; for this allows little room to walk, and without that the birds uſually become melancholy. The moſt proper of all ſhapes is the high and long, but narrow.

If theſe birds eat too much they grow over fat, loſe their ſhape, and their ſinging is ſpoiled; or at leaſt they become ſo idle, that they will ſcarce ever ſing. In this caſe their victuals is to be given them in a much ſmaller quantity, and they will by this means be recovered, by degrees, to all their beauty, and will ſing as at firſt.

At the time that they are about to build their neſts, there muſt be put into their cages ſome hay, dried thoroughly in the ſun: with this muſt be mixed ſome moſs dried in the ſame manner, and ſome ſtag's hair; and great care is to be taken of breeding the young, in the article of food. As ſoon as the young birds are eight days, or ſomewhat more old, and are able to eat and pick up food of themſelves, they are to be taken out of the cage in which they were hatched, and each put ſeparately into another cage, and hung up in a room where it may never have an opportunity of hearing the voice of any other bird. After they have been kept thus about eight days, they are to be excited to ſing by a bird pipe; but this is not to be blowed too much, or in too ſhrill a manner, leſt they ſing themſelves to death.

For the firſt fifteen days the cages are to be covered with a black cloth, and for the fifteen days following with a green one. Five leſſons in a day from the pipe are ſufficient for theſe young creatures, and they muſt not be diſturbed with ſeveral ſounds at the ſame time, leſt they confound and puzzle them: two leſſons ſhould be given them early in the morning, one about the middle of the day, and two more at night. *Hervieux*, des Serins de Canarie.

The genius and temper of the ſeveral birds of this kind are very different. The males are almoſt always melancholy, and will not ſing unleſs they are excited to it by hearing others continually ſinging about them. The male bird of this kind will often murder the female put to him for breeding; and when there are ſeveral females together with the males, they will often do the ſame to one another with jealouſy. It is therefore not eaſy to manage the article of their breeeing well in this particular, unleſs in this manner: let two female birds be put into one cage, and when they have lived together ſome time, they will have contracted a ſort of love for one another, which will not eaſily be diſſolved. Put a male bird into the cage with theſe two, and every thing will go well; their friendſhip will keep them from quarrelling about his favours, and from danger of his miſchievous diſpoſition; for if he attacks one of them, in order to kill her, the other will immediately take her part, and after a few of theſe battles, the male will find that they are together an overmatch for him at fighting, and will then diſtribute his favours to them, and there will not fail of being a young breed or two, which are to be taken away from their parents, and educated as before directed.

Some males watch the time of the female's laying, and devour the eggs as faſt as ſhe depoſits them; and others take the young ones in their beaks, as ſoon as hatched, and cruſh them to death againſt the ſides of the cage, or ſome other way deſtroy them. When a male has been known once to have been guilty of this, he is to be ſhut up in a ſmall cage, in the middle of the large one in which the female is breeding her young, and thus he will often comfort her with ſinging all day long, while ſhe ſits upon the eggs or takes care of the young ones; and when the time of taking away, to put them into ſeparate cages, is come, the male is to be let out, and he will always after this live in friendſhip with the female.

If the male become ſick during the time of the female's ſitting or bringing up her young, he muſt be removed immediately, and only brought to the ſide of her cage at certain times, that ſhe may ſee him, till he is perfectly cured; and then he is to be ſhut up again in his cage in the middle.

PASSER *faber*, in zoology, a name given by Nieremberg to a bird, the genus of which we are not very certain about; it being alſo called *turdus chiappæ*. It is remarkable for perforating the bark of the pines, and lodging its acorns there, which it afterwards eats occaſionally. *Ray*'s Ornithol. p. 303.

PASSER *fluviatilis*, in ichthyology, the name of the common flounder, diſtinguiſhed from other fiſh of that genus by the ſmallneſs and cloſe ſituation of its ſcales, which are ſuch, that which ever way it is rubbed, the hand perceives no roughneſs; and that at the inſertion of the fins there is a ſeries of ſhort prickles bent backwards, which are eaſily perceived by the touch, or by the eye on a cloſe view. *Willughby*'s Hiſt. Piſc. p. 98.

PASSER *moſquitus*, a name by which ſome have called the *guainumbi*, or *humming bird*, the ſmalleſt of all birds. Ornithol. See GUAINUMBI.

PASSER *niger*, in ichthyology, a name given by Artedi from Charleton, to the common flounder. The *fleſus* and *fleteletus* of authors, and the *plaad* of the Germans.

PASSER *ſolitarius*, the ſolitary *ſparrow*, a name given by authors to a bird properly of the *merula* or *black-bird* kind, and of the ſame ſize and ſhape with the common black bird, and not very different from it in colour.

Its head and neck are large and thick; the upper part of its head of a duſky grey, and its back of a deep bluiſh black, but with a little whiteneſs at the ends of the feathers; its tail is of a browniſh black, and its wings are variegated with brown, black, and a little white; its breaſt, throat, and belly are beautifully variegated with black, white, and grey; its beak is long and ſtrong, and its legs of a blackiſh brown, and very ſhort: it feeds on berries and other vegetables. The male is more beautiful than the female, and has a caſt of purple in the blue of his back. It ſings very ſweetly, and loves the tops of old buildings. It builds in the ſame places, and is the bird mentioned in the book of pſalms. It is much eſteemed for its ſinging, and will learn to imitate the human voice, and talk as the ſtarling, parrot, *&c.* *Ray*'s Ornithol. p. 140.

PASSER *ſtultus*, in ichthyology, a name given by Nieremberg to a ſpecies of the *larus*, or *ſeagull*, ſo tame and fooliſh that it will ſtand ſtill for any to lay his hand upon it. *Nieremberg.*

PASSER *troglodites*, in zoology, the name by which authors call the ſmall bird known in Engliſh by the name of the *wren*.

Some have very erroneouſly called this the *regulus*, which is the name of a perfectly different bird. See REGULUS.

Our *wren*, tho' a very ſmall bird, is three times as large as the regulus, and of a browniſh colour, with tranſverſe ſtreaks of black on its back, wings, and tail; a yellowiſh throat and a white breaſt, with ſome tranſverſe ſtreaks of black alſo on its lower part, and its belly of a reddiſh hue; and ſinging very ſweetly and melodiouſly, much finer and louder in its voice than could be expected from ſo ſmall a bird. *Ray*'s Ornithol. p. 164.

PASSERINE, in botany, a name by which Ruellius and ſome other authors have called the common *alſine* or *chickweed*.

PASSION *(Cycl.)*—PASSION-*flower*, *granadilla*, in botany. See the article GRANADILLA.

The different ſpecies of this plant cultivated in the gardens of the curious are very numerous, and moſt of them very beautiful.

The three more common kinds, which are what we ſee in moſt gardens, are very hardy, and bear all the ſeverities of our climates as well as if natives of it; for, tho' the tender branches, and ſometimes even the main ſtem, are deſtroyed in our ſeverer winters, yet it always ſhoots up again from the root.

Theſe are propagated by laying down their branches, which in one year's time will take good roots, and may be removed to the places where they are deſigned to remain. The beſt ſeaſon for tranſplanting them is the latter end of March or the beginning of April: they ſhould be planted againſt a wall, or other building, which faces the ſouth eaſt or ſouth weſt; or elſe mixed among the flowering ſhrubs in quarters of large gardens: in this caſe they muſt be trained up to poles fixed in the earth for that purpoſe, and thus will flower well, and appear extremely beautiful. The beſt ſeaſon for pruning them is in the ſpring, and it is a good cuſtom to lay a foot thickneſs of mulch at the roots, which will effectually preſerve them from the ſeverity of the winter, and is neceſſary when they are planted in open quarters, and have not the defence of a wall behind them. The manner of pruning is to cut entirely off all the weak ſhoots, and ſhorten the ſtrong ones to about three feet in length. When they are planted againſt high buildings, they may be left ſomething longer than this, to fill up the wall; but this is not very neceſſary, for they are very quick growing plants, and in open quarters they ſhould be always pruned much ſhorter than this, to bring their flowers nearer the ground.

The moſt common kind with us never bearing fruit in this climate, can never be propagated any way but this; but there is another ſpecies which has by ſome been miſtaken for the ſame, tho' really very different, which conſtantly bears fruit with us; and the plants of this may be raiſed from ſeeds in the common way. *Miller*'s Gard. Dict.

Hyſteric PASSION. See HYSTERICS.

PASSIONATO, in the Italian muſic, intimates that the part to which it is annexed ought to be played paſſionately, or in a moving and affecting manner.

PASSULATUM, a name given by the antients to medicine compoſed of the pulp of raiſins paſſed through a ſieve, ſometimes alone, ſometimes with other ingredients.

PASSUM, a name given by the antients to a kind of wine made of grapes, which had been ſuffered to remain on the vines till much withered and dried up: it is hence uſed alſo by ſome of the moderns to expreſs raiſin wine.

PASTE *(Cycl.)*—PASTES, in the glaſs trade, a ſort of compoſitions of the glaſs kind, made from calcined cryſtal, lead, and metallic preparations, to imitate the ſeveral natural gems. Theſe are no way inferior to the native ſtones, when carefully made and well poliſhed, in brightneſs or tranſparence, but want their hardneſs.

The general rules to be obſerved in the making them are theſe: 1. That all the veſſels in which they are made are firmly luted, and the lute left to dry before they are put into the fire. 2. That ſuch veſſels are choſen for the work as will bear the fire well. 3. That the powders be prepared on a porphyry ſtone, not in a metal mortar, which would communicate a tinge to them. 4. That the juſt proportion in the quantities of the ſeveral ingredients be nicely obſerved. 5. That the materials be all well mixed; and if not ſufficiently baked the firſt time, to be committed to the fire again, without breaking the pot; for if this be not obſerved, they will be full of bliſters and air-bladders. 6. That a ſmall vacuity be always left at the top of the pot, to give room to the ſwelling of the ingredients. *Neri*'s Art of Glaſs, p. 127.

To make a *paſte* of extreme hardneſs, and capable of all the colours of the gems, with great luſtre and beauty, take of prepared cryſtal ten pounds; ſalt of polverine, ſix pounds; ſulphur of lead, two pounds; mix all theſe well together into a fine powder, make the whole, with common water, into a hard *paſte*, and make of this *paſte* ſmall cakes, of about three ounces weight each, with a hole in them made in their middle; dry theſe in the ſun, and afterwards calcine them in the ſtraighteſt part of a potter's furnace; after this powder them, and levigate them to a perfect fineneſs on a porphyry, and ſet this powder in pots in a glaſs-furnace to purify for three days; then caſt the whole into water, and afterwards return it into the furnace, where let it ſtand fifteen days; in which time all foulneſs and bliſters will diſappear, and the *paſte* will greatly reſemble the natural jewels. To give this the colour of the emerald, add to it braſs thrice calcined: for a ſea-green, braſs ſimply calcined to a redneſs: for a ſapphire, add zaffer, with manganeſe: and for a topaz, manganeſe and tartar. All the gems are thus imitated in this, by the ſame way of working as the making the coloured glaſſes; and this is ſo hard, that they very much approach to the natural gems. *Neri*'s Art of Glaſs, p. 142.

The colours in all the counterfeit gems made of the ſeveral *paſtes*, may be made deeper or lighter, according to the works for which the ſtones are deſigned; and it is a neceſſary general rule, that ſmall ſtones for rings, *&c.* require a deeper colour, and large ones a paler. Beſides the colours made from manganeſe, verdigreaſe, and zaffer, which are the ingredients commonly uſed, there are other very fine ones, which care and ſkill may prepare: very fine red may be made from gold, and one not much inferior to that from iron; a very fine green from braſs or copper, and a ſky colour from ſilver; and a much finer one from the common ſmall garnets of Bohemia, which are of little value. The gems alſo afford glorious colours like their own. *Neri*'s Art of Glaſs, p. 136.

The fine blue from ſilver is, probably, only from the ſmall quantity of copper uſed in the alloy.

A very ſingular and excellent way of making the *paſte* to imitate the coloured gems, is this: take a quantity of ſaccharum ſaturni, or ſugar of lead, made with vinegar in the common way; ſet it in ſand, in a glaſs body well luted from the neck downwards; leave the mouth of the glaſs open, and continue the fire twenty-four hours; then take out the ſalt, and if it be not red, but yellowiſh, powder it fine and return it into the veſſel, and keep it in the ſand-heat twenty-four hours more, till it becomes as red as cinnabar. The fire muſt not be made ſo ſtrong as to melt it, for then all the proceſs is ſpoiled. Pour diſtilled vinegar on this calcined ſalt, and ſeparate the ſolution from the dregs; let the decanted liquor ſtand ſix days in an earthen veſſel, to give time for the finer ſediment to ſubſide; filter this liquor, and evaporate it in a glaſs body, and there will remain a moſt pure ſalt of lead; dry this well, then diſſolve it in fair water; let the ſolution ſtand ſix days in a glazed pan; let it ſubſide, then filtre the clear ſolution and evaporate it to a yet more pure white and ſweet ſalt; repeat this operation three times; put the now perfectly pure ſalt into a glaſs veſſel, ſet it in a ſand heat for ſeveral days, and it will be calcined to a fine impalpable powder, of a lively red. This is called the ſulphur of lead. *Neri*'s Art of Glaſs, p. 140.

Take all the ingredients as in the common compoſition of the *paſtes* of the ſeveral colours, only inſtead of red lead uſe this powder, and the produce will well reward the trouble of the operation, as experience has often proved.

PASTE *for angling*. There are many receipts which particular people are fond of, but the following compoſition ſeems one of the beſt: take equal quantities of freſh butter and ſheep's ſuet, about half as much of good old cheeſe, and the crumb of an old ſtale white loaf, as much as will, when they are all beaten in a mortar, make the whole into a *paſte*; add a little wool or tow; that it may keep the better on the hook. The place ſhould be baited with blood and grains over night, and in the morning this *paſte* will be found an excellent bait.

PASTES *for birds*, a general ſort of food made by the people who breed up birds from the neſt, and ſuiting almoſt all kinds.

It is made in the following manner: grind half a peck of large beans, well dried, to a very fine meal; take of this meal two pounds, of the beſt ſweet almonds blanched one pound; theſe muſt be well beat together in a mortar, till perfectly mixed; then to a quarter of a pound of freſh butter, in a ſaucepan well tinned, add the *paſte*, and mix all well together over a charcoal fire, ſtirring it as it boils with a wooden ſpoon; then add the yolks of four eggs, and a little ſaffron, and finally a ſmall quantity of the fineſt virgin honey. When theſe are well incorporated, and are tolerably thin and without lumps,

the whole is to be poured into a colander made with ſuch holes as will let the compoſition paſs thro': if any of it is ſo ſtiff that it will not go thro', it muſt be beat again in a mortar, and by that means made fit to paſs the holes and mix with the reſt. When the whole is done, it is to be put into a pot, and a little clarified honey being melted and poured on it, it will keep very well for ſix months or longer.

PASTELL, *(Cycl.)* a name given by ſome to the *iſatis*, or *woad*. See the articles WOAD and ISATIS.

PASTERN *(Cycl.)*—PASTERN-*joint*, in the manege, called alſo the *fetlock* of a horſe's leg, is the joint above the *paſtern*, which ſerves for a ſecond knee in each fore leg, and a ſecond ham or hough, to each hinder leg. The *fetlock* is apt to be cut by the ſide of one of the ſhoes; and when that happens, we ſay, a horſe cuts or interferes. Sprains happen upon the *fetlock*, and cratches above it behind.

PASTINACHA, *parſnep*, in botany, the name of a genus of plants, the characters of which are theſe: The flowers are diſpoſed in umbells, and are of the roſaceous kind, being compoſed of ſeveral petals arranged in a circular order upon a cup; which finally becomes a fruit compoſed of two large oval, flattiſh, marginated ſeeds; which frequently depoſit their covering. To this it may be added, that the leaves are large and alated.

The ſpecies of *parſnep*, enumerated by Mr. Tournefort, are theſe: 1. The great broad-leaved garden *parſnep*. 2. The broad-leaved wild *parſnep*. 3. The largeſt wild *parſnep*, called by authors *panax coſtæriums*. *Tourn.* Inſt. p. 319. See the article PARSNEP.

PASTINACHA *marina*, in zoology, the name of a fiſh, called in Engliſh the *poiſon fiſh*, or *fierce flaw*. It is one of the flat cartilaginous fiſhes, and ſomething like the common ſkate. It is very broad, and is thick in the middle, and thin at the edges; ſmooth ſkined, and yellowiſh on the back, and of a ſilvery white on the belly; but the ridge, or middle part of the back and the tail, are blue. It has only two ſmall fins, which ſurround the anus; the whole body is, however, thinned off at the edges into a ſort of fins. Its ſnout is very ſharp; its eyes large and protuberant; its mouth is ſmall, and without teeth; but its jaws are rough and rugged. Its noſtrils are very large, and placed near the mouth, and of a lunulated figure. Its tail, in which all its poiſon is lodged, is long, ſmooth, and round, with a thorn, or dart, of a finger's length, toothed on each ſide like a ſaw, with the teeth ſtanding upwards, or toward the head. This is placed at the diſtance of about one third of the length of the tail; and that from this place grows very ſlender, and ends in a very ſlender point. It grows, ſometimes, to ten pound weight; and when the tail is cut off, is commonly ſold in the markets in Italy and elſewhere. See Tab. of Fiſhes, N° 6.

Authors give us many remarkable accounts of the poiſon of this fiſh, which it communicates to animals by the ſtroke of its tail. They mention alſo two kinds of it; that is, beſide the ordinary ſpecies which is ſmooth, another called the *paſtinacha marina aſpera*, which is rough and prickly. *Jonſon*, de Piſc. p. 19.

PASTOPHORI, Παστοφόροι, among the antients, prieſts whoſe buſineſs it was, at ſolemn feſtivals, to carry the ſhrine of the deity, when they were to pray to him for rain, fair weather, or the like. *Pitiſc.* in voc.

PASTOPHORIA, in antiquity, the apartments near the temples where the *paſtophori* were lodged.

Clemens Alexandrinus [a], deſcribing the temples of the Egyptians, ſays, that after having paſſed through magnificent courts, you are conducted to a temple, which is at the farther end of theſe courts, and then a *paſtophorus* gravely lifts up the veil which is at the door, to ſhew you the deity within; which is nothing but a dog or a cat, or ſome other animal. Theſe *paſtophori* alſo ſupported the ſhrine, or niche of theſe ridiculous divinities, when they were carried in proceſſion. Apuleius [b] ſpeaks of the *paſtophori* that carried the Syrian goddeſs. —[[a] *Clem. Alex.* l. 3. c. 2. Pædag. [b] *Apul.* Aſin. Aur. l. 10. c. 11. *Calm.* Dict. Bibl. in voc. *paſtophoria.*]

In the temple of Jeruſalem there were two courts ſurrounded with galleries, and all round about were ſeveral lodging rooms for the prieſts, and to lay up wood, wine, oil, ſalt, meal, ſpices, incenſe, veſtments, valuable veſſels, and proviſions neceſſary for the ſacrifices and lamps; as alſo for the ſupport and maintenance of prieſts. Vid. 1 *Chron.* ix. 26, 33. *Ezek.* xl. 17, & 18. 1 *Chron.* xxvi. 16. *Calmet.* Dict. Bibl.

PASTOR *(Cycl.)*—PASTOR *piſcis*, in zoology, the name of a fiſh of the mullet kind, caught in the American ſeas and rivers, and eſteemed a very well taſted one.

It is of the uſual ſize of our river-trout, and not unlike that fiſh in ſhape. Its ſcales are large and of a ſilvery white; and are ranged in the ſame order that thoſe of the perch are, with greyiſh lines between the ſeveral arrangements. It has ſeven fins all very large, eſpecially that on the back; and its tail is remarkably forked. All the fins are white, and the coverings of the gills are ſcaly, not bony, as in moſt other fiſhes; whence it has been ſuppoſed to have no gills. *Marggrave's* Hiſt. of Braſil.

PASTORAL, in the Italian muſic, an air compoſed after a very ſweet, eaſy, gentle manner, in imitation of the airs ſhepherds are ſuppoſed to play.

PASTURE *(Cycl.)* — *Paſture-land* is of ſuch advantage to huſbandry, that many prefer it even to corn-land, becauſe of the ſmall hazard and labour that attends it, and as it lays the foundation for moſt of the profit that is expected from the arable-land; becauſe of the manure the cattle afford which are fed upon it. Where dung is not to be bought, as is often the caſe in places diſtant from large towns, the farmer is forced to proportion his arable to his *paſture*-land, in ſuch manner, that the cattle fed on the latter may be ſufficient for a ſupply of dung, ſo neceſſary for producing the fruits of the former.

Paſture-lands are of three kinds: 1. The uplands: theſe lie ſo high as not to be overflowed by rivers, or land-floods. 2. Thoſe low lands which lie near rivers and fens. And 3. Thoſe that lie near the ſea. *Mortimer's* Huſbandry, p. 15. See the articles UP-LAND, MARSH-LAND, *&c.*

Paſture-land requires the refreſhment of dung, as well as the arable or corn-land; but there is to be a difference made in the laying it on and ſpreading it. A harrow performs the office of ſpreading the dung on ploughed lands; but the beſt contrivance for paſtures, is, to lay the dung in ſmall heaps, and draw over it a gate ſtuck full of buſhes. All dung that is laid on *paſture*-land, muſt be laid on in winter, that the rains may waſh its fatneſs into the ground before the ſun ſcorches it, or evaporates its goodneſs. Fine mould mixed with the dung, and ſpread with it over the land, is very good for *paſtures*; for it is waſhed down to the very roots of the graſs, and gives them a new and fine ſoil juſt in thoſe places where it is moſt wanted.

The beſt manure for *paſture*-land, is, the rotten bottoms of old hay-ſtacks; for theſe moulder away into a very rich ſoil, and are always full of vaſt quantities of ſeed, fallen at times from the hay, which all grow when ſpread on the ground: and thus new nouriſhment, and a new ſet of plants are given at once to the exhauſted ground. But as particularly uſeful as this is for *paſture*-ground, it is as improper for corn-land, and ſhould by no means ever be ſuffered to mix with the manure for thoſe grounds; as it will then raiſe graſs and other plants, which tho' of uſe in the *paſture*, are weeds among the corn. *Mortimer's* Huſbandry.

Artificial PASTURE. As to the difference of the quantity of *artificial paſture* made by dung without tillage, and that made by tillage without dung, the latter is many times greater, as has been proved by repeated experiments on unploughed land, whereon a dunghill had lain for two or three years, and being then removed, was planted with turneps; and at the ſame time a tilled land contiguous thereto, was drilled with turneps, and horſe-hoed. The other being hand-hoed, ſeemed to proſper beſt at firſt, but, in fine, it did not amount to a fifth part of the tilled and horſe-hoed land, either in bigneſs or in crops; ſo that the benefit of the dung and hand-hoe was inconſiderable in compariſon of the plough and horſe-hoe. The little quantity of *artificial paſture* raiſed to the other, was only near the ſurface, and did not reach deep enough to maintain the turneps till they arrived at the fifth part of the growth of thoſe which were placed in an *artificial paſture*, that reached to the bottom of the common bed of mould.

Another proof of the ſame kind, is, that ſeveral lands of turneps drilled on the level, and at three foot rows, ploughed, and doubly dunged, and alſo horſe-hoed, did not produce nearly ſo good a crop of turneps as ſix foot ridges adjoining horſe hoed, tho' no dung had been laid on them of many years.

In this caſe, there was no other difference but that the three foot rows did not admit the hoe-plough to raiſe half the *artificial paſture* as the ſix foot rows did. The dung ploughed into the narrow intervals before drilling, could operate no farther with any great effect, than the hoe-plough could turn it up and help its pulverization. Upon the whole, dung without tillage can do very little; with ſome tillage it does ſomething, with much tillage it pulveriſes the ſoil in much leſs time than tillage alone can do it in; but tillage alone, in more time, can pulveriſe it as well. Much of the dung commonly uſed on fields is to be ſaved on this principle; a little more hoeing between the rows of the plants ſupplies the place of it, and is done at much leſs expence than that of ſo much manure, of the hands neceſſary to lay it on, and the carriage. *Tull's* Horſe-hoeing Huſbandry.

PASTURE *of plants*. Plants themſelves make the *paſture* for animals; but before they are in a condition to give nouriſhment to them, they muſt themſelves receive that nouriſhment from the earth. This *paſture* of plants ſeems lodged out of the way of our ſenſes; and the ignorance in regard to this, ſeems the reaſon why husbandry, tho' one of the moſt uſeful and neceſſary arts to man, has been treated in a very ſuperficial manner by the authors who have written of it. The food, or matter of increaſe of plants, is earth; and, therefore, that may be properly enough called *their paſture*.

This *paſture* is the inner, or internal ſuperficies of the earth; or, which is the ſame thing, it is the ſuperficies of the pores, cavities

cavities and interſtices of the divided parts of the earth: theſe are of two kinds; the one natural, the other artificial. By nature the whole earth, or ſoil, is compoſed of parts; and if theſe had been in every place abſolutely joined, it would have been without interſtices or pores, and would have had no internal ſuperficies, or *paſture* for plants; but ſince it is not ſo denſe, there muſt be theſe interſtices at all thoſe places where the parts remain ſeparate or divided. Theſe interſtices, by their number and largeneſs, determine the ſpecific gravity or true quantity of every ſoil; the larger they are, the lighter is the ſoil, and the inner ſuperficies anſwers accordingly. The mouths of the veſſels deſtined to take in the food or nouriſhment of the plant, are all ſituated on the convex ſurface of the roots; and theſe take their pabulum or food, which is extremely ſmall particles of earth, blended with a due proportion of water, from the ſuperficies of the pores or cavities within which the roots are included.

It is certain that the earth is not diveſted of this pabulum by any other means than by the roots of plants, or by actual fire; for where no vegetables are ſuffered to be, the ground will always grow the richer.

Plough it or harrow it as oft as you pleaſe; let it be expoſed to the ſun in horſe-paths all the ſummer, and to the froſts all the winter; let it be covered by water at the bottom of ponds and ditches, or grind it to fine powder; the longer it is expoſed or treated by any or all of theſe methods, or any other poſſible way, except actual fire be uſed, the more fertile it will be.

Thoſe particles which are the pabulum of plants are ſo extremely minute and light, as not to be ſingly attracted to the earth, if ſeparated from thoſe parts to which they adhere, or with which they are in contact. They adhere in the earth like duſt to the ſurface of a ſmooth clay, which, tho' you turn it up and down, ſtill remains in its place, as theſe particles do to thoſe parts of the earth, till removed by ſome external agent. The proper agent for this purpoſe is the root of a plant, but this cannot act upon them unleſs they are firſt moiſtened by water; which helps to looſen them, and goes with them into the mouths of the veſſels in the root. It is neceſſary alſo that the nitre of the air come in contact with the matter of this pabulum, in order to relax and render it fit to be ſeparated and imbibed by the roots of thoſe plants which are in the way of it.

As to the ſize of the particles of this pabulum of plants, it is not unlikely that the roots may take in no groſſer ones than thoſe on which the colours of bodies depend; but to diſcover the magnitude of theſe corpuſcles, Sir Iſaac Newton thinks will require a microſcope that will repreſent things five or ſix hundred times bigger than they appear to the eye at a foot diſtance, and that with ſufficient diſtinctneſs.

We are well aſſured, that the fine particles of the food of plants, after they have been received into the bodies of plants, do perſpire thro' their pores in a large quantity, and fly off into the air: this affords us a proof, that they are not to be ſeparated from the parts of the earth with which they are in contact, otherwiſe than by means of plants; for if they could, then all our ſtirring and digging the earth would make it the poorer, by giving them occaſion to evaporate; the contrary of which is found by experience.

Water alone affords in appearance nouriſhment to plants, ſince they will grow in water; but this water is allowed never to be free from earth, and that makes it ſo very nutritive to plants, even when freſh rained down. This is the earthy matter, which is properly the pabulum or food of plants, which is continually in great abundance evaporated from plants and trees into the air, and in a manner fills the whole atmoſphere about them; this is met by and embodied in the watry vapours in their aſcent, and again brought down to the earth in ſhowers of rain with them.

Hence it is no wonder, that rain-water proves ſo very nutritive to plants, ſince it contains the very matter of their food, ready ſeparated from the reſt of the earth, and mixed in that very vehicle with, and by means of which alone it can be received into the bodies of plants, through the mouths of the veſſels of their roots.

The pores, cavities, and interſtices of the earth being of two ſorts, *viz.* natural and artificial, the one affords the natural, the other the artificial *paſture* for plants; all depending on the different nature of the internal ſuperficies of the earth. *Tull*'s Horſehoeing Huſbandry. See the article *internal* SUPERFICIES.

PATA, in zoology, the name by which the Portugueze in Braſil call a large and very beautiful American duck, known among others by its Braſilian name, *ipecati-apoa*. It is nearly of the ſize of the gooſe. See IPECATI-*apoa*.

PATÆCI, in mythology, images of certain gods carried by the Phœnicians on the prows of their gallies. *Hoffm.* Lex.

Herodotus, lib. 4. calls them Παταϊκοὶ. The word is Phœnician, and derived from *pethica*, i.e. *titulus*. See *Bochart*'s *Chanaan*, l. 2. c. 3. but Scaliger does not agree. Morin derives it from Πίθηκος, monkey, this animal having been an object of worſhip among the Ægyptians, and hence might have been honoured by their neighbours. Vid. *infra*.

Mr. Elſner [a] has lately obſerved, that Herodotus does not call the *patæci*, gods; but that they obtained this dignity from the liberality of Heſychius and Suidas, and other antient lexicographers, who place them at the ſtem of ſhips, whereas Herodotus placed them at the prow. Scaliger, Bochart, and Selden [b], have taken ſome pains about this ſubject. [[a] In Mem. de l'Acad. de Berlin, Tom. 2. p. 379. [b] *Gale*, Not. ad Herodot.]

Mr. Morin has alſo given us a learned diſſertation on this head, in the Memoires de l'Acad. des Inſcript. and Belles Lettres, Tom. 1. but Mr. Elſner thinks it defective in point of evidence. He alſo rejects the etymologies of Bochart, Scaliger, and Morin; he himſelf thinks that the *patæci* were the ſame as the Dioſcuri [c], not Caſtor and Pollux, invented by the Greeks, but the Dioſcuri of oriental and higher antiquity. [[c] Children of Jupiter, Διοσκωροι, or Διοσκοροι; for we may meet with both. See *Hemſterhuys* in Lucian. Dialog. Deor.]

Herodotus ſays, the *patæci* reſembled the little ſtatues of Vulcan. Pauſanias tells us they were about a foot high. They were eſteemed the protectors of navigation. See *Eſner*, loc. cit.

PATAGONULA, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: The cup is an extremely ſmall perianthium, divided into five ſegments, and remains after the flower is fallen. The flower conſiſts of a ſingle petal, with ſcarce any tube, the margin of which is divided into five acute oval ſegments. The ſtamina are five filaments of the length of the flower. The antheræ are ſimple. The germen of the piſtil is oval and pointed. The ſtyle is ſlender, and ſlightly bifid; its ramifications are alſo bifid again. This is of the ſame length with the ſtamina, and remains when the flower is fallen. The ſtigmata are ſimple. The fruit is an oval and pointed capſule, ſtanding on a large cup, made up of five long ſegments emarginated, or rimed round their edges. The ſeeds of this plant are yet unknown; but the conſtruction of the cup in which the capſule ſtands is alone a ſufficient diſtinction for this genus. *Linnæi* Gener. Plant. p. 66.

PATANGHI, in botany, a name by which ſome authors have called the tree whoſe wood is the logwood, uſed in dying and in medicine. *Herm.* Muſ. Zeyl. p. 42.

PATE *(Cycl.)*—PATE, in zoology, a name given by the people of the northern counties of England to the *badger*. See the article TAXUS.

PATEE *(Cycl.)* in heraldry, a term uſed by ſome to expreſs a ſort of irregular line, differing from the indented, ingrailed, and all the other regular and common lines, and called by ſome the dovetail line.

It is ſomewhat like the joint called by our joiners by this laſt name, but it is not in general uſe, and is by ſome reckoned among what the French call the *clatte*, a term they have for ſuch irregular lines as they find in old engravings or figures, tho' not in uſe in any arms preſerved to this time. *Niſbet*'s Heraldry. See CLATTE.

PATELLA, *(Cycl.)*—This is a ſmall bone, ſituated above the ſpine of the tibia, reſembling a large cheſnut. It is about half as thick as long, and its length and breadth are nearly equal. It is divided into a baſis, apex, and two ſides, one convex, the other concave. The baſis is the ſuperior and thickeſt part of the bone, and is marked with a very conſiderable muſcular impreſſion, which runs down for a little way on the convex ſide. The apex is obtuſe, and ſerves for the inſertion of a ſtrong ligament, which ties the *patella* to the ſpine of the tibia. The anterior ſide is convex, with ſome ſmall inequalities and furrows upon it. The poſterior ſide is concave, covered with a cartilage, reaching near the apex, and terminating at an unequal cavity or foſſula, which is an impreſſion for the ligament already mentioned. This cartilaginous ſide is parted in two by a ridge which goes between the baſis and apex, and the two parts are exactly ſuited to the pulley of the os femoris, the external part being broader than the internal, which is likewiſe obſervable in the pulley. The *patella* remains long cartilaginous, and in offifying it becomes entirely cellular, except the ſurfaces of its two ſides and the impreſſions. It is connected with the tuberoſity of the tibia by a thick ſhort ligament; and, indeed, it may be looked upon as belonging in a particular manner to the tibia, or as a moveable olecranum; which again may be looked upon as a fixed *patella*. *Winſlow*'s Anat. p. 94.

Fracture of the PATELLA. The *patella* or *knee-pan* is much more ſubject to a tranſverſe fracture than to one in any other direction. The longitudinal fracture of this bone happens more rarely, but when it does, is much more eaſily cured; becauſe the fragments of the bone in this caſe, generally keep in their right places, but when the bone is broken not only tranſverſely, but into ſeveral pieces, the caſe is yet more difficult and dangerous. The cure of this fracture muſt be attempted in this manner: in a longitudinal or perpendicular fracture, the patient muſt be laid upon his back, and, extending the foot, the ſurgeon muſt replace the fragments on both ſides with the preſſure of his hands, binding them up carefully with the uniting bandage; which muſt be applied in this caſe in the ſame manner with that uſed in large wounds in the belly or forehead. But when the *patella* is broken tranſverſely, or into ſeveral pieces, the patient being laid in the ſame poſture, and extending his foot as before, the ſurgeon is with great

care to endeavour with the palms of both hands, aſſiſted by his fingers and thumbs, to bring together and replace the fragments in their natural ſituation; and when that is done, they muſt be retained firmly together, by means of a plaiſter made in form of a half moon, or properly perforated, and then the foot and leg are to be bound up, and placed ſo that they cannot be eaſily moved: but to prevent the bone from being diſplaced again, the patient muſt not uſe his leg till after the ninth or tenth week. *Heiſter*'s Surg. p. 134.

PATELLA *luxated.* The *patella* is moſt uſually luxated either on the internal or external ſide of the joint, tho' phyſicians give accounts of its being ſometimes luxated both above and below it. Whenever the knee itſelf is perfectly luxated, the *patella* can ſcarce avoid being diſplaced at the ſame time, becauſe of its ſtrong connection to the thigh and to the tibia.

The reduction of a luxated *patella* is uſually no great difficulty. The patient is to be laid flat on his back upon a table or bed, or upon an even floor, ſo that his leg may be pulled out ſtreight by an aſſiſtant; when this is ſufficiently extended, the ſurgeon muſt graſp the *patella* with his fingers, and afterwards, by the aſſiſtance of his hand, preſs it ſtrongly into its proper place. This may be alſo poſſibly effected while the patient ſtands upright: when this is done, there remains nothing but carefully to bind up the part, and let the patient reſt for ſome days; ſometimes gently bending and extending his leg in the mean while, that it may not become ſtiff. *Heiſter*'s Surg. p. 171.

PATELLA, the *limpet*, in natural hiſtory, the name of a genus of ſhell-fiſh, the characters of which are theſe: It is an univalve ſhell, of a gibbous ſhape, always fixed in its natural ſtate to a rock or to ſome other hard body, and having its apex or ſummit ſometimes ſharp pointed, ſometimes obtuſe, ſometimes ſtreight, ſometimes crooked, ſometimes whole, and ſometimes perforated. There are ſeveral ſpecies of each of theſe kinds. See Tab. of Shells, N° 1, 2.

Of the *limpet* with a ſharp pointed ſummit, there are the following ſpecies: 1. The pyramidal mucronated *limpet*. 2. The pyramidal furrowed *limpet*. 3. The grey *limpet*: this, tho' a plain ſpecies in its rough ſtate, is very beautiful when its outer coat is taken off by poliſhing. 4. The ten-ribbed *limpet*.

Of the *limpets* with depreſſed heads are the following: 1. The furrowed marbly *limpet*. 2. The nipple *limpet*: this reſembles the nipple of a woman's breaſt. 3. The ſtriated *limpet*, jagged at the edge. 4. The finely ſtriated *limpet*: the lines in this ſpecies are as fine as hairs. 5. The ſtriated and prickly *limpet*: this, when poliſhed, makes a very different figure, and is like a ſhield with variegations of colour like thoſe of tortoiſe-ſhell. 6. The red-ſpotted *limpet*. 7. The red and white ſtriped *limpet*. 8. The goat's eye *limpet*, ſo called from its variegations on its inſide, repreſenting the eye of a goat. 9. The carbuncle *limpet*, ſo called from a glowing red in the ſhell: this is beſt ſeen when the ſhell is poliſhed, and held againſt a ſtrong light. Hiſt. Nat. Eclairc, P. 2. p. 237.

Of the *limpets* with perforated tops we have the following ſpecies: 1. The cancellated open *limpet*. 2. The high-ridged *limpet*. 3. The fine ſtreaked *limpet*, with ſtreaks like hairs. 4. The oblong *limpet*, with two holes: this, when its ſurface is taken off by poliſhing, makes the fine red *limpet* ſeen in many collections; and the ſame ſhell, with the coat juſt eraſed from the ſurface, ſo as not to penetrate to the red part, makes the grey *limpet* with the double aperture, alſo frequently ſeen in the cabinets of collectors. Hiſt. Nat. Eclairc, P. 2. p. 238.

The Latins call this ſhell *patella* from its reſemblance to a diſh, and the Greeks named it *lepas*, as if they meant to call it a ſcale or flake of the ſtone. Indeed this fiſh always adheres to rocks, as if a part of the ſtone; and the rock ſerves it in the place of a ſecond ſhell, to defend it from the injuries of the weather. Aldrovand and Rondeletius have carried this thought ſo far, as to place the *limpet* among the bivalve ſhells; but no author has followed them in this. Bellonius obſerves, that when they are found adhering to ſtones in great numbers, as they frequently are, they reſemble the heads of ſo many large nails driven into the ſtone. Columna diſtinguiſhes four kinds of the *limpet*: the firſt he calls the common *limpet*, becauſe it was moſt common of all the ſpecies about Naples where he wrote; this is of an oval figure and of an aſh colour. The ſecond he calls the great exotic *limpet*: this he had from Spain; it was large and hard, and had ſeveral ribs, which ended into many dents at the verge. The third he calls the wild *lepas*: this is a ſmall *limpet*, of an irregularly oval figure, and of an aſh colour, and has a hole at the top, out of which the excrements are evacuated. The fourth kind he calls the royal *limpet*, becauſe he ſays it is worthy to come to the table of a king: this is rough and has ſeveral holes at the top. The number of holes in the laſt is either accidental, or elſe it is a ſpecies of *limpet* unknown at preſent; the others may be eaſily found among the already mentioned ſpecies. *Bellonius. Fab. Columna* Aquat. et Terreſt. p. 11.

Some *limpets* are concamerated within, or formed into ſeveral diſtinct apartments. Of theſe there are the following ſpecies: 1. The oblong beaked *limpet*. 2. The rounded arched *limpet*. 3. The large Chineſe *limpet*. 4. The *limpet* with a ſtyle riſing within it from the bottom. 5. The irregularly ſhaped longed beaked *limpet*. 6. The ſemi-concamerated *limpet*: this has ſeven remarkable ribs running from its top, which terminate in ſeven ſpines at the baſe. This ſpecies is hence radiated like a ſtar at the verge, and is thence called by ſome *aſtrolepas*.

Of the *limpets* with crooked tops are the following ſpecies: 1. The long and crooked headed *limpet*. 2. The red nipple *limpet*. 3. The grey *limpet*, of an elegant roſe colour within. 4. The *limpet* with a crooked top ending at the limb, and making the whole ſhell thus repreſent, in ſome meaſure, a deeply ſtriated pecten or ſcallop: this is hence called by ſome *concholepas*. 7. The leſs ſtriated *concholepas*.

PATELLA, in the hiſtory of inſects, a name given by Liſter and ſome others to a certain little huſk or ſhell found on the bark of the cherry, plum, and roſe trees, and ſome others, containing an animal within, and uſeful in colouring. Theſe *patellæ* are of a globular form, except when they adhere to the tree, and are of a ſhining cheſnut colour in moſt kinds. The huſk itſelf ſtrikes a very fine crimſon colour on paper, and within it is found a white maggot of no value: this, in time, hatches into a very ſmall but beautiful bee. The whole ſize of this bee is not more than that of half the body of an ant. They have the ſting of bees, and the three ſpots placed in a triangle on the forehead, which are ſuppoſed to be eyes. They are black, and have a large round whitiſh or pale yellow ſpot upon the back. The upper pair of wings are ſhaded and ſpotted, but the under pair are clear.

The ſhells or huſks deſerve a trial, to find whether the colour they yield might not be brought to uſe; it is to be obſerved, that the deepeſt coloured huſks afford the fineſt and deepeſt purple: they muſt be alſo uſed while the creature contained in them is in the maggot form; for when it is changed into the bee ſtate the ſhell is dry and colourleſs. Dr. Liſter, who firſt obſerved theſe *patellæ*, went ſo far on the comparing them with the common kermes, as to declare that they were of the ſame nature with that production; but his hiſtory of their being the workmanſhip of a bee, to preſerve her young maggot in, is not agreeable to the true hiſtory of the kermes; for that is an inſect of a very peculiar kind. This author has been too juſtly cenſured for his precipitancy of judging of things, and perhaps has fallen into an error by means of it here.

It is very poſſible that theſe *patellæ* may be the ſame ſort of animal with the kermes, but then it produces its young within this ſhell or huſk, which is no other than the ſkin of the body of the mother animal; but as there are many flies, whoſe worms or maggots are lodged in the bodies of other animals, it may be, that this little bee here deſcribed may love to lay its egg in the body of the proper inſect here deſcribed, and the maggot hatched from that egg may eat up the proper progeny, and undergoing its own natural changes there, iſſue out at length in form of the bee. This may have been the caſe in ſome few which Dr. Liſter examined, and he may have been miſled by this to ſuppoſe it the natural change of the inſect. Phil. Tranſ. N°. 72.

PATELLA *fera*, the wild *limpet*, a name very improperly given by Rondeletius and Aldrovand to the *auris marina*, or *concha veneris*. This is by no means of the *patella* kind. See the article EAR-*ſhell*.

PATENT-*leaf*, among botaniſts. See LEAF.

PATER *patratus*, among the Romans, the firſt and principal perſon of the college of heralds, which formed a kind of board or council to examine the differences that aroſe between neighbouring ſtates, and endeavour amicably to accommodate the ſame. *Danet* in voc.

PATETÆ *uvæ*, a name given by the antients to grapes dried on the vine. See PATETHISÆ.

PATETHISÆ *uvæ*, a name given by the antients to grapes which were ſuffered to remain on the vine till they were greatly dried and withered. They were alſo called *patetæ uvæ*, and were ſuffered to hang thus to make a peculiar wine called *paſſum*.

PATH (*Cycl.*)—PATH-*fly*, the name given by us to the fly called in Latin *humiſuga*; it is found in foot-paths, and ſuppoſed to live by ſucking the ground. It is of a grey colour, ſtreaked with duſky white. See HUMISUGA.

PATHOGNOMIC *ſigns*, in medicine. See ASSIDENT.

PATIENCE, in botany, the name by which ſome people call the monks rhubarb; but the French, from whom we have borrowed the word, mean by it all the ſpecies of the *lapathum* or dock kind. See the article LAPATHUM.

PATIENTIÆ *muſculus*, in anatomy, a name given by Spigelius to a muſcle of the ſhoulder, which he alſo calls by the more expreſſive name of *ſcapulam attollens*. The French call it the *releveur propre de l'omoplate*, and Albinus, Morgagni, Cowper and others *levator ſcapulæ*.

PATIN-*ſhoe*, in the manege, a kind of horſe-ſhoe, under which is ſoldered a ſort of half ball of iron, hollow within. It is uſed for hip-ſhot horſes, and put upon a ſound foot, to the end, that the horſe not being able to ſtand upon that foot without pain, may be conſtrained to ſupport himſelf upon the lame foot, and ſo hinder the ſinews to ſhrink, and the haunch to

dry up. We likewiſe clap *patin-ſhoes* upon horſes that are ſprained in the ſhoulders.

PATIS, in zoology, the name of a ſmall ſea-bird, deſcribed by Oviedus, and ſeeming to be the ſame with the ſtormſink deſcribed by Hoier in his epiſtle to Cluſius. It is a little larger than our ſparrow, and ſkims the ſurface of the water very nimbly, and is ſuppoſed a fore-runner of ſtorms.

PATLAHOCA, in botany, the name given by ſome authors to the tree which produces the reſin, commonly called *gum-copal*. *Hernand*, p. 46.

PATREZ, a name for a ſort of vermichelli, a paſte made of flour and water, and formed into beads. This and all other kinds of vermichelli are often ſtained with ſaffron.

PATRICIDE, *patricidium*, the ſame with *parricide*. See the article PARRICDE, *Cycl.*

PATRIMI *and* MATRINI, among the Romans, children whoſe father and mother were both living.

It was by a certain number of theſe that hymns were ſung to ſupplicate the gods. V. *Liv.* 37, 3.

PATTALIA, in natural hiſtory, a word uſed by Ariſtotle and the reſt of the old Greek writers, to expreſs a ſtag or deer of two years old. The interpreters of Ariſtotle have generally rendered this by the Latin word *ſubulo*; but that is of a very vague and uncertain ſenſe, and this Greek word of a very determinate one, never being uſed to expreſs any animal except the ſtag at this age. Pliny and the Roman authors in general uſe the word *ſubulo*, indeed, ſometimes for a young ſtag; but they oftener uſe it to expreſs that imaginary beaſt the oryx or unicorn. Pliny ſays, that nature has given this animal *cornua ſimplicia*, ſingle horns, as it is generally underſtood to mean; but the phraſe may as well be tranſlated plain, uniform, and unbranched horns. The word may have been thus uſed to diſtinguiſh the horns of this creature, whatever it was, from the ſtag, and not to imply that each of them had only one horn: in this ſenſe, however, it is no proper tranſlation of the word *pattalia*, which ſignifies a ſtag of a certain age, not any other animal.

PAVANA, in botany, the name of the plant which produces the *grana tiglia* of the ſhops. It is a ſpecies of *ricinus*. *Jonſ.* Dend. p. 458. See RICINUS.

Pavana-wood, when freſh, operates very violently, both by vomit and ſtool: when dried, it is much more gentle, never vomiting at all; but at preſent it is ſcarce heard of in the ſhops.

PAVIA, in botany, the name of a genus of plants deſcribed by Boerhaave and Linnæus, the characters of which are theſe: the perianthium conſiſts of one leaf, and is coloured, of an oval figure, and divided into five obtuſe ſegments at the edge. The flower conſiſts of five oval petals, the upper ones longer than the others; the longeſt of all are very long, and are inſerted into the cup. The ſtamina are eight ſubulated filaments, ſomewhat crooked, and of the length of the flower. The antheræ are roundiſh, the germen of the piſtil is of an oval figure, the ſtyle is ſubulated, and the ſtigma acute. The fruit is a coriaceous turbinated capſule, of an obtuſely four ſquare form, compoſed of four valves, and containing four cells; in each of which is contained a ſingle roundiſh ſeed. *Linnæi* Gen. Pl. p. 158.

PAVICULA, among the Romans, a rammer, or inſtrument for beating down and levelling a ſpot of ground.

It conſiſted of a block of wood one foot long and half a foot thick, with a long handle. *Pitiſc.* in voc.

PAVILIONS, among jewellers, the under ſides and corners of the brilliants, lying between the girdle and the collet. *Jeffries* on Diamonds. See GIRDLE, *&c.*

PAULA *gumda*, in natural hiſtory, a name given by the people of the Eaſt Indies to a ſpecies of foſſil of the *oſteocolla* kind, found in ſome ſprings, the waters of which are loaded with ſpar. Theſe people uſe it in medicine, giving it in milk for gonorrhœas, and that with good ſucceſs.

PAULADADUM, a name given by ſome authors to the medicinal earth of the iſland of Malta, called *terra melitenſis*, and *gratia ſancti Pauli*. Some have given this name alſo to a ſpecies of white bole found in ſome parts of Italy, which is made into cakes, and ſealed, and ſerves in the place of this and other white earths.

PAULINIA, in botany, the name of a genus of plants, according to Linnæus, taking in the *ſeriana* and the *cururu* of Plumier. The characters are theſe: the perianthium is compoſed of four oval and expanded leaves, and remains when the flower is fallen. The flower conſiſts of four oblong and cordated petals; theſe ſtand expanded, and are of twice the bigneſs of the leaves of the cup. The ſtamina are eight ſimple and ſhort filaments. The antheræ ſmall. The germen is three cornered, obtuſe, and of a turbinated form. The ſtyles are capillary, and are three in number, and very ſhort. The ſtigmata are ſimple and broad. The fruit is a large three cornered capſule, compoſed of three valves, and containing three cells, in each of which is a ſingle ſeed of an oval figure. The difference between the *cururu* and *ſeriana* of Plumier is, that the *ſeriana* produces its ſeeds in the baſe of the cells, and the *cururu* in the cells of them. *Linnæi* Gen. Pl. p. 170. *Plumier* Gen. 35.

PAUNCH, or PANCH, on ſhip-board, thoſe matts made of ſinnet, which are made faſt to the main and fore yards, to keep them from galling againſt the maſt.

PAVO, *(Cycl.)* The *peacock*, in the Linnæan ſyſtem of zoology, makes a diſtinct genus of birds of the *gallina* kind; the diſtinguiſhing characters of which are, that the feet have each four toes, and the head is adorned with an erect ornament of feathers, in form of a plume. *Linnæi* Syſtem. Naturæ, p. 47.

PAVO, in ichthyography, the *peacock-fiſh*, one of the larger ſpecies of the *turdus*, or *wraſſe*, but of a middle nature between the long and the flat bodied kinds. Its uſual ſtandard, as to ſize, is about three pounds weight; and its colour on the back a mixture of blackiſh and a duſky blue: the blue is diſpoſed in three or four longitudinal parallel lines, on a duſky blackiſh ground; about the head and gills the blue lines are more bright and numerous. Its lower jaw is almoſt wholly blue, and its belly is of a fine ſaffron colour or reddiſh yellow. It has thick lips, and very ſharp tho' not very large teeth. Its back fin is, on the anterior part, of a fine deep blue, with an edge of purple, and ſometimes of yellow; and the reſt of the fin is red at the bottom and yellow at the top, and in the middle is finely variegated with blue ſpots. The foremoſt nerves of the back fin are rigid and prickly, and have ſoft and flexile rays accompanying them beyond the limb or edge of the fin, and of more than their own length. Its gill-fins are a mixed red and yellow, and its belly-fin behind the anus of a pale fleſh colour, with a variegation of blue and yellow. The other belly-fins are of the ſame colours, and the tail is wholly blue. It is a moſt remarkably beautiful fiſh, and from the ſpots and variegations of its fins has obtained its name. *Ray*'s Ichthyol. p. 321. See Tab. of Fiſhes, N° 59.

PAVONIUS-*lapis*, the *peacock ſtone*, a name given by Ludovicus Dulcis, and other writers of his time, to a ſtone of which they ſay many idle things, ſuch as its having the virtue of gaining a perſon's love to another, and the like. They have left us no deſcription of it, but probably it was one of the variegated agates.

PAURAEDRASTYLÆ, in natural hiſtory, the name of a genus of cryſtals. The word is derived from the Greek παυρος, a few, ἕδρα, a ſide or plane, the privative particle α, not, and στύλος, a column; and expreſſes a foſſil compoſed of but a few ſides or planes, and having no column.

The bodies of this genus are cryſtals compoſed of two pyramids joined baſe to baſe, without the intervention of a column; theſe being both hexangular, and conſequently the whole body compoſed only of twelve planes; the others of the ſame ſtructure being compoſed of ſixteen. *Hill*'s Hiſt. of Foſ. p. 167.

Of this genus there are only four known ſpecies: 1. A whitiſh one with ſhort pyramids, found in many parts of France. 2. A brown one, with long pyramids, found in great plenty in ſome parts of Scotland. 3. A crooked or ſlanting one, very clear and colourleſs: this is common both in the Eaſt and Weſt Indies, but no where ſo plentiful as in New Spain. And, 4. A bright and blackiſh one, with very ſhort pyramids: this is found in Italy, Germany, France, and England, but with us is uſually met with very ſmall. It is commonly found in cluſters together. See Tab. of Foſſils, Claſs 3.

PAUSANIA, Παυσανια, in antiquity, a feſtival in which were ſolemn games, wherein freeborn Spartans only contended. It had its name from Pauſanias, the Spartan general, under whoſe conduct the Grecians overcame Mardonius in the famous battle at Plateæ, there being always an oration in praiſe of him. *Potter*, Arch. Græc. B. 2. c. 20. T. 1. p. 424.

PAUSEBASTOS, in natural hiſtory, the name of a beautiful ſtone dedicated to Venus, and called alſo *paneros*. It ſeems to have been a beautiful agate.

PAUSICAPE, Παυσικαπη, among the Athenians, a kind of puniſhment. A round engine was put about the neck in ſuch a manner, that the ſufferer could not lift his hand to his head. *Potter*, Archæol. Græc. T. 1. p. 131.

PAUSIS, a word uſed by the old phyſicians for a remiſſion in acute diſeaſes.

PAUXI, in zoology, the name of an American bird deſcribed by Nieremberg, and ſeeming to be the ſame with the *mitu* of the Braſilians deſcribed by Marggrave, and with the *tepetototl* of Nieremberg: the whole difference is, that this, inſtead of a creſt, has a fleſhy protuberance at the baſis of its bill; this is of the ſhape of a pear and as hard as a ſtone, and is of a beautiful turcois colour, or fine pale blue. *Ray*'s Ornithol. p. 305. See the article MITU.

PAW, *(Cycl.)* in the manege. A horſe is ſaid to *paw* the ground when his leg being either tired or painful, he does not reſt it upon the ground, and fears to hurt himſelf as he walks.

PAWLE, in a ſhip, a ſmall piece of iron bolted to one end of the beams of the deck, cloſe to the capſtan; but yet ſo eaſily as that it can turn about. Its uſe is to ſtop the capſtan from turning back, by being made to catch hold of the whelps; therefore they ſay, *Heave a pawle*; that is, heave a little more for the *pawle* to get hold of the whelps; and this they call *pawling the capſtan*.

PAWN *(Cycl.)*—PAWN, among miners, is a pledge of money put into the bar-maſter's hand, at the time when the plaintiff cauſes

cauſes the bar-maſter to arreſt the mine. *Houghton*'s compl. Miner in the Explan. of the Terms.

PAYING, in the ſea language. When the ſeams of a ſhip are laid over with a coat of hot pitch, it is called *paying her*; and when this is done with canvas, *parcelling*. Alſo when after ſhe is graved, and her ſoil burned off, a new coat of tallow and ſoap, or one of train oil, roſin and brimſtone, boiled together, is put on her; that is called *paying of a ſhip*. They ſay alſo ſometimes, when in tacking about, a ſhip's ſails being back ſtayed, fall all flat againſt the maſts and ſhrouds, *ſhe is paid*.

PEA, *piſum*, in botany. See PISUM.

Chick-PEA. See the article CICER.

PEACH, *perſica*, in botany. See PERSICA.

The curious in fruits account twenty-eight ſorts of *peaches*, but many of them ſeem very trifling diſtinctions. The fineneſs of this fruit, in general, depends on the firmneſs of the pulp, the delicacy of the flavour, and the thinneſs of the ſkin. A fine *peach* ſhould be of a fine deep red next the ſun, and of a pale whitiſh hue next the wall; and the pulp ſhould be of a yellowiſh caſt, and very juicy; and the ſtone ſhould be ſmall, tho' the fruit in general be large.

The varieties of the *peach* are produced like thoſe of the finer flowers, by ſowing the ſeeds; and tho' many raiſed this way will be of little value, as is alſo the caſe in flowers, yet probably among a parcel of ſtones, ſaved from the finer kinds of *peaches*, there would be ſome new kinds produced; which, as they were raiſed here, would be eaſily kept up in their perfection; which is not to be expected of thoſe brought from other countries.

The beſt method of ſaving the ſtones is, to let ſome of the fineſt *peaches* of the beſt kinds hang till they drop of themſelves from the tree, and then the ſtones ſhould be immediately planted on a bed of light rich earth, planting them four inches deep in the earth, and at about ſix inches aſunder. The beds ſhould be covered, to preſerve them in the winter; and in ſpring, when the trees come up, they muſt be cleared of weeds, and well watered. The next ſpring they ſhould be carefully taken up, and planted in the nurſery, at greater diſtances; and after two or three years ſtanding here, they may be removed to the places where they are to remain; or they may at that time, when the condition of their fruit is known, be grafted on other ſtocks, which is the common way now uſed to propagate theſe trees.

The common method of propagating the *peach* is, by grafting. In order to this, ſome good ſtocks ſhould be provided, which ſhould be of the muſcle, or white pear-plum. When theſe ſtocks are two or three years old, they will be ſtrong enough to bud; and the common ſeaſon for doing this is about Midſummer. The buds ſhould be choſen from a healthy tree, which produces a great deal of fruit: they muſt be taken from the trees either in a cloudy day, or elſe in the morning or evening, when the ſun has not much power: they ſhould be then inoculated on the ſtocks as ſoon as poſſible, and the ſtocks treated with the uſual care afterwards. See INOCULATION.

When theſe are to be tranſplanted where they are to remain, the moſt proper ſoil for them is, a light rich paſture-land, taken up with the turf, and rotted together, before it is to be uſed; and the borders to be made with this cannot be too wide, and ought to be raiſed five or ſix inches above the level of the ground; or if the ſoil be moiſt, more than that. They muſt be tranſplanted in autumn, as ſoon as the leaves are fallen off; and ſhould never be ſet at leſs than fourteen feet diſtance from one another. The heads of the trees are then to be raiſed up againſt the walls, to keep the roots from being moved by the wind; and they ſhould be watered at times, with a noſe on the watering pot, and the water ſprinkled all over them. In the middle of May the new ſhoots are to be nailed to the wall, training them horizontally; and the foreright ſhoots are to be rubbed off: in October the new branches ſhould be pruned, ſhortening them according to the ſtrength of the tree; if ſtrong, they may be left eight inches long; if weak, they ſhould only be left five; and the ſame care is to be taken of them for the ſucceeding years.

There are two general rules always to be obſerved in the pruning of *peach* and nectarine trees, which are, 1. Always to have enough bearing wood. And 2. Not to lay in the branches too cloſe to one another. All *peach* trees produce their fruit from the young wood either of the ſame, or at the moſt, of the former years ſhoot; for this reaſon the branches are to be ſo pruned, as to encourage them to throw out new ſhoots in every part of the tree: and this is to be done in May; when by pinching, or ſtopping the ſtrong ſhoots, there may be new wood forced out in any part of the tree. This is the method of the ſummer pruning; the winter pruning is uſually done in February or March, but is much better done at Michaelmas, as ſoon as their leaves begin to fall; and the wounds will then have time to heal before the ſevere froſts come one.

In pruning of theſe trees it muſt always be obſerved alſo, that it is beſt done under a wood bud, not a bloſſom bud; which may be diſtinguiſhed by the wood buds being leſs turgid and longer, and narrower than the bloſſom bud; for if the ſhoot have not a leading bud where it is cut, it will commonly die down to the leading bud. In nailing the ſhoots to the wall, they ſhould be placed at as equal diſtances as poſſible; and ſo far apart that the leaves may have room; and they muſt always be trained as horizontally as poſſible, that the lower part of the tree may be well wooded, which it will not be if the branches are ſuffered to run upright. *Miller*'s Gard. Dict.

PEACH-*colour*, the pale red colour of the bloſſoms of the *peach*-tree.

To give this beautiful colour to glaſs, add at different times, and in ſmall quantities, the powder of prepared manganeſe to the maſs, for the making of lattimo, or milk-white glaſs while in fuſion. This alone gives the *peach*-colour; but the metal muſt be immediately worked when of a right tinge, for the colour is very apt to go off. *Neri*'s Art of Glaſs, p. 99. See the article LATTIMO.

PEACH-*colour*, in the manege. See BLOSSOM.

Wolf's PEACH. See LYCOPERSICON.

PEACH *flowers*. Theſe are uſed as a purge for children, made into a ſyrup, and are by ſome recommended as great deſtroyers of worms; but there is a circumſtance attending them which is little taken notice of, and yet greatly alters their virtue. The cuſtom of gardeners is, to graft the *peach* upon the almond, or the plumtree, and the flowers partake of the nature of the ſtock; thoſe which are produced on *peach*-trees grafted on plum-ſtocks, being much more purgative than thoſe from almonds; the reaſon of which ſeems plainly, that the plum is a purgative fruit, the almond not at all ſo. The flowers of the leaſt eſteemed ſorts of *peaches* are alſo uſually found to be the beſt for medicinal uſe.

In examining theſe flowers, they are found to contain more than three fourths of a ſuperfluous humidity. The buds contain a little leſs than the blown flowers; which is very natural to ſuppoſe, becauſe it is their being afterwards charged with a larger portion of humidity which makes them open. The buttons, or buds of the flowers, are found on experiment, however, to be ſomewhat more purgative than the flowers when open.

If four pounds of theſe flowers are diſtilled in a *balneum mariæ*, they yield 12 or 13 ounces of a whitiſh liquor, ſweet to the taſte, and of an agreeable ſmell, reſembling that of bruiſed *peach* kernels; and this is ſo ſtrong in the water, that a few drops of it will very agreeably ſcent a larger quantity of any thing. If the buds are uſed to this purpoſe, inſtead of the open flowers, the ſame ſort of liquor is drawn over; but it is of a ſomewhat coarſer and more earthy ſmell. The reſiduum of theſe diſtillations put into a retort, and diſtilled by a reverberatory fire, gradually raiſed to its ſeveral degrees, yields both acid and alkaline ſubſtances; and, finally, a red ſpirit comes over, full of fuliginous particles, and containing ſome oil, part of which ſwims at the top of the liquor, and the other part which is heavier, ſinks to the bottom. This is what a chemical analyſis ſhews in theſe flowers, different from other vegetable matters. Spirits of wine draws a very weak tincture from theſe flowers; it is indeed much weaker than an infuſion of them in common water. An infuſion in water of half an ounce of freſh *peach*-flowers, or of a dram of dry ones, (for, as before obſerved, they contain three fourths of ſuperfluous moiſture) is a very gentle and agreeable purge. This method of infuſion is much better for theſe and all other purgative flowers, than the taking the expreſſed juice; for in that caſe there is always a large quantity of purgative matter remaining in the reſiduum; which water in a warm infuſion is able to take out. The infuſion of roſe or *peach*-flowers, keeps alſo better than their expreſſed juice. The juice always turns ſour very ſoon, but the infuſion, with the common caution of pouring a little oil on the ſurface, will keep good even for years.

When oil is uſed to this purpoſe, there ſhould always be care taken that it be ſuch as does not freeze eaſily; for in that caſe the air gets in between the cake of frozen oil, and the ſides of the veſſel, and ſpoils the liquor. Oil of almonds is greatly to be prefered to oil of olives on theſe occaſions; as it freezes with much more difficulty. Another way of preſerving the infuſions is, the evaporating about half the liquor; and thus they will often keep a long time: infuſions keeping better than the juices of plants, ſeems to ſhew, that the former contains more of the principles than the latter.

The young leaves of the *peach* made into an infuſion in the ſame manner as the flowers, are more purgative than they, but leſs agreeable; they are to be taken in the ſame manner. Mem. Acad. Par. 1714.

PEACH-*gall-inſect*, in natural hiſtory, a ſmall *gall-inſect*, found in great plenty on the *peach*-tree. It is of an oblong figure, flat at the belly, and prominent on the back; pointed, and not unaptly reſembling in miniature a ſmall boat turned bottom upwards. Their longer diameter is uſually extended in the ſame direction with the length of the branch; ſometimes a little obliquely, but ſcarce ever perpendicular to that direction. Their exterior ſkin, the only part of them one ſees, as they are attached to the tree, is very like the fine, thin,

and

and glofſy outer bark of many trees, as that of the cherry, &c. Their colour is uſually a faint brown, ſometimes it approaches to a coffee colour, ſometimes to a bright cheſnut, but more frequently it has ſomething reddiſh in it.

The young ſhoots of the *peach*-tree are often covered with theſe on all ſides; ſometimes they are more diſtant and fewer in number. All that one ſees of this kind at this ſeaſon have the ſame lifeleſs appearance, and all appear perfectly motionleſs; but they are, however, of very different ſtates and conditions, for uſually ſome are in full life and vigour, others already dead, and others even the ſpoils of thoſe of a former ſeaſon, which remain in the places on which they died without the leaſt ſenſible alteration in their appearance. Thoſe, however, on the old wood may be judged to be dead ones, but thoſe on the branches of the preſent year are uſually found alive and well. The dead ones, if touched, appear as a mere film, and fall off in their ſcales from the branch; but the others, if cruſhed, yield a viſcid juice, like that from the cruſhing of other living inſects. The living animal is at this ſeaſon ſo cloſely affixed to the tree, that it is not eaſy, by the fingers alone, to ſeparate them without deſtroying them; but with caution they may be eaſily raiſed unhurt, by getting the point of a knife between them and the bark: in this caſe, the part of the tree from whence they are raiſed is ſeen covered with a cottony matter. The belly of the animal, which is naturally applied againſt this downy matter, is at this ſeaſon puffed up, as it were, and ſeems as full as it can well hold. A little later than this ſeaſon, if others are raiſed from the tree, it is then leſs eaſy than before to know them to be animals.

If in a fortnight, or a little more, after the time of their being as full as can be, they are removed from their place, they then make no other appearance than that of one of thoſe dead and dry ones before mentioned, no more of the full fleſhy appearance is to be ſeen, but they appear merely a thin flake of tortoiſe ſhell, or ſome other ſuch ſubſtance, covering a vaſt number of ſmall bodies cloſe lodged together, but as looſe from one another as ſo many grains of ſand, and fall to the earth on raiſing the ſhell, unleſs it be done with great care.

Theſe ſmall bodies are ſomewhat reddiſh, and when examined by the microſcope, the oval figure of them will not let one doubt but that they are eggs; and the whole inſect might now appear to any one no other than a caſe prepared by ſome animal for the ſafety of its eggs. A little afterwards, if the animals in this ſtate be examined, the ſhell is found, inſtead of eggs, filled with ſmall living inſects, among a quantity of looſe powder. No more eggs are found entire: theſe are the animals hatched from them, and the ſhells are what now make the looſe powder.

The galls, and ſuch excreſcences on vegetables, are always found pierced with holes, out of which the fly iſſues, which, in its worm ſtate, had been nouriſhed there; and that there might be no reſemblance wanting in theſe creatures to galls, their ſkins are often found pierced in two or three different places, nay, and flies are ſeen ſometimes iſſuing out of theſe, which had lived within them in the worm ſtate. That theſe are of a certainty animals, and not galls, is evinced, however, beyond doubt and diſpute, by raiſing one of them in an intermediate time between that of its being found full of eggs, and that of its appearing only diſtended and ſwelled; becauſe in this interval the animal will be found in the act of laying them, and may be ſeen doing ſo.

The young animals hatched from theſe eggs are for many months ſeen in the condition of other ſmall inſects; but as they become full of eggs, they ſwell, and, by degrees, loſe their true ſhape: they grow in ſize as theſe eggs grow in them, and when full grown and ready to lay, their bellies are ſmooth and even, and the rings of which they are compoſed are not to be diſtinguiſhed: in another ſtate it is eaſy to diſtinguiſh theſe; they are five in number, and the paſſage for the eggs is in the laſt. The animal has ſix legs, which not having been uſed of a long time, are found cloſely applied to its belly; and a little above the firſt pair there may be ſeen a ſmall prominence, which is the part by which the creature takes in its nouriſhment. The cottony bed that lies under theſe inſects on the tree, ſhews extremely plain the impreſſions of all the parts of the animal; the legs, rings, &c. are eaſily diſtinguiſhable here.

It is a general law of nature, that inſects periſh when they have done all that was neceſſary for the multiplying of their ſpecies; that is the caſe alſo with this little animal. It lives but a little while after it has laid its eggs, and its dried body makes an excellent covering and defence for them; and what is very remarkable is, that as this inſect is now immoveable, and cannot draw itſelf over its egg, they are not thrown out behind its body, as the eggs of other animals; but as they are laid, are drawn under the belly, and evenly arranged there. The eggs are ten or twelve days before they hatch, and when hatched, the young animals remain quiet under the cover of their mother's carcaſs for ſeveral days.

After ſome time, when their parts are duly ſtrengthened, they get out and enjoy their liberty: theſe new-born inſects are ſo extremely ſmall, that it requires a microſcope to obſerve them; but they are in nothing like what their parent was, or what they are to be hereafter; they are very nimble and active, and march backward and forward with prodigious ſwiftneſs. There is now nothing ſingular in their form; they are ſomewhat flattiſh, and of an oval figure, and have two horns or antennæ, as well as their ſix legs, very eaſily diſtinguiſhable. The number of young ones hatched by each parent is very great, often not leſs than four thouſand. The young ones have an eaſy paſſage from under the ſhell made of their parent's body in this, that the hinder extremity of that ſhell is ſplit, and is not, as are all the other parts, faſtened to the branch.

It has been ſuppoſed, that the young *gall-inſects* eat up their mother's body, and eat holes through it to get out; but this is by no means the caſe; the opening already mentioned gives them a free paſſage, and the holes we ſometimes ſee on the backs of theſe animals are ever made by extraneous animals, ſmall flies, which have in the worm ſtate grown and been nouriſhed within the body of the animal, as they do in the bodies of caterpillars and many other inſects; and which, when hatched into the fly ſtate, make themſelves theſe holes for their eſcape.

It is uſually about the beginning of June that the young inſects get at liberty from under the body of their parent; they may then be found running very nimbly all over the branches of the tree, but are not diſtinguiſhable otherwiſe than by examining the branches with a microſcope. The branches thus covered with theſe young animals, are in a few days cleared again, and the inſects found in form of ſmall ſcales, covering the leaves, and now large enough to be ſeen by the naked eye. They are of different colours; ſome white, ſome yellow, ſome greeniſh, and ſome reddiſh: and in this ſtate they are ſo very flat, and withal ſo immoveable, that they may naturally be miſtaken for the ſkins quitted by ſome inſects; but on cruſhing them with one's nail, a yellowiſh juice is always ſqueezed out, which ſhews them to have been real animals; but the greateſt proof of it is to be had from obſervation, for after ſome time they will be found again very ſwiftly in motion.

Thus theſe little animals, after being hatched on the branches, run over them in ſearch of the leaves for nouriſhment: they do not eat theſe, however, but ſuck the juices from their veſſels by a fine trunk, and it is only while they are employed in this that they in this ſtate appear immoveable. Theſe trunks are placed a little above the firſt pair of legs; but we are not to look for them in the young inſects, it is only in the full grown ones that they are diſtinguiſhable, and in thoſe not without difficulty. In theſe, however, with attention, one may obſerve in this part a ſmall hollow, or ſhort fleſhy pipe, out of which the inſect can at pleaſure thruſt a fine white trunk, as ſmall as a fine hair, and of half the length of its body.

The more careful gardeners always clear their beſt fruit-trees from theſe inſects, eſpecially their orange-trees, well knowing that they drain the juices of the tree, and will ſometimes even kill it. This is not to be ſuppoſed owing to what juices they take in for their nouriſhment alone, but they occaſion the waſte of a vaſt deal beſides: under ſeveral *peach*-trees, and particularly under diſtinct parts of them which are loaded with theſe *gall-inſects*, it is common in the middle of May, or between that and the beginning of June, to ſee the earth as wet as if newly watered, while that all about is dry; a very large quantity of the juices of the tree continually making their way through the holes left by the trunks of theſe innumerable little animals. At the ſame time that one finds the young *gall-inſects* on the leaves, one finds them alſo on the young ſhoots of the *peach*-trees, and the reaſon is the ſame, that theſe parts are more eaſily pierced by the tender organs of the young animals than the branches and harder parts of the tree. Their backs in this ſtate are not ſmooth and even, but, examined by the microſcope, are found to be wrinkled and channelled in a beautiful and regular manner.

Not only the *gall-inſects* of the *peach*, but all the other ſpecies, after a certain time, become immoveably fixed to the place where they are, and no longer able to uſe their legs. Their growth is very ſlow from the time of their hatching, through the months of July, Auguſt, September, and October; at the beginning of November they are found ſomewhat enlarged in breadth, but they are yet no thicker, and at this time they are all become of the ſame colour, which is ſomewhat reddiſh.

In the beginning of March they begin to ſwell and be filled with the growing eggs; their backs become a little convex, and, viewed with a microſcope, appear covered with little tubercles; and one may, at this time, perceive ſeven or eight long threads, which run from ſeveral parts of their bodies: theſe faſten themſelves to the branch at a diſtance from the creature, and fix it immoveably in its place. In the beginning of April they become much more convex, and tho' they can no longer walk about, they yet have at this time ſufficient motion to ſhew an animal life. At this time, by very ſlow motions, they change their ſkin; and it is after this change that they aſſume ſo exactly the figure of galls, and grow ſo very quickly to their full ſize. Seven or eight days now make ſuch a change in them, that they are not to be known for the ſame animal; but it is not till the beginning of May that they ar-

rive at their utmoſt ſize. About the 15th of May they are in a condition to lay, and as the eggs are diſcharged, the belly is puſhed cloſer and cloſer to the back; and when all are laid, becomes the ſhell before deſcribed, and the young ones are hatched under it, and become full of eggs, and do the ſame office afterwards to their young.

One great difficulty, however, is to conceive by what means they are fecundated: ſome have imagined them each to be male and female in the ſame individual, and hermaphrodites of a very ſingular kind; for as in ſnails, worms, and ſome other inſects, which are both male and female in the ſame individual, there ſtill is the congreſs of another animal of the ſame ſpecies required for propagation; in theſe it ſhould ſeem, on the contrary, that one alone was ſufficient. Others imagine them males and females, as other animals, and that they perform theſe offices during the three or four firſt days after they are hatched, while they are running on the branches. Had theſe obſervers known that the animals were in a condition to move during all the winter months, that is during the greater part of their lives, they would not have been reduced to the improbable conjecture of their performing this office as ſoon as produced: the truth is, however, that it is not known that they do it at all, theſe obſervers never having ſeen the thing, but only judging it an indiſpenſible neceſſity; but a cloſe obſervation will furniſh grounds for an opinion of another kind.

In the end of April the branches of the *peach* and other trees covered with theſe inſects, will be found to be greatly frequented by a ſort of ſmall flies, beautiful enough to demand attention: their head, breaſt, body, and legs are all of a deep red; they have only two wings, but thoſe very large, being nearly twice as long as their bodies: theſe, in the fly's common poſture, are croſſed on the back, and the upper almoſt entirely hides the under one; they are leſs tranſparent than thoſe of the common flies, and are of a duſky white, bordered with an edge of a fine bright and beautiful red: but what chiefly diſtinguiſhes them from all other ſpecies is, that they have two long white threads which run from their hinder part, and are of twice the length of their wings; between theſe there is alſo a remarkable part, a ſort of tail made like a piercer, and of a third or fourth part of the length of theſe threads. This is like all other ſtings, thicker at its baſe than at its point, and is bent a little downwards.

The antennæ of this fly are adorned with long bodies, hairy, and larger at their extremities than at their inſertions on the antennæ. It is eaſy at firſt ſight to conceive, that theſe are the flies that had been produced of worms fed in the bodies of the *gall-inſects* of a former year, and that they were now ſearching an opportunity to depoſit their eggs in the bodies of theſe little creatures, to be hatched into worms there, and thence to come out in flies, as they themſelves before had done.

The piercer at their tails made this the more probable, as it ſeemed to refer them to the ichneumon claſs; but a cloſer attention to the whole progreſs of theſe inſects will give much more room to believe, that theſe flies are the male *gall-inſects*. They are, indeed, very ſmall in proportion to the females, but this will give the judicious naturaliſt no cauſe to doubt their being the males of the ſame ſpecies, any more than their having wings and the females not; ſince the ſame difference and diſproportion is found in beetles and many other inſects; the colour of their juices, when cruſhed, and their ſmell, are in both exactly the ſame. And another obſervation adds greatly to the probability, which is, that many branches of the *peach*-tree are ſo loaded with the young *gall-inſects* that have newly fixed themſelves, that one would wonder what muſt become of them when they ſwell in bulk, as there could be no room for their growth on the branch on which they already ſtood ſo cloſe as to touch one another.

But examining theſe branches afterwards, at the ſeaſon when theſe flies appear, multitudes of theſe *gall-inſects* are found converted into mere ſhells, out of which ſomething has eſcaped and gone; and theſe are ſo compleat, and ſeem to have been quitted in ſo very different a manner from the broken ſpoils of the female *gall-inſects*, that there is all the probability in the world of theſe flies having been let out of them, which had before lain there in the form of nymphs: ſeveral of theſe, in the very ſtate of nymphs, Mr. Reaumur found in theſe ſhells; and the whole remaining queſtion is, whether theſe were the proper animal, or whether they were owing to the egg of ſome fly accidentally depoſited there, and hatched in the body of the animal. The former, however, ſeemed on all conſiderations to be the more probable opinion; for no obſervation at a proper ſeaſon will ever ſhew a living worm in the body of the *gall-inſect*: and the manner of the fly's egreſs is not that of theſe unnatural births, which are always by a hole made by the fly; but the ſhell in this caſe readily opens at a proper ſeaſon, and lets out the fly, by parting all round at the commiſſure of the belly and back, which ſeems too natural for any thing but the very manner deſtined for the production of the proper ſpecies.

The flies examined on the branches with a glaſs will alſo be found to introduce this ſeeming piercer always at the ſame place into the body of the *gall-inſect*, and this is that cleft in the hinder part of the body, out of which the young ones when hatched, afterwards find their way. The flies, which lodge their eggs or young worms in the bodies of other inſects, if cruſhed at that ſeaſon, will be always found to contain ſuch eggs or ſmall worms; and the microſcope never fails to diſcover them in the matter cruſhed out of flies even ſmaller than theſe, but in theſe no obſervation ever ſhews any ſuch. See Tab. of Inſects, N° 29

Notwithſtanding that the *peach-gall-inſect* is the only ſpecies in which the male fly has been obſerved, there is no room to doubt but that the other ſpecies all have males of the ſame kind. The orange *gall-inſect* has been obſerved not univerſally fecundated, but that there is only a part of the animals that lays eggs; probably the others are thoſe which hatch into the male flies: and the kermes, the nobleſt and moſt valuable of all the *gall-inſects*, is known often to produce a white winged fly, very like that of the *peach-gall-inſect*. And Brennius, who gave ſome time ſince a hiſtory of the ſcarlet grain of Poland, the *coccus Polonicus*, a kind of *pro-gall-inſect*; tho' in the firſt account he gave into the opinion of both ſexes being included in each of theſe animals, and that each was in itſelf ſufficient for the propagation of its ſpecies: yet afterwards, to his very great honour, he added an account of his having diſcovered the male of this ſpecies, which he deſcribes to be a ſmall fly, with a red body and white wings bordered with red; a fly in all reſpects like the male of the *peach-gall-inſect*.

Theſe flies, carefully examined, and preſſed gently on their belly, and at the ſame time obſerved with a good microſcope, will be ſeen to thruſt out of the part which reſembles the piercer of the ichneumon race, a fine, ſlender and ſoft white thread. Were this in reality the ſame with the piercers of the ichneumons, this part muſt have been hard and horny, to be able to enter hard ſubſtances; on the contrary, it is ever found ſoft and fleſhy, and is undoubtedly no piercer, but the organ of generation in the male inſect.

It is much to be doubted, whether the *gall-inſects*, in form of a boat inverted, are not the ſame ſpecies living on different trees: this is certain, that the animal taken from one tree will live and multiply on another; and the diſtinctions between the ſpecies, even ſo different in their maturity, are often not eaſy while the animals are young, the boat-faſhioned, the orbicular, and the reniform being not diſtinguiſhable till the time they acquire the greateſt ſize, and with that ſize, this their natural figure. The *gall-inſects* of the hazel and lime, which are of the half-round kind of the *peach*, and the perfectly orbicular one of the oak, are all inſtances of this; and all between the time of their being a ſimple flat body, and their acquiring an orbicular or partly orbicular figure, aſſume one much like that of the boat-faſhioned ones. *Reaumur*'s Hiſt. Inſ. Tom. IV. p. 1, to 44.

PEANTIDES, the name of a ſtone to which the antients attributed great virtues for promoting delivery,

Theſe ſtones were found in Macedonia and other places; and all the deſcription we have of them is, that they reſembled water congealed by froſt. Probably the antients meant by this name the *ſtalactitæ*, or ſtony icicles, which, as they hang from the roofs of caverns, greatly reſemble the droppings of water from the eves of houſes congealed in froſty weather.

PEARCH, *perca*, in ichthyology. See PERCA.

PEARCH-*glue*, in mechanics, the name of a kind of glue, of a remarkable ſtrength and purity, the manufacture of which we owe to the Laplanders, from whom Scheffer has deſcribed it. They take a number of large *pearches*, and ſlitting them open, they carefully pick away the fleſh with a knife, ſo as to leave the ſkin pure. They put a number of theſe ſkins into a veſſel of warm water, which they expoſe to the ſun, and by that means keep it in a continual moderate heat for ſeveral days; when the ſcales become looſe by this maceration, they take out the ſkins and rub them clean off. The ſoft and clean ſkin then remains alone, and feels as ſoft as a wetted bladder. Theſe clean ſkins they throw into a ſmall quantity of freſh water, and boil them gently over the fire, ſtirring the whole together, and toward the end beating it forcibly with little ſticks. The ſkins by this means at length wholly diſſolve in the water, and the whole becomes a thick tranſparent liquor; which, when boiled as long as the thickneſs of it will permit, without burning, they pour out on a flat ſtone, and as it cools they cut it into cakes exactly reſembling our glue, but that they want the coarſe reddiſh colour it has, and have no diſagreeable ſmell. When they would uſe this, they diſſolve it in more water, exactly as we do our glue. The bows of this people give us a very great proof of the ſtrength of this ſort of glue: they are made of two pieces faſtened together with it, and tho' put to the moſt forcible trials, as theſe people are very ſtrong, and uſe them in ſhooting bears, rain-deer, *&c.* yet the glue part is never known to ſtart. *Scheffer*'s Hiſt. Lapland.

PEAR, *pyrus*, in botany. See the article PYRUS.

All the ſorts of *pears* propagated in gardens, are produced by budding, or grafting them upon ſtocks of their own kind; which are commonly called *tree-ſtocks*, or elſe upon the quince or whitethorn ſtocks; but the laſt are now generally diſuſed, the fruit produced this way being apt to be dry and mealy. The quince-ſtocks are, however, in great eſteem

for the trees deſigned for dwarfs or for walls; becauſe they do not let the ſhoots grow ſo faſt and luxuriant. But there are objections againſt even theſe, which are of ſome conſequence; for there are many kinds of *pears* which will not do upon them, but will die, or become weak and good for nothing after three or four years; and the hard-breaking *pears* are rendered very unpleaſant by being grafted on theſe ſtocks, while the buttery or melting ones are meliorated by them. And it is to be added, that no ſort of *pear* will thrive upon a quince ſtock in a poor or gravelly ſoil.

PEAR-*trees* planted either againſt walls, or in eſpaliers, muſt not be placed nearer to one another than twenty foot. *Pear*-trees commonly produce their bloſſom-buds firſt, at the extremity of their laſt year's ſhoots; the common way of pruning is very prejudicial, therefore, as it takes off the part which ſhould bear the fruit, and occaſions new ſhoots from the ſame branch, which will over-fill the tree with wood, the trees ſhould always be carefully looked over in ſummer, and all the foreright ſhoots taken off; by which means the fruit will not be over ſhaded, and the trees will need but little winter-pruning. The ſeveral ſorts of ſummer *pears* all ripen beſt in eſpaliers, but the winter *pears* require a ſouth-eaſt or ſouth-weſt, or elſe an eaſt wall. *Miller*'s Gardener's Dict.

It is ſaid that crabs and wild *pears*, ſuch as grow in the wildeſt and moſt barren clifts, and on hills, may make the richeſt, ſtrongeſt, moſt pleaſant and laſting wines that England yields. See Phil. Tranſ. N° 477. Sect. 4.

Indian PEAR, a name given by ſeveral writers to the fruit of a large tree in the Eaſt Indies. The bark of this tree is reddiſh without and white within, and very ſmooth; the leaves are ſmall, thick, and of a pale green; the flower conſiſts of three long triangular leaves, which, when ſhut up, form a ſort of triangular pyramid; this is of a very diſagreeable ſmell. The fruit is alſo of a conic figure, its broad part being joined to the pedicle: this is of a woody texture, and of the thickneſs of one's finger; it divides itſelf into ſeveral filaments, which run thro' the whole body of the fruit. When the fruit is ripe, its rind or ſkin is red, very ſmooth and thin, which is contrary to the common courſe of nature in the Indian fruits, to which nature has given very thick rinds, in order to make them able to bear the great heats they are expoſed to. The inſide of this fruit is full of a white, ſoft, and ſweet ſubſtance, which is uſually ſcooped out with a ſpoon, and is of a very pleaſant taſte: within this fruit there are ſeveral ſmooth, black, kernels, like thoſe of our common *pears*. When this fruit is mellow, the pulpy part of it falls away from the fibres, and they remain hanging to the pedicle for a long time.

Chio PEAR. See CHIO PEAR.

PEARCH, in ichthyology. See PERCA.

PEARLS *(Cycl.)*—Mr. Reaumur was very happy in his conjectures as to the nature, origin, and differences of *pearls*, founded on what he ſaw in the coarſe *pearls* of the *pinna marina*. He very judiciouſly obſerves, on that occaſion, that often the leaſt valued things are thoſe which moſt of all explain, even by their imperfections, the manner of formation and the true hiſtory of the moſt perfect.

The *pearls* found in the *pinna marina*, are of two kinds; ſome being white and gloſſy, like the common *pearls*, and others browniſh, reddiſh, or blackiſh. He very well obſerves, that they are all formed of extravaſated juices; which have made their way out of broken veſſels, and therefore are the effect of a diſtempered ſtate of the animal, and are formed in the manner of bezoars in the ſtomachs of animals, or the ſtones in their bladders. The inner ſurface of the ſhell of the *pinna* is of a ſilvery white, or of the nature of mother of *pearl*, to a certain depth, after which it is reddiſh or browniſh. Theſe are the two colours alſo of the two ſorts of *pearls*.

The ſhells of fiſhes Mr. Reaumur ſuppoſes, are formed merely like thoſe of ſnails, of a viſcous matter, ſecreted from their bodies, which hardens by degrees into a ſort of ſtony texture; and that the *pearls* in this fiſh owe their colour to their being formed of the extravaſated juices of the white or the brown parts of the ſhells. The juices of theſe parts are ſeverally intended to form their part, and the bed or plate of ſhelly matter formed of either, in its proper and natural ſtate, could be only white or brown, as the liquor was coloured; and, conſequently, ſo muſt be the diſtempered production of *pearl*. The breaking of the veſſels of the inner *pearly* coat, both in this and other ſhells, ſeems much more frequent than that of thoſe of the browner external part; and it is eaſy to ſee, that this may much eaſier make its way into the hollow of the ſhell than that from the more outward part; but it is alſo eaſy to ſee that, provided the brown juices of this outer part could be extravaſated, and find their way into the hollow of the ſhell, they could only form *pearls* of their own colour.

In this ſhell of the *pinna marina*, the white or *pearly* inner part is formed of a vaſt number of flat plates or beds, laid one upon another; and the brown external part is formed of tranſverſe fibres, not formed into ſuch plates, but running in long ſtriæ. The *pearls* of the two different colours have alſo this difference in their ſtructure; not but that both the one and the other are compoſed of concentric beds or plates, but theſe are much leſs diſtinguiſhable in the brown than in the white ones; and each of them may in theſe be ſeen to be made up of filaments exactly as the brown part of the ſhell, to the extravaſated juices of which they owed their origin, and whoſe texture therefore they could not but emulate. Mem. Acad. Par. 1708.

PEARLS, in commerce, increaſe in value as the ſquare of their weight: thus, the price of a *pearl* of one carrat being ſettled at 8 s. to find the price of a *pearl* weighing ſix carrats: firſt find the ſquare of ſix, *viz.* 36; which multiplied by 8 gives 288 ſhillings, or 14 l. 8 s. the price required. *Jeffries* on Diamonds, p. 64.

PEARL, in ichthyology, a name given by us in the parts about London, to that fiſh which is called in Cornwall, and other parts of the weſt of England, *lug-a-leaf*; it is the *rhombus lævis* of the generality of authors; and, according to the new ſyſtem of Artedi, it is a ſpecies of the *pleuronectes*, diſtinguiſhed by the author by the name of the *ſmooth bodied pleuronectes*, with the eyes on the left ſide. See the articles RHOMBUS, PLEURONECTES, and LUG-A-LEAF.

PEARL-*barley* affords to the microſcopic obſerver, a peculiar kind of mite worthy attention, and very different from the common ſpecies. The bodies of theſe have ſome brown marks upon them, and have not ſuch long hairs as the common mites have; the hinder part of the body alſo is of a different make. They have eight legs; and before the head there ſtand two weapons twice as thick as the legs, and of about half their length: theſe are divided toward the ends with joints like fingers, and theſe have at their ends a ſort of nails formed with ſharp and crooked claws; and one of the longeſt joints is ſerrated at the edge like a ſaw. Theſe weapons ſerve not only as arms and hands to ſeize hold of things, but they alſo ſerve as a defence; for as ſoon as any danger threatens the creature's head, it erects them both, and makes them meet and fold into one another over the head, as we can join our hands and fingers together in the ſame erect poſture. Phil. Tranſ. N° 222.

PEARL *colour*, in glaſs. This beautiful colour is given to glaſs in the following manner: Put tartar calcined to a whiteneſs into putrified cryſtal, while in fuſion, at ſeveral times, in ſmall quantities, mixing it well every time, till the glaſs is become of the deſired colour; and when it is, work it as quick as can be, for it is a colour that is quickly gone. *Neri*'s Art of Glaſs, p. 103.

PEARL-*fiſhing*, in the north of Ireland. See an account of it in the Philoſophical Tranſactions, N° 198.

PEASE, *piſa*, in botany. See PISUM.

We have ſeveral ſorts of *peaſe* cultivated for uſe in the gardens about London and elſewhere; and as many people are deſirous of having them very early, it is a common practice to raiſe them on hot beds. The method of doing this is, to ſow the *peas* under warm hedges or walls. In the middle of October, when the plants are come up, their ſtalks are to be kept earthed up, and thus they are to remain till the beginning of January, or even till February, covering them againſt the ſevere froſts with *peas*-haulm, or other light covering. In January or February, there muſt be made a moderate hot-bed; the dung muſt be laid about two foot thick, and carefully beat down, and covered about ſix inches deep with light freſh earth; and when the frames have been ſet on about four days, the plants muſt be planted in the earth, at about a foot diſtance, in rows, and placed in each row at about two inches one from another. They muſt be watered and ſhaded till they have taken root, and then they muſt have as much air as may be; and when they begin to fruit, they ſhould be watered more frequently than before, which will occaſion their producing a larger quantity of fruit.

The common dwarf *pea* is the ſort always uſed on this occaſion, as all the reſt ramble too much in their ſtalks.

The firſt ſort of *pea* to be ſown to ſucceed thoſe on the hot-beds is, the hotſpur; of which the gardners reckon three or four ſorts, which differ very little from each other; but that called the maſters hotſpur is uſually preferred to the reſt. Theſe are to be ſown in October, as thoſe intended for the hot-bed, and treated every way in the ſame manner; but in ſpring theſe are ſubject to be deſtroyed by ſlugs and other vermin; the beſt method of deſtroying which is, to ſlake a little lime, and throw over the earth among the plants. For fear of this crop miſcarrying by the ſeverity of weather, it is always proper to ſow two others after this, at the diſtance of a fortnight each; and after this there ſhould be no others ſowed till the end of January; and after theſe there ſhould be others at the beginning and end of February. To ſucceed theſe, which will ſupply the table with early *peaſe*, the Spaniſh morotto, which is a large *pea*, and a very plentiful bearer, ſhould be ſowed in rows on a clear plat of ground; the rows ſhould be two foot and a half diſtant, and the *peaſe* dropt at an inch or two aſunder: theſe muſt be all very carefully covered two inches deep with earth, and the rooks, mice, *&c.* prevented from getting at them. A fortnight after this another ſpot ſhould be ſowed with this or ſome other

large *pea*, and this continued every fortnight till the latter end of May. *Miller*'s Gardner's Dict.

Field-PEASE. The common white *pea* ſucceeds beſt in a light land, ſomewhat rich: the time of ſowing them is in the middle of April. Three buſhels are the common allowance for an acre; and they kill the weeds a land is ſubject to, better than any other crop. In Staffordſhire they ſow the garden rowncivals in fields, and they grow and yield very well, tho' they are left trailing upon the ground without any ſupport of ſticks.

The white and rowncival *pea*, are only to be ſown with a broad caſt, and harrowed in; but the common grey *pea*, which is more frequently ſown in fields than either of them, muſt be ſown under furrow, and delights moſt in a cold wet clay. Theſe are to be ſown in February; and the common quantity of ſeed is two buſhels to an acre. The blue *pea* is the beſt kind for light ſandy land, and is to be early ſown; all *peaſe* love land manured with lime or with marle. In Suffolk they plough up their lays in the beginning of March, and turning the turf well, they have a croſs-ſtick ſet with iron pegs, which they ſtrike down with their feet: theſe pegs make holes at an even diſtance; into which they have boys and girls following to put the *peaſe* ſingly, till all the land is ſet. As ſoon as this crop is cut, they plough the land a-croſs, and harrowing it well they plough it again, and ſow it about Michaelmas with wheat, and the next year with barley, then with oats; after which the land requires new improvement. *Mortimer*'s Husbandry.

PEASE *bloom-damp*, in natural hiſtory. See the article DAMP, *Cycl.* and *Suppl.*

PEAUCIER, in anatomy, a name given by Winſlow, in his treatiſe on the head, and by other of the French writers, to the muſcle called by Albinus *latiſſimus colli*; and by others *detrahens quadratus*, and *quadratus genæ*. Santorini has called the part of this which ariſes from the cheek, *muſculus riſorius novus*; and ſome call the whole *platyſma myoides*.

PEBBLES, *calculi*, in natural hiſtory, the name of a genus of foſſils, diſtinguiſhed from the flints and homochroa, by their having a variety of colours. Theſe are defined to be ſtones, compoſed of a cryſtalline matter, debaſed by earths of various kinds in the ſame ſpecies, and then ſubject to veins, clouds, and other variegations; uſually formed by incruſtations round a central nucleus, but ſometimes the effect of a ſimple concretion, and veined like the agates, by the diſpoſition, the motion of the fluid they were formed in gave their differently coloured ſubſtances.

The variety of *pebbles*, were it of England alone, is ſo great, that a haſty deſcriber would be apt to make almoſt as many ſpecies as he ſaw ſpecimens. A careful examination will teach us, however, to diſtinguiſh them into a certain number of eſſentially different ſpecies, to which all the reſt may be referred, as accidental variations. When we find the ſame ſubſtances and the ſame colours, or thoſe reſulting from a mixture of the ſame, ſuch as nature frequently makes in a number of ſtones, we ſhall eaſily be able to determine that theſe are all of the ſame ſpecies, tho' in different appearances; and that whether the matter be diſpoſed in one or two, or in twenty cruſts laid regularly round a central nucleus, or thrown without a nucleus into irregular lines, or, finally, blended into a ſort of uniform maſs.

Theſe are the three ſtates in which we are liable to find every ſpecies of *pebble*; for if it have been moſt naturally and regularly formed by incruſtation round a central nucleus, we find that ever the ſame in the ſame ſpecies, and the cruſts not leſs regular and certain. If the whole have been more haſtily formed, and have been the reſult only of one ſimple concretion, if that has happened while its different ſubſtances were all moiſt and thin, they have blended together and made a mixed maſs of the joint colour of them all; but if they have been ſomething harder when this has happened, and too far concreted to diffuſe wholly among one another, they are found thrown together into irregular veins. Theſe are the natural differences of all the *pebbles*; and having regard to theſe in the ſeveral variegations, all the known *pebbles* may be reduced to thirty-four ſpecies. *Hill*'s Hiſt of Foſſ. p. 512, ſeq.

Theſe are, 1. A yellowiſh grey one, with a bluiſh white cruſt, very common in the gravel pits about London. 2. A yellow-centered one, with whitiſh grey and reddiſh cruſts, very common in moſt of the gravel pits about London. 3. A yellow-centered one, with white, black, brown, and ſtraw-coloured cruſts. This is a very beautiful one, and is very common on Hampſtead-heath. 4. A dull brown-centered one, with whitiſh, bluiſh, and brown cruſts. This is a tolerably beautiful ſtone, and is common about London. This, in a certain ſtate, is a very fine ætites or eagle ſtone. See ÆTITES. 5. A ſhining brown-centered *pebble*, with white and brown cruſts. This is a very elegant ſtone, and is found plentifully in the gravel-pits about Iſlington, and more rarely on Hampſtead-heath. 6. A ſmall browniſh yellow-centered *pebble*, with white, brown, red, and yellow cruſts. This is an extremely elegant ſtone, and is not uncommon in our gravel-pits about London, and would be worth the cutting into toys. 7. A ſmall brown-centered *pebble*, with greyiſh white, pale brown, brown, and reddiſh cruſts. This is another very beautiful *pebble*, and is common in the gravel-pits on Hampſtead-heath. 8. A reddiſh brown-centered *pebble*, with yellow, red, and bluiſh white cruſts, common about Kenſington, and in ſome other places. 9. A brown-centered one, with white, orange-coloured, brown, and dusky yellow cruſts. This is an extremely elegant ſtone, and is common about London. 10. A dull brown centered one, with thick whitiſh, browniſh, and yellowiſh cruſts. This is a very ſcarce ſpecies, and is of the coarſeſt texture of all the *pebbles*. 11. A bluiſh white large centered *pebble*, with yellowiſh-brown, and aſh-coloured cruſts; very common on Hampſtead-heath and about Windſor. 12. An elegant large white-centered one, with fleſh-coloured, brown, and bluiſh-white cruſts. This is found principally in Hertfordſhire, and is ſometimes wrought into toys, and ſold in London by the name of an *agate onyx*. 13. An elegant white-centered kind, with red, yellow, and fleſh coloured cruſts. This is found on Hampſtead-heath; and we ſometimes meet with it wrought into vaſes. 14. A greyiſh-white-centered kind, with very thin and numerous brown, and yellow cruſts. This is common in Hertfordſhire, and is ſometimes found on Hampſtead-heath. 15. A greyiſh-white-centered *pebble*, with brown, yellow, and white cruſts; common on Hampſtead-heath, and in the gravel-pits about Iſlington. 16. A very white-centered one, with white, grey, yellow, and fleſh-coloured cruſts; common in the gravel-pits about London. 17. A browniſh-white-centered one, with browniſh-white, ferrugineous, and yellowiſh cruſts; found about Windſor, and ſometimes in Northamptonſhire, bedded in the ſtrata of ſtone. 18. A bluiſh centered one, with brown and grey cruſts; common in Hertfordſhire. 19. A grey-centered thick-coated one, with whitiſh and red cruſts. This is a ſcarce ſpecies, but is ſometimes found about Paddington, and in ſome parts of Northamptonſhire. 20. A very elegant bluiſh-white one, with fleſh-coloured and bright red cruſts; found frequently about London. 21. A bluiſh-grey one, with brown, yellow, and fleſh-coloured cruſts; common on Hampſtead-heath, and frequently wrought into tops of ſnuff-boxes. 22. A greeniſh-blue-centered one, with white, yellow, fleſh-coloured, and red cruſts; common in many parts of England. 23. A fleſh-coloured centered one, with whitiſh brown and yellowiſh cruſts, and a very thick white external coat. This is a very uncommon ſpecies about London, but in Northamptonſhire and Leiceſterſhire is found in great abundance. 25. A red-centered one, with black, white, and fleſh-coloured cruſts. This is a very rare ſpecies, but is ſometimes found on Hampſtead-heath. 26. A yellow-centered one, with yellow and greeniſh white cruſts. This is found principally on the ſhores of Yorkſhire. 27. A red-centered one, with purple and pale yellow cruſts; found on the ſhores of Suſſex, and ſometimes in the gravel-pits about Oxford. 28. A yellow-centered one, with grey and pale-red cruſts; found principally on the Yorkſhire ſhores. 29. A pale grey-centered one, with red, purple, bluiſh, and brown cruſts. This is a very ſcarce ſpecies, and found principally in Hertfordſhire. 30. A black-centered one, with black and white cruſts. This is a very beautiful ſtone, and is ſometimes wrought into ſeals, *&c.* under the name of the *onyx*. 31. A yellowiſh-brown one, with brown and greyiſh black cruſts; very common in Hertfordſhire and ſome other countries, but ſeldom ſeen about London. 32. A pale-grey-centered kind, with white and greeniſh cruſts. This is a very elegant ſtone, and is found on the ſhores of the Thames, and in the gravel-pits about Iſlington. 33. A browniſh white-centered one, with yellowiſh brown and black cruſts. This is well known among our lapidaries by the name of the *Ægyptian pebble*. And, laſtly, 34. A deep green-centered *pebble*, with yellow and pale-cruſts. This is ſometimes found in the gravel-pits about London, but is not common. *Hill*'s Hiſt. of Foſſ. p. 540.

In all the ſtrata of *pebbles* there are conſtantly found ſome which are broken, and whoſe pieces lie very near one another; but as bodies of ſuch hardneſs could not be broken without ſome conſiderable violence, their preſent ſituation ſeems to imply, that they have ſuffered that great violence in or near the places where they now lie. Beſide theſe, there are others alſo found which have as plainly had pieces broken off from them, tho' thoſe pieces are no where to be found; whence it ſeems equally plain, that whatever has been the cauſe of their fracture, they have been brought broken, as we find them, from ſome other place, or elſe that the pieces broken from them muſt at ſome time or other have been carried from this place to ſome other diſtant one.

Several of theſe broken *pebbles* have their edges and corners ſo ſharp and even, that it ſeems evident they never can have been toſſed about or removed ſince the breaking; and others have their ſides and corners ſo rounded, blunted, and worn away, that they ſeem to have been roughly moved and rolled about among other hard bodies, and that too either with great violence, or for a very long continuance; ſince ſuch hard bodies could not have been reduced to the condition we now ſee them in without long friction.

It may be ſuppoſed by ſome, that theſe ſtones never were broken,

broken, but have been naturally formed of this ſhape; but it will be eaſily ſeen by any one who accurately ſurveys their veins or coats that ſurround the nucleus, like the annual circles of a tree, that they muſt have been originally entire; and this will be the more plain if they are compared with a ſtone broken by art. Such *pebbles* as are found in ſtrata, that lie near the ſurface of the earth, are much more brittle than thoſe which lie in deeper ſtrata.

The more clear and tranſparent the ſand is, which is found among *pebbles*, the more beautiful the *pebbles* are generally obſerved to be.

The uſe of theſe ſtones, and their diſpoſition in the earth, is a ſubject of great admiration; and may ſerve as one of the numerous proofs of an over-ruling Providence in the diſpoſal of all natural bodies. The ſurface of the earth is compoſed of vegetable mould, made up of different earth mixed with the putrid remains of animal and vegetable bodies; and is of the proper texture and compages for conducting the moiſture to the roots of trees and plants: and under this are laid the ſands and *pebbles* which ſerve as a ſort of drain to carry off the redundant moiſture deeper into the earth, where it may be ready to ſupply the place of what is conſtantly riſing in exhalations; and leſt the ſtrata of ſand ſhould be too thick, it is common to find thin ones of clay between, which ſerve to put ſome ſtop to the deſcent of the moiſture, and keep it from paſſing off too ſoon; and leſt theſe thin ſtrata of clay ſhould yield and give way, and by their ſoftneſs, when wetted, give leave to the particles of ſand to blend themſelves with, and even force their way through them, there are found in many places thin coats of a poor iron ore placed regularly above and below the clay; and by that means not only ſtrengthening and ſupporting the clay, but effectually keeping the ſand from making its way into it. Phil. Tranſ. N° 483.

Ridged PEBBLES. It is not uncommon to meet with *pebbles* in our gravel-pits which have one or more ridges, or white lines, ſtanding above the ſurface of the reſt of the ſtone, in form of a rib or zone, laid on the ſtone after its formation. This, however, is not the caſe; but the lime or zone always goes through the whole body of the *pebble*: the matter forming this *ridge* is always harder than the reſt of the ſtone; and it ſeems probable, that at firſt it was not extant or elevated, but level with the reſt of the ſurface; but being not ſo eaſily worn away by accidents, and when the whole *pebble* came in the way of rubbing among harder bodies, this would be leſs rubbed away, and conſequently would be left more elevated than the reſt. We daily ſee on the ſea-ſhores numbers of ſtones rounded by the continual rolling and toſſing among the waves, and in theſe the ſofter parts have given way firſt and been worn into holes, while the harder have been left prominent. It ſeems probably to have been the caſe with theſe *pebbles* alſo; but they are not found on the ſhores, but in our gravel-pits, at a great diſtance from the ſea: and it is evident, that theſe have had their ſurfaces thus ground and worn down between the time of their being formed by concretion in the waters of the deluge, and their being depoſited where we now find them. This could only happen by means of the hurry and rapid motion of the waters of the deluge, at the time of their running off from the ſurface of the earth into the ocean or great abyſs, at the bottom of it: for, by numerous obſervations, it is plain, that the force of this water thus returning off from the earth was ſo great, that in many places it tore up the ſolid ſtrata, and waſhed off vaſt maſſes from them, tumbling them afterwards along, and rounding and ſmoothing their ſurfaces in its paſſage, and finally leaving them where its force began to abate. This we have inſtances of in all parts of the world, and that ſmaller pieces of ſtone were thus rounded we ſee in the caſe of theſe *pebbles*, the harder parts of which are left ſtanding higher than the reſt, and in many other the like inſtances.

The ſmoothneſs of the ſurfaces of ſome *pebbles* and flints, which we find with their natural coats or cruſts worn off, is another proof of the ſame thing. Theſe *pebbles*, in this unnaturally naked ſtate, as well as the ribbed and lineated ones, are found in our pits under the ſtrata of earth; and we doubtleſs find them where they have lain undiſturbed ever ſince the time of their having been depoſited there at the going off of the general deluge: and yet they are in exactly the ſame condition with thoſe which have been toſſed about and rounded on the ſea ſhores.

This is a plain indication, that they have been, before their being depoſited there, toſſed and rolled about in the ſame manner with the others; and there remains no time at which this ſhould have been done, but that of the going off of the waters of the deluge, when a much larger body of water was evidently in a much greater agitation, and conſequently could do in a very little time what we ſee done on the ſea ſhores in a longer ſpace

Swallowing of PEBBLES. There are many people of opinion, that the ſwallowing of *pebbles* is very beneficial to health, in helping the ſtomach to digeſt its food, and a *pebble* poſſet is an old woman's medicine in the colic in many parts of England. They uſually order the ſmall white ſtones to be picked up out of gravel walks for this purpoſe, and eat them in large quantities in ſome ſort of ſpoon meat, of which milk is an ingredient.

The thing that has given occaſion to this practice ſeems to have been, that people obſerve the birds to pick up the gravel, and that they are never well unleſs they have frequent recourſe to this to help their digeſtion: but this is no ſimilar caſe at all, for the gizzard or ſtomach of a bird is made very ſtrong, becauſe the creature hath no teeth to chew its food; and this gizzard is lined with a rough coat, by the help of which and theſe ſtones, the food they ſwallow whole is ſo ground, as to yield its juices to the nouriſhment of the animal. But the ſtomach of man is formed ſo very differently, that it can never require thoſe aſſiſtances to the comminution of food. Many people have, however, accuſtomed themſelves to ſwallow not only theſe ſmall white ſtones, but large *pebbles*, even to the ſize of a walnut each; and theſe will often paſs ſafely, and people who have long accuſtomed themſelves to ſwallow them, boaſt of receiving no injury from them: we can never know, however, that the death of ſuch perſons is not owing to them at laſt; and as they can do no good, it is beſt always to avoid them. There is one inſtance on record, of much miſchief done by them; this is in our Philoſophical Tranſactions. Phil. Tranſ. N° 253, p. 190.

A man of about twenty-ſeven years of age, and lean habit, had been uſed for three years before to ſwallow round white *pebbles*, as a cure for ſome windy diſorders to which he was ſubject, and they uſed to paſs thro' him eaſily, and give relief for the time. In one of his fits, at the end of this time, having ſwallowed his uſual number, which was nine, and they not paſſing thro' him, he ſwallowed more and more, to the number of two hundred. None of theſe paſſed off at the time, nor even in the ſpace of two years and an half; at the end of which time he applied for relief in a miſerable way: he could digeſt no food, but vomited up all he ſwallowed. On examining his belly, the ſtones were found lodged, not in the ſtomach, but almoſt as low as the os pubis; they might be felt with the hand thro' the integuments, and rattled as if in a bag; if the man was hanged up by the feet to a ladder for a ſmall ſpace of time, they would get up into his ſtomach again; but upon ſetting him on the ground they would ſoon fall into their old place, and that ſo plainly to the ſenſes, that they might be diſtinctly heard and counted one by one. If his body was not laxative, he certainly vomited all he eat; if it was, he had a little reſpite at times; and as he lay in bed he could perceive the ſtones alſo higher than their uſual place, and give him great diſturbance. He was on theſe occaſions always forced to get up, and on ſtanding or kneeling he could perceive them fall down into their old place again, and could count them as they fell. He uſually on theſe occaſions could count more than an hundred: at length he became unable to work or move for them, and voided large quantities of blood by ſtool, after diſturbing them by any violent motion. The uſe of proper medicines relieved him in many of theſe ſymptoms, but no means ever made uſe of was able to carry off one ſingle ſtone.

PECHEM, in the materia medica, a name given by the modern Greek writers to the root called *behem* by Aviſenna and Serapion. Many have been at a loſs to know, what this root *pechem* was; but the virtues aſcribed to it are the ſame with thoſe of the *behem* of the Arabians; its deſcription the ſame, and the diviſion of it into white and red, is alſo the ſame as that of the *behem*. Nay, the word *pechem* is only formed of *behem*, by changing the B into a P, which is very common, and the aſpirate h into χ, or ch, which is as common.

Myrepſus, who treats of this root, ſays the ſame thing that the Arabian Aviſenna ſays of *behem*, namely, that it was the fragments of a woody root much corrugated and wrinkled on the ſurface, which was owing to its being ſo moiſt whilſt freſh, that it always ſhrunk greatly in the drying.

PECHYAGRA, a name given by authors to the gout affecting the elbow.

PECHYS, a name uſed by ſome anatomical writers for the elbow.

PECHYTYRBE, an epithet uſed by ſome medical writers for the ſcurvy.

PECORA, *locks*, in the Linnæan Syſtem of zoology, a claſſical term, comprehending a whole order of quadrupeds. The characters of this order are, that the creatures have *dentes inciſores*, or *cutting teeth*, in their under-jaw, but none in their upper: they have no *canini*, or *dog-teeth*, and have five molares each way. The paps of this order of animals are ſituated in their groin, and their feet have hoofs. Of this order are the camel, ſtag, goat, ſheep, and ox. *Linnæi* Syſt. Nat. p. 41.

PECTE, in botany, a name given by ſome of the old Greek writers to the *great comfry*, called alſo *oſſipagina*, from its agglutinating broken bones.

PECTEN (*Cyd.*) in natural hiſtory, the name of a genus of ſhell-fiſh, the characters of which are theſe: it is a bivalve ſhell, ſhutting cloſe in all parts, of a flatted ſhape, ſtriated in the manner of a comb, and often auriculated, ſometimes only ſemiauriculated, and in ſome ſpecies not auriculated at all. There are alſo ſome few ſpecies which are elate, not flat as the others.

This

This genus of ſhells has had its name *pecten* from the longitudinal ſtriæ with which its ſurface is covered, which reſemble the teeth of a comb. According to the general character of this ſhell, it will be eaſy to perceive that it is meant to include the cockles as well as the ſcallops; theſe being the *pectens* without ears, and with leſs flat or elated ſhells. Theſe are called by all authors by a name which is only a diminutive of *pecten*, *pectunculus*. And tho' the having ears is the common mark of diſtinction between the *pectens* and the *cockles*, which laſt uſually have none, yet the genera are not diſtinct, as ſome have ſuppoſed; for there are ſhells allowed to be *pectens*, or ſcallops, which have yet no ears, and others univerſally allowed to be *pectuncles*, or cockles, which have ears. Hence appears the error of Liſter, who made theſe two diſtinct genera, and gave the ears and the equal convexity of both ſhells as the great characters of them: theſe, tho' good marks to diſtinguiſh the ſpecies by, are by no means unalterable enough to found different genera upon. Hiſt. Nat. Eclairc. p. 340.

The genus of *pectuncles*, or *cockles*, has been made by all authors a very extenſive one, but the reader will find all the ſuppoſed ſpecies of it very aptly received into the genus of the *cordiformis*, or *heart-ſhell*, and the *pectens*.

According to this eſtabliſhment of the genus of the *pecten*, the ſpecies are to be enumerated under ſeveral diſtinct heads. Thus, ſome *pectens* are auriculated on both ſides: of theſe we have the following ſpecies; 1. The red *pecten*, called the *ducal mantle* 2. The yellow *ducal mantle pecten*. 3. The coral *pecten*, with beautiful red tubera. 4. The variegated *pecten*, called the St. *James's ſhell*. 5. The yellow variegated *pecten*, called the St. *Michael's ſhell*. 6. The gold yellow *pecten* of the Caſpian ſea. 7. The great reddiſh *pecten*. 8. The variegated bluiſh *pecten*. 9. The red deep furrowed *pecten*. 10. The umbrella *pecten*, or, as ſome call it, the *ſun pecten*: this is yellow at the upper part of the ſhell, and white on the under. 11. The *pecten* which is variegated on the upper part, and white on the under. 12. The yellow high-ribbed *pecten*, with a bordered lip. 13. The *pecten* with both ſhells equally hollow. 14. The pear-faſhioned *pecten*. 15. The beautiful *pecten*, called by Rumphius, *virgineus*. 16. The *amuſium*, or ſmooth poliſhed *pecten* of the ſame author. 17. The rough *pecten*, variegated with brown ſpots. Hiſt. Nat. Eclairc. p. 338.

Of theſe *pectens*, which are ſemiauriculated, we have the following ſpecies: 1. The black ſpinoſe *pecten*: this is all over beſet with ſharp points. 2. The red ſpinoſe *pecten*. 3. The grey ſpinoſe *pecten*. 4. The yellow ſpinoſe *pecten*. 5. The variegated ſpinoſe *pecten*. 6. The ſmooth white *pecten*.

Of thoſe *pectens* which have no ears at all, we have the following ſpecies: 1. The rough *pecten*, called the *file cockle*. 2. The oblong white rough *pecten*. 3. The yellowiſh ribbed and jagged *pecten*. 4. The variegated *pecten*, jagged at the edge. 5. The thick *pecten*, with blue, yellow, and brown ſtreaks. 6. The ſmooth variegated *pecten*. 7. The white globoſe *pecten*, called the *common cockle*.

This ſhell-fiſh is one of the ſpinners of the ſea, having a power of ſpinning or forming threads like the muſcle; but they are much ſhorter and coarſer even than thoſe of that fiſh: ſo that they can never be wrought into any ſort of work, in the manner of the longer and finer threads of the *pinna marina*. The uſe of theſe threads which the *pecten* or *ſcallop* ſpins, is to fix the creature to any other body that is near, whether it be a ſtone, a piece of coral, or another ſhell. All theſe threads proceed, as in the muſcle, from one common trunk; they make their way out of the ſhell in thoſe *pectens* which have only one ear, a little below that ear; in the others probably they iſſue out on both ſides. It is an evident proof, that the fiſh has a power of fixing itſelf at pleaſure to any ſolid body by means of theſe threads, that after ſtorms the *ſcallops* are often found toſſed upon rocks, where there were none the day before; and yet theſe are fixed by their threads, as well as thoſe which had remained ever ſo long in their place. They form their threads in the very ſame manner with the muſcle, only their organ which ſerves for ſpinning is ſhorter, and has a wider hollow, whence the threads are neceſſarily thicker and ſhorter. See MYTULUS.

PECTINATION, *combing of the head*. Frequent *pectination* is recommended by many phyſicians to women, and men who wear their hair, as an exerciſe; and at the ſame time, a kind of friction.

PECTORAL *(Cycl)*.—PECTORALIS *internus*, in anatomy, a name given by Riolan and others to a muſcle of the breaſt, now generally known by the name of the *triangularis ſterni*; called by the older writers, *ſextus thoracis*.

PECTORALIS *major*, a large, thick, and fleſhy muſcle, covering the breaſt from the ſtomach, where it is very broad, to the axilla, where it contracts in its paſſage to the arm. It is naturally divided into two portions, one ſuperior and ſmall, and the other inferior and large; the firſt may properly be called the *clavicular portion*, the other the *thoracic*.

The *clavicular portion* is fixed by a fleſhy inſertion in almoſt half the clavicle next the ſternum, ending under the inſertion of the ſterno-maſtoidæus; from thence it runs obliquely down towards the axilla, contracting by ſmall degrees, and finally ending in a flat tendon or tendinous band. The *thoracic* portion is broad, and in ſome meaſure radiated. It is fixed by its anterior circumference in the lateral part of the outſide of the ſternum, in the outſide of the cartilages, and in a ſmall part of the bones of all the true ribs, and of the firſt and ſometimes the ſecond falſe rib; all theſe inſertions are like ſo many digitations. The inſertions in the ſternum, end by a great number of very ſhort tendons, which run towards the middle of the bone, meeting and decuſſating thoſe from the ſame muſcle on the other ſide.

This muſcle, together with the deltoides, ſends off an aponeuroſis, which joining that of the biceps, is ſpread over the muſcles of the arm: it partly covers the pectoralis minor, and ſerratus major; and by its broad tendon covers tranſverſely the brachial channel, and the tendon of the biceps lodged there. Laſtly, it forms the anterior border of the hollow of the axilla, as the poſterior is formed by the latiſſimus dorſi. *Winſlow's* Anat. p. 180.

PECTORALIS *minor*, a muſcle called alſo *triangularis*. It is ſmall and fleſhy, ſomething of a triangular ſhape, and is ſituated at the ſuperior, lateral, and anterior part of the thorax. By its baſis it is inſerted into the external labium of the upper edge of the ſecond, third, fourth and fifth true ribs, near their union with the cartilages, by the ſame number of digitations, or ſeparate fleſhy portions, between the intervals of the ribs; and for that reaſon it has been called the *ſerratus minor anticus*. From hence theſe portions run up more or leſs obliquely toward the ſhoulder, and form a fleſhy belly, which contracts as it paſſes before the two firſt ribs; and then becoming a ſhort, flat, and broad tendon, is inſerted in the upper part of the apophyſis coracoides of the ſcapula, reaching all the way to the point of that proceſs. This muſcle is covered by the *pectoralis major*, and adheres very cloſely to the external intercoſtal muſcles. The digitations commonly taken notice of cover and hide ſeveral others, by which the number of fibres and thickneſs of this muſcle is increaſed. Its tendon unites a little at the apex of the coracoide apophyſis, with the inſertion of the coraco-brachialis, and with that of one portion of the biceps.

PECTOREL, in our old writers, armour for the breaſt, a breaſt-plate or *petral*, for a horſe. It is mentioned Stat. 14. Car. II. c. 3.

The word *pectorel* comes from the Latin *pectus*, a breaſt.

PECTORIS *oſſa*, in fiſhes. The bones of the breaſt and belly are beſt ſought after in the cetaceous and ſpinoſe kinds. In the ſpinoſe kinds they are theſe: the clavicles, the ſternum, the ſcapulæ, or bones, to which the *pinnæ pectorales* are affixed at their baſis, the bones at the roots of the *pinnæ ventrales*. The number, ſituation, and figure of theſe differ greatly in the ſeveral kinds of fiſh, and make very eſſential characters. *Artedi* Ichthyol.

PECUARII, among the Romans, thoſe who farmed the public paſtures, in order to let them again to advantage. *Pitiſc.* Lex. Ant. in voc.

PECULATOR, one who is guilty of the crime called *peculate*. See PECULATE, *Cycl.*

PEDARIAN, in antiquity, thoſe ſenators who ſignified their votes by their feet, not their tongues; that is, ſuch as walked over to the ſide of thoſe whoſe opinion they approved of, in diviſions of the houſe.

The origin of the word Dr. Middleton thinks owing to this, that tho' the magiſtrates of Rome had a right to a place and vote in the ſenate, as well during their office as after it, and before they were put upon the roll by the cenſors, yet they had not probably a right to ſpeak or debate there on any queſtion, at leaſt in the earlier times of the republic. For this ſeems to have been the original diſtinction between them and the antient ſenators, as it is plainly intimated in the formule of the conſular edict, ſent abroad to ſummon the ſenate, which was addreſſed to all ſenators, and thoſe who had a right to vote in the [a] ſenate. From which diſtinction, theſe laſt, who had only a right to vote, were called by way of ridicule, *pedarian*; becauſe they ſignified their votes by their feet, not their tongues, and upon every diviſion of the houſe, went over to the ſide of thoſe whoſe opinion they approved [b]. It was in alluſion to this old cuſtom, which ſeems, however, to have been wholly dropt in the later ages of the republic, that the mute part of the ſenate continued ſtill to be called by the name of *pedarians*, as we learn from Cicero [c], who in giving an account to Atticus, of a certain debate and decree of the ſenate upon it, ſays, that it was made with the eager and general concurrence of the *pedarians*, tho' againſt the authority of all the conſulars [d]. [a *Feſtus* in voc. ſenatores, *A. Gell.* l. 3. 18. b Vid. *A. Gell.* ibid. *Feſt.* in pedarius. c Ad *Attic.* 1, 19. d *Middlet.* of Rom. ſen. p. 86. ſeq.]

PEDATURA, in Roman antiquity, was uſed for a ſpace or proportion of a certain number of feet ſet out. *Pitiſc.* Lex. Antiq. in voc.

The word occurs frequently in writers about military affairs: thus in Hyginus de Caſtrametatione we meet with, *memineri-mus itaque ad computationem cohortis equitatæ milliariæ pedaturam ad milletrecentos ſexaginta dari debere*; which is to be thus explained: the *pedatura*, or ſpace allowed for a cohors equitata, or provincial cohort, conſiſting of both horſe and foot, (ſee COHORS *equitata*) could not be the ſame as the *pedatura* of an uniform body of infantry, of the ſame number, but muſt exceed

ceed it by 360 feet: for the proportion of the room of one horſeman to one foot ſoldier he aſſigns as two and an half to one. Vid. Phil. Tranſact. N°. 482. ſect. 3.

PEDETICHE, in natural hiſtory, a name given by ſome of the Greek writers to the chamois goat, the creature whoſe ſkin affords us the chamoy leather.

The antient Greeks called this creature *ixaros*, and from thence came the word *iſarus* and *yſſaros* or *yſardos*. The Latin authors of antiquity call this *dama*, but authors have ſince applied the word *dama* to the *cervus platyceros*, or broad-horned ſtag.

Ariſtotle has called this laſt animal *prox*, and his tranſlators have rendered the word *dama*; but they are in this to be underſtood as meaning the *dama* of their own times, not that of the antients, or this *pedetiche*, or chamois goat.

PEDICULARIS (*Cycl.*)—PEDICULARIS, *louſewort*, in botany, the name of a genus of plants, the characters of which are theſe: the flower conſiſts of one leaf, and is of a perſonated form, and divided into two lips; the upper one hooded, the lower divided into three ſegments: the piſtil ariſes from the cup, and is fixed in manner of a nail to the hinder part of the flower. This afterwards ripens into a capſule, divided into two cells, and containing oblong, flatted, and marginated ſeeds. See Tab. 1. of Botany, Claſs 3.

The ſpecies of *pedicularis* enumerated by Mr. Tournefort, are theſe: 1. The common meadow yellow *pedicularis*, called yellow rattle and cockscomb. 2. The taller meadow yellow *pedicularis*, with horny flower cups. 3. The Alpine *pedicularis*, with pale yellow ſpiked flowers. 4. The ſerrated clammy-leaved meadow yellow *pedicularis*. 5. The umbellated Spaniſh *pedicularis*. 6. The narrow-leaved mountain *pedicularis*. 7. The ſpiked Italian *pedicularis*, with changeable coloured flowers. 8. The ſea *pedicularis*, with long ſerrated leaves. 9. The narrow-leaved annual Alpine yellow *pedicularis*. 10. The leaſt ſpring annual purple *pedicularis*, called by ſome purple eye-bright. 11. The leaſt annual white flowered ſpring *pedicularis*. 12. The ſhort blunt-leaved Engliſh red *pedicularis*, called alſo red eye-bright. 13. The blackiſh red-flowered Alpine *pedicularis*, with teucrium leaves. 14. The ſpeedwell-leaved Pyrenean *pedicularis*. 15. The tall germander-leaved Portugal *pedicularis*. 16. The late flowering purple *pedicularis*. 17. The late flowering yellow *pedicularis*. 18. The narrow flax-leaved *pedicularis*. 19. The Portugueſe graſſy-leaved meadow *pedicularis*. 20. The Spaniſh marſh *pedicularis*, with glaſs wort leaves. 21. The yellow Alpine *pedicularis*. 22. The great fern-leaved Alpine *pedicularis*. 23. The ſmall fern-leaved Alpine *pedicularis*. 24. The ſpleen-wort leaved Alpine *pedicularis*. 25. The purple Alpine *pedicularis*, with aſphodel roots. 26. The broader leaved, aſphodel-rooted, Alpine, red *pedicularis*. 27. The common meadow purple *pedicularis*. 28. The white-flowered meadow *pedicularis*. 29. The taller red meadow *pedicularis*. 30. The taller white meadow *pedicularis*. *Tourn.* Inſt. p. 172.

A decoction of *pedicularis* is eſteemed good againſt hæmorrhages and fluxes of all kinds. *Demery*, Dict. des drogues.

PEDICULUS, the *louſe*, in the hiſtory of inſects. See LOUSE.

PEDICULUS *marinus*, a name given by ſome to the Molucca crab. *Ray*'s Ichthyogr. p. 3. See SQUILLA.

PEDILUVIUM. The uſes of warm bathing in general, and of the *pediluvium* in particular, are ſo little underſtood, that they are often prepoſterouſly uſed, and ſometimes as injudiciouſly abſtained from. Med. Eſſ. abr. Vol. I. p. 244.

In the Medical Eſſays of Edinburgh, we find an ingenious author's opinion of the warm *pediluvium*, notwithſtanding that of Borelli, Boerhaave, and Hoffman, to the contrary, to be: that the legs becoming warmer than before, the blood in them is warmed; this blood rarifying, diſtends the veſſels; and in circulating imparts a great degree of warmth to the reſt of the maſs: and as there is a portion of it conſtantly paſſing through the legs, and acquiring new heat there, which heat is, in the courſe of circulation, communicated to the reſt of the blood; the whole maſs rarifying, occupies a larger ſpace, and of conſequence circulates with greater force. The volume of the blood being thus increaſed, every veſſel is diſtended, and every part of the body feels the effects of it; the diſtant parts a little later than thoſe firſt heated. The benefit obtained by a warm *pediluvium* is generally attributed to its making a derivation into the parts immerſed, and a revulſion from thoſe affected, becauſe they are relieved; but the cure is performed by the direct contrary method of operating, *viz.* by a greater force of circulation through the parts affected, removing what was ſtagnant, or moving too ſluggiſhly there. Warm bathing is of no ſervice where there is an irreſoluble obſtruction, tho' by its taking off from a ſpaſm in general, it may ſeem to give a moment's eaſe; nor does it draw from the diſtant parts, but often hurts by puſhing againſt matter that will not yield with a ſtronger impetus of circulation than the ſtretched and diſeaſed veſſels can bear: ſo that where there is any ſuſpicion of ſcirrhus, warm bathing of any ſort ſhould never be uſed. On the other hand, where obſtructions are not of long ſtanding, and the impacted matter is not obſtinate, warm baths may be of great uſe to reſolve them quickly. In recent colds, with ſlight humoral peripneumonies, they are frequently an immediate cure. This they effect by increaſing the force of the circulation, opening the ſkin, and driving freely through the lungs that lentor which ſtagnated or moved ſlowly in them. As thus conducing to the reſolution of obſtructions, they may be conſidered as ſhort and ſafe fevers; and in uſing them we imitate nature, which by a fever often carries off an obſtructing cauſe of a chronical ailment. Borelli, Boerhaave, and Hoffman are all of opinion, that the warm *pediluvium* acts by deriving a larger quantity of blood into the parts immerſed. But arguments muſt give way to facts: the experiment related in the Medical Eſſays ſeems to prove to a demonſtration, that the warm *pediluvium* acts by rariſying the blood. Vid Med. Eſſ. abr. Vol. I. p. 245. ſeq.

A warm *pediluvium*, when rightly tempered, may be uſed as a ſafe cordial, by which circulation can be rouſed, or a gentle fever raiſed; with this advantage over the cordials and ſudorifics, that the effect of them may be taken off at pleaſure. Med. Eſſ. Edinb. abr. Vol. I. p. 237.

Pediluvia are ſometimes uſed in the ſmall pox; but Dr. Stevenſon thinks their frequently tumultuous operations render that ſuſpected, and at beſt of very doubtful effect; and he therefore prefers Monſ. Martin of Lauſanne's method of bathing the ſkin, not only of the legs, but of the whole body, with a ſoft cloth dipped in warm water, every four hours, till the eruption; by which means the puſtules may become univerſally higher, and conſequently more ſafe. Med. Eſſ. abr. ib. p. 248.

PEDO, in natural hiſtory, a name given by ſome writers to the *tipula*, or father long-legs; called alſo by others, *Gruina*, or the crane-fly.

PEDRO *de Porco*, a ſort of bezoar, called by the Portugueſe *pedro de vaſſar*, and found in the gall bladders of the wild boars in the Indies. It is uſually of the ſize of a filbert, and of an irregularly oval ſhape; it is generally of a pale greeniſh colour, and of a very ſmooth ſurface.

This ſort of bezoar is extremely valued; the Dutch Eaſt India fleets are ſeldom able to bring home more than five or ſix of the ſtones, and they are purchaſed at three or four hundred livres each, by the opulent burghers, either for preſents to the great, or elſe to be handed down to their poſterity in their families; ſo great is their opinion of their virtues.

The Indians call this ſpecies of bezoar, *maſticha de ſcho*, and have as high a veneration for its virtues as the Dutch. The Inhabitants of Malacca alſo eſteem it greatly, not as an antidote againſt poiſon, but as a remedy for the mordixi; a diſeaſe to which they are ſubject, and which is as fatal as the plague with us. It is alſo eſteemed a very valuable medicine in the ſmall pox. The method of uſing it is to ſuſpend it in wine or water, till it has given it an agreeable bitterneſs; and this is to be drank every morning, and as often beſide as the nature of the diſorder may require. The common method of keeping it is in a gold box, bored full of holes, and having a gold chain faſtened to it: by this means they can dip it into liquors as they pleaſe, without taking it out of the box; and by that means prevent the miſchiefs it might get by handling. *Bont.* Med. Ind.

PEDUNCLE, among botaniſts, expreſſes that little ſtalk which grows from the trunk or branches of a plant, and ſupports the parts of fructification, the flower and the fruit, or either: when this is produced from the ſtalk, it is called *caulimus*; when from the alæ of the leaves, *alaris*; when it terminates the plant or its branches, *terminalis*.

PEDUNCULARIA, in botany, a name by which ſome authors have called the *ſtaphiſagria*, or ſtaveſacre; a plant whoſe ſeeds are uſed to kill vermine. *Ger.* Emac. Ind. 2.

PEE, in mining, is uſed for the place where two veins meet and croſs one another, thus +. *Houghton*'s compl. Miner, in explan. of the terms.

PEGANELÆON, a word uſed by the antients to expreſs oil, in which the leaves and flowers of rue had been infuſed and inſolated.

PEGANERON, a name given by ſome old authors to a plaiſter in which rue was a principal ingredient, from *peganon*, the Greek name of rue.

PEGANON, or PEGANUM, a name uſed by ſome authors for the *ruta ſylveſtris*, or wild rue; called *harmala*, or *harmel*, in the ſhops. *Ger.* Emac. Ind. 2. See HARMALA.

PEGEMUS, one of the many names by which the Chemiſts have called mercury.

PEGMA, among the Romans, a wooden machine, uſed in theatrical entertainments, which was raiſed and let down by ſecret engines, whence it was ſaid to grow. *Pitiſc.* Lex. Ant. in voc.

PEGOMANTIA, Πηγομαντεια, in antiq ity, a ſpecies of divination, which was performed with fountain water. See the article HYDROMANTIA.

PEGORELLA, in ichthyography, a name by which ſome have called a fiſh of the truttaceous kind, caught in the Mediterranean, and more uſually called *callarias*. *Bellonius* de Piſc. See the article CALLARIAS.

PELADA, a kind of alopecia, or diſtempered ſtate of the body, occaſioning the ſhedding of the hair, ariſing from a venereal cauſe. *Caſtel.* Lex. Med.

PELÆAS, Πελαιας, in zoology, the name by which the antients called that ſpecies of pigeon now known by the name of the *livia* and *ſaſſaroilo*; a grey pigeon, of a very ſmall ſize, and with ſome variegations of purple and green. *Ray*'s Ornithol. p. 136. See LIVIA.

PELAGIA, (*Cycl.*) in natural hiſtory, a name by which Pliny, and other of the antient naturaliſts, have uſually called the *purpura*. See PURPURA.

PELAMYS, in zoology, a name by which the antients expreſſed the young brood of the *thynnus*, or tunny fiſh, at a certain age and ſize; but later writers have appropriated the word for the name of a diſtinct ſpecies of fiſh, of the ſame genus, called by others *ſarda*; and by ſome by the two names joined into one, *pelamys-ſarda*.

It is a ſea-fiſh, of the ſhape of the tunny; but of a ſmooth ſkin, and free from ſcales every where, except about the gill-fins. Its teeth are large, long, and crooked. Theſe are the only external marks by which it is to be known from the young brood of the tunny; but when brought to the table, it is eaſily diſtinguiſhed by the hardneſs of its fleſh. *Ray*'s ichthyography, p. 179.

PELAMYS *vera*, a name given by Rondeletius, and ſome other authors, to the fiſh more diſtinctly known by the name of *amia*. *Willughby*'s Hiſt. Piſc. p. 180. See AMIA.

PELANI, Πελανοι, among the Athenians, a kind of cakes uſed in their libations. *Pett.* T. 1. p. 214.

PELATÆ, Πελαται, in antiquity, a particular kind of ſervants among the Athenians.

The *pelatæ* were free-born citizens, who, by reaſon of their indigence, were forced to ſerve for wages. They had no ſuffrage in public affairs, as not being maſters of an eſtate proper to qualify them for giving their votes; but this reſtriction was not perpetual. They were otherwiſe called *thetes*, and continued in the condition of ſervants only during their own pleaſure and neceſſities; for they had power either to change their maſters, or (if they became able to ſubſiſt themſelves) wholly to releaſe themſelves from ſervitude. *Pott.* Arch. Græc. T. 1. p. 57.

PELECANUS, a name given by ſome authors to the *platea*, or ſpoon-bill; a bird very different from the pelican, being of the ſtork, or heron kind. *Aldrovand.* de Avib.

PELECINUS, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the papilionaceous kind, and from its cup ariſes a piſtil, which finally becomes a flat, bicapſular and bivalve fruit, containing ſeveral flat ſeeds, uſually approaching to a kidney-like ſhape.

There is only one known ſpecies of this genus, which is the plant called by ſome the ſmooth-podded *ſecuridaca*, and by others the radiated *lunaria*. *Tourn.* Inſt. p. 417.

PELICAN, (*Cycl.*) in the Linnæan ſyſtem of zoology, makes a diſtinct genus of birds of the order of the *anſeres*, or gooſe kind; the characteriſtic of which is to have a beak of a depreſſed form, with a hooked point, and furniſhed with a large bag or purſe beneath. *Linnæi* ſyſtem. Nat. p. 46.

PELLA, in zoology, a name by which many have called the common grey heron. See the articles ARDEA and HERON.

PELLACK, the name of a young ſpout-whale, often found in Zetland; where they run into creeks, and ſo entangle themſelves among the rocks, that they are caſt on ſhore, or eaſily taken. Phil. Tranſ. N°. 473, ſect. 8.

PELLAGE, in our old writers, a cuſtom or duty paid for ſkins or leather. Rot. Parl. 11 *Hen.* IV. *Blount.*

PELLITORY *of Spain*, in the materia medica. See the article PYRETHRUM.

PELLITORY *of the wall*. See PARIETARIA.

PELOPIA, Πελοπεια, in antiquity, a feſtival celebrated by the Eleans, in honour of Pelops, for whom that nation had more veneration than for any other hero. For the ceremonies of this ſolemnity, ſee *Pott.* Archæol. Græc. l. 2. c. 20. T. 1. p. 429.

PELORIA, Πελωρια, in antiquity, a feſtival not unlike the Roman ſaturnalia, celebrated by the Theſſalonians. *Pott.* Archæol. Græc. l. 2. c. 20. T. 1. p. 425.

PELORIDES, in natural hiſtory, a name given by ſome to a peculiar ſpecies of chama. Bellonius, who firſt uſed the word, never gives it alone as the name of the ſhell, but only uſes it as an epithet derived from *peloro*, the name of the place where a particular ſpecies of chama was very frequent.

PELT-*wool*, wool ſtripped of the ſkin or *pelt* of a dead ſheep. Stat. 8 Hen. VI. c. 22. *Blount*, *Cowel.*

PELTASTES, Πελταστης, among the antients, one who uſed the buckler called *pelta*. See PELTA, *Cycl.*

PELTATED-*leaf*, PELTATUM *folium*, among botaniſts. See the article LEAF.

PELVIS (*Cycl.*)—The *pelvis* is the third and loweſt part of the trunk, conſiſting chiefly of two large pieces, called *oſſa innominata*; which being united anteriorly by a cartilaginous ſymphyſis, and poſteriorly to the two ſides of the os ſacrum, repreſent a kind of baſin. When conſidered ſeparately, they are of no determinate figure; being of different breadths in different parts, and unequally convex on the outſide, and unequally concave within. Each bone is but one piece in adults, but in children each conſiſts of three pieces, joined together by a cartilage; which afterwards perfectly oſſifies, leaving commonly no veſtige of the firſt diviſion. Anatomiſts conſider it, however, even in adults, as made up of three portions; and diſtinguiſh them by different names, as if they were three different bones. Of theſe three bones the largeſt is ſuperior and poſterior, and is called *os ilium*. The ſecond inferior called *os iſchium*: and the third and ſmalleſt anterior called *os pubis*. Without entering on the particular deſcription of theſe, (which, ſee under their proper heads) it is to be obſerved, that there are in the entire bone ſeveral common parts, or parts which belong to more portions of it than one, *viz.* a deep cartilaginous cotyloide cavity, called in Latin *acetabulum*: this is formed by all the three portions. A large opening, called the *foramen ovale*, formed by the *os iſchium* and *os pubis*. A large poſterior notch or ſinus, called the *iſchiatic* notch, and formed by the *os iſchium* and *os ilium*. An oblique eminence, or protuberance, above the *acetabulum*, toward the *foramen ovale*, made by the *os ilium* and *os pubis*: and to theſe may be added, a ridge on the inſide the *pelvis*, which divides the wide upper part from the bottom, to which alone the antients gave the name *pelvis*. *Winſlow*'s Anatomy, p. 69.

PELUS *armena*, in the materia medica, a name given by ſome of the old writers to the drug that we at preſent call *bole armoniac*. This was the original name, and the term *bolus armena* is not to be found, but in the later writers.

PEMPHINGODES, an epithet beſtowed by Hippocrates on fevers by flatulencies and inflations, in which the patient feels a kind of wind paſſing along under the ſkin, and the phyſician may perceive it in the ſame places riſing againſt the preſſure of his finger, called by ſome an inflative fever.

PEMPTÆUS, a word uſed by medical writers, as the name of an ague, the fits of which return always on the fifth day.

PENDANT-*gardens*. See PENSILES *horti*.

PENDULOUS *roots*, among botaniſts, ſuch as are fixed to the ends of fibres, whence they ſeem to hang. See ROOT.

PENDULUM (*Cycl.*)—Mr. Poleni ſeems to think, that if a long *pendulum* were made to ſwing in the place of the meridian, and another of equal length in a plane perpendicular to the meridian, ſome difference might be found in their vibrations from the centrifugal force ariſing from the earth's rotation about its axis. See Phil. Tranſ. N°. 468. ſect. 1.

Pendulum clocks reſting againſt the ſame rail, have been found to influence each other's motions. See the Phil. Tranſ. N°. 453, ſect. 5 and 6, where Mr. Ellicot has given a very curious and exact account of this phænomenon.

PENELOPE, in zoology, the name uſed by authors for the bird commonly known in England by the name of the *wigeon*; called alſo in ſome places the *whewer*; and by the Germans the *ſchmey*. The head and upper part of the neck in this bird are of a reddiſh hue, variegated with black ſpots; but toward the beak the colour is paler, and blended with ſome white and yellow. The upper part of the breaſt and the ſides are of a deep reddiſh hue, and variegated with tranſverſe ſtreaks of black, and the back is brown; the head is proportionably ſmaller than that of the wild duck. It feeds on weeds and ſmall ſhell-fiſh. *Ray*'s Ornithol. p. 288.

PENETRALE, among the Romans, properly denoted the chapel conſecrated to the *penates*, or houſehold gods. *Pitiſc.* Lex. Ant. in voc. See PENATES, *Cycl.*

PENGUIN, in zoology, a name given by ſailors of different nations to two different ſpecies of water-fowl, both web-footed, and both wanting the hinder toe.

The *penguin* of the Engliſh is the bird more commonly known by the name of the *goiſugel*.

It grows to the ſize of a common tame-gooſe, and is black on its back, or upper part, and white on the belly. Its wings are very ſmall, and by no means fit for flying. Its beak is ſomewhat broad and long, compreſſed on the ſides and back, and has toward the extremity ſeveral furrows, ſeven or eight on the upper ſide, and about ten on the under; and the lower chap ſwells into a protuberance downward. Its head has two white lines reaching from the beak to the eyes. It tail is very ſhort, and it has no hinder toe.

The *penguin* of the Dutch is the *anſer magellanicus* of Cluſius. *Ray*'s Ornithol. p. 242. See the article DUCK.

PENICILLI *marini*, in natural hiſtory, a ſort of marine tubuli, or caſes of ſea-worms, making a diſtinct genus of thoſe ſhells. They are defined to be ſhelly tubes, very ſlender, and terminating in the ſhape of a painter's pencil; many of them in their native ſtate adhering to ſtones, &c. on the ſea-ſhores, by means of a ſoft and lax ſubſtance. Some of theſe are white and pellucid, others yelloviſh or brown; and the more common ſort are about a finger's length, and about the thickneſs of a wheaten ſtraw; and ſome are of a ſort of funnel-like ſhape, and have their mouths ſurrounded by a ſort of hairs, or filaments. Theſe are called by ſome *proboſciplectani*, others are called *cadi*, and others *entalia*. *Klein*, de Tubul. Marin. p. 1.

PENIS (*Cycl.*)—Bleeding in the vena dorſalis of the *penis* is uſually found to ſurpaſs all remedies whatever in abating inflammatory diſorders of this member. This large vein, which runs along the back or upper ſide of the *penis*, being generally pretty much diſtended and conſpicuous in an inflammation of this part, may be opened about the middle, and kept bleeding till the member becomes flaccid, and a ſufficient quantity of blood be diſcharged proportionably to the urgency of the caſe; which done, a compreſs muſt be applied, and kept on by bandage. There muſt, however, be great caution in this operation not to injure the arteries or nerves which enter the *penis* near this vein, as alſo not to make the bandage too ſtrict,

ſtrict, by which the inflammation and ſymptoms may become worſe than before. *Heiſter*'s Surgery, p. 284.

PENIS *primus muſculus*, in anatomy, a name given by Veſalius and others, to a muſcle of the *penis* now generally known by the name of *accelerator*.

PENITENTS, in the church of Rome. See POENITENTES.

PENNANT, in a ſhip, a ſhort rope made faſt at one end to the head of the maſt, or to the yard-arm, with a block at the other end, and a ſhiver to receive ſome rope into. All the yard-arms, except the miſen, have *pennants*.

PENNATED-*leaf*, in botany. See LEAF.

PENNEVISCH, in zoology, a name given by ſome to the moſt common ſpecies of the fiſh called *bagre*, caught in the Eaſt and Weſt Indies. *Ray*'s Ichthyol. Append. p. 4. See the article BAGRE.

PENNY *(Cycl.)* — PENNY-*earth*, in agriculture, a term uſed by the farmers for a hard loamy, or ſandy earth, with a very large quantity of ſea ſhells intermixed in it; ſome of which being round and flat, and in ſome meaſure reſembling pieces of money, have occaſioned the earth's being called by this name. It is an earth not eaſily dug, but is uſually undermined with pick-axes, and then falls in large lumps; which, with the froſts, break to pieces, and leave the ſhells looſe. It is prepared by breaking and mixing well with water, and then makes very deſirable floors. The Jerſey combers combpots are alſo made of it, and the ſides and roofs of ovens are plaiſtered with it; and being rightly managed, it combines into a floor almoſt as ſtrong as plaiſter of Paris. *Moreton*'s Northampt. p. 66.

PENNYROYAL, *pulegium*, in botany, *&c.* See PULEGIUM.

The ſeveral ſorts of *pennyroyal* all propagate themſelves very faſt by their trailing branches, which take root at every joint; ſo that no more is required in their culture and propagation than to cut off and plant out theſe rooted branches: they ſhould be planted at a foot diſtance every way, that they may have room to grow. The beſt ſeaſon for this is in September, that the plants may be rooted before winter. They love a moiſt ſoil, and generally grow very faſt. *Miller*'s Gardener's Dict.

PENSILES-*horti*, in antiquity, gardens raiſed on arches by the kings of Babylon. Q. Curtius makes them equal in height to the walls of the city, *viz.* fifty feet. Trees of a very large ſize grew and flouriſhed here. *Hofm.* Lex. in voc. Q. *Curt.* l. 5. c. 1.

PENTACEROS, in natural hiſtory, a name given by Linkius, and ſome other authors, to a kind of *ſtella marina*, or *ſea ſtar-fiſh*, compoſed of five principal rays, with ſeveral tranſverſe hairy or downy proceſſes.

PENTACTINODOS, in natural hiſtory, a name given by ſome authors to thoſe ſpecies of ſtar-fiſh which are compoſed of a body divided into five rays.

PENTADACTYLON, *five fingers*, in botany, a name given by ſome authors to the *ricinus* or *palma chriſti*, from the figure of its leaf. *Ger.* Emac. Ind. 2.

PENTADACTYLOS *piſcis*, *the five fingered fiſh*, in zoology, the name of a fiſh common in all the ſeas about the Eaſt Indies, and called by the Dutch there *viif vinger viſch*.

It has this name from five black ſtreaks which it has on each ſide, reſembling the prints of five fingers. It grows to about a foot and a half long, and its head is ſmall in proportion to its body. Its ſnout is long, and its fins large, and reaching almoſt to its tail. Its general colour is very bright and elegant, a yellow with an admixture of purple and of a ſilvery gloſs. It has no ſcales, and is a dry but not ill-taſted fiſh. *Ray*'s Ichthyogr. Append. p. 6.

PENTADACTYLOS-ASTER, in natural hiſtory, a name given by Linkius, and ſome other authors, to a ſpecies of *ſtar-fiſh*, compoſed of a ſmall body, and five principal rays, which have each ſeveral proceſſes coming from them, covered with down.

PENTAEDROSTYLA, in natural hiſtory, the name of a genus of ſpars. The word is derived from the Greek πεντε five, ἑδρα ſides, and στυλος a column.

The bodies of this genus are ſpars, in form of pentangular columns, terminated by pentangular pyramids at one end, and irregularly affixed at the other to ſome ſolid body.

Of this genus there are three known ſpecies: 1. One with a very long pyramid. This is found in the mines on Mendip-hills. 2. One with a thick column, and a very ſhort and large pyramid. This is found in the Hartz foreſt in Germany and in Cumberland. And 3. One with a broad depreſſed pyramid. This is found, ſo far as is yet known, only in the mines at Rammelſberg in the Hartz foreſt in Germany. *Hill*'s Hiſt. of Foſſ. p. 220.

PENTAGON-ASTER, in natural hiſtory, a name given by Linkius, and other authors, to a kind of *ſtella marina*, or *ſtar-fiſh*, compoſed of five rays, with a number of tranſverſe proceſſes iſſuing from them, covered with a hairyneſs.

It is one of the general claſſes of the *ſtellæ crinitæ*, ſo called from this hairyneſs.

PENTAGONOTHECA, in botany, the name given by Vaillant to the plant called by Linnæus, Plumier, Houſton, and others, *piſonia*. It has this laſt name from Piſo, the great botaniſt, and the other from the figure of its ſeed-veſſel, which is of a ſort of pentangular figure, but contains only one cell. *Vaillant* Act. Germ. See PISONIA.

PENTANDRIA, in botany, a claſs of plants which have hermaphrodite flowers, with five ſtamina or male parts in each. See Tab. 1. of Botany, Claſs 1.

The word is formed of the Greek πεντε five, and Ἀνηρ male. Of this claſs of plants are the primroſe, willow-herb, bindweed, *&c.*

PENTANGLE, in geometry, a figure with five angles.

PENTAPHARMACUM, a medicine conſiſting of five ingredients: it has alſo been uſed in the ſame ſenſe to aliments. Adrian the emperor was, as we are informed, particularly fond of a diſh of five ingredients, called by this name. The ingredients were the udder of a ſow, ham, peacock, brawn, and a ſort of paſte.

PENTAPHYLLOIDES, in botany, the name of a genus of plants, the characters of which are theſe: The flower and fruit are the ſame with thoſe of the common cinque-foils, but the leaves do not grow as in that at the tops of the ſtalks, but arranged along them, as in the other plants.

The ſpecies of *pentaphylloides*, enumerated by authors, are theſe: 1. The erect *pentaphylloides*, called by authors the *ſtrawberry-cinque-foil*. 2. The procumbent *pentaphylloides*, called by authors the *creeping ſtrawberry-cinque-foil*. 3. The ſilvery *pentaphylloides*, with alated leaves, called by authors, *argentina*, *potentilla*, *ſilver-weed*, and *wild fanſy*. 4. The upright ſhrubby *pentaphylloides*. 5. The red-flowered marſh *pentaphylloides*. 6. The red-flowered marſh *pentaphylloides*, with thicker and hairy leaves. *Tourn.* Inſt. p. 298.

PENTAPLEURUM, a name given by ſome botanical writers to the common ſmall plantain, uſually called *ribwort* and *plantago quinquenervia*, from its leaves always having juſt five ribs running along them.

PENTAPTEROPHYLLUM, in botany, a name by which Dillenius has called the *myriophyllum* of other authors, characterred under that name in the genera plantarum of Linnæus, p. 459. See MYRIOPHYLLUM.

PENTAUREA, a name given by ſome fabulous authors to a ſtone ſaid to have been firſt found by Apollonius Tyaneus, and to poſſeſs the virtues of all the other ſtones, and to attract them all to it, as the magnet does iron.

PENTECONTARCHA, among the antients, the captain, or commander of a galley, called *penteconteros*. *Pitiſc.* Lex. Ant. in voc. See PENTECONTEROS, *Cycl.*

PENTELICUM-*marmor*, in the works of the antients, a name given to a very beautiful and gloſſy ſpecies of white marble, of which many of the columns and ſtatues of larger ſize of the antients were made: the Parian marble, from certain cracks and fiſſures in the ſtrata, ſeldom affording blocks of more than five foot in length.

PENTEXOCHE, a name given by authors to a ſpecies of echinites, reſembling the ripe fruit of a medlar, and thence called alſo *meſpileus lapis*.

PENTHORUM, in botany, the name of a genus of plants, the characters of which are theſe: The cup is very ſmall and permanent; it is compoſed of one leaf divided into five ſegments at the edges. There is no flower, the ſtamina are ten ſetaceous filaments of double the length of the cup. Theſe are permanent, the antheræ are roundiſh and fall off very quickly. The germen of the piſtil is divided into five parts, and terminates in five ſtyles, which are conic, erect, and of the length of the ſtamina. The ſtigmata are obtuſe; the fruit is a capſule divided into five parts, and containing five cells. The ſeeds are numerous, ſmall, and compreſſed. *Linnæi* Gen Plant. p. 204.

PENTODRYON, in botany, a name given firſt by the Greek writers, and after that by the Romans, to a kind of *ſtrychnum* or *nightſhade*, which cauſed madneſs in thoſe who eat of it. This was called by others *manicum ſtrychnum*, and by ſome ſimply *manicum*.

PENTOPHTHALMOS, in zoology, the name of an Eaſt Indian fiſh, approaching to the European *liparis* or *butterfiſh*, but larger, and called by the Dutch there *viifoog*. It has theſe names from five round ſpots in the tail-fin, reſembling five eyes. It is of a yellowiſh colour, and is covered with a ſmooth ſkin, having no ſcales. Its body is thick; its head ſmall; its beak long. It has two red fins, and its tail is bluiſh. It is an inhabitant of the freſh waters, and is a very well-taſted fiſh. *Ray*'s Ichthyogr. Append. p. 6.

PEPIN-*cyder*. See CYDER.

PEPITA, in the materia medica, a name given by ſome authors to the *faba ſancti Ignatii*, or *St. Ignatius's bean*. *Dale* Pharm p. 328.

PEPLION, or PEPLOS, names given by the antients to medicines which they uſed as briſk cathartics to purge off the bile and other humors.

PEPLIUM, in botany, a name given by the antient Greek writers to a ſhrub which had pinnated leaves and papilionaceous flowers. It is tranſlated by many *ſena*; but this does not appear certainly to be right: the ſeveral ſpecies of *colutea* agree as well with this deſcription as the *ſena*, and they have indeed been called *ſena* by many; probably it was one of theſe.

PEPLUS,

PEPLUS, Πεπλος, among the antients, a kind of garment worn by women. *Pitiſc.* in voc.

The *peplus* was a long robe that reached to the feet, without any ſleeves, and ſo exceeding fine that the ſhape of the body could eaſily be diſcovered through it. Hiſt. l'Acad. Inſcr. vol. 3. p. 401.

The *peplus* of Minerva is very famous among antient mythologiſts. The Athenians uſed a great deal of ceremony in the making the *peplus*, and dreſſing the ſtatue of this goddeſs with it. See *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 421.

PEPLUS, in botany, a name given by ſome authors to the ſmaller round-leaved ſpecies of *tithymal*, or *ſpurge*, as they call the narrow-leaved ones *eſula*. See the article TITHYMALUS.

PEPO, the *pompion*, or *pumpkin*, the name of a genus of plants allied to the melon and cucumber kinds. The characters of the genus are theſe: The flowers conſiſt of one leaf each, ſhaped like a bell, wide open at the mouth, and divided into ſeveral ſegments at the end. Of theſe flowers ſome are male or ſteril, having no embryo; others are female or fruitful, having an embryo, which ripens into a large fruit, with ſometimes a ſmooth, ſometimes a rough bark. The figure is ſometimes oval, ſometimes round, and the bark often very hard, tuberous, and hollow: it is divided into three cells within, and contains flat ſeeds ſurrounded with a ſort of ring, and fixed to a ſpongy placenta.

The ſpecies of *pompion*, enumerated by Mr. Tournefort, are theſe: 1. The great long-fruited *pompion*. 2. The great round-fruited *pompion*. 3. The orange-fruited *pompion*. 4. The ball *pompion*, or *ball gourd*, called by authors *cucurbitula pilæ palmariæ figura*. 5. The ſmall round fruited-*pompion*, called the *ſmall rough-fruited yellow gourd*. 6. The round-fruited variegated *pompion*. 7. The *pompion* with a variegated fruit of a turbinated form. 8. The turbinated white *pompion*. 9. The turbinated yellow *pompion*. 10. The leaſt turbinated *pompion*. 11. The pear-faſhioned *pompion*. 12. The oval yellow *pompion*. 13. The rough oval yellow *pompion*. 14. The variegated yellowiſh oval *pompion*. *Tourn.* Inſt. p. 105.

We generally eſteem the *pompion* but an unwholſome food, but there is another uſe in it worth enquiring into. The world heard much of the fame of a ſecret medicine prepared by Petrus de Caſtro, chief phyſician to the duke of Mantua, for the cure of pleuriſies. When the ſecret of this was diſcovered and publiſhed in the Acta Leipſienſia, it appeared to be no more than the rinds of the oblong Italian *pompions*, pared clean from the pulp, and boiled many hours together in old oil of olives.

PEPPER *(Cycl.)* — *Ciapa* PEPPER, *pimienta de Ciapa*, a name given by the Spaniards to a ſort of ſpice which they diſcovered in Ciapa, a province of Guatimala in New Spain, and of which they were at firſt very fond, both in food and medicine.

In medicine it is a very good cephalic and ſtomachic. It is recommended very ſtrongly alſo by ſome of the Spaniſh writers, as a cure for the epilepſy and the gutta ſerena, but thoſe who have tried it in theſe caſes do not confirm ſuch accounts.

The deſcriptions we have of it are, that it has the taſte of cloves, pepper, cinnamon, and ginger, all blended together; and Redi is of opinion, that it is no other than our *pimenta*, or *Jamaica pepper*. *Redi*'s Eſperien.

PEPPER-*muſhroom*, in botany, a name given by Dr. Liſter to a new ſpecies of fungus, diſcovered by him in the woods of Yorkſhire, whoſe juice is acrid and hot as pepper. This is ſomewhat larger than the common eſculent muſhroom, but of the ſame ſhape with that, having a round head and open gills underneath. The head is very fleſhy, and the pedicle alſo is ſolid, not hollow, as in moſt other of the larger funguſes: any part of this *muſhroom* being cut or broken, it bleeds very freely a white milky juice, like that of the tithymals. This juice taſtes like pepper, only that it is much hotter. It is not viſcous or clammy to the touch, and the air does not much diſcolour it; nor does it render the blade of the knife, with which it is cut, black, as moſt other vegetable juices do. When let out of the plant it very ſoon concretes into a firm and dry maſs, making a ſort of cake; and when thus dried into a ſolid ſubſtance, it retains its white colour and pungent taſte. It is very remarkable, that this *muſhroom*, tho' ſo hot to our tongues as not to be endured, yet is ſo well ſuited to the palates and nature of certain inſects, that they can not only feed on it, but live comfortably in the midſt of it. The yellow naked ſnail feeds greedily on the plant while growing, and the ſtalks of it at ſuch times as the juice is ſharpeſt of all, that is, while it is growing to the full ſize, are full of the maggots or worms hatched from the eggs of flies, depoſited there for a nidus and food for them in that ſtate. The juice has a great affinity with euphorbium, and may be brought into medicinal uſe, perhaps, to very good purpoſe.

John Bauhine deſcribes a *muſhroon* much reſembling this, but ſmaller and leſs fleſhy; and the Pruſſians and Polanders have a ſort of great *muſhroom*, which they call *groozdiſhys*, which agrees with this in many particulars; but it is larger and thicker. Phil. Tranſ. N° 89. See the article GROOZDISHYS.

PEPPER-*tree* of Jamaica. See PIMIENTA.

PEPPER-*water*, a liquor prepared by the curious for examination by the microſcope, as always affording a great number of ſmall animals.

The method of preparing it is this, put common black *pepper* groſsly powdered, into an open veſſel ſo as to cover the bottom of it half an inch thick, and put to it rain or river water, till it covers it an inch, ſhake or ſtir the whole well together at the firſt mixing, but never diſturb it afterwards: let the veſſel be expoſed to the air uncovered; and in a few days there will be ſeen a pellicle or thin ſkin ſwimming on the ſurface of the liquor, looking of ſeveral colours.

This is a congeries of multitudes of ſmall animals; and being examined by the microſcope, will be ſeen all in motion: the animals, at firſt ſight, are ſo ſmall as not to be diſtinguiſhable, unleſs to the greateſt magnifiers; but they grow daily till they arrive at their full ſize. Their numbers are alſo continually increaſing, till the whole ſurface of the liquor is full of them, to a conſiderable depth. When diſturbed they will ſometimes all dart down to the bottom, but they ſoon after come up to the ſurface again. The ſkin appears ſooneſt in warm weather, and the animals grow the quickeſt; but in the ſevereſt cold it will ſucceed, unleſs the water freezes. *Baker*'s Microſcope, p. 71.

About the quantity of a pin's head of this ſcum, taken up on the nib of a new pen, or the tip of a hair pencil, is to be laid on a plate of clear glaſs; and if applied firſt to the third magnifier, then to the ſecond, and, finally, to the firſt, will ſhew the different animalcules it contains, of ſeveral kinds and ſhapes as well as ſizes Phil. Tranſ. N° 284.

The animalcules found in this liquor, are principally of ſix kinds: 1. The largeſt kind of all is in length about the diameter of a hair, and of ſcarce a fourth part of that meaſure in breadth: they are very thin and tranſparent, but their back is darker than their belly: they turn about very frequently and nimbly in the water; their ſides are fringed with a great number of minute feet, which are ſeen principally at the two ends; and at one end there are alſo ſome briſtles longer than the feet, which make a ſort of tail. They are very nimble, and walk as well as ſwim, and will climb up a hair if put in among them.

2. There is a ſmaller ſort, whoſe length is about a third of a hair's breadth; but their tail is five or ſix times as long as their body. This they either carry ſtrait, or in a ſpiral form; and at the other end they thruſt out a ſort of bearded tongue: theſe make a conſtant current of water toward them.

3. There is a ſmaller ſort than theſe, which are ſometimes ſeen of an oval figure, and ſometimes long and flat like a flounder: theſe alſo have feet which are plainly ſeen when the water is evaporating.

A fourth kind appear like ſlender worms, fifty times as long as broad: their thickneſs is not above the hundredth part of a hair's breadth; and they move with equal eaſe either forward or backward. There are a fifth ſort extremely minute and round; and a ſixth kind which are longer than theſe, but not larger; and probably there may be yet many kinds not diſcovered. Theſe ſmall animals are eaſily deſtroyed; a little diſſolved ſalt or ſugar, or ſpirit of vitriol, or even ſpittle will kill them; and in the drying away of the waters many of them burſt. Phil. Tranſ. N° 203.

PERÆQUATORES, among the Romans, aſſeſſors appointed to regulate the *cenſus* according to every man's circumſtances, by eaſing thoſe that were overcharged, and raiſing the taxation if too low. *Pitiſc.* in voc.

PERANEMA, in zoology, the name of a Braſilian fiſh, of the ſize of the pearch, being ten or eleven fingers in length, and about three fingers broad in the broadeſt part.

Its mouth is large and round, and has no teeth, but ſeveral very rough and ſharp prominences. Its eyes are large, and it has one long fin running down the back, which is ſupported by rigid and prickly rays. Its tail is not forked; its whole body is a ſilvery white, with a faint bluſh of red. Its ſcales are extremely ſmall, and of a triangular figure, and its belly is very white. It is a ſea fiſh, and is wholeſome and well-taſted. *Marggrave's* Hiſt. Braſil. *Willughby*'s Hiſt. Piſc. p. 339.

PERANITES, the name of a ſtone mentioned with many idle ſtories of its origin, by the writers of the middle ages.

It ſeems originally to have been only a corruption of the word *peartides*, a name by which the antients ſeem to have called our *ſtalactites* or *dropſtone*.

PERCA, the *pearch*, in the Linnæan ſyſtem of zoology, the name of a genus of fiſhes of the order of the acanthopterygii. The characters of theſe are, that the membrane of the gills has ſeven bones, and the back has one or two fins. Of this genus are the *perca*, *lucioperca*, *lupus*, &c. *Linnæi* Syſtema Naturæ. p. 53.

In the Artedian ſyſtem of ichthyology, the characters of the *pearch* are theſe: It is of the acanthopterygious kind. The branchioſtege membrane on each ſide, contains ſeven bones. The ſcales are very hard and rough, or armed with a ſort of little

little hooks at the ends; and the upper lamina of the coverings of the gills is ſerrated at the edges. There are ſometimes two fins on the back, ſometimes only one.

Of the former ſort, or thoſe which have two fins on the back, the ſpecies are, 1. The *pearch* with ſix tranſverſe black lines, and with the fins of the belly red. This is our common *pearch*. 2. The pale ſpotted *pearch*, with two teeth in the jaws, on each ſide, larger than the others. This is the *lucioperca* or *harſe*. 3. The *pearch* with eight or nine black tranverſe lines on each ſide. This is the *aſper piſciculus* of authors.

Of thoſe *pearch* which have only one fin on the back, the following are the ſpecies: 1. The *pearch* with one back-fin, and a cavernous head. This is the *cernua* of authors. 2. The *pearch* with one back-fin, with black longitudinal lines on each ſide. This is the fiſh called by the Germans *ſchraitſer*. 3. The *pearch* with ſeven tranſverſe black lines on each ſide, and with red and blue marks on the head and belly. This is the *perca minima auctorum*. 4. The *pearch* with thirteen rays in the back-fin, and forty in the *pinna ani*. This is the *labrax* of authors, by ſome called the *lupus marinus*; and by others *ſpigola*; we call it a *baſſe*. *Artedi* Gen. Piſc. p. 38.

The name *perca* is of Greek origin, and is derived from the word πέρκος, which ſignifies variegated with black or duſky ſpots; a character common to moſt of the ſpecies of this fiſh.

The common *pearch* affords good ſport for the angler. The beſt time for their biting is, when the ſpring is over, and before the heats of ſummer come on. At this time they are very greedy, and the angler, with good management, may take at one ſtanding all that are in the hole, be they ever ſo many.

The proper baits are a minow or young frog; but the worm called the *branding*, well ſcowered, is alſo excellent at all times of the year. When the *pearch* bites, he ſhould always have a great deal of time allowed him to ſwallow the bait. The *pearch* will bite all day long, if the weather be cloudy; but the beſt time is from eight to ten in the morning, and from three till ſix in the afternoon. The *pearch* is very abſtemious in winter, and will ſeldom bite in this ſeaſon of the year; if he does at all, it is in the middle of the day; at which time indeed all fiſh bite beſt at that ſeaſon.

If the bait be a minow, which is the bait that affords moſt diverſion to the angler, it muſt be faſtened to the hook alive, by putting the hook thro' the upper lip or the back-fin; it muſt be kept at about midwater, and the float muſt be a quill and a cork, that the minow alone may not be able to ſink it.

The line muſt be of ſilk, and ſtrong; and the hook armed with a ſmall and fine wire, that if a pike ſhould take the bait, as is not unfrequently the caſe, he may be taken. The way to carry the minows or ſmall gudgeons alive for baits, is this: A tin pot is to be provided with holes in the lid, and filled with water, and the fiſh being put in this, the water is to be changed once in a quarter of an hour by the holes, without taking off the lid at any time, except when the bait is to be taken out.

A ſmall caſting-net made for theſe little fiſh ſhould be taken out with the *pearch* tackle, and one or two caſts of this will take baits enough for the day, without any farther trouble. When the bait is a frog, the hook is to be faſtened to the upper part of the leg. The beſt place for the fiſhing for *pearch* is, in the turn of the water near ſome gravelly ſcour. A place of this kind being pitched upon, it ſhould be baited over night with lobworms choped to pieces; and in the morning on going to it, the depth is to be regularly plumbed, and then the hook is to be baited with the worm or other bait; and as it drags along, the *pearch* will ſoon ſeize upon it.

PERCA *amboinenſis*, in zoology, the name of a freſh water fiſh, ſomewhat reſembling our pearch, but differing in that it is of a brown colour, and has ſeveral blue lines under its ſnout, and ſome blueneſs in the adjoining fins, but its back and belly fins are green. It is caught in the lakes and rivers of freſh water, at Amboina, and is a very delicately taſted fiſh. *Ray*'s Ichthyogr. Append. p. 1.

PERCA *aurata*, the *gilded pearch*, a fiſh of the ſhape of the pearch, but remarkable for a gold colour about its gills: it is common in our rivers, and is called in Engliſh a *ruffe*; its more common name among authors is *cernua*. *Geſner* de Piſc. p. 825. See CERNUA.

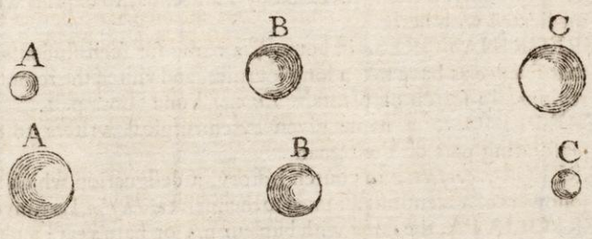
PERCA *marina*, the *ſea pearch*, in zoology, the name of a ſea fiſh, much reſembling the common freſh water pearch in ſhape, ſize, and colours, but ſomething thinner in proportion to its length, and more variegated.

Its back is variegated with ſix or ſeven blackiſh tranſverſe lines, like thoſe of the pearch, and the intermediate ſpace is of a ſomewhat reddiſh hue, eſpecially toward the head. Its whole head, and part of its belly, are very elegantly variegated with red and blue ſtreaks. Its back fin is of a pale yellow, with ſeveral reddiſh yellow ſpots, and is very long, and has its anterior rays terminated in ſpines. Its mouth is extremely wide, and almoſt always gapes open; its teeth are ſharp, and its eyes very large. It is very common in the Mediterranean, and is a well-taſted fiſh. *Rondelet.* de Piſc. p. 120. *Geſner* de Piſc. p. 819.

PERCOLATION *(Cycl.)*—Many have attempted the condenſing of wines by *percolation*, or ſeparating from them that ſuperfluous moiſture or water, which dilutes them below the true ſtandard of vinous liquors, in order to make them richer and fitter for keeping; but it does not appear that ſuch attempts have as yet ſucceeded. See *Stahl*, de concentr. vin.

PERCUNOS, the name of an antient Pruſſian idol. See the article POTRIMPOS.

PERCUSSION *(Cycl.)*—If an elaſtic body ſtrike a larger elaſtic body at reſt, the ſmaller body will always rebound, and move in a contrary direction to what it did at firſt, and alſo give the larger body a greater quantity of motion than what was originally in the ſmaller body. And this quantity of motion communicated, may be greater than the original motion, in any ratio leſs than that of 2 to 1. For ſuppoſing the ſmall body and its velocity, to be denoted by unity, and the larger body at reſt by x, the velocity of x after the ſhock will be $\frac{2}{1+x}$, and its quantity of motion will be $\frac{2x}{1+x}$. But tho' the proportion of $2x$ to $1+x$ increaſes when x increaſes, yet its limit will be the proportion of 2 to 1; which is the limit to which the motion of x may approach indefinitely near.



Hence it follows, that if the force of moving bodies be meaſured by their quantity of motion, a body may, by *percuſſion*, immediately communicate a greater force than itſelf has to another, and this in any proportion leſs than double.

But if other elaſtic bodies be interpoſed, a body may mediately communicate a greater force than its own to another larger body x, in any proportion leſs than that of $x\sqrt{x}$ to 1. Thus if $x = 1000000$, the body 1 with the velocity 1, may, by the means of intermediate bodies, give it the force 999000000; and the ſum of the abſolute forces of all theſe bodies taken together, ariſing from the *percuſſion*, may exceed the force of the firſt or unity, in any ratio leſs than $2x\sqrt{x}$ to 1, or 2000000000 to 1, altho' the relative force in all caſes remains as at firſt $= 1$.

Theſe are paradoxes which cannot be urged againſt thoſe who maintain the forces of bodies to be meaſured by their maſſes and the ſquares of their velocities.

It is alſo to be obſerved, that thoſe who meaſure force by the quantity of motion, muſt deny that there is any force loſt by the impreſſions made on ſoft bodies, or by the bending of elaſtic bodies: for if any were loſt from ſuch cauſes, the ſum of the quantities of motion of bodies moving the ſame way, could not remain the ſame before, during, and after the ſhock, which is an univerſal rule admitted by the Newtonians. But they admit that a ſpring bent between two bodies may, by unbending itſelf, generate motion in theſe bodies. Hence it follows, that according to this doctrine, tho' a ſpring may give motion to bodies, it cannot, by a contrary action, take it away; which ſeems no ſmall paradox.

If a body A move towards the body C, at reſt, and an intermediate body B of a mean magnitude be placed at reſt between them, ſo that A firſt impels B, and then B impels C, a greater motion will be given to C than if A had ſtruck it directly. And if B be a mean proportional between A

and C, the velocity communicated to C will be the greateſt that can be. *Huygens*, de mot. Corp. ex Percuſſ. Prop. 12.

If more bodies be interpoſed between A and C, the motion of C will be greater; and it will be the greateſt when the bodies interpoſed conſtitute a ſeries of mean proportionals between A and C. Ibid. Prop. 13.

If there be a ſeries of an hundred bodies in the proportion of 1, 2, 4, 8, 16, &c. and the motion begins by the greateſt body, the velocity communicated to the ſmalleſt will be to that with which the greateſt moved nearly as 2,338,500,000,000 to 1. And if the motion begins by the leaſt body, the quantity of motion will be increaſed on the whole nearly as 1 to 4,677,000,000,000. *Huyg.* ib.

But it is to be obſerved, that there is a miſtake in the impreſſion of Huygens's book, as to the firſt number, which is there printed 14,760,000,000, inſtead of 2,338, &c. ſo that the velocity thus given to the ſmalleſt body is 150 times greater than what the printed copy of Huygens aſſigns. *Bernoulli*, Diſc. ſur le Mouv. Oper. Tom. 3. p. 34. and *S. Graveſande*, Pref. ad Huygen. Oper. Poſth. Tom. 2. Amſt. 1728.

This ſtupendous augmentation of the quantity of motion, is a remarkable inſtance of the falſity of the Carteſian prin-

ciple, that the ſame quantity of motion is always preſerved in the world.

Some have thought this augmentation no ſmall difficulty againſt thoſe who maintain the moving force or power of action in bodies, to be proportional to their quantities of motion. This difficulty does not preſs the Leibnitians; for it is to be obſerved, that notwithſtanding the prodigious increaſe of motion here aſſigned, yet there is no increment of the *vis viva* of this ſyſtem of bodies. See the articles FORCE and VIS *viva*

A learned author has urged, that if the force of bodies were in proportion to their quantities of motion, the increaſe in the motion here mentioned might be employed to reſtore the motion of the firſt body, and hence make a perpetual motion. But it is anſwered, that as the motion of the laſt is increaſed in the ſame direction with the firſt, the motion of all the reſt will be in the contrary direction, and equal to that of the laſt diminiſhed by unity: hence the ſum of the motions in the ſame direction, remains as it did, equal to that of the firſt and ſmalleſt body, which we ſuppoſe unity. See *Maclaurin*'s Demonſtrat. des Loix du choc des Corps, p. 21. Paris, 1724. and *S. Graveſand.* rem. ſur la poſſibilité du mouvement perpetuel in Journ. Liter.

It is to be obſerved, that there is a limit which the velocity communicated to the laſt body never amounts to, (ſuppoſing the firſt and laſt bodies, and the velocity of the firſt before the ſtroke, to be given) but to which it approaches continually, while the number of ſuch bodies interpoſed between the firſt and laſt is always increaſed. And this limit is to the velocity of the firſt body before the ſtroke, in the ſubduplicate ratio of the firſt body to the laſt.

Mr. Huygens has not mentioned this limit, but the curious may ſee the determination of it in Mr. Maclaurin's fluxions, art. 514. In the caſe mentioned by Huygens, this limit will be a number expreſſed by fourteen figures, for its logarithm is 14.9004850.

PERDIX, the *partridge*, a bird well known and eſteemed at table, of which naturaliſts enumerate five ſpecies. 1. The common *partridge*. 2. The Braſilian *partridge*, called *iambu*, of a duſky yellow colour, ſpotted with brown: of this there are two ſpecies, a larger and a ſmaller. See the article IAMBU. 3. The *perdix damaſcena* of Aldrovand, which reſembles our *partridge*, but its feet are yellow and its beak longer. 4. The red-legged *partridge*, common in France and Italy, and called there *cotumo*. See COTUMO. And, 5. The Græcian *partridge*, which is twice as large as ours, and not ſeeming to differ from the *cotumo* in any thing but ſize: they are all very finely taſted birds, but none are ſo delicate as the *cotumo*. *Ray*'s ornithology, p. 119.

PERDIX *alba*, the white *partridge*, a name given by many to the *lagopus*, a rough-footed bird of the gallinaceous kind, common on the ſnowy mountains, and by ſome called the *rabolane*. See the article LAGOPUS.

PERDIX *marina*, the *ſea-partridge*, a name given by ſome authors to the ſoal-fiſh, from the firmneſs and delicacy of its fleſh. *Bellon.* de Aquat. Vol. I. p. 34.

PERDIX, in conchyliology, a name given by authors to a genus of ſhells, ſuppoſed to reſemble the partridge in the ſhades and diſpoſition of the colours.

The partridge-ſhell is of the *dolium*, or *concha globoſa* claſs, and is ſtriated and ſpotted in a peculiarly elegant and regular manner. See DOLIUM.

PERDONIUM, a term, invented by Paracelſus, to expreſs wine medicated with herbs.

PEREGRINATORES, in botany, a name for ſuch ſtudents in that ſcience as have taken long journies, and viſited the remoteſt regions, in ſearch of plants. *Linnæi* Fund. Bot. p. 1.

PERETERION, a name given by chirurgical writers to the perforating part of the trepan.

PERFECT, *perfecti*, in church hiſtory, a deſignation which the followers of Valentinus aſſumed to themſelves. *Hoffm.* Lex. invoc.

PERFOLIATA, the ſame with bupleurum, or hare's ear; a plant recommended by authors as a vulnerary of the firſt claſs. It is applied externally to contuſions, freſh wounds, and luxated joints.

There are many who eſteem it a remedy even for the king's evil, and its virtues in the cure of navel-ruptures have long been famous: but all this wants proof. See HARE's *ear*.

PERFOLIATE-*leaf*, among botaniſts. See LEAF.

PERFORATA, in botany, a name given by ſome authors to the *hypericum*, or St. John's wort, from the ſmall holes ſeen all over its leaves, if held up to the light. *Ger.* Emac. Ind. 2.

PERFORATUS *(Cycl.)*—PERFORATUS *brachii*, in anatomy, a name given by Placentini to a muſcle of the arm, now generally known by the name of the *coraco-brachialis*. It has been by many diſputed not to be a diſtinct muſcle. Veſalius calls it only *pars interioris principii cubitum flectentium primi carnoſa*, eſteeming it only a part of that muſcle. Many of the writers who followed Veſalius have given it alſo the name of *pars* and *portio*, not eſteeming it a diſtinct muſcle: and Caſſerius, who wrote after Placentini, calls it only *portio carnoſa*, and cenſures that author for thinking it a diſtinct muſcle, and calling it *perforatus*.

PERIAMMA, a word uſed by ſome medical writers to expreſs an amulet.

PERIANTHIUM, in botany, expreſſes that ſort of cup which conſiſts of ſeveral leaves, or elſe of one leaf divided into ſeveral ſegments, and ſurrounds the lower part of the flower. See the article CALYX.

PERIAGOGE, Περιαγωγὴ, in rhetoric, the ſame with peribole. See the next article.

PERIBOLE, a word uſed very frequently by Hippocrates, and in different places, in very different ſenſes. Sometimes it ſignifies a tranſlation of the humors from one part to another; ſometimes only the dreſs or garments of a patient. In the firſt of theſe ſenſes, the word is frequently uſed to expreſs a tranſlation of the morbific matter from the center to the ſurface, in the termination of a diſeaſe, by the breaking out of puſtules all over the body.

PERIBOLE, Περιβολὴ, in rhetoric, is uſed where many things are accumulated into one period; which might have been divided into ſeveral. We have an inſtance in Cicero's defence of Flaccus: *Quod ſi eſſet aliquando futurum, ut aliquis de L. Flacci pernicie cogitaret; nunquam tamen exiſtimavi, Judices, Decium Lælium, optimi viri filium, optimâ ipſum ſpe præditum, ſummæ dignitatis, eam ſuſcepturum accuſationem, quæ ſceleratorum potius civium odio, & furori, quam ipſius virtuti, atque inſtitutæ adoleſcentiæ, conveniret.*

Now this long period might very well have been divided into the three following: 1. *Quod ſi eſſet aliquando futurum, ut aliquis de L. Flacci pernicie cogitaret; nunquam tamen exiſtimavi, judices, Decium Lælium, eam ſuſcepturum accuſationem.* 2. *Eſt enim is optimi viri filius, optimâ ipſe ſpe præditus, ſummæ dignitatis.* 3. *Accuſatio vero hæc ſceleratorum potius odio et furori, quam ipſius virtuti atque inſtitutæ adoleſcentiæ, conveniret. Voſſii* Rhet. l. 6. p. 439. ſeq. See PUNCTUATION, *Cycl.*

PERICALAMITIS, in the materia medica of the antients, a name given by ſome to the *adarce*.

We find the word *pericalamitis* in a deſcription recorded in Galen, and it has generally been underſtood to mean *ſtyrax*, that being called *calamita*: but the *adarce* is the thing ſignified by the name, which expreſſes its manner of formation, it being always found concreted about the ſtalks of reeds that grow on the edges of waters. *Galen* l. 1. See ADARCE.

PERICARDIUM *(Cycl.)*—We read of a *pericardium* of a monſtrous ſize, out of which above three pounds of coagulated blood and ſerum were taken. See Medic. Eſſ. Edinb. Vol. V. art. 56.

PERICARPIUM, among botaniſts, a covering or caſe for the ſeeds of plants: it is the germen of the piſtil enlarged. There are no leſs than nine ſpecies of *paricarpia*: 1. A capſule. 2. A conceptaculum. 3. A pod. 4. A legume. 5. A nut. 6. A drupe. 7. An apple. 8. A berry. 9. A ſtrobilus. See CAPSULE, CONCEPTACULUM, *&c.*

PERICHAREIA, a word uſed by the antients to expreſs a ſudden ſurprize of joy, ſuch as has been frequently known to occaſion death.

PERICHRISIS, a word uſed by the antients for a liniment, principally of the oleaginous or ſpirituous kinds, and as thin and fluid as oil.

PERICLASIS, a word uſed by the antients for a fracture of a limb, attended with a large wound, by which the broken ends of the bone, or part of it, are laid bare.

PERICLYMENUM, *wood-bind* or *honey-ſuckle*, in botany, the name of a genus of plants, the characters of which are theſe: the flower conſiſts of one leaf, and is tubular, and divided into ſeveral ſegments at the edges; the cup finally becomes a roundiſh juicy fruit or berry, containing a compreſſed ſeed of a rounded ſhape.

The ſpecies of *periclymenum*, enumerated by Mr. Tournefort, are theſe: 1. The ever green Virginian long flowering *periclymenum*: and, 2. The yellow flowered Indian *periclymenum*. *Tourn.* Inſt. p. 608.

PERICNEMIA, a word uſed by ſome medical writers for the parts about the calf of the leg.

PERIDONIUS *lapis*, in natural hiſtory, a name given by ſome of the writers of the middle ages to the *pyrites*, which they call alſo *perithe*.

PERIDROMIDES, Περιδρομιδες, in antiquity. See XYSTI.

PERIDROMOS, a word uſed by the old Greek writers to expreſs the extreme edge of the hairs of the head, when hanging down in their natural form.

PERIESTECOS, in medicine, an epithet for diſeaſes, ſigns, and ſymptoms, which are ſalutary, and prognoſticate the future better health of the patient.

PERIGRAPHE, a word uſually underſtood to expreſs a careleſs or inaccurate delineation of any thing: but in Veſalius it is uſed to expreſs the white lines or impreſſions that appear in the muſculus rectus of the abdomen.

PERILEUCOS, in the natural hiſtory of the antients, a name given to an agate; but not of a diſtinct ſpecies, but only a particular appearance of the lead-coloured agate, more uſually known among them by the name of *phaſſachates*. See the article PHASSACHATES.

PERINEUCOS, an epithet given to a peculiar ſort of irregular pulſe common in hectic patients, in which the artery beats more ſtrongly in ſome parts than in others. See the article EPINEUCOS.

PERIOSTEUM *(Cycl.)*—The bones of the human body in their natural ſtate, are for the moſt part covered exteriorly by a membrane, called by the general name *perioſteum*. This is extended over the cartilages and ligaments alſo, as well as the bones; but when it covers the cartilages, it is called *perichondrium*, when the ligaments, *perideſmium*.

The *perioſteum* in general is a fine ſtrong membrane, or membranous expanſion, not equally thick in all its parts, more or leſs tranſparent, of a very cloſe texture, not eaſily yielding, extremely ſenſible, and compoſed of ſeveral planes of fibres differently diſpoſed, and mixed with a great number of fine veſſels and nervous filaments.

This membrane does not immediately ſurround thoſe portions of bones which are covered by cartilages, nor thoſe in which ligaments or tendons are inſerted; neither does it cover thoſe portions of cartilages which are expoſed to friction, as in the moveable articulations, channels, *&c.* and laſtly, it does not cover thoſe portions of the teeth which lie out of the ſockets and gums. The innermoſt plane of the fibrous texture of the *perioſteum*, or that which immediately adheres to the ſurface of the bones, is fixed thereto by an infinite number of ſmall fibrous extremities, brought from all the planes, and which enter the pores of the bones. Theſe extremities are accompanied by capillary veſſels and nervous filaments, which having run for ſome ſpace between the different planes of the *perioſteum*, perforate the innermoſt at the orifices of the pores of the bones. The *perioſteum* is of different thickneſſes, but this difference of thickneſs does not appear near ſo much on the outer ſurface, as on the inner; which is marked in many places with impreſſions, owing to the ſulci, depreſſions, lines, and inequalities on the ſurface of the bones.

Some anatomiſts have been of an opinion, that this membrane was not only united to, but cloſely braced round the bones; and that therefore it might ſet bounds to their growth. It is probable they had only examined a few bones on this occaſion, for had they conſidered thoſe which have concave ſurfaces, depreſſions, and inequalities, they would there have found only a ſimple adheſion of the *perioſteum*, without any tenſion. In places where it is only fixed to the bone by the filaments of its innermoſt plane, it is eaſily pulled off from the bones; but where the fibres of the other planes likewiſe penetrate the bones, eſpecially when theſe planes are very numerous, and where the inſertions of tendons and ligaments mingle with theſe fibres, the ſeparation is much more difficult.

The *perioſteum* in general ſerves to ſupport that admirable texture of an infinity of capillary veſſels, by which the bones and all the parts belonging to them are nouriſhed: it likewiſe ſupports a vaſt number of nervous filaments, by which ſenſation is communicated not only to this and to the internal membrane of the bones, but even, in ſome degree, to ſome portions of the bones themſelves. *Winſlow*'s Anat. p. 116.

PERIPHALLIA, Περιφαλλια, in antiquity, the ſame with *phalagogia*. See PHALLAGOGIA and DIONYSIA.

PERIPLOCA, in botany, the name of a genus of plants, the characters of which are theſe: the flower conſiſts of only one leaf, and is very open at the mouth, ſo as to reſemble a wheel; from the cup there ariſes a piſtil, which is fixed like a nail into the back part of the flower, and ripens into a fruit ſo like that of the *apocynum* or dog's bane, that authors in general have confounded the two genuſes. The pod is long, and is compoſed of two vaginæ, and ſplits open lengthwiſe from the baſe to the apex. *Tourn.* Inſt. p. 93.

The ſpecies of *periploca*, enumerated by Tournefort, are theſe: 1. The long-leaved *periploca*, with purple flowers. 2. The long and narrow-leaved one, called by the Ægyptians *ſecamone*. 3. The *periploca* of Monpelier, with roundiſh leaves, called by many authors *ſcammonia Monſpeliaca*. 4. The Montpelier *periploca*, with ſharp pointed leaves. 5. The American *periploca*, with a ſomewhat echinated fruit. 6. The broad American *periploca*, with a hard, oblong, ſmooth and tumid pod. 7. The white flowered climbing *periploca* of America, with very narrow willow-like leaves. 8. The low ſpreading American *periploca*, with leaves like thoſe of toad-flax. 9. Citron-leaved umbelliferous creeping *periploca* of America, with red flowers. 10. Creeping white-flowered American *periploca*, with leaves like thoſe of money-wort. 11. Citron-leaved climbing American *periploca*, with a very large fruit. And, 12. The climbing bindweed-leaved American *periploca*, with an alated fruit.

PERIPLYSIS, a name given by ſome authors to a diarrhœa, in which the ſtools are extremely thin and watry, and very frequent and large in quantity.

PERIPNEUMONY *(Cycl.)*.—This diſeaſe is very frequently confounded with the pleuriſy, and then one is miſtaken for the other, ſometimes even by phyſicians. As this, however, is a diſorder of the lungs, and the other of the pleura, there are ſymptoms attending them by which they may be certainly diſtinguiſhed. See PLEURISY.

PERIPYEMA, a word uſed by chirurgical writers to expreſs a collection of matter, wholly ſurrounding any part.

PERIRRHANTERION, Περιῤῥαντηριον, in antiquity, a veſſel, uſually of ſtone or braſs, filled with holy water, with which all thoſe that were admitted to the ſacrifices were ſprinkled; and beyond which it was unlawful for any one that was Βεβηλος, or profane, to paſs. Some ſay it was placed in the Αδυτον, or inmoſt receſs of the temple, into which none entered but the prieſt: but Caſaubon will have it to be placed at the door of the temple, which opinion ſeems moſt probable, becauſe all perſons who were Αβεβηλοι, or unpolluted, were permitted to paſs beyond it. *Potter*, Archæol. Græc. l. 2. c. 2. T. 1. p. 189.

PERISCYLACISMUS, Περισκυλακισμος, a method of purification in frequent uſe among the Greeks. It was done by drawing a whelp round the perſon to be purified. *Potter*, Archæol. Græc. T. p. 223. The word comes from σκυλαξ, a whelp.

PERISSON, in botany, a name given by the antient Greeks, and afterwards by the Romans, in the time of Pliny, to a kind of night-ſhade, which made thoſe people who took it internally run mad. It was called alſo *pentadrygon* and *anhydron*, and by ſome *manicum ſtrychnum*, or ſimply *manicon*. See the article STRYCHNUM.

PERISSOSIS, a word uſed by Hippocrates to expreſs a redundance of humours.

PERISSOLOGY, Περισσολογια, in rhetoric, a quality of ſtile directly oppoſite to *brachylogy*, and is otherwiſe called *macrology*. See MACROLOGY, BRACHYLOGY, and DICTION.

PERISTERION, in botany, a name given by ſome authors to the *ſcabioſa minor*, or ſmall ſcabious. *Ger.* Emac. Ind. 2.

PERISTERITES, the *pigeon-ſtone*, in natural hiſtory, a name given by ſome whimſical people to an odd conformation of a pebble, which they ſuppoſe to repreſent very exactly a pigeon without its wings. It ſeems to have been a mere *luſus naturæ*, in the formation of a common pebble. The variations of figure in the common pebbles are ſo infinite, that a perſon of a fertile imagination might find reſemblances to all the parts of the creation in the ſtones of a ſingle gravel-pit. The giving names to ſuch accidental things is not only unneceſſary, but miſchievous, as it cauſes great confuſion in natural hiſtory.

PERISTERNA, in anatomy, is uſed for the lateral parts of the thorax.

PERISTIARCHUS, Περιστιαρχος, in antiquity, a name given to the perſon that officiated in a luſtration. *Potter*, Archæol. Græc. T. 1. p. 35.

The word comes from Περιστια, another name for Καθαρμαλα.

PERISTOMA, in anatomy, a word uſed by authors to expreſs the villous coat of the inteſtines.

PERISTYLION, Περιστυλιον, among the Athenians, a large ſquare place, tho' ſometimes oblong, in the middle of the *gymnaſium*, deſigned for walking, and the performance of thoſe exerciſes which were not to be performed in the *palæſtra*. *Pott.* Archæol. Græc. l. 1. c. 8. T. 1. p. 39.

PERITERE, in architecture, a place encompaſſed round with columns, and with a kind of wings about it. Here the pillars ſtand without, whereas in the periſtyle they ſtand within.

PERITEXIS, a word uſed by the old medical writers to expreſs a colliquation.

PERITHE, a name by which ſome of the writers of the middle ages have called the *pyrites*; they ſay it has great virtues againſt the gout: ſome of them alſo have called it the *lapis peridonius*.

PERITONEUM *(Cycl.)*—In the fiſh kind, the *peritoneum*, or membrane ſurrounding the abdomen, is very variouſly coloured. In ſome it is of a ſhining ſilvery whiteneſs, as in the cyprini, perch, eſoces, *&c.* In others it is of a fine pale fleſh colour, as in the ſalmon; and in ſome it is wholly black, or elſe variegated with very numerous black ſpots, as in the clupeæ, gadi, cotti and ſpari. *Artedi*'s Ichthyolog.

PERIWINKLE, in natural hiſtory, the Engliſh name of a ſpecies of ſhells, called by authors *buccina*. See BUCCINUM.

PERIWINKLE, *pervinca*, in botany. See PERVINCA.

PERIZOMA, a word uſed by ſome authors for a truſs.

PERMISSION, *permiſſio*, in rhetoric, a figure which differs in nothing from *conceſſion*, except that the latter relates only to argument and pleading, but the former to action: E. G. *Quoniam, omnibus rebus ereptis, ſolum mihi ſupereſt animus et corpus: hæc ipſa, quæ de multis relicta ſunt, vobis et veſtræ condono poteſtati. Vos me quo pacto vobis videtur, utamini, atque abutamini; licebit impunè. In me, quicquid libet, ſtatuite,* &c.

PERNIONES, *childblains*. When theſe tumours tend to ſuppuration, it is proper to treat them like other recent abſceſſes; the beſt method is firſt to cleanſe the wound with ſome digeſtive ointment, then to dreſs it with balſam of Peru, or other the like application; and laſtly, to apply ſome of the lead or litharge plaiſters. Oil of myrrh *per diliquium* is alſo found of vaſt ſervice in theſe caſes, as is alſo the applying a compreſs dipped in a mixture of equal parts of lime-water and camphorated ſpirit of wine, over the other remedies.

In people who have been uſed to be afflicted with *chilblains* at the return of a certain ſeaſon, it will be found a great preſervative againſt thoſe troubleſome tumours, to anoint the parts where they are expected to appear, both before and during the acceſs of the ſevere cold, with oil of turpentine or petroleum; and when the diſorder firſt begins to ſhew itſelf, it is a very good method to wrap round the affected part a piece of a hog's bladder, well wetted with one or other of thoſe oils, and care taken to keep off the cold. *Heiſter*'s Surg. p. 211.

PERODACTYLÆUS, in anatomy, a name given by Riolan and others to one of the muſcles of the foot, called by Albinus the

the *flexor longus digitorum pedis*, and by Winslow, the *perforans pedis*, and the *accessorius perforantis pedis*.

PERONÆUS (*Cycl.*)—PERONÆUS *maximus*, a muscle of the leg, commonly called *peronæus posterior*.

It is long and penniform, and lies on the fibula. It is fixed above to the anterior and outer part of the head of that bone, and to a small portion of the head of the tibia; then to the outside of the neck of the fibula, to the upper half of the external angle of that bone, and to the aponeurosis tibialis; which at that place makes a septum between this muscle and the extensor pollicis; from hence turning backward according to the direction of the bone, it forms a considerable tendon; which running down behind the external malleolus is inserted in the side of the basis of the first metatarsal bone, and a little in the basis of the os cuneiforme majus. *Winslow*'s Anatomy, p. 221.

PERONÆUS *medius*. This is commonly called *peronæus anticus*, and is a long muscle situated anteriorly on the middle part of the fibula. It is fixed above by fleshy fibres to more than the middle third part of the anterior or outside of the fibula, and to the neighbouring part of the aponeurosis tibialis. It is likewise fixed to a production from the inside of that aponeurosis, which runs to the upper part of the tibia, and there serves for a middle septum between this muscle and the extensor digitorum longus; from thence it runs down and forms a tendon, which going in the direction of the oblique line of the fibula, passes behind the external malleolus, and then thro' an annular ligament common to it and to the *peronæus maximus*, and is afterwards inserted in the tuberosity, at the basis of the fifth metatarsal bone, sending off a small tendon to the first phalanx of the little toe. *Winslow*'s Anatomy, p. 218.

PERONÆUS *minimus*, a small muscle vulgarly thought to be a portion of the extensor digitorum longus, tho' it is easily separable from it.

It is fixed by fleshy fibres in the lower half of the inside of the fibula, between two oblique bony lines, on one side of the lower part of the extensor digitorum longus, to which muscle it is simply contiguous; from thence it runs down, contracting in breadth, and passes, with the extensor longus, thro' the common annular ligament, forming a flat tendon, which soon separates from those of the extensor, and is inserted near the basis of the fifth metatarsal bone. It is distinguished from the other two *peronæi* by a septum, or production of the ligamentary aponeurosis of the tibia. *Winslow*, Ibid.

PEROQUETTE, in zoology, the name of a small species of the *psittacus* or parrot kind, with a long tail.

There are several kinds of this bird: 1. The common, which is green, red, and yellowish, and was the first species of parrot brought into Europe, and well known among the antients. 2. The *peroquette*, which is green all over, without any variegation. 3. The pale, green, and red kind. 4. The red and green crested kind. 5. The red kind, with wings variegated with black and green.

Beside these, Marggrave has described seven other Brasilian kinds, called the *tuiaputejuba*, *tuitirica*, *jendaya*, *tuiete*, *tuipara*, *anaca*, and *quijubatui*, which see under their several names; and two others, to which no particular name has been given; one of the size of a swallow, all over green, with a black beak and a very long tail; and the other of the size of a starling, of a deep green on the back, and paler green on the belly, and with a shorter tail. *Ray*'s Ornithology, p. 76, 77, 78.

PERPENDICULAR-*roots*. See FIBROSE-*roots*.

PERSIAN-*shell*, a species of dolium. See DOLIUM.

PERSICA, the *peach-tree*, in botany, the name of a genus of trees, the characters of which are these: The flower is of the rosaceous kind, being composed of many petals, arranged in a circular form. The pistil arises from the cup, and finally becomes a fleshy fruit of a roundish figure, sulcated lengthwise, and containing a stone rough and full of irregular holes, containing an oblong kernel.

The species of *peach*, enumerated by Mr. Tournefort, are these: 1. The common green white soft fleshed *peach*. 2. The double flowered *peach*. 3. The *peach* with blood-red juice. 4. The hard *peach*, with white or flesh-coloured pulp. 5. The hard *peach*, with box-coloured pulp. 6. The summer apricot *peach*, or john *peach*. 7. The early ripe *peach*. 8. The fine flavoured corbelian *peach*. 9. The hardest *peach*. 10. The paler *peach*. 11. The *peach* with sweet-scented fruit, with a smooth skin. 12. The *peach* with a round dusky red, very sweet-tasted fruit. 13. The *peach* with a large round firm sugar-like fruit. 14. The large round yellow late *peach*, called the *admirable yellow*. 15. The *peach* with large round blackish late-ripening fruit. 16. The great scarlet *peach*. 17. The *peach* with a fruit variegated with purple and red, and of a rich vinous taste. 18. The early violet-coloured vinose *peach*. 19. The *peach* with red, roundish-flatted fruit, with red flesh. 20. The dwarf African *peach*, with single flesh-coloured flowers. 21. The dwarf African *peach*, with double flesh-coloured flowers. *Tourn.* Inst. p. 614. See PEACH.

PERSICA *concha*, in natural history, a name given to a very remarkable and beautiful sea shell, which authors have long been at a loss to reduce to any genus.

Aldrovand has thrown it to the end of his work, and says, it would be of the turbinated kind, if it did not want the turba. It is truly of the genus of the *concha globosa*, or *dolium*. See DOLIUM.

PERSICA *terra*, in natural history, an earth of the ochre kind, known in the colour shops of London by the name of *Indian red*.

It is a very fine purple ochre, of a considerably compact texture, and great weight; while in the earth it is of a pure blood colour, and is not to be cut with the spade, but is dug with iron crows, and falls in irregular masses. It is of a rough dusty surface, and full of considerably large bright glittering particles: these are white and of a fine lustre. It adheres firmly to the tongue, is rough and harsh to the touch, stains the hands very deeply, and is of a rough astringent taste, and makes a very violent effervescence with acid menstruums.

It is dug in the island of Ormuz, in the Persian gulf, and in some parts of the East Indies. *Hill*'s Hist. of Foss. p. 58.

PERSICARIA, *arsmart*, in botany, the name of a genus of plants, the characters of which are these: The flower is of the apetalous kind, consisting of several stamina which arise from a cup divided into several segments. The pistil finally becomes a fruit of a flatted oval figure, and pointed at one end, and contained in the capsule, which was the cup of the flower.

The species of *persicaria*, enumerated by Mr. Tournefort, are these: 1. The common mild or spotted *arsmart*. 2. The spotted *arsmart*, with spots of the figure of a horse-shoe. 3. The mild *arsmart* without spots. 4. The white flowered mild *arsmart*. 5. The burning *arsmart*, or water pepper. 6. The burning *arsmart*, with white flowers. 7. The lesser *arsmart*. 8. The white flowered lesser *arsmart*. 9. The narrow-leaved *arsmart*. 10. The long and narrow-leaved *arsmart*, called the *long-leaved and water pondweed*. 11. The long-leaved Valentia *arsmart*. 12. The *arsmart* with leaves hoary underneath. 13. The great dock-leaved *arsmart*, with purple cups. 14. The black-leaved alpine *arsmart*, with white cups. 15. The *arsmart* with lepidium leaves. 16. The long procumbent *arsmart*, with narrow not spotted leaves, and long slender spikes. 17. The white flowered shrub spotted Virginian *arsmart*. 18. The shrub spotted Virginian *arsmart*, with flesh-coloured flowers. *Tourn.* Inst. p. 509.

The common *arsmart* without spots, is by some esteemed a good diuretic, but it seems too acrid to be given internally without great caution. Externally it is used by many in cataplasms against indurated tumors, and in inveterate ulcers. That with spotted leaves has no virtues.

PERSOLATA, in botany, a word used by Pliny as the name of a kind of burdock, different from the *personata*.

He has, in the beginning of the chapter, spoken of the arcium of the Greeks, which he says the Latins sometimes called *personata*, and afterwards adds this *persolata*; which, he says, was a plant vulgarly known and called by the Greeks *arcium*.

He seems to allow, that the Greeks called both these plants by the same name; but he distinguishes the *persolata* from *personata*, by saying that the former has leaves like those of the great gourd, but larger and more hairy. It is probable, therefore, that he distinguishes under these two names, the two different species of the great burdock common with us, the one with simple, the other with woolly heads.

PESONATA, in botany, a name by which some have expressed the common great burdock. *Bauhin*, v. 3. p. 111.

PERSONATED-*flower*. See PERSONATI, *Cycl.*

PERSPECTIVE (*Cycl.*)—*Military* PERSPECTIVE, that wherein the eye is supposed to be infinitely remote from the table or plane.

PERSPICUITY, *perspicuitas*, in rhetoric, is a principal virtue of stile, to which all the ornaments and beauties of speech ought to give way.

A discourse is equally obscured by too much conciseness and profuseness. (See BRACHYLOGY and MACROLOGY.) Several rhetorical figures are likewise destructive of *perspicuity*. See *Voss.* Rhet. l. 4. c. 1. p. 30, seq.

PERSPIRATION (*Cycl.*)—*Perspiration* is influenced by the passions of the mind. Thus anger and joy increase, and fear and sadness lessen both *perspiration* and urine. Anger causes a strong motion in the membranes of the heart, and quickens its contraction and dilatation, and thereby quickens the contraction and dilatation of the blood vessels and secerning ducts, and of consequence increases the discharges of *perspiration* and urine; and that more or less, in proportion to the strength and continuance of the passion.

Joy affects these discharges in like manner as anger. In the passions of fear and sorrow, *perspiration* and urine are lessened, by the depression of the activity of the soul under those passions. Dr *Bryan Robinson* of the Food and Discharges of Hum. Bodies, p. 77, seq.

The proportion of *perſpiration* to urine is increaſed by all thoſe exerciſes which increaſe the motion of the blood, and warm the ſkin. Dr. *Bryan Robinſon* of the animal Œconomy, p. 280.

We have an account of a perſon, who by paſſing many nights in aſtronomical ſpeculations, had his *perſpiration* ſo obſtructed by the cold and damp of the air in Holland, that a ſhirt he had worn for five or ſix weeks was as clean as if it had been worn but one day. The conſequence of this was, that he gathered ſubcutaneous waters, but was cured in time. Phil. Tranſ. N° 8. p. 138.

We have ſeveral obſervations, experiments, and tables, relating to the quantity of *perſpiration*, urine, and ſtool, in South Carolina, by Dr. John Lining. See Phil. Tranſ. N° 470 and 475.

PERTICA, a ſort of comet, being the ſame with *Veru*. See the article VERU.

PERTICA, among the Romans, a long rod for beating the fruit from trees. It was likewiſe uſed for a long meaſure. See PERCH, *Cycl.*

PERVIGILIA, in antiquity, an appellation given to nocturnal feſtivals, celebrated in honour of ſeveral deities, as Ceres, Venus, Fortune, *&c.* They were ſo called becauſe the nights were ſpent in waking.

PERVINCA, *periwinkle*, in botany, the name of a genus of plants, the characters of which are theſe: The flower conſiſts of one leaf, and is of the funnel-ſhaped kind, but ſo very wide at the mouth, that it approaches to the ſaucer-ſhaped ones, and is divided into ſeveral ſegments at the rim. The piſtil ariſes from the cup, and is fixed in the manner of a nail to the hinder part of the flower: this, afterwards, becomes a ſeed veſſel, compoſed of two capſules, containing an oblong ſeed, uſually of a cylindric figure, and ſulcated. See Tab. 1. of Bot. Claſs 2.

The ſpecies of *pervinca*, enumerated by Mr. Tournefort, are theſe: 1. The common broad-leaved *periwinkle*, with blue flowers. 2. The common broad-leaved *periwinkle*, with white flowers. 3. The common narrow-leaved *periwinkle*, with blue flowers. 4. The common narrow-leaved *periwinkle*, with white flowers. 5. The common narrow-leaved *periwinkle*, with red flowers. 6. The common narrow-leaved *periwinkle*, with double blue flowers. 7. The common narrow-leaved *periwinkle*, with double flowers, of a deep purple. 8. The variegated double flowered *periwinkle*. 9. The broad-leaved variegated *periwinkle*. And 10. The narrow-leaved variegated *periwinkle*. The tree called *padrus*, approaches very much to this genus. *Tourn.* Inſt. p. 119.

The *pervincæ* are eaſily known, even when not in flower or ſeed, by their branches being long and trailing, and their leaves ſmooth and gloſſy, and approaching to the ſhape of bay-leaves. Theſe plants ſeldom ripen their fruit; and the way to make them do it is, to plant them in a ſmall pot, and cut off all the trailing branches; by which means the nouriſhment will be carried up to the ripening the fruit. *Tourn* Inſt. p. 120.

PERUVIAN *bark* (*Cycl.*)—The virtues of this medicine are at this time ſufficiently known; but the largeneſs of its doſe in the common forms of powder, or infuſion in wine or in water, are great diſadvantages; and our common method of giving it in the extract or reſin, as we prepare them, not certain, and have their inconveniency.

Mr. Geoffroy has attempted a method of giving the *bark* in all its efficacy, without its ill taſte, and in one third of the uſual doſe, by means of his dry extract; twenty four grains of which, it is very certain, contains the whole efficacy of a dram of the choiceſt *bark* in powder; and is found by experience to be wholly as efficacious, as certain, and as ſpeedy, and really poſſeſſes all that the juices of the ſtomach can extract from thrice the quantity of powder, without loading it with ſo large a quantity of uſeleſs matter.

The experiments this gentleman made to be aſſured of what was the efficacious, what the uſeleſs part of the *bark*, and what the quantity of each in the whole, were theſe. He put into a matraſs a dram of choice *bark* in fine powder, and pouring on it an ounce and a half of rectified ſpirit of wine, ſet the veſſel in a balneum mariæ till the ſpirit was high coloured, and had extracted all the tincture it could, and filtering this tincture, and evaporating it on a China-plate in a balneum mariæ, he obtained twenty grains of a dry extract; and then putting on two ounces of water on the remaining powder, he drew what tincture he could by this means, and evaporating that in like manner, he obtained three grains and a half of extract in the like dry form.

Thus, by the niceſt proceſs, twenty-four grains were all that could be ſeparated of the efficacious matter from a dram of *bark*, and the remaining powder, which was perfectly inſipid, weighed as much as was required to make up the dram, excepting ſix grains, which the author ſuppoſes to have been the fibrous and inſipid powder remaining in the filtre.

Hence it appears very evident, that when we take the *bark* in ſubſtance, it is only about a third part of what we are forced to ſwallow that can be of any uſe to us; and that the ſame portion is all we can expect in the virtues of any decoction or infuſion of it.

The reſin of the *bark* is of ſuch a nature, that it is capable of being penetrated by, and ſuſpended in boiling water, poured on the ſubſtance in fine powder; and ſo long as this water retains a certain degree of heat, it remains ſuſpended and inviſible in it, and the water is of a clear browniſh colour; but when the liquor becomes cooler, the reſin can be no longer ſuſpended, the whole becomes milky, and the reſin precipitates itſelf.

Wine, which is a liquor partly aqueous, partly ſaline, and partly ſpirituous, is a menſtruum much properer to extract the virtues of the *bark* than mere water, as it is much more able to diſſolve the juices or ſap condenſed and inſpiſſated in the *bark* of the tree; and for this reaſon a ſtrong infuſion of *bark* in this menſtruum remains clear, and keeps the reſin ſuſpended when cold. Thus it is the fire alone which can ſuſpend the reſin in a watry infuſion of the *bark*; and in a vinous one, the ſpirituous and inflammable part of the liquor does the ſame thing: and as the reſin of the *bark*, which there is great reaſon to believe poſſeſſes all the virtues of that medicine, is wholly precipitated from watry infuſions when cold, it is plain that there can be very little dependance placed on the common clear infuſions in this menſtruum: the remaining taſte in theſe infuſions is only a faint bitterneſs, which ariſes from the gummoſe and ſaline parts of the dried juices of the *bark*; the whole concrete which alone poſſeſſes the virtue of the medicine, being of the nature of thoſe bodies properly called *gum reſins*; which are but very imperfectly ſoluble in water, and of which wine is the proper diſſolvent.

In making the dry extract by means of water, the ſame author put a dram of fine powder of pick'd *bark* into a large quantity of water, and keeping it in a conſiderable heat in a matraſs twenty-four hours, and after that, filtring the liquor as hot as poſſible, that the reſin might not coagulate, he ſet it to evaporate on a balneum mariæ in China-veſſels; the reſin ſoon began to ſeparate itſelf, and a pellicle appeared on the ſurface of the liquor, of all the changeable colours of the breaſt of a pigeon; and this covering the extract when dry, made it appear as if gilt or browned over. This infuſion from a pint and half of liquor, yielded twenty grains of extract perfectly dry; and an ounce and half of ſpirit of wine being poured on the remaining powder, when it had extracted all the tincture it could, left only three grains of extract; ſo that the reſult of this proceſs was much the ſame with that begun with ſpirit of wine; and from the whole it appears very evident, that by this method of management, the whole virtue of the *bark* may be given in a third part of the doſe. Memoirs Acad. Science Par. 1738.

Peruvian-bark has been found very effectual in preventing colds. The method in which it was uſed, in a caſe mentioned in the Philoſophical Tranſactions, was, after due preparation, by bleeding or purging, to take two ounces of it every ſpring and fall. By this method, an habitual taking of cold, and a conſequent ſore throat was cured. Phil. Tranſ. N° 478. p. 3.

We have many accounts of the great effects of the *peruvian-bark* in the cure of gangrenes and mortifications. See Med. Eſſ. Edinb. Vol. 3. Art. 5. or its Abridgment, Vol. 1. p. 175, ſeq. We have alſo ſeveral accounts of the good effects of this medicine in ulcers and the ſmall pox. See Med. Eſſ. Vol. 5. Art. 10. or Abridgment, Vol. 1. p. 187.

Many inſtances are recorded in medical writers of the jaundice, dropſy, aſthma, and all the train of nervous diſorders, brought on in a ſurpriſingly ſhort time after an injudicious adminiſtration of the *bark*: among others the curious may conſult the Med. Eſſ. Edinb. Vol. 4. Art. 24.

The *peruvian-bark* is diſcovered to be effectual in the cure of mortifications from an internal cauſe. The hiſtory of this diſcovery is: In 1715, Mr. Ruſhworth, ſurgeon in Northampton, gave it to a patient labouring under a mortification; and having afterwards other proofs of its good effects in this diſeaſe, communicated his diſcovery in 1731. Mr. Amyand ſoon tried it in ſuch caſes, and found it ſucceſsful in ſeven. Mr. John Douglas confirmed this by the hiſtory of a patient of his, which he publiſhed in 1732; and Mr. Shipton ſoon after related his ſucceſs by this medicine, to the Royal Society. Mr. Ruſhworth and Mr. Amyand confine its uſe to mortifications, from an internal cauſe; the former thinks it is not proper in all caſes of that kind, particularly where there is no intermiſſion of the fever. Mr. Douglas ſeems to think it will ſucceed in all mortifications. All theſe three gentlemen gave half a dram for a doſe every fourth hour. Mr. Shipton increaſed the doſe to two ſcruples, and gave it while the fever continued. He propoſed to have it tried in nomæ, phagedenæ, herpes, or other chironian ulcers. Mr. William Arrot, who lived a conſiderable time in Peru, deſcribes the tree from which the *peruvian-bark* is got.

It grows in the country between two and five degrees ſouth latitude; it is tall, without branches to near the top, where it ſpreads out into a hemiſphere; its bark is of a dark colour

on the outside; its leaves resemble those of a plum-tree. There are four sorts of the *bark*, the reddish, the yellowish, the curling, and the whitish. The two first are the best kinds; the curled is got from young trees, and the white soon becomes insipid. The best sort grows about the city of Loxa. The Indians slice off the *bark* from the trees, and carry it to houses to be dried [a]. M. de la Condamine [b] says this tree is called *casscarilla*, and is very different from the *quina quina*. [[a] See Phil. Transf. N°. 446. sect. 1. [b] Mem. de l'Acad. des Scienc. 1738.]

PERYGUA, in botany, a name given by some authors to a plant of the cassine kind, called the *cassioberry* bush, and by some the *Paraguay tea*. *Dale* Pharm. p. 319.

PERYSIAS, a word used by authors to express wine of the last year's vintage.

PES *(Cycl.)*—Pes *leonis*, in botany, a name by which some authors express the *alchymilla*, or ladies mantle. *J. Bauhin*, V. II. p. 3981. *Chebræus*. 172.

PESCE *vacca*, the *cow-fish*, a name given by Augustino Scilla to a kind of dog-fish, not described by any author before his time, but accurately drawn by him in his book on petrifactions, on occasion of its teeth: many species of the *glossopetræ* of the island of Malta, and other places, being plainly the same with the teeth in the jaws of this fish.

PESSOMANTIA, Πεσσομαντεια, in antiquity, the same with *clromantia*, which see.

PESTERABLE, in our old writers, an epithet for such wares as *pester*, or take up much room in a ship. Stat. 32 *Hen.* VIII. c. 14. *Blount*, *Cowel.*

PESTILENTIAL *buboes*. By *buboes* in *pestilential* cases, the writers in physic not only express such tumours as arise under the arms, under the ears, and in the groin; but comprehend under this term those also which are situated in the neck, breast, arms, legs, and other fleshy parts of the body, which swell and inflame in *pestilential* fevers, and seem the consequences of the endeavours of nature to throw out the pestiferous matter which lay concealed in the body.

Pestilential buboes are distinguished from other tumors by their happening at a time and in conjunction with the plague, and from their being accompanied by the symptoms proper to that disease. These tumours appear sometimes sooner, sometimes later, in the course of the disease; in some they appear before the patient knows he has the infection, and in others two or three days elapse before their appearance: they are very seldom known to appear later than on the fourth day, and are sometimes joined with carbuncles; but tho' the *buboes* frequently appear without these, yet the carbuncles never appear without tumors.

Persons who have these tumors come on without any very bad symptoms, and have them maturate speedily, are in general the soonest freed from the distemper, insomuch, that the best method of giving relief in this terrible disease, consists in the carefully promoting and keeping up the *buboes* and tumors. All discutient or dispersing medicines are carefully to be avoided, and the physician's business is to assist nature in the throwing out, and most speedily bringing these tumors to suppuration.

The patient is to be confined to his bed on the first appearance of these, and with the help of internal medicines proper to hasten the suppuration of tumors, the parts affected are to be rubbed pretty strongly with the hands or cloths, and external, maturating and emollient cataplasms to be applied; of this kind is that of yeast, salt, and mustard-seed, all mixed together, or of yeast alone: by means of these the tense parts are relaxed and stimulated, and the suppuration greatly promoted; as also by the cataplasms of roasted onions, with Venice-treacle and butter; or of crumb of bread, with milk and saffron. Plaisters are also very useful on some occasions, in these cases, as the frequent renewal of the cataplasms exposes the patient too much to the external air, and these are not attended with that inconvenience.

The most famed plaisters on these occasions are that of Barbet, made of the diachylon, with the gum and mucilage plaister, of each half a pound; mustard seed in powder, three ounces; basilicon, four ounces, all mixed and made into a plaister: and that of Dr. Hodges, made of three ounces of oxycroceum, an ounce of galbanum, the same quantity of gum caranna, and two ounces of black pitch, reduced to the consistence of a plaister.

This may be used like the former; nor is that plaister to be esteemed a trifle, which is made of honey, flour, and the yolks of eggs.

Blistering and cupping, so much used by the antients to forward suppuration, are entirely laid aside by the modern physicians: but the celebrated German physician, Beintern, asserts, that *pestilential buboes* have been very frequently discussed, without being brought to suppuration, by the application of warm ashes alone; and that with very happy success: and he observes, that in this case the *pestilential* venom is not absorbed into the blood again, but is attracted and carried off by the ashes.

In some cases in this terrible distemper, the tumor comes to suppuration in a few days; in others it is some weeks before it can be brought to it, by all that can be done. When thoroughly suppurated, it is to be opened with the scalpel, if it does not break of itself; and after thus opening, when the matter has been discharged, it must be well cleansed. The best digestive in this case is the common ointment used on that occasion, mixed with a small quantity of Venice treacle, and balsam of sulphur made with oil of turpentine. At each dressing the matter is to be gently squeezed out of the abscess, and the ointment applied without tents, unless the opening prove very narrow; then applying over all a plaister of the common diachylon, or of honey and flower, the whole may be bound on, and this dressing continued till it is a proper time to heal with some vulnerary balsam.

There has been much dispute between the physicians of different ages about the proper time for opening *buboes* of this kind; some have been for making an immediate incision, and others even for extirpating the whole swelling, as soon as it appeared, by means of the knife; but the first of these methods has been found to be frequently attended with the ill consequences of ill conditioned fistulæ, stiffness, and loss of motion in the limb, and sometimes even with mortifications and gangrene; and the other too harsh, and dangerous in many parts of the body: and the present practice universally disallows both methods, being always for bringing the swelling to suppurate. *Heister*'s Surg p. 200.

The poison of the matter of these sores has been nicely and boldly enquired into, as to its nature and properties, by Dr. Alpranus of Prague, in the time of the plague there in 1680. This gentleman having launced a *pestilential* boyle, collected the matter from it, and putting it into a retort, luting the junctures with the receiver very closely and exactly, and applying by proper gradation the several degrees of fire; at first there came over a water, then a more fat and viscid liquor, of an oily nature; and lastly, there appeared in the neck of the retort, a salt.

The fire being taken away, and the vessels cooled, the Doctor prepared himself for the opening of them by stopping his ears with cotton, his nostrils with pessaries, and his mouth with pieces of spunge, all soaked in vinegar and Venice treacle. The moment the vessels were opened, however, there proceeded out of them a stench more horrible than can be conceived, and striking the Doctor with an universal trembling, in spite of his defence. He proceeded, however, to break the neck of the retort, and separating the fœtid salt from it, he ventured himself to taste it, and desired Mr. Reshel, the person from whom the matter was obtained, to do the same: it was found to have a most dreadfully piercing acrid taste, which the Doctor compares to that of *aqua regia*.

Hence he infers, that the most terrible symptoms of this fatal disease are to be accounted for: the stomach, wounded by so acrid a juice as this mingled among the blood, nauseates food, and is afflicted with continual vomitings: the guts, infested by the same unwelcome guest, are thrown into violent perturbations, whence arise those diarrhœas which often accompany the patient to his death; and from the horribly acrid quality of this juice, it is no wonder that such piercing pains are found in the *buboes*, and such burnings in the carbuncles that attend this disease.

Hence also, as he observes, it is, that sudorifics are the best remedies, since they allay the acrimony, and tend to expel the venomous juices thro' the pores. In this sickness at Prague this gentleman observed, that almost all who sweat plentifully recovered, whereas those who did not sweat, were mostly taken off. *Hook*'s Philosoph. Collect. N°. 2. p. 18.

Pestilential *carbuncle*. This is an inflammation that arises in time of *pestilential* contagion, with a vesicle or blister, almost like those which are caused by burning; but this inflammation generally terminates in a mortification, and putrefies the adjacent parts down to the bone, all about becoming as black as a coal.

This kind of inflammation always breaks out very speedily, sometimes even in an hour or two, attended with the most intolerable heat and pain. On opening it, there is always discharged a darkish limpid or watry sanies, and the flesh underneath is of a black colour, the mortification having then already seized it, and spreading more and more by degrees; but in those who recover, the mortification at length stops, and the putrefied flesh suppurates, and parts from the sound.

The size and number of these inflammations in the same patient, are both very various and uncertain; there is no part of the body but what they may infest, and they are generally, if not always, accompanied by buboes.

The immediate cause of these is a violent inflammation, excited in the blood by the *pestilential* venom; and the inflammation, from the nature of the case, is ever speedy, and always followed by sphacelation and corruption of the parts. What is remarkable is, that the parts and juices do not suppurate into matter, as is usual in other tumors, but whatever is internally corrupted, separates and entirely falls off: for the inflamed parts suppurate at the margin of the inflammation, so that if the patient does not die suddenly, the sphacelated parts are separated, and naturally thrown off.

Carbuncles are always a worse symptom than buboes in these cases,

caſes, eſpecially if the eruptions turn directly either livid or black; but if they are red firſt, and then gradually turn to a citron colour, the danger is leſs.

Thoſe *carbuncles* alſo which ariſe in the face, neck, breaſt, or arm-pits, are always accounted the worſt, and uſually kill the patient.

The chief buſineſs of internal medicines, in this caſe, is to keep the patient in a conſtant breathing ſweat; and the buſineſs to be aimed chiefly at in external applications, is to procure, as ſoon as poſſible, the ſeparation of the ſphacelated parts from the ſound. Some, therefore, uſe ſcarification alone in this caſe, and that with very good ſucceſs; for, by making a great number of inciſions in the corrupted parts, they let out the *peſtilential* venom which corrupted the blood. Others only open the bliſters, and afterwards waſh the parts with a mixture of camphorated ſpirit of wine and Venice treacle, and afterwards apply a maturating cataplaſm, made of four ſpoonfuls of honey, three ſpoonfuls of yeaſt, the yolks of two eggs, and half an ounce of ſoap, which are all to be mixed and applied warm to the part: others on the ſame occaſion uſe alſo, as a cataplaſm, a mixture of two ounces of flour and half an ounce of vinegar, made with water or ſkimmed milk into a proper form, and with an ounce of honey, and an ounce of powder of ſaffron, thoſe ingredients are to be thoroughly mixed in, and the cataplaſm to be applied warm, and renewed frequently, till the whole carbuncle ſeparates and falls off from the ſound parts; and this is a much better and ſafer method of extirpating the *carbuncle*, than by cutting it out at once, by which operation ſome have been known to have been killed upon the ſpot. When the greateſt part of the *carbuncle* is, however, of its own accord ſeparated from the ſound parts, the part where it adheres may always be ſafely divided with the ſcalpel; and this, indeed, is abſolutely neceſſary.

If an ill-conditioned and luxuriant fleſh grows internally in this caſe, either of itſelf, or from the extirpation of the *carbuncle* being made too ſoon, this muſt ever be neceſſarily entirely conſumed by the application either of the Ægyptian ointment, or of the following: Take two ſpoonfuls of honey, the yolks of two eggs, and of burnt alum, gentian, and birth-wort root in powder, each an ounce, make the whole into an ointment.

If the inflammation inclines the adjacent parts to a gangrene, it will be moſt proper to uſe the following application: Take ſalt of wormwood, half an ounce of the herb ſcordium, and of elder and chamomile-flowers each a handful, and of river water two pints and an half; when theſe have been well boiled and ſtrained, mix with the liquor ſix ounces of camphorated ſpirit of wine, and two ounces of Venice treacle; and let this be applied hot to the parts by means of double linnen rags being well wetted in it, and repeated frequently till the violence of the inflammation abates.

When the mortified fleſh of the carbuncle has ſeparated itſelf from the ſound part, it is neceſſary to cleanſe the ulcer perfectly with digeſtive ointments, leſt any of the matter remain there, and mix itſelf again by degrees with the blood; and this deterging of the ulcer is always to be continued till there remain no more ſymptoms of the *peſtilential* infection in the patient; and after this the wound may be healed like other ulcers.

In the laſt great plague in London, and in many other the like caſes, it was found the beſt and happieſt method with *carbuncles* to extirpate them at once by the actual cautery, or red hot iron, till the dead parts being burnt to the quick ones beneath, there were no relicts of the *carbuncle* left in the patient. And in ſome caſes this may be a very proper method, but there are others where prudence will not allow the uſe of it; as where the patient is too much terrified by it, where the parts on which the carbuncle is ſituated are of the utmoſt tenderneſs and conſequence: in theſe it will be readily determined, that the milder treatment before adviſed muſt be greatly preferable.

Another famous remedy is the applying to the parts butter of antimony. The circumjacent parts being anointed with this, the diſorder is prevented from ſpreading, and an eſchar is readily made, which divides the ſound from the corrupted parts, and at length wholly ſeparates and throws off the latter.

There are not wanting, however, phyſicians who are againſt the uſe of butter of antimony on theſe occaſions; but where the actual cautery might have been applied, this ſurely is a ſomething milder, and not much leſs effectual remedy. *Heiſter*'s Surg. p. 205.

PESTILENTIAL *diſeaſes*. Many think that the cauſe of all theſe is in the air, and is exhaled in vapours through the pores of the earth.

It is generally obſerved, that *peſtilential diſeaſes* ſeize firſt the cattle; which is not wonderful, ſince they naturally carry their noſes near the ground, and ſuck in the vapours as they riſe, or feed on the herbage that is infected by them. It often happens, that the vapours do not riſe ſo high as to affect men at all; but tho' in this caſe the plague would be naturally confined to the cattle alone, yet it gets among men by means of the food eaten by them, and before tainted with the contagion. There is no doubt but that the fleſh of animals that die of diſeaſes, partakes ſomewhat of the nature of theſe diſeaſes; and when they are *peſtilential*, may ſpread a peſtilence among us, which, perhaps, would otherwiſe never have reached us.

The plague once begun, frequently joins itſelf with ſuch other diſeaſes as the people it attacks are moſt ſubject to; hence, in the northern nations, where the ſcurvy is frequent, it is often ſeen that the plague and ſcurvy appear mixed. Theſe two diſeaſes, in their nature ſomewhat agreeing, make each other the worſe and more violent; but, on the contrary, there are other diſeaſes, depending on ſuch contrary cauſes, that the plague, if the patient ſurvives, proves a cure to them.

Dr. Hodges inſtances the conſumption, and the king's evil, as two diſeaſes of this kind; which, tho' in themſelves of the moſt terrible kind, and when in an advanced ſtage uſually baffling all remedies, yet he ſaw perſons in the plague that laſt raged in London, cured of both by the plague: the ſymptoms of the diſeaſe appearing more mild in theſe than in other caſes, and the patients at once recovering of both complaints.

He alſo tells us of ſome people terribly afflicted with the gout for many years, who being at that time affected by the contagion, had the plague with leſs violent ſymptoms than others; and were, on its going off, cured of the gout alſo.

A fever is uſually a concomitant ſymptom of the plague, but it is not an inſeparable ſign of it. A palpitation of the heart is another of the uſual, but not conſtant ſymptoms; where this comes on, it is uſually very violent, and often is ſo loud, that it may be heard at a conſiderable diſtance.

The plague is leſs contagious than is uſually ſuppoſed, and thoſe who eſcape the terror of it, often eſcape it wholly. Hodges gives us an inſtance of a poor woman who had the plague ſoon after her delivery, and ſuckled her young child as ſhe lay ill of it. She had a carbuncle on her breaſt near the nipple which the child ſucked at, and yet the mother recovered, and the child never caught the infection at all; tho' this ſeemed a circumſtance under which there could be no eſcaping.

Hodges, treating of the prognoſtics of an imminent plague, tells us, that one very remarkable one is the change of chronic diſtempers in general into acute ones, and thoſe attended with very violent ſymptoms; and a murrain among the cattle happening at the ſame time, form together a prognoſtic not eaſily to be got over, without the terrible ſequel of a general *peſtilence*.

If the plague is very terrible at its firſt appearance, it never is of long duration; and on the contrary, when it comes, from a ſcarce perceptible beginning, more and more violent, it is generally of a long continuance. What time it takes from the beginning to the height, the ſame it takes from the height to the final period.

The moſt fatal ſymptoms in the laſt plague in London, and which uſually preſaged death very near, were hæmorrhages from the noſe or ears, fluxes of the menſtrua in women, diarrhœas, dyſenteries, and greenneſs and blackneſs of the excrements.

The firſt ſweats coming on without giving eaſe, and long naufeouſneſs continuing afterwards, are alſo terrible ſymptoms. The pulſe and urine, which are the two great things to judge by in moſt illneſſes, in theſe preſage nothing at all. The pulſe is fallacious in the higheſt degree, and the urine often appears as well in the height of the plague, as while the perſon was in health.

Among the ſeveral preſervatives for particular places, the two beſt are the burning ſweet-ſcented woods in the time, and ſome of the reſins, ſuch as frankinſence and the like; the other is the firing a number of cannon every morning and evening. *Hodges* de Peſt.

PETAL, among botaniſts, that part of the flower which conſtitutes the corolla: it generally diſtinguiſhes itſelf by its ſingular colour.

When the corolla conſiſts only of one *petal*, its lower tubular part is called the *tube*; its upper expanded part, the *limb*: when ſeveral *petals* go to make up the flower, the narrow part where they are inſerted is called *unguis*; their broader part towards the end, *bractea*. See COROLLA.

PETARDEER, in the military art, is he who loads, fixes, and fires the *petard*.

PETASITES, *butterburr*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the floſculous kind, being compoſed of many ſmall floſcules, divided into ſeveral ſegments at their edges, and placed on the embryo fruit, and all ſurrounded by a ſort of a cylindric cup, divided into many ſegments. The ſeeds, when ripe, are winged with down, and the flowers of this plant appear before the leaves, early in the ſpring.

The ſpecies of *petaſites*, enumerated by Mr. Tournefort, are theſe: 1. The great or common *petaſites*. 2. The leſſer *petaſites*, with white flowers and angular leaves. 3. The ſmall *petaſites*, with colt's-foot leaves. 4. The leſſer Alpine *petaſites*, with ſmall angular leaves. *Tourn.* Inſt. p. 450.

The common *butterburr* is famous as a cordial and alexipharmic. It has been made an ingredient in moſt of the compound medicines of that intention. The plague-water of the

old diſpenſatories owed the greateſt part of its virtues to it. The root is the part principally uſed; and beſide theſe virtues, it has thoſe of an aperient and detergent. It is preſcribed in ſuppreſſions of the urine and menſes, and in coughs, aſthmas, and other diſeaſes of the breaſt. See BUTTERBURR.

PETASUS, among the Romans, a covering for the head, not unlike our hats; it had a broad brim, and was uſed in journeys to ſave the face from being ſun-burnt.

The *pileus* differed from the *petaſus*, as having no brim. *Pitiſc.* in voc. See PILEUS.

The *petaſus* is obſerved upon the head of antient figures of Mercury; who wore it in the quality of the god of travellers and merchants. *Calmet.* Dict. Bibl.

PETECHIAL *fever*. See *catarrhal* FEVER.

PETELMA, in the Turkiſh military orders, is the procurator general of the effects of the janizaries. When any one dies under the protection of this body, he ſeals up their houſes, to ſecure the tenth part of their effects; which are due to the janizaries. *Pocock*'s Egypt, p. 168.

PETIA, a word uſed by medical writers in different ſenſes. It is commonly underſtood to mean a piece of rag, uſed to tie up medicinal ingredients in, to be uſed by infuſion in liquors; but *petia oculi* ſignifies an hæmorrhage of the eye.

PETICULÆ, the ſame as *petechiæ*, purple ſpots appearing on the fleſh in malignant fevers.

PETIGO, a word uſed by ſome authors for *impetigo*. See the articlee IMPETIGO, *Cycl.*

PETILIUS-*flos*, a name uſed by ſome botanical authors for the African marygold. *Ger.* Emac. Ind. 2.

PETIMBUABA, in ichthyography, the name of a fiſh caught in the American ſeas, and called by ſome, in Engliſh, the *tobacco-pipe fiſh*; a name more commonly uſed for the *acus ariſtotelis*. See Tab. of Fiſhes, N°. 40.

It grows to the length of three or four feet; its body is like that of an eel, long and ſlender; and its mouth without teeth. The length of the noſe is conſiderable, and the upper jaw is ſhorter than the lower. Its eyes are remarkably large, not ſmaller than a hazel nut, and ſomething of the ſame figure. Its ſkin is ſmooth, like that of the eel, and of a liver-colour on the back and ſides, with ſeveral rows of blue ſpots diſpoſed in three rows on the back, two on the head and one on each ſide; there are alſo ſome green ſpots every where interſperſed among the blue ones. The belly is white, but has ſomething of a browniſh red caſt, and is flat. It is a well-taſted fiſh. *Willughby*'s Hiſt. Piſc. p. 234.

PETIOLATE-*leaf*, among botaniſts. See LEAF.

PETIOLE, *petiolum*, among botaniſts, expreſſes that ſtalk which ſupports the leaves of a plant, as the peduncle does the fructifications.

Some uſe the word *petiolum* to denote the whole middle rib of a leaf of any plant, which is the ſtrongeſt part of it, and runs from the ſtalk by which the leaf adheres to the tree or plant to its extremity, and from which the lateral fibres or nerves, as they are uſually called, commonly ariſe.

The authors who have written on the ſubject of the anatomy of leaves, have had occaſion to be accurate about the diſtinctions of the ſeveral parts; and they have called this main or middle rib, the *petiolus*. The ſide branches going off from this, they call *rami*; and the ſubdiviſions of theſe into more minute fibres *furculi*: theſe generally are interwoven into a reticular plexus one with another, and make up the ſubſtance of the leaf, with the bladders of a liquid matter, which are contained in their interſtices.

All theſe ſolid parts of leaves, the *furculi* and *rami*, as well as the *petiolus*, are congeries of oblong fibres extended evenly together, and collected into one body; and the fibres in all parts of plants are divided into two kinds; the one containing juices, and called *ſucciferæ*; the other giving paſſage only to air, and therefore called *tracheæ*.

Lewenhoek has diſtinguiſhed the ſucciferous veſſels into two kinds, which he calls veins and arteries: the latter, he obſerves, receive the ſap from the root, where it is firſt collected, and carry it up to the reſt of the plant, and the others bring it back again from thence, in the manner of veins. Perralt has joined a great number of experiments to Lewenhoek's, in order to prove this ſyſtem of the juice veſſels, but Fontenelle, and ſome others, have doubted either the exiſtence, or at leaſt the uſe of the *tracheæ* or air veſſels, ſuppoſing them either imaginary veſſels, or deſtined for other purpoſes. The vine branches, however, examined either by a microſcope, or by a good eye in a good light, will ſhew evidently that ſuch veſſels exiſt, and that in very great numbers: and the veſſels in the *petiole* and *furculi* of leaves, when ſtrictly examined, are found to be of both theſe kinds. Act. Erudit. 1722. See TRACHEÆ.

PETIOLUS, a word uſed by botanical writers to expreſs the ſtalk of a fruit.

PETIVERIA, in botany, the name of a genus of plants, the characters of which are theſe: The perianthium is compoſed of three ſlender, erect, obtuſely-pointed leaves, and remains to incloſe the ſeeds. There are no petals; the ſtamina are ſix ſubulated equal erect filaments, of the length of the cup; the antheræ are ſimple; the germen of the piſtil is oblong, and of a compreſſed figure; the ſtyles are four, they are ſubulated and ſtrait; the ſtigmata are ſimple and permanent; the ſeed is ſingle, of an oblong figure, narrow at the bottom, broader at the top, emarginated and crowned with the ſtyles, which are rigid, acute, and ſomewhat bent. *Linnæi* Gen. Plant, p. 156. *Plumier*, Gen 39.

PETOLIN, in natural hiſtory, the French name for a ſhrub of the piſtachia kind, famous for affording bladders or tubercles on its leaves and tender branches, in the manner of the common turpentine-tree; which are found full of inſects. Theſe inſects are always found to be of the puceron kind, and ſome of them are winged, others not, as is known to be the caſe in that genus of animals. Theſe bladders, and thoſe of the turpentine-tree, called its *horns*, have been by ſome ſuppoſed to be the natural production of the trees, but they are in reality only a peculiar ſpecies of bladder-galls, formed by theſe animals, one female of which making her way into the leaf, while the young raiſes its covering membrane into a bladder, in which ſhe produces her young ones; which by ſucking its ſides, derive the juices to it, and occaſion its increaſe. *Reaumur*'s Hiſt. of Inſ. p. 34. See the article PUCERON.

PETRÆA, in botany, a name given by Houſton to a genus of plants, in honour of the name of the Lord Petre. This author, however, was guilty of an error in the characters of this genus; for he deſcribed the flower of this, and the fruit of another very different genus, the *tetracera*. The external reſemblance of theſe two trees led him into the error; but Linnæus has given its characters more fully, and without any ſuch miſtake. They are theſe: The perianthium is very large and coloured; it is compoſed of one leaf divided into five obtuſe expanded ſegments, and remains with the fruit. The flower conſiſts of one leaf, and is irregular and ſmaller than the cup; its tube is very ſhort; its verge plain, and divided into five ſegments, which are roundiſh; and the loweſt of which is larger than the others. The ſtamina are four filaments, two being longer than the others, and all hid in the tube of the flower. The antheræ are ſimple; the germen of the piſtil is of an oval figure; the ſtyle is ſimple, and of the length of the ſtamina; and the ſtigmata is obtuſe. The error of Houſton, in regard to the fruit, has left the world wholly in the dark as to what it really is. *Linnæi* Gen. Pl. p. 298. *Houſt.* Act.

PETRIFACTIONS *(Cycl.)*—The knowledge of this part of natural hiſtory is but of very late years arrived at any degree of perfection. Dr. Hook, Steno, Boerhaave, and Auguſtino Scilla, have been among the firſt who treated judiciouſly of theſe things; but great honour is to be done to Fabius Columena, who, before the time of any of them, publiſhed two admirable diſcoveries upon the parts of aquatic and terreſtrial animals, and of plants buried in the earth, and which he had himſelf ſeen dug up in the mountains of Andria, Apulia, and other places. He boldly declares, that theſe could be depoſited there by no other means but by the general deluge in the days of Noah; and enters into the reaſons why, in ſome places, theſe remains of animal and vegetable bodies are found perfect and intire, and in others corrupted or altered; and obſerves, that they anſwer ſo exactly in every lineament to the recent bodies of the ſame kind, that there can be no doubt of their having once been alſo ſuch.

It is a very remarkable obſervation, in regard to the really and certainly determining the origin of *petrifyed* ſhells, that they are not all alike altered by lying in the earth, but that they differ according to the matter among which they have lain to *petrify*. Thus the ſame ſpecies of ſhell *petrifyed* in a looſe ſand-ſtone, is never nearly ſo hard as when *petrifyed* in a ſolid quarry, or in a hard lime-ſtone; ſo that it is evident they were brought into the places where they now lie, in the ſtate of ſhells; and that the ſtone in which they are depoſited, having imparted to them its own nature, they are harder or ſofter, in proportion to its hardneſs. We find in pits where the ſhells are depoſited in looſe earth, that they are often not *petrifyed* at all, but rendered more ſoft and crumbly than before.

The echini marini, and other ſuch hollow and open-mouthed ſhells, are very often found filled up with earth or ſtone, the ſame with that in which they lie; and refuſe matter is ſometimes found among this, ſuch as the fragments of other ſhells, and the ſpines of ſome other echini. All theſe ſerve to prove that the ſhell, in its recent ſtate, was ſuſpended in water among ſuch ſubſtances as theſe. And it is not to be ſuppoſed, with ſome authors, that they are found originally as foſſils within the ſhell; ſince, in this caſe, they would be ſometimes doubtleſs found of ſuch a ſize as could not have got in at the mouth of the living animal; but this is never the caſe. And upon the whole it appears very plain, that after the membranes which covered the mouths of theſe ſhells in their recent ſtate, were decayed or waſhed away, theſe extraneous bodies found entrance at them along with the marle, chalk, ſtone, or whatever other

ſubſtance

ſubſtance they were among, which was evidently all ſoft and fluid at that time. *Auguſtino Scilla* de Petrifact.

The *petrified* vertebræ of fiſhes cannot be ſuppoſed real foſſile productions, but are plainly remains of animals; and when examined ever ſo accurately, they are found to agree with the ſame bones in the recent animal in every lineament. Scilla mentions a foſſile lobſter's claw preſerved in his muſæum, and found in the hills near Meſſina, in which a piece of a ſcallop-ſhell was found clenched juſt in the manner in which that animal ſeizes its prey. Thoſe who ſuppoſe theſe foſſiles to be really produced in the earth, ſurely cannot ſuppoſe that there could be any ſeminal principle only for the claw of an animal. In Poland there is a kind of ſtone called *niec kamni*, which they bring from a place called by the ſame name. This ſtone has very much the appearance of the grain of wood, and is probably wood *petrified*. Rzaczinſki, in his hiſtory of Poland, mentions the place, and tells us, that there are many whole roots and parts of the trunks of trees *petrified* there. He tells us alſo of an old beech tree in Podolia, whoſe lower part is not only *petrified*, but that into the hardeſt and pureſt of the common ſtones; it being converted wholly into flint, and ſerving the country people thereabout for their common uſes as ſuch. The author tells us, indeed, that the lower parts of trees become *petrified* there as they ſtand, and while the upper parts continue growing; but this ſeems ſcarce credible.

We have indeed ſome other accounts of the ſame nature, but not from authors of ſufficient authority to build our faith on, in ſo ſeemingly unnatural a caſe. This author, in particular, ſeems too credulous in many inſtances; among other things, giving us an account of ſome earthen veſſels found at conſiderable depths in the earth, which he ſuppoſes to have been formed there by nature. We have other accounts beſide this of foſſile urns, but the authors of them all have either miſtaken the cruſtated ferrugineous bodies for urns, or elſe they have ſuppoſed things natural which are certainly artificial. *Rzaczinſki*'s, Hiſt. Polon.

Mr. Boyle mentions a kind of ſandy earth found in England, which turns wood into ſtone, tho' there be no *petrifying* ſpring near the place: and this, he ſays, is done in a better manner than by any water he ever ſaw. See Works Abr. Vol. 1. p. 161.

Animal PETRIFACTIONS, a term uſed to expreſs ſuch *petrifactions* as are found in the ſeveral parts of the bodies of living creatures.

Of theſe the human body affords many which are the occaſions of very terrible and generally incurable diſeaſes. The philoſophical tranſactions afford us two very ſingular inſtances of this ſort of *petrifactions*; the one in a woman, whoſe whole left kidney was intirely *petrified*, not being filled up in its cavity with a ſtony concretion, as frequently happens in nephritic caſes, but its whole ſubſtance converted into abſolute ſtone, only covered with a thin ſkin.

The other inſtance is in the caſe of a conſumptive perſon, whoſe lungs were found, on diſſection, full of ulcers, and thoſe having almoſt all of them, more or leſs gravel in them; but this was not all, for ſeveral large pieces of the lungs were found, as the kidney in the other inſtance, wholly concreted into ſtone, only covered with a thin ſkin. Phil. Tranſ. N° 71.

PETRIFACTIONS *of Lough Neagh*. The moſt noted place for *petrifactions* in our dominions is, the famous lake called *Lough Neagh*, in Ireland. Moſt of the antient writers who have given accounts of Ireland, have mentioned the power the waters of this lake have of turning wood into ſtone; and ſome of them have added the abſurd to the marvellous, by affirming, that it would turn that part of the wood which was buried in the mud into iron, that part that was in the water into ſtone, while the part which was above water remained mere wood ſtill.

Some late authors, as Molyneux Nevil, Smyth, Woodward, and others, ſuppoſe this effect not to be found in the water of this lake, but that it either is in the earth about the lake, or elſe that the *petrifactions* found there are not ſuch as have been formed there, but *petrified* elſewhere, and long ſince, and brought thither by the waters of the deluge.

Mr. Smyth affirms, that no experiment ever made has proved that the water of that lake has any power of *petrifying* wood; and gives an example of a gentleman's having planted two ſtakes of holly in the lake, on purpoſe to try; which were taken up after 19 years, without the leaſt advance made toward *petrifaction*. It is certain, indeed, that vaſt quantities of *petrified* wood are found in the lake, and even whole trees with their roots and branches all turned to ſtone, have been found buried in the mud of it; and it ſhould ſeem the moſt rational account of their being found there, that they had grown in their natural ſtate on the banks of the lake, and had, in fine, fallen in, and been there *petrified*. And it is equally certain, that of the great quantity of wood met with here, the different pieces are in different degrees of *petrifaction*; and that ſeveral of them are ſeen to be *petrified* in different degrees in their parts; nay, that one ſide of a large piece is often ſeen to be mere rotten wood, while the other is hard ſtone.

It is not to be aſſerted, becauſe ſtakes driven down in ſome one part of the lake are not *petrified* in a ſmall number of years, that therefore the water has no where a *petrifying* virtue; ſince it is poſſible that there may be ſprings ariſing in ſome parts of it, the waters of which may be ſo highly impregnated with ſtony matter, as to *petrify* wood, if they meet with it near their origin; yet the waters of theſe, when mixt with that vaſt body of water which makes the whole lake, may not be able to communicate that *petrifying* quality to ſo large a quantity.

There is ſcarce any water that does not contain ſaline and ſtony particles, which may be ſeparated from it by evaporation; and the generality of *petrifying* ſprings, when examined by this proceſs, are found to be very full of calcarious, or other ſtony matter, and frequently of ferrugineous and vitriolic kinds. Thoſe which contain calcarious matter, when they drop upon ſticks, moſſes, or other vegetable bodies, act on them by incruſtation; their calcarious particles being left behind while the water goes off, and forming by this means ſucceſſive cruſts ſometimes to a great number, which adhere cloſely to one another, and form a ſtony coat to the wood: if theſe be broken at different periods of time from their formation, ſome of them will be found with the wood remaining ſound within them, others with the wood rotten; and others with a ſtony matter of the ſhape of the wood, ſupplying its place, and formed by the depoſition of ſtony particles in the cavity left by the periſhed wood. Sometimes, indeed, theſe waters permeating the pores of wood, fill them up with the calcarious particles they leave behind them; and when the vegetable matter is periſhed, the calcarious concretion remains in its place and exact ſhape. The bodies in this laſt ſtate approach much more to the nature of *petrifactions* than the others, but they all differ greatly from the genuine *petrifactions*; becauſe it is not true ſtone that they conſiſt of, but merely a ſpar or calcarious matter, which readily ferments with, and is ſoluble in acids, and by a ſlight calcination is reduced to lime, in the manner of other ſpars.

The *petrifying* waters, which contain particles of true and genuine hard ſtone, and perhaps with them ſome ferrugineous or other metallic ones, do not act in this manner by incruſtation, but always leave the ſurface naked, and penetrate into the inner ſubſtance of the wood, filling every pore with the hard matter they depoſit; which, in fine, without altering their texture or ſize, adds greatly to their gravity, and gives them the hardneſs of a ſtone. In many parts of Ireland there are great quantities of the incruſtations of calcarious matter on vegetables; but the *petrified* wood found in the Lough Neagh, and on its ſhores, is wholly of the other kind; and ſhews no covering of any foreign matter, but preſerves the grain and all the veſtigia of wood; all the alteration is in the weight and cloſeneſs reſulting from the ſtony matter having filled all the pores: theſe make no effervescence with acids, nor will be calcined into lime in a common fire, as the calcarious incruſtations are.

It is probable, that the *petrifying* matter with which the water of ſome part of this lake is endued, is owing to ſeveral ſprings; which running in their courſe thro' mountains where there is abundance of ſtony and mineral matter, waſh off and carry with them great quantity of the particles of one or both theſe ſubſtances; which they afterwards depoſit in the wood they meet with, where they are diſcharged up thro' the mud of this lake; and that tho', when blended among the general water of the lake, they have not this property, yet if the ſtakes of holly had been driven down juſt where thoſe ſprings were, they would probably have been *petrified*, tho' there was no ſuch quality in the reſt of the water of the lake. And that there are theſe ſprings in ſeveral parts of the lake, is certain from hence, that when in the great froſt in the year 1740, the great lake in general was frozen over ſo as to bear men on horſeback, yet ſeveral circular ſpaces remained unfrozen.

The *petrified* wood is found in conſiderable plenty on the ſhores of the Lough, but moſt abundantly after ſtorms; and this rolling about of the *petrifactions* at the bottom in ſtorms, makes it not eaſy to fix upon the place where they received their alteration.

Nor are the *petrifactions* found only in and about the lake, but they are turned up by the plough almoſt daily in all places, at two or three miles diſtance from it; and ſome have believed that they were all *lapides ſui generis*, and never had been wood till the roots of trees were found in their natural poſition in the ground, with their ſmaller ramifications and every other part wholly *petrified*.

Many of theſe are much ſofter than the *petrifactions* in the lake, and may be cut and cleaned with a knife, tho' not near ſo eaſily as other wood. It is not impoſſible, but that many of theſe may have been originally *petrified* in the lake, which may have either once extended over a much larger ſpace of ground than it now does, or elſe have loſt on one ſide what it has gained on the other; not that it is neceſſary to ſuppoſe this, ſince there is no doubt but that mineral ſteams and exhalations being highly ſated with ſtony particles, are often found to have a *petrifying* virtue; and ſuch effluvia ariſing thro' the earth may operate on wood accidentally buried

in that ground; and this seems to be the most probable opinion as to the origin of the *petrifactions*, not only of our fields, but of those found in many parts of the world among sand or gravel.

It is to be observed also, that the finer the lapidific particles are, the more beautiful and natural the *petrifaction* will appear. Of this kind there was once found a beautiful specimen on the shores of the Lough Neagh. This was a root of the common yellow flag-flower, with the bottom part wholly converted into stone, but yet retaining all the fibres, and every part of the texture of the root; the pith in the middle was turned into a whiter stony substance, and the upper surface had all the traces of the several tubercles, or first shoots of leaves, tho' a very hard stone; and the outer covering of some of these retained its vegetable nature still so far, as to be flexile in a small degree, while all within was solid stone.

Some of the pieces of *petrified* wood, found on the shores of the lake, have curious veins of a red and blueish colour, and others are beautifully variegated with black and white striæ. The woody part of them gives a red tincture to aqua fortis, and when taken out of that menstruum, shews some red spots in its pores, which, perhaps, are its first approaches towards *petrifaction*, and are either of a mineral or stony matter.

It is common to find in the cracks of these stones, nay, and of such parts of them as are yet wood and not turned into stone, great numbers of very beautiful and regular, tho' small, crystals: these are transparent and hexangular, and of the same kind with the small crystals found in the cracks of ferrugineous stones, and within our common flints. When calcined, the powder yields to the magnet, which shews that they have some ferrugineous as well as stony particles: and it is not unfrequent to meet with pieces of unaltered wood in the very center of the largest of these *petrified* masses; and the *petrified* parts of the masses, when examined by the microscope, appear extremely beautiful, their pores being all visibly filled with pure and very bright crystal. The different degrees of *petrifaction* appear very various in the several pieces, some are woody on the outside, and altogether stony within; and others outwardly stony, and inwardly unaltered wood; and others having the woody or the stony part appearing only in thin lines and coats on different parts. The harder or more stony parts of these *petrifactions* always give fire with steel. Phil. Transf. N°. 481.

Some of them shew the grain of ash, some of holly, and some of fir, others of oak; but these are more rare. They frequently have the plain traces of knots and other irregularities, and some are found bent and half broken, and plainly have been worked by art before they were *petrified*.

It is a common opinion, that these stones are what are used for hones in different parts of England; but this is an error, the substance of which these are made being real stone, and not found here, but at Drogheda. Those *petrifactions* of the lake, which have part wood, part stone, usually lose the wood afterwards, by its cracking and falling to pieces as the stone dries; but if examined while it remains on the stone, it is very convincing, as to the reality of the origin of the whole from wood. Id. ibid.

PETRIFICATION, in medicine. See ANCUBITUS.

PETRIFIED *Ivy*. See the article IVY.

PETRIFYING *waters*. Alonso Barba gives an account of some *petrifying* waters of Peru, which greatly exceed all those we have in Europe in the quantity of stony matter they contain. He tells us, that they soon choak up their own passage by the stony matter they deposit there; and that all the cattle that drink of them die. He adds another story, which he probably took a little too hastily upon credit, which is, that they have moulds of the shape of our bricks, which they fill with this water, and that on being exposed to the sun a few days, the water is wholly converted into a stone of the same shape; and that they build their houses and other buildings with these stones. *Alonso Barba* de Metal.

PETROCOSSYPHUS, in zoology, a name given by some authors to the bird more usually called from its colour the *cæruleus*.

It lives among the rocks, in woody mountains, and sings very sweetly. See CÆRULEUS.

PETROL, or PETROLEUM—*(Cycl.)*

Mr. Boulduc made several experiments with the white *petroleum* of Modena, an account of which he gave to the Paris academy.

It easily took fire on being brought near a candle, and that without immediately touching the flame; and when heated in any vessel, it will attract the flame of a candle, tho' placed at a great height above the vessel, and the vapour it sends up taking fire, the flame will be communicated to the vessel of heated liquor, and the whole will be consumed. It burns in the water, and when mixed with any liquor swims on the surface of it, even of the highest rectified spirit of wine, which is $\frac{1}{7}$ heavier than pure *petroleum*. It readily mixes with all the essential oils of vegetables, as oil of lavender, turpentine, and the rest, and seems very much of their nature: nor is this very strange, since the alliance between these bodies is probably nearer than is imagined, as the essential oils of vegetables may have been originally mineral ones, and drawn up out of the earth into the vessels of the plant. Mem. Acad. Par. 1715.

Petroleum, when shaken, yields a few bubbles; but they sooner subside than in almost any other liquor, and the liquor resumes its clear state again almost immediately. This seems owing to the air in this fluid being very equally distributed to all its parts, and the liquor being composed of particles very evenly and nicely arranged.

The extensibility of this oil is also amazing. A drop of it will spread over several feet of water, and in this condition it gives a great variety of colours, that is, the several parts of which this thin film is composed, act as so many prisms. The most severe frost never congeals *petroleum* into ice, and paper wetted with it becomes transparent, as when wetted with oil; but it does not continue so, the paper becoming opake again in a few minutes, as the oil dries away.

Spirit of wine, which is the great dissolvent of sulphur, has no effect upon *petroleum*, not even with ever so long a digestion. It will not take fire with the dephlegmated acid spirits, as oil of cloves, and other of the vegetable essential oils do: and in distillation, either by balneum mariæ, or in sand, it will neither yield phlegm nor acid spirit; but the oil itself rises in its own form, leaving in the retort only a little matter, thick as honey, and of a browniſh colour. Whoever, therefore, would use this oil in medicine, must take it as nature has prepared it, art having no power to make any alteration in it. Mem. Acad. Paris 1715.

Alonso Barba, in his book of metals, gives a very melancholy instance of the power of *petroleum* of taking fire at a distance: he tells us, that a certain well, yielding *petroleum* on the surface of its water, being to be repaired, the workman took down into the well with him a lanthorn and a candle in it; there were some holes in the lanthorn, through which the *petroleum*, at a considerable distance, sucked out the flame of the candle, and taking fire, burst up with the noise of a cannon, and tore the man to pieces. *Alonso. Barba* de Met.

The people of mount Ciaro, in Italy, have some years since found out a much easier way of finding *petroleum*, than that they formerly had been used to.

This mountain abounds with a sort of greyish salt, which lies in large horizontal beds, mingled with strata of clay, and large quantities of a spar of that kind called by the Germans *selenites*; which is the common sort, that ferments with acids, and readily dissolves in them, and calcines in a small fire. They pierce these slates in a perpendicular direction till they find water, and the *petroleum* which had been dispersed among the cracks of those slates, is then washed out by the water, and brought from all the neighbouring places to the hole or well which they have dug, on the surface of the water of which it swims after eight or ten days. When there is enough of it got together, they lade it from the top of the water with brass basons, and it is then easily separated from what little water is taken up with it. It is remarkable, that all the *petroleum* got by this means is white, whereas that of Modena is yellow, and that of Parma brown. These wells or holes continue to furnish the oil in different quantities for a considerable time, and when they will yield no more, they pierce the slates in some other place. Mem. Acad. Scien. Par. 1736. See the article NAPHTHA.

Petroleum is never used among us; but the French give it internally in hysteric complaints, and to their children for worms: some also give it from ten to fifteen drops in wine, for suppressions of the menses. This, however, is rather the practice of the common people than of the faculty.

PETROMARULA, in botany, a name given by several authors to the pyramidal rapunculus of the island of Crete, called by Mr. Tournefort, *rapunculus creticus seu pyramidalis alter*. See RAPUNCULUS.

PETROMYZON, the *stone-sucker*, in the Linnæan system of zoology, the name of a genus of fishes of the chondropterygii order, comprehending the lamprey, &c. The characters of this are, that the apertures of the branchiæ are seven on each side. *Linnæi* System. Natur. p. 52.

The name is originally Greek, and is derived from the words πέτρον, a stone, and μυζαω. to suck; this fish being usually found in rivers adhering to the stones by sucking, and so keeping its place.

The characters of this genus, according to Artedi, are these: the foramina, or apertures of the branchiæ, or lungs, are seven on each side; they are placed longitudinally, and beside these, there is one single aperture in the head, placed immediately between the eyes. The body is long, and nearly of a cylindric figure; it is smooth, and has only two fins, and those are both placed on the back.

The species of this genus, enumerated by Artedi, are these: 1. The *petromyzon*, with only one row of minute teeth in the verge of the mouth, except the large lower ones. This is the *lampetra fluviatilis minor* of authors, or the lamprey eel: and the *lampetræ medium genus*, called by the Germans the *brick*, is only a variety of this, not a distinct species. 2. The spotted *petromyzon*, with about twenty rows of teeth. This is the *lampetra major* of authors, and is called in English the *lamprey*. 3. The *petromyzon* with an annulated body, and with two appendages on each side of the mouth. This is the *enneophthalmus cæcus* of au-

authors. The body consists of eighty-four rings, and it has no teeth. *Arted.* Gen Pisc. 42.

PETRONELLUS, in zoology, a name under which some have described the bunting.

PETRONIA *marina*, in zoology, the name of a small bird of the œnanthe kind, or nearly allied to that genus. Its beak is strong and sharp, like that of the chaffinch; its head is of a brownish grey, but has usually a long whitish streak running along it; its neck is ash-coloured, and at the bottom is variegated with black; the rump is of a brownish green; the long wing-feathers are blackish, with edges and tips of green, and are white underneath; the breast is of a dusky white, and the tail brownish, variegated with yellow. It is, however, distinguished from all other birds by a fine large yellow spot, which it has on the middle of its throat. *Aldrovand.* de Avib. l. 17. c. 38.

PETROSELENI *radix*, *parsley-root*. See PARSLEY.

PETROSELINUM *Macedonium*, in the materia medica, the name of a seed used in medicine. The plant which produces it is a native of the warm countries; and the seed should be chosen for use clean, well fed, longish, and of a brownish green colour, and well tasted, and aromatic. The buyer should be careful in the choice of this seed, because it is commonly adulterated, and the seeds of the common *parsley*, or those of a sort of smallage, are too frequently sold in its place. It is aperitive, provokes urine and the menses, and expells wind; and, in form of a cataplasm, is said extremely to help the gout. It is an ingredient also in the Venice treacle. *Lem.* Dict. of Drugs.

PETROSUM *sal*, in natural history, a name given by some of the old writers to the nitre of Ægypt, used in the antient times; and by others to the common nitre, which we use at present, and call by a similar name, *salt petre*.

PETTY *bag (Cycl.)* — In antient times the chancellor was likewise chaplain to the king, and it was his business, in the time of the justiciar, to write the diplomata; that is, all charters and commissions from the king: therefore, when the power of the justiciar was broke, he obtained the *officina brevium* and *chartarum regiarum*; from thence all the extraordinary jurisdictions, touching granting of charters, as likewise all inquests of office to entitle the crown, were returned into this office; and the exchequer, in which these things were antiently transacted, became only an ordinary court of revenue, to let leases to the king's farmers, and to get in the king's debts: and therefore the office in the exchequer was only an office of instruction, of what lands were in the king in particular counties; but to invest lands in the crown *de novo*, it was necessary to have an office under the great seal, and so to grant lands from the crown, unless it were merely farms granted for years. Vid. New Abr. Law, Vol. I. p. 587.

From hence, at this day this court has a jurisdiction to hold plea upon a *scire facias*, to repeal the king's letters patents upon petitions, *monstrans de droit*, traverses of offices, *scire facias* upon recognizances, executions upon statutes, &c. which being registred in this court, the process thereupon issues, and is returnable there, and entered in the office called the *petty bag*; whereas the writs which were the foundation of the business of the other courts, were put together in the hamper, which gave the distinction of those names, and begat distinct officers in the court. 4 Inst. 80.

If in this court the parties descend to issue, the chancellor cannot try it, but is to deliver the record, with his proper hand, into the king's-bench, where judgment is to be given; but upon a demurrer, the chancellor is to give judgment [a]: so if the issue is to be tried otherwise than by a jury, as by the bishop's certificate, judgment shall be given in chancery [b]. [a Vid. New Abr. Law, Vol I. p. 587. b 1 Jon. 80.]

Also all personal actions, by or against any officer or minister of this court, in respect of their service or attendance, may be determined in this court; but in these no jury process can issue, therefore the record is to be removed into the king's-bench, as before mentioned.

PETULANTIUM *festum*, in antiquity, a festival celebrated by the Athenians and Lacedæmonians in honour of the moon, under the name of Venus: at which the men assisted, dressed in womens cloaths; and the women in the habits of men. *Hoff.* Lex univ. in voc

PETUNTSE, or as it is usually called *petunse*, one of the two earths or fossile substances of which the porcelain ware of China is made. The other is named *kaolin*. See KAOLIN.

The *petuntse* is sprinkled all over with bright glittering particles. It is beaten to powder, and afterwards made up into a sort of bricks, and in that form it is sent to the places where it is to be wrought. It is of a hard texture, and of a somewhat greenish colour. Mr. Reaumur, of the academy of sciences of Paris, who was extremely industrious in searching into the nature of porcelain, obtained some specimens of the *petuntse*, both in its native state, and in form of the brick, which is given it after it is powdered and reduced to a paste.

Mr. Reaumur found that the *petuntse* was so far from being an earth, as usually supposed, that it was truly of the nature of the European flint or pebble, as he establishes the character of that body: but to understand this rightly, it is to be observed, that this author makes the flints and pebbles a very large class of bodies, some of which are more, some less transparent; and that this *petuntse* is of the nature of the coarser, or less transparent kind, the surface of which, when broken, is not so smooth and polished as that of the ordinary flint. The great character of these stones for the porcelain manufactures is, however, that they are very easily vitrified, without the assistance of any salt, and without the immediate contact of the fire, the operation succeeding in a crucible, which is not at all the case in regard to the European flints, they very differently melting alone in a crucible, and then only into a whitish opake glass.

It being certain from hence, that one of the two ingredients of the china-ware is easily vitrifiable, it follows, from the experiment of the whole mixture, or china-ware not being reducible into glass in a large fire, that it is a composition of a vitrifiable, and a not vitrifiable (or at least not easily vitrifiable) substance; and consequently, that the kaolin is a scarce vitrifiable body, and that the result of the action of fire on a mixture of these two, is a semivitrification; which is what we call the china-ware.

If we, therefore, could, in Europe, provide the materials of china, or such as were like them, we might reasonably hope to succeed; and this appears far from improbable. The *petuntse* is easily supplied by many of our own earths, stones, and sands, as nothing is required in it more than a property of running easily into a white glass. The kaolin seems most to be resembled by our European talcs. Mem. Acad. Par. 1727. See the article KAOLIN.

PEUCEDANUM, *hogs-fennel*, in botany, the name of a genus of plants, the characters of which are these: the flowers stand in umbells, and are of the rosaceous kinds, being composed of several petals arranged in a circular form, and placed upon a cup, which afterwards becomes a fruit, composed of two flat, oval, marginated, and striated seeds. To this it is to be added, that the leaves are alated, narrow, grassy, and divided always into three parts.

The species of *peucedanum*, enumerated by Mr. Tournefort, are these: 1. The greater Italian *peucedanum*. 2. The smaller or German *peucedanum*. 3. The French *peucedanum*, with fewer and shorter leaves. And, 4. The French *peucedanum*, with fewer and shorter leaves, with purple flowers. *Tourn.* Inst. p. 318.

The common *hogs fennel* is found in wet and moorish places, and about fen ditches. It flowers in June and July. Its root is esteemed of great use, as an expectorant and attenuant. It is prescribed in diseases of the breast and lungs, particularly in those in which those parts are loaded with a tough phlegm. It is also recommended in all obstructions of the viscera. It promotes urine, and is recommended in nephritic cases. The old authors have spoke greatly of its efficacy in all nervous cases, and have recommended it as a singular remedy in lethargies, palsies, epilepsies, and the like.

PEWIT, in zoology, the English name of a common bird of the *larus*, or sea-gull kind, called by some authors *larus cinereus*, and by others *cepphus*, and in some of the counties of England the *black cap*, and *sea-crow*.

It is about the size of a pidgeon. Its beak is red; its head and throat of a greyish black, and its neck, tail, breast, and belly white; the middle of its back grey. It has its English name from its note, which seems to express the word *pewit*. It is affirmed by many, that the head of this bird is only black at a certain season of the year. *Ray's* Ornithol. p. 264.

PHACOIDES, a word used by the antient physicians to express any thing that in size and shape approached to a lentill. Thus the crystalline humor of the eye was so called.

PHACOPTISANA, a medicine often mentioned by the antient writers as a nourishing and strengthening thing: it was a ptisan with lentills.

PHACOSIS, a word used by the antients to express a disorder of the eye, appearing in form of a black spot, of the size and round figure of the lentill.

PHÆCASIA, in antiquity, a kind of shoes. For the different opinions concerning which, see *Hofm.* Lex. Univ. in voc.

PHAGEDENIC-*water*, a name given to lime water, to every pint of which twenty or thirty grains of sublimate has been added. It is a great deterger of foul wounds; whence it has its name.

PHAGESIA, φαγησια, in antiquity, a festival in honour of Bacchus, celebrated during the Dionysia. See DIONYSIA, *Cycl.* It was otherwise called *phagesipolia*, φαγησιποσια; which names come from φαγειν, to eat, and πινειν, to drink; because it was a time of good chear. *Potter*, Archæl. Græc. l. 2. c. 20. T. 1. p. 434.

PHAGON, φαγων in antiquity, a festival of the same nature with that called *phagesia*. See PHAGESIA.

PHAGRUS, the *sea bream*. The Artedian system of ichthyology does not allow this fish a peculiar generical name, but makes it a species of the large genus of the *spari*: the author distinguishes this from the others by the name of the *reddish sparus*, with the skin hollowed into a sinus at the roots of the back fins. See SPARUS.

PHAGUS, in botany, a name given by many authors to the exulus, or sweet and esculent oak, found in Greece and Dalmatia. *Parkins.* Theatr. p. 1387.

PHALACRA, a word used by Hippocrates to express all the blunt

blunt inſtruments uſed in ſurgery; ſuch as probes and others, with buttons at the ends.

PHALACROCEPHALUS *indicus*, in zoology, the name of an anadromous fiſh of the Eaſt Indies. Its neck and head appear naked and bald, as it were. It is all over of a greyiſh white in colour, and is variegated with red ſpots about the mouth. The eyes are large and very prominent, and their iriſes yellow. Its uſual ſize is about a foot and a half in length, and it lives part of its time in the ſea, and part in rivers. It is an extremely delicate-taſted fiſh, and eſteemed one of the fineſt of that part of the world. It is called by the Dutch *kael kop*. *Ray*'s Ichthyogr. Append p. 2.

PHALAIA, a word invented by Baſil Valentine, and uſed as the name of a *panacæa*, or univerſal medicine; but Rolfink has ſince uſed it to expreſs a tincture of jalap.

PHALANGIUM, in the hiſtory of inſects, the name of a peculiar genus of *ſpiders*, the characters of which are theſe: They do not move regularly and evenly as other *ſpiders*, but hop in the manner of fleas. This was a character recorded of them by Pliny, and the antients, and is found at this time in all ſpecies. They have a ſquare forehead; and in this are placed eight eyes of different ſizes, and diſpoſed in form of a part of a circle. They have alſo the forelegs greatly longer and ſtronger than any of the others. Of theſe there are four principal kinds: 1. The grey *ſpider*, variegated on the belly, with ſix tranſverſe faſciæ meeting in an angle in the middle. Theſe are alternately black, and of a ſilvery white. It is of a middle ſize, and its grey colour ſeems a mixture of a deep black and a ſilvery white. It is common in woods and about old walls. 2. The reddiſh brown *ſpider*, variegated with two large black marks, and a foliaceous obſcure figure on the body. This is ſomewhat ſmaller than the former, and is found about old walls, but not frequently. 3. The yellowiſh *ſpider*, with green eyes, and with three yellow lines on the hips. This is of a middle ſize, but it is a very rare ſpecies. 4. The reddiſh rock *ſpider*. This is a moderately large kind, and is of a reddiſh cheſnut colour. It is a very ſcarce *ſpider*, and lives among rocks and on heaths. *Ray*'s Hiſt. of Inſects, p. 36. See OPILIO.

PHALANGIUM *apulum*, the *apulian phalangium*, a name given by authors to that large and poiſonous ſpecies of ſpider called by the vulgar, the *tarantula*, from the name of a city of Calabria, Tarantum; near which it is very common. Valetta, a monk of Apulia, who had always reſided about the places where this miſchievous animal is moſt frequent, and had had many opportunities of tracing its ſeveral qualities, publiſhed a ſuccinct, but very accurate hiſtory of it in the year 1706, under this name.

It had its name *phalangium*, from the three phalanges or joints of its legs, and this name equally ſuiting many other ſpiders, as well as this, it ceaſed to be its appropriated name, and was applied as a generical term to ſeveral other ſpiders of the larger kind; among which this ſpecies was always diſtinguiſhed by the epithet *apulian*, from the place where it was ſo frequently found.

The *tarantula*, or *apulian phalangium*, is frequent in all parts of this country, in uncultivated places, but more eſpecially it breeds moſt in ſunny dry hills, and particularly in ſuch parts of them as are expoſed to the ſouth. It is ſaid not to be found any where, except in Apulia; but probably it is an inhabitant of many other places, tho' its poiſon may not be violent enough any where elſe to bring on the effects it does there: as we find in vipers and many other poiſonous creatures, that the ſtrength of their poiſon differs greatly in degree in different places. As this ſpider is very tender, and eaſily injured by cold winds and rain, it always digs itſelf a cave in the ſide of a hill for its habitation; and uſually chuſes for this purpoſe the hardeſt ground it can find, which is better able to defend it, and which it eaſily works into with its forceps and claws. This always is hollowed upward in the hill, and by that means is ſafe from wet, all the water in rainy ſeaſons running down over its top. Sometimes it burrows itſelf a cave in a valley or plain, but then it always chuſes a dry, uſually a chalky ſoil. In this caſe the entrance into its cave is ſmall, and within there are ſeveral winding paſſages: if it happens to be ſurpriſed with wet in this place from hard rains, it quits the floor and hangs by its feet againſt the top of the cave. It preys upon a number of ſmall inſects with which the fields of Apulia abound, and ſeldom appears in the day-time, but creeps out about the time of ſun-ſet, and preys at large upon the animals which are then betaking themſelves to reſt; without the danger it would be expoſed to from its own enemies by day-light. If at any time he remains the whole evening in his cave or den, it is only to practiſe another method of hunting his prey. In this caſe he comes forward to the mouth of the hole, and there lies in wait; his fore-legs are placed at the extremity of the hole, and his eyes have a clear view all round. The other inſects are not aware of this trick, but as they walk near his hole he burſts out upon them, and ſeizing them, conveys them into his habitation; where, as ſoon as he has eaten them, he retires back into his cell to diſpoſe of the wings and other fragments, till he can carry them out at a more convenient time, and then places himſef in his former poſture for another prey.

The peaſants of Apulia have a method of getting him out of his hole in the day-time, in order to deſtroy him. This they do by making a ſoft hiſſing noiſe thro' an oat ſtraw; whether it be that the creature loves this ſound, or rather that he takes it for the voice of ſome inſect that he is uſed to prey upon, he always comes out, and falls a ſacrifice to his greedyneſs.

This creature has eight legs, and walks very well; his legs have each three joints, and are covered with a fine downy hairyneſs: they are of a whitiſh colour at the bottom, and variegated with black lines, and are wholly black in their upper part, where they are joined to the breaſt. Theſe all ariſe from a kind of oval ſhield, which is placed upon the breaſt, and is black, hairy, and very hard. This is called by ſome the *ſpeculum* of the *tarantula*. From the ſhoulders there grow a pair of horns, at leaſt they are uſually called ſo, tho' they ſeem much better to deſerve the name of *arms*. The uſe of theſe is to hold faſt the prey, that it may not be able to eſcape while he is killing it with his forceps. Theſe horns or arms have the ſame number of joints that the legs have, but they greatly differ from the legs, in that they are ſhorter and of a yellowiſh colour. They are alſo covered with a longer and thicker hair, for the more certainly holding the prey, and are terminated by black claws, and they are much ſmaller and more capable of motion every way. The belly is either white, or of a pale yellow, and is marked with a tranſverſe black ſtreak: this is ſurrounded with ſeveral other ſmall ſpots of the ſame colour, and is cloathed with a very fine and ſhort down. The whole body beſide is covered with longer hairs, and is of a whitiſh or browniſh colour. The apex of the head, the ſhield of the breaſt, and the ends of the forceps, are as hard as a crab's claws, but the reſt of the body is covered with a tender and ſupple ſkin. The eyes are very large, and of a fine ſhining black; they are continually in motion, and when ſeen in the night or in a duſky place, they ſhine like the eyes of a cat. In the place where the mouth is placed in other animals, there ariſes in this a black hard forceps; the upper part of this inſtrument is covered with a yellow hairyneſs, and it is terminated by extremely fine and ſharp claws, which the creature can open or cloſe up at pleaſure. While the arms hold the prey in a proper poſition, theſe ſharp points make wounds in the body, and the other parts of the forceps ſqueeze the body till all its juices are preſſed out, and the creature feeds on them. The mouth is placed much below theſe, and ſtands exactly in the proper place to receive the juices expreſſed by this operation. The *tarantula* ſleeps in his cave the whole winter, and a great part of the autumn and ſpring; and if during this time he is ploughed up, as is often the caſe, or is any other way taken out of his hole, he is found quite torpid and numbed, and is unable to do any miſchief by biting.

The hole or mouth of a tarantulous cave always gives ſome idea of the ſize of the creature within: he makes it ſmall if he enters while young; and as he grows larger he eats away more and more of the earth to widen it ſtill more, ſo that the diameter of it is uſually about equal to the diameter of the body. The ſize of a cheſnut is about the ſtandard of a full grown *tarantula*; but there are ſome old ones found much larger and more hairy. The female is known from the male by having longer legs and a larger belly. They copulate in June and July, and at that ſeaſon the females are often met with in the fields carrying the males upon their back. In Auguſt and September they lay their eggs, which remain the whole winter; and in the ſummer after are hatched. Pliny tells a ſtory of the young ones always eating up their mother for the firſt food, which is countenanced by the relation of the peaſants in thoſe parts, who ſay that they all ſwarm about her and ſuck her juices from many places at once, till they leave her lifeleſs carcaſs on the field, and then go each their ſeveral way in ſearch of other food. The bite of the *tarantula*, as it is called, is not properly a bite, but a wound inflicted in a very peculiar manner. The creature pierces the ſkin with its forceps, and at that inſtant injects from its mouth a poiſon into the wound. The time in which their wounds are fatal, is that of their copulation; at this time they are in their utmoſt vigour and power of hurting. People of faſhion are rarely hurt by them, but principally the poor labourers, who ſleep half naked in the field, and the women who travel the country with naked feet, gathering medicinal herbs.

Authors are divided about the nature of the poiſon of the *tarantula*. Cardan ſays it is a cold one, and Scaliger ſays it is a hot one; but be this as it will, its effect is very ſudden: it is no ſooner received into the fleſh but the veins take it up and carry it to the heart, where it becomes diffuſed thro' the whole maſs of blood, and gives an immediate trembling of the limbs, and a difficulty of breathing. The next part it ſeizes is the brain, where it produces different effects in different ſubjects; and according to their ſtate of health, and the condition of their juices, brings on various ſpecies of phrenſies.

The patient ſees a thouſand phantoms, ſometimes all jovial and merry ones, and ſometimes imaginary ſcenes of blood and cruelty. Some are fond of ſeeing little ſtreams of water trickling down into a baſon; others are never eaſy unleſs they have green leaves before them: this indeed is almoſt an univerſal ſymptom. Some are delighted with various colours, and ſome are fond of violent motion, ſuch as dancing, leaping, and the like; and ſome are in love with ſlow and graceful movements, as walking majeſtically, bowing, and dancing ſlow dances. Some are military mad, and call out for the noiſe of drums and trumpets, and the claſhing of ſwords; but all of them, as well the briſk and noiſy as the lethargic and dull, are pleaſed with muſic.

They will get up and dance to any inſtrument; and the moment it ceaſes playing they will fall down to the ground as if apoplectic, and not ſtir again till the muſic is renewed. Many people have laughed at the whole hiſtory of the bite of the *tarantula*, from this one accident of its poiſon being cured by muſic; but all who have been upon the ſpot atteſt it; and there ſeems no reaſon to call in queſtion the various authorities on which we have it related. *Valett.* de Phalang. Apulo.

PHALANGIUM *dectícum*, in natural hiſtory, a name given by all the old Greek writers to a poiſonous kind of field ſpider, the ſame with the *ſolipuga* of the Latins, or *ſolifuga*, as ſome write it. It is a ſmall inſect that buries itſelf in the ſand, and if it bites a man does very great miſchief; the part ſwelling, and the perſon becoming ſick as if bitten by a viper: ſome ſay the bite is actually mortal; but this ſeems to be going too far. Solinus tells us that this creature is peculiar to Sardinia, but we find Pliny mentioning it in Ethiopia; and Lucan tells us that it was one of the poiſonous reptiles that were in his time the peſt of Africa.

PHALANGIUM, *ſpiderwort*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is liliaceous, and conſiſts of four petals; from the center of which there ariſes a piſtil, which finally becomes a roundiſh fruit divided into three cells, and filled with angular ſeeds; to this it is to be added that the root is fibrous.

The ſpecies of *phalangium*, enumerated by Mr. Tournefort, are theſe: 1. The large flowered not branched *phalangium*. 2. The ſmall flowered not branched *phalangium*. 3. The branched *phalangium* with ſmall flowers. 4. The iris-leaved alpine marſh *phalangium*. 5. The iris-leaved Engliſh marſh *phalangium*. 6. The leaſt iris-leaved Scotiſh marſh *phalangium*. *Tourn.* Inſt. p. 368.

PHALANGOSIS, in ſurgery, the name of a tumor and relaxation of the eye-lids, which is often ſo great as to deform the eye, and very much impede viſion. Sometimes the relaxed eye-lid ſubſides or ſinks down, occaſioned either by a palſy of the muſcles which ſuſtain and elevate the eye-lid, or elſe from a relaxation of the cutis above, from various cauſes. Sometimes alſo an œdematous or aqueous tumor is formed on the eye-lids, ſo as almoſt entirely to exclude viſion; but this laſt caſe ſhould be well diſtinguiſhed from the other, and may be remedied without much difficulty, by the uſe of internal and topical medicines; ſuch as purges and diuretics given inwardly, and a compreſs dipped in warm ſpirit of wine and lime water.

But in the paralitic or relaxed caſe, the uſe of cordial and nervous medicines muſt be propoſed internally, and outwardly balſam of Peru and hungary water are to be employed. If all theſe fail, the remaining method is to extirpate a ſufficient quantity of the relaxed cutis; and then, after healing up the wound, the remainder will be ſufficiently ſhortened. *Heiſter's* Surgery, p. 367.

PHALANX (*Cycl.*) — PHALANX, in natural hiſtory, a term uſed by Dr. Woodward, and ſome other writers of foſſils, to expreſs an arrangement of the columns of that ſort of foſſile coralloide body found frequently in Wales, and called *lithoſtrotion*.

In the great variety of ſpecimens which are found of this, ſome have the whole *phalanx* of columns cracked through, and others only a few of the external ones; but theſe cracks never remain empty, but are found filled up with a white ſpar, as the ſmaller cracks of ſtone uſually are. This is not wonderful, as there is much ſpar in the compoſition of this foſſil; and it is eaſily waſhed out of the general maſs to fill up theſe cracks, and is then always found pure, and therefore of its natural colour white.

The *lithoſtrotion* or general congeries of theſe phalanges of columns, is commonly found immerſed in a grey ſtone, and found on the tops of the rocky cliffs about Millford in Wales. It is uſually erect, tho' ſomewhat inclining in ſome ſpecimens, but never lies horizontal. It ſeems to have been all white at firſt, but to have been ſince gradually tinctured with the matter of the ſtone in which it lies. The ſingle columns which form each *phalanx*, are uſually round or cylindric, tho' ſometimes flatted and bent; ſome of them are alſo naturally of an angular figure; theſe, however, are not regular in the number of their angles, ſome conſiſting of three ſides, ſome of five, and ſome of ſeven; ſome are hexangular alſo, but theſe are ſcarce. They are from five or ſix to ſixteen inches in length; and the largeſt are near half an inch over, the leaſt about a quarter of an inch; the greater number are very equal to one another in ſize; but the ſides of the columns being unequal, the ſame column meaſures of a different thickneſs when meaſured different ways: the phalanges or congeries of theſe are ſometimes of a foot or more in diameter.

The columns are often burſt, as if they had been affected by external injuries; and it is evident, that they were not formed before ſeveral other of the extraneous foſſils; for there are found ſometimes ſhells of ſea-fiſhes and entrochi immerſed and bedded in the bodies of the columns. It appears plainly from hence, that when theſe bodies were waſhed out of the ſea, and toſſed about in the waters which then covered the tops of theſe cliffs, which cannot reaſonably be ſuppoſed to have been any other than thoſe of the univerſal deluge; this elegant foſſil, together with the ſtony bed in which it is contained, were ſo ſoft that theſe other bodies found entrance into their very ſubſtance, and they were formed, as it were, upon them. This foſſil takes an elegant poliſh, and makes in that ſtate a very beautiful appearance, being of the hardneſs of the common white marble, and carrying the elegant ſtructure viſible in the ſmalleſt lineaments. *Woodward's* Coll. of Foſſ. p. 11.

PHALARIS, in the Linnæan ſyſtem of botany, the name of a peculiar kind of graſs called *phalaroides* by Scheuhzer and others; and with this author making a diſtinct genus of plants, the characters of which are: That the cup is a glume, containing only one flower; this glume is large, bivalve, obtuſe, and compreſſed, each of the valves being of a boat-like ſhape, flatted, obtuſe above, with ſtrait edges meeting one another in parallel lines. The flower is alſo bivalve, and is ſmaller than the cup; the exterior valve of it being oblong, pointed, and folded, the interior much ſmaller. The ſtamina are three capillary filaments, ſhorter than the cup; the antheræ are oblong; the germen of the piſtil is roundiſh; the ſtyli are two in number, and are capillary ones; the ſtigmata are hairy; the flower ſerves for a cloſe covering to the ſeed, not at all gaping from it; the ſeed is ſingle, ſmooth, and roundiſh, but pointed at both ends. *Linnæi* Gen. Plant. p. 14.

PHALENÆ, in natural hiſtory, the name by which authors diſtinguiſh thoſe butterflies which fly by night, and which the French thence call *papilions nocturnes*, and we vulgarly *moths*.

All the creatures of this claſs are quiet by day, remaining fixed to the ſtalks or leaves of plants, except only ſome of the males, which are now and then found fluttering about in the woods in ſearch of the females; but as ſoon as night approaches they all fly about. This diſpoſition is very remarkably implanted in their nature; for when kept ſhut up in boxes they always remain quiet without changing place all day, but as ſoon as the ſun is about ſetting, they always begin to flutter about and fly as much as their priſon will permit them. The ſpecies of theſe are more numerous even than thoſe of the day butterflies. The day kinds all have trunks fitted for the ſucking the juices of flowers for their nouriſhment, but many of the *phalenæ* wholly want them: theſe, however, have always the beards which ſerve to defend the trunk from injuries in the day-flies, and ſometimes in the place of the trunk within theſe, there is found a ſmall white protuberance or two. It is certain, therefore, that many of the *phalenæ* have no organs of eating, nor take in any food during their whole lives in that winged ſtate. *Reaumur's* Hiſt. of Inſ. Vol. 1. P. 1. p. 363.

The grand diſtinction of the *phalenæ* is into thoſe which have trunks, and thoſe which have not; or at leaſt which have not any ſenſible to the eye of a common obſerver; according to theſe, and to other eſſential diſtinctions, theſe, in the manner of the *papilios* or day-flies, are arranged into ſeven claſſes. See PAPILIO.

Claſs 1. This contains the *phalenæ* which have priſmatic antennæ, or ſuch as are of an equal thickneſs in almoſt all their length, and have their anterior part rounded, but their hinder part formed of two planes meeting in an angle; ſo that a tranſverſe ſection of one of theſe antennæ repreſents a curvilinear triangle. All the *phalenæ* of this claſs have trunks, and the greater part of them have their wings ſo diſpoſed, that they form a flat ſurface when the creature is at reſt, and leave the upper part of the body naked; and this uſually terminates in a point. The inferior wings are ſmall in compariſon of the ſuperior, and their inferior edge is ſhorter, and uſually very much ſo, than the ſuperior; and the end of this reaches to the end of the body, or beyond that, whereas the other uſually leaves two or three rings of it uncovered.

Thoſe moths which have large and heavy bodies, and have ſhort under-wings, and narrow, tho' long upper ones, always make a great noiſe in flying, and cannot ſupport themſelves in the air without agitating their wings very ſwiftly. This is alſo the caſe with ſome of the day-butterflies.

Many of the very large and beautiful *phalenæ* are of this firſt claſs, particularly that which is produced of the beautiful ſpurge caterpillar.

Claſs 2. This comprehends the *phalenæ* which have conic horns or antennæ, which regularly decreaſe in diameter from

their origin to their extremity, and terminate in a very fine point. These *phalenæ* also have trunks, as well as those of the former class; and their antennæ are usually very slender.

Class 3. This comprehends the *phalenæ* which have antennæ of the same form with those of the former class, but have no trunk.

Class 4. This comprehends the *phalenæ* which have bearded antennæ and a trunk.

Class 5. This comprehends those which have bearded antennæ and have no trunk.

There are several genera of each of these classes, distinguished by the particular structure of their antennæ, tho' of the general form described in the character of the class. Those which are composed of several vertebræ joined end to end, which make the length, have great differences in the size and proportion of these joints, and some of them are hairy, others smooth. These, however, tho' very certain and unerring distinctions, are not to be perceived without the assistance of the microscope; whereas the same animals offer us much more plain and obvious distinctions, and those equally certain, in the different manners in which they fly, and carry their wings when at rest. The butterflies have different manners of carrying their wings, but these are but few in comparison of the moths; so that if the classes in these last were to be established according to this character, they would be greatly too numerous; tho' this gives very happy subdistinctions of the peculiar genera of each class, of which we shall give some instances hereafter, in regard to this class.

Class 6. This comprehends a very peculiar sort of *phalenæ*, the females of which have no sensible wings. Several of those caterpillars which have long parcels of hairs at their heads resembling horns, give *phalenæ*, the females of which have no wings; and the creeping ones, with ten legs, also give some. *Reaumur*'s Hist. Inf. V. 1. P. 1. p. 408.

Class 7. This comprehends a set of *phalenæ* which are much more distinctly characterised by nature than any of the former: they have wings shaped like those of birds, and composed of true and proper feathers. All the *phalenæ* of this class are small, but their singular structure makes them worthy a peculiar attention.

It is scarce possible to determine exactly, whether they belong to the *phalenæ* or butterfly class most properly: they have the conic antennæ, which character a former class of the *phalenæ*; but they are often found flying about in the day time, in the manner of the day-flies: their changes also are made in the same manner with those of the day-flies; so that upon the whole, it is, perhaps, most proper to account them a peculiar class of the *papilio*, considered as a general term, but without regard to the first distinction of day and night kinds, or of moths and butterflies.

There are three genera of this class, each of which carries its distinctions from the others very obvious and distinct, so as not to be in any danger of being mistaken.

Those of the first genus are all of a remarkable whiteness; they always stand upon all their six legs, and the two hinder ones are much longer than the others. This creature never carries its wings lying on its body, as the generality of *papilios* do; but they are placed in a direction perpendicular to the length of its body, or nearly so. When it is at rest, the wings are closed somewhat in the manner of those of birds; yet in this state we may see that they are made of feathers, which, when we view them with the microscope, appear to be so many segments into which the wings are divided; the upper being divided into two, and the lower into three, each of which is edged on both sides with real feathers. Mr. Hook has figured this creature in his micrographia, and has given but two divisions to the under wing; but that was probably an oversight, the middle one being easily overlooked. When this little creature flies, it separates the segments of its wings farther off, and expands its feathers so, that they perfectly resemble those of a bird; and the two wings are in this state so placed together as to resemble only one. As beautiful, however, as these wings are to look at, they are but of very little use to the creature in flying. It is not known to fly at all by night, and in the day it takes only very small and short flights.

The creature given by Reaumur as an instance of the second genus of this class, is of a fine bright brown colour, as are all of the genus. When this creature is in a state of rest, its wings are not seen to be feathery, nor even to be wings at all; but are so folded up, as to resemble arms stretched out at length: and the creature in this posture looks like the miniature figure of a man upon a cross, the two wings of each side being folded into a sort of cord, and turning hooked at the ends. The inferior wings are composed each of three plumes, and are lodged in a furrow made by the upper ones, which are convex externally, and concave within, and are divided only about a sixth part of their length, but their segments are well feathered at the edges for half their length.

This species also differs from the former, in that it stands only on its four anterior legs, the two hinder ones being usually extended along the sides, and forming a sort of tail after they have crossed one another behind.

The creatures of the third genus of this class are small, and are frequently seen on the glass of our windows; and their wings are the most truly plumose of those of any species. They are of a brown colour, with somewhat of a gilded look when closely viewed, and have a few black spots in different parts. They carry their wings flat, or horizontally, when at rest; and these appear like the wings of the common butterfly, but when nearly examined, they are found to be composed of real feathers; and their seeming continuity is only owing to the close arrangement of these feathers. This is a very tender creature, and easily crushed to pieces; but when caught carefully, and examined by the glass, each upper wing is found to be composed of eight feathers, and each under one, of four; and the quill part of the pedicle of these feathers, is in all the wings separate to the very point at the top, which is very different from the others, where the wing is only divided a little way into segments; and the upper and under wing of each side are so nicely fitted together when the creature flies, that they only resemble one very large wing. Yet even these feathered wings, when viewed by powerful microscopes, are found not to be truly feathered; but what we term plumes are in reality only a nice arrangement of scales, like those of other butterflies upon the deep segments of the wing. This species has conic antennæ and a trunk. Its origin is unknown, but it seems to be produced of some of the teniæ which live in our houses, since it is always found within doors, never in the fields; and is seen in the month of March, which is earlier than the field butterflies are seen: they are also found in August, September, and October, and sometimes later than that month. *Reaumur*'s Hist. Inf. V. 1. P. 1. p. 419.

Mr. Reaumur has given an example of the manner of distinguishing the subordinate genera of the other classes, in those of the second, fifth, *&c.* before mentioned. In this he has regard to the position and direction of the wings, which is sufficiently certain and determinate, and is the most obvious of all characters; according to this he has established the following genera of this extensive class:

Genus 1. The *phalenæ* of this genus carry their wings parallel, and in an horizontal direction; but they cross one another, one of the upper wings lying in great part over the other. Sometimes it is the right that crosses over the left, and sometimes the left that crosses over that; but however this be, the under wings always lie folded underneath them. Many of the caterpillars which feed on our garden herbs, afford *phalenæ* of this genus, of which there are several of the second class.

Genus 2. This comprehends those *phalenæ* whose wings lie parallel, as in the former genus: they also cover in the same manner the under wing, but these never cross one another. Of this genus there are several subdivisions.

Genus 3. This comprehends those *phalenæ*, the upper wings of which have their interior edges applied one against the other: and tho' they are in general held parallel to the horizon, yet that part of them which covers the body has not the same parallelism with the rest; but are bent round about the body, and so moulded, as it were, upon it, that they shew the shape of that part of it which they cover. We have an instance of this genus in that *phalena* which is produced of the caterpillar which feeds upon the young and green seeds of the nettle. Its wings are variegated with white, and with a deep brownish black, in an elegant manner.

Genus 4. This genus comprehends those *phalenæ* which carry their upper wings in an horizontal direction, but which, instead of crossing, or even touching one another, are so wide asunder, that they do not cover any part of the body, but leave both that and the under wings naked. This genus comprehends a great number of species, which are distinguished according to the different distances to which they expand the wings in sitting; some having them little less so at rest than when flying.

Genus 5. This comprehends those which have the interior edges of the upper wings joined one to the other, and raised above the surface of the body, so that they form a sort of canopy over the creature. In this case, the under wings are always necessarily hid. We have an instance of this genus in the second class, one of the *phalenæ* of that being a very beautiful one, variegated with red and black, always carrying its wings in this manner very remarkably.

Genus 6. This comprehends a set of *phalenæ* which somewhat resemble the former in the placing of their wings, insomuch, that they meet at the interior edges, and form a canopy over the body; but as this is strait and angular in the former genus, it is rounded or arched in this: the inner part of each outer wing being bent, as it were, into the shape of the body. We have a very frequent instance of this genus in one of the *phalenæ* of the third class, which has conic antennæ and no trunk: the caterpillar of this species feeds on the rotten trunks of trees.

Genus 7. This comprehends a great number of *phalenæ*, the greater part of which are very small in size, and carry their wings almost horizontally, forming a very depressed canopy over their bodies. These are remarkably thick about the shoulders, or origin of the wings, and are known by many by the name of the *large-shouldered*. When these are in a state of rest, their largest diameter is either at the origin or at the middle of the breast, at or near the insertion of the wings.

We have many *phalenæ* of this kind produced from thoſe caterpillars which artfully roll up the leaves of trees, particularly one bred from a ſmooth caterpillar of this kind, with ſixteen legs.

Genus 8. This comprehends thoſe *phalenæ*, the wings of which are laid cloſe down upon the body, ſo as to be moulded on it, and take its exact ſhape: theſe cover the body exactly as the wings of birds do theirs. There are humbers of ſmall moths of this ſpecies, which are produced of thoſe kinds of caterpillars which live all their time in ſociety in one common web; of theſe there are many ſpecies.

Genus 9. This comprehends a ſet of *phalenæ* ſmaller than the former, which carry their wings in the ſame manner, cloſely folded upon their bodies; but differing in this, that they are extended to a conſiderable length, and towards their extremity riſe up above the level of the body, and form a ſort of tail like that of a cock. The *phalenæ* of this genus are diſtinguiſhed by ſome under the name of *cock-tailed*; and tho' they are ſmall, yet they are very numerous, and of very great variety; and when examined with the microſcope, appear of a beauty equalling almoſt any kind. Their wings thus viewed are frequently found variegated with gold and ſilver in appearance, the yellow and white ſpots frequent in them having a brightneſs which a painter could give us no idea of, but by uſing thoſe metals. The moths of the teniæ of ſeveral ſpecies are of this kind: their antennæ are uſually of the conic kind, and as ſlender as hairs; and it is difficult to ſay whether they have any trunk, it being, if they have any, of a very minute kind.

Genus 10. This comprehends a ſet of *phalenæ* whoſe upper wings are very remarkably folded over the body, one of them ſurrounding it in a manner, and the other turning itſelf ſpirally round that; ſo that a very great part of one of the upper wings is always covered by the other. *Reaumur*'s Hiſt. Inſ. V. 1. P. 1. p. 394, 396.

PHALERA, the name of a bandage for the noſe, deſcribed by Galen in his treatiſe on bandages.

PHALERÆ, among the antients, horſe-trappings. See the article TRAPPINGS.

PHALLUS *marinus*, a name given by ſome authors to a ſpecies of *canalis* or *tubulus marinus*, found about Amboina, and called by the French writers *priape* and *arroſoir*. It is an oblong ſhell, with a large head, which is pierced full of holes; ſo that it at once reſembles the *glans penis*, and the noſe of a watering-pot uſed by gardeners.

PHARI, among the antients, a kind of candleſtick. See the article BRANCH.

PHARICUM, the name of a famous poiſon among the antients: it was ſaid to be compoſed of many ingredients, but we know nothing of it at this time.

PHARMACI, φαρμακοι, among the Greeks, an appellation uſed for two perſons who were employed in the luſtration or purification of cities. *Pott.* T. 1. p. 400.

Theſe were two men, according to ſome; but others ſuppoſe them to have been a man and woman, to repreſent the male and female ſex, for each of which they offered a ſacrifice. It was uſual for the man to carry about his neck figs, called ισχαδες, of a blackiſh colour; and the woman ſuch as were white. *Pott.* Archæol. Græc. T. 1. p. 400, ſeq. See the article LUSTRATION, *Cycl.*

PHARMACIA, φαρμακεια, in antiquity, denotes the art of effecting ſtrange and wonderful things, by means of medicated and inchanted compoſitions of herbs, minerals, &c. Theſe things themſelves were called *pharmaca*, ſome of which being taken inwardly, were ſaid to cauſe blindneſs, madneſs, love, &c. Such were the medicaments by which Circe transformed Ulyſſes's ſoldiers; others infected by touch, ſuch was the garment Medea ſent to Creüſa; others ſpread their venom afar off, and operated upon perſons at a great diſtance.

There were alſo *pharmaca ſoteria*, φαρμακα σοτηρια, which were amulets againſt the former; ſuch was the herb moly, which preſerved Ulyſſes from Circe's inchantments; the laurel, the ſallow-tree, the rhamnus, or Chriſt-thorn, flea-bane, the jaſperſtone, and many others mentioned by Albertus Magnus, and Orpheus, in his book de lapillis. *Pott.* Archæol. Græc. l. 2. c. 18. T. 1 p. 353. See AMULET.

PHARMACITIS *terra*, in the materia medica, a name which ſome authors have given to the common *ampelites* or cannel-coal. See AMPELITES.

PHARMACOCHEMIA, a term uſed to expreſs that part of the chemical art which treats of the preparation of medicines.

It is thus called by way of diſtinction from that chemiſtry which is wholly employed about the tranſmutation of metals by means of the philoſopher's ſtone; this being called *ſpagirico-chemia*.

PHARMACY *(Cycl.)*—Moſt of the natural bodies being ſome way or other employed as ſubjects of *pharmacy*, the materia medica is extremely large, and its operations various. Its materials in the earlieſt ages, indeed, were very few, and the ways of managing them very ſimple: ſubjects afterwards multiplied, operations increaſed, and at preſent we ſeem abundantly ſtocked with both ſimple and compound medicines.

Diſeaſes muſt have been very early, if the firſt inhabitants of the earth experienced the ſame changes of ſeaſons, breathed the ſame kind of air, and uſed a like kind of diet and regimen of life with ourſelves: but ſoon after the diſeaſe afflicts, the patient ſeeks a remedy; and this appears to have been the foundation of *pharmacy* in different parts of the world.

Experiments being thus multiplied, and the preparations of ſimples better made, *pharmacy* became at length an art. Hippocrates, however, when he came to compile a kind of ſyſtem of phyſic from the obſervations of antiquity, deſcribed but few, and thoſe generally ſimple. *Shaw*'s Lectures, p. 193. Succeeding phyſicians then enlarged the materia medica; Galen conſiderably ſwelled the catalogue, and the Arabians much more; and when learning began to revive in Europe, the materia medica was again enlarged, and great changes wrought upon it by chemiſtry.

The art of *pharmacy* muſt be conſidered under the management of phyſicians, apothecaries, trading chemiſts, and druggiſts. To the phyſician it belongs to direct the medicines, and to give the rules of extracting and managing the ſimples. To the apothecary belongs the reduction of the materia medica into certain forms of medicines, according to the direction of the phyſician. And the deſign of trading chemiſts and druggiſts, is to furniſh medicinal matters to the apothecary, who cannot always detect an artificial counterfeit, or a dexterous ſophiſtication; and perhaps many remedies, well deſigned by the phyſician, have failed or had miſchievous effects on this account. *Shaw*'s Lectures, p. 195.

PHARMUTHI, in the Ægyptian chronology, one of the months of their year, which anſwered to the month of April among the Romans *Hoffm.* Lex. univ. in voc.

PHARYNGÆUM *ſal*, a name given by authors to an artificial ſalt, of uſe in the quinſey, and caſes of the like kind, when the *pharynx*, or fauces are incommoded by a diſcharge of ſerous or other humours.

It is prepared of cream of tartar and nitre, each an ounce, with half an ounce of burnt alum; all theſe are to be diſſolved in vinegar, and coagulated according to art. This ſalt mixed with honey, and diſſolved in plantain water, makes an excellent gargle.

PHASEOLUS, *kidney-bean*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the papilionaceous kind, and its piſtil, which ariſes from the cup, finally becomes a long pod, containing ſeveral kidney-ſhaped, or elſe oval ſeeds. To this it is to be added, that the leaves always ſtand three upon a ſtalk, and the whole trace and habit of the plant is peculiar, and diſtinguiſhes it from the other papilionaceous flowered genera.

The ſpecies of *phaſeolus*, enumerated by Mr. Tournefort, are theſe: 1. The common garden *phaſeolus*. 2. The common *phaſeolus*, with black fruit. 3. The common *phaſeolus*, with yellow fruit. 4. The common *phaſeolus*, with red fruit. 5. The common *phaſeolus*, with livid fruit. 6. The common *phaſeolus*, with pale coloured fruit. 7. The common *phaſeolus*, with violet coloured fruit. 8. The common *phaſeolus*, with fruit variegated with black and red. 9. The common *phaſeolus*, with white fruit, variegated with black lines and ſpots. 10. The common *phaſeolus*, with purple fruit, variegated with circles of white. 11. The leſſer garden *phaſeolus*. 12. The leſſer *phaſeolus*, with pods bending upwards, and with white fruit. 13. The black-fruited leſſer *phaſeolus*, with pods bending upwards. 14. The white-fruited leſſer *phaſeolus*, with pods bending upwards, and with black or purple circles variegating the fruit 15. The large *phaſeolus*, with broad white fruit, ſtriated with numerous black veins. 16 The large *phaſeolus*, with broad, compreſſed, perfectly white fruit. 17. The large *phaſeolus*, with large flat white ſtriated fruit. 18. The large *phaſeolus*, with ſmall ſnow-white tumid fruit. 19. The *phaſeolus*, with greeniſh black fruit, reſembling thoſe of the anagyris. 20. The *phaſeolus* with red fruit, reſembling that of the anagyris. 21. The ſmall *phaſeolus*, with white fruit, marked with a black ſpot. 22. The narrow-leaved exotic *phaſeolus*. 23. The narrow-leaved exotic *phaſeolus*, with variegated black and white fruit. 24. The ſmall-leaved foreign *phaſeolus*, with white, and ſometimes with variegated fruit. 25. The foreign *phaſeolus*, with the pod and the fruit both black. 26. The foreign *phaſeolus*, with variegated fruit. 27. The foreign *phaſeolus*, with reddiſh fruit, variegated with black lines. 28. The foreign *phaſeolus*, with white fruit, of the ſhape of a pigeon's egg, and marked with a ſingle black ſpot. 29. The foreign *phaſeolus*, with black fruit, variegated with a white ſpot. 30. The Æthiopian *phaſeolus*, with black pods, ridged with rough veins, and with a black ſhining ſeed. 31. The Æthiopian *phaſeolus*, with yellow leaves and a black ſeed. 32. The Æthiopian *phaſeolus*, with deep red pods and black ſeeds. 33. The black-fruited Ægyptian *phaſeolus*. 34. The red-fruited Ægyptian *phaſeolus*. 35. The American *phaſeolus*, or lablab, with roſe-coloured fruit. 36. The Indian *phaſeolus*, with cochleated flowers. 37. The ſcarlet-flowered *phaſeolus*. 38. The ſmalleſt flowered *phaſeolus*, with a green fruit of an oval ſhape. 39. The garden *phaſeolus*, with white ſmall oval ſeeds. 40. The American *phaſeolus*, which propagates itſelf by its tendrils. 41. The African *phaſeolus*, with ſmall white fruit. 42. The ſmalleſt *phaſeolus*, with very long pods. 43. The Braſilian *phaſeolus*, with a black fruit, of the ſize of a pea. 44. The ſmall perennial African *phaſeolus*, with bright

bright red flowers. 45. The American *phaſeolus*, with a ſinuated and ſpear-pointed leaf. 46. The knotty-rooted American *phaſeolus*, with purple flowers, and very narrow pods. 47. The knotty-rooted American *phaſeolus*, with yellow flowers and knotty pods. 48. The hairy *phaſeolus* of America, with knotted pods. 49. The largeſt American *phaſeolus*, with a great pod, and a hard ſcarlet fruit. 50. The large American *phaſeolus*, with a great flower and with ſlender crooked pods. 51. The hairy American *phaſeolus*, with jointed pods. 52. The American *phaſeolus*, with a tuberous eſculent root, and with hairy, and, as it were, jointed pods. 53. The American *phaſeolus*, with a cochleated flower, and falcated pods. 54. The American ſea *phaſeolus*, with a hard fruit and variegated ſeed. 55. The American *phaſeolus*, with ſmall pods and variegated ſeeds. 56. The American *phaſeolus*, with a pyramidal ſpike of flowers, and red ſeeds, marked with a black ſpot. 57. The American *phaſeolus*, with a remarkable large vexillum to the flower, and with ſtrait cylindric-ſhaped pods. 58. The round-leaved ſea *phaſeolus*, with a purple flower, a ſhort-creſted pod, and brown ſtriated ſeeds. And, 59. The pernicious wood *phaſeolus* of America, with open pale purple flowers, and ſlender black pods, and ſmall ſpotted ſeeds. *Tourn.* Inſt. p. 412. ſeq.

There are at preſent three ſorts of *kidney-beans* propagated for the table in England. Theſe are, 1. The common white or Dutch *kidney-bean*. 2. The ſmaller *kidney-bean*, commonly called the Batterſea *kidney-bean*. And, 3. The upright ſort, called the tree *kidney-bean*.

The firſt ſort was ſometime ago greatly propagated in England, and is ſtill in Holland: it grows very tall, and requires long ſtakes and poles to climb on, and its beans are conſiderably broad; this makes them leſs ſaleable in the markets, people ſuppoſing them to be old becauſe they are broad; and they are hence grown into diſuſe, tho' a much more valuable kind for eating than any other.

The ſecond, ſort or Batterſea bean, is what is more univerſally cultivated; it never grows very tall nor rambles far, and the air can eaſily paſs between the rows, becauſe of its moderate growth; and this makes it bear plentifully and ripen well for the table. It is the beſt-taſted bean, except the laſt.

The third, or tree *kidney-beans*, is alſo a plentiful bearer, and never rambles, but grows up in form of a ſhrub; but its beans are broader than the Batterſea kind, and are not ſo well-taſted.

They are all propagated from ſeeds which are to be put into the ground in the latter end of March or beginning of April for an early crop, but theſe ſhould have a warm ſituation and a dry ſoil; they muſt alſo be planted in a dry ſeaſon. The manner of planting them is, to draw lines with a bough over the bed, at two foot and a half diſtance, into which the ſeeds are to be dropped at about two inches aſunder, and the earth is to be drawn over them with the head of a rake, to cover them about an inch deep. In a week after ſowing, the plants will appear, and the earth ſhould be drawn up about their ſtalks as they riſe up; for a few days after this they will require no farther care, except to be kept clear from weeds, and when the beans appear, to have them gathered twice a week; for if the beans are ſuffered to hang on too long, they not only become of no value, but they weaken the plant.

The firſt crop of *kidney-beans* will continue a month in good order; and to ſupply the table afterwards, there ſhould be freſh ſowings in March, April, May, and June, the laſt of which will continue till the froſts come to deſtroy them. Some raiſe their early crops on hot-beds; and this is to be done exactly in the ſame manner as the raiſing the early cucumbers. *Miller*'s Gard. Dict. See the article CUCUMBER.

PHASSACHATES, in the natural hiſtory of the antients, the name of a ſpecies of *agate*, which, in its different appearances, they ſometimes called alſo *leucachates* and *perileucos*.

The ſame *agate*, from the various proportion or manner of admixture of its particles in different ſpecimens, often makes a very different figure; but no ſpecies is ſo liable to remarkable diverſities of this kind as this. It is but of a ſmall variety of colours, yet is often very beautiful; its ground or baſis is always a pale bluiſh grey, approaching to what we call a lead colour, or dove colour. Sometimes it is equally and evenly of this colour, thro' the whole maſs, but often alſo it is variegated within with veins of a deep black and of a pure and clear white: theſe ſometimes approach the ſurface of the ſtone, but more uſually they are only near the center; and they are almoſt always diſpoſed in concentrical, but irregular circles, round one, two, or more points. The pieces of this ſtone, cut where there are many of theſe veins, much reſemble parts of onyxes.

It is found in the Eaſt Indies, and in Bohemia, and ſome other parts of Europe. When the whole matter of the veins and baſis of this ſtone are all blended together into one equal maſs, as is frequently the caſe both with this and many other of the naturally veined ſtones, the whole becomes of a deeper greyiſh blue, or a dove colour, and is then the *phaſſachates*; when the veins are kept diſtinct and clear, it is the *leucachates* and *perileucos*, agreeing with all the deſcriptions of the antients. *Hill*'s Hiſt. of Foſſ. p. 480.

PHAUSINGES, a name given by the antients to red circles on the legs, occaſioned by fire: it is by ſome alſo extended to ſeveral other ſpots and blemiſhes on the ſkin.

PHEANTIDES, in natural hiſtory, a name given by ſome to the ſtone called *encymonites*; it was of the nature of our ſparry incruſtations on the roofs of ſubterraneous caverns. It was ſuppoſed to have great virtues in promoting delivery, and was given to women when they fell in labour.

PHEASANT, in ornithology, a bird ſo nearly allied to our common poultry, that it would naturally appear a very eaſy thing to breed them up from young; but the proper food of them is not ſufficiently enquired into. Tho' they eat corn when full grown and in health, yet they have recourſe in their young ſtate, and when ſick, to another ſort of food, preying on ſeveral inſects, and that in a very voracious manner.

The young *pheaſants* and partridges prey upon ants; and they will never ſucceed with us if they have not a proper quantity of ants to have recourſe to, as ſoon as they leave their rooſt in a morning. When muſty corn, or want of due care in cleaning their houſes has made them ſick, a repaſt of ants will often recover them. When that fails, they may be offered millepides or ear-wigs, or both together, which will always do much better than either ſingly. To this medicine muſt be added a proper care that their common food of corn be very ſweet, their habitation kept nicely clean, and their water ſhifted twice a-day. They muſt not be let out of the houſe in a morning till the dew is off the ground; and after ſun-ſet they muſt be immediately taken in again: in the heat of the day they muſt be allowed to baſk in the ſun in a dry ſandy place. With theſe regulations the birds of this kind will ſucceed much better than they uſually do. The *pheaſant* is a bird of a ſullen diſpoſition, and when the coupling time is over, there are ſeldom found more than one in a place. Phil. Tranſ. N° 23.

The way of taking *pheaſants* is, firſt to be acquainted with their haunts and breeding places; which are uſually young, thick, and well-grown coppices, free from the diſturbances of cattle, and having no path-way thro' them, for the *pheaſant* is an extremely timorous bird. When the haunts are diſcovered, the next thing to be attempted is, to find where the eye or brood is. In order to this, it is to be conſidered, that the *pheaſant* comes out of the wood three times a-day to feed in green corn, freſh paſtures, or the like places. The times of coming out are in the morning ſoon after ſun-riſe, at noon, and at ſun-ſet. The ſides of the wood where they are ſuppoſed to come out, are to be carefully watched on this occaſion, and the young ones will be ſeen following the female juſt as a flock of chickens follow the hen. The wood may be alſo well watched in the evenings, and the noiſe of the cock and hen calling the young ones together will ſoon be heard; and the ſportſman is on this occaſion to get as near as he can to the place, and being very ſtill and ſilent he may obſerve their numbers and diſpoſition, and learn how to ſpread his nets ſo as to take the whole brood with great eaſe; but if his leaſt motion when near them diſcover him, they will all take to their legs and run to a great diſtance; they ſeldom riſe on the wing, except very cloſe frighted indeed. Practice will make ſome people ſo expert at the imitating the voice of the old *pheaſant*, that he will be able to call the young ones together to any place that he pleaſes, when the haunts are once found out, and by this means they are eaſily led into the nets.

The beſt time for uſing the call is, in the morning or evening; and the note imitated ſhould be that by which the old ones call them out to feed; but by learning to imitate the other notes they will be brought together at any time of the day. The ſportſman who can make this call, muſt ſhelter himſelf in ſome cloſe place, and begin by very ſoftly making the note; then if none are near enough to be within hearing, he is to raiſe it to more and more loudneſs, and at length he will be anſwered as loud, if any are within hearing, tho' at a conſiderable diſtance; whereas if he ſhould ſet up the call too loud at firſt, and any of the birds ſhould happen to be very near, they would be frighted away.

As ſoon as a *pheaſant* anſwers, the ſportſman is to creep nearer and nearer, ſtill calling, tho' not ſo loud; he will ſtill be anſwered, till at length he will be led by the bird's voice within ſight of her. As ſoon as this is the caſe, he is to ſpread his net, and then begin to call again, keeping in ſome cloſe and well-ſheltered place behind the net: in this place he is to call till the bird approaches; and when he has drawn her under the net, he is to appear ſuddenly, and the bird riſing up will be caught in the net.

Another method of taking *pheaſants* much quicker than by this means is, the having a live cock *pheaſant* to uſe as a ſtale: this bird is to be fixed under the net, and by his crowing he will ſoon entice others in. The ſportſman muſt lie concealed, and as ſoon as another *pheaſant* comes in, he is to draw the net over him. Many people have a method of taking *pheaſants* in ſpringes or horſe-hair ſnares: the ſucceeding in this depends on the carefully ſearching out their haunts and the places by which they go out of the woods into the fields. When theſe are found, a peg is to be fixed in the ground at each, and at each peg two ſpringes are to be laid open; the one to take in the legs, the other the head. As

ſoon

ſoon as the ſpringes are ſet, the ſportſman is to go into the woods, and getting behind the birds, he is to fright them with ſome little noiſe, ſuch as ſhall not be enough to raiſe them to the wing, but only to ſet them a running. They will naturally make their way out of the wood thro' their accuſtomed paſſes, and be then caught in the ſpringes.

There is another method yet of taking theſe birds in the winter, provided that there is no ſnow. This is to be done with a net made like a caſting net, but with the meſhes much wider; they may be five inches wide. Some peas or wheat are to be taken out, and the path of the *pheaſants* being diſcovered, which may eaſily be done by their dung, a pint or thereabout of corn is to be thrown down in the path in a place marked, ſo that the ſportſman can come to it again. This is to be done for ſeveral days, till at length the *pheaſants* are expecting it every day regularly; and all the birds of this kind that frequent the place, are brought together to feed there, and then the net is to be fixed over the place; its top being tied up to ſome bough of a tree, and its bottom fixed down all round, except in one place, where the walk of the *pheaſants* lies. In this place it is to be raiſed in form of an arch, and the entrance is to be lined with ſeveral rods of hazel; the thick ends of which are to be tied to the net, and the thin ones let into the ſpace covered by it; and thus the *pheaſants* will eaſily get in by parting the ſmall ends of the ſticks, as fiſh into a wheel, but they will not eaſily get out again. The nets are to be dyed of a ruſſet colour, by laying them in a tan-pit; and they muſt, when planted for this purpoſe, be covered with boughs, ſo that the birds do not diſcover them, and then they will eaſily run into them, and be all taken at once.

PHECOS, in botany, a name uſed by ſome authors for the *ſagittari*, or *water-arrow-head*. *Ger.* Emac Ind. 2.

PHELLANDRIUM, *water-hemlock*, in botany, the name of a genus of plants, the characters o which are theſe: The flowers ſtand in umbells, and are of the roſaceous kind, each being compoſed of ſeveral heart-faſhioned leaves, diſpoſed in a circular form. The cup finally becomes a fruit compoſed of two ſmall ſeeds, lightly ſtriated and gibboſe on one ſide, and flat and plain on the other.

The ſpecies of *phellandrium*, enumerated by Mr. Tournefort, are theſe: 1. The common *phellandrium*, or *water-hemlock*. 2. The alpine *phellandrium*, with purple umbells, called by ſome *meum alpinum* and *mutellina*. *Tourn.* Inſt. p. 316.

PHELLOS, in botany, a name uſed by ſome authors for the cork-tree. *Ger.* Emac. Ind. 2.

PHELLOS, φελλος, in antiquity, a feſtival in honour of Bacchus, being a preparative to the Dionyſia. See DIONYSIA, *Cycl. Potter*, T. 1. p. 436.

PHENGITES, in the natural hiſtory of the antients, the name of a very beautiful ſpecies of alabaſter. It is a very rude and irregular maſs, very ſhattery and friable, yet of a brightneſs ſuperior to that of moſt of the other marbles, and excelling them all in tranſparence: it is in colour of an agreeable pale, yelloviſh, white, or honey colour; the yelloviſh is more intenſe in ſome places than in others, and ſometimes makes an obſcure reſemblance of veins. It is very weak and brittle in the maſs, and when reduced to ſmall pieces, is eaſily crumbled between the fingers into looſe, but conſiderably large angular pieces, ſome perfect, others complex, irregular, or mutulated, and all approaching to a flat ſhape.

The antients were very fond of this ſpecies in their public buildings; and the temple of fortune, built wholly of it, has long been famous. Its great beauty is its tranſparence; from which alone this temple was perfectly light when the doors were ſhut, tho' it was built without a window, and had no other light but what was tranſmitted thro' the ſtone its walls were built with. It was antiently found in Cappadocia, and is ſtill plentiful there: we have it alſo in Germany and France, and in our own kingdom in Derbyſhire, and ſome other counties. It takes an excellent poliſh, and is very fit for ornamental works where there is no great ſtrength required. *Hill*'s Hiſt. of Foſſ. p. 490.

PHEOS, in botany, a name given by Theophraſtus, Dioſcorides, and others, to a plant uſed by the fullers in dreſſing their cloths, and of which there were two kinds, a ſmaller called ſimply *pheos*, and a larger called *hippopheos*.

The name of this plant is ſometimes written *phleos*; and it is by that confounded with a kind of marſh cudweed, or *gnaphalium*, called alſo by that name; but it may be always found which of the two plants an author means, by obſerving the ſenſe in which the word is uſed, and the uſe to which the plant was put. The *pheos*, properly ſo called, that is, the cudweed, was uſed to ſtuff beds and other ſuch things, and to pack up with earthen veſſels to prevent their breaking; but the *pheos*, improperly called *phleos*, only about cloths; this was, however, alſo called *ſtæbe* and *cnaphon*.

Theophraſtus deſcribes the *pheos* and the *hippopheos*, and calls them the ſame plant, only differing in ſize and ſome other ſmall particulars. And he ſays, in many places, that this plant was alſo called by many *ſtæbe*; he mentions them often together, and ſeveral times compares ſome one plant to them both; ſo that there ſeems to have been only the difference of ſize between them. Galen alſo, as well as this author, calls the *hippopheos ſtæbe*.

Dioſcorides, however, has ſomewhat perplexed the matter, by deſcribing the *pheos* and the *hippophes*, ſo he writes the *hippopheos*, in different places of his works, and not ſeeming to allow any ſimilitude or alliance between them. The virtues he aſcribes to them are alſo plainly different; he tells us, that the *ſtæbe* or *pheos* binds, is good in dyſenteries; and, on the contrary, that the *hippopheos* is a purgative, and carries off the bile. The *ſtæbe* is numbered by him among the ſmooth plants, and the *hippopheos* among the prickly ones. Upon the whole, the names *ſtæbe* and *pheos* with this author, ſeem applied only to the plant properly called *phleos*, that is, *gnaphalium*; and he treats of this *ſtæbe* either as a thing univerſally known, or elſe as unknown even to himſelf; for he no where gives any deſcription of it. *Theophraſt.* l. 6. c. 5.

PHEREPHATTIA, φερεφαττια, in antiquity, a feſtival at Cyzicum, wherein a black heifer was ſacrificed to Pherephatta or Proſerpine. *Potter*, Archæol. Græc. T. 1. p. 436.

PHILADELPHIA-*ſtones*, a name given by ſome authors to what are called by others *Chriſtian's bones*, found in the walls of that city. It is a common error, that theſe walls are built of bones, and the tradition of the country is, that when the Turks took the place they fortified it for themſelves, and built their walls of the bones of the Chriſtians whom they killed there. Dr. Smyth in one of his epiſtles mentions this wall as an inſtance of the Turkiſh barbarity; but this is an idle opinion, what paſſes for bone being only a looſe and porous ſtone of the ſparry kind, found in an old aquæduct which is ſtill in the wall. Sir Paul Rycaut brought home pieces of theſe ſtones, which he alſo ſuppoſed to have been bones, but on examination they proved to be no other than various bodies, chiefly vegetable, incruſted over and preſerved in a ſpar of the nature of that which forms incruſtations in Knareſborough ſpring, and other places with us. Theſe bodies are often cemented together in great numbers by this matter, and their true ſhape loſt in the congeries, till a diligent and judicious eye traces them regularly. *Woodw.* Catal. of Foſſ. V. 2. p. 14.

PHILANTHROPOS, in botany, a name uſed by ſome authors for the common *aparine*, *cleavers*, or *gooſe-graſs*. *Ger.* Emac. Ind. 2.

PHILANDER, in zoology. See the article DIDELPHIS.

PHILETERIUM, in botany, a name uſed by ſome authors for the *behen album*, the common white flowered bladder campion, called *white ben*. *Ger.* Emac. Ind. 2.

PHILLEREA, a garden ſhrub, which, in the Linnæan ſyſtem of botany, makes a genus, the characters of which are: That the cup of the flower is very ſmall, indented into four ſeeming diviſions, and does not fall off with the flower. The flower is compoſed of one petal, beginning with a very ſhort tube, and dividing into four ſegments placed evenly, and each pointed; the ſtamina are ſhort, two in number, and placed oppoſite one to the other; the antheræ ſingle and erect; the piſtil is compoſed of a roundiſh germen, a ſingle ſtyle of the length of the ſtamina, and terminated by a ſomewhat larger ſtigma; the fruit is a ſingle berry, containing one large orbicular ſeed. *Linnæi* Gen. Plant. p. 2.

PHILOMEDIUM, in botany, a name uſed by ſome authors for the *great celandine*. *Ger.* Emac. Ind. 2.

PHILONIUM (*Cycl.*)—PHILONIUM *Londinenſe*, the name by which the medicine commonly called *philonium romanum*, is called in the late London diſpenſatory. The compoſition is alſo much altered, as well as the name, and is now ordered to be made thus: Take white pepper, ginger, caraway-ſeeds, of each two ounces, opium ſix drams, ſyrup of diacodium boiled to the conſiſtence of honey, three times the weight of all the reſt. The opium is to be diſſolved in a little wine, and then mixed with the ſyrup; after which the powders are to be ſtirred in, and the whole made into an electuary. *Pemberton*'s Lond. Diſp. p. 342.

PHILOSOPHIC *chemiſtry*, an art of dividing or reſolving all the bodies in our power by means of all the inſtruments that can be procured, and that as well into integrant as into conſtituent parts, and joining theſe parts together again, ſo as to diſcover the principles, relations and changes of bodies, make various mixtures and compoſitions, find out the phyſical cauſes of phyſical effects, and hence improve the ſtate of natural knowledge and the arts depending on it. *Shaw*'s Lectures, p. 1. See the article CHEMISTRY.

PHILOSOPHIC *ſpirit of wine*. See the article WINE.

PHILOSOPHY (*Cycl.*)—By *philoſophy* we mean the knowledge of the reaſons of things, in oppoſition to hiſtory, which is the bare knowledge of facts; or to mathematics, which is the knowledge of the quantity of things or their meaſures.

Theſe three kinds of knowledge ought to be joined as much as poſſible. Hiſtory furniſhes matter, principles and practical examinations, and mathematics compleat the evidence. *Philoſophy* being the knowledge of the reaſons of things, all arts muſt have their peculiar *philoſophy* which conſtitutes their theory: not only law and phyſic, but the loweſt and moſt abject arts are not deſtitute of their reaſons, which might uſefully

employ the time of the ſtudious. It is true, thoſe who call themſelves *philoſophers* and learned men have as yet done little towards forwarding the intelligence of arts: but we ſpeak not of what is done, but of what ought to be done.

One great obſtacle to the progreſs of arts and ſciences has been the neglect of practice in ſpeculative men, and the ignorance or contempt of theory in mere practical men. What chimeras and abſurdities the neglect of experience and practice has produced, need not be mentioned; the miſchiefs ariſing from a neglect of theory, are not ſo obvious: yet certainly it retards the progreſs of arts. All invention or improvement muſt be either caſual or rational, including analogy or inference from ſimilar caſes, under the term rational. Now altho' the foundations of arts have often been owing to ſome caſual diſcovery, as gunpowder or the loadſtone; yet is this not to be truſted to alone. Improvements do not always flow from this ſource, but rather from the reflexions of artiſts; and if theſe reflexions were rendered more diſtinct, more communicable and eaſier to be retained, by the proper uſe of ſigns and other *philoſophical* helps, great advantages might be expected: it being certain, that *philoſophical* knowledge is more extenſive, and more ſure in the application; and beſides, gives a pleaſure to the mind not to be expected from that which is merely hiſtorical.

It is to be obſerved, that the bare intelligence and memory of *philoſophical* propoſitions, without any ability to demonſtrate them, is not *philoſophy*, but hiſtory only. However, where ſuch propoſitions are determinate and true, they may be uſefully applied in practice, even by thoſe who are ignorant of their demonſtrations. Of this we ſee daily inſtances in the rules of arithmetic, practical geometry, and navigation; the reaſons of which are often not underſtood by thoſe who practiſe them with ſucceſs. And this ſucceſs in the application produces a conviction of mind, which is a kind of medium between *philoſophical*, or ſcientifical, and hiſtorical knowledge. The ingenious author of the Analyſt has gone ſo far as to ſuggeſt, that mathematicians have no other conviction of the truth of the doctrine of fluxions.

Philoſophy may be divided into three parts, intellectual, moral, and phyſical. The intellectual part comprizes logic and metaphyſics. The moral part contains the laws of nature and nations, ethics and politics. And laſtly, the phyſical part comprehends the doctrine of bodies, animate or inanimate. Theſe, with their various ſubdiviſions, will take in the whole of *philoſophy*.

Wolfius makes the three parts of *philoſophy* to be the doctrine of God, the human ſoul, and of bodies [a]. However, when he ſubdivides, and comes to treat the ſeveral branches ſeparately, his diviſions readily come under the three heads intellectual, moral, and phyſical, before mentioned. The doctrine of God and the human ſoul may be ranged under the ſame head metaphyſics, the notion of the divine nature being formed from that of the human ſoul, excluding limitations and imperfections [b]. [[a] *Wolf.*. Diſc. Prælim. Logic. ſect. 56. [b] *Wolf.*. Theol. nat Part. 1. ſect. 1059.]

We have ſaid that *philoſophy* is the knowledge of the reaſons of things. It may be aſked what is the reaſons of things, or what is the explication of phænomena or facts. An ingenious author tells us, that the explication conſiſts only in ſhewing the conformity any particular phænomenon hath to the general laws of nature, or, which is the ſame thing, is diſcovering the uniformity there is in the production of natural effects. This he thinks evident to whoever ſhall attend to the ſeveral inſtances, wherein philoſophers pretend to account for appearances. By a diligent obſervation of the phænomena within our view, we may diſcover the general laws of nature, and from thence deduce, tho' not demonſtrate other phænomena, all deductions of this kind depending on a ſuppoſition that the author of nature always operates uniformly, and in a conſtant obſervation of thoſe rules we take for principles; which we cannot evidently know. *Berkeley*, Princip. of Hum. Knowl. Sect. 62 & 107.

If we take a view of the ſeveral phænomena, and compare them together, we may obſerve ſome likeneſs and conformity between them. For example, in the falling of a ſtone to the ground, in the riſing of the ſea towards the moon, in coheſion and cryſtallization, there is ſomething alike, namely an union or mutual approach of bodies: ſo that any one of theſe, or the like phænomena, may not ſeem ſtrange or ſurpriſing to a man who has nicely obſerved and compared the effects of nature: for that only is thought ſo which is uncommon, or a thing by itſelf, and out of the ordinary courſe of our obſervation. That bodies ſhould tend towards the center of the earth, is not thought ſtrange, becauſe it is what we perceive every moment of our lives; but that they ſhould have a like gravitation towards the center of the moon, may ſeem odd and unaccountable to moſt men, becauſe it is diſcerned only in the tides; but a philoſopher, whoſe thoughts take in a larger compaſs of nature, having obſerved a certain ſimilitude of appearances, as well in the heavens as the earth, that argue innumerable bodies to have mutual tendency towards each other, which he denotes by the general name attraction, whatever can be reduced to that he thinks juſtly accounted for. Thus he explains the tides by the attraction of the terraqueous globe towards the moon, which to him doth not appear odd or anomalous, but only a particular example of a general rule or law of nature.

If, therefore, we conſider the difference there is betwixt natural philoſophers and other men, with regard to their knowledge of the phænomena, we ſhall find it conſiſts not in an exacter knowledge of the efficient cauſe that produces them, for that can be no other than the will of a ſpirit; but only in a greater largeneſs of comprehenſion, whereby analogies, harmonies, and agreements are diſcovered in the works of nature, and the particular effects explained: that is, reduced to general rules, which rules, grounded on the analogy and uniformneſs obſerved in the production of natural effects, are moſt agreeable and ſought after by the mind; for that, they extend our proſpect beyond what is preſent and near to us, and enable us to make very probable conjectures, touching things that may have happened at very great diſtances of time and place, as well as to predict things to come; which ſort of endeavour towards omniſcience, is much affected by the mind. *Berkeley*, Princ. of Hum. Knowledge, Sect. 104, 105.

PHILYRA, in natural hiſtory, a name given to the ſubſtance of which ſome of the moſt antient books are written. It is the inner bark of the *tilia*, or common lime-tree. The emperor's library at Vienna has a book written by Tully, never yet publiſhed, which is written on this ſubſtance. *Munting.* de Plantis.

PHLEBOTOMY, *(Cyc.)* in ſurgery, the opening of a vein by a proper ſharp-edged and pointed inſtrument of ſteel, for letting out a proper quantity of blood, either for the preſervation or recovery of a perſon's health.

This appears not only to be one of the moſt uſeful, but one of the moſt antient operations in ſurgery, ſince we find by Hippocrates, Celſus, *&c.* that it was practiſed near three thouſand years ago. The operation is frequently performed in different parts of the body, as the hand, the foot, the forehead, temples, neck, tongue, penis, and other parts; yet it is moſt generally performed in that vein of the arm which lies near the joint of the cubit. *Heiſter*'s Surg p. 273.

In bleeding it ſometimes happens, that an artery is opened either inſtead of, or together with, the vein: an accident of this kind is attended with the utmoſt danger. An artery is known to be wounded when the blood ſpins out very forcibly from the orifice, and that by ſtarts or leaps, not in an even ſtream, and extends itſelf in a greater arch from the orifice to the baſin. The colour of the blood from an artery is alſo much more florid than from a vein; to which add, that on preſſing the finger on the veſſel below the orifice, the blood ſtarts out more violently than before; and ſtops, or at leaſt abates, on preſſing above the orifice; quite the contrary of what happens on the opening a vein.

In an accident of this kind, the ſurgeon ſhould have preſence of mind not to betray the caſe by his fears to the patient, or attendants: he ſhould obſerve whether the blood flows freely from the orifice, or whether it inſinuates itſelf in any conſiderable quantity between the integuments. If the firſt is the caſe, he muſt take a large quantity of blood away, even till the patient faints, perſuading the attendants, that the heat of the blood requires it; and while the patient is in his fainting fits, as the flux then ceaſes, he may commodiouſly dreſs and bind up the wound; and by this precaution hinder a freſh hæmorrhage or an aneuriſm. The ſurgeon muſt place ſome ſmall piece of money between the folds of the firſt compreſs; and on this place two, three, or more compreſſes, each larger than the other: and then bending the cubitus, apply two bandages in this manner, as after bleeding in the vein, only a little tighter; and lay a thick, long, and narrow compreſs over the artery, from the cubitus to the axilla: and the patient muſt be warned to wear his arm in a ſling, pinned to his cloaths, for a fortnight, and refrain from all uſe of it. *Heiſter*'s Surg. p. 287.

If the blood from the wounded artery is found to inſinuate itſelf between the integuments, the orifice muſt be immediately compreſſed, and tied up as before directed; and the arm often inſpected, to ſee whether a bleeding within the integuments does not yet continue. The patient muſt be frequently bled in the other arm, and if a large quantity of blood ſhould be lodged from the wounded artery under the integuments, it will be neceſſary to open the integuments to diſcharge it.

It is too common an accident to find a nerve or tendon punctured in bleeding, and this is generally known to be the caſe by the patient's making a ſevere outcry at the time; and eſpecially if he complains afterwards of acute pains, and the limb begins to ſwell and be inflamed, convulſed, ſtiff, and extended as in the cramp: which ſymptoms, if not timely relieved, threaten convulſions of the whole body, a gangrene of the part, and even death in a ſhort time.

The beſt method to be taken in theſe accidents, is to firſt bathe the part with a mixture of oil of turpentine and ſpirit of wine, and then inveſt the whole arm with the diachalciteos plaiſter, melted down in oil of vinegar and roſes, retaining it on by the expulſive bandage; which beginning upon the hand, aſcends gradually by ſpiral turns to the top of the ſhoulder; by which means the impulſe of the blood on the part is not only much abated, but alſo the pain and inflammation much diminiſhed: and laſtly, the following cataplaſm ſhould be applied

to

to the arm, to compleat the cure: take of flour of barley and of bitter vetch, of each two ounces; chamomile flowers and melilot flowers, of each two handfuls; freſh butter, an ounce and half: boil theſe into a cataplaſm with ſoap ſuds, and apply them to the arm till the pain and other bad ſymptoms are removed. *Heiſter*'s Surg. p. 286.

PHLEBOTOMY *in the eyes.* There are ſeveral ways of performing this operation, but the beſt ſeems to be this. The patient being ſeated on a chair, and his head held in a proper poſture, a tranſverſe inciſion is to be made, with a fine lancet, upon the turgid ſmall veins in the corners of the eye, ſo as to open them or cut them quite aſunder. The eye-lids muſt be held apart with one hand, whilſt the veins are opened with the other; and ſome uſe a pair of fine ſciſſars for this purpoſe, inſtead of a lancet, and others elevate the veins with a crooked needle before they divide them: but in this operation the better way would be to make the needles with edges, that when the veins were thus elevated, they might divide them without the help of any other inſtrument. When the inciſion is made, the diſcharge of blood muſt be promoted by means of fomentation, with a ſpunge dipped in warm water; and if the diſcharge is not ſufficient, the inciſion may be repeated two or three times: but few patients can be brought to ſuffer this, and there is no practiſing it at all upon infants, becauſe they will not keep the eye ſteady. *Heiſter*'s Surg. p. 377.

PHLEGMASIA, a word uſed by ſome of the medical writers for an inflammation. Hippocrates alſo ſometimes uſes it to expreſs the violent heat in fevers.

PHLEGMON *(Cycl.)*—If the proximate cauſe of theſe tumors be enquired into, we ſhall find it generally riſes from too thick or viſcid a ſtate of the blood, ſtagnating in the anaſtomoſes of the ſmalleſt veins and arteries; ſo that the blood being propelled in larger quantities than can paſs thro' thoſe veſſels, it muſt of conſequence excite the ſymptoms that are the attendants of this tumor, and occaſion great diſorder at every part where ſuch ſtagnation is made.

No part of the body, whether external or internal, is perfectly exempt from this ſort of tumor, not even the bones themſelves; but it is more common in the fat and glands than elſewhere.

The cauſes of this ſtagnation of the blood are either external or internal.

Among the external, are all wounds, fractures, luxations, contuſions, punctures, by thorns and ſplinters, with a too great compreſſion of the veſſels, whether by too ſtrict a bandage, or by other means; each of which obſtructing the paſſage of the blood thro' its minute veſſels, either by dividing, bruiſing, compreſſing or diſtorting them, may give riſe to this tumor. And to this may be added, burns of all kinds, with too violent cold, the too great motion of the body, the external application of ſharp and ſtimulating ſubſtances to the ſkin, and others, which ſtop the pores of the ſkin, and impede the circulation of the blood.

Among the internal cauſes, are to be reckoned the too great acrimony of the blood, as in ſcorbutic habits, the blood's abounding in too great quantities, or being of too thick a conſiſtence, or, laſtly, its circulating in the body with too violent a motion; for by this laſt means, the groſſer particles of the blood are protruded, and wedged in, as it were, in the ſmaller veſſels, thro' which they cannot find a paſſage; and this is eſpecially the caſe, when a ſudden cold is given to the body from a ſtate of extreme heat. In ſhort, every thing will produce an obſtruction that makes either the particles of the blood too large, or the mouths of the veſſels too ſmall and narrow to receive them.

The reſolution or diſperſion of a tumor of this kind is only practicable when the tumor is of a milder kind; when it is in a ſound habit of body, and when the blood is not yet too viſcid, or too violent in its motion: but ſuppuration follows when the inflammation is more violent, the circulation more rapid; but yet the maſs of blood ſomewhat temperate and free from acrimony. That is, when the blood becoming more inſpiſſated, and its larger particles ſticking in the more minute veſſels, can find no paſſage; but the ſmall veſſels are burſt by the preſſure and impulſe of the obſtructed blood, ſo that their contents are extravaſated in the fat, fleſh, and adjacent parts. Upon this extravaſation, the more ſubtle and fluid parts of the blood putrefy, by means of the great heat, and become fœtid and acrimonious, and corrode the adjacent parts: the fluids thus changed or corrupted, are, by the ſurgeons, called matter or pus; and this is of ſeveral kinds, according to its conſiſtence and colours: it is either white, yellow, greeniſh, reddiſh, or party-coloured.

When the forementioned ſymptoms are much more violent, and the blood at the ſame time more acrimonious than it ought to be, this inflammation generally terminates in a gangrene: for in that caſe, the ſmalleſt arteries and veins are corrupted, burſt, and broke; and hence the adjacent parts are diſſolved and corrupted by theſe extravaſated acrimonious humors, and particularly the ſkin is very ſubject to be filled with puſtules, when its cuticle has been ſeparated, as in burns. The ſanies contained in theſe puſtules and elſewhere, is uſually termed ichor, and is generally of a pale reddiſh caſt, and ſometimes brown or livid, which is much worſe; for unleſs the patient in this caſe is timely aſſiſted, the ſymptoms of inflammation all go off, the tumor, reſiſtance, heat, redneſs, pain, and pulſation, gradually diſappear, and the limb becomes flaccid and cold; it afterwards turns pale, and becomes dead and inſenſible, and the inflammation creeps to ſome other part.

If this caſe be treated with medicines too hot, too aſtringent, cooling, fat, acrimonious, or narcotic; or if the parts be bound too tight, the fleſh quite dies, its paleneſs turns to a livid lead colour; and the incloſed ſanies finding no vent, becomes more acrimonious, and ſo greatly corrodes the adjacent parts, as to deſtroy all ſenſe and motion, and brings on an entire ſphacelation of the whole limb. But if the inflamed part be full of glands, and the blood very thick, glutinous, and tough, the ſmall veſſels are then ſtrongly ſtuffed up with it, and impacted together; and the parts loſing their ſenſation, become changed into a hard tumor, called a ſcirrhus. The cure of *phlegmons* is by diſperſion or ſuppuration: the methods for bringing on theſe, ſee under the heads DISPERSION and SUPPURATION. *Heiſter*'s Surg. p. 178.

PHLEOS, in botany. See the article PHEOS.

PHLEUM, in the Linnæan ſyſtem of botany, a graſs called *typhoidea*, or cat's-tail graſs by Scheuhzer, which makes, with this author, a diſtinct genus of plants, the characters of which are: that the cup is a glume, containing one flower; it is bivalve, oblong, ridged, and compreſſed, and opens into a double-pointed ſummit; the valves are erect, hollowed, compreſſed, equal in ſize, and bearded; the flower is compoſed of two valves, ſhorter than that of thoſe of the cup, the outer one, which is the larger, ſurrounding the inner or ſmaller one; the ſtamina are three capillary filaments, longer than the cup; the antheræ are oblong, and divided into two at the ends; the germen of the piſtil is roundiſh; the ſtyles are two in number, ſmall, and bent; and the ſtigmata are plumoſe; the cup and flower incloſe the ſeed, which is ſingle, and of a roundiſh form. *Linnæi* Gen. Plant. p. 14.

PHLOGIDAUGIA, in natural hiſtory, the name of a claſs of inflammable foſſils, of a pure texture, and in ſome degree tranſparent.

Of this claſs are the ſulphurs, orpiments, zornics, and amber. They are by this name diſtinguiſhed from the *phlogiſcieria*, or inflammable foſſils, of a coarſe texture, and opake; ſuch as the ambergreaſe, jet, and aſphalta, and the ampelites and common coal. *Hill*'s Hiſt. of Foſſ. p. 399.

PHLOGINOS, the name of a ſtone found in Ægypt, and called by ſome *chryſitis*, from its colour, reſembling gold.

Pliny deſcribes it as reſembling the Attic oiſter, as the paſſage is uſually printed; and hence Agricola and ſome others have ſuppoſed he only meant the *oſtracites*, or foſſile oiſter-ſhell, by this name, tho' the other name, *chryſitis*, could not well be applied to that body. Salmaſius has very well explained the paſſage, by obſerving, that as the antients have no where mentioned the Attic oiſter, the words probably were originally *Attic ochre*; the ſenſe is then plain, and the ſtone is only ſaid to be of a fine yellow, like gold; or the *Attic*, that is the brighteſt yellow *ochre*. It probably was an agate of the cerachates kind.

PHLOGISCIERIA, in natural hiſtory, the name of a claſs of foſſils, the characters of which are, that the bodies contained in it are inflammable, of a coarſe and impure texture, and not pellucid.

The word is derived from the Greek φλόγωσις, inflammable, and σκίερος, opake. The bodies of this claſs are divided into two general orders, and under thoſe, into five genera. Thoſe of the firſt order, are ſuch as are found looſe, and in detached maſſes: thoſe of the ſecond, ſuch as are found conſtituting whole ſtrata. The genera of the firſt order are, ambergreaſe, jet, and the aſphalta; and thoſe of the ſecond, cannel and common coal. *Hill*'s Hiſt. Foſſ. p. 411. See AMBERGREASE, GAGATES, ASPHALTA, AMPELITES, and LITHANTHRAX.

PHLOGITES, in natural hiſtory, a name given by Pliny and other authors to a ſtone, which, they ſay, had the appearance of flames of fire, bubbling up and riſing to ſeveral points within it. It is ſometimes called alſo *phlegonites*.

Some have ſuppoſed that the antients meant no more by this diſtinction, than to expreſs a fire colour lodged in the ſtone, and have meant it as a name for the opal; but as the Germans have at this time an odd ſtone among them, which they commonly call petrified flames of fire, it is poſſible the antients might have had the ſame ſtone, and called it by this name.

The abſurdity of petrified fire is too groſs to need refutation, but the whole that is meant by the name, ſeems to be, that the ſtone had ſome ſtrait and erect rays, of fire colour.

Pliny ranks the *phlogites* among the gems, but Sabinus and others place it among the larger ſtones: and we have from ſome parts of Germany, a ſpar, with radiations of a fiery red in a white ground, which looks as like flames as any thing one could expect in a ſtone; but whether this, or ſome other, be the ſtone called petrified flames of fire by the collectors of that nation, we are not aſſured; the name only having as yet come to us, without the ſubſtance itſelf.

PHLOGONIÆ, in natural hiſtory, the name of a claſs of foſſils, uſually included by authors with many others of a very different kind, under the general name *pyritæ*. Theſe are de-

fined to be compound, inflammable, metallic bodies, found in ſmall maſſes, and of determinately angular figures. Of this claſs of bodies there are three genera.

1. The *pyricubia*, which are *phlogoniæ* of a regularly cubic figure. 2. The *pyroctagonia*: theſe are *phlogoniæ* of an octohædral figure, or compoſed of eight planes. And, 3. The *pyripolygonia*: theſe are *phlogoniæ* of a dodecahædral figure, or compoſed of twelve planes. *Hill*'s Hiſt. of Foſſ. p. 618, 619. See PYRICUBIUM, *&c.*

PHLOGUS, in botany, a name given by ſome of the antients to the ſeveral ſpecies of the *iris* and *gladiolus*. and by ſome to the *flammula jovis*, a ſort of clematitis, ſo called becauſe of the violent heat of its leaves to the taſte.

Theophraſtus mentions this in the ſame part of his work with the violet and other ſpring flowers, and this, not becauſe they are allied to one another in their characters, but becauſe they all flower at the early time of the year. Pliny miſtakes the author's meaning in this ſo far, as to ſuppoſe that he placed it among the violets as a plant of that kind; and has accordingly mentioned it as a violet with a flame-coloured flower.

This plant ſeems to have owed its name *jovis flamma* to a miſtake of Pliny's, who copying Theophraſtus, and finding him mention this *phlogus*, or *phlogium*, and another flower, called *dioſanthos*, or Jove's flower, together, has ſeemed to blend the two names, and make out the word *flamma*, or *flammula Jovis*, between them.

PHLOMIS, in botany, the name of a genus of plants, the characters of which are theſe: the flower is labiated, conſiſting of one leaf; the upper lip is hooded, and the lower, over which this lies, is divided into three ſegments: the piſtil ariſes from the cup, and is fixed in the manner of a nail to the hinder part of the flower, and ſurrounded with four embryos, which finally ripen into four ſeeds, of an oblong ſhape, contained in a pentangular cup, which is the cup of the flower.

The ſpecies of *phlomis*, enumerated by Mr. Tournefort, are theſe: 1. The ſhrubby *phlomis*, with a broad and roundiſh ſage-like leaf. 2. The ſhrubby *phlomis*, with a narrow and longer ſage-like leaf. 3. The round leafed purple-flowered ſhrubby *phlomis*. 4. The pointed-leaved purple-flowered ſhrubby *phlomis* of Portugal. 5. The purple-flowered clary-leaved *phlomis*. 6. The purple-flowered very white Spaniſh ſhrubby *phlomis*. 7. The herbaceous very white Spaniſh *phlomis*. 8. The taper *phlomis*, commonly miſtaken for a ſpecies of mullein, and called by authors *verbaſcum anguſtis ſalviæ foliis*, or the narrow ſage-leaved mullein, and the wild yellow mullein, with gaping flowers. *Tourn.* Inſt. p. 177.

PHLOMON *ſtephanomaticon*, in the botanical writings of the antients, a name given to the common white mullein. The upper part of the thyrſus, or ſpike of flowers of this plant, was frequently uſed in the garlands and coronæ of the antients; and it is named by Dioſcorides and others among the yellow flowers in general uſe on that occaſion.

It is remarkable, that Dioſcorides, tho' he mentions this plant in the claſs of garland herbs, among the elychryſa and other yellow flowered herbs, no where mentions it under the mullein, where he is deſcribing the characters and ſpecies of that plant. It ſhould ſeem from this, and from ſome other ſuch paſſages, where this author deſcribes the ſame plant twice without knowing it; or omits it in its proper place, and treats of it only occaſionally in ſome other, that he had not a perfect knowledge of the botany of his time: but that, like Pliny, he collected what he has left us from the works of other authors now loſt.

PHLYSIS, a term uſed by the antients to expreſs an eruption on the ſkin, from a redundance of humors.

PHLYZATION, a puſtule or inflammation on the ſkin, or the bliſters ariſing on it after being burnt or ſcalded with a hot liquor.

PHOCA, the *ſea-calf*, in the Linnæan ſyſtem of zoology, a diſtinct genus of animals, the characters of which are, that they have two paps placed near the navel, feet adapted to ſwimming, and have no ears.

There are two kinds of this animal: the common one, called the *ſea-calf*, which has its canine, or dog-teeth, encloſed like the others in its mouth; and the other, which ſome improperly call the *hippopotamus*, or ſea horſe, which has theſe teeth exſerted or thruſt out. *Linnæi* Syſtem. Natur. p. 36.

We have a draught of this animal in the philoſophical tranſactions, numb 469, by Dr. Parſons, who obſerves, that Aldrovandus, Johnſton, Rondeletius, and Geſner, have made ſeveral miſtakes in the figure of this creature, ſo as to convey no juſt idea of it.

Upon diſſecting one of theſe animals, the ſtomach, inteſtines, bladder, kidneys, ureter, diaphragm, lungs, great blood-veſſels, and pudenda, were like thoſe of a cow; the hairs of the whiſkers were very horny and clear; the ſpleen was two foot long, four inches broad, and very thin; the liver conſiſted of ſix lobes, each hanging as long and as lank as the ſpleen, with a very ſmall gall-bladder. The beaſt was long and flabby in its contexture in general, having a large foramen ovale, and very great columnæ carnoſæ. In the lower ſtomach were about four pounds weight of flinty pebbles, all ſharp and angular, as if the animal choſe them of that form for cutting the food. The uterus was of the horned kind, each of the cornua being thicker than the body or duct leading to them. The ovaria were very large, being granulated on the ſurface with the ova, under a very thin membrane; and the opening into the tubes leading to the cornua is a great hole.

The authors who have treated on this animal, are Ariſtotle, Pliny, Aldrovandus, Rondeletius, Geſner, Wolfgangius, and Johnſton. Phil. Tranſ. N°. 469.

This animal is viviparous, and ſuckles its young by the mamillæ, like quadrupeds; and its fleſh is carnous and muſcular. That diſſected by Dr. Parſons was ſeven foot and an half long, tho' very young, having ſcarce any teeth, and having four holes regularly placed about the navel, which in time become papillæ.

PHOCÆNA, in zoology, the name uſed by authors for the *porpeſſe*, diſtinctively from the dolphin, a fiſh very like it, and by many confounded with it. See DELPHINUS.

The *phocæna* is of a roundiſh, not flat body, growing gradually ſmaller toward the tail; and juſt at the root of the tail is a little flatted. Its noſe is long and pointed, and furniſhed with ſtrong muſcles; by means of which it is able to turn up the mud and ſand, to ſeek after ſmall animals. Its ſkin is ſmooth, and but thin: its back is of a duſky bluiſh hue, almoſt black in ſome of the fiſh; and from the middle of the ſides downwards, it is whitiſh: it has no gills, nor any apertures in the place of them; but in the middle of the upper part of its head, it has a ſpiracle, in form of a half moon, divided by a ſubſtance reſembling a coxcomb, into two noſtrils, which, as they run inward, join and make one canal, which opens within the mouth a little below the œſophagus. This canal is provided with muſcles, to keep it ſhut againſt the admiſſion or emiſſion of any fluid, but at the creature's pleaſure; and by means of this he diſcharges the water taken in with his food. Its eyes are ſmall: its auditory paſſages extremely minute: its teeth alſo ſmall: it has two fins on the breaſt, and one on the back: and its tail is ſlightly forked, and placed horizontally, not vertically, as in other fiſhes: its lungs are like thoſe of quadrupeds: it is common in many places, and ſometimes is ſtranded on the Engliſh coaſt: its fleſh is not at all valued. *Ray*'s Ichthyol. p. 31.

PHŒNICOPTERUS, in zoology, the name of a very remarkable water-bird, called alſo *flammant* and *flamingo*.

It has extremely long legs, and an extremely long neck. Its beak is broad, and of a very ſingular figure; the upper chap being bent, depreſſed, and dentated; the lower, much thicker, and firmer. It is black at the end, and in the other part of a duſky blue. Its neck and body are white; the long flight feathers of its wings black, but the ſhorter feathers, which make the covering of the wings, are of a very elegant and bright red, whence the bird has its name: it is web-footed, tho' ſo remarkably long legged: it lives about waters, and feeds on fiſh: it is common in many parts of America, and is ſeen at times in many parts of Europe: it was well known to the antients, and its tongue was accounted a very great delicacy among the nice eaters of old times. See Tab. of Birds, N° 46. *Ray*'s Ornithol. p. 240.

One thing very remarkable about it is, that its beak is ſo long and crooked, that the whole head muſt be immerſed before the water can get into it. *Pitiſc* in voc.

PHŒNICOPUS *gallinula*, in zoology, a name by which ſome authors have called a bird, more uſually known by the name *tringa*. *Geſner* de Avib. See TRINGA.

PHŒNICURUS, φοινικερος, in zoology, a name by which the antient naturaliſts called the *ruticilla*, or redſtart. See the article RUTICILLA.

PHŒNIX, (*Cycl.*) in botany, a name given by medicinal writers to the graſs called *lolium rubrum*, and in Engliſh, *ray-graſs*. *C. Bauhin.* p. 9.

PHOENIX is alſo the name given by Kæmpfer and Linnæus to a genus of plants, called by others *elate* and *katovindel*. The characters are theſe: it produces ſeparate male and female flowers, in both the whole ſpatha ſerves for a cup: in the male the petals are three in number, and are of an oval figure, and concave: the ſtamina are three ſlender filaments, and the antheræ are very ſhort: in the female flower the germen of the piſtil is of a roundiſh figure: the ſtyle is ſhort and pointed, and the ſtigma is acute: the fruit is an oval berry, having only one cell; this contains one ſeed, which is of a bony hardneſs, and of an oval figure, with a deep longitudinal furrow reaching from one end to the other. *Linnæi* Gen. Pl. 513. Mus Cliff, 12. Hort. Mal 3, 23.

PHOENIX, φοινιξ, among the antients, a muſical inſtrument not unlike the *cithara*. *Hoffm.* Lex. in voc. See the article CITHARA, *Cycl.*

PHŒOPUS, in zoology, a name uſed for two different birds; the one called by the Germans *brachvogel*, and the other the *whimbrell*, or *aquata minor*, the ſmall curlew of authors.

The firſt of theſe, or the *brachvogel*, is of a deep black colour, ſpotted with a yellowiſh and a reddiſh brown: its beak is long, ſlender, and black, and is moderately bent: its neck is grey, tending to reddiſhneſs towards the bottom, and its belly is white. Mr. Ray ſuſpects this not eſſentially to differ from the other, but the ſight of the bird alone can determine that. *Geſner* de Avib. *Aldrovand* de Avib. L. 20. c. 41.

PHOLAS, in natural hiſtory, the name of a genus of ſhells, the characters of which are theſe: It is an oblong multivalve ſhell, compoſed of five ſhells, tho' in ſome, improperly accounted ſpecies of this genus, only of two. It is ſmooth in ſome ſpecies, in others rough, and in ſome reticulated; in ſome ſpecies it ſhuts cloſe and even, in others it gapes always open.

Of the oblong ſhells, uſually called *pholades*, and conſiſting only of two ſhells, we meet with the following ſpecies: 1. The ſmooth *pholas*, of Rondeletius. 2. The ſmooth narrower *pholas*, of Aldrovand. 3. The wood-*pholas*, of Rumphius. 4. The ſmooth muſcle-like *pholas*. 5. The finger-*pholas*, of Bonani. 6. The pale red and white *pholas*.

Of the oblong and irregular *pholades*, which conſiſt only of two valves, we have the following ſpecies: 1. The great American *pholas*. 2. The broad *pholas*, with the long trunk.

Of the oblong irregular *pholas*, conſiſting of five valves, we have only one known ſpecies, which is the *pholas* of Liſter. See Tab. of Shells, N°. 29. and Hiſt. Nat. Eclairc. p. 356.

The word *pholas* is derived from the Greek, and ſignifies no more than any thing which is hidden; the name was given to this genus of ſhell-fiſh from their cuſtom of making themſelves holes in earth, ſand, ſtones, or wood, and living hidden in them. Many being of opinion, that theſe fiſh could not work themſelves into the ſubſtance of hard ſtones, have thought that they were hatched in holes accidentally formed in ſtones, and that the ſhells naturally grew of ſuch a ſhape as was neceſſary to fill the cavity. Nor is this the only error propagated concerning the *pholas*; for as all that was ſignified by the name being only that the ſhell was hidden in ſome ſolid ſubſtance, whenever an author found a ſhell-fiſh of whatever kind thus buried in ſtone, he deſcribed it under the name of *pholas*.

There are many ſpecies of the ſhell-fiſh, and theſe of ſeveral different genera, which thus hide themſelves in ſtone; and theſe have therefore been called by different authors *pholades*; and hence it has been ſaid, that the *pholas* was in ſome ſpecies a bivalve, and in others a multivalve ſhell. The true *pholas*, which Liſter has very well deſcribed, is a genuine multivalve, being compoſed of five pieces; but this is a very ſcarce fiſh, and ſeveral of the muſcles and of the chamæ being often found in ſtone, they have all been called bivalve *pholades*; and ſuch as have found the chamæ thus immerſed, and found them really to conſiſt of only two ſhells, have cenſured the authors of error who have deſcribed the *pholas* as having five. Hiſt. Nat. Eclairc. p. 362.

All the ſpecies of ſhell-fiſh which are found in ſtone, have certainly been the means of making the holes in which they are found: the fact is inconteſtible, but the means yet wholly unknown. Perhaps when ſome accurate obſerver ſhall have an opportunity of examining the fiſh alive, the myſtery will be cleared up. All that we know at preſent is, that they are firſt buried in the ſtone while very ſmall; ſince the aperture on the ſurface of the ſtone is uſually much ſmaller than the diameter of the ſhell contained within, and only ſerves to admit the ſea water, or to give paſſage to the proboſcis of the incloſed fiſh.

The chamæ, which are frequently known among us under the name of the *pholas*, and common about our ſhores, are often found in a ſoft ſtone of the ſeptaria or ludus Helmontii kind; and as there is a great reſemblance between this ſtone and a hardened clay in its external appearance, many have fallen into an opinion of its being a petrified clay. On this principle it has ſeemed eaſy to account for the ſtrange phænomenon of the *pholades* or chamæ being found in it, ſince it has been ſuppoſed that they made their way into it while in the ſtate of clay, and that it afterwards became petrified or hardened into ſtone while they were in it. But not to mention the error of the opinion of this ſort of ſtone being a petrified clay, or the abſurdity of ſuppoſing that ſuch a petrifaction, were it made at all, could be effected in ſo ſhort a time as during the life of the fiſh. It is eaſy to anſwer this opinion by another obſervation, which is, that on the coaſts of Italy it is not uncommon to find wrought pieces of hard marble, formed into pillars and other ornamental parts of building, in which are lodged the true *pholades*, as alſo chamæ and muſcles, in the ſame manner as in our ſofter ſtones. It is not to be ſuppoſed that theſe pieces of marble were ever any thing elſe but marble; and we have an account from Woodward of certain columns of marble which were dragged up out of the ſea, after their having been loſt there but a few years before, and theſe were all full of *pholades*. If any thing could be wanting after this to prove the certainty of the fact, that the *pholades* make themſelves the holes they live in, it might be added that they are often found lodged in wood, as well as in different kinds of ſtones; the bottoms of ſhips being frequently pierced by them. There is an opinion among the vulgar, that the *pholades*, after a time, change into butterflies; but this is too abſurd to need a refutation. The fiſh is very good to eat, and is taken in quantities on breaking the ſtones; for they never live ſingly, but many in the ſame ſtone.

In the memoirs of the academy of ſciences it is ſaid, that the ſhell of the *pholas* is compoſed of three pieces, two of which are equal in ſize and alike in ſhape; and the third, which is vaſtly ſmaller than theſe, is placed near the ſummit of the others, and fills up a little ſpace, which they leave empty: this is uſually of the figure of a lozenge, one of the ſharp ends of it coming in contact with the other ſhells at their tops; but ſometimes it is only pointed at both ends, and rounded in its intermediate part, and the external ſurface of it is uſually convex. The two large valves of the ſhell are twice or three times as long as they are wide, and the cardo, which joins them, is placed near one end; they grow gradually ſmaller to the other extremity, where they terminate in an oval. They are furrowed and channelled in the manner of a file, having many longitudinal ſtreaks croſſed by a great number of tranſverſe ones; theſe lines mark the age or different growths of the fiſh, and their ridges are often beſet with ſmall points like prickles. The two valves of the ſhell are uſually open, and are capable of expanding to a great width; but they do not expoſe, or leave naked the body of the fiſh on this occaſion; for they are connected together by a membrane which opens to give them room, and forms with the two ſhells a ſort of caſe for the body of the fiſh; and indeed this was the more neceſſary, as the figure of the ſhells is ſuch, that they cannot ever perfectly cloſe together, for when they come into contact in one part, another neceſſarily remains open from their ſhape. Mem. Acad. Par. 1712.

The holes in which the *pholades* lodge are uſually twice as deep, at leaſt, as the ſhell is long; and the figure of theſe holes is, that of a truncated cone, except that they are terminated at the bottom by a hollow rounded cavity, and their poſition is uſually ſomewhat oblique to the horizon. The openings of theſe holes are what betray the *pholas*'s being in the ſtone; but they are always very ſmall, in proportion to the ſize of the fiſh. There ſeems to be no progreſſive motion of any animal in nature ſo ſlow as that of the *pholas*; it is immerſed in the hole, and has no movement except a ſmall one toward the center of the earth; and this is only proportioned to the growth of the animal. Its work is very difficult in its motion, but it has great time to perform it in, as it only moves downward, ſinking itſelf deeper in the ſtone as it increaſes itſelf in bulk. The part by means of which it performs this, is a fleſhy ſubſtance placed near the lower extremity of the ſhell; it is of the ſhape of a lozenge, and is conſiderably large in proportion to the ſize of the animal; and tho' it be of a ſoft ſubſtance, it is not to be wondered at that in ſo long a time it is able, by conſtant work, to burrow into a hard ſtone. The manner of their performing this may be ſeen by taking one of them out of the ſtone, and placing it upon ſome ſoft clay; for they will immediately get to work in bending and extending that part allotted to dig for them, and in a few hours they will bury themſelves in the mud in as large a hole as they had taken many years to make in the ſtone. They find little reſiſtance in ſo ſoft a ſubſtance, and the neceſſity of their hiding themſelves evidently makes them haſten their work. The animal is lodged in the lower half of the hole in the ſtone, and the upper half is filled up by a pipe of a fleſhy ſubſtance and conic figure, truncated at the end: this they uſually extend to the orifice of the hole, and place on a level with the ſurface of the ſtone; but they ſeldom extend it any farther than this. The pipe, tho' it appears ſingle, is in reality compoſed of two pipes, or at leaſt it is compoſed of two parts ſeparated by a membrane. The uſe of this pipe or proboſcis, is the ſame with that of the proboſcides of other ſhell-fiſh, to take in ſea water into their bodies, and afterwards to throw it out again. In the middle of their bodies they have a ſmall green veſſel, the uſe of which has not yet been diſcovered; this, when plunged in ſpirit of wine, becomes of a purple colour; but its colour on linnen will not become purple in the ſun like that of the murex; and even if it would, its quantity is too ſmall to make it worth preſerving. Mem. Acad. Par. 1712.

The true or multivalve *pholas* is compoſed of two large ſhells, two other ſmall ones at the back, and one long narrow and crooked one at the cardo. The three ſmall ſhells always fall off as ſoon as the creature is dead; hence we uſually ſee the true *pholas*, with only two ſhells, in cabinets, and hence ſome have called it a bivalve, and others a trivalve ſhell, having found one of the three other valves. Some alſo pretend, that the Engliſh *pholades*, beſide the five pieces already mentioned, have another, which ſerves as an operculum. Many are of opinion, that the *pholades* bore their way into the ſtones, by means of their rough ſhells, but Bonani is of opinion, that they do it with certain teeth. *Liſter*'s Hiſt of Animal. Engl. p. 172. *Aldrovand* de Teſtac. l 3. *Bonani* Recreat. Ment. et Oculi. p. 36.

PHOLIS, in natural hiſtory, the name of a genus of foſſils of the claſs of the gypſums or plaiſter ſtones, the diſtinguiſhing characters of which are, that the bodies of it are conſiderably hard, compoſed of ſomewhat broad particles, and of a bright cryſtalline luſtre.

The word is derived from the Greek φολὶς, a ſcale, or ſmall flake, from theſe bodies being compoſed of particles of that form.

The ſpecies of this genus are the moſt valuable of all the gypſums, as burning to the beſt and fineſt plaiſter, but ſo far as is yet known there are but two of them. The fine plaiſter ſtone of Montmartre in France, called by us *plaiſter of Paris ſtone* and *Parget*; and the other the coarſer and ſomewhat reddiſh kind, common in many parts of England, and called *hall plaiſter*. *Hill*'s Hiſt. of Foſſ. p. 112. See the article PARGET.

PHOLIS, in zoology, the name of a ſmall anguilliform fiſh, the back of which is brown, the belly white, and the whole back and ſides ſpotted, and the ſkin ſoft and not covered with ſcales, but with a tough mucilaginous matter like the eel. This moſt of all approaches to the *alauda*, and tho' uſually ſomewhat larger, yet Mr. Ray doubts whether it really differs from it in any thing eſſential; its great diſtinction being its colour, which tho' a very obvious, is a very precarious one. *Rondelet.* de Piſc. p. 20. *Ray*'s Ichthyography, p. 135.

PHOLLIDES, a word uſed by the antient phyſicians for ſoft and fungous tumors of the legs, ſuch as thoſe of people in an anaſarca, or leucophlegmacy.

PHONASCI, in antiquity. See PHONASCIA, *Cycl.*

PHORBÆA, or PHORBEIA, in the muſic of the antients, a name given to a ſort of *frenum* or *bandage*, applied to the mouths of people who played on the pipe.

It was a ſort of leather band, which went firſt a-croſs the forehead, then behind each ear, and from thence making one or two turns round the head, it paſſed over the mouth, where its office was to reſtrain the lips from emiting too much breath at once, and cauſe them to diſcharge only juſt ſo much as would ſerve to inflate the pipe.

Simonides deſcribing the trial of ſkill between Marſyas and Apollo, mentions this *phorbeia* or *capiſtrum*, and ſome antique gems yet remaining among us, have the figure of a Marſyas's head, with the *phorbeia* upon it.

By the different ſtructure of the *phorbeia*, as expreſſed on the different coins, we find, however, that there were two ſpecies of it, the one was leſs complex, conſiſting only of a perpendicular piece down the cheek, and a tranſverſe one, runing a-croſs the lips, and covering the whole orifice of the mouth, only leaving a hole cut thro' it, at which the mouth-piece of the pipe was to be put in. The other conſiſted of ſeveral bandages, as at firſt deſcribed, and the lower tranſverſe piece of theſe did not come over the mouth, but only bore up the lower lip, in a forcible manner, againſt the upper. The old Greek writers diſtinguiſhed theſe by two different names added to the original word *phorbeia*; the firſt, or ſimple one, was called *monomeres*; and the other, or more complex one, *diemeres*: they were both called alſo by Soranus, and others, *epideſma*, and ſometimes ſimply *deſma*. *Soranus* de Epideſmis.

PHORIMOS, a name given by ſome authors to *roach alum*. See the article ALUM.

PHORINE, a word uſed by ſome authors to expreſs the ſkin of a hog; ſome alſo underſtand it to mean a skin of any kind, extending it even to the human cutis.

PHORMIX, among the antients, the ſame with *cithara*. See the article CITHARA, *Cycl.*

PHORMORAPHIS, in the materia medica, a name often uſed by the later Greek writers, and generally looked on as one of their unintelligible words, or the name of ſome drug not known at this time.

If we may gueſs at the reſt of their unintelligible words, however, by this, it is probable that ſomething might be done toward the explaining and underſtanding them, by conſulting the other medical writers neareſt their times, and particularly the Arabians.

Aviſenna mentions the drug called *carpeſium*, or *carpeſia*, which, he ſays, was a common ſubſtitute, in his time, for cinnamon. Galen alſo tells us, that the ſame uſe was made of the *carpeſium* in his days; they add deſcriptions of the drug, by which it appears probable, that it was either the young ſhoots of the cubeb tree, or of ſome ſuch ſhrub. The later Greek writers generally copy their accounts of things from theſe, and they give exactly the ſame deſcription of the *phormoraphis* as theſe do of the carpeſia: its uſe, as a ſubſtitute for cinnamon, is alſo mentioned by them. And upon the whole it appears, that it was the name the later Greeks gave to the *carpeſium*, or *carpeſia*, of their predeceſſors. It is to be obſerved here, that there is another very different ſubſtance given in the old Greek writers under the name of *carpeſium*; and this word is ſometimes written *carpeſium* and *carpeſia*. This was a gum reſembling myrrh in ſmell and colour, but of a poiſonous nature: the *carpeſia* here mentioned was, on the contrary, an aromatic medicine. See CARPESIA.

PHOS, a word uſed by ſome medical writers to expreſs a diſtemperature of the eye, in which there is ſeen a black circle wholly ſurrounding the pupil.

PHOSCAS, in zoology, the name of a freſh-water fowl of the duck kind, and of the ſize of the common wigeon. Its body is remarkably flat; its beak and legs are blue; its head and neck are of a browniſh colour, variegated all over with numerous triangular black ſpots; and on the top of the head theſe ſpots are larger than elſewhere, and are of a ſomewhat greeniſh hue; the back, wings, and tail are of a duſky brown, but the edges of the feathers are pale or whitiſh; the wings are variegated by two long white ſtreaks; the breaſt and ſides are of the ſame colour with the back, but paler; and the belly of a fine white, but with a few duſky ſpots under the tail. *Ray*'s Ornithol. p. 289.

PHOSPHORIA, φωσφορια, in antiquity, a feſtival in honour of Phoſphorus or Lucifer. *Potter*, Archæol. Græc. T. 1. p. 436.

PHOSPHORUS *(Cycl.)*—*Phoſphori* may be divided into ſeveral kinds; ſome ſhine of themſelves naturally, as the glow-worm and dates; or adventitiouſly, as the fleſh of animals, which moſt probably ariſes from a degree of putrefaction, ſometimes too ſlight to be obvious to our ſenſes. Other bodies become luminous by attrition, heat, the free action of air; and laſtly, by imbibing and retaining the rays of light. Thoſe bodies that are luminous by attrition, are, amongſt others, ſome diamonds, and the hairs of animals; by heat, ſeveral ſorts of gems, and mountain cryſtals; from the free acceſs of the air, the *phoſphori* of Kraft and Homberg; from the aſpect of light, the Bolognian luminous ſtone, the preparation by Chriſtian Adolphus Baldwin, of chalk diſſolved in ſpirit of nitre, as well as ſeveral others diſcovered by the late Monſieur du Fay, who found, that whatever ſubſtances would by calcination be converted into a calx, or whoſe concrete, from a ſolution in the acid of nitre, would bear fire enough to become red-hot, theſe bodies were adapted to imbibe and retain light.

The greateſt number of *phoſphori* are of the laſt mentioned kind. Some of theſe are natural, others artificial; but of theſe laſt the preparation is ſo ſlight, as not to change the nature of their conſtituent parts.

The natural *phoſphori* are either foſſile, vegetable, or animal. The foſſile are, though very different in degree, ſome ſorts of earths, white ſand, lime ſtones, ſtalactites, and ſeveral other figured ſtones, iſland cryſtals, flints, ſome ſpecies of agates, white arſenic; but no ſort of metals, metallic or ſulphureous bodies, as jet, amber, except the before-mentioned arſenic. On the other hand, ſalts imbibe light, provided they are diveſted of every metallic principle; otherwiſe not, though as pellucid as poſſible. For this reaſon none of the vitriols will imbibe light; but other ſalts will, tho' with a conſiderable difference as to quantity; for ſal gem and rock ſalt imbibe very little; ſea ſalt, if dry, and in cryſtals, much more; and in like manner, ſal ammoniac. ſal catharticum and nitre yet more. This power is weak in the natron of the antients, and alum; but brighteſt of all in borax.

In the vegetable kingdom we find very few *phoſphori*; that of dry rotten wood is weak and not laſting; it appears chiefly upon the edges and inequalities of the ſurface. But this is moſt remarkable in the rotten wood of the fir-tree, and ſome others, where, in the dark, you ſee ſhining ſpots as big as tares; whereas in full light the whole ſurface appears alike. Some few barks are luminous, but not conſiderably ſo; but no fruits, ſeeds, or their meals. Cotton and the cryſtals of tartar, appear very bright, but fine loaf ſugar appears the moſt luminous of all, both without and within: gums and reſins retain no light.

There is a vaſt variety of *phoſphori* in the animal kingdom, ſuch as the bones and teeth; to theſe may be added the ſhells of fiſh, egg-ſhells, the human calculus, bezoar, and in whatever parts of animals the terreſtrial principle is very predominant. But where there is a conſiderable quantity of oily matter, as in the hoofs, horns, and feathers, no light is manifeſt.

Beccari propoſes ſome queries concerning the natural *phoſphori*, of which the firſt is, In what and how great a light the object ought to be placed? He tried different *phoſphori* in different degrees of light, and found them imbibe moſt light from the ſun itſelf; next in quantity when the ſky was clear; and the leaſt in foggy weather. Theſe experiments ſhould be made in the open air, and not in a houſe with the glaſs-windows ſhut; becauſe many bodies appear luminous when the light has come directly to them, which will not have that appearance when the light has paſſed through the glaſs. He laſtly tried what light they would imbibe from very bright flame, and found that alabaſter itſelf, which is ſaturated more than any ſubſtance by the ſun's rays, imbibed exceedingly little. The next query is, How long theſe bodies ſhould remain in the light to be ſufficiently ſaturated? Four or five ſeconds were found the utmoſt length of time required for that purpoſe. The other query is, How long the received light will continue in theſe *phoſphori*? It does not laſt the ſame time in all; but continues more or leſs, from two ſeconds to eight, in proportion to the ſtrength of the *phoſphorus* and the quantity of light received.

Phoſphori are, it is well known, often produced by art; ſome are made by the maceration of plants alone, and without any fire; ſuch as thread, linnen cloth; but above all paper. The luminous appearance of this laſt is greatly increaſed by heat. This is confirmed by two experiments; the firſt is, by expoſing the paper, ſpread upon an iron-grate to the naked fire, yet not near enough to ſcorch it, and then laying a warm brick thereon to retain the heat; by which means it was obſerved, that where the paper was not skreened by the iron grate, it was moſt luminous; ſo that by the lights and ſhades you might diſtinguiſh in the dark the image of the iron-

iron-grate a conſiderable time. The other experiment is, the application of the paper to a plate of warm braſs; from which, when in the dark, you might very eaſily, by its being leſs luminous, diſtinguiſh the margin of the paper that had not been warmed by the braſs. The forementioned author takes notice alſo of thoſe *phoſphori* which become ſo by the aſſiſtance of fire; but the fire here ſpoken of is not great enough to diſſolve their conſtituent parts, but only ſuch as may affect the external parts of their texture, and that but gently; ſo that the proceſs here mentioned is only drying or roaſting. For it is not the watry or the ſaline parts in bodies which are torrified; but the oleaginous, wherewith many vegetables, and moſt animals abound. The white fleſh of animals, ſuch as that of chickens, becomes a *phoſphorus* by roaſting, as well as the tendons; and whatever parts of animals become glutinous by boiling, ſuch as carpenters glue, iſing-glaſs, *&c.* to theſe may be added cheeſe. Bones, though they imbibe light without any preparation, have that property in a much greater degree when burnt, and their luminous appearance is much more lively. But roaſting has not this effect upon feathers, hoofs, horns, or whites of eggs. The ſame operation which produces ſeveral *phoſphori* from the animal kingdom, gives alſo ſeveral from the vegetable. Thus, by gently toaſting gums, as myrrh, gum tragacanth, and others, they appear luminous tho' different in degrees; and this light is clear in proportion to the gentle evaporation of their aqueous parts. By this treatment nuts of every kind, pulſe, corn, coffee-berries, meal, bread, and wafers, alſo become *phoſphori*. Turpentine, amber, and ſome reſins, require more fire before they imbibe light; ſo that you muſt diveſt them of their acid, and their light etherial oil, to make them appear luminous. But here great care muſt be taken that they boil no longer than from being white they turn yellow; for if you proceed longer, your labour is loſt. Thoſe *phoſphori* produced by torrefaction, ſoon loſe their power, which, perhaps, neither time nor a thorough diſſolution of their parts can deprive the natural ones of. In general, as long as the *phoſphori* gained by torrefaction, preſerve their power, their light is more ſharp and ſtriking, but the natural more weak. Thoſe that are gained by calcination, and Baldwin's *phoſphorus*, ſeem to poſſeſs both the ſtriking light of thoſe gained by torrefaction, and the weaker light of the natural *phoſphori*: the laſt they preſerve a long time, but the former is loſt by degrees much ſooner. The well calcined aſhes of plants, or rather their terreſtrial parts remaining after the ſolution of their fixed ſalts by waſhing, and neutral ſalts, continue *phoſphori* after many years: ſo that, as far as we can judge, the luminating power which is gained by calcination, tho' not ſo intenſe, continues perpetual; whereas that gained by torrefaction always decreaſes, and in a very little while is no longer viſible. Some even by this method, continue to imbibe light much longer than others. Gum arabic, which continues longeſt, laſts ſix days; bread not one, and coffee only a few minutes. However, at any time, by a freſh torrefaction, you may recover theſe languid *phoſphori*; in which property they have great likeneſs to the Bolonian ſtone, and other *phoſphori* prepared by art. The *phoſphori* gained by torrefaction, as well as that of Bolonia, will not imbibe light while they are warm; and this laſt does not appear ſo luminous when firſt prepared, as when it has been ſo for ſome time. The natural *phoſphori* do not differ only in the before-mentioned particulars, but alſo in the colour of the light itſelf. The light of the natural generally appears either perfectly bright, or ſomewhat inclining to yellow; the artificial produces a red, and ſometimes a brown light; but there are ſome exceptions to both theſe rules. From theſe different appearances it may be conjectured, that there are two ſorts of fire ariſing from different principles; *viz.* that in torrified ſubſtances from a ſulphureous, and that of the natural from a terreſtrial principle. In obſerving a piece of lapis tutiæ, that was rough and unequal on its convex ſide, but ſmooth and ſomewhat poliſhed on the concave, Beccari, to his great ſurpriſe found, that the rough ſide was luminous, and the ſmooth one not: being very deſirous of inveſtigating the cauſe of this appearance, he remembered that ſome poliſhed marbles did not imbibe light, or very little, and that at their edges; but having loſt their poliſh, they did admit and retain it. He therefore conjectures, that bodies, according to the diſpoſition of their ſurfaces for the reflection of the light, either ſuffer or prevent its entrance into them. If this poſition hold good in the reflection, Why ſhould it not with regard to the refraction? The ſame author produces two experiments, which he apprehends not foreign to the preſent purpoſe. Expoſing a glaſs-bottle full of well water to the light, and, as ſoon as poſſible, obſerving it in the dark, it was found to have imbibed no light; upon pouring into it ſome oil of tartar, it became turbid and whitiſh, from the well-water being uſually impregnated with calcarious matter. Upon obſerving it then in the dark, after having been expoſed as before, it retained enough of a pale light to diſtinguiſh the ſhape of the bottle. In a bottle of rain water he diſſolved ſome talc; which ſtone, by rubbing, will diſſolve in water as ſalts do, without rendering it opaque; to this ſolution he added oil of tartar, and this mixture was luminous as the preceding. He therefore concludes, that ſo long as earthy corpuſcles are very ſmall, ſeparate, and agreeing in their ſurfaces with the water in which they float, they readily tranſmit the light they receive; for which reaſon 'tis impoſſible they ſhould retain light enough to appear luminous in the dark. But by the affuſion of the ſaline principle, the earthy corpuſcles unite with the water and ſalt; and from the union of theſe principles the mixture grows thick, whereby the ready tranſmiſſion of the light is prevented; ſo that if this mixture is without colour, or any thing metallic, the light will be ſtopped long enough to be viſible in the dark. But if, inſtead of oil of tartar, you add ſugar of lead, the mixture will be turbid, but retain no light. In theſe two experiments the water becomes a *phoſphorus*. Gems, cryſtal, and glaſs, whether whole, or powdered ever ſo fine, retain no light; ſo that neither their tranſparency nor whiteneſs contribute to their becoming luminous in the dark. Of ſeveral diamonds in all appearance perfectly the ſame, ſome were very luminous, others not at all. Of many opaque ſubſtances, whether rough, poliſhed, or finely powdered, ſome were luminous, others not: ſo that it appears that not only the external, but the internal texture of bodies alſo, may conduce ſometimes to their being luminous.

Almoſt all bodies, by a proper treatment, have that power of ſhining in the dark, which, at firſt, was ſuppoſed to be the property of one, and afterward only of a few. How this is brought about is not eaſy to ſolve. If we ſuppoſe with ſome, that the light from a luminous body, enters and abides in the *phoſphori*, we ſhall find ſomewhat new to admire in light itſelf. It is no new opinion, that this fluid conſiſts of very fine particles, which are continually darted forth from a luminous body in all directions, with a very great velocity: but it has by no body been laid down hitherto, that theſe particles are not diſſolved by the violence of their agitation, not diſperſed, nor immediately ceaſe to exiſt; but ſubſiſt ſtill, and adhere to what bodies come in their way, as heat does. If therefore the particles of light are not diſſolved as ſoon as they are emitted from a radiant body, but continue ſome time, what elſe is required but that we allow its atmoſphere to every lucid appearance? If the *phoſphori* ſhine with a borrowed light, but not with their own, and that only when put in motion, and fired by the rays of a ſhining body, which ſome experiments ſeem to confirm, then other new doctrines will ariſe. There muſt be then a hidden, a ſecret principle in bodies, to be lighted up by this moſt ſubtle fire. There will be in the univerſe a certain perpetual fire from theſe *phoſphori*; the matter of which, tho' conſtantly diſſipated by burning, does not waſte enough to be obvious to our ſenſes. See Phil. Tranſ. N° 478.

PHOSPHORUS *of urine.* The ſucceſsful method of making this famous ſubſtance is this: evaporate any quantity of freſh urine over a gentle fire, to a black and almoſt dry ſubſtance; then, with two pounds thereof, thoroughly mix twice its quantity of fine ſand; put the mixture into a ſtrong coated retort of ſtone, and having poured a quart or two of water into a large receiver with a long neck, join it to the retort, and work it in a naked fire: let the heat be ſmall for the two firſt hours, and then increaſe it gradually to its utmoſt violence, and continue thus for three or four hours; at the expiration of which time there will paſs into the receiver a little phlegm and volatile ſalt, much black fœtid oil, and laſtly, the matter of the *phoſphorus*, in form of white clouds; which will either ſtick to the ſides of the receiver, like a fine yellow ſkin, or elſe fall to the bottom, in form of a ſmall ſand. Now let the fire go out, but take not away the receiver before it is cold, for fear of ſetting the *phoſphorus* on fire by admitting the air. Take out the matter of the *phoſphorus*, and put it into a little tin ingot mould, along with water; heat the mould to make the matter all run into a maſs, then add cold water, till it is congealed into a ſolid maſs like bees-wax; cut this into long ſlender pieces, which put into a phial, and fill it up with water, and then cork it cloſe. *Shaw's* Lect. p. 403.

This *phoſphorus* is nothing but the animal ſulphur. Now all animals, on which experiments have been made, are found to contain more or leſs of the phoſphoreal principles; ſome inſects conſtantly ſhine, or emit light, in the open air; many ſorts of fiſh are luminous, if expoſed to the air a ſhort time; nay, even the bubbles of the ſea water appear like fire in the dark: ſome quadrupeds have been obſerved to emit light on very ſlight friction of their hair, as the necks of horſes, the backs of cats, and the like; and there are many inſtances in our own ſpecies of many parts of the body appearing luminous, and even of the exhalations from it adhering to the cloaths, cauſing them to ſhine likewiſe. We have ſeveral curious obſervations relating to this ſubject in the Phil. Tranſ. N° 476. p. 444, 445, 456, 457, *&c.*

Upon this principle of *phoſphorus* exiſting in animals, ſome attempt to explain the cauſe of thoſe accidental accenſions or burnings which have happened to ſome of the human ſpecies, as that of the lady at Ceſena in Italy, the carpenter in Hampſhire, and the woman lately at Ipſwich. It ſeems moſt probable, that they were all ſet on fire by lightening. It may be ſaid, many are ſtruck by lightening, but not ſet on fire. But it is to be remarked, that the lady at Ceſena had charged

all

all her pores and abſorbent veſſels with a great quantity of camphor. The woman at Ipſwich had drank plenty of gin; which circumſtances muſt greatly promote the kindling the *phoſphoreal* fire in them: and as this pabulum was conveyed into the moſt minute capillary veſſels, it might produce an almoſt inſtantaneous deflagration and diſſolution of all the ſolid containing parts. Phil. Tranſ. N°. 476, p. 447. ſeq.

Ammoniacal PHOSPHORUS, in chemiſtry, the name of a *phoſphorus*, compoſed of ſal ammoniac and lime, which Mr. Homberg firſt diſcovered.

The method of preparing it is this: take one part of ſal ammoniac in powder, and two parts of lime extinguiſhed by lying in the air: mix them exactly together, and fill a crucible with the mixture; ſet it in a ſmall melting heat. As ſoon as the crucible grows red hot, the matter in it will melt, and it muſt be ſtirred with an iron rod, leſt it ſwell over the edges of the crucible: as ſoon as the whole is melted, pour it into a copper baſon; it will appear of a greyiſh colour and vitrified, and if it be ſtruck upon with any hard body, there will be ſeen a fire all over the place where the blow was given. As this matter is brittle, however, and the ſame maſs will not ſerve often for the experiment, the beſt method is to dip iron rods in it while melting, and theſe will be covered with the matter, and will anſwer the purpoſe eaſily and often. Mem. Acad. Par. 1693.

Antimonial PHOSPHORUS, in chemiſtry, the name of a ſubſtance having the qualities of the *phoſphorus* diſcovered by Mr. Geoffroy in his experiments on antimony. This gentleman had prepared a ſoap from pot-aſhes, quick-lime, and oil, with which he made ſeveral experiments on antimony; among others he was deſirous, by means of this, to reduce ſome diaphoretic antimony, which he had before made from two parts of the regulus of antimony, and three parts of nitre; but inſtead of the reduction which he was labouring after, his operation afforded him a much more ſingular phænomenon: the reſult of them being a *phoſphorus*, which he had never thought of; a matter, which after having remained perfectly quiet while cloſe ſtopped down, took fire as ſoon as ever it was expoſed to the air; and that with a violent detonation, and darting every way a ſhower of fire.

It is eaſy to ſee, that there are in the preparation all the requiſites for ſuch an effect; nitre, charcoal furniſhed by the burnt ſoap, and ſulphur both from the ſoap and from the regulus of antimony; and to all theſe, a ſort of calx, either from the ſoap, or from ſome earthy parts of the antimony. It is eaſy to conceive, that all theſe ſubſtances coming to a mixture together, ſhould be ready to catch fire and blaze upon a proper application; but it is not leſs difficult to account for this effect's being produced merely by the air, after the whole had been for a long time in a ſtate of reſt.

The method of preparing this new ſpecies of *phoſphorus* is this: Mr. Geoffroy mixed two ounces of his ſoap with one ounce of this diaphoretic antimony; this mixture being put by little and little into a red hot crucible, took fire, and ſwelled very much. After it had done flaming, the maſs ſubſided, and became a red or fire-coloured ſubſtance, of an even ſurface, but ſtill throwing up a vaſt quantity of bluiſh-green luminous vapours: and all this regularly happened on every freſh throwing in of the matter, without the leaſt variety. When the whole quantity was thrown in, and had ceaſed to give any flame or luminous vapour, it remained in the crucible in the form of an inverted muſhroom, being hollow, very porous, and of a black colour. When the crucible was taken out of the fire, the edges of this ſubſtance were beaten down into the middle, and the whole covered with an ounce of freſh ſoap. When this laſt ſoap was burnt, and a ſmall blueiſh flame appeared upon the ſurface of the maſs, the crucible was covered with a lid, and a large quantity of charcoal laid upon it, and the fire blowed up very briſkly, by an hundred blaſts of the bellows, or thereabouts; but notwithſtandig the fierceneſs of the fire, there was no fluid ſcoriæ formed, but the whole maſs remained ſpungy and porous. The fire was then ſuffered to go out, and the crucible placed in a corner of the elaboratory at reſt for five hours. In the evening, when the crucible was perfectly cold, Mr. Geoffroy went to examine the matter, and a ſervant went to uncover the maſs, by removing its ſurface with an iron inſtrument; but the moment the air was admitted, the whole maſs took fire, burning with a very conſiderable noiſe, and darting its flames every way to a great diſtance.

Mr. Geoffroy repeated the proceſs ſeveral times, and always with the ſame ſucceſs, whether he uſed his own diaphoretic antimony, or that made in the common manner. The great caution to inſure the ſucceſs, ſeems to be the taking care of not carrying the fire too far before the addition of the laſt quantity of ſoap. Mem. Acad. Scien. Par. 1736.

Aquatic PHOSPHORUS, a name given by Dr Leigh, in his hiſtory of Lancaſhire, to a water found near Wigan in that county, which takes fire on holding a lighted candle to it. It is not properly the water, however, that takes fire in this caſe, but a ſteam which burſts out of the ground with it. The author alſo calls it a ſulphurated water; but that very improperly, for it contains no ſulphur, but only iſſues out in company with this bituminous vapour.

PHOSPHORUS *of the bearne-ſtone*, in natural hiſtory, is a name given to a ſtone, (which, when heated, becomes a ſort of *phoſphorus*) from the place where it is found; as the famous one of Bologna is called alſo from its native region.

The *bearne-ſtone* is of a moderate hardneſs, conſiderably pellucid, and uſually colourleſs, or whitiſh, tho' ſometimes with a tinge of green, yellow, or ſome other colours: it is compoſed of numbers of plates, or flakes, laid one over another, in the manner of the iſland cryſtal; and therefore, like that body, is plainly a ſpar. It breaks into ſeveral faces, and has different angles; but of a ſomewhat determinate meaſure, the acute ones being of ſixty degrees, and the obtuſe ones of 120. Mem. Acad. Par. 1724.

This ſtone, when heated at one of its angles with the flame of a lamp or candle, ſplits by means of the flame's inſinuating itſelf into the interſtices of the plates that are leſs firmly united; and theſe ſeparate, and ſome fragments uſually fly off with conſiderable violence. One of theſe pieces carried into an obſcure place, appears ſurrounded with a blue flame, which laſts about a minute. And it is to be obſerved, that theſe pieces which fly off, have all the ſhape of an irregular pyramid, with an uneven baſe. If this ſtone be put into a crucible, and ſurrounded with coals, it becomes a very beautiful *phoſphorus*. The whole bottom of the crucible is ſeen, even tho' it be in broad day light, ſhining with a bright and beautiful blueiſh white; and if it be carried into a dark place, the light is ſeen much more beautifully. If, after it is cold, it be again heated in a crucible, in the ſame manner it ſhews the ſame bright appearance. After this, if it be tried a third time, it does not ſhine at all. According to all theſe phænomena, the effects of fire upon this ſtone ſeem to depend on a ſulphur contained in it, probably of the ſame nature with that which enters the compoſition of the metals. This may, by means of a heat, ſuch as that given by the candle or in the crucible, diſengage itſelf ſo far from the body of the ſtone as to take fire; and when it has burnt ſo long as to conſume itſelf, the luminous property of the ſtone ſeems to ceaſe.

The coloured gems are cryſtals of a peculiar kind, tinged with the ſulphurs of metals: this ſulphur gives them their colour, and conſequently it ought to give them the properties of the *bearne-ſtone*, if it were not too fixed to be diſſipated in the ſame eaſy manner, and to take fire in the diſſipation. And it appears on trial, that the baſtard emeralds of Auvergne and other places, the matrix of the amethyſt, the fragments of ſome of the accidental jaſpers, the jacynths, and ſome ſort of rubies, are all *phoſphoruſes* of the nature of the *bearne-ſtone*, but with different degrees of brightneſs. The mother of the emerald, the yellow jaſper, the water ſapphire, the malachite, the opal, and the garnet, have none of them any of this property. Mem. Acad. Par. 1724.

Since the ſame ſulphurs which take fire in the *bearne-ſtone*, are what give colour to theſe other ſtones, it ſhould ſeem, that thoſe which are not of this *phoſphorus* kind, nor give a light after being heated, ſhould not loſe their colours in the fire; and this is found to be true in the garnet, which does not loſe any part of its colour, nor is it at all luminous; whereas the hyacinth, and ſome of the jaſpers and other ſtones, which loſe a part of the colour, not the whole, in the fire, become alſo in part luminous, or more ſo, in degree, according to the quantity of colour which they loſe. This, however, is no certain rule, ſince the mother of the emerald, the topaz, and ſome other ſtones, loſe all their colour, and yet are not at all luminous. The reaſon of this ſeems to be, that the ſulphurs are driven out of theſe ſtones ſo ſlowly, and in ſuch minute quantities, that they are not at any time collected into body enough to be capable of flame. There is nothing to be objected as to the *bearne-ſtones* ſhining; tho' they are uſually white, they may poſſeſs no ſmaller portion of ſulphurs than the coloured ſtones; only in thoſe the ſulphurs may be colourleſs, or white in themſelves.

It may be poſſible alſo, that the ſulphurs, in a ſtone of this kind, may be diſperſed in ſuch ſmall molecules, as not to form a body ſufficient to give any colour; but when collected, in order to be driven off in the fire, they may then be ſufficient in quantity to give a blue tinge to the flame.

The iſland cryſtal, which is alſo a ſpecies of ſpar, and which greatly reſembles this *bearne-ſtone* in many particulars, flies to pieces alſo in the ſame manner, on being heated; and when carried into the dark, this alſo gives ſome ſparks of light, but they are few in number, and looſely ſcattered over the ſurface: when this ſtone is burnt a little in a crucible, there is ſome ſmall appearance of flame, with a ſmell of ſulphur, and the matter in the bottom of the crucible is found ſhattered to pieces; but all the pieces are regular parallelopipeds, as was the original maſs. Mem. Acad. Par. 1724.

It is to be obſerved, that the *bearne-ſtone*, and others of the ſame kind, which only ſhine in the dark, and that only for a few minutes, when firſt taken out of the fire, are, properly ſpeaking, endued with no other luminous quality, than that of a burning coal; but their light having been generally unobſerved, and requiring darkneſs to ſhew it, has obtained them the ſpecious title of *phoſphori*.

PHOSPHORUS *fæcalis*, a very fine kind of *phoſphorus*, exhibiting many wonderful phænomena, and prepared from human dung mixed with alum.

Mr.

Mr. Homberg, who was the inventor of it, gives the method of preparing it in the following manner: take four ounces of human dung newly made, mix it with the same quantity of roach alum grosly powdered; put the mixture into a small iron ladle, capable of holding about a pint; set it over the fire in a chimney, and it will melt together, and become as fluid as water; let it boil gently over a small fire, continually stirring it with an iron spatula, till it is dry: it will then be difficult to stir, but it must be kept stirring about, and all the lumps it runs into must be broken, and what adheres to the sides of the ladle stirred in and blended with the rest: this must be continued till it is perfectly dry, and the ladle must be now and then taken from the fire, and the matter stirred about in it that it may not grow red-hot. When the whole is thus perfectly dried, it will still be in little lumps, and when cold it must be rubbed to powder in a metal mortar; it must then be put into the ladle and set over the fire again, it will then become a little moist again, and run into clods and grumes, but it must be again stirred till dry; when cold it is to be powdered again, and a third time put into the ladle; and when perfectly dried this time, it is to be laid by in a paper in a dry place: thus is the first or preparatory operation finished.

Take two or three drams of this powder, put it into a small matrass, capable of holding an ounce and half of water, and which has a neck six or seven inches long; put a paper stopper lightly into the neck of the matrass, then take a small crucible of three or four fingers breadth high, put two or three spoonfuls of sand into it, then set the bottom of the matrass on the sand, and take care that no part of it touches the sides of the crucible; fill up the rest of the crucible with sand, and let the whole body of the matrass be covered with it; then set the crucible in one of the common little earthen furnaces, and make a charcoal fire about it; for the first half hour let the coals only reach up to the middle of the crucible, but afterwards lay them up to the rim of it; continue this fire about half an hour, or till the powder within the matrass is red-hot, then pile up more charcoal above the rim of the crucible, and continue this fire an hour, after which let the whole cool. There will arise a large quantity of fumes during the operation, and they will often throw out the stopper of the matrass; but this must be replaced, and the fire a little abated in that case: when these fumes cease, the fire may be raised without hurting the process, when the crucible is so cool that it may be taken out of the furnace without burning the hands. This is to be done, and the matrass is to be half raised out of the sand to make it bear the cold by degrees, and its mouth must then be stopped closely with a cork, instead of its paper stopper. If, on shaking the matrass about, the matter falls into powder, it is a proof that the operation has been well performed; but if it hang together in form of a cake, 'tis a sign that the matter was not well roasted in the ladle before the putting it into the matrass.

When the operation has been well performed, and the matter is in powder in the matrass, pour out a small quantity of it on a piece of paper, and immediately stop the matrass again: the powder upon the paper will immediately fume and take fire, burning the paper, and any other combustible matter that is in the way. If there has been too much of the powder poured out of the matrass, it must not be returned in again; for tho' that should be done before it begins to smoak, yet it will certainly set fire to all that is in the matrass; from this it may be easily seen also, that the matter cannot be emptied out of the matrass into a phial, but must always be in the vessel in which the calcination was made.

If too much alum be used, the powder will not take fire at all: it will be of different colours, according to the vessel the first calcination was made in, and according to the degree of fire that was used; hence it is sometimes black, sometimes brown, sometimes red, green, yellow, or white.

It takes fire equally well in the day-time and in the night, and that without the mixture of any other substance, or without the least rubbing, or any other circumstance beside the mere exposure to the air. In this it differs from all the other known artificial *phosphori*; for that of urine requires a small degree of heat, in order to its burning; the smaragdine *phosphorus* requires a considerable degree; the Bononian stone does not shine except after having been exposed to the day-light; and all the others require violent rubbing, or a smart blow to produce their light.

If it be desired to keep this powder good for any time, it must be put in a dry place where there is not too much heat: the mouth of the matrass must be kept close stopped, and its body covered with paper; and the place where it stands must not be in too strong a light, for the open day-light has been often known to weaken its power; and, in fine, wholly to spoil it thro' the glass. Mem. Acad. Par. 1711.

Fulgurating PHOSPHORUS. See FULGURATING.

PHOSPHORUS *metallorum*, a name given by some chemists to a preparation of a certain mineral spar, which is found in the mines of Saxony and other places, where there is copper. The spar to be used on this occasion is, that kind which is tinged green, and from its, in some degree, resembling the colour of the emerald, is called by some *pseudosmaragdus*, and by others *lapis smaragdi mineralis*. This is to be powdered very fine, and this powder is to be laid on a flat plate of copper, iron, or any other metal: this plate is then to be set over some lighted charcoal, and the whole placed in a dark place. The spar will receive its necessary degree of heat for shining long before the metal will, and, consequently, as soon as it begins to shine, the fire is not to be made any brisker. While the plate of metal is held in this degree of heat, and does not appear at all red, the powder upon it will shine like a lighted coal, and will continue so for some time. If it be removed away, and suffered to cool, it will be fit to repeat the experiment a second time with, but its light will not be so strong as before. Phil. Trans. N° 244. p. 365.

PHOSPHORUS *of sulphur*, the name given by the French academicians to a new-discovered species of *phosphorus*, which readily takes fire on being exposed to the open air.

The invention was Mr. Le Fevre's, and the process is this: The ingredients are two drams of common *sulphur*, half an ounce of steel filings, ten grains of colophony, and six drams of common water. These things being all weighed and set apart, powder about half a dram of the *sulphur* in a small mortar, then add the colophony, and afterwards the remainder of the *sulphur*. When this is all reduced to a fine powder, put in the filings of steel, and rub the whole together till it is so thoroughly mixed, that the steel does not appear; but the colour of the whole looks every where uniform and regular: then add about twenty drops of the water; and after beating the whole together add as much more, and continue to do so till the mass is of the substance of a paste, but not too moist. Put this paste into a small matrass that will contain about three ounces, and pour on it more of the water till it swim above the surface of the paste near a quarter of an inch. The matter of the paste will then break, and appear in form of a granulated powder under the water; put the matrass on a sand furnace, but give it no greater heat than that the hand can bear to lie upon the matrass. When it begins to heat, the mixture will ferment and swell, and become black; it is then to be stirred with an iron rod, and a little more water must be added every quarter of an hour, till the whole is used. The matter will then be very black and liquid; and it is to be then taken from the fire, and set by for the whole night. This is the first and most essential part of the operation, and in this great care is to be taken that the fire be not too violent; for if the *sulphur* be burnt, the operation will be spoiled, and the matter would ferment so high as to run over at the mouth of the vessel.

To finish the operation, a little water must be added to the matter, so as to swim over it, and the vessel must be again set in the sand, and a stronger fire given than before; this is known to be strong enough when there is any humid vapour observed to arise out of the mouth of the vessel. This fire is to be continued about two hours, that the greater part of the humidity may be evaporated; which is known by the iron rod finding some resistance when put into the vessel, and the matter it brings up being granulated and solid, or no longer moist; it must then be immediately taken from the fire, and the whole is then finished. It is necessary to be very exact in this last critical minute; for a very little longer standing on the fire will burn the *sulphur*, and render all the former care of no effect. The black matter remaining in the matrass is to be taken out, and the sides scraped clean with an iron rod; any piece of this that happens to fall upon a paper takes fire in a very little time, and burns away like the other *phosphorus*. The process is a very nice one, but by observing all the rules here laid down, several persons have succeeded in making the *phosphorus* to perfection: the whole intent of the operation seems to be to join together the minute particles of steel and *sulphur*; which when thus joined cannot fail to be very inflammable, and to take fire on receiving the smallest humidity from the air to make them ferment.

It cannot but be observed, that this *phosphorus* is founded on Lemery's experiments of steel and *sulphur*, taking fire together; but this is a greatly more nice and accurate operation, and a fine improvement on the original plan, which was only by mixing large quantities of steel-filings and *sulphur* together into a paste with water, and burying this in the earth to make it take fire of itself, and thus represent the natural phænomena of vulcanos, thunder, lightening, &c. Mem. Acad. Par. 1728.

Phosphorus may be kindled by the effluvia of electricity. See Phil. Trans. N° 475. Sect. 14.

PHOSSA, in zoology, a name understood by some to express the whole genus of pigeons, but more properly it is the name of one species only, the *palumbes*, *torquatus*, or *ring-dove*. See the article RING-*dove*.

PHOTINX, φωτιγξ, in antiquity, a kind of flute in use among the Greeks: it was the same with the *plagiaula* of the Romans. *Hofm.* Lex. Univ. in voc.

PHOXINUS, in zoology, a name given by some to the *rutilus*, or *common roach*. *Rondelet.* de Pisc. See the article RUTILUS.

PHOXINUS *squammosus*, in zoology, the name of a small fresh-water fish, called by some the *bambele*, by others the *riemling*, and by some the *pink*. It seldom is found beyond the length of two or three inches; its head is large in proportion to the rest of its body, and is blackish; and the roots of all its fins have something of a saffron colour; and the joint of the gill fins has a little prominence, which in some is yellow, and in others reddish; its scales are small and whitish, and the lines on its sides reaching from the gills to the tail are brown; its belly and sides are a little yellowish; it has one fin on the back, one behind the anus, a pair at the gills, and another pair on the belly; they love running waters; and when dressed have a bitterish taste. *Gesner*, de Aquat. p. 484.

PHRÆNIAN, in the botanical writings of the antients, a name given to a kind of *anemone*, used in making garlands and other ornaments.

The scholiast on Theocritus observes from Solibius, that the Lacedæmonians called the *anemone* in general *prænion*; and Nicander seems to comprehend under this title several beautiful species of the *anemone*, which he distinguishes from the *chelidonian anemones*; but Athenæus informs us, that others have made the *chelidonian* and *phrænian anemonies* the same. Some have supposed the *anemonies* of the antients used in garlands, and those used in medicine to be different, but the generality of authors do not warrant this.

PHRATRIARCHUS, φρατριαρχος, among the Athenians, a magistrate that presided over the *phratria*, or third part of a tribe. He had the same power over the *phratria*, that the *phylarchus* had over the tribe. *Potter*, Archæol. Græc. T. 1. p. 78. See the article PHYLARCHUS.

PHRENITIS *(Cycl.)* — The preceding symptoms of this disorder are, long watchings, troubled sleep, and very restless dreams, acute and terrible pains of the head, an entire forgetfulness of every thing, and a wandering of the mind, discovering itself by inconsistent answers to questions, a small desire of liquors, tho' the heat of the mouth plainly indicates all that can occasion the most intense thirst; large and slow respiration, a weak and slow pulse, and suppression of urine. All these signs predict an approaching *phrenitis*; but when it has already seized the patient, the blood-vessels of the head all swell, and the temporal arteries have so strong a pulsation, that they are seen to beat very forcibly; the eyes sparkle and look wild and fierce; the talk is all wild and raving; and at certain times the patient has usually violent fits of struggling to get out of bed; the extremities are cold, and the urine thin, white, and pellucid.

The persons most subject to a *phrenitis* are those of a sanguineous and plethoric habit, and much given to anger; such as are addicted to a hot diet, and the use of strong liquors; such as are many hours together exposed to the sun in hot weather in their daily occupations; and such as have been subject to violent head-achs, or have had habitual hæmorrhages at the nose stopped upon them, or have had the blood usually discharged by the hæmorrhoids thrown up into the head; and women who have had the menses stopped upon them, and the blood in the same manner thrown up into the head. These persons are, from such circumstances and accidents, subject to the *phrenitis* as an idiopathic distemper, dependant on no other. But besides these, others are also very subject to it as a symptom in other diseases. People in acute fevers are very often thrown into it by an incompleat critical congestion of blood about the head; and this principally happens to such as have been treated by apothecaries in an improper and injudicious manner. From the sudden checking of sweats many have also been thrown into it, and some from improper bleedings, and more than all these by a too hot regimen.

Method of cure. A clyster is one of the first things to be prescribed in this case; or if this cannot be given from the violence of the patient, the bowels must be gently relaxed by large draughts of warm emollient liquors, with a small addition of nitre; after this bleeding is to be ordered, where the pulse and condition of the patient shew it to be necessary, and gentle alexipharmics are then to be given in repeated small doses, such as the mixtura simplex highly camphorated, and the like; and in the intermediate times the violent emotions of the blood are to be quieted by the use of powders of nitre, tartar of vitriol, crab's eyes, and a small portion of cinnabar; these are to be given with cooling emulsions; a placid regimen must be observed, and the patient kept in a gentle perspiration; and external applications are sometimes of great service, such are spirit of wine and camphor, rubbed on the forehead and temples, and frictions, cataplasms of various kinds, and blisters laid to the soles of the feet. *Junker*'s Consp. Med. p. 304.

Others in this case apply epithems to the forehead, either of the absolutely repellent kind, such as vinegar of roses, or of lavender; these are most proper in the beginning; and if these do not succeed, the resolvents are left afterwards to be tried; such are spirit of wine and camphor, and spirit or tincture of saffron; bags of camphor and nitre in powder, may also be applied, and if these fail it is proper to put on leeches to the temples and behind the ears; bleeding in the jugular vein is another method; and blisters are to be applied to the legs and arms, and sinapisms to the feet, composed of yeast and strong vinegar, with mustard-seed, nitre, and other ingredients of that kind; and, finally, when all these fail, an irritation of the nostrils to promote an hæmorrhage, and bleeding in the nose, as practised in Egypt, and some other countries, is proper. *Heister*'s Consp. Med. p. 125.

Dr. Friend has recommended bleeding at the jugular veins, in a *phrenitis* coming upon a fever; but Dr. Langrish endeavours to prove the bleeding in this case to be rather hurtful; and he thinks the cases quoted by Dr. Friend to prove his opinion, either do it not, or may be turned against him. See Med. Ess. Abrid. Vol. 2. p. 457.

PHRICODES, a term used by the antients for a kind of fever which is attended with a coldness and shivering, not only at the beginning of the fit, but at different intervals throughout its whole continuance. The semitertian fever is of this kind. The usual symptoms of these fevers are a remarkable lowness of the pulse, which is scarce to be felt, but recedes as it were from the finger. The belly is tumified, and a rumbling noise is heard in it, and the tongue is very humid, and irrigated with a sharp acid humor, as with the saliva.

PHRONTIS, a word used by Hippocrates as the name of a peculiar disorder of the general nature of the melancholy affections. In this case the patient, he says, feels, as it were, a thorn pricking the abdominal viscera; he is extremely restless and uneasy, and always avoids light and company. He dreads being touched, and becomes timorous and afraid of every thing; he is molested with troublesome dreams, and imagines that he frequently sees spectres and frightful objects.

PHRYCTE, a word used by the antient physicians as a name for common resin.

PHRYGANIDES, in natural history, a name given by authors to the fly which is produced from the *phryganium*, or common cadosworm, found in ditches, and used as a bait for fish. This has a long body, four brown wings, and a forked tail, and is found in the month of August very frequent on waters.

PHRYGANICUS, in botany, a term used by Dioscorides and many other of the antient Greeks, to express such herbaceous plants as have hard and woody stalks, such are the garden thyme, and several others of that kind: they also called these plants *xylodes*, ξυλωδες, and ξυλωιδεα ποα.

PHRYGIAN, *(Cycl.)* in antient music, the third species of the *diapason*. See the article DIAPASON.

PHRYGIAN *stone*, *phrygius lapis*, in natural history, the name of a stone described by the antients, and used in their time in dying; probably from some vitriolic or aluminous salt contained in it, which served to enliven or fix the colours used by the dyers.

It was a light spungy mass, resembling a pumice, and the whitest and lightest were esteemed the best. Pliny gives us an account of their preparing it for use for dying, which was by moistening it with urine and then heating it red-hot, and suffering it to cool again: this calcination was repeated three times, and the stone was then fit for use; and Dioscorides recommends it in medicine after burning; he says it was drying and astringent.

PHTHIRION, in botany, a name used by some authors for the *pedicularis*, or *red rattle*. *Ger.* Emac. Ind. 2. See the article PEDICULARIS.

PHTHISIS *(Cycl.)*—This disease is properly an ulcerous disposition of the lungs, taking its origin from a stasis of blood in that viscus, which in time degenerates into matter, and which is attended with a very remarkable wasting of the flesh and loss of strength. A *phthisis* in different persons, and at different times, differs in degree; in some cases it is only a tendency to ulceration in the lungs, but in others it is an actual ulceration in that part.

In the first of these cases, where there is only a tendency to an ulceration, the lungs are only stuffed up with a quantity of tenacious and viscid matter, or of a mucous fluid, with a mixture of blood. This matter, by degrees, becomes more and more hard and tough, by the dissipation of its more fluid parts; and hence gives a schirrous hardness to that part of the lungs where it is contained, but is not easily changed into absolute matter. In this case the patient may live many years, and often there is no suspicion of his being in a *phthisis*.

In the second case, or an actual exulceration of the lungs, the disease cannot long remain unknown, but the hectic fever, which is its constant attendant, readily discovers it; and the wasting of flesh, and spitting of matter, soon bring the patient to his end, if speedy and efficacious remedies are not applied.

Many are very anxious about the distinguishing a true *phthisis* from an abdominal hectic; but this is a distinction of very little use in practice, since both cases require the same regimen: the gently resolvent and discutient medicines, and balsamics, which have nothing acid in them, are the proper method in a *phthisis*, and are equally necessary in this hectic. The principal differences, however, between them are these: The abdominal hectic always is attended with a fever, whereas the *phthisis* is often free from a fever, or at least is not attended with one of any consequence. If, in a strong inspiration, on drawing as much breath as may be into the lungs,

the cough is always brought on, and there is a pain and ſtraitneſs in the breaſt, that alſo declares the ſeat of the diſorder to be in the lungs.

Atrophies are alſo much of the ſame nature with a *phthiſis*, differing only in regard to the part they affect, and to the age of the patient. An atrophy is an injury of the glands of the meſentery, pancreas, or liver, and is common to infants; whereas the *phthiſis* is a like diſtemperature of the lungs, and affects perſons nearer the time of their growing to man's eſtate.

A true *phthiſis* is, however, to be carefully diſtinguiſhed from that maraſmus which frequently affects old perſons: this ariſes from many different cauſes, but never from that of a *phthiſis*, or diſtemperature of the lungs. The vomica pulmonum is alſo by ſome confounded with a *phthiſis*, but improperly; for tho' theſe diſtempers are nearly allied to one another, and often degenerate into each other, yet their origin is different. The *phthiſis* takes its origin from an ulcer, properly ſo called; the vomica is an abſceſs, or impoſthumation. The ulcer in a *phthiſis* affects the humid parts of the lungs, where there is leaſt blood; the vomica, on the contrary, is always ſeated in thoſe parts where there is moſt abundance of blood: ſince it generally happens, that a vomica is a ſhorter diſeaſe in its period, and carries the patient off earlier; the *phthiſis* does it more ſlowly and gradually. When a vomica, indeed, does not carry off the patient at firſt, it uſually degenerates into a true *phthiſis*; and on the other hand, when the matter lodged in the lungs in a true *phthiſis* is ſo acrid as to corrode the veſſels, then a vomica pulmonum often comes on in the courſe of that diſeaſe; but theſe are accidental degenerations of one diſeaſe into another, and tho' the firſt caſe is frequent, the other is more rare.

Signs of a phthiſis. This diſeaſe, when it begins ſlowly and gradually, has ſcarce any ſigns at all by which it may be known: the utmoſt ſymptoms of it in this caſe, is a cough, which, tho' not violent, will not be cured. This cough, by degrees, increaſes, and holds the patient always, in ſpite of medicines: in ſome caſes it is moderate, but in others it becomes in a little time very violent. This cough is in ſome attended with a conſiderable ſpitting, in others with very little, and in ſome perſons, both at the beginning and end of the diſtemper, with no ſpitting at all.

It is, however, a vulgar error to ſuppoſe every cough attended with ſpitting to be a conſumption, for very frequently the faults of the firſt concoction will give origin to coughs more violent, and attended with greater ſpitting than thoſe in a genuine *phthiſis*. Hence, for the proper diſtinguiſhing of a *phthiſis*, many other ſymptoms are neceſſary: theſe are, that the patient be of an age ſuited to this diſeaſe, in general, between fifteen and thirty-five: the cough alſo, in a true *phthiſis*, is continual, and always becomes much more violent on being expoſed to the cold, as alſo on drawing the breath very deeply, or taking the effluvia of any acrid ſubſtances: when the matter ſeems fetched up from very deep, and is ſtreaked with blood, or is of an ill ſmell, and approaching to the nature of matter; this alſo denotes the caſe to be a true *phthiſis*. This diſeaſe is always attended alſo with a decay of ſtrength, a ſenſation of a ſtraitneſs in the breaſt, a want of appetite, or a deſire for nothing but cold foods and drinks. The ſleep in this caſe alſo rather tires and weakens than refreſhes the patient, and the mouth is dry, the ſaliva glutinous, and the temper uſually peeviſh, and affected ſtrongly at trifles; the body alſo becomes extremely ſenſible of all changes of the weather. If theſe ſymptoms happen in a caſe where there is either an hereditary diſpoſition to a *phthiſis*, or where there has been any prior injury done to the lungs, there is no room to doubt but that the caſe is a true conſumption or *phthiſis*.

Theſe prior injuries of the lungs may be either from preceding diſeaſes, ſuch as a ſpitting of blood, a peripneumony, or the like; or from external contuſions or wounds of the breaſt; or finally, from frequently being among the vapours of corroſive medicines: and when theſe are attended with a hectic, or loſs of fleſh in the whole body, and particularly in the face, there is not the leaſt room to doubt but that the caſe is a dangerous *phthiſis*. The ſpitting of purulent matter is one of the moſt certain ſigns of a perfect *phthiſis*, but it is not an univerſal one; for there are ſome caſes in which the bronchia and membraneous portions of the lungs only are affected, in which a *phthiſis* may arrive at its greateſt degree without any ſuch ſpiting. It is alſo to be obſerved, that the common thick, yelloviſh, or greeniſh matter, which is frequently voided in large quantities in ſimple coughs, is not to be confounded with the purulent matter voided in a continued *phthiſis*.

The urine of people in this diſeaſe is uſually very like that of perſons in health, except that it retains its froth longer; this, however, is no certain ſymptom of the diſeaſe, for it frequently happens in caſes of ſimple colds, in people of phlegmatic habits.

If a vomica pulmonum comes on from a *phthiſis*, the fever, which was before a ſlow one, aſſumes the appearance of an acute one; and the pain that attends the cough becomes more violent, and reſpiration more difficult; finally, colliquative ſweats, and diarrhœas, are very fatal ſymptoms, uſually appearing towards the laſt ſtages.

Perſons ſubject to a PHTHISIS. Theſe are principally young people of a plethoric habit, accuſtomed to perfect health, and of florid conſtitutions, particularly ſuch as live idle lives. Thoſe who labour hard, or are of a ſcorbutic or phlegmatic habit, are more than all others free from this diſeaſe. Perſons who are ſubject to hæmorrhages of any kind, or to violent pains in the head, and thoſe who find their breath very ſhort after a little exerciſe, and particularly ſuch as have had at any time ſpitings of blood, are moſt ſubject to this diſtemper; as thoſe, on the contrary, who are ſubject to cattarrhal defluctions, to ſimple coughs, or to diarrhœas, or cutaneous eruptions, or external ulcers, are uſually free from it. Women in general are much more expoſed to *phthiſes* than men; and that for this plain reaſon: the ſuppreſſion of any habitual hæmorrhage, endangers the patient as to this diſeaſe; and women are well known to be more ſubject to evacuations of blood than men; and alſo to the ſuppreſſions of thoſe evacuations.

Old people are very ſeldom found to have *phthiſes*, unleſs they ariſe from violent external injuries; and very young perſons are as ſeldom liable to them, unleſs from ſuppreſſions of large and habitual hæmorrhages by the noſe.

Cauſes of a PHTHISIS. The remote cauſe of this diſeaſe, is a plethoric habit; the proximate cauſe is a congeſtion of florid, rarely of ſerous blood, in the breaſt. The occaſional, or accidental cauſes, are either external injuries from blows, falls, or bruiſes on the breaſt, a violent cough in the autumn, at which ſeaſon the air is peculiarly bad for all perſons inclined to a *phthiſis*; the abuſe of ſpirituous liquors, the immoderate uſe of venery, the receiving the fumes of corroſive medicines, and finally, the improper cure of other diſeaſes, particularly the ſuppreſſing of fevers and hæmorrhages by aſtringents, without any previous cautions. An hereditary diſpoſition is alſo frequently in fault; the cough which attends this diſeaſe is only an effort of nature, to break through the congeſtion in the firſt ſtages, and in the latter, to throw up the matter occaſioned by it.

Prognoſtics in it. A true *phthiſis*, even in its beginning, is a dangerous diſeaſe, and admits but of a very dubious prognoſtic; but when in an advanced ſtate, it is always fatal. The reaſon of this is evident, becauſe there are in this caſe real ulcers in the lungs, and we well know that no ulcer can be cured till it is firſt perfectly cleanſed, and that is not eaſy in an internal part; and after this, the healing up of a wound in the lungs is ſcarce to be expected, as thoſe parts are continually diſturbed by the very drawing in and voiding the breath, and greatly more ſo by the cough. There have been, however, inſtances of cures in the beginning of a *phthiſis*, in which there have been evident proofs of a reſtitution and cicatrization of the parts.

People of a dry habit are much ſooner carried off by it than thoſe of a moiſt one; as are alſo thoſe of a briſk diſpoſition, than thoſe of a more languid temper; and finally, younger perſons uſually die ſooner in it, than thoſe who are more advanced in years. Women, as they are more ſubject to a *phthiſis* than men, ſo they are more eaſily cured. This diſtemper is often brought upon them merely from a ſuppreſſion of the menſes, and in that caſe it is often cured only by regularly bringing them again to their proper periods. The hectic fever in theſe caſes is what haſtens the death of the patient; ſo that the leſs of that fever the patient has, the longer he lives under it.

When the ſpitting of true purulent matter is come on, and is attended with colliquative ſweats and a diarrhœa, there is no farther hope for the patient; and in general, what is reported of the curing of conſumptions, is founded on errors, and other caſes have been miſtaken for it. A catarrhal cough become habitual, and attended with a voiding of a thick, pulpy, greeniſh matter, is often miſtaken for a conſumption: as is alſo a ſlow fever, attended with copious ſweats, and an extenuation of the body; or a recent hectic, ariſing from a continued ſlow fever; or a merely aſthmatic diſorder of the breaſt; or finally, a hæmoptyſis has been miſtaken for a *phthiſis*. In all the caſes ſaid to have been *phthiſes*, and perfectly cured, either one of theſe has been the caſe, or the mere ſtrength of nature, aſſiſted by happy circumſtances in the conſtitution, not to be expected from one perſon in a thouſand, have carried the patient through it.

Method of Cure. The general method in a genuine *phthiſis*, is to reſpect firſt the reſolving, abſtergiog, and diſcuſſing the ulcerous matter in the lungs; and after this to attempt the cleanſing and healing of the ulcers; afterwards to reſtore the ſtrength by analeptics, and to give the weakened parts their due tone again: and during this, the ſeveral ſymptoms, ſuch as the cough, fever, *&c.* are to be palliated as much as may be.

To this end, in the beginning of the courſe, gentle laxatives are by all means to be given; ſuch as ſmall doſes of rhubarb, with manna, tamarinds, and the like: and in ſubjects abounding with bad humors, jalap, ſena, and, in ſome caſes, even mercurius dulcis are found neceſſary; but this laſt medicine is only to be given with the utmoſt caution, for fear of a ſalivation. After a few doſes of the laxatives, the reſolvent, abſtergent, and diſcutient medicines are to be given for ſeveral weeks together; ſuch are, decoctions of pimpernell, elecampane, florentine, iris, birth-wort, and freſh arum-

root,

root, with maidenhair, horehound, hyſſop, and daiſy-leaves: the gum-reſins are alſo to be given in ſmall doſes; ſuch as ammoniacum, ſagapenum, and the like; and mixtures of crabs eyes ſaturated with lemon juice, with vitriolated tartar diſſolved in the pectoral waters, are to be given every day three or four times: a little nitre cautiouſly given in the intermediate times, will alſo be of great uſe in abating or taking off the fever. After this, the healing the ulcerated parts is to be attempted by the more temperate balſamics; ſuch as boiled turpentine, maſtic, olibanum, balſam of Peru and capivi, and Lucatellus's balſam: with theſe there always muſt be joined ſuch things as will nouriſh and give ſtrength; ſuch are emulſions made rich with ſweet almonds, with jellies and conſerve of roſes.

If the violence of the diſorder is found to remit on this Method, it will be proper to give a mixture of ſpirit of ſal armoniac, with tincture of ſalt of tartar, in doſes of about twenty drops, three times a day: this is greatly ſerviceable in reſtoring the parts to their due tone; and if the cough ſtill continues violent, it will be proper to give ſmall doſes of the ſtorax-pill at night. If the diſeaſe is finally taken off by this method, it will be proper afterwards, by way of prevention, to bleed freely in the foot every ſpring and autumn; to recall, by all poſſible means, any habitual diſcharges of blood that had been ſtopped or ſuppreſſed; and particularly in men to promote a diſcharge by the hæmorrhoidal veins, by applying leeches to the part: the patient is not to be loaded with medicines in this caſe, but it will be ſufficient always to keep the bowels moderately open, and to uſe moderate, but not violent exerciſe, with diets that are ſoft and eaſy of digeſtion. *Junck.* Conſp. Med. p. 160, ſeq.

Mr. de Sault endeavours to prove, that a conſumption of the lungs always depends on tubercles, and that an ulcer there is only an effect of theſe tubercles; and when the diſeaſe is in its laſt ſtadium, and incurable, it then only becomes contagious, by ſmall worms, which it communicates to others. The cure which he propoſes for the conſumption, before it comes to the laſt ſtage, is to reſolve the tubercles with mercury, ſteel, millepedes, and the aperient and antiſcorbutic plants. He remarks, that the liver is generally hard in this diſeaſe; and therefore he applies a warm mercurial plaiſter to the right hypochondriac region, rubbing ſome mercurial ointment every night on the ſkin of that part; then continues in the uſe of tablets made with ſteel, millepedes, benzoin, coral and crabs-eyes, of each half an ounce; cinnamon, three drachms; ſugar, half a pound; mix all with the mucilage of gum-tragacanth, made with orange-flower water. The doſe of theſe tablets is two drachms, morning and evening, waſhing it down with a ptiſan made of the roots of nettles, two ounces of the juice of water-creſſes, and as much juice of cervill. Med. Eſſ. Edinb. He ſays this method, with riding, has often been ſucceſsful.

Dr. Cheyne thinks that a total milk and ſeed diet, with frequent phlebotomies, vomits, bark in the morning and rhubarb at night, will totally cure conſumptions. See his Nat. Method. of Cures, p. 264.

Morton reckons among the ſpecies of *phthiſis*, thoſe proceeding from the diarrhœa, dyſentery, gonorrhœa, hæmorrhage, and dropſy, and from many other diſeaſes; and perhaps there are many other remote cauſes which can produce a conſumption, without varying the common immediate cauſe of the diſeaſe, or the method of cure. Med. Eſſ. Edinb. V. I. p. 266.

This diſtemper, according to ſome, is principally to be cured by frequent bleedings in ſmall quantities. Med. Eſſ. Edinb.

PHU, in botany, a name by which ſome authors call the great garden valerian. *C. Bauh.* p. 164.

PHYCIS, in zoology, the name of a fiſh of the truttaceous kind, more uſually called *callarias*, or *aſellus callarias*, and *tinca marina*, or ſea-tench. *Geſner*, de Piſc. p. 819. See the article CALLARIAS.

PHYCIS, in ichthyology, is alſo a name given by Artedi, after Ariſtotle, Pliny, and the reſt of the antients, to a fiſh nearly allied to the genus of the *blenni*, and called by ſome *trebius* and *fuca*; and according to Rondeletius, the *tinca marina* of the Italians. Salvian, however, denies that it is the *tinca marina*, and the matter is yet undecided among the writers on this ſubject. See TINCA *marina*.

PHYCITES, in natural hiſtory, the name given by the antients to a ſtone which had the impreſſion of a ſea plant of the fucus or alga kind; probably in the manner in which our black coal ſlate is frequently found to contain the impreſſions of fern and other vegetables.

PHYLACISTÆ, among the antients, officers to whoſe keeping the ſlaves in priſons and work-houſes were committed. *Pitiſc.* Lex. Ant. in voc.

PHYLARCHUS, φυλαρχος, among the Athenians. The *phylarchi* were magiſtrates who had each of them the government of a tribe committed to his charge; and their buſineſs was to take care of the public treaſure belonging to each tribe, to manage all their concerns, and call them together as oft as any thing happened that required the preſence of the whole body. *Potter*, Archæol. Græc. l. 1. c. 13. T. 1. p. 78.

PHYLATERIA, a name given by ſome botanical authors to the *polium*, or poly-mountain. *Ger.* Emac. Ind. 2.

PHYLLA, among the antients, wreaths, or fillets, that hung from the womens head dreſs, in form of flowers. *Pitiſc.* Lex Antiq. in voc.

PHYLLANTHUS, in botany, the name of a genus of plants, called by Martin, in his centuries, *niruri*, as alſo in the hortus amſtelodamenſis, and malabaricus.

The characters are theſe: the flowers are ſome male and others female, produced on the ſame plant. In the male flowers the cup is compoſed of one leaf, of a campanulated form, and divided into ſix oval and obtuſe ſegments: theſe are coloured, and are the whole flower, for there are no petals. The ſtamina are three filaments, ſhorter than the cup, ſtanding cloſe at the baſe, and expanding towards the points. The antheræ are double in the female flower. The cup is the ſame as in the male, and there are no petals. The nectarium is a ſort of rim of twelve angles, ſurrounding the germen of the piſtil. This germen is roundiſh, but obtuſely trigonal. The ſtyles are three, they ſtand expanded, and are obtuſely bifid at the extremities. The ſtigmata are obtuſe. The fruit is a roundiſh capſule, marked with three furrows, and containing three cells, each compoſed of two valves. The ſeeds are ſingle and roundiſh, and do not wholly fill the cells of the capſule. *Linnæi* Gen. Pl. 447. *Martin*, Cent. 1. p. 9. Hort. Mal. Vol. 10. p. 27.

PHYLLEN, in botany, a name given by ſome of the old authors to the *mercurialis*, or male and female French mercury. *Ger.* Emac. Ind. 2.

PHYLLEREA, *phillerey*, in botany, the name of a genus of plants, the characters of which are theſe: the flower conſiſts only of one leaf, and is of a bell like ſhape, and divided into four ſegments at the edges. The piſtil ariſes from the cup, and is fixed in the manner of a nail to the hinder part of the flower. This finally becomes a fruit of a roundiſh figure, containing roundiſh ſeeds.

The ſpecies of *phyllerey*, enumerated by Mr. Tournefort, are theſe: 1. The broad-leaved ſmooth *phyllerey*. 2. The broad-leaved prickly *phillerey*. 3. The *phyllerey* with lightly ſerrated leaves. 4. The privet-leaved *phyllerey*. 5. The common narrow-leaved *phyllerey*. 6. The longer narrow-leaved *phyllerey*. 7. The narrow-leaved prickly *phyllerey*. 8. The *phyllerey* with long and deeply ſerrated leaves. 9. The box-leaved *phyllerey*. 10. The Spaniſh bay-leaved prickly *phyllerey*. 11. The Spaniſh nerium-leaved *phyllerey*. 12. The dwarf American *phyllerey*, with thick yellow roots, and ſharp-pointed leaves. And, 13. The dwarf American *phyllerey*, with a thick roſe-coloured root and roundiſh leaves. *Tourn.* Inſt. p. 596.

PHYLLITIS, *hart's tongue*. The ſeveral ſpecies of this plant ſee enumerated under the word LINGUA *cervina*.

It is recommended by many as an aſtringent, and has a place in moſt of our diſpenſatories. The common kind is eſteemed the beſt for medicinal uſe; it is found in old wells, and under damp walls, ſometimes in the ditches under very thick hedges. It is given, in powder or decoction, in ſwellings and indurations of the ſpleen; as alſo in diarrhœas, and in ſpitting of blood, or other hæmorrhages, externally: it is accounted a good mundificative for old ulcers. Ray, in his hiſtory of plants, tells us alſo, that the powder of the dried leaves does wonders in palpitations of the heart, and hyſteric affections.

PHYLLITIS *marina*, *ſea-hart's tongue*, in natural hiſtory, a name given by ſome authors to a ſpecies of ſea-plant, the leaves of which, in ſome degree, reſemble thoſe of the common *hart's tongue*. It grows on the rocks at great depths, and is ſeldom ſeen, unleſs when taken up by the coral fiſhers. Its leaves are ſometimes ſingle, ſometimes they divide into two: they are of a duſky green colour, and are about two inches in length: they have each a nerve or rib running along their middle: they are very thin and tranſparent, and are of a ſort of cartilaginous ſtructure; and each has ſeveral rows of ſmall points on each ſide of the middle rib, which not unaptly reſemble the ſeed ſpots on the leaves of ſome of the capillary plants; but not on thoſe of the *phyllitis*, or hart's tongue in particular, becauſe they are in that plant not round but oblong, and ſtand only in a ſingle row on each ſide the rib. When this plant is viewed by the microſcope, it appears in all parts of the leaf full of little holes; and thoſe which are ſo plain to the naked eye, are no other way different from the imperceptible ones, but in that they are larger. The plant has no root, and therefore takes in its nouriſhment by theſe numerous holes in its ſurface. *Marſigli*, Hiſt. Mer.

PHYLLITIS *marina Triumfetti*, in natural hiſtory, the name of a ſea plant, deſcribed by count Marſigli and others, and taking its denomination from Triumfetti's judging it like the common *hart's tongue*, which grows on the ſides of wells, and in other ſuch places. It is found in great abundance on the coaſts of the Mediterranean in ſeveral places at different depths, and grows to the rocks and ſtones. It grows to about three inches in height, and its colour is a yellowiſh green; it is ſoft and tough while in the water, but when dried it becomes very brittle, and may be rubbed to powder between the fingers. It is very elegantly branched, and its leaves are diſpoſed with great ſymmetry and regularity, and are placed in a nice order for the properly receiving nouriſhment and conveying it all over the plant. On examining theſe leaves with a microſcope, they are found to be in reality only ſo many tubes, hollow all the way along, and having an aperture at the extremity,

tremity, by which they admit the ſea water: as theſe ſtand above one another on the main ſtalks, each receives its portion of fluid, and tranſmits it without mixing with the reſt, pure to that part of the ſtalk where it joins: they are all nicely jointed on to the main ſtalk or trunk, and that alſo is hollow as well as the leaves. The leaves of moſt of the ſea plants, on being examined by the microſcope, appear to be full of glandules and tubercles, which are in reality ſo many ſmall pipes deſtined to admit the ſea water; but in this plant, as that water is admitted in ſufficient plenty by the extremities of the leaves, the reſt of their ſurface is kept ſmooth and perfectly even. *Marſigli*, Hiſt. de la Mer, p. 76.

PHYLLOBOLIA, φυλλοβολια, in antiquity, a cuſtom that prevailed among the antients to ſtrow flowers and leaves on the tombs of the dead. The Romans adopted this cuſtom from the Greeks, and added likewiſe wool. See the article BURYING.

The *phyllobolia* was alſo uſed on occaſion of a victory obtained at any of the public games; when not only the victors, but likewiſe their parents, were ſtrowed with flowers and leaves. *Hofm.* Lex Univ. in voc.

PHYLOBASILES, φυλοβασιλεις, among the Athenians, magiſtrates, who, with reſpect to particular tribes, had the ſame office that the *baſileus* had, with reſpect to the commonwealth.

They were choſen out of the eupatridæ or nobility, had the care of public ſacrifices, and other divine worſhip peculiar to their reſpective tribes, and kept their court in the portico called *baſileion*, and ſometimes in the *buculeian*. *Potter*, Archæol. Græc. T. 1. p. 78.

PHYRAMA, in the materia medica, a name given by ſome of the old writers to the gum ammoniacum, particularly to that kind of it which was ſoft and ductile between the fingers. It is not clear that the gum ammoniacum of thoſe times was the ſame thing which we now know by that name; at leaſt it is certain, that the other kind of it, which they called *thrauma*, or *ammoniacum thrauſtum*, was not; for Dioſcorides deſcribes this as being of a reddiſh-brown colour, and very friable; and Aviſenna ſays, that it marked a fine yellow or gold colour upon paper. Theſe are properties by no means agreeing with our gum ammoniacum; and if juſtly applicable to that, muſt prove that it could not be the ſame; and the characters given by Aviſenna of its bitterneſs, and making a yellow ſtain upon paper, ſeems to make it the *gamboge*. This, however, by no means can agree with the other virtues attributed to it.

PHYSALUS, a name given by Rondeletius to a ſpecies of ſea inſect, of the *ſcolopendra marina* kind, ſuppoſed by ſome to be the ſame with the *ſcolopendra marina*, or *centipes* of the Iriſh ſea, deſcribed by Molyneux; but this does not appear to be the caſe, on a ſtrict enquiry. The *phyſalus* of Rondeletius has no mouth, whereas the ſea *centipes* of Ireland has a remarkably large one: that of Rondeletius is wider in the middle, and tapers at each end; but the Iriſh kind is largeſt at the head, and tapers from thence all the way to the tail. Rondeletius's has tubercles on the back, but the Iriſh one has only hairy ſtripes; and his is a poiſonous animal, whereas that of Ireland was found in the ſtomach of a cod-fiſh, which had eaten it as food. The figure given by Rondeletius agrees alſo very well with the account he gives, but not with the figure of that drawn upon the ſpot from the Iriſh fiſh, and given in the Philoſophical Tranſactions. On the whole, nothing is more plain than that theſe are two diſtinct ſpecies of animals, tho' of the ſame genus. Phil. Tranſ. N° 225. See the article SCOLOPENDRA.

PHYSETER, in ichthyology, the name of a genus of fiſhes of the *plagiure* kind, the characters of which are theſe: The teeth are crooked, and are placed only in the lower jaw There is one high fin or ſpine on the back, and a fiſtula or hole in the forehead. There are only two known ſpecies of this genus; theſe are, 1. The *phyſeter* with the upper jaw longer than the under one, and with a long ſpine on the back. The head of this fiſh is ſo large, that it is half as long as the body, and thicker than the thickeſt part of it. The lower part of the upper jaw runs out two foot beyond the under one, and its upper part more than five foot. The eyes are remarkably ſmall, ſcarce longer than thoſe of a haddock; the fiſtula or pipe, is placed a little above the center of the head; it is divided into two channels, and covered with one common operculum; the teeth are in number forty-four, and all of the ſhape of a reaper's ſickle, roundiſh and a little flatted, thickeſt and moſt arched in the middle; and at the end terminating in a cone very ſharp-pointed; the baſe is thinner than the middle of the tooth. 2. The *phyſeter* with a very high back-fin, with the tops of the teeth flat. This is a ſpecies of whale, deſcribed, as well as the former, by Sibbald The head is very large; the fiſtula, or pipe, is in the middle of the head; the fin ſtands ſo high in the middle of the back, that it has been compared to the mizzen maſt of a ſhip. *Artedi*, Gen. Piſc. See the article BALÆNA.

The name *phyſeter* is of Greek origin, and is derived from the verb φυσαω, to blow. It has this name from its quality of taking in a great quantity of ſea water, and then blowing it out again with great force and violence.

PHYSIOLOGI, in botany, thoſe authors whoſe writings tend to ſet that ſtudy in its cleareſt light, by explicating and enumerating the various diſpoſitions of the male and female parts in the flowers of plants. *Linnæi* Fund. Bot. p. 2.

PHYSOCELE, a word uſed by many authors to expreſs a *wind-rupture*.

PHYSTA, in ichthyology, a name given by Geſner, and ſome others, to the fiſh called by the Greeks, and many of the later authors, *ballerus* and *balerus*. Artedi denies its right to any general name, reducing it to the genus of the cyprini, to which it evidently belongs, and diſtinguiſhing it from the others of that numerous genus by the ſpecific name of the very broad and thin *cyprinus*, with forty rays in the pinna ani. See the articles BALLERUS and CYPRINUS.

PHYSTE, in the writings of the antient phyſicians, a word uſed to expreſs a maſs of meal macerated in a cloſe veſſel with wine, but not left to ferment.

PHYTALIA, a word uſed by the antients in two very different ſenſes; with ſome expreſſing the latter part of the winter ſeaſon, and with others a place where vines are planted, whither in ſtandard vineyards or otherwiſe.

PHYTOLACA, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the roſaceous kind, conſiſting of ſeveral petals arranged in a circular order; from its center ariſes a piſtil, which finally becomes a ſoft fruit or berry of an oval figure, or nearly round, and containing ſeveral ſeeds diſpoſed in a circular order.

The ſpecies of *phytolaca*, enumerated by Mr. Tournefort, are theſe: 1. The larger fruited American *phytolaca*, called by authors the *great red cluſter-fruited Virginian nightſhade*. 2. The American *phytolaca*, with ſmaller fruit. *Tourn.* Inſt. p. 299.

PHYTOLOGI, *phytologiſts*, authors who have written any treatiſe on botany, or the hiſtory or uſes of vegetables. *Linnæi* Fund. Bot. p. 4.

PIA *mater (Cycl.)* —According to Mr. Le Cat, the *pia mater* gives three membranes to the eye; the firſt lines the ſclerotic coat, and is joined to it; the ſecond is the choroid coat, and the third is the villous mammary one, proceeding from the choroid, and is commonly called *Ruyſche's coat*. Med. Eſſ. Edinb. abrid. Vol. II. p. 482.

PIABA, in ichthyology, the name of a ſmall freſh-water fiſh, caught in all the freſh rivers and brooks in the Braſils, and ſome other parts of America.

It is of the ſize of the common minow; its eyes have a fine black pupil, and a yellow iris; it is covered with ſmall ſcales, and has a triangular fin on its back, two under the belly, two at the gills, and one behind the anus; its tail is forked; its head is of a mixed yellow and white, and of the brightneſs of gold and ſilver; its back is of a ſilvery hue, with an admixture of green, and in ſome parts of a fine ſtrong blue; and the ſides of a ſilvery white and blue, without any admixture of green; and its belly of a mixed yellow and white, with only a ſlight caſt of blue; behind each of the gills it has a fine deep blue ſpot, and immediately behind that another of the ſame colour, but of a lunated ſhape; and two other oblong ones of the ſame colour, near the origin of the tail; its tail and back-fins are yellow; its belly-fins red; it is a well-taſted fiſh, and much eſteemed by the natives. *Willughby*'s Hiſt. Piſc. p. 269.

PIABUCU, in zoology, the name of an American fiſh eaten by the natives in many places. It is a ravenous fiſh, and ſo greedy of blood, that if a man goes into the water with a wound in any part of his body, this fiſh will make up to it to ſuck the blood. It is a ſmall fiſh, ſeldom exceeding four inches in length, and of no great breadth; its belly is ſomewhat protuberant, and the whole fiſh is covered with bright ſilver-coloured ſcales. The lines running one on each ſide from the gills to the tail are broad, and not ſhining like the reſt of the body; the back is of a greeniſh olive-colour, and the fins are white. *Marggrave*'s Hiſt. of Braſil.

PIAFFEUR, in the manege, is a proud, ſtately horſe, who, being full of mettle, or fire, reſtleſs and foreward, with a great deal of motion, and an exceſſive eagerneſs to go forwards, makes this motion the more that you endeavour to keep him in, and bends his leg up to his belly. He ſnorts, traverſes if he can, and by his fiery action ſhews his reſtleſsneſs; whence ſome, though very improperly, ſay, he dances. Such horſes as theſe, or ſuch as are bred to paſſage upon a ſtraight line, are much admired in carouſels and magnificent feſtivals. See the articles SNORT and PASSADE.

PIANISSIMO, in the Italian muſic, is uſed to ſignify that the part to which it is added ſhould be played very ſoftly, and ſo as that the ſound may ſeem at a great diſtance, and almoſt loſt in air. See *Corelli* Concerto VIII. in fine.

PIANO, in the Italian muſic, ſignifies ſoft and ſweet, by way of an echo.

PIANO PIANO, or PIU PIANO, in the Italian muſic, is nearly the ſame with *pianiſſimo*, or rather a degree between it and *piano*.

Piu PIANO, in the Italian muſic, ſignifies more ſlow, or more ſoft, and is much the ſame with *piano piano*.

PIC, an Eaſt Indian weight, containing 100 catis. See the article CATI.

PICA, the *pye*, or *magpie*, in the Linnæan ſyſtem of zoology, the name of one whole order of the bird kind; the character of which is, that they have a convex beak, flatted above. The birds of this order are, the bird of paradiſe, the magpie, the crow, the cuckow, the wood-pecker, the ſitta, the creeper, the hoopoe, and the iſpida. *Linnæi* Syſtema Naturæ, p. 44.

Of this genus of birds, authors enumerate the following ſpecies: 1. The *pica varia caudata*, or common *magpie*. 2 The *pica braſilienſis*, called *toucan*. (See the article TOUCAN.) 3. The *pica glanduria*, or common jay. 4. The *garrulus argentoratenſis*, or roller. (See the article ROLLER.) 5. The *pica marina*, or ſea *pie*, a very beautiful ſpecies, being all green except the head, neck, and feet, and a ſmall part of the wings; the head is cheſnut-coloured on the top, and yellow at the ſides, and its feet brown; its claws black and very ſharp, and it has a ſmall variegation of cheſnut colour on its wings. This Mr. Ray ſuſpects, however, to be no other than the *garrulus argentoratenſis*, or roller. 6. The *pica perſica*, or Perſian *pie*, variegated with yellow; and two others mentioned by Charleton, the *pica caudata indica*, or long-tailed Indian *magpie*; and the *mimus*, or *pica garrula indica*; a bird reſembling our jay, but much ſmaller: theſe two laſt, however, are mentioned by no other author, and have never been ſeen in Europe. *Ray*'s Ornithology, p. 87, 88, 89, 90.

PICA is alſo a name by which ſome have called the *lanius*, or butcher bird. *Ray*'s Ornithology, p. 52. See the article LANIUS.

PICA *marina*, in ornithology, the name of a bird called in Engliſh the *ſea pie*, and by Bellonius and ſome others, the *hæmatopus*. It is of the ſize of the common *magpie*; its beak is three fingers breadth long, ſtrait, and of a reddiſh, or a blackiſh colour, and ending in a point, and ſeeming well-fitted for its buſineſs of rooting up the limpets from the rocks, the bodies of this fiſh being its common food; its legs are red; it has no hinder toe, and has its other toes ſo far connected by a membrane, as to ſeem almoſt of a middle nature between the web-footed and other birds; its head, neck, back, throat, and half its breaſt are black, as is alſo its rump; its tail is half black, and half white, as are alſo its wings. It is common on the weſtern ſhores of England, and on the ſhores of Wales. *Ray*'s Ornithology, p. 230.

PICA *marina* is alſo uſed by Geſner very improperly for the bird commonly known by the name of *anas arctica cluſi*. *Aldrovand.* de Avib. T. 3. p. 315. See the article DUCK.

PICA *naſi*, in medicine, a name given by Cohauſen to the immoderate taking of ſnuff. It ſeems a whimſical term, but he chuſes to treat this habit as a diſeaſe, and has written an expreſs treatiſe concerning it. The word *pica*, in general, denotes an abſurd and unnatural appetite; and the deſire of taking the powder of tobacco in this manner, is called a diſtempered appetite of the part into which it is taken, that is, the noſe.

The conſequences of the taking ſnuff immoderately, are, that the ſenſe of ſmelling is either entirely deſtroyed, or at leaſt greatly impaired: for the nervous tubercles of the noſtrils being continually vellicated by this powder, are by degrees clogged up, or wholly deſtroyed, and the ſenſible membrane, which lines the noſtrils, is rendered callous, and wholly unfit for the diſcharge of its office in ſmelling. The voice is next affected by this powder; for it cauſes a ſort of aſtriction at the bottom of the noſe, which affects the palate, and conſequently the ſpeech; this gives the perſon who takes it a continual deſire of taking more and more, to rid himſelf of that ſtoppage. *Cohauſen*, de Pica Naſi.

PICACIA, a name given by the antients to that diſtempered appetite of women with child, and maidens at a certain time of life, which makes them long for things not fit for food. It is more uſually called *pica*.

PICACUROBA, in zoology, the name of a Braſilian ſpecies of pigeon, of a greyiſh colour variegated with a reddiſh brown, and with very red legs and feet. *Marggrave*'s Hiſt. of Braſil.

PICARDS *(Cycl.)* — PICARD, in our old writers, a kind of large boat, of about fifteen tons or upwards, uſed on the river Severn. Stat. 35 Hen. VIII. c. 9. 13 Eliz. c. 11.

PICICITLI, in zoology, the name of a bird of the Spaniſh Weſt Indies, deſcribed by Nieremberg. Its head and neck are black, and its whole body grey; it is a ſmall bird, and makes its appearance in Mexico after the rainy ſeaſons; it is a bird of paſſage, and it is not known where it breeds. *Ray*'s Ornithol. p. 305.

PICK, among miners, is a tool with which they uſe to cut down the cliſts and rocks of ſtone to make paſſages in the earth *Houghton*'s Compl. Miner in the Explan. of the Terms.

PICK-*ax*, in the military art, a tool carried by the pioneers to dig up ground that is too hard for the ſpade; they are of great uſe for mending the ways, and in fortification.

PICKER, or *horſe*-PICKER, in the manege, an iron inſtrument five or ſix inches long, bent or crooked on one ſide, and flat and pointed on the other. It is uſed by the grooms to cleanſe the inſide of the horſes feet, and to pick out the earth, ſand, or ſmall ſtones that get into them.

PICKERELL, in ichthyology, an Engliſh name uſed by ſome authors for the *jack* or *pike*.

PICOLOS, the name of an antient Pruſſian idol, to which human ſacrifice was offered. See the article POTRIMPOS.

PICOTA, a name given by ſome authors to a diſtemper which they deſcribe as conſiſting wholly in an eruption of a number of very minute pimples upon the ſkin, all over the body; it is attended with no danger, unleſs they are ſtruck in.

PICRIS, in botany, the name given by Linnæus to a genus of plants called by Vaillant *helminthotheca*; the characters of which are theſe: The common cup is double; the outer cup is very large, and compoſed of five cordated leaves; the interior is imbricated and of an oval figure, and is not cloſe at the mouth, as the other, but open. The flower is of the compound kind, it is imbricated and uniform; and the ſmall flowers of which it is compoſed, are equal and numerous; each is compoſed of one petal, and is narrow, ligulated, and truncated at the end, where it is divided into five ſegments; the ſtamina are five capillary filaments, ſo ſhort that they are hardly ſeen; the antheræ are cylindric and tubulate; the germen of the piſtil ſtands under the flower; the ſtyle is of the length of the ſtamina, and the ſtigmata are two in number, and reflex. The cups both remain when the flowers are fallen, and ſerve as capſules for the ſeeds, which are ſingle, ventricoſe, obtuſe, and crowned with a plume of down; the receptacle is naked.

In ſome of the ſpecies of this genus, the ſeeds are crooked, and have a ſeſſile down; in others they are ſtrait, and their down is placed on a pedicle. *Linnæi* Gen. Pl. p. 377.

PICTA *toga*, among the Romans. See TOGA *picta*.

PICTAVIENSIS *colica*, the name of a kind of very terrible nervous colic, more uſually called *colica pictonum*; and by the natives in the Weſt Indies, where it rages, the *dry belly-ach*. It is ſo popular a diſeaſe in the Leeward Iſlands, that it may be very juſtly reckoned endemic among them, moſt of the people there having been at one time or other ſubject to it in all its fury. See the article COLIC.

PICUIPINIMA, in zoology, the name of a Braſilian ſpecies of pigeon, very ſmall, ſcarce exceeding the lark in ſize. Its head, neck, and wings, are all of a pale-lead colour, with a black ſemilunar mark at the extremity of each wing; but its long wing feathers, which are ſeen when the wings are expanded in flying, are of a reddiſh-brown on one ſide, and blackiſh on the other, with black ends or tips; the tail is long, and is variegated with black, white, and brown; the belly is covered with white feathers, every one of which has a brown mark of the ſhape of a half moon at the end. *Marggrave*'s Hiſt. of Braſil.

PICUS, or PICUS *martius*, in zoology, the name of a large genus of birds, of the wood-pecker kind, the characters of which are theſe: They have a ſtrait, very hard, ſtrong and ſharp beak, proper for making holes in trees; and a very long cylindrical-ſhaped tongue, terminated by a rigid and ſharp bony ſpine, ſerrated or notched at each end, proper for the ſeizing on, and tearing to pieces, of worms and other inſects; and this they can, at pleaſure, thruſt out to a great length; and ſtriking it into the cliſts of trees, faſten it into inſects that lie there, and draw them out with it. Their thighs are very ſhort and ſtrong, and their toes four in number, placed two before and two behind; their tails are rigid, and bent downwards, and their feathers bare at the ends, the ſtumps aſſiſting the creature in climbing: they live only on inſects, and have only ten feathers in their tail. *Ray*'s Ornithology, p. 91.

Some underſtand the word *picus* in a larger ſenſe, making it take in the *ſitta*, *picus murarius*, *junco*, *certhia*, and all the birds that climb trees. In which caſe the characters of the genus are only, that they have very ſhort, thick, and ſtrong legs, adapted to the running up the bodies and branches of trees.

The *pici*, or wood-peckers, properly ſo called, however, are a very large and numerous family; they are, 1. The great black wood-pecker, which is all over black, except that the crown of his head is of a fine florid red. This is called the *picus niger maximus*, by authors, and is the largeſt of the whole genus: it is common in the woods of Germany, but not in England. 2. The *picus viridis*, or common green wood-pecker, well known by its beautiful colours, and its loud and diſagreeable noiſe. 3. The *picus varius major*, the great ſpotted wood-pecker. This is ſomewhat larger than the thruſh, and has a yellowiſh breaſt and beautiful redneſs near the tail. 4. The *picus varius minor*, called in Engliſh the *hickwall*. (See HICKWALL.) 5. The *picus varius Braſilienſis*, or ſpotted Braſilian wood-pecker, called the *ipecu*. (See IPECU.) 6. The *jynx*, or wry neck. (See JYNX.) 7. The *jacamaciri* of the Braſilians. 8. The *curucui*. 9. The *guira-acangatara*. 10. The *aracari*; and 11. The *guira-tangemia*; and 12. The *japu* of the ſame nation; all which ſee under their ſeveral names; and beſides all theſe, Aldrovandus deſcribes another ſpecies, which he calls the *picus luteus cyanopus perſicus*, or blue-footed yellow Perſian wood-pecker. This is of the ſame ſize with the common wood-pecker; but its head and neck are thicker, and its beak longer; its feet are blue, and its general colour yellow; but with

with a broad line of a ferrugineous brown down the back. *Ray*'s Ornithol. p. 96. *Aldrovand.* de Avibus, l. 12. c. 35.

In the Linnæan ſyſtem of zoology, the *picus* makes a diſtinct genus of birds, of the order of the pyes. The characters of this genus, according to this author, are, that the feet have two toes before; the tail is rigid and of the ſhape of a wedge; the bill is angular, and terminates in the form of a wedge; the tongue is pointed, hard, and ſharp.

Of this genus are the black, green, and variegated woodpecker, and the three-toed ſpecies, deſcribed in the acta literaria ſueciæ in 1740. *Linnæi* Syſtem. Natur. p. 45.

PICUS *imbrifœtus*, in zoology, the name of an American bird, deſcribed by Nieremberg, and called by the natives *quatotoni*. It is of the ſize of the hoopoe, and is variegated with black and brown. It is of the wood-pecker kind, having a beak three finger's breadth long, with which it perforates trees. Its head is ſmall and red, and has a fine red creſt; but the feathers are black on their upper ſide. It has on each ſide of the neck a broad white line, reaching to the breaſt. Its legs and feet are of a bluiſh colour. It builds in high trees, and is principally found near the ſhores of the ſouth ſea. It feeds on inſects. *Ray*'s Ornithol. p. 301.

PICUS *murarius*, in zoology, the name of a bird called in Engliſh the *wall-creeper*, and but improperly ranked among the *pici*, as wanting many of the characters of that genus. It is about the bigneſs of the common ſparrow; its bill is black, ſlender, and long; its head, neck, and back grey; its breaſt white, and its wings partly grey and partly red; its tail is ſhort and black; its long wing-feathers alſo, and the lower part of its belly, and its legs, are of the ſame colour; its legs are ſhort, but its feet are not placed as in the wood pecker; but are three before, and one behind: it is very common in Italy, Germany, and ſome parts of France; it is a very lively and chearful bird, and as the common wood-pecker climbs trees, and feeds on the inſects in their cracks; ſo this bird runs up old walls, and feeds on what it finds in the cracks of the ſtones. *Aldrovand.* de Avib. L. 12. c. 37.

PICUS *nidum ſuſpendens*, a name by which ſome authors have called the *galbula*; a yellow bird of the thruſh kind, very remarkable for its beauty, and for the ſtructure and manner of hanging its neſt. *Aldrovand.* de Avib. See GALBULA.

PICUS *ſalutiferus*, in zoology, a name under which Nieremberg has deſcribed a Mexican bird, called by the natives *henquecholtotol*.

It is of the ſize of the common black-bird, and has a long and black beak: its head and a great part of its neck are red: its breaſt and belly are grey, and it has a creſt of red feathers upon its head. It is of the wood-pecker kind, and has its name from the ſuppoſed virtues of its feathers, particularly thoſe of the creſt, in curing the head-ach. *Ray*'s Ornithol. p. 301.

PIEDRA *de la hyada*, in natural hiſtory, the name given by the Spaniards to a ſtone found in many parts of America, particularly in New Spain; and famous among the Indians for curing the colic on being applied to the navel.

It is green, and is a ſpecies of jaſper, approaching to the nature of the *lapis nephriticus*, and is called by many *colicus lapis*, from its virtues.

PIERRE *d'automne*, a French name tranſlated from the Chineſe. It is the name of a medicinal ſtone, famous throughout the eaſt for curing all diſorders of the lungs.

Many people ſuppoſe it had its name of the *autumn-ſtone*, from its being only to be made at that ſeaſon of the year; but it may be made equally at all times, and the origin of the name is to be farther ſearched into.

The Chineſe chemiſts, like thoſe of all other nations, delight in a ſort of gibberiſh. A part of this is, the referring the ſeveral parts of the body to the ſeveral ſeaſons of the year. The lungs are in this ſcheme referred to autumn. This appears in their writings; and thus the ſtone for diſeaſes of the lungs came to be called *autumn-ſtone*.

It is a tedious preparation of human urine, and made as follows: they put thirty pints of the urine of a ſtrong and healthy young man into a large iron pot, and ſet it over a gentle fire; and when it begins to boil, they add to it, drop by drop, about a large tea-cup full of rape-oil: it is then left on the fire till the whole is evaporated to a thick ſubſtance reſembling black mud; they then take it out of the pot, and laying it on a flat iron, they dry it ſo that it may be powdered very fine.

This powder they moiſten with freſh oil, and put the maſs into a double crucible, ſurrounded with coals; where it ſtands till thoroughly dried again. They finally powder this again, and putting it into a china veſſel, covered with ſilk cloth and a double paper, they pour on boiling water, which makes its way, drop by drop, thro' theſe coverings, till ſo much is got in, as is ſufficient to reduce it to a paſte. This paſte is well mixed together in the veſſel it is kept in, and this is put into a veſſel of water, and the whole ſet over the fire. The matter thus becomes again dried in balneo mariæ, and is then finiſhed. Obſerv. ſur les Cout. de l'Aſie, p. 258.

PIERIDES, among the antients, an epithet given to the muſes, upon account of their having been born in that part of the country of Macedon which was called *Pieria*. *Pitiſc.* in voc.

PIESMA, a word uſed by the antients to expreſs the remaining maſs after the expreſſion of any fluid ſubſtance from among its more ſolid parts. Thus the cake remaining in the bag after the expreſſion of oils, is called by this name: but there are inſtances of authors calling the expreſſed juice, inſtead of the reſiduum, by this name. Thus Dioſcorides calls the expreſſed juice of the bay-berries, the *pieſma laurinum*; and others, the expreſſed juice of roſes, *pieſma roſarum*, paying no regard to the roſe-cake left behind.

PIESTER, the name uſed by the antients for the preſs which they employed in preparing the ſeveral juices of plants, &c. hence the word *pieſma*, which ſee.

PIESTRON, a word uſed by Hippocrates to expreſs a ſort of forceps, which he recommends to be uſed in difficult labours, to break the bones of the cranium of the fœtus, when its head is too large to ſuffer it to paſs whole.

PIETERMAN, in zoology, the name uſed by ſome for a fiſh of the *cuculus* kind, approaching to the nature of the *draco marinus*, or weaver; and more uſually called among authors by its Braſilian name *niqui*. *Willughby*'s Hiſt. Piſc. p. 289. See Tab. of Fiſhes, N°. 49. and the article NIQUI.

PIETOSO, in the Italian muſic, ſignifies to play or ſing in a ſoft manner, fit to move pity or compaſſion.

PIETRA *emboſſata*, in natural hiſtory, a name given by the Italians to the Florentine marble, ſo remarkable for its delineations.

This marble is found in thin ſtrata, and is full of cracks; in theſe cracks there is uſually found a black mineral matter, which getting into the ſubſtance of the ſtone a little way on each ſide of the crack, forms there various delineations, or the figures of pieces of moſs buſhes, and the like: the paler pieces of the marble uſually have theſe delineations; the darker coloured having the forms of trees and houſes, or the ruins of old buildings. *Woodw.* Hiſt. Foſſ. V. II. p. 19.

PIEXE-*gallo*, in zoology, a name given by the Portugueſe to a fiſh caught about the ſhores of the Braſils, and much reſembling our *doree* or *faber piſcis*; more uſually known among authors by its Braſilian name, *abacatuaia*. *Willughby*'s Hiſt. Piſc. p. 295. See ABACATUAIA.

PIEXE-*porco*, in zoology, a name by which ſome authors have called the *monoceros*, or unicorn fiſh of Cluſius. The name is Portugueſe, and ſignifies hog-fiſh; this little creature having a mouth like a hog. *Willughby*'s Hiſt. Piſc. p. 150.

PIG *Guinea*. See GUINEA.

PIGAYA, in natural hiſtory, a word uſed by the natives of Braſil as a name for the famous *ipecacuanha*-root.

The firſt European who brought this root into uſe was an apothecary of Braſil, whoſe name was Michael Triſtaon. The book which this author publiſhed on this ſubject falling into the hands of the Engliſh, is tranſlated into our language, and ſtands, among a number of like accounts, among Purchas's pilgrims.

He ſays it is an excellent remedy againſt dyſenteries and fluxes of all kinds. He ſays alſo, in its deſcription, that the ſtalks are a quarter of a yard long, and the roots nearly as much; and that the leaves grow only four or five upon a plant.

This agrees very well with all that we have ſince diſcovered of this plant, and the method of uſing it at that time, we find, was not as a vomit; but they bruiſed the freſh root, and ſteeped it about twelve hours in water, at the end of which time, the patient drank the water early in the morning: it operated by ſtool; but after its operation, the natural purging and voiding of blood ceaſed. This ſeems the original account we have of this drug.

De Laet from this compiled his account; which is almoſt a literal tranſlation of this into Latin: from his hint Piſo and Marggrave enquired after it more carefully upon the ſpot, and from them came the firſt accurate accounts we had of it; ſo that all ſeems, *ab origine*, deduced from Michael Triſtaon's account of it.

PIGEON, in zoology. See COLUMBA.

PIGEON-*holes*, in brick-making. See BRICK.

Turbit PIGEON. See TURBIT.

PIGNOLETTI, in ichthyography, a name uſed by many for the *aphua cobites*, a ſmall fiſh of the *gobius*, or ſea-gudgeon kind, common in the Mediterranean, and brought to the markets of Rome and Venice. *Willughby*'s Hiſt. Piſc. p. 207. See the article APHUA.

PIGUS, in zoology, the name of a ſpecies of leather-mouthed fiſh, very much approaching to the nature of the carp.

It is of the ſame ſhape and ſize with the common carp, and its eyes, fins, and fleſhy palate wholly the ſame. From the gills to the tail there runs a crooked dotted line: its back and ſides are bluiſh, and its belly reddiſh: it is covered with large ſcales, from the middle of every one of which there riſes a fine, pellucid, and very ſharp prickle.

It is a finer fiſh than the carp for the table, and is in ſeaſon in the months of March and April. It is caught in lakes in ſome parts of Italy, and is mentioned by Pliny, tho' without a name.

It is a ſpecies of *cyprinus*, according to Artedi, and is diſtinguiſhed by that author under the name of the *cyprinus*, called *piclo* and *pigus*. He adds, that the tail is forked, and the ſcales large; and that in ſpring and autumn there grow out of them

them white pyramidal prickles, which remain about five or six weeks, and then fall off. The back is of a blackish blue, and the belly white, with a faint cast of red. It never grows to more than five or six pound weight: the flesh is well tasted. It is found in the lakes in the northern nations. *Willughby*'s Hist. Pisc. p. 247. *Rondelet* de Pisc. p. 64.

PIISSKER, in zoology, the name of a fish of the *mustela* kind, usually called the *mustela fossilis*, or *piscis fossilis*, the fossile fish.

This fish is usually found of a hand's breadth long, and as thick as one's finger; but they grow sometimes to be much longer. The back is of a grey colour, spotted with a great number of spots, and transverse streaks, partly black and partly blue. The belly is yellow, and is spotted with red and white and black; the white ones are the larger, and the others look as if made with the point of a needle; and there is on each of the sides a longitudinal black and white line. There are certain fleshy excrescences at the mouth, which in swimming they expand; and when out of the water, they contract them.

They run into caverns in the earth, in the sides of rivers, in marshy places, and penetrate a great way, and are frequently dug up at distances from waters; and often, when the waters of brooks and rivers swell beyond their banks, and they are again covered by them, they make their way out of the earth into the water, and when it deserts them, are left in vast numbers upon the ground, when they are eaten by the swine.

This seems very much of the kind of the *fisgum* fish, and possibly is no other than the same species; and possibly also the præcilia of Schonefeldt is the same. *Gesner* de Aquat.

PIKE, in ichthyology, a name given by us to the fish called by authors the *lucius* and *esox*, and by the old Greek writers *oxyrynchus*. See LUCIUS and ESOX.

This fish is the tyrant of the fresh waters, and is at once the most voracious and the longest lived of all fish, according to the generality of naturalists.

The very large *pike* are esteemed as a pompous fish at the tables of great people; but they are coarse, and the middling ones are in reality much the best.

The *pike* never swims in shoals, as most other fish do, but always lies alone, and is so bold and ravenous, that he will seize upon almost any thing less than himself. This fish breeds but once in a year, which is in March. It is found in almost all fresh waters, but is very different in goodness, according to the nature of the places where it lives. The finest *pike* are those which feed in clear rivers; those in ponds and meres are inferior to these, and the worst of all are those of the fen ditches. They are very plentiful in these last places, where the water is foul and coloured, and their food, such as frogs and the like, very plentiful, but very coarse; so that they grow large, but are yellowish and high-bellied, and differ greatly from those which live in the clearer waters.

The fishermen have two principal ways of catching the *pike*; by the ledger, and by the walking-bait.

The ledger-bait is fixed in one certain place, and may continue while the angler is absent: this must be a live bait, a fish or frog; and among fish, the dace, roach, and gudgeon, are the best: of frogs, the only caution is to chuse the largest and the yellowest that can be met with. If the bait be a fish, the hook is to be stuck thro' the upper lip, and the line must be fourteen yards at least in length: the other end of this is to be tied to a bough of a tree, or to a stick driven into the ground near the *pike*'s haunt, and all the line wound round a forked stick, except about half a yard. The bait will by this means keep playing so much under water, and the *pike* will soon lay hold of it.

If the bait be a frog then the arming wire of the hook should be put in at the mouth, and out at the side; and with a needle and some strong silk the hinder leg of one side is to be fastened by one stitch to the wire-arming of the hook. The *pike* will soon seize this, and must have line enough to give him leave to get to his haunt and poach the bait.

The trolling for *pike* is a pleasant method also of taking them: in this a dead bait serves, and none is so proper as a gudgeon This is to be pulled about in the water till the *pike* seizes it, and then it is to have line enough, and time to swallow it: the hook is small for this sport, and has a smooth piece of lead fixed at its end to sink the bait; and the line is very long, and runs through a ring at the end of the rod, which must not be too slender at top.

The art of feeding *pike*, so as to make them very fat, is the giving them eels, and without this it is not to be done under a very long time; otherwise perch, while small, and their prickly, tender fins, are the best food for them. Bream put into a *pike*-pond are a very proper food: they will breed freely, and their young ones make excellent food for the *pike*, who will take care that they shall not increase over much. The numerous shoals of roaches and ruds, which are continually changing place, and often in floods get into the *pike*'s quarters, are food for them for a long time.

Pike, when used to be fed by hand, will come up to the very shore, and take the food that is given them out of the fingers of the feeder. It is wonderful to see with what courage they will do this, after a while practising; and it is a very diverting sight when there are several of them nearly of the same size, to see what striving and fighting there will be for the best bits, when they are thrown in. The most convenient place is near the mouth of the pond, and where there is about half a yard depth of water; for, by that means, the offal of the feedings will all lie in one place, and the deep water will serve for a place to retire into and rest in, and will be always clean and in order.

Carp will be fed in the same manner as *pike*; and tho' by nature a fish as remarkably shy and timorous as the *pike* is bold and fearless, yet by custom they will come up to take their food out of the person's hand; and will, like the *pike*, quarrel among one another for the nicest bits. See the article FEEDING *of fish*.

Half PIKE, in the military art, is the weapon carried by an officer of foot. It differs from a *pike*; because it is but eight or nine foot long, and the spear is smaller and narrower.

PIKE, is also the name of an Ægyptian measure, of which there are two kinds, the large and the small.

The larger *pike*, called also the *pike* of Constantinople, is $27\frac{920}{1000}$ English inches. They measure all foreign goods with this, excepting only such as are made of flax and cotton: for these they use the small *pike*, called *pike belledy*, or the *pike* of the country; because they measure with it all the manufactures of the country. This *pike* consists of about $25\frac{576}{1000}$ English inches. *Pocock*'s Ægypt, p 175.

PILA *(Cycl.)*—PILA *marina*, the *sea-ball*, in natural history, the name of a substance very common on the shores of the Mediterranean, and in some other places. It is usually found in form of a ball, about the size of the balls of horse-dung, and composed of a multitude of fibrillæ, irregularly complicated.

Its origin has been very variously guessed at by different authors. John Bauhine says, that it consists of small hairy fibres and straws, such as are found about the sea-plant called *alga vitriariorum*; but he does not pretend to ascertain what plant it owes its origin to. Imperatus judged it to consist of the exuviæ both of vegetable and animal bodies. Mercatus doubts whether it be a congeries of the fibrillæ of plants, wound up into a ball by the motion of the sea-water; or whether it be not the workmanship of some sort of beetle living about the sea-shore, and analogous to our common dung-beetles ball, which it elaborates from dung for the reception of its progeny. Schreckius will have it composed of the filaments of some plant of the reed kind: and Welchius supposes it composed of the pappose part of the flowers of the reed. Maurice Hoffman thinks it the excrement of the hippopotamus: and others think it that of the phoca, or sea-calf.

But Klein, who had thoroughly examined as well the bodies themselves, as what authors had conjectured concerning them, is of opinion, that they are wholly owing to, and entirely composed of, the capillaments which the leaves growing to the woody stalk of the *alga vitriariorum* have, when they wither and decay. These leaves, in their natural state, are about the thickness of a wheat straw, and they are placed so thick about the tops and extremities of the stalks, that they enfold, embrace, and lie over one another; and from the middle of these clusters of leaves, and, indeed, from the woody substance of the plant itself, there arise several other very long, flat, smooth, and brittle leaves: these are usually four from each tuft of the other leaves, and they have ever a common vagina, which is membranaceous and very thin. This is the style of the plant, and the *pila marina* seems a cluster of the fibres of the leaves of this plant, which cover the whole stalk divided into their constituent fibres; and by the motion of the waves, first broken and worn into short shreds, and afterwards wound up together into a roundish or longish ball. *Klein*, de Tubul. Marin. p. 22.

PILARIS, or PILARIS *turdus*, in zoology, the name by which authors in general call the field-fare. See the article FIELDFARE.

PILATIO, a word used by the antients to express a minute fissure in the cranium, when not larger than a single hair of the head.

PILATRO, or PILATRO *di Levante*, a salt used in the glass trade in some particular cases. It is extracted from the froth of the sea, coagulated by heat in the hot countries. *Merret*'s Notes on Neri. p. 349.

PILCHARDUS, the common *pilchard*, in zoology, a fish much approaching to the nature of the common herring, but smaller and differing in several other particulars.

The distinguishing characters of it are these: it never exceeds six or seven inches in length: its body is thicker in proportion than that of the herring, and its belly less sharp: its scales are very large, round, and very thin: its back is of a bluish green, and its belly white; and near the upper angle of the gills, it has a black spot on each side; sometimes also there are four or five other smaller in a strait line behind these: the head is flatted, and the mouth large; but it has no teeth, neither in the jaws nor palate.

It is generally found swimming in vast shoals, and is caught on many parts of the English shores. Its flesh is better tasted than that of the herring.

PILE *(Cycl.)*—PILE *worms*, are a kind of *worms* found in the *piles* of the ſea dikes in Holland. Theſe *worms* are of various ſizes, ſome of the young ones are not above an inch or two in length; but others have been found of thirteen or fourteen inches long.

The heads of theſe creatures were covered with two hard ſhells, or hemicrania; which together form a figure reſembling an augur; and with which they bore the wood. The beſt remedy againſt them is, to perforate the *pile* with many ſmall holes, about an inch aſunder; then it muſt be done over with a varniſh in the hotteſt ſun; and while the varniſh is hot, brick duſt muſt be ſtrewed over it; and this being ſeveral times repeated, the *pile* will be covered with a ſtrong cruſt, impenetrable to all inſects. See a farther account of theſe creatures in Phil. Tranſ. N° 455. Sect. 5.

PILES, the popular name for the *hæmorrhoides*. See the article HÆMORRHOIDES, *Cycl.* and *Suppl.*

PILEÆ, a name given by ſome authors to a genus of *echinodermata*. See the article CONULUS.

PILENTUM, among the Romans, an eaſy kind of chariot, uſed by the Roman ladies at games and religious proceſſions. *Pitiſc.* in voc.

PILEUS *presbyteri*, in botany, a name given by ſome writers to the *euonymus* or *fuſanus*, a ſhrub which grows in our hedges, and bears a ſquare fruit ſomewhat reſembling the cap worn by ſome orders of prieſts.

PILHANNAW, a name given by the Indians to a bird found in the foreſts on the back of ſome our American plantations.

It is a bird of prey very large and bold; it is deſcribed by Joſſelin as four times as big as our goſhawk, and having a remarkably large head. All the birds are terrified at its approach; but it principally feeds on quadrupeds, as the young fawns and the like.

PILIMICTIO, a word uſed by ſeveral authors to expreſs a diſcharge of ſmall and long filaments, which reſemble hairs among the urine.

PILL (*Cycl.*)—*Aromatic* PILLS, *pilulæ aromaticæ*, a form of medicine in the New London Diſpenſatory, intended to ſtand in the place of the *pilulæ diambræ* of the former, and the *pilulæ alephanginæ*, or *aloephanginæ* of that, and ſome other Diſpenſatories.

The compoſition is this: Take ſocotrine aloes, an ounce and half; gum guaiacum, an ounce; the aromatic ſpecies and balſam of Peru, of each half an ounce; let the aloes and gum guaiacum be powdered ſeparately, and afterwards mixed with the reſt, and formed into a maſs with ſyrup of orange-peel. *Pemberton*'s Lond. Diſp. p. 326.

PILLS *of colocynth with aloes*, *pilulæ e colocynthide cum aloe*, a name given in the New London Pharmacopœia, to the purging-*pill*, commonly known by the name of *pilulæ cocciæ minores*.

As this is originally a preſcription of Galen's, and the manner of proportioning the ingredients has been altered for the worſe, ſince his time, by enlarging the quantity of that nauſeous ingredient the *colocynth*; the college have reduced it to its former proportions, and ordered it to be made in this manner: Take ſocotrine aloes and ſcammony, of each two ounces; pith of coloquintida, one ounce; oil of cloves, two drams; let the dry ſpecies be reduced to powder ſeparately, the oil mixed among them, and the whole formed into a maſs, with ſyrup of buckthorn. *Pemberton*'s Lond. Diſp. p. 327.

PILULÆ *e colocynthide ſimpliciores*, a name given in the late London Pharmacopœia, to the purging-*pill* commonly known by the name of *pil. ex duobus*. It is made of equal parts of colocynth and ſcammony, with a conſiderable proportion of oil of cloves; and is beat up to a conſiſtence with ſyrup of buckthorn. *Pemberton*'s Lond. Diſp. p. 327.

Mercurial PILLS, *pilulæ mercuriales*, a form of medicine preſcribed in the late London Pharmacopœia, and containing crude mercury mixed for internal uſe.

The compoſition is to be made as follows: Take of pure quickſilver, five drams; of Straſburg turpentine, two drams; of the cathartic extract, four ſcruples; rhubarb in powder, one dram; grind the quickſilver with the turpentine till it makes one uniform maſs, and then add the other ingredients, and beat up the whole into *pills*. If the turpentine be too hard, it muſt be ſoftened with a little oil of olives. *Pemberton*'s Lond. Diſp. p. 329.

Soap PILLS, *pilulæ ſaponaceæ*, a form of medicine preſcribed in the late London Diſpenſatory, and ordered to be made in the following manner: Take almond *ſoap*, four ounces; ſtrained opium, half an ounce; eſſence of lemons, a dram; ſoften the opium a little with wine, and beat that and the *ſoap* with the eſſence, till it be reduced to the form of a *pill*.

This is intended to ſtand in the place of the *pill*, commonly called *Mathew's pill*, and is very happily corrected in regard to the taſte of the *ſoap*, by the addition of the eſſence of lemons. *Pemberton*'s Lond. Diſp. p. 231.

Ward's PILL. See WARD'S *pill*.

PILLAR *(Cycl.)*—It ſeems not impoſſible for ſtone to be caſt into the ſhape of *pillars*. We find mention made in the Philoſophical Tranſactions, of two *pillars* of ſtone, at Fontevraud, in France, each about 60 feet high, all of one ſolid piece, which are ſaid to have been run. N° 481. p. 328. in Not.

Pillars of ſtone were antiently erected as ſepulchral monuments, near the highways; and alſo in memory of ſome victory. We find traces of this cuſtom in Cornwall and Wales, where theſe *pillars* are often found, and called *meinigwir*, a ſtone for play, perhaps in memory of funeral games; and ſometimes *llech*, that is, *tabula ſaxea*. Phil. Tranſ. N° 458. p. 471.

PILLVENKEGEN, in zoology, the name of a bird approaching to the ſnipe kind, deſcribed by Aldrovand, and ſuppoſed by ſome to be the bird we call the *knot*. See KNOT.

PILLOW *of a plough*, a term uſed by the farmers to expreſs that part of a *plough* which ſerves to raiſe or ſink the beam, and with it the ſhare, as the land is to be *ploughed* ſhallower or deeper.

This *pillow* is a croſs piece of wood, reaching from one of the crowſtaves or uprights, to the other; and as they are bored with two rows of holes, this *pillow* can be ſliped up or down to any height, and kept there by pegs or cords in the holes. *Tull*'s Huſbandry. See PLOUGH.

PILLOW, in a ſhip, is that piece of timber whereon the bowſprit reſts at its coming out of the hull aloft, cloſe by the ſtern.

PILOSE *leaf*, among botaniſts. See the article LEAF.

PILOSELLA, the common *mouſe-ear*, is eſteemed a great medicine by many, as abſtergent and aſtringent. It is preſcribed in dyſenteries, and all other hæmorrhages, and particularly in bleedings at the noſe. Some have given it a great character alſo in the cure of ruptures; and its juice is ſaid to be a very great remedy in the milliary herpes, rubbed on the part.

PILOTING, *in navigation*. See the articles NAVIGATION and PILOT, *Cycl.*

PILULARIA, *pepper-graſs*, the name of a very remarkable little plant, of which Mr. Bernard de Juſſieu has given a very accurate account in the Memoirs of the Academy of Sciences of Paris.

It is a low and creeping plant, always being procumbent upon the earth; its roots are long, ſlender, white filaments, which pierce perpendicularly down, and have at their extremities a few ſhort fibres. Every one of theſe roots is fixed to the baſe of one of the leaves that ſtand on the branches. The branches are divided and ſpread about, and are all ſo regular in ſize, and ſo oddly interwoven among one another, that it is not eaſy to ſay which of them is the main ſtalk, which the ramifications; but the ſeveral radicles which uſually go down very deep, keep the whole lengths of the branches cloſe down to the ground. The branches are round, green, and knotty; and their ramifications are placed alternately, and are terminated by a protuberance or ſoft button, or a ſmall leaf rolled up in a ſpiral form.

The leaves ſtand alſo alternately on the branches, and are ſtrait, narrow, and ſomewhat cylindric in ſhape, and pointed at the end; they reſemble, in ſome ſort, the young ſhoots of ruſhes, and are ſeldom more than four inches long; nor are the ſtalks uſually more than ſix.

The flowers of this plant ſtand in the alæ of the branches, and four flowers, each enveloped by its own peculiar membrane, which is very fine and delicate, are always contained in one common covering; which reſembles a ſphere ſet all over with prickles or hairs. This globule increaſes at length to the ſize of a pepper-corn; and when mature, it opens into four quarters, each of which has its peculiar pedicle, by which it adheres to the branch.

The membrane which envelopes each particular flower, or as it may be called, each quarter of the globule, is very fine and delicate; and each has three faces; one convex, and the other two in form of ſemi-circles. The inferior angles of theſe three faces terminate in one common point; and the ſemi-circular faces open a little at the oppoſite end, to diſcloſe the flower. See Tab. of Moſſes, N° 21.

Every quarter of the globule is hollow, and has the ſhape of a quarter of a regular hollow ſphere, and contains its perfect flower, which is of the hermaphrodite kind, containing ſtamina and piſtils, arranged on, and fixed to a common placenta. This placenta is a membranaceous band, faſtened to the inner ſpherical part of the membrane, which incloſes the flower; it occupies only about half the cavity, and is ſo formed as to repreſent, in ſome meaſure, two thirds of a creſcent; from which one of the points had been cut off. This placenta is, in a manner, ſurrounded with piſtils, having four ſeries of them on each ſide; ſome of which ſtand oppoſite to others, and ſome are erect, while others lie horizontally. The piſtils fill up two thirds of the cavity of the flower, and the reſt is occupied by the ſtamina; which are ſo many little horns all growing from a little head, which ſtands in the angle made by the ſides of the placenta. The ſtamina diverging from this point, form a ſort of pyramidal cluſter. The number of the piſtil is various in different flowers; ſome having twelve, others twenty; they are each of them of an oval figure, and are enveloped each in a fine thin membrane, which is folded and wrinkled. They have no ſtyle, but have only a downy prominence on their upper extremity, which may be properly called the ſtigma.

Theſe piſtils are ſo many embryo ſeeds; the ſtamina are uſually more than thirty in number, and are ſo ſmall as not to be eaſily diſcoverable to the naked eye; and 'tis from this minute-

minuteneſs of the ſeveral parts of the flower of this plant, that it has been generally ſuppoſed, by botaniſts, to have no flower at all; the globule at the root of the leaves having been uſually eſteemed merely a capſule for the ſeeds.

The pedicles, on which theſe globules ſtand, are not more than a twelfth of an inch long; and it has uſually, at its baſe, two or three ſmall leaves of the ſame ſhape with the other leaves of the plant. The globules uſually ſtand ſingly at the bottom of each leaf. The ſtamina of the flowers, examined by the microſcope, appear compoſed of a fine tender membrane, incloſing a number of ſmall round bodies; and the whole aſſuming a conic form: theſe put into a drop of water before the microſcope, received the humidity into them, and ſwelled into the figure of an oblong pearl, and ſoon after burſting open tranſverſely, they diſcharged their grains of fine powder with an elaſtic force: theſe grains, which are the globules of the farina, are regularly round and rough on the ſurface; they ſwell on lying in the water, but never burſt. The piſtils, on being put into water, looſe their folded and wrinkled figure, and ſwell into a ſort of bladder: theſe piſtils finally become each a perfect ſeed, which is rounded at the bottom, and terminates in a point at the top, and of a ſomewhat yelloviſh white colour.

The ſeeds of the *pilularia* ſend up ſingle leaves of the ſhape of thoſe which afterwards appear on the whole plant; and the herb is therefore of the order of the *monocotyledones*; and, according to the opinion of Mr. Juſſieu, approaches more to the nature of the *ferns* than to any other claſs of plants, tho' ſo widely different from them in the manner of growth: he is for allotting it a place, however, next the *ferns*, and that for the following reaſons:

1. Becauſe the *pilularia* imitates the diſpoſition and arrangement of the branches of many of the *ferns*, tho' in ſo extremely different a form, creeping over the ground with its horizontal roots, in the manner of the common female *fern*, and like it, having its leaves and branches placed in an alternate manner.

2. Becauſe the young leaves of the *pilularia* are enveloped like thoſe of the *ferns*, with a ſort of down, and are rolled up in the ſame manner, in a ſpiral form; from which they gradually expand.

3. Becauſe the taſte is the ſame with that of the *ferns*, viſcous, with a gentle aſtriction.

4. Becauſe the ſmell of the leaves, when bruiſed, is wholly the ſame with that of *fern*; and, finally, becauſe the ſummits of the ſtamina, when nicely examined, appear to have a great analogy with ſome parts of the fructifications of the *ferns*. Memoirs Acad. Scien. 1739.

PIMIENTA, in botany, the Jamaica *pepper-tree*; the characters of which are theſe: Its trunk is as thick as one's thigh, riſing ſtreight about 30 feet high, covered with an extremely poliſhed or ſmooth ſkin, of a grey colour, and branched out on every hand; having the ends of its twigs ſet with leaves of ſeveral ſizes; the largeſt being four or five inches long, two or three broad in the middle, where broadeſt; whence it decreaſes to both extremes, ending in a point, ſmooth, thin, ſhining, without any inciſures, of a deep green colour, and ſtanding on inch-long foot ſtalks; when bruiſed very odoriferous, and in all things like the leaves of a bay-tree. The ends of the twigs are branched into bunches of flowers, each footſtalk ſuſtaining a flower made up of four herbaceous pale-green petala, bowed back, or reflected downwards; within which are many ſtamina of the ſame colour. Theſe are followed by a bunch of crowned or umbilicated berries, (the crown being made up of four ſmall foliola or leaves) which are bigger, when ripe, than juniper-berries, at firſt when ſmall, greeniſh; but when ripe they are black, ſmooth, and ſhining, containing in a moiſt, green, aromatic, and biting pulp, two large *acini*, or ſeeds, ſeparated by a membrane lying between them, each whereof is a hemiſphere, and both joined make a globe or ſpherical *acinus*; whence Cluſius makes it one ſeed, diviſible into two parts.

It grows on the hilly parts of Jamaica, and is much cultivated there; becauſe of the great profit from the cured fruit ſent in great quantities yearly into Europe.

It flowers in June, July, and Auguſt, ſooner or later, according to its ſituation and the different ſeaſons for rain; and after it flowers, the fruit ſoon ripens.

There is little difficulty in curing and preſerving this fruit for uſe, which is done thus: the Negroes climb the trees and pull off the twigs with the unripe green fruit, and afterwards carefully ſeparate the fruit from the twigs, leaves, and ripe berries; which done, they expoſe them to the ſun from its riſing to ſetting, for many days, ſpreading them thin on cloaths, turning them now and then, and carefully avoiding the dews. By this management they become a little rugous or wrinkled, dry, and from a green change to a brown colour, and then they are fit for the market.

The ripe berries are very carefully ſeparated from thoſe to be cured; becauſe their wet and plenteous pulp renders them unfit for cure.

It is accounted the beſt and moſt temperate, mild and innocent, of common ſpices, and fit to come into greater uſe, and to gain more ground than it hath yet done. It ſurpaſſes moſt of the Eaſt Indian aromatics in promoting the digeſtion of meat, attenuating, tough humors, moderately heating, ſtrengthening the ſtomach, expelling wind, and doing thoſe friendly offices to the bowels we generally expect from ſpices.

Cluſius takes it to be the *garyophyllon* of Pliny; and by others it is ſuppoſed to be the *amomum* of the antients; but 'tis not likely that it was known to the antients, not being known to grow in the Eaſt, but Weſt Indies; whence it was brought to England, and ſent to Cluſius, who firſt deſcribed and figured it, giving it the name of *amomum quorundam*, or *caryophyllon Plinii*. Phil. Tranſ. N° 192. See the article PIPER.

PIMP-*tenure*, a kind of *tenure* mentioned in our old writers.—Willielmus Hoppeſhort, *Tenet dimidiam Virgatam terræ, per ſervitium cuſtodiendi ſex Damiſellos ſcil. Meretrices, ad uſum Domini Regis.* 12 Ed. 1. *Blount's* Ten. 39.

PIMPERNELL, *pimpinella*, in botany, the name of a genus of plants, the characters of which are theſe: The flower conſiſts of one petal, which is of a rotated form, and is deeply divided into four ſegments, and contains a vaſt number of ſtamina, or a fimbriated ſtyle. The cup finally becomes a fruit uſually of a quadrangular figure, and pointed at each end: this is ſometimes divided into two cells, ſometimes it conſiſts only of one; and it contains numerous ſeeds, uſually of a longiſh figure.

The ſpecies of *pimpinella*, enumerated by Mr. Tournefort, are theſe: 1. The common greater *pimpinella*, called *Burnet ſaxifrage*; and by moſt authors *pimpinella ſanguiſorba major*. 2. The great rigid very tall *pimpinella*, with auriculated leaves. 3. The great Spaniſh *pimpinella*, with a pale-red ſpike. 4. The great Spaniſh *pimpinella*, with cluſtered flowers. 5. The American *pimpinella*, with long red ſpikes. 6. The greateſt American *pimpinella*, with white ſpiked flowers. 7. The ſweet agrimony-leaved *pimpinella*. 8. The ſmaller hairy *pimpinella*. 9. The ſmall ſmooth *pimpinella*. 10. The ſmall ſcentleſs *pimpinella*. 11. The ſmaller *pimpinella*, with large thick ſeeds. And 12. The prickly ever green *pimpinella*, called by ſome authors *poterium*, and by others *colchicum*. *Tourn.* Inſt. p. 157.

The ſeeds of this plant are warm, carminative, and diſcutient: they are given with ſucceſs in colics and flatulencies, and in ſuppreſſions of urine. The leaves and roots alſo poſſeſs the ſame virtues; and when the diuretic property only is expected from it, the root alone freſh taken up, cut ſmall, and boiled in water, is the beſt. The decoction is to be drank in large draughts, and often repeated.

Red PIMPERNELL, *anagallis*, in botany, the name of a genus of plants, the characters of which are theſe: The flower conſiſts of one leaf, and is rotated and divided into ſeveral ſegments. The piſtil ariſes from the cup, and is fixed in the manner of a nail, to the lower part of the flower: this afterwards becomes a ſhelly fruit, of nearly a globular figure; which, when ripe, divides tranſverſely into two parts, and diſcovers a number of angular ſeeds affixed to a placenta.

The ſpecies of *anagallis*, enumerated by authors, are theſe: 1. The common red flowered *anagallis*. 2. The larger leaved red-flowered *anagallis*, with leaves growing four at a joint. 3. The common blue-flowered *anagallis*. 4. The blue-flowered *anagallis*, with two or three leaves at every joint. 5. The ferrugineous flowered *anagallis*. 6. The duſky purple-flowered *anagallis*. 7. The pale red-flowered *anagallis*. 8. The white-flowered *anagallis*. 9. The broad-leaved Spaniſh *anagallis*, with large blue flowers. 10. The round-leaved Portugal *anagallis*. 11. The broad-leaved Portugal *anagallis*, with a ſmall flower. 12. The great toad-flax-leaved *anagallis* of Portugal. 13. The narrower-leaved *anagallis* of Portugal. 14. The ſmalleſt *anagallis*. 15. The ſmall French, ſea, round-leaved *anagallis*.

Authors name, beſide theſe, ſeveral other plants *anagallis aquatica*, the *brooklime*, &c. but theſe are properly either of the genus of the *veronica*, or that of the *ſamolus*. *Tourn.* Inſt. p. 142. See the article SAMOLUS, *&c.*

PIMPILIM, in botany, a name by which ſome authors have called the plant which produces the long pepper, uſed in medicine. *Piſo*, Mant. 182.

PIMPINELLA. See PIMPERNELL, ſupra.

PIMPLE, in medicine, a ſmall puſtule ariſing on the face.

By mixing equal quantities of the juice of houſe-leek, *ſedum minus*, paſſed through paper, and of ſpirit of wine rectified by itſelf, a white coagulum of a very volatile nature is formed, which Dr. Burghart commends for curing *pimples* of the face; and ſays, that the thin liquor ſeparated from it, with ſugar-candy, is an excellent remedy for thick viſcid phlegm in the breaſt. Satyr. Sileſiac. Spec. 4. Ob. 2.

PINACOTHECA, among the antients, a place where pictures, ſtatues, and other curioſities were kept. *Pitiſc.* in voc.

PINACIA, πινακια among the Athenians, tablets of braſs, whereon the names of all the perſons in each tribe duly qualified, and willing to be judges or ſenators of the Areopagus, being ſeverally written, they were caſt into a veſſel provided on purpoſe; and into another veſſel were caſt the ſame number of beans, an hundred of which were white, and all the reſt black. Then the names of the candidates and the beans were drawn, one by one; and thoſe whoſe names were drawn out together with the white beans, were received into the ſenate. See the article PROBULEUMA.

In

In Solon's time there were only four tribes, each of which elected an hundred ſenators; ſo that the Areopagus conſiſted of four hundred members: but the number of tribes being afterwards encreaſed, the number of ſenators was conſequently augmented by ſome hundreds; but the manner of election remained the ſame. *Pott.* Archæol. Græc. T. 1. p. 97. See the article AREOPAGUS, *Cycl.*

PINARII, among the Romans, an order of under-prieſts belonging to Hercules, who offered ſacrifices to that god morning and evening. They were only ſervants to the *potitii*. *Danet.* in voc. See the article POTITII.

PINCHING *(Cycl.)*—PINCHING, in horſemanſhip, a term uſed to expreſs a method of trying a horſe's mettle, or vigour, and of ſhewing it to a purchaſer when the creature is on ſale. The whole method is, when the rider is on his back, he keeps him ſtanding ſtill, and keeping him faſt with the bridle-hand, he applies the ſpurs to the hair of the ſides. If the horſe is impatient under this, and draws himſelf up, and wants to go forward, it is a ſign of vigour and mettle. But the purchaſer ought to try the thing himſelf on the horſe's back; for the jockies have the art of making the dulleſt horſe ſeem to have mettle in theſe trials. The purchaſer muſt alſo diſtinguiſh between the reſtleſsneſs of the horſe under this treatment that ariſes from vigour, and that which ariſes from the horſe's being tickliſh, and which goes off immediately. See the article METTLED.

PINDAIBA, in botany, the name uſed by ſome authors for the tree which produces the cubebs of the ſhops. *Piſo*, p. 144.

PINE-*tree*, *pinus*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the amentaceous kind, being compoſed of a great number of ſtamina, but it is barren: the embryo fruit appear in other parts of the tree, and finally become a ſort of cone; between the ſeveral ſcales of which, eachhaving two hollows, there are found two ſeeds contained in a ſtony huſk, which is frequently alated. To this it is to be added, that the leaves grow more than one out of the ſame theca.

The ſpecies of *pine*, enumerated by Mr. Tournefort, are theſe: 1. The common manured *pine*. 2. The common wild mountain *pine*. 3. The tender fruited wild *pine*, called *cambro*. 4. The mountain *pine*, called by authors *mugho*. 5. The wild ſea-*pine*, with the cones growing firmly to the branches. 6. The Idæan ſea-*pine*. 7. The ſmall ſea-*pinaſter*. 8. The dwarf *pine*, with pale or greeniſh juli. 9. The dwarf *pine*, with purple juli. And, 10. The *pine* with erect cones, called by ſome the Auſtrian *pinaſter*. *Tourn.* Inſt. p. 585.

The leaves and tender tops of *pine* and fir are uſed for diet-drinks, and allowed to be antiſcorbutic and diuretic.

The reſinous exſudations of *pines* and firs are an important branch in the materia medica, and not only uſeful in the preſcriptions of phyſicians, but have alſo been thought otherwiſe conducive to health. Pliny tells us, that wines, in the time of the old Romans, were medicated with pitch and reſin. And Jonſtonus, in his dendrographia, obſerves, that it is wholeſome to walk in groves of *pine*-trees, which impregnate the air with balſamic particles. It is known that all turpentines and reſins are good for the lungs, againſt gravel alſo, and obſtructions: and it is ſaid, that the medicinal properties of thoſe drugs are found in tar-water, which operate without heating the blood or diſordering the ſtomach. See the article TAR-*water*.

Pitch, tar, roſin, and turpentine, are all made from theſe trees by a very familiar proceſs. In the ſpring time, when the ſap is moſt free in running, they pare off the bark of the *pine*-tree, to make the ſap run down into a hole which they cut at the bottom to receive it; in the way, as it runs down, it leaves a white matter like cream, but a little thicker: this is very different from all the kinds of reſin and turpentine in uſe, and it is generally ſold to be uſed in the making of flambeaux, inſtead of white bees-wax. The matter that is received in the hole at the bottom, is taken up with ladles, and put into a large baſket; a great part of this immediately runs thro', and this is the common turpentine. This is received into ſtone or earthen pots, and is ready for ſale. The thicker matter, which remains in the baſket, they put into a common alembic, and adding a large quantity of water, they diſtil this ſo long as any oil is ſeen ſwimming upon the water; this oil they ſeparate from the ſurface in large quantities, and this is the common oil or ſpirit of turpentine: the remaining matter at the bottom of the ſtill, is common yellow reſin. When they have thus obtained all that they can from the ſap of the tree, they cut it down, and hewing the wood into billets, they fill a pit dug in the earth with theſe billets; and ſetting them on fire, there runs from them while they are burning, a black thick matter: this naturally falls to the bottom of the pit, and this is the tar. The top of the pit is covered with tiles, to keep in the heat; and there is at the bottom a little hole, out at which the tar runs like oil: if this hole be made too large, it ſets the whole quantity of the tar on fire; but if ſmall enough, it runs quietly out.

The tar being thus made, is put up in barrels; and if it be to be made into pitch, they put it into large boiling veſſels, without adding any thing to it: it is then ſuffered to boil a while, and being then let out, is found, when cold, to be what we call pitch. Phil. Tranſ. N°. 243. p. 291.

Silver PINE, in botany. A branch of this tree being brought from the Cape of Good Hope, by Mr. Goddard, and preſented to the royal ſociety, Dr. Sloane gave the following account of it: The twig of this tree had a great many leaves ſet round it, very cloſe to one another, ſo as to hide the twig itſelf there where they grow; each of the largeſt being about four inches long, and three quarters of an inch broad in the middle where broadeſt, from whence they decreaſe towards both extremes, ending in a point; being like thoſe of the oſier willow, only broader, and all covered over with the thickeſt, fineſt, and longeſt, white ſilken hair, or down, that ever any plant the doctor remembers to have ſeen. The cones are of the bigneſs of thoſe of the cedars of Lebanon, and of the ſame ſhape; The cuticula, or ſmall ſkin of each ſcale, being covered over with a white ſhort down or wool, ſhining alſo like ſilk. Between the ſcales is lodged the ſeed, which is almoſt as large as the *pine* nut, near the ſame ſhape, of a dark brown colour, and having a riſing eminent line or belly running through the middle of it from end to end. This ſeed lies in a thin, reddiſh brown membrane, which has on its top four feathers, like thoſe belonging to the ſeed of the clematitis; which being between the ſcales, and riſing above them, adds a very great beauty to the cone, and may likewiſe ſerve for wings, by means of the wind, to looſen or carry the ſeed to diſtant places, thereby propagating itſelf. Dr. Plucknet calls it *leucodendros*. Phil. Tranſ. N°. 198.

Spunge-leaved PINE, in botany. A branch of this tree being brought from the Cape of Good Hope by Mr. Goddard, and preſented to the royal ſociety, Dr. Sloane gave the following deſcription of it: The bark was of a brown colour and ſmooth; its wood whitiſh and hard, with only a ſmall pith; the leaves were round it, without any order, very thick ſet, having no foot-ſtalks; being about two inches and an half long, and about one third of an inch broad near the farther end, where broadeſt; ſmooth, hard, and of a browniſh or dirty green colour: on the top of the branch comes the fruit, which is ſurrounded by three or four twigs overtopping it, and with their leaves almoſt hid in it: it is about five inches long, and is made up of many ſcales, hard and red, incloſing one another; the lowermoſt and outwardmoſt being very ſhort, the innermoſt four inches long, each of them ending in a point; ſome ſcales, having on their outſides a gummy piece: In the middle of theſe ſcales were the firſt rudiments of many ſeeds, the ſame not being fully ripe; each of which is ſet about with a great quantity of yellow, fine, ſilken down, about three quarters of an inch long, having a ſtylus, or ſtring, two inches long, and yelloviſh membranes incloſing the ſtylus and tomentum; being feathered at top for their better diſperſion, in order to propagate themſelves. Philoſ. Tranſ. N°. 198.

PINE-*apple*, a delicious fruit, called by authors *ananas*. See the article ANANAS.

There are ſeveral varieties of it, but the principal are five: 1. The oval *pine*-apple, with white fleſh. 2. The pyramidal kind, with yellow fleſh. 3. The ſmooth-leaved kind. 4. The ſhining-leaved kind, with ſcarce any ſpines on its edges. And, 5. The pyramidal olive coloured kind, with yellow fleſh. There are a multitude of other varieties of leſs note, and probably there might, by proper management in the ſowing, be raiſed as many kinds as we have of apples and pears in our orchards.

The plant grows wild in vaſt abundance in many parts of Africa, and has been long cultivated in the hotter iſlands of the Weſt Indies, where they are now very plentiful and very fine. It is now ſome time alſo ſince it has been introduced into the gardens of Europe, where, with proper management, it ſucceeds very well. There is an opinion, that there are none raiſed ſo good from the American plants, as from thoſe originally propagated by M. la Cour of Leyden, the firſt who ever ſucceeded in the bringing it to fruit in Europe; but this is an error, occaſioned by ſome of the indifferent kinds having been at firſt frequently ſent over from America; but of late we have had much finer from thence than ever M. la Cour knew. The firſt ſort is the moſt common in Europe, but the ſecond is greatly preferable to it; being much larger and better flavoured, and the juice being leſs aſtringent, the fruit may be eaten with leſs danger in large quantities. This uſually produces ſix or ſeven ſuckers alſo under the fruit, from whence it may be propagated, and therefore is the moſt fit for culture of any. The third ſort is propagated merely as a curioſity, the fruit being much inferior to that of the others. The fifth is the moſt valuable of all, and is had from Barbadoes and Montſerrat. The fourth is what is called in America, the *king-pine*; they are propagated by planting the heads or ſuckers: theſe are to be ſet in pots of five or ſix inches over at the top, filled with good freſh light earth, mixed with a little rotten dung; this mixture muſt be often turned, to make it mix the more perfectly, and the plants, when ſet, muſt have a little water, to ſettle the earth to their roots; and the pot then plunged into a well-tempered bed of tanners bark. See the article HOT-BED.

They

They must have frequent but gentle waterings, and if the heat of the bed decreases, new bark must be mixed with the old, which will make it ferment again, and renew the heat.

In August and September, as the nights grow cool, the covering must be increased over the glasses; and towards the latter end of October, the plants must be removed out of the bark-bed into the stove.

During the winter season, great care must be taken to regulate the heat in the stove, never suffering the spirit in the thermometer to fall below the degree for *pine* apples in the botanical ones, nor ever to rise above five degrees more. They must be frequently watered, and the water used to them must always be first kept four and twenty hours in the stove.

In the beginning of February the plants will shew in their center their bud for the fruit; and in the middle of February the hot-bed of tanners bark must be prepared, that the heat of it may be in some measure over before the plants are set into it, which must be about the middle of March. The pots must be at first but half way buried in the bark; about a month after this they should be raised up, and the bed stirred about with a fork; and after this, the pots are to be plunged into it, up to their rims. They are now to have frequent waterings during the summer season; they are to be frequently watered, and shaded from the violence of the sun, in very hot days, and the glasses are now and then to be raised a little, to give them air; the bark must be stirred from the bottom, and, if necessary, a little fresh bark added to it to encrease the heat; and this may be repeated two or three times in a summer. The time of the ripening of the fruit in greatest perfection, is from the beginning of July to the end of September: they are known to be ripe by their strong and agreeable smell, and by gently pressing the protuberances with a thumb and finger; which, if they feel soft and give way, afford certain signs that the fruit is ripe. When ripe, it ought to be gathered; for, in a day or two, it loses its high flavour: and when gathered, they ought to be eaten at the utmost within twenty-four hours. It is always best to keep the crown on till the time of eating the fruit.

Many make their hot-beds for the cultivating this fruit in frames of about three feet deep; but it is a much better way to erect a stove on purpose, with bark pits in it for the hot-bed. These stoves need not be higher than to admit a person to walk upright on the back side, and may be brought sloping down at the front till the glass touches the bed. *Miller*'s Gard. Dict. See the article STOVE.

PINE-*apple*, in metallurgy, a word used to express a sort of mould, used in the refining silver. It has this name from its shape, resembling the fruit of that name.

When the refiners have taken the mixture of the silver and mercury together out of the cauldron, and strain it through two coarse wetted cloths, to make it the thicker, they then beat it with a sort of battledoors, to drive out yet more of the quicksilver; and straining it again after this, they take out the remaining thick amalgame, and forming it into little pellets, they put these carefully into the moulds called *pine-apples*, pressing them down. The amalgame, when put into this vessel or mould, is usually so rich as to be about one fifth silver. The manner of divesting this of the quicksilver afterwards, is by means of fire; in which the quicksilver rises in vapour, and the silver is left pure behind: but the carelessness of the workmen in doing this, and particularly the using bad vessels, or the not luting them close, causes a waste of this mineral greater than could be conceived. Alonso tells us, that in the city of Potosi alone, at the time of his writing, when the trading in metals ran but low, above thirty thousand pieces of eight were wasted in quicksilver that was lost one year with another. To prevent this, they then principally studied the means of keeping the silver as dry of quicksilver as they could, in the *pine-apple*; but it then holding four fifths of the whole mass in quicksilver, the great waste was in the separating it afterwards. *Alonso Barba* de Metal.

PINE-*salt*, a name given to a preparation of the bark of the *pine*-tree, used as a sort of seasoning to food in the manner in which we use salt.

The Laplanders are very fond of this, and the manner of their preparing it is given in Scheffer's history of that country: they peel off the bark from the lower part of the bodies of those trees, and separating the outer rough part, they take the inner bark, which they carefully divide into its several thin coats: when they have thus reduced them to as thin pieces as they can, they expose them to the sun in their summer months to dry, and when thoroughly dried, they tear them into thin and narrow slips, and put them up in boxes made of the outer bark of other trees fresh taken off. They bury these boxes in deep holes dug in the sands, and let them remain thus one day; on the day following they bring together a number of stumps of trees, and other wood, and laying them over the place where the bark is buried, they set them on fire: the next day they take out their buried boxes, and the heat having penetrated so deep into the earth in a mild degree, the bark is found to have been greatly affected by it, and to have received a red colour, and a very agreeable flavour, somewhat sweetish. This is their general sauce; they eat it with all their food, as we do salt, but it has so little of the nature of salt, that the name is but ill adapted to it.

There is another vegetable substance, which, tho' of a disagreeable taste to us, yet custom teaches them to be fond of. This is the angelica petrosa: they cut the large stalks of this plant before it runs to seed, and roast them; they eat this in considerable quantities with their *pine-salt*, and esteem it not only an agreeable, but a more than ordinarily wholesome sort of food.

PINGUICULA, *butterwort*, in botany, the name of a genus of plants, the characters of which are these: the flower consists of one leaf, and is of a sort of bilabiated form, in some degree resembling the violet flower, and ending in a sort of heel: the pistil arises from the cup, and is fixed in the manner of a nail to the hinder part of the flower; and finally becomes a fruit or capsule, containing a great number of small seeds affixed to a placenta.

The species of *butterwort*, enumerated by Mr. Tournefort, are these: 1. The common *butterwort*, called also *mountain sanicle*, and *Yorkshire sanicle*. 2. The white flowered *butterwort*, with a very small flower and short heel. 3. The purple *butterwort*, with a very large flower and a very long heel. 4. The smaller *butterwort*, with a flesh-coloured flower. *Tourn.* Inst. p. 167.

The characters of this genus, according to Linnæus, are, that the cup is a small acute labiated perianthium, which remains when the flower is fallen; its upper lip being erect and trifid, its lower reflex and bifid: the flower is labiated, and made up of a single petal: the longer lip is strait, obtuse, trifid, and laid flat; the shorter is bifid, more obtuse, and spread more open: its nectarium is in the figure of a horn, and is produced from the bottom of the petal: the stamina are two cylindric filaments, crooked, and inclined upwards, and shorter than the cup: the antheræ are roundish: the pistil has a roundish germen, a very short style, and a stigma composed of two lips; the upper of which is large, plain, bent backward, and covers the antheræ; the lower is very narrow and short, and is placed erect, and is bifid: the fruit is an oval-shaped capsule, compressed at the top, and naturally opening there, and containing only one cell, full of very numerous and cylindric seeds placed loose in it. *Linnæi* Genera Plant. p. 5.

PINHONES, the name by which the Portuguese call the purging nuts, as they are called, of America; the fruit of a great ricinus, or palma-christi. *Piso*, 169.

PINIROLO, in zoology, the name of a bird of the tringa kind, somewhat approaching to the land-piper, but larger. Its beak is a little more than a finger's breadth long, and black: it is of a mixed chesnut colour, and brown on the back; and its belly and breast are perfectly white: it is common in the Italian markets, and very much resembles the common tringa: *Ray*'s Ornithol. p. 223.

PINK, *caryophyllus*, in botany, the name of a genus of plants, the characters of which are these: the flower is composed of several petals, disposed in a circular form, and produced out of a tubular cup, of a cylindric shape and membranaceous substance, and scaly at the bottom. The pistil arises also from the same cup, and finally becomes a cylindric fruit; which, when ripe, opens at the summit, and is surrounded by the cup, and filled with flat, and, as it were, foliaceous seeds, which adhere to a placenta. See Tab. 1. of Botany, Class 1.

The species of *caryophyllus*, enumerated by Mr. Tournefort, are these: 1. The common great red *pink*. 2. The broader-leaved great *pink*. 3. The great *pink*, with variegated flowers. 4. The great *caryophyllus*, with very double flowers, of a variegated red and white. 5. The great very double *caryophyllus*, with scarlet, red, and white flowers. 6. The great very double, deep red *caryophyllus*, with three white pointals in the middle. 7. The great round-flowered *caryophyllus*, with scarlet and white flowers. 8. The great *caryophyllus*, with blackish, purple, and snow-white flowers. 9. The great double *caryophyllus*, with violet and white flowers. 10. The great double *caryophyllus*, with vermillion and white flowers. 11. The common, tall, variegated, double *caryophyllus*. 12. The great white *caryophyllus*. 13. The red and blood-coloured *caryophyllus*. 14. The white *caryophyllus*, with dots and lines of red. 15. The double *caryophyllus*, with purplish red flowers. 16. The flesh-coloured and white double *caryophyllus*, with spots and lines of red. 17. The double *caryophyllus*, with every leaf of the flower half white and half red, and variegated with red spots. 18. The crimson and snow-white *caryophyllus*. 19. The great double whitish *caryophyllus*, with deep purple spots. 20. The great bright white and scarlet *caryophyllus*. 21. The great round-flowered double *caryophyllus*, of a deep red and white. 22. The great double flesh-coloured and white *caryophyllus*. 23. The great double white-flowered *caryophyllus*, with a mixture of bright red. 24. The great double *caryophyllus*, with dusky white flowers, and spots of a ferrugineous colour. 25. The great broad-leaved *caryophyllus*, of the colour of the peach-bossom. 26. The great double purple *caryophyllus*, with spotted leaves. 27. The great purple *caryophyllus*, with spots of a deeper purple. 28. The greenish-flowered *caryophyllus*. 29. The lesser white *caryophyllus*, with lines of scarlet or violet colour. 30. The red-lead-coloured *caryophyllus*, with flowers white in the center. 31. The double violet-coloured *caryophyllus*. 32. The double orange-

coloured *caryophyllus*. 33. The dappled *caryophyllus*, of a white and orange colour. 34. The middle-sized *caryophyllus* altilis, with pale violet-coloured flowers. 35. The small *caryophyllus* altilis, with pale yellowish flowers. 36. The little variegated *caryophyllus* altilis. 37. The common single garden-*caryophyllus*, with large flowers. 38. The common garden single *caryophyllus*, with flesh-coloured flowers. 39. The single garden-*caryophyllus*, with variegated flowers. 40. The great wild *caryophyllus*, with variegated flowers. 41. The common double small garden-*caryophyllus*. 42. The procumbent garden-*caryophyllus*, with double-red flowers, spotted with white. 43. The double-jagged garden-*pink*. 44. The double-jagged garden-*pink*, with flesh-coloured flowers. 45. The garden-*caryophyllus*, with very finely divided flowers. 46. The flesh-coloured finely divided garden-*caryophyllus*. 47. The white finely divided garden-*caryophyllus*. 48. The white scentless jagged-flowered wild *caryophyllus*. 49. The sweet-scented jagged-flowered wild *caryophyllus*. 50. The white-flowered sweet-scented jagged-flowered wild *caryophyllus*. 51. The jagged-flowered wild *caryophyllus*, with sweet-scented stamina. 52. The jagged-flowered sweet-scented *caryophyllus*, without stamina. 53. The cretic shrubby *caryophyllus*. 54. The single *caryophyllus*, with small pale-red flowers. 55. The small single *caryophyllus*, with spotted flowers. 56. The procumbent broad-leaved single *caryophyllus*. 57. The single procumbent narrow-leaved *caryophyllus*. 58. The double purple *sweet-william*, or *caryophyllus barbatus*. 59. The double white *sweet-william*. 60. The rose coloured *sweet-william*. 61. The single broad-leaved *sweet-william*, with flesh-coloured flowers. 62. The single broad-leaved *sweet-william*, with purple flowers, and with variegated leaves. 63. The purple broad-leaved single *sweet william*. 64. The white broad-leaved single *sweet-william*. 65. The single broad-leaved *sweet-william*, with variegated flowers. 66. The pale red-flowered narrow-leaved *sweet-william*. 67. The deep red-flowered narrow-leaved *sweet-william*. 68. The narrow-leaved *sweet-william*, with milk white flowers, with red spots. 69. The narrow-leaved *sweet-william*, with white flowers with red edges. 70. The narrow-leaved *sweet-william*, with plain snow-white flowers. 71. The narrow-leaved *sweet-william*, with a few pale-red flowers. 72. The narrow-leaved *sweet-william*, with purple flowers and white edges. 73. The narrow-leaved *sweet-william*, with snow-white and purple flowers. 74. The wild *sweet-william*, or common wild *pink*. 75. The wild proliferous, or childing *pink*. 76. The white flowered proliferous wild *pink*. 77. The single-flowered proliferous wild *pink*. 78. The common wild broad-leaved *pink*. 79. The many-flowered mountain-*pink*. 80. The Italian umbellated *pink*, with yellow and ferrugineous flowers. 81. The common narrow-leaved wild *pink*. 82. The wild *pink*, with large scentless hairy flowers. 83. The little creeping *pink*, with one flower on every stalk, called by many the *maiden-pink*. 84. The red wild *pink* of Caryntha. 85. The purplish blue woolly or hairy-flowered wild *pink*. 86. The wild *pink* with hairy white flowers. 87. The common little wall-*pink*. 88. The common wild *pink* of the warm climates. 89. The alpine *pink*, with rose-coloured flower and greenish umbilicus. *Tourn.* Inst. p. 330, seq.

PINNA *(Cycl.)*—PINNA, a *fin*, in natural history, the name of that part of a fish which distinguishes it from other aquatic creatures, no animal but a fish having *fins* and wanting legs.

The *fin* is properly a part standing out, or hanging from, the body of the fish, and consisting of a membrane supported by several rays or oblong bones; which are in some hard and firm, and in others cartilaginous.

This definition of a *fin* properly excludes all those other parts of a fish which may be prominent from the body, and may be of a membranaceous structure, and even carry the appearance of a *fin*, tho' they have none of the rays or little bony substances within them, and therefore cannot serve the creature in the office of *fins* in swimming; for the cartilages or bones, which support the membranes of the *fins*, are what give them their due and necessary strength and firmness to bear against the water for the motion of the body of the fish: those other membranaceous appendages to the bodies of fishes cannot do this; for wanting the support of these rays, the simple and soft membrane has no more power of moving the water, than the water has of moving it. Hence appears the use of the bones or rays, supporting the *fins*, and the truth of the definition, that nothing is properly a *fin* which wants them.

The *fins*, by their differences, make very obvious distinctions among the several species of fishes; and these differences are, in regard to number, situation, figure, and proportion.

The number of the *fins*, including the tail, is very different, in different fish. 1. In some there is only one *fin* to the whole fish. This is the case in the ophidium lumbriciforme, and in the muræna. 2. The *fins* are two in number in others, as in the petromyzæ and the like. 3. There are many which have three *fins*; as the conger, the eel, the common ophidium, the greenland whale, the sea-cow, and the like. 4. Many have four *fins*, of the number of which are the dolphin, the phocæna, and the second kind of the acus Aristotelis. 5. Several have five *fins*; as the ammodytes or sand-eel, the sword fish, the lupus marinus, the mola or sun-fish, and many others. 6. The lump-fish gives us an instance of six *fins*; for the seeming first *fin*, on the back of that fish, is not a real *fin*, but only a cutaneous prominence. 7. Many fish have seven *fins*; as the gudgeon, the pleuronectes, the cyprinus, the clupea, the coregones, the osmeri, the salmons, the cobites, the esoces, the cernua fluviatilis, the gasterosteæ, the spari, the labri, the silurus, the mugil alatus, the remora, the capriscus, the hippurus, the pompilus, and the accipenser. 8. Many fish also have eight *fins* each; of this number are some of the pearches, the clarea, the cottus, the mugil, the labrax, the sudis, the mulli, the ling, the trachurus, the scyæne, the trachinus, the uranoscope, and that little fish called the *anguella* by the Venetians. 9. The scorpæna of Rondeletius gives us an instance of the *fins* being nine in number; and, finally, the scombri and thynni, give us instances of eleven *fins* in the same fish.

The differences in situation are less numerous than these, as to number, but they are not less obvious and essential. 1. They are generally placed both on the back and belly, as we see in most of the species of fishes. 2. They are sometimes placed only on the back. This is the case in the petromyzæ, the acus lumbriciformis, and some others. 3. Some have them, on the contrary, only on the belly; of this kind are the Greenland whale, the sea-cow, and the like: and to this it is to be added, that the back and belly *fins* differ greatly in the several fish, in their being placed more or less backward or forward.

The differences of shape or figure in the *fins* of fishes, are also very obvious. 1. They are in some nearly triangular, as in the cyprini, and salmons, *&c.* 2. Some few fish have them round. And 3. Some have them of an oblong square, or parallellogram figure.

Finally, the difference in proportion is not to be omitted; for they are in some much shorter and smaller than the body; as is the case in the generality of fishes; but in others they are of an equal length with the body. Of this kind are the pectoral *fins* in some of the legyræ, and the ventral *fins* in the mugil alatus of Rondeletius, and other authors. *Artedi*, Ichthyol. p. 4.

Aculei PINNARUM, in ichthyology. Every apophysis or eminence on the head or body of a fish, which is so sharp at the end as to be capable of pricking, is called an *aculeus*; but the *aculei pinnarum* in particular, are those prickly *radii* or bones, which serve to support the fins; and being carried out beyond the rim of the membrane, end in so many points.

These *aculei* are simple cylindric ossicles, whereas the other ossicles, which sustain the fins, are less rigid, and are bent and not prickly: and these are not simple, but are composed each of two ossicles closely cohering one to another. Many of these *radii* are divaricated at their extremity into two, three or more branches; these when they are carried out beyond the rim of the membrane, are harmless, and are seen to be composed of two ossicles, as the body of the radius is. The *aculei* of the back and belly of all fishes are so far of the same nature, that they never stand single, as some have supposed them to do in particular instances; but they are always connected one to the other at the bottom, by a membrane, tho' that be ever so small and low, as in some it is scarce visible.

PINNARUM *radii*. See the article RADII *pinnarum*.

PINNA *marina*, in natural history, the name of a shell-fish, by the latest writers on these subjects referred to the genus of muscles. See the article MYTULUS.

This shell-fish is like the muscle, held in its place by a number of threads, which proceed from its body, and are fixed to any adjoining substance, and is one of those fish, which, like the muscle, has a power of spinning in the manner of the spider and caterpillar. See the article MUSCLE.

The threads which these fish spin, are infinitely finer and slenderer than those of the muscle, notwithstanding that the fish is vastly larger; its shells being often found two foot long. These threads are indeed scarce, less fine than the single silk threads of the silkworm, and like it have in all times been worked into use. The finest kind of the byssus of the antients was wrought out of these threads, and at present they are manufactured at Palermo, and at many other places, into gloves, stockings, and other sorts of wearing apparel.

It is easy to conceive, that threads so fine as these can be of no great strength; but what is wanting in the force of each, is made up in the number of them; which are spun by every fish, for this is almost infinite. They differ in nothing from the threads of the muscles, beside their fineness and their length; which is in these much greater, and therefore makes them greatly the more valuable. They are probably formed in the same manner with those of the muscles; and the *pinna* may be called, by way of distinction, the silkworm of the sea; and the muscle, the caterpillar. See Tab. of Shells, N°. 20. Mem. Acad. Par. 1711.

PINNARUM *dilatator proprius*, in anatomy, a name given by Santorini to one of the muscles of the face, which he has also called *myrtiformis nasi*, and which Cowper has called *depressor labii*

labii ſuperioris, ſive conſtrictor alæ naſi, and Albinus the *depreſſor alæ naſi*. See the article DEPRESSOR.

PINNATED *leaf*, among botaniſts. See the article LEAF.

PINNATIFID *leaf*, among botaniſts. See the article LEAF.

PINNATUS, in heraldry, a term uſed by the Latin writers on theſe ſubjects, to expreſs that ſort of line in arms which is called by our heralds the *embattled line*, or *crenelle*. It is alſo called by ſome *linea pinnis aſperata*, and by Sylveſter Petro Sancto *murales pinnulæ*. When this line is only embattled on one ſide, it is properly expreſſed by this word; but when it is embattled on both ſides, as in ſome arms, it is called *breteſſe* and *contre breteſſe*. See the article EMBATTLED.

PINT *(Cycl.)*—In the Engliſh beer meaſure, the *pint* is the eighth part of a gallon; conſequently contains $35\frac{1}{4}$ cubical inches. Tr. Pract. Geom. p. 112. See the article GALLON.

As to the *pint* uſed in Scotland, there are different opinions concerning the number of cubical inches it contains. Dr. Gregory makes them 109; others, from ſeveral careful menſurations of the ſtandard kept at Edinburgh, make the Scotch *pint* to contain $103\frac{4}{10}$; and thoſe in common uſe are ſaid to contain betwixt 105 and 106 cubical inches. Another experiment was made with a caſk, which was found to contain $46\frac{7}{8}$ Scotch *pints*, and $18\frac{1}{10}$ Engliſh ale gallons. Suppoſing this menſuration juſt, the Scotch *pint* will be to the Engliſh ale gallon as 289 to 750; and if the Engliſh ale gallon be ſuppoſed to contain 282 cubical inches, the Scotch *pint* will contain 108.664 ſuch inches. Tr. Pract. Geom. p. 114.

The Paris *pinte* is nearly equal to an Engliſh wine quart. Tr. Pract. Geom. p. 117.

PINTADO, or AFRA AVIS, in natural hiſtory, a name given by the antient Roman authors to the Guinea hen.

Varro, Columella and Pliny, with many others, make the *pintado* and the *meleagris* the ſame ſpecies of bird; but Suetonius, Scaliger, and ſome others, are of opinion, that the antients meant two very different birds by theſe names; and the latter of theſe authors endeavours to bring Varro over to his ſide, by altering the pointing in the paſſage of that author which relates to it.

The bird is of late become very common in England, and breeds with us in great plenty. The hen lays her eggs and ſits upon them in the ſame manner with the common hen; but the eggs are ſmaller and not ſo white as the hens eggs, but have a tinge of fleſh colour and ſome black ſpots. They are not ſo tame and domeſtic as our own fowls, and particularly they will not lay in houſes; but get into the hedges and among buſhes, where they lay and hatch; but this is the occaſion of great loſs among them, the wild vermin deſtroying a great part of their young brood. The female alſo is leſs careful about the great buſineſs of hatching and taking care of them, than any other bird we are acquainted with. She will often leave her neſt when the eggs are near hatching, and never return to it again; and often will deſert the young as ſoon as hatched, if ſhe remains at her neſt till that time. The beſt method, therefore, is to ſet other fowls upon the eggs of this kind. The young fowls of this kind are very beautiful; they look like ſo many partridges. Their beaks and legs are red, and their whole plumage is at that time of the colour of the partridge. See Tab. of Birds, N°. 21.

The hen, if her neſt is found, and the eggs at times taken away, but ſo as always to have one there, will continue to lay till ſhe has depoſited an hundred, or ſometimes an hundred and fifty eggs, which are very well-taſted. This is a very active and ſprightly bird, and of an unquiet and troubleſome diſpoſition to the owner. It runs very ſwiftly in the manner of the quail and partridge; but its wings are ſhort, and it is not made for flying; yet at night it will not rooſt among other fowl, but gets upon a houſe or tree, or any other high and ſafe place. The cry of the bird is ſharp and diſagreeable to many ears, and it is almoſt continually making it. It is of a quarrelſome diſpoſition, and will be miſtreſs of the yard: its agility, and the ſharpneſs of its beak, generally obtain it the victory with what ever bird it fights.

The *pintado* is ſo common in America, that many have ſuppoſed it native there; but this is not the caſe. The origin of the bird is in Guinea, and the firſt that were ever brought into America, were brought in the year 1508, with the cargoes of negro ſlaves. The Spaniards neither at that time nor ever ſince, have attempted to tame them, or render them a domeſtic uſeful bird, but let them go looſe and wild in the ſavanhas; where they have increaſed to ſuch prodigious numbers, that they may well appear native, and are ſeen in vaſt flocks together, and are called *marroon pintades*, by the Spaniards and French. Obſerv. ſur les Cout. de l'Aſie, p. 190.

PINUS, the *pine-tree*. See the article PINE.

PIONY, *pæonia*, in botany. See the article PÆONIA.

The ſeveral ſorts of this plant are all very hardy, and will grow in almoſt any ſoil and ſituation; they are propagated by parting the roots, which multiply very faſt. They ſhould be planted in Auguſt, or the beginning of September, and will then flower the ſucceeding ſummer. The off-ſets ſhould not be too ſmall, and ſhould all have a fair bud or eye. The ſingle kinds may alſo be propagated by ſowing their ſeeds in Auguſt in a light earth, and managing them in the method of all other ſeedling plants. There may probably be ſome good varieties of the flowers produced this way. The ſingle Portugal *piony* is of ſo ſweet a ſmell as to deſerve a place in any garden, tho' but a ſingle flower. *Miller*'s Gard. Dict.

Piony-root, is a celebrated medicine in nervous caſes. We have inſtances well atteſted, of epilepſies cured by it alone. It is good alſo in all diſorders of the head, in hyſteric complaints, and obſtructions of the viſcera.

PIPE *(Cycl.)*—The Turkiſh *tobacco-pipe* is very long, the tube is made of wood or reed, and the bowl of earthen ware; thoſe they carry with them when they travel, they have made in two or three joints, to put into a bag; they cover the tube ſometimes with cloath, and dip it in water to make it ſmoak cool. *Pocock*'s Egypt, p. 186.

PIPE, in mining, is where the ore runs forwards endways in a hole, and doth not ſink downwards or in a vein. *Houghton*'s Compl. Miner in the Explan. of the Terms.

PIPER, *pepper*. Baldæus tells us, that the *pepper* thrives beſt in the cooleſt and moſt ſhadowy places, and that the plant has a weak ſtem like that of the vine, which muſt be ſupported by ſomething to climb upon. Theſe commonly grow about ſix cluſters on every branch, each cluſter is a foot long, and in colour like unripe grapes. They gather it while green in October and November, and expoſe it to the ſun to dry, by which means it grows black in a few days. *Baldæus* de Ind. Orient. p. 99.

PIPER *chiapæ*, in botany, a name given by ſome authors to the clove berry-tree, or *caſſia caryophyllata*. *Redi*, Lat. p. 132.

PIPER *Jamaicæ*, the *pepper-tree* of Jamaica. See the article PIMIENTA.

PIPER *nigrorum*, *negro pepper*. The plant called at preſent by this name is the capſicum, or Guinea *pepper*, a remarkable herb, bearing large pods as red as coral, of which the Cayan butter is made in America. But this is not the plant that was antiently known by this name. Aviſenna and Serapion, both mention a plant which they call *fulful alſuaden*, the Engliſh of which is, the *pepper* of the black people. But this was properly what has been ſince called the *Ethiopian pepper*; a ſort of hot ſeeds approaching to the nature of the common *pepper*, and contained ſeveral together in pods. Aviſenna tells us, that the plant properly and rightly called *piper nigrorum*, had pods like thoſe of the kidney-bean, which were of a black colour, and that the ſeed was hot and biting to the taſte like *pepper*. There was alſo another thing called by the ſame name, that is, the *zelem* of theſe authors; this was brought from Barbary, and was a fruit of a high flavour, of the bigneſs of a vetch, and was yellow on the outſide and white within. Serapio abſolutely diſtinguiſhes this by the name of *zelem*, from the other *piper nigrorum*, properly ſo called; yet Guillandinus has been the occaſion of many errors in regard to theſe fruits, by attributing to the *zelem* the things which that author expreſsly ſays of the other *piper nigrorum*, or *Ethiopian pepper*: it is not eaſy from the accounts we have left, to ſay what it is; but they have left deſcription enough of it for us to ſay what it is not, and to find that they have all been miſtaken, who have ſuppoſed it to be either the root tarſi, or the bulbus of the Arabians, which laſt was as large as a pear.

PIPER *tavaſci*, in botany, the clove-berry-tree, or *caſſia caryophyllata*; a tree whoſe bark is uſed in medicine. *Hernand.* p. 30.

PIPERAPIUM, an old name of a plant found in Apuleius, and ſaid to have its name from its heat to the taſte; which was ſo offenſive to the bees, that if a piece of it were hung up in their hive it would drive them all out.

This is a very ſtrange account, and as we meet with nothing to countenance it in any other author, there is reaſon to ſuſpect it to be an error; and there ſeems this foundation for it. The acorus root is ſaid by Dioſcorides to be the root of a plant allied to the papyrus, or paper reed of the river Nile; and is thence called by that author *papyraceus*. Aviſenna and Serapion copy this, and liken the acorus plant to the papyrus; but in all the copies of the Greek author, it is often found written πεπεραχιον. This word *peperacion*, may have been formed by Apuleius into *piperapium*, by way of amendment, and all the reſt might be occaſioned by this.

PIPERITIS, in botany, a name given by ſome authors to the *momordica*, or male balſam apple. *Tourn.* Mat. Med. p. 357.

PIPERIVORA *avis*, in zoology, a name given by ſome authors to the *toucan*, or Braſilian magpye, from its feeding on pepper. *Ray*'s Ornithol. p. 88. See the article TOUCAN.

PIPRA, in zoology, a name given by Ariſtotle, and other antient writers, to the *picus varius major*, the great ſpotted wood-pecker, or witwall. See the article PICUS.

PIQUE, in natural hiſtory, a name given by the Spaniards to an inſect of the ſize of a flea, called by the Indians *tung*. It is common in the Eaſt and Weſt Indies, and eats its way into the fleſh under the nails, &c. See the article TUNG.

PIQUETTE, among the floriſts, a term uſed for a certain ſort of carnations, which have always a white ground, and are ſpotted, or as they call it, pounced with ſcarlet, red, purple, or other colours.

PIQUI-

PIQUITINGA, in zoology, the name of a ſmall American river-fiſh. It ſeldom exceeds two inches in length: its mouth appears very ſmall, but it can at pleaſure open it to a great width: its eyes are very large and black, with a ſilvery iris: it has ſix fins beſides the tail, which is forked; its head is of a ſilvery white: its back olive colour, and its belly and ſides are covered with ſilvery ſcales; the fins are all white, and the ſide-lines are broad, and very bright and ſhining. *Marggrave*'s Hiſt. Braſil.

PIRA-*aca*, in zoology, a name by which Marggrave and ſome other authors have called a little horned fiſh of the Weſt Indies, called by Cluſius and others, the *monoceros piſcis*, or unicorn fiſh. *Willughby*'s Hiſt. Piſc. p. 150. See the article MONOCEROS.

PIRA-*acangata*, in zoology, the name of a Braſilian fiſh, reſembling the perch in ſize and ſhape. It is of a ſmall ſize, ſeldom exceeding four or five inches in length: its mouth is ſmall: its tail is forked; and it has on the back only one long fin, which is ſupported by rigid and prickly ſpines. This it can depreſs at pleaſure, and ſink within a cavity made for it in the back. Its ſcales are of a ſilvery white, but have an admixture of a fine yellow and reddiſh gloſs, eſpecially on the back: the ſides are more purely white, and the belly is of a ſomewhat bluiſh green, mixed with the white: the back fin is very pellucid, and of a ſilvery white, and is variegated with brown ſpots: the ſide fins are white, and the belly ones, and the end of the tail, are blue. It is a wholeſome and well-taſted fiſh. *Marggrave*'s Hiſt. Braſil. *Willughby*'s Hiſt. Piſc. p. 338.

PIRA *bebe*, in zoology, a name uſed by ſome authors for the *milvus*, or kite-fiſh. *Dale*, Pharm. p. 376.

PIRA-*coaba*, in zoology, the name of an American fiſh of the truttaceous kind, much eſteemed for the delicacy of its flavour. It grows to about twelve inches in length: its noſe is pointed, and its mouth large; but without teeth: the upper jaw is longer than the other, and hangs over it in form of a cartilaginous prominence: its eyes are very large, and its tail forked: under each of the gill-fins it has a beard made of ſix-white filaments, and is covered all over with ſilvery ſcales. *Marggrave*'s Hiſt. Braſil.

PIRA-*jurumenbeca*, in zoology, the name of a Braſilian fiſh, called by many the *bocca molle*. It lives in the muddy bottom of the American ſeas, and is a long-bodied not flatted fiſh. It grows to a vaſt ſize, being ſometimes caught of nine, and ſometimes even of ten or eleven foot long, and two foot and an half thick. It has one long fin on the back, the anterior part of which is thin and pellucid; and has a cavity on the back, into which the creature can depreſs the fin at pleaſure: its tail is not forked: its ſcales are all of a ſilvery colour and brightneſs, and moderately large: it has a greeniſh caſt on the back, mixed with a ſhade of yellow; and it has a line running along the middle of each ſide, of the ſame ſilvery hue with the reſt of the body, but raiſed above the common ſurface of the part. It is a very well-taſted fiſh. *Marggrave*'s Hiſt. Braſil.

PIRA-*pixanga*, in zoology, the name of a Braſilian fiſh of the turdus or wraſſe kind, and called by ſome the *gat-viſch*. Its uſual length is four or five inches. its mouth is conſiderably large, and furniſhed with very ſmall and ſharp teeth: its head is ſmall, but its eyes large and prominent: the pupil of a fine turgoiſe colour, and the iris yellow and red in various ſhades: the coverings of the gills end in a triangular figure, and are terminated by a ſhort ſpine or prickle: its ſcales are very ſmall, and ſo evenly arranged and cloſely laid on the fleſh, that it is very ſmooth to the touch: its tail is not forked, but rounded at the end: its whole body, head, tail, and fins, are of a pale yellow, variegated all over with very beautiful blood-coloured ſpots; theſe are round, and of the bigneſs of hemp-ſeed on the back and ſides, and ſomething larger on the belly: the fins are alſo ſpotted in the ſame manner, and are all marked with an edge of red. It is caught among the rocks, and about the ſhores, and is a very well-taſted fiſh. *Marggrave*'s Hiſt. Braſil.

PIRANHA, in zoology, a name given to the American fiſh more commonly known by the name *piraya*. *Marggrave*'s Hiſt. Braſil. See the article PIRAYA.

PIRAQUIBA, or IPIRAQUIBA, in zoology, a name originally Braſilian, by which ſome authors expreſs the *remora*, or ſucking fiſh. *Marggrave*, 180.

PIRATIA-*pua*, in zoology, the name of an American ſea-fiſh, which grows to a very large ſize, and, while young, is eaten and accounted a delicacy; but, when full grown, is too coarſe, rank, and ſtrong. Its jaws are both well armed with teeth; the under all the way on both ſides, the upper only in the middle on each. The lower jaw is ſomewhat longer than the upper, and the mouth very large. It is of an oblong and rounded body. Its back is a little prominent, but its belly altogether flat and even. It has ſix fins beſides the tail, which is made of a very large fin, of a ſomewhat ſquare figure, and is not at all forked. It is all over of a duſky orange colour, but more obſcurely ſo on the back than elſewhere; and its ſides are variegated with grey ſpots, ſo diſpoſed as to repreſent a ſort of network. *Piſo*'s Hiſt. Braſil.

PIRATIAPIA, in zoology, the name of a Braſilian fiſh, approaching to the nature of the turdus or wraſſe. Its body is oblong, not flatted, and very thick. It is a large fiſh, and ſometimes grows even to fifty pound weight. Its lower jaw is conſiderably longer than the upper, and its teeth are very ſharp. Its mouth and tongue are red on the inſide, and its eyes are large and prominent. It has only one long back fin, the anterior rays of which are prickly, the hinder ſmooth. Its tail is not forked, its ſcales are ſmall, and its back and belly are of a fine bright red. Its ſides of a ſilvery grey, with a duſky caſt. It is all over ſpotted alſo with the ſame colour in large round ſpots. The fins are all red, with a line of white and a fringe of black at their edges. It is a very delicate and valuable fiſh. *Marggrave*'s Hiſt. Braſil.

PIRAUMBU, in zoology, the name of a Braſilian fiſh, ſomewhat approaching to the nature of the turdus, and called by the Portugueſe *chayquarona*. It is of the figure of the carp, and its uſual length is ſix or ſeven inches, and its breadth in the broadeſt part about three inches; but gradually diminiſhing to the tail. Its eyes are large and prominent. Its mouth like that of the carp. It has two fins on the back. Its ſcales are very broad, of a ſilvery whiteneſs, with a ſmall admixture of yellow. Its tail is forked. The upper half of every ſcale is, however, browniſh, and the fins are all grey. Its belly and the under part of the head, are of a fine ſilvery white. It is caught among the rocks, and near ſhores, and is a well-taſted fiſh. *Marggrave*'s Hiſt. Braſil.

PIRAYA, in zoology, the name of a fiſh caught in the American rivers. There are two kinds of it: the one growing to a foot long, and very broad in proportion; with a hunched back, and lips that cover its mouth cloſely and hide its teeth: its head is blunt and ſhort, and its back and ſides of a pale bluiſh grey, and its belly of a duſky yellow: this loves the muddy bottoms of rivers. The other is much of the ſame ſize, but has two fins on his back, whereas the other has but one; and has a fine yellowiſh and reddiſh caſt mixed among the bluiſhneſs on the back, and its belly of a fine clear and ſtrong yellow, between a gold and a ſaffron colour: this loves the ſandy bottoms of rivers. There is alſo a ſmaller ſpecies of this: all three are eatable fiſh. *Marggrave*'s Hiſt. Braſil.

PIRIT, in natural hiſtory, a name given by the people of the Philippine iſlands to a peculiar ſpecies of ſparrow, which is very common with them. It is much ſmaller than our common ſparrow, and feeds only on the ſeeds of the canary-graſs, which is very commonly wild there.

PISCES *(Cycl.)*—PISCES, *fiſhes*. According to the new Artedian ſyſtem, *fiſhes* in general are divided into five diſtinct orders. The generality of fiſhes have the tail placed perpendicularly, but a few of them have it horizontally. Of thoſe which have the tail perpendicular, ſome have the rays of the fins bony; and theſe either have the gills covered with a membrane, containing ſeveral bones, or they have no ſuch membrane: of thoſe which have this membrane, with the bones over the gills, ſome have the rays, tho' bony, yet not pungent; theſe are called the *malacopterygii*, or the ſoft-finned fiſhes. Others have them with the rays prickly; theſe are the *acanthopterygii*, or prickly-finned fiſhes. Thoſe which have no bones in the membrane over the gills, make only one genus, and are called the *branchioſtegi*. The other kind, which have not bony, but cartilaginous rays in the fins, are called *chondropterygii*. And finally, thoſe *fiſh* which have the tail placed not perpendicularly, but horizontally, are called *plagiuri*. See MALACOPTERYGII, &c.

The *fiſh* thus conſtituting the order of the *malacopterygii*, are again divided into ſeveral ſeries. 1. Thoſe which have only one fin on the back, and that placed nearly the middle of the back. 2. Thoſe which have one fin placed in the middle of the back, and another ſtanding farther behind. 3. Thoſe which have only one fin on the back, and that placed far backwards. 4. Thoſe which have one or more fins running all the way down the back. 5. Thoſe which have one long back fin, ſcarce diſcernible from the tail. 6. Thoſe which have either only one very ſmall fin on the extremity of the back, or have no fin at all there. Theſe are the principal diſtinctions of the *malacopterygii*.

The *acanthopterygii* are divided only into two ſeries: the one conſiſting of thoſe whoſe head is ſmooth; the other of thoſe whoſe head is rough.

Artedi has given a very ſhort definition of a fiſh, which ſevers it from all other creatures; and ſeparates from the fiſh kind many creatures which ſome authors have confuſedly treated of among them, as properly of the ſame claſs of animals. The definition is this: *A fiſh is a creature having no legs, and always having fins.* There is no other aquatic animal which has not legs, and has fins properly ſo called; and it is very improperly, that creatures, wanting the characters of this definition, are by ſome ranked among fiſhes; as the inſects which have legs, and the ſerpent kind, which have no fins. The definition may be rendered longer and more expreſs in the following form: A fiſh is an animal having fins, having no legs, always reſpiring either by means of lungs or gills; inhabiting the waters, except on extraordinary occaſions; and moving itſelf either ſolely by its fins, or by the additional help of a flexuous motion of the body, ſometimes coming out of the water on the earth; and ſometimes flying or riſing into the air, and continuing

tinuing there ſome time, carrying itſelf along by means of the pectoral fins. The laſt quality belongs only to the flying fiſh, and a very few others. *Artedi* Ichthyology, p. 1.

PISCIS *foſſilis*, in ichthyology, a name given by Jonſton to a kind of the cobitis, found buried in the ſand, and dug out by the people of many parts of Germany for food. It is called by many authors the *muſtela foſſilis*, and by ſome the *pæcilia*. It is properly a ſpecies of cobitis, and is called by Artedi the *bluiſh cobitis*, with five longitudinal black lines on each ſide of the body. *Artedi*, *Jonſton*, de Piſc.

PISCIS *ſancti petri*, in ichthyology, a name given by Jovius and ſome other authors to the faber or John Doree. It is properly a ſpecies of zeus. See ZEUS.

PISCIVOROUS *animals*, are ſuch as feed on fiſh. See the article BIRD.

PISMIRE, in zoology, See FORMICA.

PISONIA, in botany, the name given by Plumier, in honour of Piſo, to a genus of plants, called by Vaillant *pentagonotheca*. The characters are theſe: it produces ſeparate male and female flowers; in the male flower the cup is erect, very ſmall, and divided into five ſegments: the flower is of a funnel-ſhape, the tube is ſhort, and the mouth very wide: it is lightly divided into five ſegments, and lies open: the ſtamina are five pointed filaments, longer than the flower: the apices are ſimple. In the female flower, the cup is the ſame as in the male; but it ſtands on a germen: the flower is the ſame as in the male: from the germen there ariſes a ſingle, erect, cylindric ſtyle, which is longer than the flower, crowned with five oblong ſtigmata: the fruit is an oval capſule, compoſed of five valves, and having an obſcurely pentangular appearance, but having only one cavity within: the ſeed is ſingle, ſmooth, and of an oval or oblong figure. *Linnæi* Gen. Pl. p. 474. *Plumier*, Gen. 11. *Houſton*, 13. *Vaillant*, Act. Germ.

PISSASPHALTUM, in natural hiſtory, the name of a genus of foſſils, the characters of which are theſe: They are fluid mineral bodies, of a ſomewhat thick conſiſtence, duſky, and opake; of a ſtrong ſmell, and readily inflammable, but leaving a reſiduum of greyiſh aſhes after burning.

There are three known ſpecies of this genus: 1. A thinner blackiſh kind, called *oleum terræ*. 2. A thicker black one, called *piſſelæum Indicum*, or Barbadoes tar. And, 3. A black and viſcous one, called ſimply *piſſaſphaltum* in the ſhops. See the articles OIL *of the earth*, and PISSELÆUM.

Piſſaſphaltum is as tough and viſcous as bird-lime, and of the ſame conſiſtence when old. It very much reſembles the common black pitch, when ſoftened a little by heat; and has been generally thought to have ſomething of the ſmell of that ſubſtance: but this ſeems to have ariſen from its being too frequently adulterated by mixing pitch with it, and the true genuine ſubſtance has no other ſmell than the rank one of all the bitumens, which ſomewhat reſemble that of oil of amber. It is produced in ſeveral parts of the world, and there are large quantities of it in Germany, in Perſia, and in France. It yields a limpid oil by diſtillation, which very much reſembles the native petroleum, and is too often ſold with us under this name, being annually imported in large quantities from thoſe parts of Germany where it is manufactured, and having itſelf no particular name in the ſhops of our druggiſts. *Hill*'s Hiſt. Foſſ. p. 422.

Piſſaſphaltum was much recommended by the antients for external uſe, as an emollient, maturant and digeſtive: with this intention it was uſed in cataplaſms, for ripening all ſorts of tumors, and againſt the ſciatica and other pains of the limbs. They alſo had recourſe to it for ſtrengthening the limbs, after the reduction of diſlocations. It is little uſed at preſent, the petroleum being thought very proper to ſupply its place.

PISSELÆUM *indicum*, in the materia medica, a ſubſtance commonly known by the name of *Barbadoes tar*. It is a heavy, thick, and duſky-looking mineral fluid, of the colour and conſiſtence of common treacle, and of a very opake hue; it is of a diſagreeable ſmell, faintly approaching to that of oil of amber, and is very inflammable. It is found trickling down the ſides of the mountains at the back of ſeveral of our plantations in America, and is in great eſteem there for coughs and diſorders of the lungs. We meet with very little in England that is genuine, ſeveral different ſophiſtications of it being in common uſe, even upon the ſpot. *Hill*'s Hiſt. Foſſ. p. 421.

PISSEROS, the name of an ointment greatly recommended by Hippocrates in many caſes, as in burns, freſh wounds, *&c.* It was made of oil of roſes, bees-wax, and pitch, proportioned ſo as to give the whole a ſoft conſiſtence. It was of the nature of our modern black baſilicon, found a good ointment in many caſes.

PISSINUM. Pliny ſays it was cuſtomary for the antients to hold fleeces of wool over the ſteam of boiling tar, and ſqueeze the moiſture from them, which watery ſubſtance was called *piſſinum*.

Ray will have this to be the ſame with the *piſſelæum* of the antients; but Hardouin, in his notes on Pliny, thinks the *piſſelæum* to have been produced from the cones of cedars. What uſe they made of theſe liquors antiently is not known; but it may be preſumed they were uſed in medicine, tho' at preſent it does not appear they are uſed at all.

PISSITES, a name given by the antients to a wine impregnated with the virtues of liquid pitch or tar. To prepare it, the tar was ordered to be waſhed in ſea water or brine, and afterwards in freſh water many times; and after a tedious preparation of this kind, two ounces of it were ordered to be put to eight gallons of muſt, which is to be ſuffered to work together, and then the clear liquor to be bottled off.

This was accounted a warm wine, very aſſiſtant to concoction, and of an abſterſive faculty, and a good pectoral: on theſe accounts it was given in diſorders of the breaſt, and in obſtructions of the liver, ſpleen, and uterus, if not attended with a fever; and was a common medicine in coughs and aſthmas, of all kinds.

PISSOCEROS, a name given by the old naturaliſts to a ſubſtance found very frequently in the hives of bees, and conſiſting of a mixture of propolis and wax. The antients were well acquainted with the uſe of this ſubſtance, which was uſed for ſtopping up the cracks and chinks in the hives: they mention, indeed, three ſorts of matter uſed by the bees for this purpoſe; the metys, the *piſſoceros*, and the propolis: but later authors call them all by the general term propolis, the *piſſoceros* and metys being only the ſame ſubſtance, mixed with wax in different proportions. This propolis is a reſinous ſubſtance, of a ſoft and viſcous conſiſtence, collected from the beds of the poplar and other trees. *Reaumur*'s Hiſt. Inſ. Vol. 10. p. 84. See the article PROPOLIS.

PISSOSIS, a word uſed by the old writers on medicine for the depraved appetite of young women about the firſt eruption of the menſes, and of ſome women with child.

PISTACHIA *trifolia*, in botany, a name improperly given by ſome authors to the trifoliate American bladder-nut. See the article STAPHYLODENDRON.

Piſtachias are eſteemed reſtorative, and peculiarly recommended to prevent obſtructions of the liver: they are alſo found of ſervice in nephritic complaints, and are ſaid to be great provocatives to venery: the faculty, however, ſeldom preſcribe them.

PISTANA, in botany, a name by which ſome authors have called the *ſagittaria aquatica*, or water arrow-head. *Ger. Emac. Ind.* 2.

PISTATIO, among pharmaceutic writers, a word uſed to expreſs that preparation of ſimples which conſiſts in covering them with, or including them in, a paſte, and ſending them to a baker's oven till tender throughout. Squills are ſometimes prepared thus.

PISTIA, in botany, the name given by Linnæus to a genus of plants, called *kodda-pail* by Plumier; and in the hortus Malabaricus. The characters are theſe: There is no cup; the flower conſiſts of one unequal petal, which is cucullated and turbinated, with a ſingle, oblique, and long lip, bent and folded at the ſide; there are no ſtamina, but ſix double antheræ grow to the piſtil under the ſtigma; the germen of the piſtil is of an oval oblong figure; the ſtyle is ſhorter than the flower; the ſtigma is peltated, and obtuſely divided into ſix ſegments; the fruit is a capſule of an oval figure, attenuated at the baſe, and contains ſix cells; the ſeeds are truncated. This genus ſeems nearly allied to the birth-worts. *Linnæi* Gen. Pl. 438. *Plumier*, 39.

PISTIL, among botaniſts, the female organ of generation in flowers. It is compoſed of three parts, the germen, the ſtyle, and the ſtigma: the germen ſupplies the place of the uterus in plants; its ſhape is various, but it is always ſituated at the bottom of the *piſtil*, and contains the embryo ſeeds: the ſtyle is a part of various figures alſo, but is always placed on the germen; in ſome it is extremely ſhort, in others it ſeems entirely wanting: the ſtigma is alſo of various figures; its place, however, is certain, as it always ſtands on the top of the ſtyle, and if there is no ſtyle, on the top of the germen. See the article GENERATION *of plants*.

PISTIS, in the materia medica of the antients, a name given to the gum bdellium, particularly to that kind of it which was brought from Arabia, and was of a fine yellowiſh white, and in ſmall round drops, or lumps of a roundiſh ſhape, and firm conſiſtence.

PISTOLOCHIA, in botany, a name uſed by ſome authors for the plant of which the Virginian ſnake-root of the ſhops is the root. *Park.* Theat. 420.

PISUM, the *pea*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the papilionaceous kind, and from its cup there ariſes a piſtil, which finally becomes an oblong pod, containing roundiſh ſeeds: to this it is to be added, that the ſtalks are weak and hollow, and the leaves ſo ſurround them, that they ſeem perfoliate; the reſt of the leaves are placed two and two upon a middle rib, which ends in a tendril.

The ſpecies of *peaſe*, enumerated by Mr. Tournefort, are theſe: 1. The large ſquare *pea*, with brown fruit. 2. The large ſquare *pea*, with grey fruit. 3. The large ſquare *pea*, with yellowiſh fruit. 4. The upright *pea*, with cluſtered or umbellated pods. 5. The common garden *pea*, with a white flower and white fruit. 6. The common large garden *pea*, with purple flowers. 7. The common large garden *pea*, with variegated flowers and variegated fruit. 8. The great podded garden *pea*. 9. The great *pea*, with the fruit marked with a black

black line. 10. The *pea* with eatable huſks. 11. The dwarf *pea* with firm ſtalks. 12. The angular-leaved *pea*. 13. The garden *pea* with a crooked or foliated eatable pod. 14. The *pea*, with red ſtriated flowers. 15. The field-*pea*, with a greeniſh yellow fruit. 16. The field-*pea*, with a white fruit. 17. The field-*pea*, with a green fruit. 18. The field-*pea*, with a grey fruit. 19. The field-*pea*, with a blue fruit. 20. The field-*pea*, with black fruit. 21. The field-*pea*, with roſe-coloured flowers and variegated fruit. And 22. The wild Engliſh ſea-*pea*. *Tourn.* Inſt. p. 394.

PIT (*Cycl.*)—*Brine*-PITS, the name given by the people of Worceſterſhire and Cheſhire, to the wells or *pits* affording the ſalt water, out of which they extract the ſalt.

Theſe waters, tho' they all contain ſalt, yet have other things alſo in them, and theſe not in ſmall quantity. They all contain a very large proportion of ſtony matter; this is common to the whole ſet, but particular ſubſtances beſide this are found in the particular *pits*. At Northwich in Cheſhire, there are four *pits*, the water of all which ſtinks very ſtrongly of ſulphur, and contains ſo much vitriol, that it will turn black like ink, with a decoction of galls; yet this is boiled into a very fine and pure kind of ſalt, common at our tables under the name of baſket-ſalt, and having no ſuch properties.

There is a vaſt quantity of ſtony matter precipitated from theſe pans of *brine* in the boiling them to ſalt; this is partly ſaved in ſmall pans ſet at the ſide of the boiler, and partly precipitates to the bottom of the pan, where it forms a cruſt like that at the bottoms and ſides of our tea-kettles, which the workmen find it neceſſary to remove every week; but there is no vitriol or ſulphur ſeparated. Phil. Tranſ. N° 150.

In the country near where theſe *brine-pits* are, the inſtruments uſed in boring often bring up fine and hard ſalt; ſo that they give proofs of there being rocks of ſalt in many places. All along the river Weever, on each ſide, the earth affords *brine* wherever it is opened: but all theſe are not fit for boiling, many of the *pits* affording a *brine* too weak to be worked to any advantage. The very ſtrongeſt *pits* ſometimes alſo become at once too weak; this is owing to the irruption of freſh ſprings into them, and ſometimes the river itſelf makes its way into them, and overflows them with ſuch a quantity of freſh water, that they are utterly ſpoiled. The *brine-pits* at Weſton near Stafford, afford a *brine* that ſtinks like rotten eggs; this turns inſtantly to ink with galls, and purges and vomits violently, if taken even in a ſmall quantity. This in boiling depoſits a white flaky ſand, or ſtony matter, without ſmell or taſte, and the ſalt is pure and fine.

The *pit* at Droitwich in Worceſterſhire, affords no ſand in the boiling, nor any the leaſt ſediment of the ſtony matter at the bottom of the pan, and the ſalt is the pureſt of all the others: and by the people of the country it is eſteemed the moſt wholeſome; becauſe of its being without the ſand. This and the other *pits* hereabout, all have the ſmell of rotten eggs, eſpecially after a little reſt, as on the Monday morning after the Sunday's reſt. If meat be put to pickle in the brine of theſe *pits*, inſtead of being preſerved it will ſtink in twenty-four hours, ſometimes in twelve, yet they yield the beſt ſalt of any inland *pits* in the world.

The ſulphur ſpaws of Yorkſhire, which are very numerous in different parts of the county, all ſtink violently of rotten eggs; but if well drawn and worked, they would prove as inoffenſive as the reſt, and only ſo many weaker or ſtronger brine *pits*; and the ſmell is no other than that of the Cheſhire and Staffordſhire brine, when it has been left ſome time at reſt. It is remarkable, that tho' the ſtony matter is depoſited in ſuch vaſt plenty by the waters of all our ſalt ſprings, it is not found in any abundance in thoſe places where ſalt is made out of ſea ſand, as in Lancaſhire and ſome other places; ſo that it is much more than the natural quantity of ſpar contained in water that is thus depoſited; and indeed it appears from trial, that the brine of our ſalt ſprings, in general, contains more than twenty times the quantity of ſpar that common water does.

This ſtony matter ſeparates itſelf from the water before the ſalt does, and thus it appears in many other waters impregnated with mineral particles. The vitrolic waters all contain ochre and ſalt, and in all theſe the ochre ſeparates itſelf firſt in the boiling, and then the vitriol; and the ſtony matter precipitated from common ſalt ſprings affords, on an analyſis, the ſalt called *nitrum calcarium*, in conſiderable abundance. Phil. Tranſ. N° 156.

PIT-*fiſh*, or PIT-*viſch*, in zoology, the Dutch name of an Eaſt Indian fiſh, approaching very much to the nature of the European turdus, but that it has no ſcales. Its body is not flat but rounded, and is variegated with blue and yellow ſpots; its eyes ſtand very prominent, and the fiſh is able, at pleaſure, to thruſt them out or draw them in; its back-fin is prickly. It loves muddy and foul places, yet is a very well-taſted fiſh. *Ray*'s Ichthyogr. Append. p. 6.

PITANGUAGUACU, in zoology, the name of a Braſilian bird of the ſtarling kind, called by the Portugueſe there the *bemetre*. It is of the ſize of the common ſtarling; its beak is long, thick, and of a pyramidal figure; its head broad and flatted; its neck ſhort, which as it ſits it contracts alſo, ſo as to make it appear much ſhorter; its legs and feet are of a duſky brown; it has a very loud and ſhrill voice; its head, neck, back, wings, and tail, are all of a browniſh black, with a faint admixture of green; the lower part of the throat, the breaſt, and the belly, are yellow, the upper part of the throat white; its beak is very ſharp-pointed. *Marggrave*'s Hiſt. of Braſil.

PITCH (*Cycl.*)—The antients had a peculiar kind of *pitch* called *brutia*, which was inſpiſſated to a higher than ordinary degree for certain uſes; ſuch as the receiving a proper quantity of bees wax, to render it the zopiſſa uſed in coating the bottoms of ſhips; which the common *pitch* could not do, being of too ſoft a conſiſtence for this uſe. Pliny tells us, that it was made in this manner: The wood was cleaved and formed into a pile, with proper trenches cut in the earth to receive what run from it in burning. When the pile was lighted, the firſt thing that flowed into theſe trenches was a thin fluid liquor like water. This, he ſays, was called *cedrium* in Syria, and was uſed in Egypt in the preſerving dead bodies. The next liquor that ran out from the pile, he ſays, was thicker, and was *pitch*; and that a part of this was afterwards boiled in braſs veſſels, with an admixture of vinegar, and then became very ſolid and hard, and was called by this name of *brutia*.

However right this author may be in his account of the *brutia*, it is evident that he errs in making the firſt runnings of the wood the *cedrium*; for this was peculiarly the name of the tar of the cedar; and as there are plenty of turpentine trees in Syria, and the *pitch* and tar of that country were always made of thoſe trees, it is very improper to give the name *cedrium* to it: no one ever called the turpentine and cedar by the ſame name; nor is there any reaſon why their products ſhould be thus confounded. Vitruvius is very expreſs in aſcertaining the ſenſe of the word *cedria* to the produce of the cedar; he ſays, that the cypreſs and pine yield their ſeveral fat juices or reſins, and that the cedar in like manner yields its oil; which is thence called *cedrium*, or *cedria*, and has ſo much of the peculiar virtues of the wood, that it preſerved books and other things, on which it was rubbed, from being eaten by worms.

This author, however, tho' he diſtinguiſhes the product of the cedar from that of the cypreſs and pine, yet he confounds together the two ſubſtances, called by the Greeks *cedrium* and *cedrelæum*. The *cedrium* was properly the *pitch* of the cedar; this was the hard ſubſtance produced by burning the wood; but the thin liquid ſubſtance called *cedrelæum*, which was the only thing that could be uſed for rubbing over books, *&c.* was an oil ſeparated from this *cedrium*, or *pitch* of the cedar by melting.

PITCH *of Caſtro*, in the materia medica, the name given by Boccone and ſome other writers, to a thick kind of bitumen found iſſuing out of the cracks of ſome rocks near the village of Caſtro; from whence it has its name: it is famous in the eccleſiaſtical ſtate for its medicinal virtues. *Boccone* Muſ. de Fiſci.

PITCH is alſo uſed by architects and builders, for the angle which a gable-end, and conſequently the whole roof of a building is ſet to. If the length of each rafter be $\frac{3}{4}$ of the breadth of the building, then they ſay that roof is of a *true pitch*; but if the rafters are longer, they ſay 'tis a *high* or *ſharp-pitched roof*; if ſhorter, they call it a *low* or *flat-pitched roof*.

PITCHED, in the ſea language. They ſay the maſt is *pitched*, when it is put or let down into the ſtep; alſo the maſt is *pitched* too far aft, when placed too near the ſtern.

PITH, (*Cycl.*) in vegetation, the ſoft ſpungy ſubſtance contained in the central part of plants and trees. As the ſubſtance of the trunk in trees become more woody, the *pith* is compreſſed and ſtraitened to ſuch a degree, that it wholly diſappears.

It is plain from this, that the office of the *pith* in vegetation cannot be very great, ſince it is not of perpetual duration. By its ſpungy ſtructure, it ſeems fitted to receive any ſuperfluous moiſture that might tranſude thro' the pores of the woody fibres. If by the exceſs of ſuch moiſture, or from any other cauſe, it happens to rot and periſh, as frequently happens in elms, the tree is found to grow fully as well without it; a proof it is of no eſſential uſe in vegetation. *Boerhaave*'s Chem. p. 139.

The *pith* of trees is continued farther into their minute parts than is generally conceived; the ſmalleſt branches and pedicles of the leaves and flowers have their ſhare of it, according to the nature of the tree they belong to; and even the middle ribs of the leaves, when examined by the microſcope, are not without it: a tranſverſe ſection of one of theſe ribs of the leaf of a *pithy* tree, ſhews a very beautiful arrangement of veſſels, or little bladders, containing a quantity of clear liquor, and reſembling in all reſpects thoſe of which the *pith* in the branches is compoſed. The *pith* in theſe is not round, however, as in the others, but flat, and runs from one end of the pedicle to the other, in form of a thin white rib, gradually leſſening to a point.

The *pith* of plants, in fine, ſeems what the marrow is in animals, a congeries of an infinite number of veſicles, which

ſeem deſtined to ſeparate a finer juice than is neceſſary for the nouriſhment of the coarſer parts of the tree. It is obſerved of plants which have a larger than ordinary ſhare of *pith*, that they produce larger quantities of flowers than others; inſtances of this are ſeen in the roſe, the lilac, and the common elder: and in the ferulaceous plants, the quantity of flowers is not only profuſely large, according to the great quantity of *pith* in their ſtalks, but the *pith* ſeems carried up the ſtalks all the way to the ſeeds themſelves; the long ſeeds of the ſweet myrrhis, and other the like plants, while not ripe, being only *pith*. Mem. Acad. Scienc. 1709.

PITHECALOPEX, the *ſemivulpa*, or *ape-fox*, a name given by Aldrovandus and ſome others, to that ſtrange American animal which we call the *opoſſum*.

The name is compounded of that of the *fox* and the *ape*; of the natures of both which animals it is ſuppoſed by ſome to participate. See the article OPOSSUM.

PITHIAS, or PITHITES, with ſome writers, a ſort of comet, or rather meteor, in form of a tub. Of theſe it is ſaid there are divers kinds, *viz.* ſome of an oval figure, others like a tun or barrel ſet perpendicular, and ſome like one inclined, or cut ſhort off; others having a hairy train or buſh, *&c.*

PITHYUSA, in botany, a name uſed by many authors for a ſmall ſpecies of ſpurge. See the article TITHYMALUS.

PITUINA, in the materia medica, a name for the reſin of the pitch-tree.

PITYIDES, a name uſed by ſome authors for the kernels incloſed in the cones of the fir or pitch-tree; they are recommended by the old phyſicians, in diſorders of the breaſt.

PITYLISMA, a name of one of the exerciſes preſcribed by the antient phyſicians, as of great ſervice in chronic caſes. It conſiſted in a perſon's walking on tip-toe, and ſtretching his hands as high above his head as he could, keeping the whole body alſo as much upon the ſtretch as might be. In this condition the patient was to walk as far as he was well able, all the while moving about both hands as much as he could, in all directions.

PITYRIASIS, a name given by the antients to a ſcurfy diſorder of the head and eye-brows, and of any other part where there is hair. It makes the ſkin ſeem as if covered with bran, and is attended with a troubleſome itching.

PIVA, in the Italian muſic, a hautboy, or a cornet. See the articles HAUTBOY and CORNET, *Cycl.*

PLACAGNODIAUGIA, in natural hiſtory, the name of a genus of ſpars.

The word is derived from the Greek πλαξ, a cruſt, ἀγνὸς, pure, and διαυγὴς, pellucid.

The bodies of this genus are cryſtalline terrene ſpars, or ſparry bodies with much of the brightneſs and tranſparence of cryſtal, but debaſed by an admixture of earthy matter, and are imperfectly pellucid, and formed into thin plates with flat ſurfaces, but covered at times either in part or entirely, with tubercles or botryoide prominences, and are compoſed of arrangements of oblong concretions, of no determinately angular figure.

Of this genus there are only two known ſpecies, tho' theſe vary ſo much at times in figure, that they might lead an inaccurate obſerver into imagining there were many diſtinct ſpecies of each. 1. A hard ſemi-pellucid and yellowiſh brown one. This is found in many parts of England; in ſome places encruſting over the ſides of fiſſures of ſtone, and in others coating over vegetable bodies in ſprings, *&c.* 2. A brittle pellucid and whitiſh one, found on the ſides and tops of our ſubterranean caverns on Mendip hills and elſewhere, and in form of a roundiſh ball, ſeemingly compoſed of threads, in the neighbourhood of Eſperie in Hungary. *Hill*'s Hiſt. of Foſſ. p. 342.

PLACAGNOSCIERIA, in natural hiſtory, the name of a genus of ſpars.

The word is derived from the Greek πλαξ, a cruſt, ἀγνὸς, pure, and σκιερὸς, opake.

The bodies of this genus are dull and opake cryſtalline terrene ſpars, formed into cruſts, and of an irregular and not ſtriated texture within.

Of this genus there are three known ſpecies: 1. A hard whitiſh brown one, found very frequently on the roofs and ſides of caverns on Mendip hills, and in other parts of England. 2. A dull crumbly whitiſh one, found in many parts of England, encruſting the ſides of caverns, and of fiſſures of ſtone. And 3. A dull pale brown friable one, of a very coarſe texture. This is the moſt common of all the bodies of this genus, and is found in variety of forms, among others encruſting the ſides and bottoms of our tea-kettles, and other veſſels, in which water is frequently boiled. *Hill*'s Hiſt. of Foſſ. p. 346.

PLACE *(Cycl.)*—*Place* is uſed in the doctrine of artificial memory: and theſe *places* may be either ſuch in a proper ſenſe, as a door, a window, a corner, *&c.* or familiar and known perſons; or any other thing at pleaſure, providing they be placed in a certain order, animals, plants, words, letters, characters, hiſtorical perſonages, *&c.* tho' ſome of theſe are more and ſome leſs fit for the purpoſe; but ſuch kind of *places* greatly help the memory, and raiſe it far above its natural powers. *Bacon*'s Works Abr. Vol. II. p. 474, 475. See the article MEMORY, *Cycl.* and *Suppl.*

PLACE-*bricks*. See making of BRICK.

PLACENTA *(Cycl.)*—The *placenta* has generally been looked upon as an original part among the ſecundines; but according to Dr. Thomas Simſon of St. Andrews, it ſeems to have no place in the ovarium, nor in the uterus, till once the ovum becomes contiguous to the fundus, and then every contiguous part becomes really a *placenta*. He thinks the fundus uteri, a place peculiarly fitted for the growth of the *placenta*, as proper ſoils encourage the growth of the roots of trees and ſhurbs, many of which are propagated by the branches however placed; ſo that every part of them ſeems equally fitted to be root or branch. Hence he thinks extra uterine conceptions can have no *placenta*; and he ſays, there are no inſtances in authors to contradict his opinion. See Med. Eſſ. Edinb. Vol. IV. Art. 13.

The *placenta* does not increaſe in the ſame proportion which the fœtus does: for the ſmaller the fœtus is, the *placenta* is proportionally larger. *Monro*, in Med. Eſſ. Edinb. p. 145. from *Ruyſch*.

The *placenta* generally adheres to, or near the fundus of the womb, and is covered on the ſide next to the womb, with a fine membranous continuation of the chorion. Vid. *Monro*, Medic. Eſſ. Edinb. Vol. II. p. 128. and the authorities there quoted.

The ſeparation of the *placenta* from the womb muſt produce abortions, and this may be occaſioned by different cauſes operating in various manners, and requires very different treatment to prevent the loſs of the fœtus. See *Monro*, in Med. Eſſ. Edinb. Vol. II. Art. 11. or it's Abridgment, Vol. I. p. 338, ſeq.

PLACENTA, in botany, a term improperly given by Mr. Houſton, in the Philoſophical Tranſactions, N° 421, to what is uſually called *receptacle*. See RECEPTACULUM *ſeminum*.

PLACENTA, in natural hiſtory, the name of one of the claſſes of the echini marini. The characters of theſe are, that they are of a depreſſed or flatted form, and are wrought in various ſhapes, as the paſtry people make their cakes; they all have a cinquefoil flower at their top, and their mouth is in the middle of the baſe; the aperture for their anus is uſually near the edge. See Tab. 8. N° 9, 10.

Of this claſs there are three genera: 1. The *mellita*. 2. The *laganum*. And 3. The *rotula*. Which ſee under their ſeveral heads. *Klein*'s Hiſt. Echin. p. 30.

PLACENTA, among the antients, a kind of cheeſe-cake, the moſt ſimple kind of which was made of flower mixed with oil and cheeſe, to which honey was added: but the more luxurious ſort of people added likewiſe a great variety of herbs and fruits, as alſo ſugar, eggs, butter, *&c.* *Pitiſc.* Lex. Antiq. in voc.

PLAGIAULOS, πλαγιαυλος, among the antients, a kind of flute.

PLAGIOPLATEUS, in natural hiſtory, a term uſed by Artedi and others to ſignify depreſſed, in oppoſition to the term *cathetoplateus*, which ſignifies compreſſed. See both explained under the article CATHETOPLATEUS.

PLAGIURI, in natural hiſtory, the name of one of the great claſſes, or families of fiſhes. The characters of which are, that the tail is placed horizontally. They reſpire by means of lungs, and have uſually a double fiſtule in the head. They are viviparous, and the males have a penis and teſtes, the females the vulva, ovaria, mammæ, *&c.* and they bring up their young with milk.

The term is derived from the Greek πλαγίος, tranſverſe, and οὐρὰ, a tail. Vid. *Artedi*, Gen. Piſc. *Linnæi* Syſtema Naturæ, p. 31.

PLAGUE *(Cycl.)*—Dr. Dover ſays he cured the *plague* among ſome ſailors, in a voyage, by one very plentiful bleeding to the quantity of an hundred ounces, and with drink ſharpened with ſpirit and oil of vitriol. Med. Eſſ. Edinb.

PLAIN *(Cycl.)*—PLAIN *ſurface*, in geometry, that which lies evenly between its bounding lines; and as a right line is the ſhorteſt extenſion from one point to another, ſo a *plain ſurface* is the ſhorteſt extenſion from one line to another.

PLAISE, in ichthyology, the Engliſh name for the fiſh called by authors *plateſſa* and *paſſer lævis*, by ſome *quadratulus*.

It is, according to the Artedian ſyſtem, a ſpecies of the pleuronectes, and is diſtinguiſhed by that author by the name of the *pleuronectes* with ſmooth ſides, and with a ſpine near the anus, and the eyes and ſix tubercles placed on the right ſide of the head. This name carries a diſtinctive character with it; and it were to be wiſhed that we had ſuch names in common uſe among authors for all the fiſh that are known to us. See PLEURONECTES.

PLAN *(Cycl.)*—PLAN *of a baſtion*, in the military art, is the ſame with the face of a *baſtion*. See FACE.

PLANE-*tree*, *platanus*, in botany, the name of a genus of trees, the characters of which are theſe: The flower is of the amentaceous kind, and is of a glomerated ſhape, and compoſed of a great number of ſtamina with their apices. Theſe flowers are barren, and the embryo fruits are found on other parts of the plant; theſe finally become larger, and contain ſeveral ſeeds winged with down.

The

The ſpecies of *platanus*, enumerated by Mr. Tournefort, are theſe: 1. The true oriental *platanus*. 2. The occidental or Virginian *platanus*. *Tourn.* Inſt. p. 590.

PLANKS, in a ſhip, are the timbers which go fore and aft on each ſide of the ſhip, whereon lie the beams of the firſt orlop.

Garboard PLANK, in a ſhip. See GARBOARD.

PLANT *(Cycl.)*—The greater the degree of heat given to *plants* to a certain degree in the natural way, the ſooner they go through the whole buſineſs of their fructification. In the northern regions, where there are but a few ſummer months, the herbs all are ripened in them in a ſurprizing manner: in Lapland, for inſtance, where the greater part of the year is ſubject to intenſe and inceſſant froſts, and for a conſiderable time to the entire abſence of the ſun, the ſummer ſeaſon affords an exceſſive heat for two months, the ſun never ſetting in all that time. This ſeaſon comes on toward the latter end of June, and the graſs and other herbs then firſt begin to appear in their young ſhoots above the ground, and the trees bud; but all vegetation is, after this, carried on with ſuch ſpeed, that in a fortnight the flowers of the herbs and trees are expanded, and the leaves of their full ſize and maturity. *Scheffer*'s Hiſt. Lapon.

The virtues of *plants* are very variable; a change of climate will alter or deſtroy them, as we ſee in many of the medicinal *plants* of other countries, brought over hither, which, tho' they ſeem to flouriſh with us, never poſſeſs their virtues in the ſame degreee as in their native climate. The bodies of different animals alſo render the effect of the ſame *plant* different: the tithymals or ſpurges are all of them very violent cathartics, when taken by us; but yet they are eaten by goats and ſeveral other animals without hurt, or without any purgative effect, and ſeem to give them a particular ſhare of vigour and ſpirits. The fiſh are, on the other hand, more ſtrongly affected by it than we are; for the juice made into paſte with flower and honey, poiſons, or at leaſt intoxicates them ſo, that they may be taken out of the water with one's hand. Bitter almonds are of no ill conſequence to us, yet they kill all ſorts of birds. *Deſlande*'s Trait. Phyſiq.

Imperfect PLANTS, in botany, a name given to thoſe *plants* which ſeem to want both flower and ſeed. Theſe were once a very large tribe of *plants*, but the more accurate obſervations of the moderns have proved, that the moſt of theſe *plants* really contained ſeeds, and thoſe very numerous, tho' ſo ſmall as not to appear obvious to the naked eye: and probably the farther diſcoveries of the microſcope will in time leave us no one *plant* deſerving the appellation of *imperfect*. In Mr. Ray's time, many whole genera of *plants* were eſteemed imperfect; but he includes the ſeveral kinds he calls ſo, under three general heads: 1. The ſubmarine. 2. The funguſes. And, 3. The moſſes. Tho' many of all theſe kinds have by later authors been ſhewn to have true ſeeds, and it is ſcarce to be doubted of the reſt. *Ray*'s Synopſ. Stirp. Brit. p. 1.

Flowering of PLANTS. See the article FLOWERING.

Analyſis of PLANTS. The common method of attempting the *analyſis of plants*, by common diſtillations, gave hopes that it would prove very uſeful in determining their virtues; but experiment ſhewed it to fail of this intent, ſince the wholeſome *plants* and the poiſonous ones afforded by this means much the ſame ſort of principles; and on the whole, theſe appeared in a great meaſure to be creatures of the fire rather than parts of the ſubject. This ſet Mr. Boulduc of the Paris academy upon trying, whether there might not be ſome way invented at once more ſimple and more certain; and with this view he attempted to examine the juices and decoctions of ſeveral *plants*, to find their eſſential ſalts, which had not been procured in their natural ſtate by the chemical trials. The *plant* this gentleman choſe as the ſubject of his experiments in this view, was the common borage.

Firſt, he made a large quantity of a decoction of borage; this he divided into three equal parts: the firſt of theſe he evaporated to a pellicle, or to the conſiſtence of a ſyrup; it was then of a blackiſh colour, and was charged with a great quantity of oily particles. This being ſet by for ſome days in a warm time of the year, covered itſelf with a thick ſkin, which was again covered by a mouldineſs. When this ſkin was removed, there appeared underneath a large quantity of chryſtals, in fine ſlender filaments like needles, mixed among a large quantity of other cryſtals, which were ſmall, and of no regular figures; all theſe were ſwimming in a liquor of the thickneſs of a ſyrup. Theſe long cryſtals being taken out of the liquor, and laid upon a hot iron, took fire, and flamed in the manner of ſalt-petre when mixed with any ſulphureous ſubſtance; and, in truth, this was a ſalt-petre, yet loaded with the oily matter of the decoction.

Here, therefore, is a clear proof, not only of the nitrous acid being in this plant, but of plain nitre itſelf; for, on pouring oil of tartar on a ſolution of this ſalt, there was no precipitation made of any ſubſtance whatever; which would have been the caſe, had there been in this ſtate any earthy matter for its baſis.

The ſecond portion of this decoction was diveſted of its oil by means of lime, and then evaporated to a light pellicle over a very gentle heat. This was ſet by to reſt for ſome days, and finer and more perfect cryſtals were found, ſhot in the form of needles in it: theſe were truly nitrous, and occupied the upper part of the liquor; below theſe there were a great number of other cubic ones, which were eaſily known to be cryſtals of ſea ſalt.

The long cryſtals of this operation took fire on a lighted charcoal, and appeared plain nitre; and the others, when dry, crepitated in the fire exactly in the manner of ſea ſalt: and when a ſolution of them was poured upon a ſolution of ſilver, made in ſpirit of nitre, it immediately occaſioned a white curd to appear, which being ſeparated, waſhed, and put to the fire, became a true luna cornea, being tranſparent and eaſily cut with a knife. Here, therefore, are plain proofs of nitre and ſea ſalt in this *plant*. Mem. Acad. Scienc. Par. 1734.

The third portion of the decoction was poured upon ſome freſh wood aſhes, and being afterwards evaporated to a pellicle, and ſet by for ſome days, there was found in this more nitre than in any of the others; and that whiter and more clear, the others being uſually coloured browniſh or reddiſh by the decoction. The occaſion of this ſeems to be, that part of the nitrous acid, which in the other experiments neither joined with any earthy matter, nor with the fatty matter of the decoction, mixed with the ſalts of the lixivium, made by pouring the liquor which contained it on wood aſhes, and thus yielded a much larger quantity of ſaltpetre than before.

The fatty ſubſtance which covered the firſt decoction being dried, was found to contain a great quantity of nitre, which it had not ſuffered to ſhoot, or form itſelf into cryſtals: this dried cruſt being laid on a burning charcoal, took fire in the ſame manner as if nitre and powder of charcoal had been thrown into a crucible made red hot.

The ſalts of the *plant* being thus obtained from its decoction, it was determined to try whether the *plant* remaining after the decoction had any more to yield. To try this, it was gently dried in a ſhade, and burned in a covered veſſel to a black coal, and afterwards, in an open fire, to aſhes.

Of theſe aſhes there was made a lixivium in the common way, in order to be evaporated for the ſalt: this lixivium being mixed with ſyrup of violets, ſcarce at all altered it from its blue colours, only juſt bringing on a faint greeniſhneſs, which ſoon went off again, and left the ſyrup of as fine a blue as before; this made it evident, either that there was very little alkali ſalt there, or elſe that it was blended with ſalts of ſome other kind, which altered its effects: and this proved to be the true ſtate of the matter on farther experiment, for, evaporating the lixivium to a pellicle, there very ſoon ſhot in it regular and beautiful cryſtals of a ſalt, having all the characters of tartarum vitriolatum. A ſecond evaporation of the lixivium afforded more of the ſame ſalt, but in ſmaller cryſtals. Evaporating the liquor to about half its quantity, and ſetting it again to ſhoot, there appeared plain cubic cryſtals of ſea ſalt; which being ſtrictly examined, were found to be perfect ſea ſalt, no way altered, but having ſtood the force of the calcination.

After theſe ſalts had been ſeparated from the lixivium, it changed ſyrup of violets immediately to a beautiful green, which colour it always retained.

It is evident from theſe experiments, that this *plant* affords four different kinds of ſalts, *viz.* nitre, ſea ſalt, tartarum vitriolatum, and the common fixed alkali; and it is hence no trivial obſervation, that the three mineral acids are found here all in one *plant*. It is not to be ſuppoſed, indeed, that the tartarum vitriolatum was actually in the *plant* in that form, but it is very evident, that the vitriolic acid did always exiſt there, ready to form it; but that being, before the calcination, enveloped in the oily matter of the *plant*, it was not eaſy to diſcover it either by its properties or effects: but as ſoon as the oil was diſſipated by fire in the calcination, the vitriolic acid immediately became free, and finding the alcaline ſalt of the *plant*, or its fixed nitre, which had remained after the deflagration, it immediately united with it, and formed a tartarum vitriolatum in the ſame manner as a tartarum vitriolatum may be made from ſalt of tartar and common ſulphur, after the oily or inflammable part of the ſulphur is burnt away.

It is not only this *plant* that yields a vitriolated tartar from a lixivium with its aſhes, but great numbers of others of the aromatic and bitter kinds: whence it appears, that the vitriolic acid, tho' the moſt fixed of all the mineral acids, yet raiſes itſelf into the juices of a great number of *plants*; and on the reſult of great numbers of experiments, it appears, that there are very few *plants* which yield a pure alkaline ſalt, perhaps ſalt of tartar is the only perfectly pure known alkali of this kind, which retains no portion of any other ſalt.

Aſhes of PLANTS. The aſhes of a *plant* carefully prepared, retains its exact form till diſturbed by accidents. The way of preparing them is this: Take a whole *plant* which has been uſed for the diſtillation of the oil, water, *&c.* lay it evenly upon a flat plate of iron, and place this on a clear fire, that no ſmoak may prevent the ſucceſs of the operation; continue and raiſe the fire, till the whole ſubſtance of the *plant* appears perfectly ignited. There firſt ariſes a light ſmoak from it, this gradually becomes darker, and at length as black as pitch; the ſmell of burning increaſes as the ſmoak increaſes, at length the ſmoak breaks out into flame, and then the ſmell in a great mea-

meaſure ceaſes: the *plant* by degrees grows black, as the ſmoak ariſes, and as ſoon as perfectly black all over, it takes fire. When the flame ceaſes, the leaves appear white; but if any black ſpots remain, there are always ſeen ſparks of fire ſcattering themſelves about on them, till the blackneſs is perfectly conſumed. The aſhes being now become perfectly white, yield no ſmell nor the leaſt appearance of fire; and they yet retain, after all this violence of fire, the perfect form of the *plant*, even to a microſcopic obſervation: for, if examined by glaſſes, there will be found every feature and lineament of the *plant*, even the hairineſs of the ſtalks, or down upon the leaves; every riſing and cavity natural to the plant, appear alſo diſtinct, and every the ſmalleſt fibre. But this only remains while they are unmoved, the moment they are diſturbed, tho' but by breathing upon them, the whole falls to duſt, and the form is irrecoverably loſt.

The aſhes thus carefully prepared, are perfectly inſipid and ſcentleſs, and when lixiviated in the common way for making the fixed ſalt, afford no ſalt at all; but only on the evaporation leave a ſmall quantity of a matter reſembling lime: the remaining aſhes are wholly terreſtrial, and ſerve excellently for the making copels, for the uſe of aſſaying. *Boerhaave*'s Chem. P. 2. p. 19.

From this we learn, that the *plant*, by having been previouſly boiled in water in the diſtillation, was diveſted of all its ſalts; and that in general, water, with a great degree of heat, is capable of extracting from any vegetable all its ſaline particles, whether volatile or fixed. We find, however, that water can never ſeparate the fixed oil, which here ſhews itſelf to have wholly remained in the *plant*, by the ſmoak, ſmell, and flame it yields; and by the ſparks of fire in the remaining black parts of the *plant*, which were wholly owing to the remains of this oil, no fire being able to make the ſmalleſt ſpark afterwards appear in the aſhes.

Air, as well as fire, is neceſſary to this oil's taking flame; for in a covered veſſel it will not blaze till the cover is taken off.

This thick oil is extremely different from what we call the eſſential oil of a *plant*, and ſeems to be the ſame in all vegetables; and to this they owe their coheſion: while the eſſential oil and ſalt are extracted from the *plant* by boiling, it yet holds together in its native figure and ſtrength; but as ſoon as the black oil is diſſipated by burning, the whole firmneſs of the *plant* is loſt, and a breath of air blaſts it to duſt.

Salts of PLANTS. It has been obſerved by all who have examined the different eſſential *ſalts of plants*, that ſome of them, when thrown on the fire, have the effects of ſalt-petre, and others of common ſea-ſalt; and it has been concluded from hence, that they really contained particles of thoſe ſalts which their roots had taken in with their nouriſhment, and conveyed up into the ſtalk and leaves with the juices; and that theſe ſalts ſtill retained their original nature, and were no otherwiſe altered than by the mixture with other ſubſtances in the plant. But as two plants of different qualities, when ſet in the ſame earth cloſely by one another, ſhall out of the ſame juices make a medicine, a ſallad, or a poiſon; it cannot be, but that the ſubſtances abſorbed by the root, be they what they will, muſt be greatly altered in the plant; inſomuch, that a ſalt purely nitrous, when received into the root, might become of the nature of ſea ſalt, or of the volatile urinous kind, according to the different organs of the plants, and the different natural fermentations it might meet with there. To be perfectly informed of this, Mr. Homberg made the following experiment:

He took a large quantity of rich black garden mould, and waſhed it in ſeveral waters, to carry off all the ſalts it might contain: this done, he divided the earth into four boxes or caſes of wood, into each of which there was put about two hundred weight. Two of theſe caſes of earth he watered with a ſolution of ſalt-petre, ſo as to make each imbibe about two ounces of that ſalt; the other two caſes were left with the earth inſipid as the waſhing had made it, and care taken to water them with none but perfectly pure water, ſo that they might remain as ſimple as poſſible. In one of the caſes of nitrous earth, and in one of thoſe of ſimple earth, he ſowed fennel; and in the other two, garden creſſes.

The herbs in all the caſes grew very well, and when they were grown to about eight inches high, they were all gathered; and when the roots were cleanſed, and the whole product weighed, thoſe plants which had grown on the ſimple earth weighed twenty-five ounces, and thoſe in the nitrous earth twenty-ſix; their ſmell and taſte manifeſted no ſort of difference in either. In order to examine theſe plants, while yet quite freſh, by means of fire, he put a pound and an half of each, with their roots, into a retort of glaſs: he placed theſe retorts firſt in a balneum mariæ, and then in a ſand-heat, in order to drive over all the aqueous humidity. The quantity of water from each retort was within a few grains of the ſame weight; and from the beginning to the end of the diſtillation, there was not the leaſt appearance of any acid.

After this, the creſſes which had grown in the inſipid earth, yielded a drachm of volatile ſalt; and that which had grown in the earth which had imbibed ſalt-petre, yielded ſeventy-five grains.

The oil of each was very nearly the ſame in quantity; that from the plants in the ſalt-petre earth weighing ſix grains more than that of the plants of the inſipid earth.

The lixivial ſalt was two drachms from the plants in the nitrous earth, and one drachm and ſixty-ſeven grains from thoſe in the inſipid.

The differences between thoſe two parcels of plants upon the analyſis, appeared on the whole ſo little, that it could not be counted any thing; ſince the more or leſs cloſe luting of the veſſels, or many other accidents in the diſtillation, might have eaſily occaſioned as much in plants perfectly the ſame in all reſpects. If there be any thing, however, to be collected from the experiment, it is, that the earth moiſtened with a ſolution of nitre, yielded more of the principles than the other; probably from its actually affording a quantity of ſalt to the juices of the plant in the growth: but as the nitrous earth afforded a plant which yielded more oil than that from an inſipid ſoil, it muſt be from this that the lotions of the earth not being able to carry off any of the fatty parts, they remained in the ſame quantity in both; but that the nitre, where it was, had contributed ſomewhat to the breaking of them, and the rendering them more fit to be abſorbed by the plants. From the different weights of the plants when gathered, after the ſame time of growth, from the ſame ſeed, and with all the ſame advantages in common, proves, that the nitrous ſalts in the earth are not eſſentially neceſſary to vegetation, ſince the *plants* in the inſipid earth grew very well without them; yet that they are very uſeful, ſince the *plants* produced there were of a greater bulk, and according to the whole analyſis, if the differences are to be depended on as reſulting wholly from the nature of the ſubjects, they yielded more of all the active principles; and therefore, that they were to all purpoſes better *plants*.

The fennel in theſe boxes was not gathered with the creſſes, but left till it began to bud for flowering: at this time there was found a very great difference, both in the ſize and appearance of the *plants* of the two ſorts of earth. That in the inſipid earth was lank, weak, and of a yellowiſh green; and being gathered, weighed only nineteen ounces: whereas the fennel growing on the nitrous earth ſeemed in a very vigorous ſtate, its leaves were of a dark green, and it weighed full two pounds. Mr. Homberg weighed nineteen ounces of each of the *plants* freſh, and with their roots, to make the analyſis of them in the ſame manner as he had before done that of the creſſes. In the firſt diſtillation the water began to taſte acid in the firſt drops, and continued to increaſe in acidity as long as it ran; and the inſipid earth left by the fennel which grew in the nitrous earth, was an ounce more in weight than the reſiduum of the *plant* which had grown in the inſipid ſoil. That of the nitrous earth yielded one drachm and twelve grains of oil; that in the inſipid, only ſixty-three grains: neither one nor the other yielded any volatile ſalt, only the laſt ounce of the aqueous liquor made ſome little efferveſcence. The firſt ſalt was in the quantity of three drachms from he fennel of the nitrous earth, and two drachms and ten grains from the inſipid earth.

The *plants* had appeared above ground in the ſame time from their ſeeds in the nitrous and in the inſipid earth, and grew equally vigorous and well for a month; but after that time, tho' both were watered in the ſame manner, and the ſame care in all reſpects was taken of them, the *plant* on the inſipid earth became languid, and that on the nitrous earth continued to grow vigorouſly and well.

It ſeems that in the firſt ſtages of the growth of the *plants*, the two lobes of the ſeed furniſhed a proper nouriſhment to the ſtalk and leaves, and required no more than mere water, a pure ſimple fluid to divide its parts and carry it up from the root; but that when theſe lobes were wholly conſumed, and the *plant* was to find its whole nouriſhment in the earth, there an earth rendered inſipid by the carefully waſhing away all its ſalts, could not ſupply a proper and ſufficient nouriſhment, but that an earth, after it had been made to imbibe a certain portion of nitre could: whence the fennel in the inſipid earth could not continue to grow vigorouſly, after the lobes of the ſeed were deſtroyed, tho' that in the earth impregnated with an adventitious ſalt could.

It is true, indeed, that the *plant* in the inſipid earth did not entirely periſh, and it is reaſonable to conclude thence, that all the waſhing we can give with hot water cannot diveſt earth of all its ſalts, but only of thoſe which are moſt eaſily ſoluble; whence it takes away not all, but only the principal fund of nutrition. All the waſhings in the world muſt alſo leave earth impregnated with all the fatty particles it ever had, and theſe are very inſtrumental to the growth of *plants*; but theſe, without ſome ſalts, ceaſe to be of their proper uſe, ſince they cannot be broken or divided into parts ſmall enough to enter

the

the veſſels of *plants*, otherwiſe than by theſe ſalts. Mem Acad. Par. 1693.

It is very obſervable, in the courſe of theſe experiments, that the creſs, tho' planted in an earth containing ſalt petre, which is well known to be an acid ſalt, yet yielded, on the analyſis, alcaline principles, and not the leaſt mark of an acid in any part of the proceſſes, and this juſt in the ſame manner as if it had grown upon an earth impregnated with dung; and that the fennel, whether growing on the nitrous earth, or on the inſipid, afforded a large quantity of acid in all its principles, not excepting even its fixed ſalt, which was very little of the alkali; and by the mixture of the acid of the plant was converted almoſt into the nature of a neutral ſalt. Hence it appears that a ſalt, tho' acid in itſelf when abſorbed into the veſſels of an alkaline *plant*, ſuch as the creſs, ceaſes to be any longer an acid; and that a *plant* naturally acid, whether it grow in an earth impregnated with an acid ſalt, or wholly diveſted of ſalts, yet it retains its acid nature, and gives proof of it in all its principles on an analyſis; whence it is very reaſonable to conclude, that the ſalts found in *plants* are made what they are in thoſe *plants*; and that the ſalts of the earth, in which the *plant* grows, be they of what nature they will, will change that nature in the veſſels of the *plant*, according to the diverſity of its organs, and of the different fermentations they undergo in the courſe of their alteration there.

The weights above mentioned are French, the word *gros* being tranſlated drachm, tho' really exceeding it by twelve grains. See WEIGHT, *C. cl.*

Tracheæ of PLANTS See the article TRACHEÆ *of plants.*

Tranſportation of PLANTS. See TRANSPORTATION *of plants.*

PLANTS *in Amber*. The cabinets of the curious afford numerous inſtances of ſmall animals, ſuch as flies, beetles, and the like, buried in *amber*; but the parts of *plants* are more rarely found thus preſerved; yet we are not without inſtances that the ſame accident may happen to them. The learned Hartman mentions a piece of *amber* in his own poſſeſſion, in which there were preſerved ſome leaves of the common alga, and another in which a ſeed of the common lime-tree, with part of its pedicle, and others in which the capſule with its ſeeds and pedicle were preſerved; the pedicle ſtanding out at the end of the piece of *amber*.

Some have given accounts of whole pinnated leaves of *plants* thus preſerved, and the moſſes are ſo common, that there is no doubt of the reality of their being naturally buried there. They are generally found only in ſingle leaves and ſmall fragments, but ſometimes in whole branches; in which caſe *amber* can ſhew no greater beauty. Pieces of ſtraws, ſticks, and the barks of trees are often found in it alſo; but the greater part of theſe, when ſtrictly examined, are found to be fragments of foſſile wood, or of the matter called by Hartman the *matrix* of *amber*; which is a fibroſe ſubſtance, and much of the appearance of wood, but is really only a bituminous earth. Theſe all muſt have been received into the *amber* in the ſame manner that the inſects were; that is, while the *amber* was yet moiſt or ſoft. Theſe things falling into its way might bury themſelves in it, and then muſt be preſerved in it in the hardened ſtate. See SUCCINUM.

Foſſile PLANTS. Many ſpecies of tender and herbaceous *plants* are found at this day, in great abundance, buried at conſiderable depths in the earth, and converted, as it were, into the nature of the matter they lie among; foſſile wood is often found very little altered, and often impregnated with ſubſtances of almoſt all the different foſſile kinds, and lodged in all the ſeveral ſtrata, ſometimes firmly embedded in hard matter, ſometimes looſe: but this is by no means the caſe with the tenderer and more delicate ſubjects of the vegetable world. Theſe are uſually immerſed either in a blackiſh flaty ſubſtance, found lying over the ſtrata of coal, or elſe in looſe nodules of ferrugineous matter of a pebble-like form, and they are always altered into the nature of the ſubſtance they lie among; what we meet with of theſe are principally of the fern kind; and what is very ſingular, tho' a very certain truth, is, that theſe are principally the ferns of American growth, not thoſe of our own climate.

The moſt frequent *foſſile plants* are the polypody, ſpleenwort, oſmund, trichomanes, and the ſeveral larger and ſmaller ferns; but beſide theſe there are alſo found pieces of the equiſetums, or horſe-tails, and joints of the ſtellated *plants*, as the clivers, madder, and the like; and theſe have been too often miſtaken for flowers; ſometimes there are alſo found compleat graſſes, or parts of them, as alſo reeds and other water *plants*; ſometimes the ears of corn, and not unfrequently the twigs or bark, and impreſſions of the bark, and fruit of the pine or fir kind, which have been, from their ſcaly appearance, miſtaken for the ſkins of fiſhes; and ſometimes, but that very rarely, we meet with moſſes and ſea-*plants*.

Many of the ferns not unfrequently found, are of very ſingular kinds, and ſome ſpecies yet unknown to us; and the leaves of ſome appear ſet at regular diſtances, with round protuberances and cavities. The ſtones which contain theſe plants ſplit readily, and are often found to contain, on one ſide, the impreſſion of the plant; and on the other the prominent plant itſelf: and beſide all that have been mentioned, there have been frequently ſuppoſed to be found with us ears of common wheat, and of the maiz or Indian corn; the firſt being in reality no other than the common endmoſt branches of the firs, and the other the thicker boughs of various ſpecies of that and of the pine kind, with their leaves fallen off; ſuch branches in ſuch a ſtate cannot but afford many irregular tubercles and papillæ, and in ſome ſpecies, ſuch as are more regularly diſpoſed.

Theſe are the kinds moſt obvious in England; and theſe are either immerſed in the flaty ſtone which conſtitutes whole ſtrata, or in flatted nodules, uſually of about three inches broad, which readily ſplit into two pieces on being ſtruck. They are moſt common in Kenton coal-pits, near Newcaſtle, and the foreſt of Dean, in Glouceſterſhire; but are more or leſs found about almoſt all our coal-pits, and many of our iron mines. See Tab. of Foſſils, Claſs 6.

Tho' theſe ſeem the only ſpecies of *plants* found with us, yet in Germany there are many others, and thoſe found in different ſubſtances. A whitiſh ſtone, a little harder than chalk, frequently contains them: they are found alſo often in a grey flaty ſtone, of a firmer texture, not unfrequently in a blackiſh one, and at times in many others: nor are the bodies themſelves leſs various here than the matter in which they are contained: the leaves of trees are found in great abundance, among which thoſe of the willow, poplar, whitethorn, and pear-trees, are the moſt common; ſmall branches of box, leafs of the olive-tree, and ſtalks of garden thyme, are alſo found there; and ſometimes ears of the various ſpecies of corn, and the larger as well as the ſmaller moſſes in great abundance.

Theſe ſeem the tender vegetables, or herbaceous *plants*, certainly found thus immerſed in hard ſtone, and buried at great depths in the earth; others of many kinds there are alſo named by authors, but as in bodies ſo imperfect, errors are eaſily fallen into, theſe ſeem all that can be aſcertained beyond mere conjecture. *Hill's* Hiſt. of Foſſ. p. 640.

Ice-PLANT See the article ICE.

PLANT-*root*, a term uſed by Dr. Grew to expreſs the radicle in ſeeds: he by this name diſtinguiſhes it from what he calls the ſeminal root; which is a very different ſubſtance diſtributed throughout the parenchyma of the ſeed, but wholly different from it, and preying upon it as the *plant-root* does upon the earth. *Grew's* Anat. of Plants. See the article SEMINAL-*root*.

PLANTAGINELLA, in botany, a name given by Dillenius to a genus of plants ſince called by Linnæus *limoſella*. *Dillen.* See the article LIMOSELLA.

PLANTAGO, *plantain*, in botany, the name of a genus of plants, the characters of which are theſe: The flower conſiſts of one leaf, and is wide, expanded at the opening, and uſually divided into four ſegments; from the bottom of this flower riſes a piſtil ſurrounded with ſtamina of conſiderable length: the piſtil becomes afterwards an oval or conic ſeed-veſſel; which when ripe ſeparates tranſverſely into two pieces, and is divided by an intermediate ſeptum into two cells, filled with oblong ſeeds.

The ſpecies of *plantain*, enumerated by Mr. Tournefort, are theſe: 1. The ſmooth broad-leaved *plantain*. 2. The broad-leaved *plantain*, with ſinuated leaves. 3. The broad-leaved *plantain*, with blood coloured leaves. 4. The broad-leaved hoary *plantain*. 5. The broad-leaved hoary *plantain*, with a white ſpike. 6. The broad-leaved roſe *plantain*, with an expanded flower. 7. The broad-leaved roſe *plantain*, with flowers diſpoſed in tufts. 8. The broad-leaved *plantain*, with a buſhy panicle. 9. The broad-leaved hoary *plantain*, with various ſpikes. 10. The ſmaller broad-leaved ſmooth *plantain*. 11. The ſmaller broad-leaved hoary *plantain*. 12. The hairy or woolly *plantain*. 13. The great narrow-leaved *plantain*. 14. The ſmall proliferous narrow-leaved *plantain*, with foliaceous tops to the ſtalks. 15. The common narrow-leaved proliferous *plantain*. 16. The narrow-leaved ſilvery *plantain*. 17. The narrow-leaved ſerrated *plantain*. 18. The ſhrubby narrow-leaved *plantain*. 19. The great broad-leaved hoary *plantain*, with three ribs to each leaf. 20. The leſſer narrow-leaved *plantain*. 21. The hairy bulboſe rooted *plantain*. 22. The narrow-leaved *plantain*, with tufts like the lagopus. 23. The narroweſt-leaved three ribbed *plantain*. 24. The alpine *plantain*, with long, narrow and blackiſh leaves. 25. The three-ribbed mountain-*plantain*. 26. The narrow-leaved and white Spaniſh *plantain*. 27. The narrow-leaved white French *plantain*. 28. The great narrow-leaved ſea-*plantain*, called by ſome the ſea *coronopus*. 29. The leſſer narrow-leaved ſea-*plantain*. 30. The ſmalleſt ſea-*plantain*, with rigid graſſy leaves. 31. The greater graſſy-leaved *plantain*. 32. The ſmaller graſſy-leaved *plantain*. 33. The ſmalleſt narrow leaved *plantain*, with heads like the hare's foot. 34. The one-flowered graſſy-leaved marſh-*plantain*. 35. The hairy ſea-*plantain* of Portugal, with a very long ſpike. 36. The hairy ſea-*plantain* of Portugal, with a ſhort ſpike.

Theſe are properly *plantains*; but the large plants commonly called by authors water *plantains*, are ſpecies of ranunculus. *Tourn.* Inſt. p. 127. See RANUNCULUS.

PLANTAGO, in the Linnæan ſyſtem of botany, is made the name of a large genus of plants, taking in, beſide the ſeveral ſpecies of *plantains*, uſually ſo called, the pſyllium, or fleawort, the coronopus or buckſhorn, and the gramen junceum, or ruſh-graſs.

The characters of this genus are these: The cup is an erect very short perianthium, divided into four at the edges, and remaining after the flower is fallen. The flower consists of one petal, in form of a cylindraceo-globose tube, with the limb cut into four parts; the segments being depressed, of an oval figure and pointed; the stamina are four extremely long, erect capillary filaments; the antheræ are oblong, flatted, and lean upon the stamina; the germen of the pistil is of an oval figure; the style is slender, and but of half the length of the stamina; and the stigma is simple; the fruit is an oval capsule, containing two cells, parting horizontally; the seeds are numerous, and oblong. *Linnæi* Genera Plant. p. 46.

PLANTE-*ver*, in natural history, the name of an herb sent over from China, where it is called *hiatsaotonetchom*; that is to say, a plant which at a certain time of the year changes into a worm. The Chinese say, that this is a plant during the summer season; but that in winter its stalk dies, and the root becomes a worm. Mr. Reaumur has well observed, that in the present improved state of natural knowledge, we can give no credit to such marvellous accounts; and of the roots sent over to the Academy at Paris, it appeared, that only a certain part of each was to undergo this change: this, however, if true, was no less a marvel than that the whole should.

Father Parenin, who sent it to France, observes, in his account of it, that it was a very scarce plant even in China; being found only at the palace of Pekin there, where also it was not native, but brought from the mountains of Tibet, and some other places on the confines of the Chinese dominions. This father had never seen the leaves or flowers of the plant, but only its roots, which were in high esteem their, not only because of their miraculous changes, but from there possessing the virtues of the famous ginseng; but with this advantage, that the use of them was not subject to be attended with those hæmorrhages which frequently affected the persons who take large quantities of that famous root. The roots of this *plante-ver* are usually about a quarter of an inch thick, and from an inch to three inches in length; but there are much larger in the places where they grow.

These roots had nothing particular in their figure or appearance; but with these the father sent some of those which were supposed to be changed into worms, concerning which he observed, that nothing could more exactly express a worm or caterpillar; the head, the eyes, the feet, and the mouth, being all plainly distinguishable, as well as the several folds and cuttings in of the body. This account was found to be perfectly true; but the mistake was the want of proper accuracy in the observation; for this body, which was supposed to be the root transformed, had in reality never been any part of the plant, but was found to be really and truly a caterpillar. This was one of the under-ground kind, or at least of those which go into the ground to pass their transformation: of these we have a great many different species in all parts of Europe, and some of them, when they are entering into their nymph state, have a custom of fastening themselves to the roots of plants. Of this kind was the Chinese insect, which when the time of its change approached, always selected the roots of this plant as of a proper size and dimension for its purpose; and gnawing off the end hollowed away the stump, so as to introduce its tail into the cavity; where it remains covered with the bark of the root, which so nicely joins to it, that people who observe it in a slight way cannot but mistake it to be a part of the root, or the remainder of the root, a continuation of its body. The more accurate naturalists will, however, easy distinguish the vegetable fibres, which make up the root from the animal ones of the caterpillar; and to an eye accustomed to such researches, the nice joining of the tail to the remainder of the root will easily discover itself. Mem. Acad. Par. 1720.

PLANTED-*coat*, in the manege. See HAIR, *Cycl.*

PLASHING, a term used by our farmers to express an operation performed at certain times upon their quickset-hedges, in order to assist their growth and continuance. This operation is performed sometimes in October, but more usually in February; and this is by much the better season for it. Suppose a hedge to be of twenty or thirty years growth, and full of old stubs as well as young shoots, this is the kind of hedge that requires *plashing* most of all.

The old stubs must be cut off within two or three inches of the ground, and the best and longest of the middle sized shoots must be left to lay down. Some of the strongest of these must also be left to answer the purpose of stakes. These are to be cut off to the height at which the hedge is intended to be left; and they are to stand at ten foot distance one from another: when there are not proper shoots for these at the due distances, their places must be supplied with common stakes of dead wood. The hedge is to be first thinned, by cutting away all but those shoots which are intended to be used either as stakes, or the other work of the *plashing*: the ditch is to be cleaned out with the spade: the ditch must be now dug as at first, with sloping sides each way; and when there is any cavity on the bank on which the hedge grows, or the earth has been washed away from the roots of the shrubs, it is to be made good by facing it, as they express it, with the mould dug from the upper part of the ditch; all the rest of the earth dug out of the ditch is to be laid upon the top of the bank, and the owner should look carefully into it that this be done; for the workmen, to spare themselves trouble, are apt to throw as much as they can upon the face of the bank; which being by this means overloaded, is soon washed off into the ditch again, and a very great part of the work undone again, whereas what is laid on the top of the bank always remains there, and makes a good fence of an indifferent hedge.

In the *plashing* the quick, two extremes are to be avoided; these are, the laying it too low, and the laying it too thick: this makes the sap run all into the shoots, and leaves the *plashes* without sufficient nourishment; which, with the thickness of the hedge, finally kills them. The other extreme of laying them too high, is equally to be avoided; for this carries up all the nourishment into the *plashes*, and so makes the shoots small and weak at the bottom, and, consequently, the hedge thin. This is a common error in the north of England. The best hedges made any where in England, are those of Hertfordshire; and they are *plashed* in a middle way between the two extremes, and the cattle are by that prevented both from croping the young shoots, and from going thro'; and a new and vigorous hedge soon forms itself.

When the shoot is bent down that is intended to be *plashed*, it must be cut halfway thro' with the bill: the cut must be given sloping, somewhat downwards, and then it is to be wound about the stakes, and after this its superfluous branches are to be cut off, as they stand out at the sides of the hedge. If for the first year or two the field where a new hedge is made can be ploughed, it will thrive the better for it; but if the stubs are very old, it is best to cut them quite down, and to secure them with good dead hedges on both sides, till the shoots are grown up from them strong enough to *plash*; and wherever void spaces are seen, new sets are to be planted to fill them up. A new hedge raised from sets in the common way, generally requires *plashing* about eight or nine years after. *Mortimer*'s Husbandry, p. 10.

PLASTER (*Cycl.*)—PLASTER, in pharmacy, an external application of a harder consistence than our ointments: these are to be spread according to the different circumstances of the wound, place, or patient, either upon linnen or leather. If the part upon which they are to be laid be naturally hairy, it must be shaved; but that they may stick the better, the natural shape of the part must be consulted, and the *plaster* spread and formed accordingly, either round, square, triangular, elleptical, in a lunar form, or in shape of the letter T. Some also are divided at both ends, and others are perforated in the middle; these last are of frequent use in fractures attended with a wound; for by this contrivance the wound may be cleansed and dressed without removing the *plaster*. These *plasters* are of different forms, according to the part they are laid on; but they are usually square, or round; and indeed there is almost no part of the body which a *plaster* of one of those forms may not be made to serve for, if it be notched about the edges with a pair of sciffers.

The uses of *plasters* are various; they are serviceable in securing the dressings, they also forward the maturation of the pus, agglutinate and heal wounds, unite broken bones, heal burns, assuage pain, and strengthen weak parts. *Heister*'s Surg. p. 18.

PLASTER *of Paris*. The method of representing a face truly in *plaster of Paris*, is this: The person whose figure is designed is laid on his back, with any convenient thing to keep off the hair. Into each nostril is conveyed a conical piece of stiff paper, open at both ends, to allow of respiration. These tubes being anointed with oil, are supported by the hand of an assistant; then the face is lightly oiled over, and the eyes being kept shut, alabaster fresh calcined, and tempered to a thinnish consistence with water, is by spoonfuls nimbly thrown all over the face, till it lies near the thickness of an inch. This matter grows sensibly hot, and in about a quarter of an hour hardening into a kind of stony concretion; which being gently taken off represents, on its concave surface, the minutest part of the original face. In this a head of good clay may be moulded, and therein the eyes are to be opened, and other necessary amendments made. This second face being anointed with oil, a second mould of calcined alabaster is made, consisting of two parts joined lengthways along the ridge of the nose; and herein may be cast, with the same matter, a face extremely like the original. *Boyle*'s Works, abr. Vol. I. p. 132.

If finely powdered alabaster, or *plaster of Paris*, be put into a bason over a fire, it will, when hot, assume the appearance of a fluid, by rolling in waves, yielding to the touch, steaming, &c. all which properties it again loses on the departure of the heat; and being thrown upon paper, will not at all wet it, but immediately discover itself to be as motionless as before it was set over the fire; whereby it appears, that a heap of such little bodies, as are neither spherical, nor otherwise regularly shaped, nor small enough to be below the discernment of the eye, may, without fusion, be made fluid, barely by a sufficiently strong and various agitation of the particles which compose it; and, moreover,

over, loſe its fluidity immediately upon the ceſſation thereof *Boyle*'s Works abr. Vol. I. p 313.

Two or three ſpoonfuls of burnt alabaſter, mixed up thin with water, in a ſhort time coagulate, at the bottom of a veſſel full of water, into a hard lump, notwithſtanding the water that ſurrounded it. Artificers obſerve, that the coagulating property of burnt alabaſter will be very much impaired or loſt, if the powder be kept too long, eſpecially if in the open air, before it is made uſe of; and when it hath been once tempered with water, and ſuffered to grow hard, they cannot by any burning or powdering of it again, make it ſerviceable for their purpoſe as before. *Boyle*'s Works abr. Vol. I. p. 341.

This matter, when wrought into veſſels, &c. is ſtill of ſo looſe and ſpungy a texture, that the air has eaſy paſſage thro' it. Mr. Boyle gives an account among his experiments with the air-pump, of his preparing a tube of this *plaſter*, cloſed at one end and open at the other, and on applying the open end to the cement, as is uſually done with the receivers, it was found utterly impoſſible to exhauſt all the air out of it; for freſh air from without preſſed in as faſt as the other, or internal air, was exhauſted, tho' the ſides of the tube were of a conſiderable thickneſs. A tube of iron was then put on the engine; ſo that being filled with water, the tube of *plaſter of Paris* was covered with it; and on uſing the pump, it was immediately ſeen, that the water paſſed through into it as eaſily as the air had done, when that was the ambient fluid. After this, trying it with Venice turpentine inſtead of water, the thing ſucceeded very well; and the tube might be perfectly exhauſted, and would remain in that ſtate ſeveral hours. After this, on pouring ſome hot oil upon the turpentine, the caſe was much altered; for the turpentine melting with this, that became a thinner fluid, and in this ſtate capable of paſſing like water into the pores of the *plaſter*. On taking away the tube after this, it was remarkable that the turpentine, which had pervaded and filled its pores, rendered it tranſparent, in the manner that water gives tranſparency to that ſingular ſtone called *oculus mundi*. In this manner, the weight of air, under proper management, will be capable of making ſeveral ſorts of glues penetrate *plaſter of Paris*; and not only this, but baked earth, wood, and all other bodies porous enough to admit water on this occaſion. Philoſ. Tranſ. N°. 122.

PLASTERING. The modern taſte runs greatly into *plaſtering*; and it were much to be wiſhed that this art could be again brought to its antient perfection. In our beſt buildings the *plaſtered* walls and ceilings crack and fly, and in a little time grow damp, or moulder to decay. The Romans had an art of rendering their works of this kind much more firm and durable, and there is no reaſon to deſpair of reviving this art by proper trials.

The antient *plaſtering* of theſe people, preſerved to this time, where it has not met with violent blows or injuries from accidents, is ſtill found as firm and ſolid, as free from cracks or crevices, and as ſmooth and poliſhed on the ſurface, as if made of marble. The bottoms and ſides of the Roman aqueducts were made of this *plaſtering*, and endured many ages without hurt, unleſs by accidents; witneſs that whereof ſome yards are ſtill to be found on the top of the Pont de Garde, near Niſmes, for the ſupport of which that famous bridge was built to carry water to the ſaid town. The roofs of houſes, and the floors of rooms at Venice are covered with a ſort of *plaſter*, made of later date, and yet ſtrong enough to endure the ſun and weather for ſeveral ages, without cracking or ſpoiling, and without much injury from people's feet.

The ſecret of preparing this Venetian *plaſter* is not among us; but it would be worth while to try whether ſuch a ſubſtance might not be made by boiling the powder of gypſum dry over the fire, for it will boil in the manner of water; and when this boiling or recalcining was over, the mixing with it reſin, or pitch, or both together, with common ſulphur, and the powder of ſea-ſhells. If theſe were all mixed together, and the water added to it hot, and the matter all kept hot upon the fire till the inſtant of its being uſed, ſo that it might be laid on hot, it is poſſible this ſecret might be hit upon.

Wax and oil of turpentine may be alſo tried as additions: theſe being the common ingredients in ſuch cements as we have accounts of as the firmeſt. Strong ale-wort is by ſome directed to be uſed, inſtead of water, to make mortar of lime-ſtone be of a more than ordinary ſtrength. It is poſſible, that the uſe of this tenacious liquor to the powdered ingredients of this propoſed *plaſter*, might greatly add to their ſolidity and firmneſs. Phil. Tranſ. N°. 93.

PLAT *(Cycl.)*—PLAT-*veins*, in the manege, called in French *arx*, are the veins in which we bleed horſes, one in the lower part of each ſhoulder, when we blood a horſe in the ſhoulders; and in the flat part of the thighs.

PLATS, in a ſhip, flat ropes made of rope-yarn, and weaved one over the other: they ſerve to ſave the cable from galling in the hawſe, or to wind about the flukes of the anchors, to ſave the pennant of the fore-ſheet from galling againſt them.

PLATANUS, the *plane tree*. See PLANE-*tree*.

PLATÆ, a word uſed by ſome anatomical writers to expreſs the ſcapulæ.

PLATAMON, a word uſed to expreſs a low and ſmooth rock, juſt appearing above water.

PLATANARIA, in botany, a name by which ſome authors have called the *ſpargarium*, or burr-reed, from its round echinated fruit, which in ſhape and ſize much reſemble thoſe of the *platanus*.

PLATE, *(Cycl.)* a term uſed by our ſportſmen to expreſs the reward given to the beſt horſe at our races.

The winning a *plate* is not a work of a few days to the owner of the horſe, but great care and preparation are to be made for it, if there is any great dependance on the ſucceſs. A month is the leaſt time that can be allowed to draw the horſe's body clear, and to refine his wind to that degree of perfection that is attainable by art.

It is firſt neceſſary to take an exact view of his body, whether he be low or high in fleſh; and it is alſo neceſſary to conſider, whether he be dull and heavy, or briſk and lively when abroad. If he appear dull and heavy, and there is reaſon to ſuppoſe it is owing to too hard riding; or, as the jockies expreſs it, to ſome greaſe that has been diſſolved in hunting, and has not been removed by ſcouring, then the proper remedy is half an ounce of diapente, given in a pint of good ſack; this will at once remove the cauſe, and revive the creature's ſpirits. After this, for the firſt week of the month, he is to be fed with oats, bread, and ſplit beans, giving him ſometimes the one, and ſometimes the other, as he likes beſt; and always leaving ſome in the locker, that he may feed at leiſure when he is left alone. When the groom returns at the feeding time, whatever is left of this muſt be removed, and freſh given; by this means the creature will ſoon become high ſpirited, wanton, and full of play. Every day he muſt be rode out an airing, and every other day it will be proper to give him a little more exerciſe; but not ſo much as to make him ſweat too much.

The beans and oats in this caſe are to be put into a bag, and beaten till the hulls are all off, and then winnowed clean; and the bread, inſtead of being chipped in the common way, is to have the cruſt clean cut off.

If the horſe be in good fleſh and ſpirits when taken up for its month's preparation, the diapente muſt be omitted; and the chief buſineſs will be to give him good food, and ſo much exerciſe as will keep him in wind, without over ſweating or tiring his ſpirits. When he takes larger exerciſes afterwards, towards the end of the month, it will be proper to have ſome horſes in the place to run againſt him. This will put him upon his mettle, and the beating them will give him ſpirits.

This, however, is to be cautiouſly obſerved, that he has not a bloody heat given him for ten days or a fortnight before the *plate* is to be run for; and that the laſt heat that is given him the day before the race, muſt be in his cloaths: this will make him run with greatly more vigour, when ſtripped for the race, and feeling the cold wind on every part. In the ſecond week the horſe ſhould have the ſame food and more exerciſe, and in the laſt fortnight he muſt have dried oats, that have been hulled by beating; after this they are to be wetted in a quantity of whites of eggs, beaten up, and then laid out in the ſun to dry; and when as dry as before, the horſe is to have them. This ſort of food is very light of digeſtion, and very good for the creature's wind. The beans in this time ſhould be given more ſparingly, and the bread ſhould be made of three parts wheat, and one part beans. If he ſhould become coſtive under this courſe, he muſt then have ſome ale and whites of eggs beaten together: this will cool him, and keep his body moiſt.

In the laſt week the maſh is to be omitted, and barley-water given him in its place, and every day, till the day before the race: he ſhould have his fill of hay, then he muſt have it given him more ſparingly, that he may have time to digeſt it; and in the morning of the race-day, he muſt have a toaſt or two of white bread, ſoaked in ſack, and the ſame juſt before he is led out to the field. This is an excellent method, becauſe the two extremes of fullneſs and faſting are at this time to be equally avoided; the one hurting his wind, and the other occaſioning faintneſs, that may make him loſe. After he has had his food, the litter is to be ſhook up, and the ſtable kept quiet, that he may be diſturbed by nothing till he is taken out to run.

PLATES, in gunnery. The *priſe-plates* are two *plates* of iron on the cheeks of a gun-carriage, from the cape-ſquare to the center, through which the priſe-bolts go, and on which the hand-ſpike reſts when it poiſes up the breech of the piece. Breaſt-*plates* are the two *plates* on the face of the carriage, one on each cheek. Train-*plates* are the two *plates* on the cheeks at the train of the carriage. Dulidge-*plates* are the ſix *plates* on the wheel of a gun-carriage, where the fellows are joined together, and ſerve to ſtrengthen the dulidges.

PLATE-*longe*, in the manege, a woven ſtrap, four fathom long, three fingers broad, and as thick as one. It is uſed for raiſing a horſe's legs and ſometimes for taking him down, in order to facilitate ſeveral operations of the farrier. Some improperly give the name of *plate-longe* to a martingale. See the article MARTINGALE, *Cycl.*

PLATEA, in zoology, the name of a bird of the long-necked kind, approaching to the nature of the ſtork and heron, and called

called in Engliſh the *ſpoon-bill*, from the remarkable figure of its beak, which is different from that of all other birds; being broadeſt at the extremity, and terminating in a large rounded, flat proceſs, reſembling a ſhovel; or, if it were hollow, a ſpoon. See Tab. of Birds, N°. 42.

This bird has been called *lucoredius*, *albardeola*, and *le'elaer*, and by ſome very improperly the *pelecanus*. It is all over very white, like the ſwan; but that there is ſome blackneſs in the wings. It builds in high trees in ſome parts of Holland. *Ray*'s Ornithology. p. 212.

PLATESSA, in zoology, a name by which Auſonius and ſome other authors have called the paſſer-fiſh, or common plaiſe. *Willughby*'s Hiſt. Piſc. p. 96.

PLATFORM *(Cycl.)*—All practitioners are agreed, that no ſhot can be depended on, unleſs the piece be placed on a ſolid *platform*; for if the *platform* ſhakes with the firſt impulſe of the powder, it is impoſſible but the piece muſt likewiſe ſhake; which will alter its direction, and render its ſhot uncertain. To prevent this accident, the *platform* is uſually made extremely firm to a conſiderable depth backwards, ſo that the piece is not only well ſupported in the beginning of its motion, but likewiſe through a great part of its recoil. However, it is ſufficiently obvious, that when the bullet is ſeparated from the piece, it can be no longer affected by the trembling of the piece or *platform*; and by a very eaſy computation it will be found, that in a piece ten feet in length, carrying a bullet of 24 lb. and charged with 16 lb. of powder, the bullet will be out of the piece before it has recoiled half an inch; whence if the *platform* be ſufficiently ſolid at the beginning of the recoil, the remaining part of it may be much ſlighter, ſince its unſteadineſs beyond the firſt half inch will have no influence on the direction of the ſhot: and hence a more compendious method of conſtructing *platforms* may be found out. New Princip. of Gunn. p. 42.

PLATIASMOS, a word uſed by many authors to expreſs a fault in pronunciation, owing to a perſon's opening his mouth too wide, and thence ſpeaking indiſtinctly.

PLATICORIA, a word uſed by medical writers to expreſs a preternatural dilatation of the pupil of the eye, uſually owing to a paralytic diſorder.

PLATONIA, in natural hiſtory, a name given by the modern Greeks to the *prox* of Ariſtotle, and of other antient writers in that language. This is the *cervus platyceros*, or broad-horned ſtag. Some have tranſlated this *dama*, but they are to be underſtood in this as meaning the *dama* of their own times, not that of the antients; that being the *iſarus*, or chamoy-goat, not any animal of the ſtag kind, nor by any means meriting that title.

PLATYCERCOS *ovis*, in natural hiſtory, the name given by Geſner and ſome others to a ſpecies of ſheep, commonly called *ovis laticauda*, or the broad-tailed ſheep.

The tail of this creature is very thick, broad, and heavy, weighing often thirty pounds. We ſometimes ſee it brought over hither as a ſhew, and find that authors have deſcribed the ſhape of its tail very inaccurately. Caius, in Geſner, ſays it is of the ſhape of the tails of other ſheep, broad at the inſertion, and growing gradually ſmaller to the end; but it is exactly the contrary of this, being narroweſt at the inſertion, and growing ſomewhat larger and broader to the extremity; ſo that on the whole, it repreſents a ſort of bag or purſe. The creature is not uncommon in Ægypt, Africa, and Arabia, and in ſome parts of Syria. *Ray*'s Syn. Quad. p. 74. See the article MACROCERCOS.

PLATYOPHTHALMON, a name given by ſome to antimony, from its uſe among the ladies of old time, to make their eye brows broad and black

PLATYSTERNOS a word uſed by the old phyſicians to expreſs a perſon with a very broad cheſt or ſternum.

PLATYRYNCHOS, in zoology, a name given by ſome to the *naſus*, or *neſe*, a freſh water fiſh, caught in the Danube, and moſt of the large rivers in Germany, and much reſembling the chub *Geſner* de Piſc. p. 213. See the article NASUS.

PLATYSMA *myodes*, in anatomy, a name given by Fallopius to one of the muſcles called by Albinus *latiſſimus colli*, and by others *quadratus genæ*.

PLAUSUS, among the Romans. See ACCLAMATION.

PLEA *(Cycl.)*—PLE, in abatement. See the article ABATEMENT, *Cycl.*

PLEADING. Among the Athenians, an equal time was allowed both parties to *plead*, which was meaſured by a water hour-glaſs; and in order to ſee juſtice done in this reſpect, there was an officer appointed to diſtribute the water to each, whence he was called *ephydor*. *Potter* Arch. Græc. l. 1. c. 21 See EPHYDOR.

PLEASURE-*boat*, among the antients. See THALAMEGUS.

PLECHAS, a word uſed by Hippocrates, to expreſs that region of the body which is terminated backward by the anus, forward by the pudenda, and ſideways by the hips.

PLECTÁNÆ, a word uſed by ſome to expreſs the cornua uteri, and by others for any plexus of veſſels.

PLECTRONITÆ. See the article CONICTHYODONTES.

PLECTRUM, a word uſed by ſome anatomical writers, to expreſs the ſtyloide proceſs of the os petroſum; by others for the uvula; and by others for the tongue.

PLECTRUM, among the antients, an inſtrument uſed in playing upon the lyre. We have a deſcription of it in Mem. Acad. Inſcrip. Vol. V. p. 168, 169. See LYRE, *Cycl.*

PLEMMYROS, a word uſed by the old Greek writers to expreſs a redundance of humors: its proper ſignification is the flowing in of the tide.

PLENNA, a word uſed by ſome writers to expreſs any mucous humor.

PLEROSIS, a word uſed by the old Greeks to expreſs the repletion or reſtoring the body to its natural ſtate, after it has been emaciated by ſickneſs.

PLESMONE, a word uſed by the antients to ſignify plenitude or ſatiety.

PLESTYA, in zoology, a name given by Bellonius to a freſh water fiſh of the leather-mouthed kind, appearing to be no way eſſentially different from the more common kind of carcaſius, called by authors *carcaſſii tertium genus*. *Ray*'s Ichthyogr. p. 250. See CARCASSIUS.

PLETHORA *(Cycl.)*—Medical writers now uſually diſtinguiſh four kinds of a *plethora*. 1. The ſimple *plethora*, which is that ſtate of the body in which the blood is too abundant in quantity, but is as yet of no bad quality. 2. The cacochymious *plethora*, which is that where the blood is abundant in quantity, and at the ſame time is ſubject to a too great thickneſs, or ſome other dyſcracy. 3. The *plethora ad vaſa*, whereby the blood, from its over great quantity, renders the veſſels turgid, without any farther ill effect. And, 4. The *plethora ad vires*, in which there is joined to too great a plenitude of the veſſels, a laſſitude, and torpor, or numbneſs of the limbs.

The ſigns of a *plethora* are, 1. A florid conſtitution of the body. 2. A tolerable uſe of the non-naturals, a good appetite to food, and a ſound ſleep: this is the caſe while the *plethora* is ſimple and unmoved, but when any commotion happens from without, the ſigns are inquietude at night, dreams of bleeding, and of wounds from ſwords or other weapons, rubicund looks in the face, and a general turgeſcence of the veſſels, a heavineſs of the limbs, an inaptitude to motion, and difficulty of breathing, a vertiginous diſorder of the head, a ſenſe of a pricking or tingling in the fleſh from the ſlighteſt heat, an eaſy heating of the body from the weather, a moiſture of the eyes, and in hyſteric women a ſenſation as if a piece of cold ice were ſuddenly laid on ſome part of the head.

Perſons moſt ſubject to a PLETHORA, are, 1. People of ſedentary lives, who live high. 2. The younger rather than perſons more advanced in years. 3. The female ſex rather than the men. 4. All perſons who have been accuſtomed to large evacuations, and have haſtily ſuppreſſed them. And, 5. Thoſe perſons who have ſuddenly changed a life of labour or exerciſe to a ſedentary one, without making the neceſſary changes in the non-naturals.

Prognoſtics from a PLETHORA. 1. *Plethoric* perſons are more ſubject to diſeaſes in general than others. 2. They are particularly ſubject to hæmorrhages, inflammations, and acute fevers. 3. The lighter diſeaſes coming upon perſons of a *plethoric* habit, are uſually more ſtubborn and dangerous than on others. 4. The *plethora* itſelf can ſcarcely be called a diſeaſe, but it is the parent of many diſeaſes. Chronic diſeaſes are with more difficulty cured in *plethoric* patients than in others, becauſe they are always averſe to exerciſe. 6. A *plethoric* habit, diſturbed by violent motion, by paſſions of the mind, or by ſtimulating medicines, is capable of producing very terrible conſequences. 7. The diſeaſes ariſing from a *plethora*, from ſtopping ſome accuſtomed evacuation, are with difficulty cured; and *plethoras* are more efficaciouſly relieved by natural hæmorrhages than by any artificial means.

Method of cure in a PLETHORA. A ſimple *plethora* is eaſily removed by bleeding and gentle exerciſe, and by a more ſpare diet; to theſe may be added, gentle purging once a month. The *plethora* with a cacochymy requires gentle purging, bleeding, and cuping, diaphoretics and diuretics. If a violent commotion of the blood happen with a *plethora*, temperance is to be firſt preſcribed, then the uſe of nitre, and crabs-eyes ſaturated with lemon juice; and other cooling and alterative remedies. *Junker*'s Conſpect. Medic. p. 4.

PLEURISY *and* PERIPNEUMONY *(Cycl.)*—Theſe are two diſeaſes which have ſome reſemblance in their general ſymptoms, and are thence ſometimes miſtaken one for the other. They are, however, extremely different in their place of origin, as well as in their ſeveral ſymptoms: the *pleuriſy* being a ſtaſis of blood in the *pleura*; and the *peripneumony* a ſtaſis of the ſame fluid in the lungs. They are both attended with an acute, continuous, and inflammatory fever, by means of which nature is labouring to break through the obſtruction made by the ſtaſis of the blood in thoſe parts.

The ſpurious *pleuriſy* is to be carefully diſtinguiſhed from theſe two diſeaſes. In the true *pleuriſy*, or *peripneumony*, a pain is felt either about or a little below the nipple; but the ſpurious *pleuriſy* generally ſhews itſelf higher, uſually about the clavicle. In the genuine diſeaſes the pains are equal and regular, anſwering to the pulſe: in the ſpurious *pleuriſy* they are vague, and wholly irregular. In the true, they are alſo continual; but in the ſpurious, they have frequent intermiſſions and remiſſions. The true have always a cough attending them, and

that

that uſually attended with a ſpitting of coloured matter, often ſtreaked with blood; but the ſpurious often has no cough at all attending it; or if it has, there is no difference ſeen in the matter voided by ſpitting. The true has always an acute continuous fever, which attacks the patient at firſt with a ſhivering; the ſpurious either has no fever at all with it, or it is at the utmoſt a ſlight and irregular one.

The true diſeaſes do not terminate in leſs than ſeven days; the others much ſooner. The true uſually attack young people; the ſpurious are common to young and old. The difference between the true and ſpurious diſeaſes, are determined by the obſervation of theſe ſymptoms; but it yet remains to diſtinguiſh juſtly the true diſeaſes from one another. This is done by the following obſervations:

The *pleuriſy* is a very rare diſeaſe; and the *peripneumony* a very common one; but this is exactly contrary to the common opinion, from theſe diſeaſes being too generally confounded with, and miſtaken for one another.

In a *peripneumony*, a ſpitting of blood uſually happens about the cloſe of the ſecond day: this is a primary ſymptom in a *peripneumony*, but is uſually erroneouſly attributed to a *pleuriſy*, tho' reaſon ſhews how eaſily ſuch a ſpitting may happen from an inflammation of the lungs; and it is very different to conceive how it ſhould happen ſo readily from an inflammation of a part ſo remote from having any communication with the organs of expectoration as the pleura.

In the *peripneumony*, the pain extends itſelf farther, affecting the whole breaſt, whereas in the *pleuriſy* it is rather fixed to the right ſide, and felt a little below the breaſt. Theſe are the ſymptoms by which theſe diſeaſes are diſtinguiſhed from one another, and the uſe of the diſtinction is principally this, that in the *pleuriſy* the application of external remedies often is of great ſervice, whereas it is of no effect in the other caſe, tho' the miſtake is of no great conſequence in this reſpect as the applications in the *peripneumony* can do no harm: but in an unhappy termination of theſe diſeaſes by ſuppuration, the diſtinction becomes of ſome conſequence; ſince in the *pleuriſy* the matter may be evacuated by a paracenteſis, or the letting in a canula; which in the *peripneumony* can by no means be done, unleſs in ſuch an accidental caſe that the diſeaſe terminates in an external *vomica pulmonum*: then indeed the matter being diſcharged from the abſceſs into the cavity of the thorax, may be let out in the ſame manner as in the ſuppurated *pleuriſy*; but this is a caſe that does not occur in an age.

The uſual opinion of medical writers, in regard to this caſe, is, that the *peripneumony* is always a diſorder affecting only the external ſurface of the lungs; and they obſerve, that even its name expreſſes this, the ſignification of it being a diſtemperature ſpreading round about the lungs: this, however, is not agreeable to obſervation or experience; for in diſſections of bodies that have died of this diſeaſe, the very internal part of the lungs is always found affected; and indeed if the ſurface only were ſo, it is not eaſy to conceive how the ſpitting of blood ſhould come on ſo ſoon as the ſecond day.

Signs of theſe diſeaſes. Theſe are in general common to both, and are the following: A vertiginous diſorder of the head uſually precedes all the other ſymptoms; this is ſucceeded by a ſhivering and chillneſs all over the body; this increaſes by degrees, and uſually brings on with it cardialgias, nauſeas, and anxieties: after this there comes on a very remarkable heat, with very intenſe thirſt, and a violent pain in the head; this is accompanyed with a ſtraitneſs of the breaſt, and difficulty of reſpiration; and the patient feels a violent and ſevere pain in the breaſt: and this becomes continual, and is always greatly exaſperated by the cough that attends the diſeaſe. The urine in the firſt days is red, and after a few days more it becomes turbid, when it has ſtood to be cold; and finally depoſits a thick pale-red ſediment. The peculiar ſymptoms of each diſeaſe are already enumerated.

Perſons ſubject to them. Theſe are diſeaſes not equally common to all ages, but they principally affect young people: they are moſt frequent in the beginning of the ſpring ſeaſon, and moſtly affect ſuch as are of a ſanguine plethoric habit. Perſons who have been ſubject to bleeding at the noſe, but have been for ſome time free from returns of them, often fall into theſe diſeaſes; and in general men are much more ſubject to them than women.

Cauſes of them. Theſe diſeaſes are brought on by any thing that gives a violent commotion to the blood, ſuch as immoderate exerciſe, the abuſe of ſpiritous liquors, and violent fits of anger. The ſuddenly cooling the body when very hot, has alſo often occaſioned them, by ſhutting the pores and forcing the blood inwards. The neglect of habitual bleedings may alſo occaſion them; and they have been ſometimes occaſioned by blows, or other external injuries on the breaſt, and by the endeavouring to lift great weights.

Prognoſtics in them. All inflammatory fevers are dangerous; but the *pleuriſy* and *peripneumony*, when they attack young perſons, or ſuch as are under thirty years of age, are attended with the leaſt danger of any, provided that they are properly treated: when they affect perſons advanced in years, they uſually prove very dangerous, in ſpite of all the care and caution that they can be treated with.

When they have been treated in a judicious manner, they uſually go off on the ſeventh, or at the utmoſt the eleventh day in copious ſweats, which come on of themſelves; after this criſis, the pulſe in a very little time returns to its natural ſtate, the violent heat goes off, and the ſtrength, appetite, and ſleep, return. When they go beyond the days of their criſes, which is often the caſe in old people, they then become very dangerous. If the urine is obſerved to be turbid before the fourth day, and afterwards depoſits a ſediment, and the reſt remain clear at the top, there is great hope that the diſeaſe will terminate happily, on the critical day, by a ſweat. When a yellowiſh matter is thrown up by coughing, and is neither very viſcid nor frothy, and particularly when in a *peripneumony* it is ſtreaked with blood, there is great reaſon to expect that the diſeaſe will go happily off: but, on the contrary, when the patient cannot ſpit at all, and the urine continues crude, there is great reaſon to fear the diſeaſe will have a fatal period.

Finally, when a diſcuſſion and reſolution of the ſtaſis cannot be effected by nature, or obtained by art, a corruption and ſuppuration follows, and often an ulcerous diſpoſition of the lungs, or true phthiſis is the conſequence.

Method of cure. The bowels are to be kept gently lax, during the whole courſe of the diſeaſe; but no irritating medicines muſt by any means be given to promote this. When there is a remarkable plethora with a narrowneſs of the breaſt, and a ſenſible ſtuffing up of the lungs, then bleeding is neceſſary; but a ſmall quantity only ſhould be taken away, and the ſame repeated the next day or oftener, if the ſame ſymptoms continue to require it: always after bleeding the patient muſt take ſome gently diaphoretic medicines, and drink plentifully of warm and weak liquors. In the uſual and more common caſes, bleeding is not neceſſary in theſe diſeaſes, tho' ſo greatly recommended by ſome. Every day before noon it is proper to give two doſes of the mixtura ſimplex, or ſome other ſuch temperate diaphoretic, with large draughts of warm liquors; and in the afternoons the antiſebrific powders of nitre, diaphoretic antimony, crabs eyes ſated with lemon juice ſhould be given; and emulſions are alſo very proper, made of ſweet almonds and barley water, or of the ſeeds of carduus mariæ. When theſe medicines have been given for ſome days, if the pain continues ſtill violent, the tincture of caſcarilla muſt be taken; and in caſes of the *pleuriſy*, cloths four or more times doubled and wetted in camphorated ſpirit of wine, are to be applied to the part. Plaſters may alſo be applied occaſionally, but they muſt not be ſuffered to remain on too long, leſt they ſtop reſpiration; an equal regimen and perfect quietneſs is to be obſerved during the whole time of the diſeaſe; but particularly on the critical days, on which nature muſt be by no means ruffled or diſturbed.

Authors differ greatly in their opinions about bleeding in this diſeaſe: ſome judge it abſolutely neceſſary in all caſes; and others wholly reject it in all. Etmuller obſerved, that bleeding in theſe diſeaſes always gave the ſtaſis a tendency to ſuppuration; others are of opinion, that it is to be done, or omitted, according to the peculiar indications in the caſe; and ſome throw aſide all the diſſolvent and diſcutient medicines, and rely on the volatile ſalts alone for the promoting ſweats, and accompliſhing the cure by that means alone, only obſerving, that if the diſeaſe will not yield to theſe, bleeding is to be added.

But the more rational practice ſeems to determine, that it is a raſh attempt to endeavour to diſcuſs a ſtaſis already formed by hot medicines, which expand the blood, and ſeem calculated only to add to it; and that the natural ſtate of the diſeaſe does not indicate bleeding, tho' the urgency of certain ſymptoms, ſuch as ſtraitneſs of the breaſt and infarctions of the lungs, in perſons of plethoric habits, may render it neceſſary and beneficial.

Perſons of very plethoric habits, who have died of theſe diſtempers, on diſſection, have been found to have one ſide of the lungs ſo ſtuffed up with blood, that it would ſink in water; and unqueſtionably in ſuch caſes bleeding is neceſſary.

Sydenham's method of curing by large and often repeated bleedings, and the uſe of gentle expectorants, is found very dangerous in its effects, and ſeems the only reproachable thing in the works of that excellent writer. And tho' Riverius gives an inſtance of a perſon cured of a *pleuriſy* in a few hours, by bleeding alone, the account does not ſeem wholly to be depended upon; for ſome circumſtances in the relation ſeem to ſhew, that the diſeaſe was not properly either a *pleuriſy*, or a *peripneumony*, but an inflammation of the liver or ſtomach. Some people recommend the flowers of the common red poppies in theſe caſes, as a ſpecific remedy; but Etmuller allows them no ſuch quality, but ſays they act in this caſe merely as a gentle opiate and anodyne; a ſort of medicines very dangerous in theſe caſes.

The ſeeds of carduus mariæ, or the milk thiſtle, are alſo by ſome recommended as ſpecifics: it is very evident that they mitigate the pain; but the fever will always continue to its regular period on the ſeventh day.

Expectorating medicines, in general, are of no uſe in theſe caſes, only if the ſpitting of a bloody matter do not ſucceed

ſufficiently by the fourth day, it may be neceſſary to give a doſe or two of ſomething of this kind; and to this purpoſe a decoction of hyſſop is preferred by many before all other medicines. Nitre is to be given boldly for the four firſt days; but after this, if the diſeaſe go on regularly, it is to be given in ſmaller quantities, and not oftener than twice in a day. All oily and fatty ſubſtances are to be excluded from external uſe, but camphor in any form is found to do ſervice.

Opiates in theſe caſes are dangerous; for as there is in all of them a tenacity of the blood, this ſtate of it requires concuſſion, reſolution, and excretion, but opiates effect the exact contrary of all theſe. Caſcarilla properly given, will almoſt always mitigate the pain; and when that fails of it effect, it is certain that opiates cannot procure it, but muſt inevitably do harm. *Junck.* Conſp. Med. p. 297, ſeq.

Mr. Du Hamel found the polygala vulgaris of ſervice in promoting expectoration in *pleuriſies*. Med. de l'Acad. Science. 1739.

Bliſters too, on the part affected, are ſaid to give great relief.

PLEUROCYSTUS, in natural hiſtory, the name of one of the general arrangements of the echini marini.

The word is derived from the Greek πλευρον, the ſide, and κυστις, the anus.

The echini of this diviſion are diſtinguiſhed from the others, by having their anus neither on the ſummit, nor in any part of the baſe, but in ſome part of the ſuperficies of one of the ſides. *Klein*'s Echin. p. 32.

PLEURONECTES, in ichthyology, the name of a genus of fiſhes of the malacopterygious kind, the characters of which are theſe: The branchioſtege membrane, on each ſide, contains ſix bones of a cylindric figure; and in the middle between theſe, but lower down, there are two others joined together at the end, but theſe are ſcarce conſpicuous. Both the eyes are placed in one ſide of the head; in ſome they are in the right ſide, and in others in the left. The eyes are covered with a ſkin. One ſide of the fiſh is always white, the other is ſpotted or obſcure.

Of theſe fiſh there are ſome which have a very ſhort ſpine at the anus, and the eyes uſually on the right ſide. The ſpecies of this ſort, enumerated by Artedi, are theſe: 1. The *pleuronectes oculis et tuberculis ſexa dextra capitis, lateribus glabris, ſpina ad anum:* this is the *plaiſe*. 2. The *pleuronectes* with the eyes on the right ſide, with rough ſcales, a ſpine at the anus, and obtuſe teeth. This is the fiſh we in England call the *dab*. 3. The *pleuronectes* with the eyes on the right ſide, altogether ſmooth. This is the *hippogloſſus* of Rondeletius; it is about a foot long. 4. The *pleuronectes* with the eyes on the right ſide, with the lateral lines rough, with obtuſe teeth, and with little ſpines at the origin of the fins. This is our *flounder*. 5. The *pleuronectes* with the eyes on the right ſide, with ſharp teeth and with the anus on the left ſide. This is the fiſh called *linguatula* at Rome, and the *pola* of Bellonius. 6. The oblong *pleuronectes* with the upper jaw longeſt, and ſcales rough on each ſide. This is the *bugloſſus* of authors, or the *ſole*. 7. The *pleuronectes* with the eyes on the right ſide, with a rough hoary body, and the lateral fins ſcarce viſible. This is brought from Amboina.

The other ſeries of the *pleuronectæ* have their eyes on the left ſide of the head, and have no ſpine, or ſcarce any at the anus. Of theſe Artedi enumerates the following ſpecies: 1. The ſmooth *pleuronectes*, with the eyes on the left ſide. This is the *rhombus non aculeatus* of Willughby, and is called the *pearl* in ſome parts of England, in Cornwall the *lugaleaf*. 2. The rough-bodied *pleuronectes*, with the eyes on the left ſide. This is our common *turbott*. 3. The left ſide-eyed *pleuronectes*, with prickly lateral lines. This is the *rhombus aculeatus* of authors. The lines on the ſide where the eyes are, are only prickly. *Artedi*, Gen. Piſc. 14.

The name is of Greek origin, and is derived from the words πλευρον, the ſide, and νηχω, a ſwimmer; and expreſſes the peculiar and diſtinctive character of theſe fiſhes; which is, that they all ſwim on one ſide, not as other fiſhes.

PLEUROPNEUMONY, a name given by medical writers to a diſeaſe approaching to, and partaking of the nature of both the pleuriſy and peripneumony.

PLEURORTHNOPŒA, a term uſed by medical writers to expreſs that kind of pleuriſy in which the patient cannot breathe, unleſs in an erect poſture.

PLICARIA, in botany, a name uſed by ſome for the club-moſs. *Dale*, Pharm. 60.

PLICATED *leaf*, among botaniſts. See LEAF.

PLINIA, in botany, the name of a genus of plants, deſcribed by Plumier and Linnæus, the characters of which are theſe: The perianthium is ſmall, plane, and conſiſts of one leaf; the flower conſiſts alſo of one petal, which is plane, and is divided into five equal parts; the ſtamina are numerous filaments, very ſlender, and of the length of the flower; the antheræ are ſmall; the germen of the piſtil is ſmall; the ſtyle is ſubulated, and of the length of the ſtamina; the ſtigma is ſimple; the fruit is a large globoſe berry, of a ſtriated or ſulcated ſurface, containing only one cell, in which is a very large, ſmooth and globoſe ſeed. *Linnæi* Gen. Pl. 239. *Plumier*, Gen. 11.

PLINTHITIS, a kind of alum found in ſome of the iſlands of the Archipelago, and called alſo *placitis*, from its uſually being found in thin cakes.

PLINTHIUM, a name given by the antients to a machine invented for the making extenſion of diſlocated or fractured limbs. Oribaſius deſcribes ſeveral kinds.

PLITE *of lawn*, in our old writers, ſeems to be an antient meaſure, as a yard or ell, at this time: 'tis mentioned in the Stat. 3 Ed. IV c. 5. *Blount.*

PLOMO, in metallurgy, a name given by the Spaniards, who have the care of the ſilver mines, to the ore of that metal when it is found adhering to the ſurface of ſtones, and incruſting their cracks and cavities in the form of ſmall and looſe grains of gunpowder. Tho' theſe grains be but few in number, and the reſt of the ſtone have no ſilver in it, yet they are always very happy in meeting with it, as it is a certain token that there is a very rich vein ſomewhere in the neighbourhood. And if in digging forwards they ſtill meet with theſe grains, or the *plomo* in greater quantity, it is a certain ſign that they are getting more and more near the good vein.

PLONKETS, in our old writers, a kind of coarſe woollen cloth. 1 Rich. III. c 8. *Blount*, *Cowel*.

PLOTTING (*Cycl.*)—PLOTTING-*table*, in ſurveying, is uſed for a plain *table*, as improved by Mr. Beighten, who has obviated a good many inconveniencies attending the uſe of the common plain *table*. See Phil. Tranſ N° 461. Sect. 1.

PLOVER, *pluvialis*, in zoology. See the article PLUVIALIS.

This bird uſually flies in exceedingly large flocks in the places they frequent; people talk of twenty or thirty thouſand being ſeen in a flock. They generally come to us in September, and leave us about the end of March. In cold weather they are found very commonly on lands lying near the ſea, in queſt of food; but in thaws and open ſeaſons, they go higher up in the country.

They love to feed in ploughed lands, but never remain long at a time on them, for they are very cleanly in their nature; and the dirt which lodges on their beaks and feet, gives them ſo much uneaſineſs, that they fly to the neareſt water to waſh themſelves. When they rooſt, they do not go to trees or hedges, but ſit ſquatting on the ground like ducks or geeſe, far from trees or hedges, when the weather is calm; but when it is ſtormy they often get under ſhelter. In wet weather they do not ſleep in the night at all, but run about picking up the worms as they crawl out of the ground: during this feeding they are continually making a ſmall cry, that ſerves to keep them together, and in the morning they take flight. If in their flight they ſpy any others on the ground, they call them up; and if they refuſe to come, the whole body deſcends to ſee what food there is in the place that detains them.

The *plover* are very eaſily taken at the time of their firſt coming over, when they have not got any other birds mixed among them; but when they afterwards pick up the teal and other ſhy birds among them, it becomes more difficult. The beſt ſeaſon for taking them is in October; eſpecially in the beginning of that month: after this they grow timorous, and are not eaſily taken again till March, which is the time of their coupling. The ſevereſt froſts are not the beſt ſeaſon for taking them in neſts, but variable weather does better. The north weſt wind is found diſadvantageous to the taking of them; and in general great regard is to be paid to the courſe of the wind in the ſetting of the nets. All ſea-fowl fly againſt the wind when the land lies that way; and the nets for the taking them are therefore to be placed in a proper direction accordingly.

PLOVER-*ſtone*, in zoology, a name uſed in ſome parts of England for the godwit, or *ægocephalus* of authors. See the article ÆGOCEPHALUS.

PLOUGH (*Cycl.*)—The advantage of digging with the ſpade, or ſuch other inſtrument, very naturally led men to the invention of the *plough*, as a greatly more expeditious way of doing the ſame thing; that is, cutting and breaking the earth into ſmall pieces; but in this the ſpade has the advantage of the common *plough*, as it goes deeper, and divides the earth more minutely; but the improvement of the common *plough* into the four coultered one, ſhews that it is eaſy to make the *plough* perform this office as much better, as it uſually does it worſe than the ſpade.

The *plough* deſcribed by Virgil had no coulter; and at this time the *ploughs* in Italy and the ſouth of France, have none; and the *ploughs* in Greece, and in the eaſtern nations in general, are of the ſame kind. Neither is it indeed poſſible to uſe a coulter in ſuch a *plough*; becauſe the ſhare does not cut the bottom of the furrow horizontally, but obliquely: in going one way it turns off the furrow to the right hand, but in coming back it turns it off to the left; therefore if it had a coulter, it muſt be on the wrong ſide every other furrow.

It is a great miſtake in thoſe who ſay that Virgil's *plough* had two earth-boards, for it had really none at all; but the ſhare itſelf always going obliquely, ſerved inſtead of an earth-board; and the two ears, which were the corners of a piece of wood lying under the ſhares, did the office of ground-wriſts. This faſhion of the *plough* continues to this day in thoſe countries; and in Languedoc this ſort of *plough* performs tolera-

bly

bly well when the ground is fine, and makes a ſhift to break up light land. This is the ſort of land that is common in the Eaſt, and the arable lands about Rome, being never ſuffered to be fallow ſo long as to come to turf: this *plough* ſucceeds very well in ſuch places, but it would be wholly impoſſible to turn up what in England we call ſtrong land, with it.

The Engliſh *ploughs* are therefore different from theſe, as the ſoil is different. Our *ploughs*, where well made, cut off the furrow at the bottom horizontally; and therefore, it being as thick on the land ſide as on the furrow ſide, the *ploughs* cannot break it off from the whole land at ſuch a thickneſs (being ſix times greater than what the eaſtern *ploughs* have to break off) and for this purpoſe it muſt have, of neceſſity, a coulter to cut it off: by this means the furrow is turned perfectly whole, and no part of the turf of it is broken; and if it lie long without new turning, the graſs from the edges will ſpread, and form a new turf on the other ſide, which was the bottom of the furrow before the turning; but is now become the ſurface of the earth, and will ſoon become greener with graſs than it was before *plughing*.

If whole, ſtrong, turfy furrows are *ploughed* croſs-ways, as is too commonly practiſed, the coulter cannot eaſily cut them; becauſe being looſe underneath, they do not make a proper reſiſtance or preſſure againſt its edge, but are apt to be drawn on heaps, and turned in all directions, but without cutting.

Some of our *ploughs* have heavy drags, with long iron tines in them; and tho' theſe broken pieces of furrows, being now looſer than before, require keener edges to cut them, theſe tines have no edges at all. Thus the clods of earth are toſſed into heaps again, and the ſurface left bare between them, and great labour and expence is uſed to very little purpoſe: all this is owing to the one coulter.

If the ſoil be ſhallow, it may be broken up with a narrow furrow, which will the ſooner be brought into tilth; but if it be a deep ſoil, the furrows muſt be proportionably enlarged, or elſe a great part of the good mould will be left unmoved, and ſo be loſt. The deeper the land is, the worſe it is broke by one coulter; that is, it is broke into larger furrows, and it requires ſuch repeated labour to conquer this, that often the beſt land will ſcarce pay the tillage.

This gives an opportunity to ſervants to cheat their maſters. They *plough* ſuch deep land with a ſmall furrow, and ſhallow, to the end that the turf and furrows may be broken the ſooner, and the ſuperficial part made fine. They pretend the *plough* will go deeper the next time; but this is never the caſe.

This ſort of land muſt not be *ploughed* the ſecond time in wet weather; for this will cauſe the weeds to multiply, and the earth will be formed into thick and heavy clods where trodden: and in dry weather, the reſiſtance of the untouched earth below, and the ſlight preſſure of the *plough* above, will always be reaſons why the *plough* will enter no deeper the ſecond time than it did the firſt.

Another way to conquer a ſtrong turf, is to plow it up firſt with a breaſt-*plough*, very thin; and when the ſward is rotten, then it is to be *ploughed* to the proper depth: but this method is liable to great objections; it is very troubleſome and expenſive, and if the turf be pared off in the winter, or early in ſpring, it is a chance but the rains come on, and ſet it to growing faſter than before: if, on the other hand, it be pared later in the year, tho' the turf be thoroughly killed by the ſucceeding dry weather, yet the time is loſt, and the farmer loſes the ſowing ſeaſon for wheat, which is the proper corn for ſuch ſtrong land.

The four-coultered *plough* is the proper inſtrument for the farmer to have recourſe to on this and many other the like occaſions. This is an improvement on the common *plough*, that makes it cut the pieces of earth into four; that is, it thus divides the earth four times as ſmall as the common *plough*.

The common two-wheeled *plough* has of late years become univerſally uſed in many counties, and is found greatly preferable to the *ploughs* they uſed before; there is an objection to it, indeed, in regard to ſome ſtiff and miry lands, in which the wheels become clogged up, and cannot turn. This, however, is eaſily remedied by twiſting thumb ropes of ſtraw about the iron circle and ſpokes of the wheels; theſe ſpreading as they turn, and as the circle twiſt bears upon the ground, throw off the dirt, and never clog. The two principal parts of this *plough* are the head and the tail: the *plough*-head contains the two wheels and their axis, or ſpindle, paſſing through a box, and turning round both in it and in the wheels. There are fixed perpendicularly in this box, two crow-ſtaves, as they are called, which are flat and narrow boards, each having on it two rows of holes, whereby to raiſe or ſink the beam of the *plough*, by pinning up or down the pillow, to increaſe or diminiſh the depth of the furrow. Behind are a pair of gallows, through which the crow-ſtaves paſs at the top by mortaiſes, into which they are pinned; and to theſe are faſtened what are called the wilds, which are rings and crooks of iron, by which the whole *plough* is drawn in the working. From the box to the center of the beam there is carried an iron-chain, conſiſting of four, five, or more long links, and called the tow-chain: this faſtens the *plough*-tail to the *plough*-head. It is fixed to an iron collar, faſtened in the beam at one end, and at the other paſſes through a hole in the middle of the box, and is pinned in with a wooden pin.

From the ſame iron-collar to which the tow-chain is fixed, there is alſo another chain faſtened, called the bridle-chain: this runs above the beam, as the tow-chain does below it, and is compoſed of ſmaller and more numerous links. At the upper end, as the tow-chain enters the box of the *plough*, this bridle-chain is fixed to the top of what is called the ſtake of the *plough*: this is a perpendicular ſtick, carried up parallel with the left crow-ſtaff, and pretty near it, and faſtened to it by a wyth or rope, or by the end of the bridle-chain itſelf, when that is long enough. This ſtake is alſo faſtened in its lower part, under the gallows, to the ſame crow-ſtaff, by another wyth or piece of rope.

Theſe are the parts of which the head-part of the *plough* is compoſed. The *plough*-tail conſiſts of the beam carried from the head to the very extremity, and ſerving as the ſupport and baſe of all the reſt. A little below the collar to which the tow-chain and bridle-chain are faſtened, this beam is pierced with a large hole, which lets through the coulter: this is a long and narrow piece, terminating in an edge, and reaching juſt to the ſhare; and it is fixed immoveably in its place by means of a wedge which is driven into the hole of the beam with it: the office of this coulter is to cut the earth as it is thrown up by the ſhare. Behind theſe, the ſame beam is pierced with two more holes, one very near its end: theſe give paſſage to two oblong pieces, called the fore-ſheat and hinder-ſheat, by which the *plough*-ſhare is ſupported in its place. To the top of the hinder-ſheat there is faſtened a ſhort handle by a wooden pin. Parallel to the hinder-ſheat there runs up a piece of wood of much the ſame form, called the drock; and to this is faſtened another horizontal piece, called the ground-wriſt: theſe are all on the right hand ſide of the *plough*, and parallel with the fore-ſheat. There runs another piece of much the ſame form with it, on the right hand; and the bottom of this is the earth-board. The long handle of this, which reaches as far that of the ſheat, is faſtened to the drock by a pin, the other end of which goes into the beam Near the lower end of the fore-ſheat, there are two flat pieces of iron, which paſs from the two ſides of it up to the beam; and being let through it, are faſtened to the upper part by ſcrews and pins. Theſe keep the ſheat in its place.

The ſtructure of the four-coultered *plough* is different, in ſome reſpects from this, tho' in general founded on it Its beam is ten foot long, whereas that of the common *plough* is but eight. The beam is ſtrait in the common *plough*, but in this it is arched in one fourth part of its length, near the *plough*-head. At the diſtance of three feet two inches from the end of the beam at the *plough*-tail, the firſt coulter, or that next the ſhare, is let through; and at thirteen inches from this, a ſecond coulter is let through: a third at the ſame diſtance from that; and, finally, the fourth at the ſame diſtance from the third, that is thirteen inches.

The crookedneſs of the upper part of the beam in this *plough* is contrived to avoid the too great length of the three foremoſt coulters, which would be too much, if the beam was ſtrait all the way; and they would be apt to bend and be diſplaced, unleſs they were vaſtly heavy and clumſy. Aſh is the beſt wood to make the beam of, it being ſufficiently ſtrong, and yet light.

The ſheat in this *plough* is to be ſeven inches broad. The fixing of the ſhare in this, as well as in the common *plough*, is the niceſt part, and requires the utmoſt art of the maker; for the well going of the *plough* wholly depends upon the placing of this. Suppoſing the axis of the beam, and the left ſide of the ſhare, to be both horizontal, they muſt never be ſet parallel to each other; for if they are, the tail of the ſhare bearing againſt the trench as much as the point, would cauſe the point to incline to the right hand, and it would be carried out of the ground into the furrow. If the point of the ſhare ſhould be ſet ſo, that its ſide ſhould make an angle on the right ſide of the axis of the beam, this inconvenience would be much greater; and if its point ſhould incline much to the left, and make too large an angle on that ſide with the axis of the beam, the *plough* would run quite to the left hand; and if the holder, to prevent its running quite out of the ground, turns the upper part of his *plough* toward the left hand, the pin of the ſhare will riſe up, and cut the furrow diagonally, leaving it half *unploughed*. To avoid this and ſeveral other inconveniences, the ſtrait ſide of the ſhare muſt make an angle upon the left ſide of the beam; but that muſt be ſo very acute a one, that the tail of the ſhare may only preſs leſs againſt the ſide of the trench than the point does.

The great thing to be taken care of, is the placing the four coulters; for on this the ſucceſs of the whole depends. Theſe muſt be ſo ſet, that the four imaginary planes deſcribed by their four edges, as the *plough* moves forward, may be all parallel to each other, or very nearly ſo; for if any one of them ſhould be very much inclined to, or ſhould recede much from either of the other, then they would not enter the ground together. In order to the placing them thus, the beam muſt be carefully pierced in a proper manner. The ſecond coulter-hole muſt be two inches and an half more on the right hand than the firſt; the third muſt be as much more to the right of the

ſecond,

ſecond, and the fourth the ſame meaſure to the right hand of the third: and this two inches and an half muſt be carefully meaſured from the center of one hole to the center of the other. Each of theſe holes is a mortaiſe of an inch and quarter wide, and is three inches and an half long at the top, and three inches at the bottom. The two oppoſite ſides of this hole are parallel to the top and bottom, but the back is oblique, and determines the obliquity of the ſtanding of the coulter, which is wedged tight up to the poll.

The coulter is two foot eight inches long, before it is worn; the handle takes up ſixteen inches of this length, and is allowed thus long, that the coulter may be driven down as the point wears away. *Tull*'s Horſe-hoeing Huſbandry, p. 132, ſeq. See COULTER.

Trenching-PLOUGH. See the article TRENCHING.

PLOUGH-*bote*, in our old writers, a right of tenants to take wood to repair *ploughs*, carts, and harrows, and for making rakes, forks, *&c.*

PLOUGH-*head*, a name given by the farmers to the foremoſt half of the *plough*, or that part containing the two wheels and their ſpindle, the box, the crow-ſtaves, the pillow, the wilds, the tow-chain and bridle chain, and the ſtake: all which, ſee under their ſeveral heads, and under the article PLOUGH. *Tull*'s Huſbandry.

PLOUGH-*tail* a name given by the farmers to that part of a *plough* which contains the beam, the coulter, or coulters, the ſhare, the ſheat and under-ſheet, the earth-board and handles, as alſo the drock, the ground-wriſts, and the retches: all which ſee under their ſeveral heads, and under the article PLOUGH. *Tull*'s Huſbandry.

PLUKNETIA, in botany, the name of a genus of plants deſcribed by Plumier, and called by this name in honour of Pluknet, the great Engliſh botaniſt.

The characters are theſe: It produces male and female flowers on the ſame plants. The male flowers have no cup, but are compoſed of four expanded petals of an oval figure, and in the place of ſtamina, there is placed in the center of the flower a ſhort pyramidal hairy body. The female flowers have no cup, and the petals in theſe are diſpoſed as in the male. The germen of the piſtillum is ſquare. The ſtyle is ſlender, very long, and crooked. The ſtigma is peltated and divided into four parts. The ſegments are obtuſe and flat, and each has a remarkable ſpot in the center. The fruit is a depreſſed ſquare capſule, hollowed at all the angles: it contains four bivalve cells: the ſeeds are ſingle, roundiſh, and compreſſed, and bluntly pointed at one end.

Linnæus obſerves, that this fructification is very ſingular, and is very deſirous that ſome perſon ſhould examine carefully the growing plant, ſince Plumier, who was not over curious about the nicer parts of the fructification of plants, may have in ſome ſort miſrepreſented this. *Plumier* 13. *Linnæi* Gen. Pl. p. 517.

PLUM-*tree*, *prunus*, in botany. See PRUNUS.

All the ſpecies of *plums* have within their fruit a hard ſtone, within which there is contained a ſoft and tender kernel: this kernel contains the ſeminal plant, from which would be produced another tree of the ſame kind, if it were ſet in the ground; and it is very natural to ſuppoſe, that the only uſe of the thick ſtone or huſk of this, was only to preſerve its tender ſubſtance from rotting too ſoon in the earth, and to give it a proper time for developing its parts, to preſerve its natural oilyneſs during that time, and to furniſh from its own ſubſtance a proper nouriſhment to the growing plant; for obſervation ſhews, that it finally breaks into a very fine powder.

There has not been found any ſpecies of *plum* which had not its kernel contained in a ſtony coat of this kind, from whatever grafts they have been propagated; nor is there any art known by which the kernel of this ſort of fruit can, while growing, be deprived of its coat.

Mr. Marchand, however, in the year 1735, ſhewed before the academy of ſciences at Paris, certain *plums*, whoſe kernels had no ſtone or ſhell round them; and found that they grew upon a tree which never had produced any others, and which had been known to produce ſuch for twenty years. The kernel in theſe was covered with a reddiſh ſkin, which was rough to the touch; and within that, with another which was thinner and white. The kernel had nothing particular in it, except that it carried on one ſide of its outer ſurface, and that always in the ſame place, a little ſtony prominence, more or leſs dented on its convex part: this is uſually a twelfth of an inch broad, and two thirds of an inch long, and has no other appearance but that of a diſtempered part of the kernel, only that all the kernels have it.

The thick wrinkled ſkin which ſurrounds the kernel, ſeems in this caſe to ſupply the place of the ſtone or hard ſhell; and in this alſo it reſembles it, that the pulp of the fruit parts eaſily and readily from it; and the hard oblong body, which is placed on one ſide of the kernel, is by no means proper for this purpoſe. Mem. Acad. Scienc. Par. 1735.

All the ſorts of *plums* are propagated by budding, or grafting them upon ſtocks of the muſcle-*plum*, the white pear-*plum*, the St. Julian, or the bonum magnum. See the article INOCULATING.

Budding is much properer than grafting for theſe trees, as they are apt to throw out a great deal of gum from the wound: and the trees ſhould be no more than one year's growth from the bud, when they are tranſplanted; for if they are more they ſeldom ſucceed well, being very ſubject to canker; and if they eſcape that, they uſually produce only two or three luxuriant branches. The whole management of planting and pruning them is the ſame with that of peaches. See the article PEACH.

If the walls againſt which they are planted are low, they ſhould be ſet eighteen feet aſunder; if they are higher, then fourteen or ſixteen.

Plums ſhould have a middling ſoil, for they ſeldom ſucceed well either in too moiſt or two dry a one; and when planted againſt walls, ſhould have an eaſt or a ſouth-eaſt proſpect. If they have one at full ſouth, they are apt to ſhrivel up, and mealy.

Plums in general ſucceed very well with proper care on eſpaliers; they will alſo bear very well as ſtandards, but the fruit will not be ſo well taſted. *Plums* do not only produce their fruit on the laſt year's wood, but alſo on ſpurs that come out of the wood of two or three years old. It is a common error to be too free with the knife in the winter-pruning, cutting off the extremities of all the branches; the conſequence of which is, that there are an over quantity of young ſhoots produced, and the fruit is ſmall and poor. *Miller*'s Gard. Dict.

PLUMBAGO, *leadwort*, in botany, the name of a genus of plants, the characters of which are theſe: the flower conſiſts of one leaf, and is of a funnel-ſhape, and divided into ſegments at the edge. The cup is tubular, and from it ariſes a piſtil, which is fixed like a nail to the lower part of the flower, and afterwards ripens into an oblong pointed ſeed, which remains in the cup to ripen.

The ſpecies of *plumbago*, enumerated by Mr. Tournefort, are theſe: 1. The ordinary *plumbago*, called by ſome *lepidium* and *dentillaria*. 2. The white flowered *plumbago*. 3. The American *plumbago*, with a large beet-like leaf. 4. The prickly climbing American *plumbago*, with a ſmaller beet-like leaf. *Tourn.* Inſt. p. 140.

PLUMBAGO, in the hiſtory of the gems, a word uſed by the Roman authors to expreſs a blemiſh common to their worſe kinds, and greatly debaſing their value. It was a ſort of bluiſh or blackiſh deadneſs in the ſtone, which mixed itſelf with the other colour, be that what it would, and rendered it dull and dead. The emerald was of all the other gems the moſt ſubject to this fault; and in this caſe, its fine green colour was always rendered cloudy and bluiſh; and in ſome lights the ſtone appeared of a duſky greyiſh blue, with no green at all in it. The Bactrian emeralds, which were in great eſteem with the antients, were often ſubject to this imperfection; and thoſe of Cyprus, taken out of the coppermines, tho' ſubject to many other imperfections, were uſually quite free from this.

PLUMBAGO, in mineralogy, a name given by many authors to a ſort of foſſil, having very much the appearance of a lead-ore, but not ſuch in reality.

It is called alſo *galena*, *blende*, and *mock-lead*. It is uſually of a plated texture, and dark blackiſh blue colour, like the lead-ores; but on trial yields no metal. See BLACK-*lead*.

PLUMBATA, among the antients, a kind of ſcourge, the thongs of which were armed with leads. *Pitiſc.* in voc.

PLUMBATÆ likewiſe ſignified leaden balls, uſed by ſoldiers to annoy the enemy with; whence the ſoldiers were called *martiobarbuli*. *Pitiſc.* in voc.

PLUMBUM *(Cycl.)*—PLUMBUM *nativum*, *native lead*. It is pretended by ſome, that the famous *lead*-mineral, found near Freyung, in the Upper Palatinate, is *native lead*: but this is an error; we have an account of it in the philoſophical tranſactions, which does not give any ground for this thought. All that is there ſaid of it is, that it was at that time much eſteemed among the aſſayers of metals, as containing no mixture of any other metal with the *lead*: this might well recommend it to them, as ſaving much confuſion, or much trouble in ſeparating its heterogene contents; but it is ſaid expreſly there, that it is an ore, not a *native* metal: there being two kinds of it, one a chryſtalline ſtone, almoſt all pure *lead*; the other not ſo rich, but of a more rough and coarſe texture. Neither of theſe could be *native lead*; and it is remarkable, that they had leſs appearance of being ſo than many of our common ores. Phil. Tranſ. N°. 3. See the article LEAD.

PLUMBUM *uſtum*. See LEAD, *Cycl.* and *Suppl.*

PLUMERIA, in botany, the name of a genus of plants, the characters of which are theſe: the flower conſiſts of one leaf, and is of the funnel-ſhaped kind, and divided into ſeveral ſegments at the edges. The piſtil ariſes from the cup, and is fixed in the manner of a nail to the hinder part of the flower. This finally becomes a podded fruit, uſually double; and when ripe, opening in the middle, and diſcharging a number of oblong foliated ſeeds, which were placed like ſcales over one another in the ſeed-veſſel, and affixed to a placenta.

The ſpecies of *plumeria*, enumerated by Mr. Tournefort, are theſe: 1. The *plumeria* with a roſe-coloured and very ſweet flower. 2. The ſnow-white-flowered *plumeria*, with long, narrow, and pointed leaves. 3. The *plumeria* with ſnow-white flowers, and ſhort obtuſe leaves. *Tourn.* Inſt. p. 659.

PLUMMER's *Æthiops*. This medicine is compoſed of the ſulphur auratum antimonii and calomel, commonly in equal parts; but this may be varied occaſionally, according to the phyſician's diſcretion. Theſe two powders muſt be well levigated together, by which the bright red colour of the ſulphur is changed into a duſky brown. We refer to the Medical Eſſays of Edinburgh, for the doſe, regimen to be obſerved, and effects of this medicine; as alſo for the manner of preparing the ſulphur of antimony according to Angelus Sala, which is ſaid to be preferable to the common method. See Med. Eſſ. Edinb. abridg. Vol. I. p. 205. and ſeq.

This medicine has been found greatly beneficial in cutaneous eruptions, in venereal infections, and in gleets remaining after the cure of a gonorrhœa. It operates by carrying off the excrements of diſtempers by inſenſible perſpiration or ſweat. It has alſo been found ſucceſsful in obſtinate glandular ſwellings. See Med. Eſſ. abrid. ibid. and alſo Vol. II. p. 433.

PLUMMING, among miners, a term uſed to expreſs the uſing a mine dial, in order to know the exact place of the work where to ſink down an air ſhaft, or to bring an adit to the work, or to know which way the load inclines when any flexure happens in it.

It is performed in this manner: A ſkilful perſon with an aſſiſtant, and with pen, ink, and paper, and a long line and a ſun dial, after his gueſs of the place above ground deſcends into the adit or work, and there faſtens one end of the line to ſome fixed thing in it, then the incited needle is let to reſt, and the exact point where it reſts is marked with a pen: he then goes on farther in the line ſtill faſtened, and at the next flexure of the adit he makes a mark on the line by a knot or otherwiſe; and then letting down the dial again, he there likewiſe notes down that point at which the needle ſtands in this ſecond poſition. In this manner he proceeds from turning to turning, marking down the points, and marking the line till he comes to the intended place; this done, he aſcends and begins to work on the ſurface of the earth, what he did in the adit, bringing the firſt knot in the line to ſuch a place where the mark of the place of the needle will again anſwer its pointing, and continues this till he comes to the deſired place above ground, which is certain to be perpendicularly over the part of the mine into which the air ſhaft is to be ſunk.

PLUMOSE *antennæ*, in natural hiſtory, a term uſed to expreſs the *antennæ*, or horns of certain moths and butterflies, which are formed in the manner of feathers, being compoſed of a ſtem and fibres, iſſuing on each ſide from it: theſe are jointed and moveable any way, and even the ſmall fibres, at their ſides, are jointed at their bottom, and are moveable, but they move all together. *Reaumur*'s Hiſt. of Inſects. See the article FEELERS.

PLUNGE, in the manege. See the article ESTRAPADE.

PLURIES, a writ that iſſues in the third place after two former writs have been diſobeyed; for firſt goes out the original writ or *capias*, which if it has not effect, then iſſues the *alias*; and if that alſo fails, then the *pluries*. Old Nat. Br. 33.

It is uſed in proceedings to outlawry, and in great diverſity of caſes. *Tabl. Reg. Writs. Blount, Cowel.*

PLUVIALIS, in zoology, the name by which Latin authors call the *plover*, a bird of which there are two kinds, the green and the grey.

The *green plover* is ſomewhat larger than the lapwing, and is all over, on the upper parts, of a blackiſh colour, variegated with very numerous ſpots of a yellowiſh green; its breaſt is of a mixed browniſh and yellowiſh green, and its belly is white: this is very much eſteemed at table.

The *grey plover* is of the ſame ſize with the green, and is, on the upper parts, of a black colour, variegated with a pale greyiſh green; and its breaſt, belly, and thighs, are white. This is very common in Italy, as well as in England, and is eſteemed nearly equal to the green at table. *Ray*'s Ornithology, p. 229.

PLUVIALIS *major*, in zoology, a name given by ſome authors to the *limoſa*, a bird in ſome reſpects reſembling our redſhank, but larger and longer legg'd. *Aldrovand.* l. 20. c. 66. See the article LIMOSA.

This bird is alſo called the *glottis* and *totanas*.

PLUVIALIS *levis*, in zoology, a name given by many to the common green *wood-pecker*, the *picus viridis* of authors, called alſo in Engliſh the *rain-fowl*, from an obſervation of its always being moſt clamorous when rain is coming on. *Ray*'s Ornithology, p. 93.

PLYMOUTH *marble*, among our artificers, a term uſed for a ſort of *marble* dug in great plenty about Plymouth, and in ſome other parts of Devonſhire, where it lies in very thick ſtrata, and whence it is brought in large quantities to us; and when wrought looks little leſs beautiful than ſome of the Italian *marbles*.

It is very hard and firm, and of a beautiful texture; its ground is a bluiſh white, and its variegations are principally a pale red, and in ſmaller quantities brown and yellow: theſe lie in very orderly beds, and often there is a very agreeable glow of a faint red diffuſed thro' the whole ſubſtance. It is remarkably even in its whole ſtructure, and is therefore capable of a more than ordinarily elegant poliſh.

PLYNTERIA, πλυντηρια, in antiquity, a feſtival in honour of Aglaurus, the daughter of king Cecrops, or rather of Minerva, who had from that lady the name of Aglaurus. For the ceremonies obſerved at this ſolemnity, ſee *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 425.

PNEUMATODES, a word uſed by Hippocrates to expreſs a perſon who fetches his breath ſhort and quick; and ſometimes for one who has his belly or ilia much diſtended by flatulencies. *Pneumatias* is alſo uſed in the ſame double ſenſe.

PNEUMATOMPHALOS, a word uſed by Hippocrates to expreſs a perſon who has a windy or flatulent rupture of the navel.

PNEUMONANTHE, in botany, a name given by many botanical writers to a ſpecies of *gentiana*, called alſo by ſome the *calathian* violet. See the article GENTIANA.

PNEUMONICS, in medicine, a term uſed for ſuch things as are good for the lungs.

PNIGITIS *terra*, in the materia medica of the antients, a name given at different periods of time, to two different ſpecies of earth; the *terra pnigitis* of Dioſcorides and Pliny, being a grey marle, and the *pnigitis* of Galen a black clay.

The laſt of theſe is a very valuable aſtringent, and is found in many parts of this kingdom, particularly in the neighbourhood of London, and well deſerves to be introduced into the practice of phyſic. *Hill*'s Hiſt. of Foſſ. p. 35.

PNIGMOS, in medicine, any kind of ſuffocation, from whatever cauſe; it is very often uſed to expreſs that of hyſteric fits in women.

PNIX, a word uſed by phyſicians to expreſs the ſuffocation from hyſteric fits, or any other cauſe.

POA, in the Linnæan ſyſtem of botany, the name of a diſtinct genus of plants of the graſs kind, the characters of which are, That the calyx is a glume compoſed of two valves, containing ſeveral flowers diſpoſed in a two-rowed oval, or oblong ſpike; the valves oval and pointed, but without awns. The flower is compoſed of two oval and pointed valves; theſe are hollowed, compreſſed, a little longer than the valves of the cup, and without beards or awns; the ſtamina are three capillary filaments; the antheræ are ſplit at their ends; the germen of the piſtillum is roundiſh; the ſtyles are two, reflex and hairy; the ſtigmata are hairy alſo; the flower adheres cloſely to the ſeed, and does not open to let it out; the ſeed is ſingle, oblong, and pointed at both ends, and ſomewhat flatted. *Linnæi* Genera Plant. p. 20.

POAKE-*root*, in Virginia, is uſed to denote the ſolanum baciferum. The Indians uſe it for a purge, tho' commonly deemed a poiſon. Phil. Tranſ. N° 454. Sect. 1.

POCHARD, in zoology, the name of a ſpecies of wild duck, called by ſome the *penelops* and *rothals*, and by many in Engliſh the red-headed *widgeon*.

It is larger than the common *widgeon*, and is ſhorter and thicker bodied. The back and wings are grey, and beautifully variegated with grey and black ſtreaks. The lower part of the neck, as alſo the rump, are black, but the whole head, and a great part of the neck, are reddiſh; the throat is white, variegated with yellow; and the breaſt and belly ſomewhat brown: but the great diſtinction of this bird from all the other ducks is, that the wings are all of the ſame colour without variegation. *Ray*'s Ornithol. p. 288.

POCKET *(Cycl.)*—POCKET, in the wool trade, a word uſed to expreſs a large ſort of bag, in which wool is packed up to be ſent from one part of the kingdom to another.

The *pocket* contains uſually twenty-five hundred weight of wool.

POCKET *inſtruments*, in ſurgery, are ſuch as a ſurgeon ought always to have in readineſs, and may conveniently carry about him in a proper caſe: theſe are two lancets of different ſizes; the one proper to open abſceſſes, the other ſmaller, for bleeding; a pair of ſtrait ſciſſars, uſeful on many occaſions; a pair of crooked ſciſſars, proper to be uſed in dividing fiſtulæ, and in ſeveral other caſes; a pair of forceps with teeth at one end, to remove dreſſings, and upon occaſion to extract ſplinters or thorns; theſe are alſo ſerviceable to the ſurgeon in his anatomical exerciſes; they are commonly made of ſteel, but thoſe of ſilver are much neater; a razor; a ſtrait inciſion knife; a crooked inciſion knife; a ſtrait double-edged inciſion knife; a probe with one end broad and thin, proper for diſcovering a fiſſure in the cranium, and of many other uſes; and the other end rounded, to examine the depth and ſituation of wounds and ulcers. The neateſt probes are made of ſilver, tho' they are frequently made alſo of ſteel, ivory, or whalebone; a grooved probe or director, to direct the edge of the knife or ſciſſars in opening ſinuſes or fiſtulæ; that by this means the ſubjacent veſſels, nerves, and tendons, may remain unhurt. The upper end of this inſtrument, ſometimes, is ornamented, and ſerves only for a handle; ſometimes it is made in form of a ſpoon, to contain powder to ſprinkle upon wounds or ulcers; ſometimes alſo this is made forked at the end, to divide the frænum of the tongue; a ſpatula to depreſs the tongue, in order to examine the ſtate of the tonſils, uvula, and fauces, when they are affected with any diſorders; it is alſo uſed to ſuſpend the tongue when the frænum is to be divided; for which purpoſe it is to be made

with a fiſſure at its extremity, and ſhould therefore rather be made of ſilver than of any other metal. Beſide theſe, there ſhould be an ordinary ſpatula for ſpreading plaiſters, ointments, and cataplaſms; and ſometimes by means of their ſulcated extremity they are of ſervice in raiſing up fractured bones of the cranium; ſeveral needles muſt alſo be kept here, ſome ſtrait and others crooked, for the ſtitching up of wounds, taking up of arteries, and many other uſes. *Heiſter*'s Surg. p. 12.

POCKET *medicines*. See the article MEDICINE.

POCO *allegro*, in the Italian muſic, is not ſo faſt as *allegro*.

Poco *largo*, intimates to play or ſing a little ſlow. See LARGO.

POCO-*meno allegro*, is uſed to ſignify that the part it is joined to ſhould be placed or ſung in a little leſs gay manner than *allegro* requires.

Poco *preſto*, ſerves to let us know that we ought to ſing or play the part to which it is annexed, not quite ſo quick as *preſto* requires it ſhould.

POCUMMA, in botany, a name given by the people of Guinea, to a ſpecies of plant which they uſe as an aſtringent. Their manner of taking it is very ſingular; for they put the leaves among their dough, and bake them into a maſs with the bread, and then eat the whole together in their food. Phil. Tranſ. N° 232.

POD, among botaniſts, a ſpecies of *pericarpium*, conſiſting of two valves which open from the baſe to the point, and are ſeparated by a membranaceous partition, from which the ſeeds hang by a kind of funiculus umbilicalis. See PERICARPIUM.

PODAGRA, a ſpecies of the gout. See the article GOUT.

PODAGRA *lini*, in botany, a name given by ſome of the later Greek writers to *cuſcuta*, or *dodder*, when found growing on the linum or flax. The Latins have called this *epilinum*, as they do the dodder growing on thyme *epithymum*; the earlier Greeks called this *linozoſtes*. Where this dodder takes root in a field of flax, it generally occupies many plants; and where it twines round them it cauſes protuberances and ſwellings, and has therefore been reſembled to the gout on that plant.

PODAGRARIA, in botany, a name given by many authors to the leſſer wild *angelica*, called alſo *herba Gerardis*. *Parkin.* Theat. p. 943.

PODERIS, in antiquity, a robe hanging down to the feet; but it is chiefly uſed to expreſs a linnen garment, a ſurplice, a ſhirt. The Jewiſh prieſts were covered with this kind of long ſurplices, during the time of their attendance in the temple; and this was the proper habit of their order. *Calmet*, Dict. Bibl.

The word is Greek ποδηρης, from πους, pes, and αἰρω, apto. Vid. *Hederic.* Lex. man. Græc. in voc.

PODICEPS, in zoology, a name given by many to the ſeveral kinds of *colymbi*, or *divers*, as they are alſo called in Engliſh *arſe foots*; from their legs being placed very backward on their bodies, by which means they have great advantages in ſwimming and diving. *Ray*'s Ornithol. p. 256. See the article COLYMBUS.

PODISMUS, ποδισμος, among the Greeks, a certain ſpace, or number of feet laid out by ſurveyors; it was the ſame with what the Romans called *pedatura*. *Pitiſc.* in voc. See the article PEDATURA.

PODIUM, in the theatre of the antients, the wall that ſeparated the orcheſtra from the ſcene. Mem. de l'Acad. Vol. I. p. 190. See ORCHESTRA and SCENE, *Cycl.*

POEANOPSIA, ποιανοψια, in antiquity, a name ſometimes given to the feſtival Pyanepſia. See PYANEPSIA, *Cycl.*

POENITENTES, in the church of Rome, a deſignation given to heretics, who being admoniſhed by the eccleſiaſtical judge, have abjured their errors, and given ſufficient ſatisfaction to the biſhop or inquiſition. Confiſcation of goods is a puniſhment common to all heretics; but if they confeſs and abjure of their own accord, without being formally proſecuted, this part of their puniſhment is uſually remitted. *Hofm.* Lex. Univ. in voc. See INQUISITION, *Cycl.*

POGGE, or CATAPHRACTUS, in zoology, the name of a ſmall ſea-fiſh, caught in the Engliſh and ſome other ſeas.

It ſeldom grows to more than five inches in length; its head is of a triangular figure, and flatted, and is very broad, and is ſurrounded at the ſides with a number of tubercles; the forepart toward the mouth has a number of extremely fine hairs, and the hinder part armed with a number of prickles; the points of which are directed backwards. Its ſnout is ſhort, and armed with four points; the two anterior ones reſembling a horned moon, and the others being prickles with their points turned backwards. The mouth is in the lower part of the head, and is of a ſemi-circular form, and has two beards at its angles, and a number of hairs under its chin.

The body of this fiſh, near its head, is flatted and of an octangular form; near the tail it is hexangular, and is of a browniſh colour variegated with black ſpots. It is covered all over with bony ſcales, in the middle of which there riſes a crooked tumor; which being continued thro' the whole number, makes the body of an angular form: toward the tail it grows very ſlender. It has two fins at the gills, two more on the belly, and two on the back, all ſpotted with black ſpots; and its tail ends in a ſmall rounded fin. It has no teeth, but very rough and rigid lips, and lives on ſhrimps and other ſuch food. It is a very well taſted fiſh.

It is caught not unfrequently on the coaſts of Yorkſhire, and in great plenty in the mouth of the Elbe. *Willughby*'s Hiſt. Piſc. p. 212. See Tab. of Fiſh. N°. 30.

There is an American *cataphractus*, much reſembling this, but having three angles on the hinder part of its head, one on each ſide, and the third in the middle; and its upper chap elliptic, and its mouth a little prominent. Its head is covered with a brown and bony helmet; and its back, ſides, and tail, with ſcales of the ſame colour, engraven with ſmall parallel lines, and of a rhomboidal figure. Its belly is covered with a thin limber ſkin. *Grew*'s Muſeum, Soc. Reg. p. 117.

POGO, a name by which the inhabitants of the Philippine iſlands call their *quail*: it is very like our common quail, but ſmaller.

POINCIANA, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the roſaceous kind, and is uſually compoſed of five petals arranged in a circular form, and filled up in the middle with a larger number of crooked ſtamina. The cup is divided into five leaves, the lower of which is crooked and imbricated: from this ariſes the piſtil, which finally becomes a hard pod of a flatted ſhape, which when ripe opens into two parts, and contains a number of roundiſh ſeeds divided from one another by a ſort of membranaceous partitions.

There is only one known ſpecies of the *poinciana*, which is the plant called by many *criſta pavonis*, and purple-flowered *acacia*. *Tourn.* Inſt. p. 619.

POINSON, in the manege, is a little point or piece of ſharp-pointed iron, fixed in a wooden handle, which the cavalier holds in his right hand when he means to prick a leaping horſe in the croupe, or beyond the end of the ſaddle, in order to make him yerk out behind.

POINT, (*Cycl.*) in geometry, is the termination of a line, and cannot be conceived to have parts. See SURFACE.

Hobbes defines a *point* to be a body whoſe magnitude is not conſidered. But his falſe notions of a *point*, line, and ſurface, have led him into many errors. Monſieur de Crouzas alſo has ſuppoſed a line to be compoſed of *points*, in his geometry and comment on the analyſe des infiniment petits. This ſuppoſition only tends to confound learners. See *Jo. Bernoulli* Oper. Vol. IV. p. 161, ſeq.

Conjugate POINT, in geometry, is uſed for that *point* into which the *conjugate* oval, belonging to ſome kinds of curves, vaniſhes. *Mac Laur.* Algebr. p. 308.

POINT *of contrary flexure*. The *points of contrary flexure* and reflexion of curves, are uſually determined by ſuppoſing the ſecond fluxion of the ordinate to be nothing or infinite, that is, $\dot{y}=0$, or ∞, or *ddy*$=0$, or ∞. See *L'Hopital* Analyſe des Inf. petits.

But this rule is liable to ſeveral exceptions, as is ſhewn very fully and clearly by Mr. Mac Laurin in his Treatiſe of Fluxions, B. i. ch. 9. and B. ii. ch. 5. art. 866.

The ordinate *y* paſſes thro' a point of contrary flexure, when, the curve being continued on both ſides of the ordinate, $\dot{y}$ is a maximum, or minimum. But this does not always happen when $\dot{y}=0$, or ∞. Mr. Mac Laurin obſerves, in general, that if $\ddot{y}$, $\dddot{y}$, $\ddddot{y}$, &c. vaniſh, the number of theſe fluxions being odd, and the fluxion of the next order to them having a real and finite value; then *y* paſſes thro' a *point* of contrary flexure; but if the number of theſe fluxions that vaniſh be even, it cannot be ſaid to paſs thro' ſuch a *point*; unleſs it ſhould be allowed that a double infinitely ſmall flexure can be formed at one *point*. Lib. cit. art. 866.

The curve being ſuppoſed to be continued from the ordinate *y*, on both ſides, if $\dot{y}$ be infinite, the extremity of the ordinate is not therefore always a *point* of contrary flexure, as $\dot{y}$ is not always, in this caſe, a maximum, or minimum; and the curve may have its concavity turned the ſame way on both ſides of the ordinate. But theſe caſes may be diſtinguiſhed by comparing the ſigns of $\dot{y}$ on the different ſides of the ordinate; for when theſe ſigns are different, the extremity of *y* meeting the curve is a *point* of contrary flexure.

The ſuppoſitions $\dot{y}=0$, or ∞, and of $\ddot{y}=0$, or ∞, ſerve to direct us where we are to ſearch for the maxima and minima, and for *points* of contrary flexure; but we are not always ſure of finding them. For tho' an ordinate or fluxion that is poſitive, never becomes negative at once, but by increaſing or decreaſing gradually, yet after it has decreaſed till it vaniſh, it may thereafter increaſe, continuing ſtill poſitive; or after increaſing till it becomes infinite, it may thereafter decreaſe without changing its ſign. See *Mac Laurin*, art. 262, 867.

POINT *of reflexion*, in geometry, is commonly uſed inſtead of *point* of retrogradation, or retrogreſſion. See the article RETROGRADATION, *Cycl.*

The general rule given by the Marquis de L'Hopital, for finding the *point of reflexion* in curves whoſe ordinates are parallel, is the ſame as that for finding the *point* of contrary flexure, and conſiſts in taking the ſecond fluxion of the ordinate of the curve, and ſuppoſing it nothing or infinite: but this rule admits of many exceptions. See *Mac Laurin*'s Fluxions, B. i. ch. 9. and B. ii. ch. 5.

POINT, in the manege. A horſe is ſaid to make a *point*, when in working upon volts, he does not obſerve the round regularly; but pulling a little out of his ordinary ground, makes a ſort of angle or *point* by his circular tread This fault is prevented by haſtening the hand. See HASTEN.

POINT is alſo uſed to denote the toes of a bow of aſaddle. See the article BOW.

POISON *(Cycl.)*—We are apt to extend the ſignification of this word very far, our common acceptation of it taking in every thing which, taken into the body, is capable of deſtroying or highly injuring it. Hence the number of *poiſons* is greatly increaſed upon the world, and the abuſe of many things, naturally wholeſome or uſeful in food or phyſic, brings them into the claſs of hurtful things. This, however, brings great confuſion into the writings or diſcourſe of ſuch who uſe it; and the ſenſe of the word *poiſon* becomes very vague and uncertain from it. A draught of cold water drank by a perſon while very hot, has been known to cauſe inſtant death; and according to this rule, cold water ſhould therefore be a *poiſon*.

Poiſons are diſtinguiſhed by ſome authors by ſeveral names, according to the different time and manner of their taking effect.

Some are called *venena terminata*. Theſe are ſuch *poiſons* as perform their fatal office, according to the opinion of the world, at certain ſtated or determinate periods of time: thus, according to the quantity given, or the nature of the ſpecies of *poiſon*, a man muſt be killed by it at the pleaſure of the giver, either in an hour, a day, a week, a month, many months, or years; the *poiſon* in this laſt caſe operating like a chronical diſeaſe, and carrying off the patient by a very tedious train of ſymptoms.

Others are called *venena temporanea*, temporary *poiſons*. Theſe will kill a man by degrees, every minute of his life growing worſe and worſe, from the time of taking them to the final period; but this is not at any ſtated or certain time.

Others are called *delibutoria venena*. Theſe are ſuch as kill without being taken internally, and are ſurely fatal if rubbed upon the ſkin, put into gloves, or the like.

As to the firſt of theſe kinds, it is very much to be doubted whether there be in nature any ſuch thing as a *venenum terminatum*, or a *poiſon* which ſhall kill at the fixed time at which the giver pleaſes; ſince all the known *poiſons* are only relatively ſuch, and depend for their effect on the peculiar ſtate of the body: the different conſtitutions of men muſt therefore vary the period of time at which death muſt happen from the taking the ſame doſe. At leaſt, if it be poſſible to contrive a terminatory *poiſon*, it muſt require the ſkill of the ableſt phyſician to prepare it, ſince he muſt at once know the true ſtate of the perſon's body who is to take it, and the exact power of the *poiſon*, in its ſeveral doſes, on other bodies.

Much, therefore, is required in the phyſician who is to cure a perſon who has ſwallowed *poiſon*; ſince the nature of the medicine, and the true knowledge of the ſtate of the patient's body, are both neceſſary in order to know what ſymptoms to expect and guard againſt.

Of the number of thoſe *poiſons* which take a long time to kill, and that different, according to their doſe and the habit of the perſon, are the venom of the toad and of the mad dog, whether the ſaliva be communicated immediately to the blood by a wound, or ſwallowed with food or with the ſpittle. The *poiſon* of the tarantula is alſo of this number; and to theſe may be added, that of the ſmall pox, meaſles, and other diſeaſes of that kind, which is evidently long dormant in the body, till certain peculiar occaſions and accidents call it forth to appear in its proper form. The *poiſon* of the hectic fever is alſo by ſome referred to this, it being accounted an alkaline virus, mixed with a viſcid matter. The *poiſon* of the French pox, *lues venerea*, is alſo of this kind, and is eſteemed highly acrid and alkaline. The *poiſon* of cantharides, the acid ones of nitre, ſalt, vitriol, ſulphur; the ſolutions or cryſtals of gold, ſilver, and the other metals; and the precipitates of mercury, and the very fatal common arſenic. To theſe are added many others, and among them ſome which act merely mechanically, by their numerous ſharp points and edges; ſuch as the powder of diamonds, glaſs, and the like: and to this claſs belong many of the delibutory *poiſons*. *Stentzel* Toxicolog.

Of the temporaneous *poiſons* many are taken under the common denominations of food and drink, and ſeem at firſt to be of no injury; but by degrees they impair the conſtitution, and bring on diſeaſes and death. Coffee, Tea, and all the ſpirituous liquors are accounted of this kind.

We may perhaps aſcribe the prodigious multiplicity of *poiſons*, and that equally numerous tribe of antidotes treated of by the antients, to the love of the marvellous: however, it cannot be denied, that ſome things are very ſuddenly and ſtrangely deſtructive to animal life, and that in very ſmall quantities. Among the reſt, there is a *poiſon* made uſe of by the Indians, ſome of which was ſent over to the royal ſociety by Mr. de la Condamine: Dr. Brockleſby has given us ſome accounts of its effects on cats, dogs, and birds, who were ſoon killed by it, only by ſprinkling a few drops of the ſolution of this *poiſon* on wounds made by a lancet. The doctor gave alſo two drachms of ſugar to a bird, and ſhortly afterwards poured a little of the ſolution into its mouth; but two drops had ſcarce touched its tongue, before the creature was convulſed, and could with difficulty be laid down before all motion was taken away.

Hence it appears, that ſugar is no ſpecific againſt this *poiſon*, even when only taken at the mouth. Phil. Tranſ. N°. 482, Sect. 12.

The negroes uſe a *poiſon* of an extraordinary nature. The doſe is very ſmall, and it hath no ill taſte; ſo that, mixed with meat or drink, it is not perceivable. It cauſes divers ſymptoms, and the effects are various, according as the doſe is large or ſmall. It kills ſometimes in very few hours, ſometimes, it is ſaid, in ſome months, and at others in ſome years. The ſymptoms are according to the quantity given; if great, it cauſes evacuations upwards and downwards; of excrements firſt, then of humours, and laſtly of blood with fainting fits and ſweatings. Death follows in ſix or ſeven hours. The negroes turn white. Phil. Tranſ. N°. 462. p. 3.

The antidote to this *poiſon* is the root of the ſenſible weed, as it is commonly called, or *herba ſenſitiva*, in decoction. Id. ibid. p. 4.

Vegetable POISONS. It has been a general complaint, and indeed too juſt a one, that the qualities of plants are much leſs ſtudied than their external appearances; and the beſt modern authors have contented themſelves with nicely characteriſing plants according to their flowers and ſeeds, and aſcertaining the proper names to each, without at all enquiring how they might be beneficial or hurtful to mankind, or diſtinguiſhing whether they were ſafe medicines or deſtructive *poiſons*. Nor, indeed, is the inveſtigating the virtues of plants, yet untried as medicines, any eaſy taſk; ſince neither chemical analyſes, nor experiments on brutes, nor even the taſte and ſmell, and other ſenſible qualities of plants, can ever certainly aſſure us what effects they will have on the human body.

Chemical analyſes alter the ſubſtance too much to give any certain knowledge; and the effects things have on one animal are no aſſurance of what they will do to another, as is familiar to us in a thouſand inſtances. Bitter almonds, and many other things, wholly harmleſs to us, kill birds; and goats will eat the tithymals, to give them an appetite when they want it, while thoſe very plants are fatal to fiſhes, and very dangerous to man. The ſenſible qualities as often deceive us, of which we ſhall give many inſtances; and what ſome have obſerved of the botanical characters of plants, telling us their virtues, or that all of the ſame claſs poſſeſs the ſame qualities, is the moſt erroneous, and, if truſted to, might prove the moſt fatal of all opinions; ſince the known *poiſons*, hemlock, phellandrium, and water-dropwort, with the *poiſonous* juice, are all umbelliferous plants, and conſequently of the ſame family with fennel and angelica.

Nothing can, indeed, aſſure us with any degree of certainty of the virtues of plants, but experiments made on ourſelves; but few are to be found who wiſh ſo well to the public, as to venture their own lives for its ſervice: and perhaps the honeſt Geſner is the only man who ever carried theſe attempts to any degree, and he unhappily died a martyr to them, periſhing by the doſe he took of the ſcorpion-rooted doronicum; the very root which has of late with us been ſo fatal, by being accidentally mixed with our gentian.

What we learn of the vegetable *poiſons* muſt therefore be either by the conſequences of the raſh preſcriptions or miſtakes of the ignorant pretenders to medicine, or by the misfortune of thoſe who have unwarily eaten them.

We have accounts in the memoirs of the academy of ſciences of Paris, of many things of this kind. An apothecary, a very honeſt man, but of no knowledge in botany, had made his extract of black hellebore from the roots of the chriſtophoriana, or bane-berries, a plant always accounted a *poiſon*, and a ſingle berry of which is capable of killing ſeveral animals; yet ſo far had the fire diveſted the roots of their *poiſonous* qualities, that twelve grains of this given as extract of hellebore, proved of no ill effect. Mem. Acad. Scienc. Par. 1739.

Another apothecary having learned, that hermodactyls were the roots of a ſpecies of colchicum, dried the roots of the common colchicum, and ſold them in its place; yet there is no knowledge of any ill effects from them.

The enquiry into things of this kind has its uſe, and that no ſmall one; ſince *poiſons* often differ only in doſe from medicines, and many of the vegetables eſteemed *poiſonous*, may perhaps be found uſeful remedies, with proper management and in proper quantities.

The laurel-leaves are well known to afford a *poiſonous* water in diſtillation, yet it is as well known that they have been long uſed in cookery, to give a taſte like that of bitter almonds to creams, *&c.* and that without any ill effect. The roſe-bay, or oleander, is well known to be a *poiſon* to goats, yet is taken by the country-men of ſtrong and robuſt habits as a purge, and that with very good ſucceſs. Nay, opium, one of the greateſt of all medicines, if it had firſt been diſcovered by perſons taking over-doſes of it, and dying by it, as they naturally muſt have done, might very naturally have been recorded to us as a very fatal *poiſon*.

The plumbago, or dentillaria of Rondeletius, is ſo violent a cauſtic, that a poor girl who once anointed herſelf with it, to

cure her of the itch, was flead alive by it; yet this properly managed, and infused in oils, has proved one of the greatest of all remedies for cancers.

The shrub used in dying, and called by the French *redoul*, by some authors *coriaria*, and by others the myrtle-leaved *rhus*, is generally known to to the world only as a drug useful in the dressing of leather; but Pliny, and some other old writers, have given it the character of an useful external medicine, and a remedy against *poisons*; yet with all this inattention of the moderns, and all the praises of the antients, this plant is truly a very terrible *poison*. The grown cattle refuse to feed upon it, but the young lambs and kids often eat of it in those parts of Europe where it is common; and if they eat the full-grown leaves, they are killed by it; if the young shoots only, which is more usually the case, they are then only affected with spasms and a sort of drunkenness, of which, after a few hours, they recover. Nor is this singular to this *poisonous* plant, since it is well known, that many plants, of very improper kinds for food, are yet eaten in their young shoots: and Linnæus has recorded it of the Laplanders, that they even eat the young shoots of the *poisonous* blue aconite, or wolf's-bane; and even in France they eat the first shoots of the clematitis, or flammula repens, the full-grown leaves of which are of so acrid a nature, that they serve the beggars to eat ulcers in their arms and legs, to give them a pretended title to charity.

The *redoul* is not only a *poison* to animals, but its fatal effects have been seen on the human species. A girl in France, where it is very common, gathering its fruit among blackberries, eat of them, and died epileptic, in spite of all the assistance that could be given her: and another instance is given from the Hotel Dieu at Paris, where an unhappy traveller, a robust man, was brought in epileptic, and died so; tho' the cause was not known, except by a vomit which was given him bringing up some of the berries of this pernicious plant, and some more of them having been found in his stomach when dissected. Mem. Acad. Scienc. Par. 1739.

POISON-*wood*, in botany. See TOXICODENDRON.

POLA, in zoology, the name of a flat fish, something resembling the soal; but shorter and smaller, commonly called *cynoglossus* and *linguatula*. See CYNOGLOSSUS.

It is caught in the Mediterranean, and sold in Rome and Venice for the table. *Bellon.* de Aquat. Vol. I. p. 37.

POLAEDRASTYLA, in natural history, the name of a genus of crystals. The word is derived from the Greek πολὺς, many, ἕδρα, sides, the privative particle α, not, and στύλος, a column; and expresses a crystal composed of many planes and having no column.

The bodies of this genus are crystals composed of two octangular pyramids, joined base to base, and consequently the whole body consisting of sixteen planes. Of this genus there are only two known species: 1. A brown kind with short pyramids, found in considerable plenty in Virginia on the sides of hills; and, 2. a colourless one, with longer pyramids. This has yet been found only in one place, which is the great mine at Gosselaer, in Saxony, and there usually lies at great depths. *Hill*'s Hist. of Foss. p. 171.

POLE *(Cycl.)*—*Hop*-POLES, the upright pieces of wood that serve for the hops to twist round and grow upon.

The number, length, and bigness of the *poles* are to be regulated according to the bigness of the hills, and their distance, and the nature of the ground, and strength of the plants.

If the hills are wide, there must be the more *poles*, sometimes four or five to a hill, or more than that; but if they stand near, two may serve for every hill. In hot, dry, and hungry ground, the *poles* should stand nearer than in rich mellow land, where they are more subject to grow gross and heavy.

If the plants are strong, and the ground rich, the *poles* must be both large and long, or else the crop will suffer greatly: if the crop be poor, it is best to have but few, and those small and short *poles*, otherwise the hop will easily run itself out of heart, and the root will be impoverished.

The *poles* should never be made over long the first year. The propereſt wood for *hop-poles* is the ash or the alder, and if they have a sort of fork at the top, they will keep up the *hop* the better. The *poles* are to be dispersed between the hills, to be in readiness; but they must not be set up till the plants begin to appear, that it may be known where they ought to be placed. This may be continued till the plants are a yard high, but it ought to be finished by that time, because the plants will be stunted or injured in their growth, if they have not something to support them when arrived at that heighth.

The *poles* must be placed not in the hill, but near that part of it out of which each plant to be supported grows. They must be driven far enough into the ground, so that they may rather break than be torn up. Their depth is to be judged by the nature of the ground, their own height, and their exposure to the wind. Let all the *poles* lean outward one from another, that they may seem to stand at an equal distance at the top, to prevent the choaking up the plants below; and they should always lean towards the south, that the sun may the better shine in among them. A sloping *pole* is always more ready to bear a quantity of *hops* than an upright one, and the sun shines on more of the plants at once by means of it. It is always necessary to keep some spare *poles*, by way of reserve, to be ready in case of the others breaking; for in this case, the *hops* are soon spoiled with lying on the ground. If a *pole* be over-burthened with *hops*, they may be unwound, and wrapped round a stronger *pole* put in the place of the other.

The largest sort of *hop-poles* should be twenty foot long, and nine inches in circumference, for hops at full growth; and they should be polled about fourteen days after the dressing in of rich land. An acre of *hop* ground generally requires about three thousand *poles*.

When the *hops* are grown to three foot high, they are to be conducted to such of the *poles* as are nearest, or have fewest *hops* on them; and they are to be wound about these *poles* according to the course of the sun, and tied to them loosely with some rushes, or with soft yarn: two or three strings are sufficient to each *pole*, and great care is to be taken that the young shoots are not broken in the doing this; they are much more brittle in the morning than the heat of the day. During the months of April and May the plants are to be carefully attended, and kept turned round the *poles*; and when out of reach, a fork, stick, or ladder are to be used to this purpose.

About Midsummer they usually leave running at length, and begin to branch; such as do not, should have the end broke off, to incline them to it, it being much to the advantage of the owner that they should branch out. From the middle of May to the end of summer, the ground between the *poles* should be dug or turned up with a plough, to kill the weeds; and the earth about the hills raised higher, to keep them moist. *Mortimer*'s Husb. p. 177. See HOP.

POLEMARCHUS, Πολεμαρχος, among the Athenians, a magistrate who had all the strangers and sojourners in Athens under his care, over whom he had the same authority that the archon had over the citizens.

It was the duty of the *polemarchus* to offer a solemn sacrifice to Enyalus, said by some to be the same with Mars, but by others to have been only one of his attendants; and another to Diana, surnamed Αγρότερα, in honour of the famous patriot Harmodius. It was also the business of the *polemarchus* to take care that the children of those who had lost their lives in their country's service, should have a competent maintenance out of the public treasury. *Potter*, Archæol. Græc. l. 1. c. 12. T. 1. p. 77.

POLEMONIUM, *polemony*, in botany, the name of a genus of plants, the characters of which are these: the flower consists of a single leaf, and is of a rotated form, and divided into segments at the edge. From the cup there arises a pistil, which is fixed in the manner of a nail to the middle part of the flower, and finally becomes a roundish fruit, or case, divided into three cells, which are full of oblong seeds.

The species of *polemonium*, enumerated by Mr. Tournefort, are these: 1. The common blue-flowered *polemonium*, called by some *Greek-valerian*, with blue flowers. 2. The common white-flowered *polemonium*, or *Greek-valerian*, with white flowers. 3. The *polemonium* with variegated flowers, or *Greek-valerian*, with flowers striped with blue and white. *Tourn.* Inst. Bot. p. 146.

POLETÆ, Πολῆται, among the Athenians, ten magistrates, who together with three that had the care of the money allowed for shews, had the power of letting out the tribute money, and other public revenues, and selling confiscated estates; all which bargains were ratified in the name of their president. Besides this, it was their office to convict such as had not paid the tribute called Μετοικιον, and sell them by auction. *Potter*, Arch. Græc. l. 1. c. 14. T. 1. p. 80.

POLGAHA, in botany, a name by which some authors have called the cocoa-nut tree, or *palma Indica nucifera* of other writers. *Herm.* Mus. Zeyl. p. 50.

POLIA *lithargyrus*, a term used by Dioscorides to express the white litharge, which we call litharge of silver.

The proper sense of the word *polia*, is hoary, or grey, and it very well expresses the colour of this substance; but the commentators have not been satisfied with this obvious meaning, but have made it *pelia*, and some of them *ficelia*. See the article LITHARGE.

POLIEIA, Πολιεια, in antiquity, a solemnity of Thebes in honour of Apollo, surnamed πολιος, *i. e.* grey, because he was represented in this city (contrary to the practice of all other places) with grey hairs. *Potter*, Archæol. T. 1. p. 426.

POLIIFOLIUM, in botany, the name of a genus of plants described by Buxbaum, the characters of which are these: the flowers are monopetalous, of the bell-fashioned globose kind; the seed-vessel is divided into five parts, and contains a number of roundish seeds; the leaves are like those of the poly-mountain, whence the name; the flowers resemble those of the arbutus, or strawberry tree; and the fruit that of the cistus.

The plant has been known among authors before, tho' ill-

named and confounded with other genera; Ray has called it *ſedum arbuti flore*. It properly belongs to the plants of the ſhrub-kind, with dry fruits, and ought to be placed after the chamærhododendros, in the regular arrangements of plants.

Beſide the common kind of this, there is an African one, the leaves of which are ſhorter and rounder than thoſe of this ſpecies, and which may be called the ſhort-leaved African ſhrub-*poliifolium*.

POLIOPUS, in zoology, a name given by Aldrovand, and ſome other authors, to the *grinetta*; a ſmall bird of the moor-hen kind. See GRINETTA.

POLISHING (*Cycl.*)—POLISHING *of ſhells*. This is an art of no long ſtanding in the world, in its preſent perfection; and as the love of ſea-ſhells is become ſo common among us, it may not be diſagreeable to the reader to find ſome inſtructions in executing ſo pleaſing a method of adding to their natural beauty, and the rules for which are at preſent ſo little known, tho' the effect of them be ſo much eſteemed.

Among the immenſe variety of ſhells, which we are acquainted with, ſome are taken up out of the ſea, or found on its ſhores in all their perfection and beauty; their colours being all ſpread by nature upon the ſurface, and their natural *poliſh* ſuperior to any thing that art could give. Where nature is in herſelf thus perfect, it were madneſs to attempt to add any thing to her charms; but in others, where the beauties are latent, and covered with a coarſer outer ſkin, art is to be called in, and the outer veil being taken off, all the internal beauties appear.

Among the ſhells which are found naturally *poliſhed*, are the porcelanes, the caſſanders, the dolia, or conchæ globoſæ, the buccinums, the cornets, and the cylinders, or as they are generally, tho' improperly called, the rhombi; excepting only two or three, as the tiara, the plume, and the buttertub-rhombus; where there is an unpromiſing film on the ſurface, hiding a very great ſhare of beauty within.

Tho' the generality of the ſhells of theſe genera are taken out of the ſea in all their beauty, and in their utmoſt natural *poliſh*, there are ſeveral other genera in which all, or moſt of the ſpecies are taken up naturally rough and foul, and covered with an epidermis, or coarſe outer ſkin, which is in many rough and downy, or hairy. The tellinæ, the muſcles, the cochleæ, and many others are of this kind. The more nice collectors, as naturaliſts, inſiſt upon having all their ſhells in their native and genuine appearance, as they are found when living at ſea; but the ladies who make collections, hate the diſagreeable outſides, and will have all ſuch *poliſhed*: it would be very adviſeable, however, for both kinds of collectors to have the ſame ſhells in different ſpecimens, both rough and *poliſhed*; the naturaliſt would by this means, beſide knowing the outſide of the ſhell, be better acquainted with its internal characters than he otherwiſe could be, and the lady would have a pleaſure in comparing the beauties of the ſhell in its wrought ſtate, to its coarſe appearance as nature gives it. How many elegancies in this part of the creation muſt be wholly loſt to us, if it were not for the aſſiſtance of an art of this kind! many ſhells in their native ſtate are like rough diamonds, and we can form no juſt idea of their beauties till they have been *poliſhed* and wrought into form.

Tho' the art of *poliſhing* ſhells is a very valuable one, yet it is very dangerous to the ſhells; for without the utmoſt care the means uſed to *poliſh* and beautify a ſhell will often wholly deſtroy it. When a ſhell is to be *poliſhed*, the firſt thing to be examined is, whether it have naturally a ſmooth ſurface, or be covered with tubercles or prominences.

A ſhell which has a ſmooth ſurface and a natural dull *poliſh*, need only be rubbed with the hand, or with a piece of chamoy leather, with ſome tripoli or fine rottenſtone, and it will become of a perfectly bright and fine *poliſh*. Emery is not to be uſed on this occaſion, becauſe it wears away too much of the ſhell. This operation requires the hand of an experienced perſon, that knows how ſuperficial the work muſt be, and where he is to ſtop; for in many of theſe ſhells the lines are only on the ſurface, and the wearing away ever ſo little of the ſhell defaces them. A ſhell that is rough, foul, and cruſty, or covered with a tartarous coat, muſt be left a whole day ſteeping in hot water: when it has imbibed a large quantity of this, it is to be rubbed with rough emery on a ſtick, or with the blade of a knife, in order to get off the coat. After this, it may be dipped in diluted aqua fortis, ſpirit of ſalt, or any other acid; and after remaining a few moments in it, be again plunged into comm n water. This will greatly add to the ſpeed of the work. After this it is to be well rubbed with linnen cloths, impregnated with common ſoap; and when by theſe ſeveral means it is made perfectly clean, the *poliſhing* is to be finiſhed with fine emery and a hair bruſh. If after this the ſhell when dry appears not to have ſo good a *poliſh* as was deſired, it muſt be rubbed over with a ſolution of gum arabic; and this will add greatly to its gloſs, without doing it any ſort of injury. The gum-water muſt not be too thick, and then it gives no ſenſible coat, only heightening the colours. The white of an egg anſwers this purpoſe alſo very well; but it is ſubject to turn yellow. If the ſhell has an epidermis, which will by no means admit the *poliſhing* of it, it is to be dipped ſeveral times in diluted aqua fortis, that this may be eaten off; and then the ſhell is to be *poliſhed* in the uſual way with putty, fine emery, or tripoli, on the hair of a fine bruſh. When it is only a pellicle that hides the colours, the ſhells muſt be ſteeped in hot water, and after that the ſkin worked off by degrees with an old file. This is the caſe with ſeveral of the cylinders, which have not the natural *poliſh* of the reſt.

When a ſhell is covered with a thick and fatty epidermis, as is the caſe with ſeveral of the muſcles and tellinæ: in this caſe aqua fortis will do no ſervice, as it will not touch the ſkin; then a rough bruſh and coarſe emery are to be uſed; and if this does not ſucceed, ſeal-ſkin, or as the workmen call it *fiſh skin* and *pummice-ſtone*, are to be taken in to aſſiſt.

When a ſhell has a thick cruſt, which will not give way to any of theſe means, the only way left is to plunge it ſeveral times into ſtrong aqua fortis, till the ſtubborn cruſt is wholly eroded. The limpets, auris marina, the helmet-ſhells, and ſeveral other ſpecies are of this kind, and muſt have this ſort of management; but as the deſign is to ſhew the hidden beauties under the cruſt, and not to deſtroy the natural beauty and *poliſh* of the inſide of the ſhell, the method of uſing the aqua fortis muſt be this: A long piece of wax muſt be provided, and one end of it made perfectly to cover the whole mouth of the ſhell; the other end will then ſerve as a handle, and the mouth being ſtopped by the wax, the liquor cannot get in to the inſide to ſpoil it; then there muſt be placed on a table, a veſſel full of aqua fortis, and another full of common water.

The ſhell is to be plunged into the aqua fortis; and after remaining a few minutes in it, is to be taken out and plunged into the common water. The progreſs the aqua fortis makes in eroding the ſurface is thus to be carefully obſerved every time it is taken out: the point of the ſhell, and any other tender parts, are to be covered with wax, to prevent the aqua fortis from eating them away; and if there be any worm-holes, they alſo muſt be ſtopped up with wax, otherwiſe the aqua fortis would ſoon eat thro' in thoſe places. When the repeated dippings into the aqua fortis ſhew that the coat is ſufficiently eaten away, then the ſhell is to be wrought carefully with fine emery and a bruſh; and when it is *poliſhed* as high as can be by this means, it muſt be wiped clean and rubbed over with gum-water, or the white of an egg. In this ſort of work the operator muſt always have the caution to wear gloves, otherwiſe the leaſt touch of the aqua fortis will burn the fingers, and turn them yellow; and often if it be not regarded, will eat off the ſkin and the nails.

Theſe are the methods to be uſed with ſhells, which require but a moderate quantity of the ſurface to be taken off; but there are others which require to have a larger quantity taken off, and to be uncovered deeper; this is called entirely ſcaling a ſhell. This is done by means of an horizontal wheel of lead or tin, impregnated with rough emery; and the ſhell is wrought down in the ſame manner in which ſtones are wrought by the lapidary. Nothing is more difficult, however, than the performing this work with nicety: very often ſhells are cut down too far by it, and wholly ſpoiled; and to avoid this, a courſe vein muſt be often left ſtanding in ſome place, and taken down afterwards with the file, when the cuting it down at the wheel would have ſpoiled the adjacent parts.

After the ſhell is thus cut down to a proper degree, it is to be *poliſhed* with fine emery, tripoli, or rotten ſtone, with a wooden wheel turned by the ſame machine as the leaden one, or by the common method of working with the hand with the ſame ingredients, when a ſhell is full of tubercles, or protuberances, which muſt be preſerved. It is then impoſſible to uſe the wheel; and if the common way of dipping into aqua fortis be attempted, the tubercles being harder than the reſt of the ſhell, will be eat thro' before the reſt is ſufficiently ſcaled, and the ſhell will be ſpoiled: in this caſe induſtry and patience are the only means of effecting a *poliſh*. A camel's hair pencil muſt be dipped in aqua fortis, and with this the intermediate parts of the ſhell muſt be wetted, leaving the protuberances dry: this is to be often repeated, and after a few moments the ſhell is always to be plunged into water to ſtop the eroſion of the acid, which would otherwiſe eat too deep, and deſtroy the beauty of the ſhell. When this has ſufficiently taken off the foulneſs of the ſhell, it is to be *poliſhed* with emery of the fineſt kind, or with tripoli; by means of a ſmall ſtick, or the common *poliſhing* ſtone uſed by the goldſmiths may be uſed.

This is a very tedious and troubleſome thing, eſpecially when the echinated oyſters and murexes, and ſome other ſuch ſhells are to be wrought; and what is worſt of all is, that when all this pains has been taken, the buſineſs is not well done; for there ſtill remain ſeveral places which could not be reached by any inſtrument; ſo that the ſhell muſt neceſſarily be rubbed over with gum-water, or the white of an egg afterwards, in order to bring out the colours and give a gloſs; in ſome caſes it is even neceſſary to give a coat of varniſh.

Theſe are the means uſed by artiſts to brighten the colours, and add to the beauty of ſhells; and the changes produced

by *poliſhing* in this manner are ſo great, that the ſhell is often not to be known afterwards for the ſame it was; and hence we hear of new ſhells in the cabinets of collectors, which have no real exiſtence as ſeparate ſpecies, but are the *poliſhed* appearance of others well known. To caution the reader againſt errors of this kind, it may be proper to add the moſt remarkable ſpecies thus uſually altered.

The onyx-ſhell, which in its natural ſtate is of a ſimple pale brown, when it is wrought ſlightly, or *poliſhed* with juſt the ſuperficies taken off, is of a fine bright yellow; and when it is eat away deeper, it appears of a fine milk-white with the lower part bluiſh: it is in this ſtate that it is called the onyx-ſhell; and it is preſerved in many cabinets in its rough ſtate, and in its yellow appearance as different ſpecies of ſhells.

The violet ſhell, ſo common among the curious, is a ſpecies of porcelane, which does not appear in that elegance till it has been *poliſhed*; and the common auris marina ſhews itſelf in two or three different forms, as it is more or leſs deeply wrought. In its rough ſtate it is duſky and coarſe, of a pale brown on the outſide and pearly within; when it is eaten down a little way below the ſurface, it ſhews variegations of black and green, and when ſtill farther eroded it appears of a fine pearly hue within and without.

The nautilus, when it is *poliſhed* down, appears all over of a fine pearly colour, but when it is eaten away but to a ſmall depth, it appears of a fine yellowiſh colour with duſky hairs.

The burgau, when entirely cleared of its coat, is of the moſt beautiful pearl-colour; but when only ſlightly eroded, it appears of a variegated mixture of green and red; whence it has been called the *parroquet*-ſhell. The common helmet-ſhell, when wrought, is of the colour of the fineſt agate; and the muſcles in general, tho' very plain ſhells, in their common appearance, become very beautiful when *poliſhed*, and ſhew large veins of the moſt elegant colours. The Perſian ſhell, in its natural ſtate, is all over white, and covered with tubercles; but when it has been ground down on a wheel, and *poliſhed*, it appears of a grey colour with ſpots and veins of a very bright and highly *poliſhed* white. The limpets in general become very different when *poliſhed*, moſt of them ſhewing very elegant colours; among theſe the tortoiſe-ſhell-limpet is the principal; it does not appear at all of that colour or tranſparence till it has been wrought.

That elegant ſpecies of ſhell called the junquil-chama, which has deceived ſo many judges of theſe things into an opinion of its being a new ſpecies, is only a white *chama* with a reticulated ſurface; but when this is *poliſhed*, it loſes at once its reticular work and its colour, and becomes perfectly ſmooth and of a fine bright yellow: and the violet-coloured *chama* of New England, when worked down and *poliſhed*, is of a fine milk-white with a great number of blue veins diſpoſed like the variegations in agates.

The aſſe's ear-ſhell, when *poliſhed*, after working it down with the file, becomes extremely gloſſy, and obtains a fine roſe-colour all about the mouth. Theſe are ſome of the moſt frequent among an endleſs variety of changes wrought on ſhells by *poliſhing*; and we find there are many of the very greateſt beauties of this part of the creation which muſt have been loſt but for this method of ſearching deep in the ſubſtance of the ſhell for them.

The Dutch are very fond of ſhells, and are very nice in their manner of working them: they are under no reſtraint, however, in their works, but uſe the moſt violent methods, ſo as often to deſtroy all the beauty of the ſhell. They file them down on all ſides, and often take them to the wheel when it muſt deſtroy the very characters of the ſpecies; nor do they ſtop at this, but determined to have beauty at any rate, they are for improving upon nature, and frequently add ſome lines and colours with a pencil, afterwards covering them with a fine coat of varniſh; ſo that they ſeem the natural lineations of the ſhell: the Dutch cabinets are by this means made very beautiful, but they are by no means to be regarded as inſtructors in natural hiſtory. There are ſome artificers of this nation who have a way of colouring ſhells all over with a different tinge from that which nature gives them; and the curious are often deceived by theſe tricks into the purchaſing them as new ſpecies.

There is another kind of work beſtowed on certain ſpecies of ſhells, particularly the nautilus; this is the engraving on it lines and circles, and figures of ſtars, and other things: this is too obvious a work of art to ſuffer any one to ſuppoſe it natural. Bonani has figured ſeveral of theſe wrought ſhells at the end of his work, but it is miſerably throwing away labour to do them; the ſhells are ſpoiled as objects of natural hiſtory by it, and the engraving is ſeldom worth any thing. They are principally done in the Eaſt-Indies.

Shells are ſubject to ſeveral imperfections; ſome of theſe are natural, and others accidental: the natural ones are the effect of age, or ſickneſs in the fiſh. The greateſt miſchief happens to ſhells by the fiſh dying in them. The curious in theſe things pretend to be always able to diſtinguiſh a ſhell taken up with the fiſh alive, from one found on the ſhores: they call the firſt a living, the ſecond a dead ſhell, and ſay that the colours are always much the fainteſt in the dead ſhells.

When the ſhells have lain long dead on the ſhores, they are ſubject to many injuries, of which the being eaten by ſea-worms is not the leaſt: age renders the fineſt ſhells livid or dead in their colours.

The fineſt ſhells are thoſe which are fiſhed up at ſea, not found on the ſhores. The other natural defects of ſhells are there having morbid cavities, or protuberances, in parts where there ſhould be none. When the ſhell is valuable theſe faults may be hid, and much added to the beauty of the ſpecimen, without at all injuring it as an object of natural hiſtory, which ſhould always be the great end of collecting theſe things. The cavities may be filled up with maſtic, diſſolved in ſpirit of wine, or with iſinglaſs; theſe ſubſtances muſt be either coloured to the tinge of the ſhell, or elſe a pencil dipped in water colours muſt finiſh them up to the reſemblance of the reſt, and then the whole ſhell being rubbed over with gum-water, or with the white of an egg, ſcarce any eye can perceive the artifice: the ſame ſubſtances may alſo be uſed to repair the battered edge of a ſhell, provided the pieces chipped off be not too large. And when the excreſcences of a ſhell are faulty, they are to be taken down with a fine file. If the lip of a ſhell be ſo battered that it will not admit of repairing by any cement, the whole muſt be filed down to an evenneſs, or ground on the wheel.

POLITICAL *(Cycl.)*—POLITICAL *arithmetic*. According to Mr. Kerſeboom's computation, the inhabitants of Holland and Weſtfriezeland, in the year 1738, amounted to 980000. He has given us a table of the particulars, exhibiting the number of people of all ages, living at the ſame time, from their birth to extreme old age. This table having the chances of mortality within the ages mentioned, he calls the table of contingency of life and death.

This table is calculated upon three principles: 1. On correct obſervations upon the tables of aſſignable annuities in Holland, which have been kept there for above 125 years; wherein the ages of the perſons dying are truly entered. 2. Upon a ſuppoſition that there are yearly born in the two provinces 28000 living children. 3. That the whole number of inhabitants, in any country, is to the number of births as 35 to 1.

From this table it appears, 1. That more than half the number of people in the two provinces are above 27 years old. 2. That by the obſervations made in England, out of 35 children born, 18 of them are boys, and 17 girls: the inhabitants of Holland and Weſtfriezeland, conſiſt of 504000 males, and 476000 females, the ſum of which is 980000.

Here follows the table of contingency of life and death.

Of above 90 years old			500	
Of 90	to 86	incl.	2500	
85	81		6500

15	11		87200	
10	6		91800	
5	to birth		131800	
			488500	ſum under 27 years old.
			491500	
			488500	
			980000	ſum of all the inhabitants.

Mr. Kerſeboom obſerves from the aſſignable annuities for lives before-mentioned, that females, one with another, live about three or four years longer than the ſame number of males.

He alſo thinks there is no reaſon to differ from the proportions aſſigned by Mr. King (in Davenant's eſſays) of the ſtate and condition of the inhabitants of England; which is, that for every 100000 inhabitants there is

Married men and women	34500
Widowers	1500
Widows	4500
Unmarried youth and children	45000
Servants	10500
Travellers, ſtrangers, *&c.*	4000
	100000

If this propoſition be admitted, then the number of each ſort in Holland and Weſtfriezeland, will be as in the following table:

In the two provinces of Holl. and Weſt.		Amſter.
Married men and women	338100	86156
Widowers ——	14700	4218
Widows — —	44100	13858
Unmarried youth and children	441000	93990
Servants — —	102900	28318
Travellers, ſtrangers, &c.	39200	14460
Total	980000	241000

The mortality of the ſeveral quarters of the year.

Spring to ſummer	307 dead.
Summer to the autumnal equinox	286
Autumn to winter	287
Winter to ſpring	286

The mortality of the different months of the year obſerved for 31 years, one with another.

Dead in	
January	102
February	88
March	95
April	77
May	112
June	100
July	92
Auguſt	95
September	99
October	93
November	95
December	99

Hence it appears, that April is the leaſt, and May the moſt fatal Month in the year; their proportion of mortality being nearly as 2 to 3: and that of the four ſeaſons of the year, moſt deaths happen in the ſpring; that is, from the vernal equinox to the ſummer ſolſtice.

Mr. Kerſeboom adds, that theſe provinces may raiſe 220000 men able to bear arms, and ſeveral other curious obſervations. His book is intitled, *Verhandeling tot een proeve, om te weeten de probable menigte des volks in de proventie van Holland en Weſtfriezlandt.* Hage 1738. 4°.

POLITICAL *diviſion of antient Egypt.* See NOME.

POLIUM, *poley-mountain*, in botany, the name of a genus of plants, the characters of which are theſe: The flower conſiſts of one leaf, and is of the labiated kind; but the place of the upper lip is ſupplied by the ſtamina. The under lip is divided into five ſegments. The piſtil ariſes from the cup; it is fixed in the manner of a nail to the hinder part of the flower, and ſurrounded by four embryos, which afterwards become ſo many ſeeds remaining in the flower-cup, which ſerve them as a capſule. The flowers of this plant are collected into heads, and grow at the tops of the ſtalks.

The ſpecies of *poley-mountain*, enumerated by Mr. Tournefort, are theſe: 1. The lavender-leaved *poley*. 2. The narrower-leaved lavender-*poley*. 3. The yellow-flowered common *poley*. 4. The common white-flowered *poley*. 5. The narrower-leaved longer-headed white-flowered *poley*. 6. The creeping *poley*. 7. The French erect ſea-*poley*. 8. The procumbent Venetian ſea-*poley*. 9. The purple-flowered tender woolly-leaved *poley*. 10. The white tender procumbent *poley*. 11. The ground ivy-leaved tender procumbent Pyrenean *poley*. 12. The purple-flowered, germander-leaved Spaniſh *poley*. 13. The ſmoother procumbent Portugal *poley*, with purple ſtalks and white flowers. 14. The purple-flowered ſhort-headed broad-leaved Spaniſh *poley*. 15. The great white Spaniſh *poley*. 16. The great yellow Spaniſh *poley*. 17. The white-flowered roſemary-leaved ſea-*poley* of Spain. 18. The red-flowered ſhrubby ſea-*poley* of Spain, with roſemary leaves. 19. The red-flowered, roſemary-leaved, dwarf mountain-*poley* of Spain. 20. The yellow-flowered procumbent Spaniſh *poley*. 21. The longer-headed Spaniſh *poley*, with variegated flowers. 22. The white-flowered, ſhort-headed, narrow-leaved erect *poley*. 23. The white-flowered Spaniſh *poley*, with hoary leaves, reſembling thoſe of toad-flax. 24. The white-flowered ſhorter-leaved Spaniſh *poley*, with toad-flax leaves. 25. The red-flowered dwarf-*poley-mountain*, with narrow green leaves and hoary ſtalks. 26. The little narrow-leaved erect *poley*, with greeniſh white ſerrated leaves 27. The leſſer procumbent white narrow-leaved *poley*, with ſerrated leaves. 28. The red-flowered erect ſmall *poley*, with ſhort, narrow, and thick cluſtered leaves. 29. The procumbent red-flowered cudweed-like mountain-*poley*, with divided leaves. 30. The white-flowered cudweed-like ſea-*poley*. 31. The whole-leaved white Spaniſh *poley*. 32. The larger erect, broad-leaved white *poley*, with ſerrated leaves. 33. The great procumbent broad-leaved *poley*, with ſerrated leaves. 34. The leſſer procumbent broad-leaved white *poley*, with ſerrated leaves. 35. The yellow Spaniſh *poley*, with marjoram-like leaves. 36. The purple-flowered ſerpyllum-leaved Spaniſh *poley*. 37. The purple-ſpiked thyme-leaved Spaniſh *poley*. *Tourn.* Inſt. p. 206.

POLLACK, in ichthyology, a name which we give to two different fiſh of the aſellus or gadus kind, with the different epithets of *raw* and *whiting*. The *raw-pollack* is the ſame ſpecies that in ſome parts of England is called the cole-fiſh, and is the aſellus niger of authors. The other is called the *whiting-pollack*; and is the *aſellus vireſcens* of Willughby and others.

Both theſe fiſh are, according to the new Artedian ſyſtem, of the genus of the gadi; and as the names taken from their colours, black and green, are very little expreſſive, the colours being not perfect, permanent, or entire, Artedi has deviſed others for them, by which they may be diſtinguiſhed at ſight from one another. The *raw-pollack*, or cole-fiſh, he diſtinguiſhes by the name of the *gadus* with three fins on the back, with no beard at the mouth, with the lower jaw longer than the upper, and the lateral line ſtrait. The other, or *whiting-pollack*, he diſtinguiſhes by the name of the *gadus* with three fins on the back, with no beard, with the lower jaw longer than the upper, and the lateral line crooked. Theſe two kinds of *pollack* are by theſe names not only diſtinguiſhed from one another, but from all the other ſpecies of the ſame genus, as the codfiſh, &c. *Artedi* Gen. Piſc. p. 35.

POLLARD *(Cycl.)*—POLLARD is a name given by ſome hiſtorians to a ſort of baſe money current at one time in Ireland, and called more uſually *crocards*.

Theſe were coins of France, and other nations, which paſſed in Ireland as pennies, tho' really not worth quite half ſo much. They were made of copper, with a very ſmall admixture of ſilver. See the article CROCARDS.

It was in the reign of Edward I. appointed lord of that kingdom in the life-time of his father Henry III. that the uſe of falſe and counterfeit money of this kind was ſo extremely common in Ireland. While his father reigned in England this prince never extended his power ſo far as to ſet up any mint, or coin any money in Ireland; but at his acceſſion to the crown he found his treaſury empty, and the current coin of his kingdoms in a very bad condition: his abſence of near two years after his father's death, having ſo encouraged the clippers and coiners of money, that little but clipped, or counterfeit money of the kingdom was to be met with; and five or ſix different ſorts of baſe and mixed money had been imported privately, and uttered in England and Ireland as pennies, tho' they were not half the value of the penny ſterling.

Theſe were the *crocards* and *pollards*, called alſo *mitres lizonnes*, *roſaries*, and by the like names, according to the things marked in the impreſſions. To remedy this evil, and reſtore the current coin of the kingdom to its antient purity and value, this prince eſtabliſhed a certain ſtandard; and as the baſe money was an admixture of a very ſmall quantity of ſilver, with a great deal of copper, he ordered that there ſhould be in every pound of money weighing twelve ounces, eleven ounces and two penny weight and a quarter of pure ſilver, and only ſeventeen pence halfpenny farthing allay.

The ſaid pound to weigh twenty ſhillings and three pence in account; the ounce twenty pence, and the penny twenty-four grains and a half. According to this regulation, the money of Ireland was alſo ordered to be made, and a new kind of money was ſtruck there in the year 1279, under Stephen de Fulbourn, biſhop of Waterford, and lord deputy of Ireland. The pieces coined at this time in Ireland were groats, or four pennies, halfpence, and farthings; and as theſe were the ſame in value, as to weight, with the Engliſh coins, they would go equally in England and Ireland: and in the twenty-ninth year of the reign of the ſame prince, that is, in 1300, the *crocards*, *pollards*, and other baſe money were decried; and it was made death, with confiſcation of goods, to import any of them.

By this means the circulation of the baſe and mixed money was in a great meaſure ſtopped, and four new furnaces were erected in the mint of Dublin, to ſupply the great demand that there was for good money; and Almander Norman de Line was appointed maſter of the coiners. This was a beginning of good money in Ireland; and in the year 1304, there were ſent over from England twenty-four ſtamps for coining of money there, *viz.* three piles with ſix croſſes, for pennies; three piles with ſix croſſes, for halfpence; and two piles with four croſſes, for farthings. In the old way of coining with the hammer, before the mill and ſcrew were invented, two kinds of punchions were in uſe, the one called the croſs, whereupon was engraved the head of the prince; and this was ſo called becauſe, antiently, a croſs was the figure ſtruck on this ſide of coins inſtead of the head of the prince: the other called the pile, contained the arms, or ſome other figure, to be ſtruck with an inſcription on the back, or reverſe of the coins. The pennies and halfpence ſtruck in this king's reign, have the king's head in a triangle full-faced. The beſt preſerved of them, found at this time, weigh twenty-two grains the penny; and the halfpence from ten grains to ten and a half. The farthings are ſo ſcarce, that it is very rare to meet with one in the collections of the moſt curious. *Simon's* Hiſt. of Iriſh Coins, p. 15.

POLLARD, in zoology, a local name for the young and ſmall fiſh of the cole-fiſh, or rawling-pollack kind. It is uſed in Cornwall, &c. *Willughby*'s Hiſt. Piſc. p. 169.

POLLEN *thuris*, in the materia medica, a term uſed by the Latin writers, to expreſs the *manna thuris*, or *manna libanotis*, of the Greeks, but that very improperly; for the word *pollen thuris* properly ſignifies the frankincenſe reduced to a powder, but this was not what the antient Greeks called *manna thuris*, but the ſmall fragments which were broken off from the large pieces, in the gathering or packing up.

The *manna* uſed in medicine by the Greeks and Arabians was not formed into large flakes, as ours is; but was compoſed of ſmall fragments or grains, and therefore they called by the ſame name the ſmall granulæ or fragments alſo of other things: it was thus that the broken frankincenſe was called *manna thuris*.

The cuſtom of the times of ſaving all the fragments of this drug, made them collect even what was in ſo ſmall pieces as to reſemble powder; but this, tho' mixed with the reſt, was not properly the *manna thuris*. This gave occaſion to the adulterating this commodity, and Dioſcorides tells us, that even in his time they had learned the trick of putting the powder of the reſin of the pine tree among it; and this growing worſe and worſe, they at laſt diſcarded it, and would purchaſe only the fragments without the powder. Theſe fragments they called *thus minutum*, to diſtinguiſh them from what was then called *manna thuris*, tho' improperly, and which was the adulterated maſs of reſin and fragments of olibanum.

POLLICIPES, the *toe-ſhell*, in natural hiſtory, the name of a genus of ſhells, the characters of which are theſe: they are multivalve flat ſhells, of a triangular figure, each being compoſed of ſeveral laminæ, which end in a ſharp point. They ſtand upon pedicles, and are furniſhed with a great number of hairs. We have only one known ſpecies of this genus, and this always found in large cluſters. See Tab. of Shells, N° 27.

POLLINCTORES, among the antients, an appellation given to thoſe who waſhed and anointed the dead. *Pitiſc.* in voc.

POLLINCTURA, a word uſed by ſome authors to expreſs the embalming dead bodies.

POLLING, in gardening, the operation of diſperſing the worm-caſts all over the walks, with long aſh-poles: this, beſides deſtroying worm-caſts, is very beneficial to the graſs of the walks. See GRASS-*walks*.

POLLUCTUM, among the Romans, a feaſt kept in honour of Jupiter Dapalis, Hercules, &c. at which ſacrifices were offered to the Gods. *Pitiſc.* in voc.

POLLUTION *(Cycl.)*—POLLUTIO *nocturna*, in medicine, the name of a diſeaſe, which conſiſts in an involuntary emiſſion of the ſeed in the night, in time of ſleep. This, in different perſons, is very different in degree; ſome being affected with it only once in a week, a fortnight, three weeks, or even a month, and others being ſubject to it almoſt every night.

The perſons moſt ſubject to this, are young men of a ſanguineous temperament, and who feed high, and lead a ſedentary life. When this happens to a perſon but once in a fortnight, or a month, it is of no great conſequence; but when it happens almoſt every night, it greatly injures the health; the patients look pale and ſickly. In ſome the eyes become weak and inflamed; ſometimes they are affected with violent defluxions, and uſually, at laſt, are circled round with a livid appearance of the ſkin.

This diſtemper is to be cured rather by a change of life than by medicines. When it has taken its riſe from high diet and a ſedentary life, a coarſer food, and the uſe of exerciſe, will generally cure it; but if any medicines are to be given, nitre alone will do more than almoſt all the reſt. This may be taken in large doſes, a ſcruple at a time, with very little liquid with it, and muſt be continued for ſome time at night going to reſt. The root of the water-lilly is greatly recommended by ſome in this caſe; and by others, the ſeeds of the agnus caſtus; but it is very doubtful, whether they have either of them any effect.

Perſons ſubject to this diſeaſe muſt never take any ſtimulating purges, and muſt avoid, as much as poſſible, all violent paſſions of the mind: and tho' exerciſe is recommended in moderation, yet if this be too violent, it will rather increaſe the diſorder than do any thing towards its cure. *Junck*'s Conſp. Med. p. 486.

POLPHOS, a word uſed by ſome authors to expreſs a bulb or bulbous root.

POLPOCH, in zoology, a ſpecies of ſerpent ſaid to be found in Jucatan, a country bordering upon New Spain. It can bite with the mouth and ſting with the tail. *Hoffm.* Lex. univ. in voc.

POLVERINE, the calcined aſhes of a plant; a ſubſtance of the nature of our pot-aſhes, or pearl-aſhes.

It is brought from the Levant and Syria; but in the glaſs trade, tho' it be of the nature of the other aſhes they uſe, it is always to be preferred to any other. The barillia, or pot aſhes of Spain, yield more pure ſalt than the *polverine* of the Levant, but the glaſs made with it has always ſome tinge of bluiſhneſs: that made with the *polverine* is ever perfectly white, and this is the ſubſtance that ought always to be uſed for the fineſt cryſtal.

The method of procuring the pure ſalt from theſe aſhes, is to ſift them and throw them in a proper quantity into a large copper of boiling water, continuing the boiling till all the ſalt of the aſhes be diſſolved by the water, and adding to the water, before the *polverine* is put in, about ten pound of tartar calcined to a blackneſs. The lee or water thus impregnated with the ſalt, muſt ſtand a conſiderable time to ſettle; and when perfectly clear, muſt be evaporated till it thicken, and begin to ſhew a white dry ſalt about its edges: then the fire muſt be kept very ſlow, and a ſkimmer full of holes being ſunk in to the bottom of the copper, the ſalt will gather and harden upon it; and this muſt be taken out every now and then, and the ſalt taken off and dried for uſe. Three hundred pound of *polverine* thus yield eighty or ninety pound of clear ſalt. When this is dried, it muſt be ſlightly calcined in the glaſs furnace, and then powdered and ſifted through a coarſe ſieve, and kept dry. *Neri*'s Art of Glaſs, p. 2.

POLYADELPHIA, in botany, a claſs of plants, whoſe ſtamina are formed into three or more ſeparate bodies.

The word is formed of the Greek πολὺς, many, and ἀδελφὰ, communities. Among the plants of this claſs are orange-trees, St. John's wort, &c.

POLYANDRIA, in botany, a claſs of plants with hermaphrodite flowers, and a large number of ſtamina, or male parts, in each. See Tab. 1. of Botany.

The word is derived from the Greek πολὺς, many, and ἀνὴρ, male. The hermaphrodite flowers of this claſs have a large number of ſtamina on each, always more than twelve, and thoſe growing to the receptacle of the future ſeeds.

Of this claſs are the water-lilly, poppy, celandine, &c.

POLYANTHEMUM, in botany, a name given by ſome authors to the water-crowfoot, from its great number of flowers. *Ger.* Emac. Ind. 2.

POLYCEPHALON, Πολυκεφαλον. in antiquity, a kind of poetry, for the nature and origin of which, ſee Mem. de l'Acad. Roy. des Inſcrip. Vol. 14. p. 438.

POLYCOMBUS, in botany, a name given by Neophytus and others to the common knot-graſs, more uſually called *polygonum*.

The name *polycombus* is formed of the Greek πολυς, many, and κομβος, a joint; and as it is uſually applicable to this, and all the other jointed plants, it is uſed by ſome for the name of the ſeveral ſpecies of equiſetum, or horſetail, as the word *polygonum* is.

Neophytus deſcribes one ſpecies of this, which he ſays is called *oreon*, from its growing in mountainous places. This, he ſays, looks like a young reed, and has ſeveral joints in the main ſtalk, which are received into one another as ſo many cups or boxes. He adds, that the leaves are like thoſe of the pine-tree: what he calls the leaves, are probably the tender branches; and then this deſcription will agree very well with our great marſh horſetail, which grows in wet places in mountainous countries, and about the ſprings in our hills. This is the horſetail to which the greateſt virtues are attributed by this author; but the whole account of the hippuris, polygonum, and equiſetum, is ſo confuſed, that there is little to be learnt from what the antients ſay of them, without repeating the trials of their virtues.

POLYCROTA, in the naval architecture of the antients, a word uſed to expreſs ſuch of their gallies as had three, four, five, or more tires of rowers, ſeated at different heights; they were diſtinguiſhed by this term from the *monocrota*, or thoſe which had only ſingle rows of oars.

The number of rows of rowers in the *polycrote* gallies has given occaſion to ſome to ſuppoſe thoſe veſſels of ſuch a height from the water as is ſcarce credible; we have, however, no warrant for this, but the commentators have given occaſion to the opinion, from their not having been able to ſtow the rowers in leſs room, and have meaſured the height of the veſſel by their own ſkill in this ſort of architecture, not by that of the people who built them. Meibom has found a way to take off a great deal from the imaginary height of theſe gallies. He has two inventions to anſwer this purpoſe: by the firſt of them, he ſhews how the lateral rowers may be ſo placed, that he who ſits behind another may move his hands and oar under the ſeat of the rower who ſits next before him; by which means three lateral rowers, which, according to Scaliger's way of reckoning, would require thirteen feet and an half, will be placed in the heighth of ſeven feet and an half.

By the ſecond invention, he finds out a place in the veſſel for almoſt half the number of rowers; foraſmuch as on the ſides of the aforeſaid rowers, he places others in the middle of the ſhip, upon tranſtra or tranſverſe ſeats, which he imagines thruſt out their oars under the ſeats of the lateral rowers; by this contrivance he has gained no leſs than nine feet in the heighth of a quinqueremis.

The different ſeries of rowers were called by different names; the *thalamitæ* were thoſe who ſat in the loweſt row; the *zygitæ* were thoſe who ſat in the tranſtra, or croſs ſeats; and the *thranitæ* thoſe who ſat uppermoſt of all in the veſſel.

The moſt ſurprizing account of a *polycrote* veſſel among the

antients, is that said to have been built for Philopater, of forty tires of rowers. The next to this is that of Ptolomy Philadelphus, which is said to have had thirty tires; and in these there sat more than three thousand rowers. It has been disputed by many, whether such immense vessels as these were ever built, or ever could be used if built. The monstrous heighth they have been calculated to be of, according to the schemes of the generality of commentators, has rendered it incredible that there ever were any such; but Meibom has found out such convenient ways of placing the rowers in them, and has taken off so great a part of this imaginary heighth necessary in them, that he is clearly of opinion, that there were such vessels actually built and used.

The triremis, according to the computation of this author, contained two hundred men; of which one hundred and eighty were rowers, and the rest were mariners: so that the Athenian fleet, of which Conon was commander, consisting of one hundred and eighty triremes, there were in it six and thirty thousand men. The quinqueremis of these times contained four hundred and twenty men, three hundred of whom were rowers, and the rest soldiers; so that there are three stupendous things to be observed in regard to the Roman fleet at Messina, and the Carthaginian at Lilybæum: one is, that the former consisted of three hundred and thirty, and the latter of three hundred and fifty vessels, most of which were quinqueremes, which, according to the most accurate computation, were a hundred and fifty feet long; the number of men they contained was, in the Roman, one hundred and thirty thousand, and in the Carthaginian, one hundred and fifty thousand. The apparatus and provisions necessary for such a numerous host, is wonderful in these early days of shipping, and the accounts would be doubted, were they not given by one of the best of historians, Polybius, who wonders, as indeed he very well may, at such an amazing equipage for sea service at such a time.

POLYEIDÆ *sphragis*, the name of a sort of troches or pastils greatly used among the antients. It consisted of alum, four drachms; myrrh and aloes, of each five drachms; pomegranate-peel, and bull's gall, of each six drachms: all which were rubbed to fine powder, and made into troches with the bull's gall, mixed with a sufficient quantity of the most austere wine.

POLYGALA, *milkwort*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the personated kind, consisting of one leaf, not perforated behind, and divided before into two lips; the upper lip is bifid, and the lower one elegantly fimbriated. The pistil arises from the lower part of the flower, and ripens at length into a fruit or capsule of a compressed figure, divided into two cells, and full of oblong seeds. The fruit is usually found surrounded with the cup of the flower, which consists of five leaves, two large and three small ones, which clasp round the seed vessel in the manner of so many wings.

The species of *polygala*, enumerated by Mr. Tournefort, are these: 1. The great blue-flowered *polygala*. 2. The great purple-flowered *polygala*. 3. The great white-flowered *polygala*. 4. The common or smaller blue-flowered *polygala*. 5. The common purple-flowered *polygala*. 6. The common *polygala*, with white flowers. 7. The painted-leaved *milkwort*, with purple flowers. 8. The painted-leaved *milkwort*, with blue flowers. 9. The narrow-leaved erect annual *polygala*, with dusky-coloured flowers, variegated with streaks of pale red. 10. The short-leaved pointed *polygala*. 11. The little mountain myrtle leaved *polygala*. 12. The shrubby Portugal *milkwort*, with very small leaves, and large flowers. 13. The greater African narrow-leaved shrubby *polygala*. 14. The lesser African shrub-*polygala*, with very narrow leaves. 15. The flax-leaved American *polygala*, with very large flowers. 16. The box-leaved shrubby African *polygala*, with very large flowers. 17. The box-leaved shrubby *polygala*, with yellow flowers. 18. The box-leaved shrubby *milkwort*, with purplish red flowers. *Tourn.* Inst. p. 147.

The virtues of this plant have been very happily enquired into by the gentlemen of the royal academy of sciences at Paris, on occasion of the trials they made of the virtues of the Senekka rattle-snake root, recommended by Dr. Tennent; and their judging, that as his was the root of a species of *polygala* or *milkwort*, the roots of our common *polygala* might possibly have the same effects.

Dr. Tennent gives his rattle-snake root, or Virginian *polygala*, in the dose of thirty-five grains in substance, or in three or four ounces of a strong infusion, or in a yet stronger, in a proportionably smaller dose. The effects of this root being found very great, it was supposed that its place might possibly be supplied by this species of our own growth. It is very certain, that the place of growth may, in some plants, make a very great alteration in their virtues; and that the different species of the same genus may, in other instances, produce different effects in the human body, some species of plants agreeing in their external forms and generical characters, while they differ in their virtues and qualities.

There appeared on trial a considerable difference to the taste between the American and the European *polygala*-roots, that of Virginia being very aromatic, acrid, and bitter, and the European only slightly acrid, with a very feeble bitterness. Another thing that gave great suspicion as to the parallel virtues of the roots of these two species was, that Gesner was found, in his account of the virtues of the European *polygala*, to call it a very brisk cathartic; a quality which might render its use very improper in many of the diseases in which Mr. Lemery and Jussieu found the Virginian kind to prove a serviceable medicine. This last was found always very speedily to allay fevers of the pleuretic kind, without increasing in any great degree the discharges by stool.

The roots of the European *polygala* being very small and slender, gave also some trouble as to the procuring them in sufficient quantity; and in hopes it might become a general medicine, it was determined to try the effects of the whole plant, root, leaf, and branch, in the disease in which the Virginian kind had been given with the greatest success, that is, in pleurisies; and this was accordingly fairly tried.

The principal instances of their trials were two; the first to a woman of twenty-two years old, who had a violent fever, with a sizy blood, and pain in the side. She was twice blooded, and had immediate but not lasting relief from it, and was ordered the common ptisans given on these occasions. The malady increased, and the expectoration was but small, and that of a thick yellow matter: a third bleeding finally was judged necessary, but was of no more service than the others; and after this she had the same ptisan continued, but with the addition of a large quantity of the common European *polygala*, stalk, root, and leaf. This took place in two or three hours, the expectoration became vastly plentiful, and the matter thin and white from being thick and yellow. The woman, in fine, was cured, and the medicine was not observed to occasion any nausea, nor did it prove, as supposed, a violent purge.

The second instance was in a man of a stout robust habit, and of twenty-five years of age. He was violently attacked with a pleurisy, he was bled seven times, and was brought into one of the hospitals delirious, and seemingly very near death: he was there blooded in the foot, which restored his senses; and he took a large quantity of the decoction of the *polygala*, which caused him to expectorate in great abundance. The matter was first blackish, then reddish, and finally white, and the patient was perfectly cured. Mem. Acad. Scien. Par. 1739.

These are such remarkable instances of the good effect of an herb to be had every where in our own country, that they seemed very worthy to be recorded. The plant grows with us on dry grounds and heaths, and is about four inches long, not erect, but trailing upon the ground: the leaves are long and narrow, of a pale green, and the flowers are large and look beautiful: they stand in spikes, and are usually blue; but very often white, and sometimes red. The herb should be pulled up root and all for drying.

POLYGAMIA, in botany, a class of plants, which have a diversity of combinations of the male and female parts of their flowers, and many ways of fructification in the same species; some having male flowers, others female, each distinct and perfect in its kind; and others mixed, or hermaphrodite, with both male and female organs of fructification in each. See Tab. 1. of Botany, Class 1.

The word is formed of the Greek πολυς, many, and γαμος, marriage.

Among the plants of this class are the orach, pellitory of the wall, the ash, &c.

POLYGAMY, (*Cycl.*) is the marriage of one man to more than one wife, or the marriage of one woman to more than one husband.

The last of these is the greater crime, as being most incompatible with the being of society, and might therefore be punished with greater severity.

It has been much disputed among the Doctors of the civil law, whether *polygamy* be adultery. In the Roman law it is called *stuprum*, and punished as such, that is, in some cases, capitally. See STUPRUM. But a smaller punishment is more consistent with the Jewish law, wherein the prohibition of adultery was perpetual, but that of *polygamy* temporary only. See Selden, L. 1. c. 9. de uxore Hebraica.

In Germany, Holland, and Spain, this offence is differently punished. By a constitution of Charles V. it was a capital crime. In England it is felony, by stat. Jac. 1. but with benefit of clergy. In Scotland it is punished as perjury. See the article BIGAMY.

POLYGLOTTA *avis*, in zoology, the name of a bird described by Nieremberg, and which, he says, he saw and heard with admiration, singing in all tones. It is of the size of our starling.

Its back is brown, and its breast and belly white; and near the neck and tail it is variegated with spots and streaks of white. Its head has a streak of white, which represents a sort of crown of silver. It is mightily esteemed, and kept in cages by the Spaniards, as infinitely superior to all other birds in melody. It feeds on almost any thing that is given it, and is most fond of the warmer climates; but endures the more temperate ones without harm. *Ray*'s Ornithology, p. 305.

POLYGONATUM, *Solomon's ſeal*, in botany, the name of a genus of plants, the characters of which are, that the flower conſiſts of one leaf, formed in the ſhape of a bell; but having a long tube, having no cup, and being divided into ſeveral ſegments at the end. From the bottom of this flower riſes a piſtil, which ripens into a ſoft roundiſh fruit, which contains a great number of roundiſh ſeeds.

There are a great many ſpecies of this plant 1. The common broad-leaved one. 2. The red ſtalked broad-leaved one. 3. The great broad leaved one. 4. The white hellebore-leaved one. 5. The red-ſtalked white hellebore-leaved one. 6. The large ſweet-flowered one. 7. The double-flowered ſweet broad-leaved one. 8. The little broad-leaved one, with large flowers. 9. The low Engliſh ſingle-ſtalked kind. 10. The narrow-leaved ſingle-ſtalked kind. 11. The narrow-leaved branched kind. And, 12. The climbing American kind. *Tourn.* Inſt. p. 78.

The root of *Solomon's ſeal* is a vulnerary of the very firſt rank; it is famous in bruiſes for taking away the marks, and for healing up freſh wounds; in both which caſes, it is applied in form of a pultice. It has alſo been greatly celebrated in the cure of hernias, and for aſſiſting in forming a callus in broken bones.

POLYGONUM, *knot graſs*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the apetalous kind, being compoſed only of a number of ſtamina ariſing from a funnel-ſhaped cup, divided into many ſegments at the edge. The piſtil finally becomes a triangular ſeed, which is covered by a capſule that was originally the cup of the flower. To this it is to be added, that the flowers grow in the alæ of the leaves, and that the roots are fibrous.

The ſpecies of *knotgraſs*, enumerated by Mr. Tournefort, are theſe: 1. The common broad leaved *knotgraſs*. 2. The white-flowered broad-leaved *knotgraſs*. 3. The long and narrow-leaved *knotgraſs*. 4. The ſhort and narrow-leaved *knotgraſs*. 5. The ſtone-*knotgraſs*. 6. The great *knotgraſs*, with long ſtalks and long leaves. 7. The broad-leaved ſea-*knotgraſs*. 8. The broad-leaved white flowered ſea-*knotgraſs*. 9. The Spaniſh ſea-*knotgraſs*, with very long ſtalks, and white flower-cups. 10. The broad-leaved ſhrub ſea-*knotgraſs*. 11. The round-leaved creeping Portugal ſea-*knotgraſs*. 12. The little hoary, ſea-*knotgraſs*. *Tourn.* Inſt. p. 510.

The antients as well as moderns have deſcribed the common kinds of *knotgraſs* under the name *polygonum*; but as they have alſo given the ſame appellation to another plant, much error has ariſen by miſtaking theſe ſynonyms. Pliny began the miſtake, and others have ſince in great numbers fallen into it, and thought Pliny's example a ſufficient excuſe.

The word *polygonum* being formed of the Greek πολὺς, many, and γονυ, joint, or knot, ſignified properly any plant that had ſeveral joints or knots. It was originally given to the *knotgraſs* very properly, ſcarce any plant having more joints; but it was afterwards given alſo to a kind of equiſetum or horſe-tail.

The deſcription of this was, that the ſtalks were hollow; the branches long, ſlender, and reſembling ruſhes, or the twigs of the broom, but without any leaves; and that they were ſo brittle, that they could not be uſed as wyths, to bind things with, which ſeems to have been a uſe the common *knotgraſs* was very frequently put to, and for which it was found very proper, becauſe of the toughneſs of its branches. This kind of *polygonum* of the antients is ſaid to grow in woods, at the roots of trees, as the horſe-tails of ſeveral kinds do at this time; and tho' the deſcriptions of this and the other *polygonum* are ſo extremely different, this having no leaves, and the other being deſcribed by all to have ſmall, oval, and pointed leaves, yet Pliny has confounded the two plants together, becauſe both called by the ſame name; and has formed out of the deſcription of different authors of theſe different plants, one general account, which he gives under the head of *polygonum*, and which can ſerve no plant at all. He ſays, it grows at the roots of trees, and climbs up them; and that it has long, ruſh-like, and brittle ſtalks, beſet with ſmall oval leaves. He even compares the branches to the hairs of a horſe's tail, and yet did not find out at the time, that he was blending the deſcription of the hippuris, or horſe-tail, called by ſome the *female polygonum*, with the common *knotgraſs*, or *polygonum* originally ſo called; a plant as different from it as one plant can well be from another. *Pliny*, l. 26. c. 13.

The common great *knotgraſs* is eſteemed a very powerful aſtringent. It is generally uſed in infuſion, and is ſaid to have great virtue in ſtopping hæmorrhages of all kinds. *Dale* Pharm.

POLYGRAM, in geometry, a figure conſiſting of many lines.

POLYHEDROUS *figure*, in geometry, a ſolid contained under, or conſiſting of many ſides. See POLYHEDRON, *Cycl.*

POLYHISTOR, is uſed for a perſon of great and various erudition. See POLYMATHIA, *Cycl.*

POLYMORPHOS, variouſly ſhaped, an epithet often given to the os ſphenoides.

POLYNOMIAL *(Cycl.)*—To raiſe a *polynomial* to any given power, may be done by Sir Iſaac Newton's binomial theorem. Among other methods of demonſtrating this, we have one by Signior Caſtillioni in the philoſophical tranſactions, numb. 464.

POLYOSTEON, a name given by authors to that part of the foot which conſiſts of a great many bones.

POLYPE, or POLYPUS, in zoology, a ſmall freſh water inſect, which, when cut into a number of ſeparate pieces, becomes in a day or two ſo many diſtinct and ſeparate animals; each piece having the ſurprizing property of producing a head and tail, and the other organs neceſſary for life, and all the animal functions. See Tab. of microſcopical Objects, Claſs 1.

The firſt diſcovery of this animal was owing to Mr. Leuwenhoek, who, in the year 1703, preſented to the royal ſociety of London, a deſcription of it, and an account of its uncommon way of producing its young: but the diſcovery of its amazing property of reproducing the ſeveral organs from its various pieces, was not made till the year 1739, by Mr. Trembley, at the Hague.

The production of its young is, indeed, different from the common courſe of nature in other animals; for the young one iſſues out from the ſide of its parent, in form of a ſmall pimple or protuberance, which lengthening and enlarging every hour, becomes, in about two days, a perfect animal, and drops from off its parent to ſhift for itſelf: but before it does this, it has often another growing from its ſide; and ſometimes a third from it, even before the firſt is ſeparated from its parent. They breed quicker in hot than in cold weather; and what is very extraordinary is, that there never has yet been diſcovered among them any diſtinction of ſex, or appearance of copulation; every individual of the whole ſpecies being prolific, and that as much if kept ſeparate, as if ſuffered to live among others.

If the method of this little animal's producing its young be very amazing, its reproduction of the ſeveral parts, when cut off, is much more ſo. The diſcovery of this was perfectly accidental; for Mr. Trembley, who had often met with the creature in the water, and from its fixed reſidence in one place, and ſome other obſervations, not being able to determine whether it were an animal or a vegetable, made the trial by cutting it aſunder, when, to his amazement, he found, that in a few days each of theſe pieces was become a perfect animal, the head part having ſhot forth a tail, and the tail a head. A thouſand other trials, by cutting the animal in different manners, firſt by Mr. Trembley, and afterwards, at his requeſt, by Monſ. Reaumur at Paris, and Mr. Folkes, Mr. Baker, and the other naturaliſts in England, were the reſult of this; and all ſucceeded in the ſame manner, by whoever they were tried.

It is not eaſy to ſay what is the ſize of this creature; for it can contract or extend its body at pleaſure from the length of an inch or more, and the thickneſs of a hog's briſtle, to the ſhortneſs of a ſingle line, with a proportionable increaſe of thickneſs. Its body is round and tubular, at one end of which is the head, ſurrounded with ſix, eight, ten or more arms, with which it catches its prey; and at the other, the anus and tail, by which it fixes itſelf to any thing it pleaſes.

There have been many different ſpecies of it diſcovered, the moſt elegant of which, the *polype a panache*, or plumed *polype*, of Mr. Trembley, ſeems much to reſemble the wheel-animal (ſo called from having the appearance of two wheels in its head) which Mr. Leuwenhoek diſcovered living in a ſheath or caſe, and affixed to the roots of duckweed.

All the ſpecies are found in clear and ſlowly running waters, adhering by the tail to ſticks, ſtones, and water-plants, and live on ſmall inſects. They are eaſily kept alive a long time in glaſſes, often changing the water, keeping the glaſſes clean, and feeding them with a ſmall red worm, common in the mud of the Thames, or with other ſmall inſects.

The creature has its name from the Greek πολὺς, many, and πὲς, a foot, ſignifying an animal with many feet; but a more appoſite one might eaſily have been invented, ſince it has in reality no feet at all. What were originally taken for feet, are what have ſince been called its horns, and of late more properly its arms, their office being to catch its prey.

The ſeveral ſtrange properties recorded of this animal, tho' very ſurpriſing, are, however, none of them peculiar to it alone. The Surinam toad is well known to produce its young not in the ordinary way, but in cells upon its back. Mr. Sherwood has very lately diſcovered the ſmall eels in ſour paſte to be each, without exception, full of living young ones. And as to the moſt amazing of all its properties, the reproduction of its parts, we know the crab and lobſter, if a leg be broken off, always produce a new one: and Mr. Bonet, Mr. Lyonet, Monſ de Reaumur, and Mr. Folkes, have all found on experiment, that ſeveral earth and water worms have the ſame property, ſome of them even when cut into thirty pieces. The *urtica marina*, or ſea-nettle, has been alſo found to have the ſame: and the ſea-ſtar-fiſh, of which the *polype* is truly a ſpecies, tho' it had long eſcaped the ſearches of the naturaliſts, was always well known by the fiſhermen to have it alſo.

Cluſter

Cluſter-POLYPE, the name of a ſpecies of ſmall inſect of the *polype* kind, called by the French naturaliſts *polype a bouquet*.

There is found on ſeveral of the water-plants, and on other ſubſtances, as ſticks, boards, and the like, accidentally fallen into the water, a whitiſh ſubſtance that at firſt ſight appears to be only a ſort of mouldyneſs; but if the bodies on which this is found, be put into a veſſel of clear water, and the matter examined with a magnifying glaſs, it is ſoon ſeen that this whitiſh ſubſtance is really a vaſt number of ſmall animals, which are almoſt continually in motion. When this is brought before the microſcope, the form and ſtructure of the creatures is very evidently diſtinguiſhed, and they are found to be minute roundiſh creatures, ſeverally affixed to the end of a ſort of ſtem or tail; and many of the ſtems are ſo interwoven and united together, that they form *cluſters*, which have occaſioned the name of the *cluſter-polype* to be given to the animal, tho' in itſelf it is really and properly ſingle from the beginning. There are ſeveral ſpecies of *polype* of this minute kind, that *cluſter* themſelves in this manner together; and according to theſe and other circumſtances, the *cluſters* are found larger or ſmaller, and more or leſs complex. Phil. Tranſ. N° 474. p. 171.

The ſmaller *cluſters* ſhould always be choſen for obſervation, as in the larger the bodies of the ſeveral animals that compoſe them are apt to hide and obſcure one another; but the moſt beautiful and accurate of all obſervations is to be formed when they are ſingle, as they are ſometimes found; and this is the only opportunity of ſeeing diſtinctly in what manner the *cluſters* are formed.

One of theſe ſingle animals is not in length above the 240th part of an inch, and is of a ſhape nearly reſembling that of a bell: the anterior part of this generally appears open when it preſents itſelf properly; and the poſterior part is fixed to the ſtem or pedicle, by the other extremity of which the creature faſtens itſelf to any ſolid body that it meets with. The body is of a browniſh colour, except at the ſmaller end, which as well as the tail is whitiſh and tranſparent; and when the anterior part is open, there may always be perceived about its edges, a very lively motion; and when the creature preſents itſelf in a better manner, there may be ſeen on either ſide of the edges of the anterior part, ſomewhat reſembling the wheels of a mill, continually moving with great velocity.

Theſe creatures are able to contract their bodies, and often do it very ſuddenly, eſpecially if any thing diſturb the ſubſtance on which they are fixed: when they are thus contracted, the edges of their anterior parts are drawn juſt into their bodies; and when the fright is over, it is a very agreeable ſight to behold theſe edges turning out again, and putting themſelves in motion as before. If the edges of the anterior parts of the bodies of theſe animals be ſtrictly obſerved while in motion, the water about them will be found to be full of extremely minute round bodies which are brought together by means of that motion, and ſerve the creature for its food: theſe may be often ſeen going down into the cavities of the body of the *polype*, and that very ſuddenly, as if forcibly driven down; and when ſwallowed too voraciouſly, are often thrown up again. Theſe obſervations are beſt made when a ſmall *cluſter* of the *polypes* are examined together.

If theſe *polypes* are kept ſome time in the rain-water, they by degrees loſe their brown colour, and become white and tranſparent throughout, except that a few ſpots of a duſky colour remain in their bodies; but if after this they are removed into other water of the ſame kind with the firſt, but newly taken out of the ditch, they in a little time recover their brown colour. When they become white, they plainly appear to be in a ſickly condition, and ceaſe to multiply; but when they have freſh water and recover their colour, they immediately begin to multiply again.

Theſe creatures are not abſolutely and immoveably fixed to the bodies on which they are placed, but they can at pleaſure quit them and ſwim about: in this ſwimming ſtate they are always found ſingle and not in *cluſters*; and they do not then appear in the ſame form as when they are fixed and open at their anterior ends. When they have ſwam about as long as they pleaſe, they either return to their *cluſters* from which they ſeparated themſelves, or affix each ſingly to any thing they meet with: and this is a circumſtance that merits to be carefully watched, becauſe it is by means of this that we ſee in what manner the creature multiplies itſelf, and the *cluſters* are formed.

As ſoon as a ſingle animal of this kind is fixed to a ſtick, a ſtone, or any other ſubſtance, it begins to lengthen its ſtem or tail, which tho' very ſhort while ſwimming, and when firſt fixed, very ſoon becomes of its priſtine length while in the *cluſter*; and after this the creature begins immediately to multiply by the moſt amazing means in the world; that is, by ſpliting itſelf to pieces lengthways. The firſt motion towards this operation is the drawing in the lips or edges; this is ſoon done, and the body then loſes its bell-like ſhape, and becomes round; the motion which was before perceived at the edges ceaſes, and there is only a ſlight tremulation to be ſeen within the body; after this the anterior part of the body becomes flat and broad, and the whole body ſhortens in proportion; and ſoon after this the whole body gradually ſplits itſelf regularly into two, from the center of the anterior part to the center of the hinder end, where it joins the tail or pedicle, and there ſoon appear two round and perfect bodies joined to that pedicle which before ſupported only one. The anterior parts of the two bodies ſoon begin to open, and gradually ſhew their edges, which perform the ſame motion the ſingle one did before. The motion is at firſt very ſlow, but it grows quicker by degrees as they open; and when they are perfectly expanded, it is as quick as it was in the original ſingle body: it is at this time that the two bodies may be eſteemed quite perfect. They are at firſt indeed leſs than the original *polype*, from which they were formed, but they grow to the ſame ſize in a very little time: the whole operation of dividing itſelf, takes up the creature about an hour; but to form a true idea of the manner in which it is performed, there muſt be many obſervations made, and the creatures muſt be examined in all views and lights while about it.

The lips of theſe *polypes*, when cloſely examined, appear to be compoſed of four or five tranſparent bands, all which have an undulatory motion. And when the newly divided *polype* is but ſlow in its motions, it is eaſy to diſcover that what afterwards appear to be like the wheels of a mill, are, in reality, only four or five oblong bodies, reſembling a ſort of fingers which alternately bend down, and extend themſelves every inſtant. Theſe are faſtened to the bands of the lips on each ſide of the mouth; and when they are put into ſwift motion in the time of the full growth and vigour of the animal, they are not to be diſtinguiſhed, as to form, nor can their motion be otherwiſe diſcovered than by its ſwiftneſs, which makes it reſemble the quick turning of a wheel.

When the ſeparation of the body of a ſingle *polype* of this kind is compleat, one ſees two regular and perfect bodies adhering ſide by ſide to the ſame pedicle, but ſoon after each of the new formed bodies begins to ſhew a pedicle of its own; theſe grow in a day's time to a moderate length, and unite at their bottoms to the end of what was the original ſingle pedicle of the body while but one; they grow to this in the manner of the branches growing to the trunk of a tree. Twenty-four hours after the ſeparation of the original body into two, theſe two begin to ſeparate themſelves in the ſame manner, each into two again; and theſe after a like time again ſeparate: each of theſe ſeparated animals has its own tail formed in a like period of time with the firſt; and the conſequence is, that the firſt ſeparation producing two, the ſecond gives four, the third eight, and ſo the ſixth ſixty-four, the ſeventh 128, and ſo on; by which means a ſingle animal, in a very few days, forms out of itſelf an immenſe *cluſter*; each animal of which is perfect in itſelf, and independent of all the reſt, and can, when it pleaſes, ſwim away and form a new *cluſter*. They will multiply as faſt in glaſs jars, as in their native free ſtate in the waters, and *cluſters* of them, begun near one another, will often join in ſuch a manner as to form one complex *cluſter* of an inch diameter: from theſe ſeveral *cluſters* there detach themſelves ſingle *polypes* from time to time, which go off and faſtening themſelves to other bodies, become the authors of new progenies. Phil. Tranſ. N° 474. p. 175.

The original branch or ſtem of the firſt *polype*, remains always in the center of the *cluſter*; but it is of no uſe, never afterwards having any body fixed to it.

There are, beſide this ſpecies here deſcribed, four other known kinds of *polypes*, which divide themſelves in the ſame manner by ſpliting into two lengthwiſe: thoſe which come neareſt to the firſt are ſlenderer, and their ſtems are more tranſparent. They are of a bluiſh colour, when many of them are ſeen together, and their ſtems or tails very aptly reſemble ſpun glaſs. When this ſpecies is perfectly formed, the motion of its lips is leſs diſtinct than in the other; but it may be diſcovered in the ſame manner while they are newly ſeparated and are but growing toward perfection, when it gradually becomes leſs and leſs diſtinct.

Another ſpecies of theſe *polypes* is ſmaller than the laſt, but more open at the mouth and deeper hollowed; and theſe are particularly diſtinguiſhed from all the others, by having a motion in their ſtems and branches, which all the others want. The ſtems draw themſelves up, and ſhorten all at once into the appearance of a ſpiral ſcrew, and in a moment can dart themſelves ſtrait out to their full length again. All theſe multiply very ſpeedily, but they have all enemies that deſtroy them in a very terrible manner, whole *cluſters* making but ſingle mouthfuls. The *funnel-polypes* are nearly allied to theſe creatures. Phil. Tranſ. N° 474. p. 180.

Funnel-POLYPE, a name given by naturaliſts to a ſmall water-inſect, in ſome reſpects approaching to the nature of the cluſter-*polype*. See *Cluſter* POLYPE, ſupra.

The *funnel polype* nearly reſembles a funnel, from which it has its name. It is long and hollow, and very wide at the anterior end. Theſe little animals are of three ſpecies, a green, a blue, and a white one: they are all too minute for the obſervation of the naked eye, and muſt be viewed with great caution, and in ſeveral different directions and attitudes, before their true form can be diſcovered; and their anterior end, particularly, when carefully obſerved, is of a much more

compound ſtructure than might at firſt be imagined; there may always be obſerved, round the edges of this part, a ſenſible motion, reſembling that of an indented wheel, or rather that of a ſcrew turned very nimbly about. Theſe, tho' they approach to the ſhape of the cluſter-*polypes*, and reſemble them in their having this motion about their mouths, yet never have any tendency to form cluſters, but are ever found looſe and ſingle. There are always a number of little round bodies, which ſeem to be animals of a very minute ſize ſwimming about in the water in which theſe *polypes* live; and theſe are continually drawn into the mouths of the *polypes*, and ſerve them for food.

The manner of theſe creatures propagating themſelves, is very amazing; they do it by dividing their own body into two; but this is not done longitudinally, as in the cluſter-*polypes*, nor tranſverſely, but diagonally from the edge of the head to the oppoſite edge of the tail; ſo that of the two thus formed out of one, the one has a head and no tail, the other a tail and no head; but theſe deficiencies are ſoon made up, and the head ſoon grows out of one, and the tail out of the other.

Mr. Trembley, in his account of this inſect, calls that of the two which has the old head, the ſuperior *polype*; that which has the old tail the inferior. The firſt particulars obſervable in a *funnel-polype* that is going to divide, are the lips of the inferior *polype*, or thoſe tranſparent edges that are ſo very conſpicuous in the creature when perfectly formed. Theſe new lips firſt diſcover themſelves upon the *polype* that is going to divide, from a little below the old lips to about two thirds of the length of the *polype*, reckoning from the head: but theſe new lips are not diſpoſed in a ſtrait line, according to the length of the *polype*, but run ſloping near half way round about. Theſe lips are diſtinguiſhed by their motion; but it is to be obſerved, that this motion is at firſt very ſlow, and requires an attentive eye and good glaſſes to diſcover it. Phil. Tranſ. N° 474. p. 180.

That portion of the body of the *polype*, which is bounded by theſe new lips, then gathers up itſelf, and theſe lips inſenſibly draw cloſe together, and finally they cloſe themſelves. By this means there is formed a ſwelling at the ſide of the *polype*, which is found, on a cloſe examination, to be the head of the new *polype*, bounded by the lips before-mentioned. Before this ſwelling is become very remarkable, it is eaſy to diſcover the true *polypes* that are forming themſelves; and after this, when the ſwelling is greatly increaſed, theſe two diſtinct animals will be found joined to one another only by a very ſmall part of their bodies. The ſuperior *polype*, in this caſe, no longer adheres to the inferior one but by its poſterior extremity, which is ſtill fixed on one ſide of the inferior one. The ſuperior one then begins to make motions, which tend to the ſeparating itſelf from its fellow; and theſe ſoon finiſh the work, and he becomes perfectly diſengaged, and ſwims away whither he pleaſes, and ſoon fixes on ſome other place. The inferior *polype* remains fixed in the place where both were before, and becomes a perfect animal; and the ſuperior one, after taking a tour in the water, ſometimes returns to the old place, and fixes himſelf by the tail to the body of the inferior one. All theſe animals are extremely minute, and are not to be ſeen diſtinctly, much leſs are their operations obſerved without the help of glaſſes; and as there is no taking them out of the water to bring them before the microſcope in the common way, without abſolutely deſtroying them, Mr. Trembley, who has obſerved them with more accuracy, than perhaps any other perſon ever did, has contrived to view them in a glaſs veſſel, in their own water, by bringing them ſo near the ſides of the glaſſes, that the microſcope glaſſes are able to reach them properly from the outſide. The ſubſtances on which they are fixed, are to be brought cloſe to the edges of the veſſel, by means of a ſet of quills framed properly together; and the microſcope glaſſes to be ſupported on a moveable arm made for that purpoſe. Phil. Tranſ. N° 474. p. 183.

Ver-POLYPE. See VER-*Polype*.

POLYPODES, a word uſed by ſome as a name for the millepedes.

POLYPODITES, a name given by the antients to a wine impregnated with polypody, and ſometimes for the juice of millepedes, expreſſed with wine.

POLYPODIUM, *polypody*, in the Linnæan ſyſtem of botany, the name of a genus of the capillary plants, comprehending the *polypodium* and *lonchitis* of Tournefort; the *lonchitis* of Linnæus being a very different genus of plants. The character of the *polypodium* is, that the fructifications are diſpoſed in round ſpots on the under part of the diſk of the leaf.

The characters of this genus, according to Mr. Tournefort, are theſe: The flowers are not diſcovered, but the ſeeds grow on the back of the leaf: theſe are contained in membranaceous capſules, of a roundiſh figure, which are placed together in cluſters, and have nothing round them, as thoſe of the trichomanes have, but are left to be burſt by the contraction of their own fibres.

The *polypodies* are not branched, but conſiſt of ſingle leaves, divided almoſt to the middle rib into oblong jags or ſegments.

The ſpecies of *polypody*, enumerated by Mr. Tournefort, are theſe: 1. The common *polypody*. 2. The common great *polypody*, with ſerrated leaves. 3. The leſſer *polypody*. 4. The large *polypody*, with pointed leaves. 5. The broad thin-leaved *polypody*, called by Muntingius, and others, ſenſitive *polypody*. 6. The narrow-leaved *polypody*, commonly called *lonchitis aſpera*, and rough *ſpleenwort*. 7. The Welch *polypody*, with leaves jagged at the edges of the pinnules. 8. The finely divided African *polypody*. 9. The great golden *polypody*. 10. The *polypody* with ſlender creeping roots. 11. The finely divided black *polypody*. 12. The *polypody* with leaves like the aſplenium. 13. The thin-leaved pendulous *polypody*. 14. The *polypody* with pointed and rigid pinnules. 15. The pendulous *polypody*, with a reddiſh hairy down. 16. The ſmooth pendulous *polypody*. 17. The leaſt pendulous *polypody*. 18. The curled *polypody*, reſembling the oſtrich's feathers. 19. The rough dentated *polypody*. 20. The ſlender undulated *polypody*. 21. The curled *polypody*, with cups. 22. The ſweet *polypody*, with the taſte of liquorice. 23. The *polypody* covered with ſilvery ſcales. 24. The brown finely ſerrated *polypody*. 25. The pellucid *polypody*. 26. The *polypody* with bluiſh punctated roots. *Tourn.* Inſt. p. 540.

The common *polypody* is the kind uſed in medicine; it is uſually found about the roots of old trees, in woods, and by hollow road ſides. There is a vulgar opinion, that ſuch of it as grows upon the ſtump of an oak, is preferable to what grows on any other tree; but there is no foundation for this.

The root is the part uſed in medicine; it is a gentle cathartic, and is particularly recommended in diſorders ariſing from obſtructions of the liver and ſpleen. It is by many eſteemed an excellent medicine in ſcorbutic and hypocondriac complaints. The country people take it in infuſion alone, but phyſicians uſually preſcribe it in compound decoctions and medicated ales. It has alſo been made an ingredient in many of the purging electuaries in the old diſpenſatories.

POLYPOSIA, a term uſed by the antients to expreſs a copious drinking of wine.

POLYPUS (*Cycl.*)—POLYPUS, the *polype*, in zoology. See the article POLYPE.

POLYPUS, in natural hiſtory, a name given by ſome of the earlier writers to the thin-ſhelled nautilus, or nautilus papyraceus. The body and arms of this creature ſomewhat reſembling thoſe of the polype, it was ſuppoſed to be a ſpecies of polype incloſed in a ſhell, which it could quit occaſionally, and go on ſhore to feed.

POLYPUS, in medicine.—Mr. Le Dran cured a *polypus* of the noſe, which he could not extract wholly, in the following manner, which may be practiſed for deſtroying all ſuch exceſcences. He introduced one end of a large ſeton, put on the point of the fore-finger of the left hand, into the patient's mouth, till he brought it behind the velum pendulum; then ſliding a pair of thin crooked forceps into the affected noſtril, he catched hold of the ſeton, after covering what was to be introduced into the noſe with a ſuppurant medicine. While he drew the cord, he endeavoured to preſerve the velum pendulum from being hurt, by introducing his finger into the mouth, and ſupporting the cord upon it. He continued the ſuppurant till he was ſenſible, by the patient's breathing freely through the noſtril, that the remains of the *polypus* was deſtroyed, and then he injected deſiccatives to cauterize the ulcer. *Le Dran*, Tom. 1. obſ. 6. ap. Med. Eſſ. Edinb.

Though Kerkringius, and others, have endeavoured to explode the notion of the formation of true *polypi* in the heart and blood veſſels, yet Malpighi, Bartholine, Tulpius, Pecklin, and others, have given us inconteſtable inſtances of the exiſtence of true *polypi* in the heart, in the ſtricteſt ſenſe; and we have three unqueſtionable evidences of the like nature, in Phil. Tranſ. N° 464. Sect. 6.

POLYSACTINODOS, in natural hiſtory, a name given by Linkius, and ſome other authors, to thoſe ſtar-fiſh whoſe body is divided into more than five rays, that being the more uſual and general number.

POLYSCHIDES *fucus*, a ſea-plant, called in Engliſh *ſea-hanger*. It is one of the largeſt ſea-plants we know, growing often to ten foot or more in length. Its root is not flat in the manner of moſt of the other ſea-plants, but is compoſed of ſeveral little hooks, all which lay faſt hold of the ſtone on which it grows: theſe, in ſome meaſure, reſemble the tendrils of the vine, and are ſomewhat broad and flatted at the end, where they are faſtened to the ſtone, tho' round elſewhere, and are about half an inch long: theſe hooks grow from a broad flattiſh part at the bottom of the ſtalk, which is often four or five inches in diameter, and is uſually hollow, being compoſed only of two membranes conſiderably tough and firm, with a cavity between them; from the center of this riſes the ſtalk, which is often twiſted and undulated at the edges; from the top of this ſtalk grows the leaf, which is divided into eight or ten ſegments; each of which is often again divided into two. Theſe ſegments are very long; and as the plant floats in the water, give it much of the appearance of a broad piece of leather cut into ſeveral thongs: theſe all terminate in ſharp points, and their colour is a browniſh green. The niceſt eye cannot diſtinguiſh the leaſt nerve or fibre, either in the ſtalk or leaf of this plant; but on great numbers of theſe plants, that curious enquirer Mr. Reaumur, found flowers of the ſame kind with thoſe which he originally diſcovered on the

the common fences: they are compoſed of ſlender filaments, not exceeding the twentieth part of an inch in length; and theſe were the more eaſy to be overlooked, as they are of the ſame colour with the leaves of the plant. Thoſe plants on which Mr. Reaumur found theſe flowers, were not, however, entirely covered with them, but they ſtood at about a twelfth of an inch diſtance from one another: it was in the month of July that Mr. Reaumur examined this plant; and at that time there were no ſeeds diſcoverable upon it; but doubtleſs at a proper ſeaſon, and with proper care in the obſerver, they will hereafter be diſcovered as plainly in this as in many other of the ſea-plants, uſually ſuppoſed by authors to have wanted them. Mem. Acad. Par. 1712.

POLYTHALAMIUM, in natural hiſtory, a name by which ſome authors have called the *tubuli marini concamerati*, a ſort of ſea-ſhell found frequently foſſile, with other ſhells, in Sweden, and brought over to us in the ſtones uſed for pavements, but not known in its recent ſtate.

It is of the ſame general ſtructure with the cornu ammonis, and thick nautilus, being compoſed of ſeveral cells or cavities, communicating with one another, by means of a ſiphunculus or pipe; but it is uſually ſtrait, tho' ſometimes its end is twiſted exactly in the manner of the cornu ammonis.

POLYTHALAMIUS, in natural hiſtory, a term invented by Breynius, to expreſs a claſs of ſhells, the character of which is, that they are hollow, ſhelly bodies, either ſtrait or regularly twiſted into a ſpiral form, always wide at the mouth, and growing narrower to the other extremity; they are divided within into ſeveral cells or chambers, which are called *thalami*, each ſeparated from the other by a diaphragm, or partition of ſhelly matter. The upper or largeſt chamber, contains the body of the animal, but all the others are perforated by a ſiphunculus, which gives them communication one with another, and which runs from the mouth to the very apex, growing ſlenderer all the way.

Of this claſs he diſtinguiſhes four genera, the orthoceros, lituus, ammonites, and nautilus, each of which ſee under their ſeveral heads. The two laſt of theſe, he obſerves, have been long well known to the world; the two firſt he gives as new, and of his own diſcovery.

Of the orthoceratitæ, which are ſtones caſt in the ſhells of the orthoceros, there are at preſent diſtinguiſhed nine kinds: theſe differ from one another principally in the poſition of the ſiphunculus, or in their external form; the cone which they deſcribe, running quicker or more gradually to a point; or, finally, by the thalami or chambers being wider or narrower. *Breynius* de Polythalam.

POLYTHRIX, the *hair-ſtone*, a name given by ſome writers to thoſe German agates which have received into their maſs, while yet ſoft, either the branches of the confervæ, or other capillary water-plants, or elſe have thin ſtreaks of a coarſer matter frequent in them, and running in the form of hairs.

POLYTRICHUM, in botany, the name of a genus of moſſes, the characters of which are theſe: The ſtalks are not much branched, and the capſules have calyptræ to cover them till mature. This calyptra is always hairy, and in many of the ſpecies is compoſed merely of long hairs, ranged lengthwiſe together, without any membrane; the others have membranaceous calyptræ, but covered with erect hairs. The leaves of thoſe kinds are rigid, and have a membranaceous appendage, by which they touch the ſtalks and ſurround them; thoſe of the others are ſofter, and have not this appendage. The baſis of the pedicle which ſupports the head, is alſo in theſe ſurrounded by a ſort of tube, round which there ſtand a number of membranaceous leaves; this is more viſible in the larger than in the ſmaller ſpecies. The capſules in ſome of theſe moſſes are ſquare, in others they are roundiſh; and the ſquare ones have uſually an apophyſis, by which they are joined to the pedicle, which the round ones never have, or at leaſt very ſeldom. See Tab. of Moſſes, N° 12.

The *polytrichum* of the firſt order, are thoſe which have ſquare capſules, which are joined to the pedicles by a round apophyſis; of theſe the following are all the known ſpecies: 1. The common large, ſquare-headed, great-leaved *polytrichum*, or great goldilocks. This is very common in woods, in boggy places, and on heaths. 2. The leſſer and ſtiffer ſquare-headed juniper-leaved heath-*polytrichum*. The leaves of this are ſhort, and the whole plant much ſmaller than the former. It is very common on heaths. 3. The ſmall hairy ſquare-headed *polytrichum*; the leaves of this are of a bluiſh green in winter, and of a reddiſh brown in ſummer. It grows in dry barren places.

The ſecond order of the *polytrichum* comprehends thoſe which have round capſules, and uſually want the apophyſis, by which the others are joined to the ſtalk. The following are all the known ſpecies of this kind: 1. The branched alpine *polytrichum*, bearing heads from its tops. The leaves of this are narrow and ſomewhat hollowed, and when viewed by a microſcope, appear ſerrated at the edges. It grows on the Welch mountains. 2. The branched *polytrichum*, bearing heads from its ſides. This grows to two inches high, and is found in the ſame places with the former. 3. The dwarf round-headed aloe-leaved *polytrichum*. This has ſcarce any ſtalk, but lies upon the ground; it is frequent by way ſides, and ripens its capſules early in the ſpring. 4. The dwarf long-headed aloe-leaved *polytrichum*. The ſtalks of this are a little longer than thoſe of the former. It grows in wet places on heaths. 5. The larger ſhort-ſhanked *polytrichum*. This is branched, tho' very low, and reſembles at firſt ſight one of the bryums, growing in round tufts. The leaves are of a deep green, and very pellucid; they have a middle rib viſible in them, and are diſpoſed in ſomewhat of a ſtellate manner at the ends of the branches. It grows in woods on the barks of old trees, and ſometimes on walls. 6. The leſſer ſhort-ſhanked *polytrichum*. This is much ſmaller than the former, and produces its capſules a little later. It grows on trees and walls, and ſometimes on the earth. 7. The ſhort-ſhanked *polytrichum*, with ſtrait and plaited leaves. This grows in tufts. Its ſtalks are an inch high, and its leaves of a dark green. It grows on rocks and old walls. 8. The fine-leaved curled *polytrichum*, with ſharp hairy calyptræ. This is found in tufts compoſed of thick branches, ſurrounded with very numerous leaves, each ending in a hair at the end. It grows in woods, and ripens its capſules in March and April. 9. The dwarf fine-leaved *polytrichum*, with cylindric heads. This grows on ſandy places in north America. *Dillen.* Hiſt. Muſc. p. 430.

Old writers are very full of the praiſes of this plant for its virtues in making the hair grow thick; but this ſeems to have been an opinion taken upon no better reaſon than the likeneſs of the ſtalks of the plant to hairs. They make a decoction of it in ſome parts of Germany, and waſh the head carefully with it in the increaſe of the moon; but there is no great reaſon for ſuppoſing this liquor does any thing more than warm water would do.

POLYTROPHEROS, a name given by the Greeks to coarſe bread, from its conveying much more nouriſhment to the body than the finer kind; which they called, by way of diſtinction, *oligotropheros*.

POLYZONOS, in natural hiſtory, a name given by the antients to a ſpecies of onyx, which had a dark or blackiſh ground, with a great number of white zones.

POMA, in the writings of the old Greek phyſicians, a word which has given the commentators a great deal of trouble rightly to explain. Dioſcorides, in deſcribing the *onyx indicus*, which we improperly call *blatta byzantia*, tells us that it was like the part of that ſhell uſually called by the name of *byzantine blatta*, but that it was in reality the *poma* of another ſhell.

Some have underſtood Dioſcorides, as if he meant that the whole ſhell of the fiſh, which he deſcribes as being like the purpura, was what he called *onyx indicus*; but it is not eaſy to ſay why ſo correct an author ſhould call a whole ſhell *poma conchyli*, nor what reſemblance there could be between a ſhell like the purpura and a human nail, *onyx?* Actuarius, and many others, ſenſible that a part of a ſhell only was meant by this name, have tranſlated it the *os naſi*; but the bone of the noſe of a ſhell-fiſh is ſo odd an expreſſion, that one ſcarce knows what to underſtand by it.

The purpura of the antients has a long tongue, with which it pierces the ſhells of the chamæ, and other fiſh that it feeds on; but whether this or the operculum, which all ſhells of this kind have, is meant by the word, is not to be aſcertained by this phraſe *os naſi*.

The true meaning of the word is to be made out before any thing can be judged of what is meant to be expreſſed by it here, where it is evidently uſed in a metaphorical ſenſe.

Braſſavolus ſays, that it means all ſorts of ſhelly or cruſtaceous coverings of fiſhes; but this is an abſolute error; for even the medical authors do not extend its ſenſe ſo far as that. The Greeks called all ſhells by the name *oſtraca*, and this author attributing a different virtue to the whole ſhell of the purpura, ſufficiently ſpeaks this *poma* to have been but a part of it.

The Arabian writers were ſenſible of this, and rendered it by the words *adfor althaib*, which ſignify fragments like nails. Serapio calls it *mukatha*, which ſignifies a morſel or piece of any thing cut from a ſolid body. The original ſenſe in which the Greeks uſed the word *poma*, was to expreſs the thing that cloſed the mouth of any veſſel with a long and narrow neck. The Latins expreſſed this by the word *operculum*, and ſometimes, as in Sulpicius Severus, by the word *umbo*.

The antients alſo uſed the word *poma* to expreſs the lid or covering of a well, or of any hole. Now the purpuræ buccina, and all thoſe other ſhells which the Greeks have called *ſtromboide*, may in ſome ſort be compared to narrow and deep veſſels, and they have all of them a ſort of *poma*; or, as the Latins have expreſſed it, an *operculum*, to ſtop the mouth of the ſhell, and prevent the ingreſs or egreſs of any thing at the creature's pleaſure. This *operculum* being what Ariſtotle has called *epicalymma*, is certainly alſo what Dioſcorides means by the word *poma*; Ariſtotle has been very expreſs in his deſcription of it, and ſays that the tongue lies under it, and that all the *ſtromboide* ſhells gave it. The *onyx indicus*, therefore, was only the *poma*, or *operculum* of an Indian *ſtromboide* ſhell, of the buccinum or purpura kind, and was of a ſweet ſmell, and thence had the term *aromaticus*, or *odoratus*. The name *onyx* is eaſily accounted for, as the *poma* of every ſhell of this kind is flat and thin, and does not unaptly reſemble the human nail.

POMATIA, in natural hiſtory, the name of a large ſpecies of garden-ſnail, ſo called from its feeding on apples and other fruit. It is originally a native of Italy, but is become of late years as familiar with us in England, as if a native with us. It is a noble remedy in conſumptive decays; and a perſon of diſtinction in England having occaſion to take great numbers, had ſeveral large parcels brought carefully alive from Italy, and turned looſe in his garden, where they multiplied to ſuch a degree, that the neighbouring woods and hedges ſoon became full of them, and they have ſince been propagated in many other places.

The *pomatia* is much larger than our common ſnail, and of a paler colour: it is of a roundiſh figure, and has five ſpires or twiſts at the head; theſe are placed very cloſe, and its mouth is large and almoſt circular, and has no duplicature or fold ſurrounding it, but it is as thin as the reſt of the ſhell.

POMEGRANATE, in botany. See PUNICA.

POMERIUM, in antiquity. See POMOERIUM.

POMOERIUM, among the Romans. Authors are not agreed as to particular circumſtances relating to the *pomoerium*; ſome will have it to be a ſpace of ground without the walls; others a ſpace within them; and others again think it was both within and without. But which ever of theſe is true, the *pomoerium* was a place eſteemed ſacred, and kept free from houſes and every other kind of obſtruction. Hiſt. Acad. Inſcr. Vol. II. p 91, ſeq.

POMPEION, Πομπειον, in antiquity, a ſtately edifice at Athens, in which were kept the ſacred utenſils, made uſe of at feſtivals, and all things neceſſary for the ſolemn proceſſions prepared. It ſtood at the entrance of the old city, which looked towards Phalerum, and was adorned with many ſtatues of the Athenian heroes. *Potter*, Archæol. Græc. l. 1. c. 8. T. 1. p. 34.

The word *pompeion* is derived from πομπευω, *cum pompa incedo*, and was likewiſe uſed for any utenſil employed on theſe occaſions.

POMPILUS, in zoology, the name of a ſea-fiſh, remarkable for following the rudders of ſhips to vaſt diſtances. It has no ſcales: it has a very broad line from the gills to the tail, under which are a number of dotted tranſverſe lines, reaching to the belly, above the line on the ſide; the back is ſpotted with different colours. The mouth is moderately large, but the teeth very ſmall. Its forehead, between the eyes, is of a gold colour, and it has four fins, two at the gills and two on the belly; and beſide theſe, one long one running all the length of the back, and another anſwering it from the anus to the tail. It tail is not forked. *Rondelet.* de Piſc. p. 250. *Geſner* de Piſc. p. 887.

POMPILUS is alſo uſed by ſome authors for the nautilus, as well of the papyraceous, as the camerated kind. See the article NAUTILUS.

POMPION, in botany. See the article PEPO.

POMPONA, a name given by the Spaniards in America to a ſort of *vanilla*, the pods of which are ſhorter and thicker than thoſe of the common kind, and of a ſtronger ſmell, tho' leſs agreeable. The pulpy matter alſo in theſe pods is more liquid than that in the common kind, and the ſeeds much larger, being as big as thoſe of muſtard. This is never brought to market alone; but the Indians who gather it, cunningly mix it among the right kind; but this ſhould be taken care of by the buyer, ſince this kind is very prejudicial, occaſioning violent head-achs in men, and in women vapours and diſorders of the womb.

It is not yet certainly known whether this be the fruit of a different ſpecies of the *vanilla* plant, or whether it be only different from the common in age, or in the place of growth of the plant.

POMUM, *apple*, a well known fruit. See APPLE.

Among the various kinds of *apples*, ſome are uſed for the deſert, ſome for the kitchin, and ſome for cyder-making.

Thoſe uſed for the deſert, are the following, placed as they ſucceſſively ripen after one another: The white juncating, the margaret *apple*, the ſummer pearmain, the ſummer queening, the embroidered *apple*, the golden reinette, the ſummer white calville, the ſummer red calville, the ſilver pippen, the aromatic pippen, la reinette griſe, la haute bonte, the royal ruſſetting, Wheeler's ruſſet, Sharp's ruſſett, the ſpine *apple*, the golden-pippen, the nonpareil, the l'api, or pomme d'api.

Thoſe for the kitchin uſe, in the order of their ripening, are theſe: The codling, the ſummer marygold, the ſummer red pearmain, the Holland pippen, the Kentiſh pippen, the courpendu, Loan's pearmain, the French reinette, the French pippen, the royal ruſſet, the monſtrous reinette, the winter pearmain, the pome violette, Spencer's pippen, the ſtone pippen, and the oaken pippen.

Thoſe moſt eſteemed for cyder are, the Devonſhire royal wilding, the redſtreak *apple*, the whitſour, the Herefordſhire under leaf, and the John *apple*, or deux annes.

The ſeveral ſorts of *apples* are deſigned either for ſtandards, or in dwarfs or eſpaliers; thoſe that are deſigned for ſtandards ſhould be grafted on crab-ſtocks, and thoſe for dwarfs or eſpaliers, on the codling, or ſome other ſpecies, which does not ſhoot freely. See the article GRAFTING.

The beſt ſeaſon for planting out theſe trees is, if the ſoil is dry, in October; but in a wet ſoil 'tis beſt to defer it till February. The diſtance at which they ſhould be planted, is forty feet ſquare, that the ſun and air may have room to come every way at them. And 'tis a very good method in large orchards, to plough and ſow the ground between them, till they are grown up. Good thriving trees of about three years grafting, are to be choſen for planting; and they ſhould be taken from a ſoil as nearly as poſſible of the ſame nature with that they are to be planted into, or rather from one that is ſomething poorer. In preparing theſe trees for planting, all the broken or bruiſed roots are to be taken off, as alſo all ſuch as croſs and gall one another, and all ſmall fibres; for theſe ſeldom ſurvive a remove. Some of the moſt luxuriant branches muſt be alſo taken off at the ſame time, and others ſhortened, but the head ſhould by no means be cut off. The holes for the planting them ſhould be made about two foot deep, and of a breadth proportioned to the extent of the root; the bottom muſt be made even, and the clods and lumps all broken. The tree is then to be ſet in the middle of the hole, and placed as upright as poſſible, and the earth carefully placed about its roots; and, finally, trod down about it with the feet; and if the weather be dry, every tree ſhould have a good watering, which will fix the earth to the roots. A ſtake ſhould alſo be fixed by the ſide of each tree to tie it to, that the wind may not ſhake it and looſen the roots. The foot of each tree ſhould be then ſurrounded with turf newly cut, with the green ſide downwards; which will greatly help to keep the earth moiſt; and if the ſeaſon be very dry, the waterings muſt be repeated at different times; but it is a very common error to water new-ſet trees too much; and this ſhould be carefully avoided. The year afterwards dig in the earth about the roots, and bury the rotted turff, which was laid about the root when planted, and there needs no farther care; the orchard will then thrive of itſelf.

Dwarf ſtandards are of the leaſt value of all *apple*-trees, never producing well-taſted fruit; and are therefore the worſt way of managing this tree.

Eſpaliers are commonly planted to ſurround the quarters of kitchin gardens. Theſe quarters ſhould be made as large as the garden-room will permit. The trees ſhould be planted at ſixteen or eighteen feet aſunder, if on crab-ſtocks, but if on paradiſe-ſtocks, twelve feet will be ſufficient; when theſe are planted in the manner above-deſcribed, they ſhould be headed to about four eyes above the graft, and they ſhould never be of more than two years old from the grafting when planted. The ſummer after they are planted, a number of ſmall ſtakes muſt be provided, of about three feet long, to drive into the ground on each ſide of the trees, four to each tree; and to theſe ſtakes the new ſhoots muſt be faſtened as horizontally as poſſible. If the trees have taken kindly, probably about Michaelmas all the four eyes will have made ſhoots; if ſo, at Michaelmas, which is the right time for pruning, the two upper ſhoots ſhould be cut off to four eyes each, but the undermoſt may be left with ſix or eight; but the branches ſhould never be ſhortened in ſummer, unleſs on occaſion of filling up ſome vacancy in the eſpalier, and then this muſt not be done after May.

In the ſecond year, all the ſhoots muſt be trained horizontally, except the fore right ones, which muſt be diſplaced as faſt as they are produced: at Michaelmus, the branches in the middle of the tree, or wherever there is want of wood, muſt be ſhortened; but after this be very careful of any great lopping, or ſhortening of branches, but leave them at full length, training them all horizontally. *Miller's* Gardners Dict.

POND *(Cycl.)*—POND-*weed*. See POTAMOGEITON.

Fiſh POND. See the article FISH.

PONENDUM *in ballium*, in law, a writ commanding that a priſoner be *bailed*, in caſes bailable. Reg. Orig. 133. *Blount*, *Cowel*.

PONENDUM *ſigillum ad exceptionem*, a writ by which juſtices are required to put their ſeals to *exceptions* exhibited by the defendant againſt the plaintiff's evidence, verdict, or other proceedings before them, according to Stat. Weſtm. 2. *Blount*, *Cowel*.

PONENDIS *in aſſiſis*, a writ granted by the ſtatute of Weſtm. 2. c. 38. which ſtatute ſhews what perſons ſheriffs ought to impanel upon *aſſiſes* and juries, and what not. Reg. Orig. 178. F. N. B. 165. *Blount*, *Cowel*.

PONTAGIA, a term uſed by Paracelſus, and his followers, to expreſs a mixing ſaline ſubſtances, with thoſe which are bitter or ſtyptic.

PONTEE, in the glaſs trade, an iron inſtrument uſed to ſtick the glaſs at the bottom, for the more convenient faſhioning the neck of it. *Neri's* Art of Glaſs, Appendix.

PONTEE-*ſtake*, in glaſs making, is the iron whereon the under ſervants place the irons from the upper workmen, when they have knocked off the broken pieces of glaſs. *Neri's* Art of Glaſs, Appendix.

PONTICA *gemma*, a name given by the antients to a ſtone of the agate kind, with a white ground and red and black ſpots, irregularly placed, and making a beautiful variegation in it. This ſeems to have been the ſame ſtone which ſome of the moderns have called the *ſmall pox ſtone*, from its ſpots reſembling the eruptions in that diſeaſe. The antients mention ſeveral kinds of it, as they were ſpotted with various colours.

PONTICA *vina*, a term uſed to expreſs acid, fæculent, and tartarous wines.

PONTICUM *mel*, a name given to a ſort of poiſonous honey

PONTICUS *mus*, in zoology, the name of a creature deſcribed by the antients, and ſuppoſed to be the ſame with our ſquirrel. See SCIURUS.

PONTLEVIS, in the manege, a diſorderly reſiſting action of a horſe, in diſobedience to his rider; in which he rears up ſeveral times, and riſes ſo upon his hind legs, that he is in danger of coming over. It is cured by clapping ſpurs ſmartly to him, as the fore feet are returning to the ground.

POOL *(Cycl.)*—POOL-*ſnipe*, in zoology, a name given in many parts of England to the redſhank.

POOR, or POWER, in ichthyology, a name given by the people of Cornwall to a ſpecies of bearded gadus. See the article GADUS.

POOSPANSCUM, in natural hiſtory, the name of a peculiar ſpecies of foſſil in the Eaſt Indies. It is of the nature of the blende, or mock-lead, with us; but is not formed into ſo large flakes, but more reſembles the ſteel-grained lead ores. It is found in the beds of rivers, and when calcined, it is uſed with the juices of certain herbs, for ulcers and other cutaneous diſorders. Before calcination it is alſo uſed by the women to make their hair of a fine gloſſy black colour, which it performs very neatly.

POPÆ, among the Romans, were ſuch perſons as attended the ſacrifices, whoſe buſineſs it was to provide victims, and to kill them after they had knocked them down. They were half naked, their ſhoulders, arms, and upper parts of their bodies being uncovered as far as their navels, and the reſt covered to the mid-leg with a linnen apron, or the ſkins of the ſacrifices; and they wore crowns of laurel upon their heads. *Danet* in voc. See POPE, *Cycl.*

POPE, in zoology, a name by which the people in many parts of England call the *anas arctica clufii*. See the article DUCK.

POPLAR, *populus*, in botany, the name of a genus of trees, the characters of which are theſe: the flower is of the amentaceous kind, being compoſed of a number of ſmall leaves, furniſhed with a great quantity of apices; but theſe are barren. The embryo fruits are produced on thoſe trees which produce none of theſe flowers; theſe are ſpiked, and conſiſt of many leaves, under which there lies a ſort of bell, which contains the embryo ſeed veſſel, which finally becomes a membranaceous pod of a compreſſed figure. Theſe are diſpoſed in a ſpiked form, and open into two parts, containing ſeeds winged with down. To this it is to be added, that the *poplar* has a peculiar and appropriated general appearance, by which it is obviouſly diſtinguiſhed from the willow. See Tab. 1. of Botany, Claſs 19.

The ſpecies of *poplar* enumerated by Mr. Tournefort, are theſe: 1. The common white *poplar*, with large leaves. 2. The common white *poplar*, with ſmaller leaves. 3. The common black *poplar*. And, 4. The *poplar* with trembling leaves, called the *aſpen-tree*. *Tourn.* Inſt. p. 592.

The *poplar*, whether black or white, may be eaſily propagated, either by layers, cutings, or ſuckers, of which the white kind always produces a great many from the root. The beſt ſeaſon for the tranſplanting theſe ſuckers is in October, when the leaves begin to decay; and they ſhould be removed into a nurſery for two or three years, at the end of which time they will have got ſtrength enough to be tranſplanted into the places where they are to remain.

When they are to be propagated by cuttings, it is beſt to do that in February, cutting off large truncheons of eight or ten foot long; which being thruſt down a foot deep in the ground, will take root very quickly, and if the ſoil be moiſt, will grow to a conſiderable ſize in a very few years.

The black *poplar* is not ſo eaſily raiſed from theſe large truncheons, but ſhould be planted in cuttings, of about a foot and a half long, planting them a foot deep in the ground. This will grow on almoſt any ſoil; but does much better on a moiſt one than on any other. They are the fitteſt of all trees for raiſing a ſhade quickly, as they will grow fourteen foot in heighth ſometimes in one ſeaſon, and in four or five years will be large trees. *Miller*'s Gard. Dict.

POPLAR-*galls*. The black *poplar* is famous among naturaliſts for producing a ſort of *galls* or protuberances, of various ſhapes and ſizes, on its leaves and branches, which have been uſually miſtaken for the lodgments of worms hatched from the eggs of an ichneumon-fly; but they are in reality produced by the operation of a viviparous inſect, called the *puceron*, for the bringing up of its off-ſpring. See PUCERON.

Theſe *galls* are of the bladder kind, being uſually ſkinned over, and more or leſs hollow within, not woody, as thoſe of the oak, &c. They proceed from different parts of the plant, ſome from the pedicles of the leaves, and many from the young ſhoots. They are very various in figure, ſome being roundiſh, others oblong, others crooked and contorted in various directions, and ſome of them are in the figure of horns, like thoſe of the turpentine tree, and of the ſame origin.

When any of theſe *galls* are opened at a proper ſeaſon, there is found in them a vaſt number of inſects of the puceron kind, all the family of one female parent, who formed the bladder or *gall* for their reception: if they are opened a little earlier than this, there is only one, that is the female parent, found in them: and finally, if they are examined later, they are found empty, the young brood having made their eſcape out of them; and at this time the ſtalks of the leaves are found twiſted about and ſwelled; and in theſe ſwellings, which are a new ſort of *gall*s, are found the young pucerons, which had eſcaped out of the larger *gall* or bladder, which had ſerved for their common home.

Mr. Malpighi obſerved theſe ſpiral tubercles on the pedicles of the leaves of this tree, and has given a figure of them in his twenty-ninth plate; but he had no knowledge of this animal which occaſions them, nor, indeed, any idea of a viviparous creature being at all concerned in the formation of *gall*s on vegetables; his whole ſyſtem being founded upon their being the effect of the eggs of a fly depoſited in them: he has therefore deſcribed theſe ſpiral ones among the reſt, as being of the ſame origin, and filled with eggs; but if he had accurately examined the bodies themſelves, he would have found them filled with real living inſects, not eggs of any kind.

Beſides theſe *gall*s on the ſtalks and pedicles of this tree, there are alſo others found on the leaves themſelves; and theſe are always joined to and prolonged from the middle rib of the leaf, which is properly only the continuation of the pedicle, and ſeem only to be the middle rib diſtended and ſwelled, the rib being wanting in the part where they are, on the upper ſide of the leaf, and on the under ſide there being only a little ſlit or crack, but with its edges nicely joined in the place of it; and if the leaf be preſſed between the fingers, this crack will open wider, and ſhew the internal cavity of the *gall* or bladder that appears on the upper ſide, and the little pucerons are ſeen living in it; but as ſoon as the leaf is left to itſelf again, the edges of this ſlit cloſe, and the creatures find themſelves as well defended from all injuries as before. There is great reaſon for theſe little creatures thus hiding themſelves, for they are, when expoſed to the view of other inſects, fed upon by many little animals; and it is a common thing, on taking one of them out of its cell, and ſetting it on the ſurface of the leaf, to ſee a little yelloviſh bug immediately come up, and ſeize upon it, and ſuck it to death with its trunk, which is extremely fine, but is eaſily introduced into the body of this creature.

The care the pucerons take to hide themſelves, and their young, from theſe enemies, is not, however, always ſufficient; for it is a very common thing to find a ſmall red inſect, of an oblong form, and endued with a very long trunk, lodged in the very cells, and eating them up in their habitations. This is ſuppoſed by Reaumur to be the bug before mentioned in its nymph ſtate, and had doubtleſs been lodged in this place by its parent in the egg, in order to feed upon the young animals.

The pucerons which live upon the poplar have another method of ſecuring themſelves from injuries. They have a method of forming a bladder of the very ſubſtance of the leaf itſelf, and this is very capacious, its cavity being much larger than that of any other kind: this is done by bringing the two edges of the leaf together, ſo that the leaf has its whole length, tho' only half its breadth, and the edges are every where faſtened together, while the whole ſpace within remains free, and is a fit receptacle for the animals. The cavity is much largeſt near the rib, and the leaves which are thus folded have not the colour or the gloſs of the others; but are covered with a vaſt number of little tuberoſities of a reddiſh colour, and of the bigneſs of a pin's head. This is uſually effected while the leaves are young and green, and at firſt there are only found a few ſmall pucerons in them; by theſe may be ſeen the true cauſe of the joining together of the leaf into a ſort of ſack or caſe. If two or three of theſe are found, as is very frequent on the under ſide of the leaf of this tree, they are always found fixed in their ſucking poſture, near the middle rib; and if the upper ſide of the leaf be examined, there will be found on it a yelloviſh or pale green tubercle, juſt oppoſite to every one of the inſects. Theſe tubercles are ſo many ſmall bladders or leaf *gall*s; and as they continually increaſe in ſize, and by that increaſe force out the middle part of the leaf on which they are placed into a ſwelling upwards, the conſequence is, the drawing together of the edges, ſo as to form a caſe or bag, of which the outſide of the leaf makes the external covering, and the inſide the lining. The regularity of the placing of theſe tubercles in the center of the leaf is the reaſon of the edges falling evenly together; and ſometimes, when the tubercles are leſs regularly ſituated, the joinings have ſeveral empty or open ſpaces between them. Theſe two or three firſt tubercles are afterwards ſurrounded by a vaſt number of new ones, which are the effects of the progeny of the firſt obſerved inſects; and thus the generality of the larger leaf or bladder-*gall*s are formed, as well on the *poplar* as on the elm, the apple, and the other trees on which they are ſo frequently found.

The pucerons which are found inhabiting the leaves of the *poplar* thus curled up, are of the ſame ſhape and figure with thoſe of the other parts of the ſame tree, and probably are the very ſame ſpecies; tho' ſome ſuppoſe them different from the dif-

different manner of their working. *Reaumur*'s Hiſt. Inſ. Vol. VI. p. 39, ſeq.

POPLITÆUS, *(Cycl.)* a ſmall muſcle, obliquely pyramidal, ſituated under the ham. It is fixed above, by a ſtrong narrow tendon, to the outer edge of the inner condyle of the os femoris, and to the neighbouring poſterior ligament of the joint; from thence it runs obliquely downward, under the inner condyle of the os femoris; its flat and pretty thick fleſhy body increaſing gradually in breadth, till it is fixed in the backſide of the head of the tibia all the way to the oblique line obſervable on that ſide. *Winſlow*'s Anat. p. 216.

POPPY, *(Cycl.)* PAPAVER, in botany. See PAPAVER.

We have many ſpecies of this plant cultivated in gardens for the beauty of the flowers. They are all eaſily propagated by ſowing the ſeeds in autumn. When the young plants come up, they are to be cleared from weeds, and thinned to a proper diſtance by pulling ſome up where they ſtand too thick; for they never thrive well if they are tranſplanted. They are to be left, according to their ſizes, at ſix, eight, or ten inches diſtance.

They are very ſhowy flowers, and make a ſplendid appearance in gardens; but they are but of ſhort duration, and are of an offenſive ſmell, which makes them leſs valued at preſent than they have been.

Some ſow theſe plants in ſpring, but it is not ſo well; becauſe they then have not time to get ſtrength before autumn, when they are to flower; and for that reaſon thoſe ſown in ſpring uſually flower weakly. *Miller*'s Gard. Dict.

Red-POPPY. The common wild red *poppy* is one of the moſt troubleſome and miſchievous weeds the farmers are plagued with among their corn, and it is the moſt difficult to thoroughly deſtroy of almoſt any other. Its ſeed will lie a long time in land unploughed, without ever ſhooting; but they will be ſure to grow with the firſt crop of corn. Mr. Tull gives an inſtance of the ſeeds of this plant being buried four and twenty years in a field of ſaint-foin, and at the end of that time, the land being ploughed for wheat, they all grew up among the corn, tho' they had lain dormant ſo long before. *Tull*'s Horſehoing Huſbandry.

It has been the general opinion of authors, that the narcotic quality of the *red poppy* lay in its flowers; but Mr. Boulduc, in his courſe of experiments for the finding out an European plant which ſhould yield us a juice of the nature of the opium of the Eaſt, without its bad effects, found that the virtue of this plant, which is very great, lay much more in the heads than the flowers; and from four ounces of theſe heads, while freſh and green, he obtained five drachms of a ſolid extract, of the nature of opium, two, three, or four grains of which were a full doſe; and which poſſeſſed the virtues of opium, and might be given with great ſucceſs and ſafety in obſtinate coughs and other ſuch caſes. Hiſt. Acad. Par. 1712.

It is ſaid, that the extract of Britiſh *poppies* is, in ſome caſes, preferable to the opium brought from Turkey. We have, in the medical eſſays of Edinburgh, the method of preparing an extract and ſyrup of *poppies*, by Mr. Arnot. See Vol. 5. Art. 11.

Yellow POPPY. The yellow horned *poppy*, called by authors *papaver corniculatum luteum*, is one of thoſe vegetable poiſons of our own growth, which may be very miſchievous by their not being generally known, or ſuſpected to be ſo. We have an account of the effects of this plant in the philoſophical tranſactions, in an inſtance of a family in Cornwall, who eat of a pye made of the roots of this inſtead of thoſe of eryngo, or ſea-holly, which it is the cuſtom of the poorer people there to make into a coarſe ſort of pye for their food.

The man of the houſe, on eating of this pye while hot, was ſeized immediately with a violent delirium, one effect of which was his thinking every thing he ſaw of a yellow colour, and taking every utenſil of the houſe to be made of gold. The man and maid ſervant eat of the pye after their maſter, and were ſoon after as mad as he, coming into the room where his friends were attending him, ſtripped naked, and dancing together. Theſe people alſo took every thing they ſaw to be gold; and a child in the cradle, to whom a ſmall piece of the pye had been given, was thrown into a drowſy diſorder, and convulſed about the mouth; but, after a few days, it recovered.

The grown people were all ſeized with moſt violent purgings, and by that means eſcaped, after being miſerably worn down by this complaint.

The ſymptom of ſuppoſing every thing gold, which ran through the whole family, and went even ſo far as to the ſuppoſing their ſtools gold, and ordering them to be ſaved, may poſſibly be in ſome meaſure owing to the idea they had of the plant whoſe roots they had been poiſoned by; its flowers being as large as a roſe, and of a fine yellow, and the juice of the whole plant being alſo yellow. Phil. Tranſ. N°. 242.

Horned POPPY. See GLAUCIUM.

POPPY-*ſeeds*. The *poppy-ſeed* is of a more delicious taſte than ſweet almonds; it is oily and farinaceous. Dr. Alſton ſays, he has eaten large quantities of the black as well as the white ſeed, and never found it ſomniferous or noxious. See Med. Eſſ. Edinb. Vol. 5. Art. 12.

Theſe ſeeds are uſed in food in ſome places, as is their expreſſed oil, which is as wholeſome as olive oil. Vid. Matthiol. p. 746. *Geoffr.* Mat. Med. Vol. 2. p. 713.

POPULAGO, *marſh-marygold*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the roſaceous kind, being compoſed of ſeveral petals arranged in a circular form; from its center ariſes a piſtil, which afterwards becomes a membranaceous fruit, conſiſting as it were of ſeveral thin capſules collected into a head. Theſe capſules all bend a little downwards, and contain oblong ſeeds.

The ſpecies of *populago*, enumerated by Mr. Tournefort, are theſe: 1. The common large flowered *populago*. 2. The ſmaller flowered *populago*. And, 3. The *populago* with double flowers. *Tourn.* Inſt. p. 273.

POPULARIA, among the Romans, were ſteps or places where the people ſat and beheld the games and horſe-races. *Pitiſc.* Lex. Ant. in voc.

PORCALA, a name given by ſome of the later Latin writers to the herb purſelain, as if it had its name from being loved by the hogs.

PORCELAIN *(Cycl.)*—The moſt juſt and regular idea we can form of the *porcelain* or china-ware is, that it is an half vitrified ſubſtance or manufacture, in a middle ſtate between the common baked earthen ware of our vulgar manufactures, and true glaſs. This is the eſſential and diſtinctive character of *porcelain*, and it is only by conſidering it in this light, that we are to hope to arrive at the perfect art of imitating it in Europe.

This attempt is to be made on theſe principles in two different manners: the one by finding ſome appropriated matter on which fire acts with more than ordinary ſtrength in the time of its paſſing from the common baked ſtate of earthen ware into that of glaſs. The other is, to compoſe a paſte of two ſubſtances reduced to powder; the one of which ſhall be of force to reſiſt a very violent fire, ſo as not to become vitrified in it; and the other a matter very eaſily vitrifiable. In the firſt caſe, the matter is to be taken out of the fire at the time when it is imperfectly vitrified; and in the other, the compound maſs is to remain in the furnace till the one ſubſtance, which is the more eaſily vitrifiable, is truly vitrified; and being then taken out, the whole will be what *porcelain* is, a ſubſtance in part vitrified, but not wholly ſo.

The firſt method is that by which the European *porcelain* has generally been made, and tho' that of St. Cloud, and ſome other places, has been very beautiful, yet it is always eaſy to diſtinguiſh even the fineſt of it from the china-ware, and the nature of the two ſubſtances appears evidently different: theſe owing all their beauty to their near approach to vitrification, are made to endure a long and violent fire, and are taken from it at a time when a very little longer continuance would have made them perfect glaſs; on the contrary, the china-ware being made of a paſte, part of which is made of a ſubſtance in itſelf ſcarce poſſible to be vitrified, bears the fire in a yet much more intenſe degree than ours, and is in no danger of running wholly into glaſs from it.

The two ſubſtances uſed by the Chineſe are well known by the names of *petunſe* and *kaolin*, and on examining theſe it appears very evident, that we have in Europe the very ſame ſubſtances, or at leaſt ſubſtances of the very ſame nature, and capable of being wrought into a *porcelain* equally beautiful and fine. Mem. Acad. Scienc. Par. 1739. See the articles KAOLIN and PETUNSE.

Theſe are the two different ſemi-vitrifications, on one or other of which all the European manufactures have hitherto been founded; and it is eaſy from the knowledge of theſe principles to determine, on breaking a piece of the china of any of our manufactures, by which of the two proceſſes it is made. If it is made by fiezing the half-vitrified maſs of a ſubſtance which would ſoon after have been wholly vitrified, then the putting it in a crucible, into an equal degree of fire, will ſoon turn it wholly into glaſs. This is the caſe of moſt of our European *porcelain*; but if it be made of two ingredients, the one of which is not vitrifiable, or at leaſt not by ſuch fires, then the matter will melt, but will not vitrify: this is the caſe with the Chineſe *porcelain*, which, if kept in fuſion a long time, yet when cold is china-ware ſtill; ſo that this is evidently made of two ſuch different ingredients.

Beſides theſe methods, there is yet another, of late invention, which makes a very beautiful china; and which, if it does not afford veſſels equal to thoſe of China, yet will afford them nearly approaching to thoſe, and at a conſiderable ſmaller price. This method conſiſts in reducing glaſs to china. See the article GLASS-*porcelain*.

The fine deep blue of the old *porcelain*-ware of China, is much valued by the curious; and it is much lamented, that the ſame colour is not uſed at this time. The art ſeems at preſent to be loſt; but perhaps it might be recovered by trials. It is certain that the Chineſe have cobalt among them, and very probably they uſed a blue colour prepared from this before they had any commerce with us: notwithſtanding all the con-

conjectures about their materials for colouring, this ſeems the moſt probable ſubſtance; and there is a way of preparing a colour from this, much ſuperior to that now in uſe, which we call ſmalt.

Cobalt is a mineral containing arſenic and a blue vitrifiable earth. The common way of preparing ſmalt is, by roaſting this cobalt in a reverberatory fire. This diſpoſes it to vitrify, and drives off the arſenic it contains in fumes, which collecting at the top, form true flowers of arſenic. It is very certain, however, from experiments, that if this arſenic could be preſerved in the cobalt, the ſmalt would be of a much finer colour; for there are ſome kinds of cobalt which yield ſmalt without previous roaſting; and as the arſenic is in a great meaſure contained in theſe, the ſmalts are much finer coloured. Arſenic added to ſmalt, while in fuſion, greatly exalts its colour alſo; and there is a way of procuring ſmalt from cobalt without fire, only by diſſolving it in an acid, and precipitating that ſolution with oil of tartar. The ſmalt thus precipitated to the bottom, is of a much finer colour than any prepared by fire; but it is much more expenſive, and prepared in leſs quantity. It is very poſſible, that the Chineſe might have the art of making this kind of ſmalt before they knew us, and that to this was owing the fine blue of their *porcelain* ware: but when we trafficked with them, and they purchaſed ſmalt ſo much cheaper of us than they could make it themſelves, they naturally diſcontinued the manufacture of their own finer kind, without conſidering how greatly inferior the colour was which the other yielded. If this be the caſe, it will be eaſy to revive this art, and the adding the true old china blue to our European manufactures, in imitation of *porcelain*, may give them a value which they have not at preſent.

The Chineſe had once a method of painting the figures of fiſhes and other things on the inſides of their veſſels, in ſuch a manner that they did not appear till the veſſel was filled with water, or ſome other clear liquor. They called this ſort of china-ware *kiatſim*, that is to ſay, the concealed blue china. The art is now in a great meaſure loſt; but there may be ſome gueſs made as to the manner in which it might be done at this time. The veſſels which are to be made in this manner, muſt be very thin: the colour muſt be laid on in form of the fiſh or other animals or figures, on the inſide, after the veſſel has been once baked. After this colour has had time to dry, the inſide of the veſſel muſt have a ſecond coat of the ſame earth, or ſtone-ware, of which the veſſel is made; and over this a varniſh of the common kind. The conſequence of this will be, that the figures of the fiſh, in a very ſtrong colour, will be buried between two coats of the ware, which together form a compleat veſſel. The outſide is then to be ground down almoſt to the figures, and when they begin to appear, a new coat of the varniſh muſt be laid over this. The figures will then be obſcure, and ſcarce, if at all perceivable; but on filling the veſſel with water, the tranſparence of the ſides will be taken off, and the liquor will make a ſort of foil behind, which will throw out the figures of the fiſh. This might be done in any ware tolerably clear and tranſparent. The *porcelain* of China would ſucceed beſt with it; but the pains and nicety required are too great, and all the attempts lately made by them have miſcarried. See the article STAINING of *porcelain*.

The Chineſe make a great variety of figures on the ſurfaces of the vaſes of white china-ware, and there is one kind of this greatly in eſteem among them, in which there are flowers and other figures; yet the ſurface is quite ſmooth, and the ſubſtance extremely thin. The manner of making it is this: they firſt form the veſſel of the fineſt materials, as thin as they can; then, when they have poliſhed it inſide and out at the wheel, they put into it a ſtamp of its own ſhape, but cut with all theſe figures: they preſs this down ſo firmly on the yet moiſt veſſel, that the impreſſion is received in a very perfect manner; and if the ſhape of the veſſel be at all hurt, they take it to the wheel again to reſtore it. They then finiſh it with the knife and ſciſſars; and when they have made it as perfect as can be, they cover it with the fine white varniſh within and without. This fills up all the cavities of the impreſſion, and gives a perfectly ſmooth and even ſurface; yet the thickneſs of this varniſh in the traces of the figures gives it a different white, and the whole figures are as finely and accurately ſeen, as if painted on the outſide. This is an artifice that might eaſily be brought to bear among us, and ſeveral of our finer wares would make a pretty figure with it.

There is a current opinion among the Chineſe themſelves, that the *porcelain*-ware of former times was greatly ſuperior to that which they make at preſent; and that the burying china in the earth for a long time, adds to its beauty; but all this is founded on error. The truth is, that our merchants beat down the price of the ware, and thereby compel them to make a worſe kind in general; but they are able to do as fine things now as ever. What gave birth to the opinion, that burying *porcelain*-ware made it good, was, that finer pieces than ordinary are ſometimes found buried. Theſe are all precious vaſes, which the poſſeſſors buried by way of ſecurity in the times of civil war; and it is no wonder, that there are none but of the fineſt kind found buried on theſe occaſions. Obſerv. ſur les Coutum. de l'Aſie.

PORCELLANA, in natural hiſtory, the *porcelain-ſhell*, or *concha venerea*, the name of a genus of ſhell-fiſh, the characters of which are theſe: they are of the univalve kind, and have for their mouth a long and narrow ſlit, dentated on each ſide, and are of a conglobated, oblong, gibboſe, or umbonated form.

This genus of ſhells originally had the name *porcellana* and *concha venerea* from the reſemblance of its mouth to the *pudendum muliebre*, called by ſome of the Roman writers, *porculus* and *porcellus*, and always alluded to under the word *Venus*. We have of late ſo far miſunderſtood the name as to ſuppoſe it derived of the word *porcelain*, from an imagination, that the Chineſe porcelain-ware was made of it. Geſner has fallen into the opinion, and Aldrovand ſeems to have been miſtaken in regard to its other name, *concha venerea*, ſuppoſing it ſo called becauſe of its beauty, and therefore ſacred to Venus. Rondeletius calls it the *remora Mutiani*; and the murex of the ſame author. *Aldrovand* de Teſt. L. 3. p. 352. *Geſner. Rondelet.* de Teſt. L. 2. p. 101.

The name *concha venerea* may be apt to create confuſion, becauſe there is another ſhell of a very different kind, a bivalve, called *concha veneris*. This genus is therefore much better diſtinguiſhed by the name *porcellana*. There is a prodigious difference among the ſpecies of this genus; ſome are heavy, others very light; ſome have the mouth placed in a longitudinal, others in a tranſverſe direction. The gibbous *porcelain* is a very remarkable ſpecies, as is alſo the egg-*porcelain*, which has two buttons at the extremities; and the egg-*porcelain* called the *navel* is not leſs remarkable than theſe; this has, inſtead of a button, a long beak at each end.

The mouth of the *porcelain* muſt be narrow and oblong; this is the great characteriſtic, and is uſually dentated either on both ſides or on one.

The ſpecies of *porcelain* are ſo numerous, that it may be proper, in the enumeration of them, to arrange them under ſome regular heads. See Tab. of Shells, N°. 16.

Some *porcelaines* are conglobated, and thick; of theſe the cabinets of the curious afford us the following ſpecies: 1. The map-*porcelain*, ſo called from its lineations, reſembling the ſtrokes of a map. 2. The lettered or Arabian *porcelain*: this is ſuppoſed in its lineations to bear ſome reſemblance to Arabic characters. 3. The tyger's ſkin *porcelain*. 4. The ſerpent's ſkin *porcelain*. 5. The ſea-louſe *porcelain*. 6. The millepede *porcelain*, 7. The punctuated *porcelain*. 8. The grey *porcelain*. 9. The Chineſe *porcelain*. 10. The *porcelain* whoſe end terminates in a ſpire; or the violet *porcelain*: this is but the former ſpecies with its outer coat taken off. 11. The reddiſh *porcelain*. 12. The variegated *porcelain*. 13. The tortoiſe-ſhell *porcelain*. 14. The guttated *porcelain*. 15. The *porcelain* with its middle divided into four zones. 16. The blue oval *porcelain*.

Some *porcelains* are thin, and of a pyriform figure. Of theſe we have the following: 1. The pear-*porcelain*, with an arched mouth, and variegated with yellow ſpots. 2. The pear-*porcelain*, with an arcuated mouth and two zones. 3. The egg-*porcelain*, with numbers of ſmall protuberances, or obtuſe umbos: this is called by ſome writers *ovum Rumphii*, or Rumphius's egg. 4. The cloth-web *porcelain*. 5. The oblong and thick *porcelain*. 6. The great Argus *porcelain*, ſo called from its being variegated with round ſpots, reſembling eyes. 7. The leſſer Argus *porcelain*. 8. The pſeudo-argus, or baſtard-eye *porcelain*. 9. The leveret *porcelain*. 10. The greeniſh ſmall-pox *porcelain*. 11. The whitiſh *porcelain*, with rough protuberances. 12. The millepede *porcelain*. 13. The mouſe *porcelain*. 14. The mole-*porcelain*. 15. The yellow *porcelain*, with four red zones. 16. The brown *porcelain*, with four yellow zones 17. The Panama *porcelain*, with amathyſtine circular ſtreaks. 18. The green ſpotted *porcelain*. 19. The virgated agate *porcelain*. 20. The blue *porcelain*. 21. The blue ſpotted *porcelain*.

Some of the *porcelains* are gibbous. Of theſe we have the following ſpecies: 1. The milky *porcelain*, with roſe-coloured protuberances and a dentated lip. 2. The white gibboſe *porcelain*, with a ſmooth lip and no tubercles. 3. The yellow *porcelain*, with a ſmooth lip and no tubercles. 4. The *porcelain* called *Congo money* and *Guinea money*: this has a dentated mouth, and has ſix protuberances on the back. 5. The great gibbous *porcelain*. Hiſt. Nat. Eclairc. p. 308.

PORCELLIONES, in the materia medica, a name given by ſome to the millepedes.

PORCELLO, in the glaſs trade, the inſtrument with which the workman, after having made the opening for the bowl of a drinking glaſs or other ſuch veſſel, with his paſſage, widens and renders it more capacious at pleaſure. *Neri*'s Art of Glaſs, p. 247.

PORCELLUS *Caſſovienſis*, in medicine, the name of a diſeaſe to which the people of Hungary and Poland are very ſubject. It is a hard tumour of the belly, attended with wind and violent pains. It is truly an infarction of the ſpleen, and is to be cured by aperitives. Phil. Tranſ. N°. 243. See SPLEEN.

PORCELLUS *Indicus*, in zoology, a name given by authors to the animal called with us the *Guinea pig*.

It is a creature properly of the rat kind, and is not improperly called by Mr. Ray *mus Americanus et Guinienſis porcelli pilis et voce*: the American or Guinea rat, with the hair and voice of a pig; tho' the ſame author ſeems to doubt, whether it has not ſomething of the rabbit kind in it, by adding after the word *mus*, that of *cuniculus*.

It is ſmaller than the rabbit, and has a ſhorter and thicker body; its ears are roundiſh, low, thin, pellucid, and very wide open, and are almoſt ſmooth; and are obſerved to be very nearly as large in the new brought forth creatures as in the full grown.

Its noſe and beard are very much like thoſe of the hare; the long hairs which ſerve for whiſkers being diſpoſed in much the ſame manner, and its upper lip is like that of the rabbit. It has no tail; its teeth are diſpoſed exactly as in the rat kind, and its hairs and grunting voice are wholly like thoſe of the pig.

It is ſometimes all over white, ſometimes all over of a reddiſh tawney; but moſt frequently it is mottled with large ſpots of both. Its fore feet have four claws, its hinder ones only three, of which the middle one is much longer than the others. It ſits often upon its buttocks, in the manner of the rabbit, but it does not walk in the leaping manner of the rabbit kind; but as the hog, by ſetting one foot before the other; and in walking bears upon the heel in the manner of the bear. It does not burrow in the earth; it brings forth ſix, ſeven, or eight young ones at a time; and theſe are not blind at firſt, as in the rabbit. It feeds on vegetables, and its fleſh is very well taſted, and much reſembles that of the hog. *Ray*'s Syn. Quad. p. 222.

PORCO, a name by which ſome authors have called the fiſh more uſually known by the name of *capriſcus*, ſuppoſed to be the *porcus* of Pliny. *Willughby*'s Hiſt. Piſc. p. 153. See the article CAPRISCUS.

PORCUPINE, *hiſtrix*, in zoology. See HISTRIX.

American PORCUPINE, *cuanda*, in zoology, the name of a ſpecies of *porcupine* very different from the European kind.

It is of the ſize of the larger monkeys, and is covered all over, except on its noſe, the lower part of its legs, and the extremity of its tail, with ſpines of two or three inches long, and has no other hair but theſe. Theſe are yellowiſh for that half which is next the body, thence they are of a deep blackiſh brown, and at the very extremity they are white: they are hollow in the manner of quills; and Hernandez affirms, that the creature has a power of throwing them from its body to a conſiderable diſtance. The body is about a foot long, the tail ſomewhat longer than that, and its farther half covered thinly with hairs much reſembling hog's briſtles. The ears are ſmall, and are hid by the ſpines which cover the head. It has two long teeth in each jaw before; the noſtrils are very wide, the eyes round, prominent, and very bright and ſparkling; the feet are like thoſe of the monkey kind, and divided into four toes. See Tab. of Quadrupeds, N°. 15.

It climbs trees, but ſlowly and with difficulty, for want of a heel or hinder toe. It uſually twiſts its tail about a bough, to keep it ſafe from falling. It makes a grunting like that of a hog. It feeds on poultry, and its fleſh is very well taſted. *Ray*'s Syn. Quad. p. 208.

PORCUS *aculeatus*, in zoology, the name of an animal, of which there are two ſpecies, both of the porcupine kind; the one with a ſhort, the other with a long tail. Each of them have alſo five toes on each foot, in which they differ from the European porcupines, which have but four. *Seba*. Vol. I. p. 81. and p. 84.

PORCUS *fluviatilis*, in ichthyology, a name given by the old Latin authors to the fiſh we at this time call the *cornua* and *aurata*, and in Engliſh the *ruffe*. It is a ſpecies of the perca or pearch kind, and is diſtinguiſhed by Artedi by the name of the *pearch* with only one fin on the back, and with the cavernous head. See Tab. of Fiſhes, N°. 20.

PORCUS *Guinienſis*, in zoology, the name of the Guinea hog.

This creature is of the ſame ſhape and make with our hog, and of a reddiſh tawney colour. Its head, however, is ſomewhat more depreſſed than in our kind, and its ears longer, and running into narrow points. Its tail is naked; but ſo long, that it reaches almoſt to its heels. Its hair is all ſhort and ſhining. It has no briſtles on the back, but only near the rump; and on the ſhoulders the hair is a little longer than elſewhere. It is a tame domeſtic creature. *Ray*'s Syn. Quad. p. 96.

PORELLA, in botany, the name of a genus of moſſes, the characters of which are theſe: the capſules contain a powder like thoſe of the other moſſes; and they have neither operculum, calyptra, nor pedicle; and their manner of ſhedding their powder is not by ſeparating into two parts, like thoſe of the ſelago and lycopodium, but by opening into ſeveral holes on all ſides. See Tab. of Moſſes, N°. 17.

Of this genus of moſſes there is only one known ſpecies; this is called by Dillenius the bluntly pinnated *porella*, and grows in wet places in Virginia, Penſilvania, Maryland, and other parts of North America. *Dillen*. Hiſt. Muſc. p. 459.

PORFILIGON, a word uſed by ſome of the chemical writers to expreſs the ſquammæ martis, or the ſcales of iron which fly off in the ſmith's hammering of it.

POROCELE, a word uſed by chirurgical writers for a callous hernia.

POROMPHALON, a word uſed by Hippocrates to expreſs a callous concretion, or a ſort of tophus formed in the region of the navel.

POROTICKS, a term uſed by the antients for ſuch medicines as would conſume calluſes.

PORPESSE, an Engliſh name given indiſcriminately to two different fiſhes, the phocæna and the dolphin.

Artedi, who has been very careful in bringing together the ſynonyma of authors, tells us, that this is properly the Engliſh name only of that ſpecies of the dolphin, the characters of which, according to his ſyſtem, is, that the body is almoſt of a conic form, the back broad, and the body ſubacute. This ſpecies is the phocæna of Ariſtotle, and the tirſio or turſio of Pliny and Rondeletius. Schoneveldt calls it the ſmall northern or oriental *dolphin*, and the Swedes the *marſuin*. See the article DELPHINUS.

We have from Dr. Liſter an account of the tooth of this creature, after death, giving an envenomed wound. The accident happened to the Doctor himſelf, and he relates it thus: in diſſecting a *porpeſſe*, which had been four days dead, he ſcratched accidentally the inſide of one of his fingers; but that not ſo deep as to fetch blood, or to occaſion any great pain. He diſregarded the accident; but at the end of four days the whole joint of the finger became tumid, and inflamed ſoon after the whole finger. After this the malady increaſed, and in ſpite of the aſſiſtance of ſurgeons, the four next fingers were in four days more affected; and after theſe the whole hand up to the wriſt, and the pain became violent. This was firſt abated by the following fomentations: frog ſpawn-water, ſix ounces; bole armeniac, an ounce and half; white vitriol, four ounces. And afterwards this: burnt white vitriol and bole armeniac, of each four ounces; camphor, an ounce; and common water, a gallon. The waſhing the hand continually with theſe, took off the pain; and after this the unguentum nutritum, and a plaiſter of diaphalma over the whole hand, perfected the cure. The Doctor obſerves, that beſide the blue look of the parts, which ſufficiently indicated the poiſon, there was a continual itching and burning heat, which was conſtant day and night. The ſkin of the whole hand and fingers came off, and the fingers did not ſo far recover, as to have their full uſe for ſeveral months after. Phil. Tranſ. N°. 231.

The fins of this fiſh are cartilaginous and flexible, not ſharp or prickly, as the antients have repreſented them. There is only one fin on the back, which is placed ſomewhat below the middle: on the belly there is only one pair of fins; and the tail is formed into the figure of a creſcent by its forkedneſs; and this tail lies parallel to the horrizon, when the fiſh ſwims, in the ſame manner that the tails of all the other cetaceous fiſhes do; whereas the tails of all other fiſh ſtand perpendicular to the horizon. The great contrivance of nature in this poſition of the tail in theſe fiſhes is, that it may ſupply the place of the hinder pair of belly-fins in other fiſh, thoſe of the cetaceous kind having none ſuch. Theſe fins in other fiſh ſerve to balance the body, and keep it under water, and anſwers alſo in many reſpects to the hinder legs of a quadruped; and hence we ſee, that thoſe fiſh which have long bodies, and have not this hinder pair of fins, nor the horizontal tail, cannot ſuſpend themſelves quietly in the water, but are forced to keep groveling at the bottom. This is the caſe of eels, and all other fiſh of that kind. The uſe of reſpiration being as neceſſary to the *porpeſſe* as to quadrupeds, and it wanting this pair of hinder fins, to poize or elevate itſelf with, nature has abundantly provided againſt the miſchiefs that would attend that defect, by giving it this tranſverſe tail; by a ſudden jerk of which it can in a moment throw itſelf up to the ſurface from the deep water. The whale, and all the cetaceous fiſhes requiring the uſe of reſpiration, have alſo this manner of raiſing their unweildy bodies allotted them by nature, inſtead of the hinder pair of fins, which muſt have been inconveniently large to be capable of this office.

The blood of the *porpeſſe* is as warm to the touch as that of quadrupeds, and the blubber, or fat, which lies in great quantity under the ſkin, covering the muſcular fleſh of the back and ſides, is to keep up the natural heat, and prevent the cold of the ſea water from chilling the circulating fluid.

The ſtomach of this fiſh is of a very ſtrange make; it is divided into two large bags, and has ſeveral other ſmaller ones annexed to them. The food of the fiſh ſeems to beſpeak its living at the bottom of the water; for the common matter found in its ſtomach, is the remains of fiſh that live in or on the bottom. The young *porpeſſes* are generally found to feed on the ammodytæ, or ſand-eels.

The kidneys in this fiſh are large, and adhere cloſely to the back; and the urinary bladder is oblong, but very ſmall in proportion to the ſize of the animal. The penis in the male is long and ſlender, and has a very ſlender and ſharp glans. This part does not appear externally; but lies buried in its ſheath in the body, and is there doubled up in the ſhape of the letter S; and the teſticles lie within the cavity of the abdomen, as they do in the hedge-hog. The diaphragm is muſcular, as in quadrupeds. The heart is large, included in a pericardium,

ricardium, and has two ventricles; and this part, as well as the lungs, agree in all reſpects with thoſe of quadrupeds. The fiſh having no neck, the larynx is conſequently very ſhort. The pipe in the head, thro' which theſe ſort of fiſhes draw in their breath, and ſpout out water, lies before the brain; it terminates outwardly in one hole, but it is within divided into two parts by a bony ſeptum, ſo as to repreſent two noſtrils; but at its lower end it again becomes one hole, and opens into the mouth by a common orifice furniſhed with a very ſtrong ſphincter muſcle, by means of which it may be ſhut and opened at pleaſure. Above this ſphincter, the ſides of the pipe are lined with a glandulous fleſh; from which when preſſed, a glutinous liquor is forced out of certain little holes in it into the inſide of the pipe: above the noſtrils is a ſtrong valve or membrane, which ſerves to ſtop the pipe at pleaſure, and prevent any water from getting into it, but when the fiſh requires it within. The fiſtula are ſix blind holes, having no outlet, four tending toward the ſnout, and two placed above the valve, which ſtops the noſtrils, and two beneath it; and two tending toward the brain, having a long and narrow cavity which ſeems intended for the uſe of ſmelling, tho', on opening the brain, no ſuch olfactory nerves or proceſſus mamillaris, as other animals are furniſhed with for this purpoſe, are to be found. The eyes are ſmall, and the ſnout is very long, and furniſhed with ſtrong muſcles; the uſe of theſe is to enable it to root up the ſand and dirt at the bottom of the ſea, and feed on the ſand-eels and other creatures it finds buried in it. The brain is large, and reſembles that of man, and probably it has been an obſervation of this that has given occaſion to the opinion of this animal having ſo great a ſhare of will and underſtanding, and has given riſe to the ſtory of Herodotus, that Arion was carried to ſhore on the back of one; and that of Pliny the elder, of one of theſe fiſh ſo fond of a certain boy, that he uſed to carry him daily from Baiæ to Puteoli, acroſs the ſea to ſchool, and wait to carry him back again at a certain time. Pliny the younger gives us alſo a ſtory of this kind in his epiſtles.

The teeth of the *porpeſs* are in each jaw forty-eight in number; they are ſhort and blunt, and reſemble ſo many pegs. The antients, particularly Ariſtotle, have ſaid that the tongue of the *porpeſs* or dolphin is tied down faſt to the lower jaw, all along the middle. Rondeletius has diſputed and contradicted this obſervation; but Mr. Ray proves it to be true, and that the modern author is in an error. Ariſtotle denies this fiſh ear-holes, and experience ſhews that he is in the right; nor has it any noſtrils, except thoſe within the fiſtula. The breaſt bone is remarkably ſmall. The name *porpeſs* is given it becauſe of its reſembling a hog; which it does in the ſnout, the fat, the viſcera, and many other particulars. Phil. Tranſ. N° 74.

PORPHYRIO, in zoology, the name of a bird figured and deſcribed by all the natural hiſtorians from one another, but which, it ſeems, none of them ever ſaw; and there is ſome room to doubt whether there be in nature any ſuch bird. According to the accounts we have of it, it appears to be of the gallinula or moor-hen kind, and is all over of a fine deep blue, only the middle of the tail is at the extremity of a greyiſh white. Its legs and feet are of a fine ſhining purple. There have been ſome fabulous things related of it, as its having five toes on each foot, and the like; but if there be any ſuch creature, it ſeems to be a moor-hen of theſe remarkable colours. *Geſner* de Avib. *Ray*'s Ornithol. p. 238.

PORPHYRIO *Americanus*, in zoology, a name by which ſome have called the *quachilto*, a very beautiful ſpecies of Braſilian moor-hen. See the article QUACHILTO.

PORPHYRY, *(Ccyl.) porphyrita*, in natural hiſtory, the name of a genus of foſſils generally, but improperly, added to the marbles, and called by us *porphyry*. They are ſtones of a plain uniform maſs, ſpotted or veined, with ſeparate concretions of great hardneſs, giving fire with ſteel, not fermenting with acids, and very ſlowly and difficultly calcining in a ſtrong fire. *Hill*'s Hiſt. of Foſſ. p. 494.

Of this genus there are only three known ſpecies: 1. The purple kind, commonly known by the name of *porphyry*, among the workmen. 2. The hard red-lead-coloured kind, variegated with black, white, and green. And 3. The very hard fleſh-coloured one, variegated with white, green, and black.

The *purple porphyry* is a ſubſtance which has been well known, and highly eſteemed in all ages of the world. It has its name from the Greek πορφύρος, purple, as that remarkable colour always afforded a very obvious diſtinction for it, from the other kinds. It is of an extreme firm and compact ſtructure, remarkably heavy, and of a fine ſtrong purple, variegated more or leſs with pale red, and white, and with a ſmall number of little, and generally diſregarded black flaky ſpecks. Its purple is of all degrees, from the deep tinge of the violet to a pure claret colour; and its variegations are uſually diſpoſed in ſmall ſpots, uſually ſmall and diſunited, but ſometimes running into one another, and making large blotches. It is very difficultly cut, becauſe of its very great hardneſs; but is capable of a very fine poliſh. It is found in great quantities in Egypt; and we find was had thence alſo in very early times. It ſerves us for ſtones for the apothecaries and colourmen, to grind or levigate their powders on, and on any other occaſion where great hardneſs is required.

The *red-coloured porphyry* is alſo an extremely beautiful and valuable ſubſtance, but is hitherto unknown among our lapidaries. It has the hardneſs, and all the other characters of the purple *phorphiry*, and greatly exceeds it in the variety of its colours. Its ground is exactly of the bright fine red of our minium or red lead, but is ſomewhat deeper or paler in the different parts of the maſs: this is beautifully veined with green, in broad and regular lines; there are alſo ſome conſiderably narrow, and among theſe ſeveral perfectly white ſtreaks, and a multitude of ſmall black ſpecks. It is of extreme hardneſs, and capable of a poliſh equal to that of the ſemi-pellucid gems. It is found in great plenty in the iſland of Minorca, but has never yet been regarded as a ſtone worth importing into England.

The *fleſh-coloured porphyry*. This is another very little known, but extremely beautiful ſtone: it is of an irregular, but very compact and firm texture, and of a pale fleſh colour, often approaching to white, and variegated with black, green, and white in large blotches, from half an inch to an inch broad; and ſometimes, tho' very ſeldom, diſpoſed in regular veins. It appears very livid and gloſſy where freſh broken, and is capable of an extremely elegant poliſh; and is ſo very tranſparent, eſpecially in its green parts, that when poliſhed one may ſee deep into its ſubſtance. It is found in immenſe ſtrata, in Arabia Petræa, and in upper Egypt, and in detached nodules is common to almoſt all parts of the world: Germany abounds with them; and we have of them in many parts of England and Ireland. They are found in many places on our ſhores, and in ſome parts of Devonſhire far from the ſea. *Hill*'s Hiſt. of Foſſ. p. 494 to 498.

Mr. Boyle tells us, that he cauſed *porphyry* to be cut by means of emery, ſteel ſaws, and water. He obſerves, that in his time, the workmen in England were ignorant of the manner of working upon *porphyry*, and that none of them would undertake to cut or poliſh it. See Works abr. Vol. I. p. 111.

PORPHYRY-*ſhell*, in natural hiſtory, a name given by authors to a ſpecies of ſea-ſhell of the *purpura* kind, with a ſhort clavicle and beak. See PURPURA.

PORPITES, the *hair button-ſtone*, in natural hiſtory, a name given by authors to a ſmall ſpecies of foſſile coral; which is uſually of a rounded figure conſiderably flatted, and ſtriated from the center every way to the circumference. Theſe are of different ſizes, and of different colours, as greyiſh, whitiſh, browniſh, or bluiſh, and are uſually found immerſed in ſtone. See Tab. of Foſſ. Claſs 7. and *Hill*'s Hiſt. of Foſſ. p. 641.

PORRUM, the *leek*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the lilliaceous kind, being compoſed of ſix petals, and of a bell-like ſhape. The piſtil which ſtands in the middle of this flower, finally becomes a roundiſh fruit divided into three cells, and containing roundiſh ſeeds. To this it may be added, that the ſtamina are broad, and are terminated by three filaments, the middle one having an apex. The flowers alſo are uſually collected into round heads, and the roots are long, cylindric, and tunicated, the ſeveral cruſts often running up into flat or hollowed leaves.

The ſpecies of *leek*, enumerated by Mr. Tournefort, are theſe: 1. The common headed *leek*. 2. The *leek* with variegated leaves, elegantly ſtreaked like thoſe of the painted graſs. 3. The broad-leaved ſectile *leek*. 4. The wild vineyard *leek*. 5. The double-headed wild *leek*. And 6. The vitigineous wild *leek* of Gerrard. *Tourn.* Inſt. p. 382.

PORT *(Cycl.)*—PORT-*laſt*, in a ſhip, the ſame as the gunwale; therefore they ſay a yard is down a *port-laſt*, when it lies down on the deck.

PORT-*ropes*, in a ſhip. See ROPES.

PORTABLE *laboratory*. See LABORATORY.

PORTE-*etrier*, in the manege. See STIRRUP.

PORTEGLO, in the glaſs trade, the inſtrument with which the founder, or conciator, ſcums the glaſs while melting. *Neri*'s Art of Glaſs, p. 241.

PORTER *(Cycl.)*—PORTER, in the manege, ſignifies to direct or puſh on a horſe at pleaſure; whether forewards or upon turns, *&c.*

PORTERAGE, a kind of duty paid at the *cuſtom-houſe*, to thoſe who attend the water ſide, and belong to the package-office. Theſe *porters* have tables ſet up, aſcertaining their dues for landing of ſtranger's goods, and for ſhipping out the ſame. Merch. Dict.

PORTISCULUS, among the Romans, an officer who had the direction of the rowers in a galley. He was otherwiſe called *pauſarius* and *hortator remigum*. *Pitiſc.* Lex. Ant. in voc. See PAUSARIUS and HORTATOR.

PORTIUS *piſcis*, in zoology, a name given by ſome to a fiſh called by others the *mugil ater*, or black mullet. It is a very ſcarce fiſh, much reſembling the common mullet in ſhape, but all over of a fine black, and having ſeveral lines of a deeper black than the reſt, running longitudinally from the gills to the tail. It has a very wide mouth, and has ſeven or eight prickles on the back, ſeparate from one another, and joined into a fin by a membrane in the uſual way; theſe are placed immediately before the back fin. *Willughby*'s Hiſt. Piſc. p. 276.

PORTOISE, aboard a ſhip, is the ſame with *port-laſt*, or the *gun-wale*; and as they ſay *the yard is down a port-laſt*, when it lies down on the deck, ſo for a ſhip *to ride a portoiſe*, is to ride with her *yard a port-laſt*, or ſtruck down to the deck.

PORTORARIUM, in anatomy, a name given by ſome authors to the duodenum.

PORTULACA, *purſelain*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is roſaceous, or compoſed of ſeveral leaves diſpoſed in a circular form. The cup conſiſts of one leaf, and is bifid; from this ariſes the piſtil, which afterwards becomes, together with the cup, a fruit or ſeed-veſſel of an oval form, and uſually containing very ſmall ſeeds: this ſeed-veſſel has two ſhelly ſubſtances at its top, the outer of which has been the bifid part of the cup; the inner is no other than the piſtil enlarged; theſe ſeparate tranſverſely when the ſeed is ripened, the lower part of the cup ſtill remaining fixed to the ſtalk.

The ſpecies of *purſelain*, enumerated by Mr. Tournefort, are theſe: 1. The broad-leaved, or garden *purſelain*. 2. The narrow-leaved, or wild *purſelain*. 3. The broad-leaved garden *purſelain*, with gold yellow leaves. 4. The broad-leaved ſea-*purſelain*, with beautiful red flowers. 5. The red-flowered procumbent *purſelain* of Curaſſo, with long, thick, and ſhining leaves. 6. The procumbent *purſelain* of Curaſſo, with leaves like thoſe of the caper's buſh and red moſſy flowers. 7. The taller upright woolly *purſelain* of Curaſſo, with leaves like thoſe of kali, and pale red flowers. 8. The woolly procumbent *purſelain* of Curaſſo, with beautiful red flowers, and ſeed-veſſels ſomewhat pointed at the ends. 9. The woolly, procumbent, kali-leaved Curaſſo *purſelain*, with ſeed-veſſels hollowed at the ends.

The ſeveral ſpecies of *purſelain*, may be known when not in flower, by their having thick and fleſhy leaves placed alternately on their ſtalks. *Tourn.* Inſt. p. 236.

PORTUGALLICA *terra*, *earth of Portugal*, in the materia medica, the name of a fine aſtringent bole, dug in great plenty in the northern parts of Portugal, and eſteemed a remedy againſt poiſons and venomous bites, and good in malignant fevers. Whatever may be its virtues of this kind, however, it is manifeſtly an aſtringent of the very firſt claſs, and is uſed with great ſucceſs in fluxes of all kinds. It is well known in ſome parts of the world, beſide the kingdom where it is produced; but is not known in the Engliſh ſhops. The cheapneſs of our ſophiſticated bole armenic, having excluded this whole valuable claſs of medicines from our practice.

The characters by which the *Portugueſe earth* is known from the other red boles, are theſe: It is of a cloſe, compact, and regular texture, conſiderably heavy, and of a fine florid red, of a ſmooth and ſhining ſurface, eaſily breaking between the fingers and a little ſtaining the hands. It adheres firmly to the tongue, melts freely and readily in the mouth, and has a ſtrongly aſtringent taſte, but leaves a little grittyneſs between the teeth. It does not ferment with acids, and ſuffers ſcarce any change of colour in the fire. *Hill*'s Hiſt. of Foſſ. p. 13.

PORTUMNALIA, among the Romans, a feſtival in honour of Portumnus, which was celebrated on the ſeventeenth of Auguſt. *Pitiſc.* in voc.

PORUS, (*Cycl.*) in natural hiſtory, a name given by authors to a peculiar kind of foſſile coral, of which there are many different ſpecies; theſe are all of a beautifully laminated ſtructure, and ſeem allied to the mycetitæ or fungitæ: they are ſeldom found looſe, but uſually bedded in hard marble, and with their pores filled up with ſparry or mineral matter. See Tab. of Foſſ. Claſs 7.

PORUS *cervinus*, in natural hiſtory, a name given by authors to a ſpecies of ſea-plant, found among the rocks in the coral fiſheries, and in other places. It grows at different depths, and ſeems to adhere to the rocks by a ſimple baſe, having no root, nor any thing in the place of one. It is branched in ſuch a manner, that with the help of a little imagination it has been forced into the reſemblance of a ſtag's horn. Its height is about an inch and half, often leſs when newly taken out of the ſea; it is of a fine ſnow white colour, but when it has lain ſome time to dry, it becomes of a duſky yellow. It is very thin, perfectly tranſparent, and ſeems compoſed of ſeveral fine membranes. When examined by the microſcope, an admirable ſtructure is diſcovered in it: the whole being compoſed of a membranous matter, in which are an infinite number of holes, and all theſe arranged into regular lines.

Count Marſigli has diſtinguiſhed this, which is the common kind of *porus cervinus*, or buckſhorn *porus*, by the name of *minor*, in order to prevent its being confounded with another leſs common kind, which Ferrante Imperato has deſcribed under the name of *porus cervinus*.

This larger kind is found alſo growing on the rocks in the coral fiſheries; but it always is found at great depths, never near the ſurface, as the other often is. It grows to the rock by a ſmall baſe, and from thence riſes to a ſhort trunk, which ſpreads itſelf out into ſeveral flat branches, divided every where into two, as thoſe of moſt of the ſea-fucuſes are; and theſe are ſo expanded as to form what people imagine, a reſemblance of a ſtag's horn. This grows to a little more than two inches in height, and is of a beautiful pale yellow, or ſtraw colour, even while growing, and looks gloſſy and ſhining, as if covered with a thin coat of varniſh. It is as thin as the fineſt paper; and when viewed by the microſcope, is found to be of a particular texture. It is ſometimes found growing to the ſhells of ſea-fiſhes; but of thoſe only which live in great depths of water. Count Marſigli has given elegant figures both of this and the ſmaller kind, not only in their natural ſtate, but as they appear to the microſcope. *Marſigli*, Hiſt. de la Mer.

POSCENIUM, or POSTSCENIUM, among the Romans, the back part of the theatre, where the actors retired to undreſs themſelves. *Danet.* in voc.

POSCENIUM was ſometimes uſed to ſignify a lady's dreſſing-room, where the paint and waſhes were kept and uſed, and where men were not allowed admittance. *Pitiſc.* in voc. See the article PARASCENIUM, *Cycl.*

POSIDIA, Ποσειδια, in antiquity, a feſtival in honour of Neptune, called Ποσειδων. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 426.

POSIDIUM, Ποσειδεων, in chronology, the ſeventh month of the Athenian year. It conſiſted of thirty days, and anſwered to the latter part of our December and the beginning of January. See MONTH.

It had this name from the feſtival Poſidonia celebrated in it.

POSIDONIA, Ποσειδονια, in antiquity, the ſame with *poſidia*. See POSIDIA.

POSIQUIT, in natural hiſtory, a name given by the people of the Philippine iſlands to a ſmall bird very common among them, and approaching to the nature of the canary bird, but ſmaller, and wanting its harmonious voice.

POSITI, among the Romans, an appellation given to the dead when placed at the door with their feet outwards, till the time of their interment. See BURIAL and BURYING. *Hofm.* Lex. in voc.

POSITION, *poſitio*, in muſic, is uſed for the putting down the hand in beating time. See THESIS.

POSITIONAL *libel*. See ARTICULATED *libel*.

POSSESSIO *fratris*, in law, is where a man hath a ſon and a daughter by one woman or *venter*, and a ſon by another *venter*, and dies, if the firſt ſon enters and dies without iſſue, the daughter ſhall have the land as heir to her brother, although the ſecond ſon by the ſecond *venter* is heir to the father: but if the eldeſt ſon dies without iſſue, not having made an actual entry and ſeiſin, the younger brother by the ſecond wife, as heir to the father, ſhall enjoy the eſtate, and not the ſiſter. 1 Inſt. 11, 15. Terms of Law.

POSSESSION *(Cycl.)*—POSSESSION, in mining, is the right to a meer of ground, which the miners enjoy, by having ſtones upon that ground; and it is taken generally for the ſtones themſelves; for it is the ſtones that give *poſſeſſion*. *Houghton*'s Compl. Miner in the Explan. of the Terms.

POSSUM, a name by which many have called the *opoſſum*. See the article OPOSSUM.

POSTERIOR *(Cycl.)*—POSTERIOR *penis*, in anatomy, a name given by many authors to a muſcle more generally known at this time by the name of the *erector*. See ERECTOR.

POSTICUM, in architecture, the poſtern gate or back door of any fabric.

POSTOMIS, among the antients, a barnacle or iron inſtrument fixed on the noſe, or put into the mouth of a horſe to make him quiet. *Pitiſc.* in voc.

POSTURE *(Cycl.)*—POSTURES *of the body*. The continued unnatural *poſtures* of the body, are the occaſions of many very unhappy effects in the human frame; crookedneſs in ſhape, is very frequently the conſequence of them. See DISTORTION. And it is no uncommon thing to ſee ſchool-boys, who are forced to be continually bending to write upon their knee, or upon a low form, very terribly afflicted by means of the compreſſion which that unnatural and continued *poſture* has given the lower part of the breaſt and the viſcera contained in the epigaſtrium; and particularly thoſe unhappy youths, who, from being ſhort-ſighted, are expoſed to a greater degree of ſtooping than the reſt, have been found terribly afflicted with diſorders of the breaſt and of the lower belly.

On applying for relief in theſe complaints, the phyſician uſually forgets to enquire into the cauſe, and hearing nothing of the continued bending *poſture* of the body, which is the occaſion of all the diſorders, the medicines he gives prove ineffectual with ſome, and with others greatly heighten the diſorder. But when the preſcriber will be at the pains of informing himſelf of the cauſe in theſe caſes, and forbid the continuance of the *poſture* which has been the ſole occaſion of them; nature alone will often make the cure, or if not alone, yet very often with this caution the methods will prove ſucceſsful, which were ineffectual, or even hurtful without it.

Other ſchool-boys have been found ſubject to ſeveral diſorders of the head, the breaſt and eyes, and to many other complaints from which the uſual methods in the like caſes have been found wholly ineffectual to relieve them; or if they have been cured from time to time, they have been always found ſubject to relapſes: and in many of the ſchools of France, no remedy could be found for theſe complaints, till Mr. Winſlow found, on enquiry, that it was a common cuſtom among theſe youths to ſleep all night with their heads thrown back,

and lying over the bolſter; and the giving orders, that they ſhould be watched, and not ſuffered to ſleep in that manner for the future, proved with moſt of them ſufficient for the cure, without any further aſſiſtance, and that in many caſes, even in maladies which had been of ſo long ſtanding as to become in a manner habitual.

How frequently does it happen, that the not regarding things of this kind, which has been the cauſe of diſeaſes, occaſions the moſt unhappy events in the courſe of their cure? nay, ſometimes irrecoverable misfortunes happen, without the phyſicians being able to gueſs why; and this ſometimes after a ſeemingly perfect cure. A very remarkable inſtance of a thing of this kind Mr. Winſlow gives, in the caſe of a woman to whom he was called to examine the cure of a fracture of the thigh. The perſon was lame after the cure, notwithſtanding that there were all the common proofs of the fracture's having been perfectly well reduced, and that the bone had united in its proper ſhape and dimenſions, and no way differed from that of the other thigh. He cauſed the perſon to be laid flat down, and when ſhe was in that poſition, placing the knees, legs, and feet perfectly even, the thigh which had been ſet appeared perfectly like the other; but obſerving, that in a moment afterwards, the leg on the fractured ſide thruſt itſelf up, as if of its own accord, out of the level of the other, and appearing then ſhorter than the other, he examined the hips; and perceiving that they were perfectly even while the leg was thus a little elevated, he again depreſſed it to the level of the other, and then the hips became uneven and oblique. It appeared very plain from this, that the thigh-bone had loſt ſomewhat of its original length from the irregular coaleſcence of the fracture; and that the ſurgeon who had ſet it, for want of examining the attitude of the hips at the ſame time with that of the thighs, had deceived himſelf, by truſting the common method of examination, into a belief that the thigh was of the proper length: what adds greatly to the occaſion of error in the common way of examining theſe reduced fractures, by comparing the length of the two legs is, that the patient, dreading pain, always gives into the deceit, and naturally depreſſes the hip, without conſidering why, till the leg, tho' really much ſhorter, appears of the ſame length with the other. Mem de l'Acad. Scienc. Par. 1740.

POT *(Cycl.)*—Pot, in our old writers, a head-piece of war. It is mentioned ſtat. 13 Car. II. c. 6. *Blount.*

Glaſs-Pots. See Glass-*pots.*

Pot-*aſh* *(Cycl.)*—The art of reducing vegetables to this ſtate is a very valuable one; the ſoap-maker, fuller, ſcowerer, dyer, and glaſs-man, as well as the chemiſt and apothecary, depending greatly on it in many particulars.

The authors who are farther to be conſulted in this caſe, are Glauber, in his proſperity of Germany; but the chemical foundation of the whole appears in Boerhaave's chemiſtry, and the papers of Stahl on this ſubject.

This ſalt has been made in New England in conſiderable quantities from rotten wood. What gave the occaſion of knowing it, was, that a white oak in that province decayed, and a third part of its ſubſtance became rotten. This rotten part was tried to burn, and was found to turn almoſt wholly into a fine alkali ſalt, or pot-aſh, much ſtronger than that which is made in the uſual way. What was moſt obſervable in the making of this ſalt was, that while the wood was burning, it would melt of itſelf, and run down into hard lumps of ſalt; and this, none of the wood of the ſame tree, which was ſound, would do, but only the rotten part: and what was moſt rotten of all, yielded the greateſt quantity of ſalt, and that the moſt readily; whereas all the common alkali ſalts of wood, made by incineration, are blackiſh at firſt; and a lixivium made of them, altho' often filtered, will ſtill be of a brown colour, occaſioned by ſome of the charcoal of the wood ſo cloſely united to the ſalt as not to be eaſily ſeparated from it. This alkali made from rotten wood was very white, even before ſolution; and the lixivium made with it was not at all tinged with brown, but clear like pure water, only a very ſmall quantity of aſhes ſubſided to the bottom. The lixivium was eaſily decanted from this, without the trouble of filtration; and when evaporated to a drineſs, left the ſalt perfectly fine and pure. In the making this ſalt, as the fire grows more intenſe, the wood is ſeen to run together into great lumps, and bubble with a hiſſing noiſe.

The weight of the *pot-aſh* prepared in the common way is very inconſiderable, in proportion to the wood uſed; but in this, the ſalt nearly equals the whole weight of the wood. In the common way of making the *pot-aſh*, the ſalt is never diſtinguiſhed by the eye among the aſhes, nor even cauſes them to run into lumps; but in this caſe the ſalt always runs into large lumps, and is as eaſily diſtinguiſhed from the reſt of the aſhes, tho' white, as ſalt of tartar of the pureſt kind would be.

It is very certain, that rotten wood in many places has been found, on trial, to yield much leſs ſalt than ſound wood; but the ſound wood of this tree being tried, was found to yield no more ſalt than other wood, and conſequently much leſs than the rotten part of it. On examining this tree on the ſpot, it was thought by good judges, that it had been at ſome diſtance of time ſtruck with lightening, it being evidently torn from the top to the bottom: on that ſide where the decayed part ſeparated from the ſound, there had been a channel of about five inches wide all the way down; but this was cloſed over by ſucceeding bark, and ſhewed no trace of the accident till on examining underneath, where the tree was found black for ſuch a ſpace, and the bark not of a piece with the reſt.

From this it may be conjectured, that the wood having been for ſo long a time, as till the growth of this bark, expoſed to the wind and weather, naturally became rotten from the wet it received; and that the lightening having penetrated the wood, had ſo altered and diſpoſed the parts and pores of it, that they attracted and retained the nitrous ſalts of the air in great abundance, even as ſalt of tartar, and other the like ſalts, do; which, as Glauber obſerves, will be reduced, in continuance of time, to an abſolutely nitrous ſalt, and the quantity alſo conſiderably increaſed.

The parts of this rotten wood were of a very different ſtructure from thoſe of ordinary wood in this condition; and tho' the lightening had not calcined it into a ſalt, yet it had, as appears, ſufficiently altered it to give that tendency to imbibe, and a power to retain the nitrous particles from the air, as well as the alkalies of vegetables perfectly calcined will do. If it ſhould be objected, that nitre alone will not calcine into an alkali, it is eaſily anſwered, that nitre with charcoal will; and the remaining wood might very well ſerve as charcoal in this proceſs. Phil. Tranſ. N°. 366. p. 121.

Some ſort of *pot aſhes* have been found to contain a large quantity of ſea-ſalt, which is probably mixed with them by the makers; not only as it is much cheaper, but as it makes them whiter, and more eaſily run into large maſſes. Med. Eſſ. Edinb. abr. Vol. I. p. 165. Not.

The French have two kinds of *pot-aſh*, the produce of their own manufactures; the method of making which M. du Fay, of the academy at Paris, deſcribes in the following manner.

The firſt which is the common or coarſer kind, is made of the beech or elm; the firſt of which trees they always find to yield the largeſt quantity.

They cut down the largeſt and moſt full grown trees, and cutting them into pieces of ten or twelve foot long, they lay them together in form of a pile, and burn them to aſhes in the open air. They gather up the aſhes, and make a very ſtrong lixivium of them in water; into this liquor they throw pieces of old rotten and ſpungy wood, which is, from its texture, capable of imbibing a great quantity of humidity: they uſe ſo many of theſe pieces as are ſufficient to ſoak up the whole quantity of their lixivium. When this is done, they dig a ſquare pit in the earth; over this they lay ſome iron bars, to ſuſtain a quantity of dry wood, to ſerve as fuel. When they have laid together a ſufficient quantity of this, they pile upon it the rotten billets which have imbibed the lixivium; and when the dry wood underneath is ſet on fire, and heats the top of the pile, the lixivium loſes its water by the heat, and the ſalt contained in it is ſeen running down through the fire, in form of a ſhower: this is received in the pit made on purpoſe for it. When all is melted out of the billets at firſt laid on, they bring others, which the fire acts upon in the ſame manner; and ſo on, till the whole pit is filled with *pot-aſh*.

When this is done, they remove the fire as quickly as they can; and with rakes clear the ſurface of the *pot aſh* as well as they can from pieces of charcoal and aſhes which have fallen into it: but with all their care, they are not able to prevent a great deal, both of coals and aſhes, remaining in it; as is eaſy to conceive from the manner of the proceſs. The ſalt after this forms one ſolid cake or maſs, and this they dig up out of the pit while it is yet hot; and barrel it up for fear of its receiving damage from the humidity of the air, which it is very ready to imbibe. This is the French *pot-aſh* of the common or coarſe kind.

The finer or purer kind is made of the ſame wood with the other, and the proceſs is conducted in the ſame manner, ſo far as to the making of the lixivium; but, when this is prepared, inſtead of ſoaking it up with rotten wood, they pour it off into an iron caldron of a large ſize, and evaporate it, ſtill adding more lixivium as the former boils away, till they have employed all they have made; they then continue the fire till the whole humidity is evaporated: they then take the dry maſs of ſalt out of the bottom of the veſſel, and put it into a furnace made with a cloſe arched top; by means of which the flame is reverberated from all parts upon the ſalt. They here give it ſo much fire as ſerves to calcine it to a whiteneſs, and then the whole operation is finiſhed.

It is ſeldom, however, quite white; but uſually retains ſomewhat of the colour it had before its calcination. This the workmen ſay is owing to the nature of the wood the aſhes were made from. They ſay that thoſe trees which grow on the tops of high hills, yield a *pot-aſh* of a pale blue colour; and thoſe which grow in wet marſhy places, yield a reddiſh ſalt. Trees which have ſtood in other ſoils and ſituations, they ſay, yield a white *pot-aſh*; but they obſerve, that none yield it in ſo large a quantity as thoſe which grow on the tops of mountains. Mem. Acad. Par. 1727.

POTAMOGEITON, *pondweed*, in the Linnæan ſyſtem of botany, a genus of plants, the characters of which are theſe:

the flower has no calyx or cup; but is compoſed of four obtuſe, roundiſh, hollow, and open petals, which fall off before the ripening of the ſeeds. The ſtamina are four plane, obtuſe, and very ſhort filaments; the antheræ are double and ſhort; the piſtillum has four germina, which are all oval and pointed: theſe have no ſtyle, but obtuſe ſtigmata. There is no other fruit than four ſeeds ſucceeding each flower; theſe are of a roundiſh, but flatted figure, gibboſe, and pointed. *Linnæi* Gen. Plant. p. 55.

The characters of this genus, according to Tournefort, are theſe: the flower conſiſts of four leaves, diſpoſed in form of a croſs, and having no cup; the piſtil becomes at length a congeries of four ſeeds, of an oblong figure, collected into a ſort of head.

The ſpecies of *potamogeiton*, enumerated by Mr. Tournefort, are theſe: 1. The roundiſh-leaved *potamogeiton*. 2. The long-leaved ſerrated *potamogeiton*. 3. The plantain-leaved alpine-*potamogeiton*. 4. The broad ſhining-leaved *potamogeiton*. 5. The curled-leaved *potamogeiton*, called *frog's lettuce*. 6. The narrow undulated-leaved *potamogeiton*. 7. The leſſer *potamogeiton*, with denſe ſharp-pointed, and not ſerrated leaves. 8. The narrow-leaved branched *potamogeiton*. 9. The graſſy-leaved *potamogeiton*, with flatted ſtalks. 10. The ſmall graſſy-leaved *potamogeiton*, with round ſtalks. 11. The *potamogeiton* with flowers at the knots of the ſtalks, called *water-milfoil*. 12. The pennated-leaved *water-milfoil*, called by ſome *feathered water-milfoil*. *Tourn.* Inſt. p. 233.

POTAMOPITYS, in botany, a name given by Buxbaum to a new genus of plants, ſomewhat reſembling the limnopeuce in its general external appearance; but greatly differing from that plant in its flower and fruit.

The ſtalk is about four inches high, and is made up of ſeveral joints, fixed in the manner of ſo many cups one into another. The leaves ſtand in form of a ſtar, eight, or thereabout, at every joint: theſe are narrow at the lower part of the plant; but toward the top, they are broader, and ſtand fewer at a joint, ſometimes only two. The flowers grow out of the alæ of the leaves, and are white and compoſed of four petals, diſpoſed in form of a croſs: they ſtand in a four-leaved cup, and have no pedicle. The piſtil occupies the center of the flower, and is ſurrounded by four ſtamina. The ſeed veſſel is round, divided into four cells, and filled with ſlender and lunated ſeeds. It flowers in May, and is common in the marſhy grounds in Thrace, near the Boſphorus. Act. Petrop. Vol. 1. p. 243.

POTATOE. The moſt advantageous way of propagating *potatoes* is, the planting them at large diſtances, and digging or horſehoeing the ground ſeveral times between them.

Mr. Tull gives an example of this, in which the hoeing ſucceeded much better than dung, and without the expence of it. A piece of ground was planted with *potatoes*, the greater part of it in the common way; but in one part, worſe than the reſt, they had been ſet at a yard diſtance every way. The reſt of the ground was dunged; this poor part had no dung, but was ploughed deep at ſeveral times four different ways, ſo that the ground was ſtirred and broken thoroughly every where about the *potatoes*. The conſequence was, that tho' no dung was uſed here, and tho' the plants appeared much weaker than in the dung part, yet the crop was greatly better than that of the other part of the field. The roots here were all large, and in the other parts of the field, where the dung had been uſed without ploughing, they were ſo ſmall, that the crop was ſcarce worth taking up.

This is one of many inſtances of the no great uſe of dunging land, without properly ſtirring it up; and ſerves to prove, what the crops of corn and every thing elſe confirm upon trial, that the ſtirring the earth ſufficiently, without any farther trouble, will anſwer better without any other manure, than all the manure in the world without it. *Tull*'s Horſehoeing Huſbandry.

POTENTILLA, in botany, a name given by many authors to the argentina, or ſilver weed; and by ſome with the addition of the epithet major, or the greater *potentilla*, to the ulmeria, or meadow-ſweet. *Ger.* Emac. Ind. 2.

POTERIUM, a word uſed by many for the prickly pimpernell. See PIMPINELLA.

POTHOS, in botany, a name uſed by Theophraſtus, and ſome other of the old writers, for the aquilegia or columbine. *Ger.* Emac. Ind. 2.

POTINCOBA, in botany, a name by which ſome authors call water-pepper, or the ſharp arſmart. *Piſo*, 221.

POTIRONE, in botany, a name given by the people of Burgundy to a ſtinking kind of fungus, found about the roots of trees. They have alſo extended the name much farther, and uſe it for a ſort of touchwood, or rotten wood of the oak, and other trees common in the foreſts of thoſe countries, which ſhines in the night, and has the ſame ſmell with that fungus.

POTRIMPOS, the name of an antient Pruſſian idol, worſhiped under oaks, and to which human ſacrifices of enemies were offered. Mem. de l'Acad. de Berlin, Tom. 2. p. 358. Percunos and Picolos were idols of the ſame kind.

POTTERN-*ore*, a kind of lead ore. See LEAD-*ore*.

POUCH, in the military art. A grenadier's *pouch* is a ſquare caſe or bag of leather, with a flap over it, hanging in a ſtrap of about two inches broad over the left ſhoulder, in which he carries his granadoes.

POUDRE *des Chartreux*. See KERMES *mineral*.

POUNCE *(Cycl.)*—POUNCE, among writing-maſters, a powder made of gum-ſandarac, which being rubbed on the paper, makes it leſs apt to imbibe the ink: it is therefore uſed in this manner by thoſe who are curious in the art of the pen, by which means the writing appears more preciſe, ſharp, and determinate.

The varniſh-makers alſo uſe to diſſolve it in oil of turpentine, or in linſeed oil, or in ſpirit of wine; from which mixture is produced a kind of liquid varniſh.

POUND *(Cycl.)*—In Scotland the *pound* is divided into two marks, or ſixteen ounces, the ounce into ſixteen drops, and a drop into thirty-ſix grains. Tr. Pract. Geom. p. 153.

POUND *averdupois*. The Engliſh *averdupois pound*, taken from the reputed ſtandard, is about 7000 Troy grains, and the ounce about 437 and an half ſuch grains. But it is to be obſerved, that the ſtandards kept at the Exchequer differ a little from each other.

The Scotch, Paris, or Amſterdam *pound*, is to the *pound averdupois* as thirty-eight is to thirty-five. Tr. Pract. Geom. p. 153.

POUND *breach*, in law. If a diſtreſs be taken, and impounded, though without juſt cauſe, the owner cannot *break* the *pound*, and take away the diſtreſs; if he doth, the party diſtraining may have his action, and retake the diſtreſs wherever he finds it: and for *pound breaches*, &c. action of the caſe lies, whereon treble damages may be recovered. 1 Inſt. 161. 2 W. & M. c. 5.

Alſo it is ſaid, that all *pound breaches* may be enquired of in the ſheriff's turn, as they are common grievances, in contempt of the authority of the law. 2 Hawk. P. C. 67. *Blount.*

POUND *land*, of old extent. This is alſo called *librata terræ*, and is uſed in Scotland to denote a certain portion of arable land, containing four oxengate, or fifty-two acres. Tr. Pract. Geom. p. 87. See Ox-*gang*.

POUND *Troy*, in Scotland, which by ſtatute is to be the ſame as the French *pound*, is commonly ſuppoſed equal to fifteen ounces and three quarters Troy Engliſh weight, or 7560 grains. But by a mean of the ſtandards kept by the dean of gild of Edinburgh, it weighs 7599$\frac{1}{2}$, or 7600 grains.

POUR *fair proclaimer, que null inject fines ou ordures en foſſes ou rivers pres cities*, &c. in law, an antient writ, directed to the mayor or bailiff of a city or town, requiring them to make proclamation, that none caſt filth into the ditches or places near ſuch city or town, to the nuſance thereof; and if any be caſt there already, to remove the ſame. It is founded on the ſtatute 12 Rich. II. c. 13. F. N. B. 176. *Blount, Cowel.*

POUR *ſeiſer terres la femme que tient en dower*, in law, an antient writ, whereby the king ſeized the land which the wife of his tenant *in capite* had for her dowry, after his diſeaſe, if ſhe married without the king's leave; by virtue of the ſtatute of the king's prerogative c. 3. F. N. B. 174. *Blount. Cowel.*

POUSSE-*pied*, in natural hiſtory, the French name for a genus of ſhell-fiſh, called by writers of other nations the *policipes*. See POLICIPES.

Rondeletius has very improperly confounded this genus of ſhells with the balani marini; but the two genera are extremely different, as well in their general figure as in this, that the *pouſſe-pied* always has a pedicle to which it is affixed, and the balanus never has any. Every *pouſſe-pied* is compoſed of ſeveral pointed ſhells or valves; the baſes of the larger of theſe are affixed to the pedicles. The outer ſurface of the ſhell is of a mouſe colour, and is rough like chagrin; but the inſide is filled with a white fleſh, which, when boiled, becomes very red, and is of a fine taſte and good nouriſhment, being in nothing inferior to the fleſh of cray-fiſhes.

The *pouſſepied* differs from the concha anatifera in this, that the anatifera is only compoſed of five pieces; and the pedicle is longer and ſlenderer, and rarely adheres to that of any other ſhell of the ſame kind; and the ſhell is only filled with a mucous fluid, and a few plumoſe ſubſtances. On the contrary, the *pouſſepied* is never found ſingle; it is always ſeen in cluſters, the pedicles joining and adhering to rocks under water, ſo that it is bare only at the time of the tide being out. The union of the baſes of the pedicles of theſe ſhells forms a ſort of tree, of which the looſe part of each pedicle makes a ſort of branch; and the tops of theſe are furniſhed with ſeveral triangular pieces, each of which has its plume belonging to it. This pedicle is ſhorter and thicker than that of the concha anatifera, and is eatable; and, indeed, is the only part of the animal that is ſo. The fiſh contained in the ſhell, is nearly the ſame with the fiſh in the concha anatifera, excepting the difference in the length and thickneſs of the arms, or branches of feathers. Hiſt. Nat. Eclairc. p. 359.

POUST, an Indian name for a very poor and coarſe kind of opium, made by boiling the ſtalks and leaves of the opium poppy in water, and then evaporating the clear liquor to the conſiſtence of a ſolid extract.

POUTING, or *whiting*-POUT, in ichthyology, a name given to a ſpecies of bearded gadus. See GADUS.

POWCHES,

POWCHES, in a ſhip. The ſeamen call by this name the ſmall bulk-heads made in the hold, to ſtow corn, goods, or the like, that it may not ſhoot from one ſide to the other.

POWDER *(Cycl.)*—*Gun*-POWDER. See GUN.

POWDER-*flasks*, in artillery, are moſt commonly made of horn, of any convenient ſize and figure, to carry *powder* for priming of cannon: this is their chief uſe in armies.

Sometimes they are ſo made as to have a meaſure for the charge of the piece at top, but this is of more uſe to gentle men in fowling, *&c.* than to ſoldiers, who have the charges of their piece put into cartridges, which they bite off, and firſt prime, and then load.

POWDER-*room*, in a ſhip, that part of the hold wherein the *powder* is ſtowed.

POWER *(Cycl.)*—If any *power* of a quantity be divided by a greater *power* of the ſame quantity, the quotient muſt be negative. For the rule for dividing any *power* of a quantity by another *power* of the ſame, is to ſubtract the exponent of the diviſor from the exponent of the dividend, and make the difference the exponent of the quotient.

For inſtance, $\frac{a^6}{a^4} = a^{6-4} = a^2$ and $\frac{a^m}{a^p} = a^{m-p}$. Hence if p be greater than m, the exponent $m-p$ muſt be negative. Thus if $p=m+n$, then $\frac{a^m}{a^p} = \frac{a^m}{a^{m+n}} = a^{-n}$.

It is obvious that $\frac{a}{a} = a^{1-1} = a^0$. But $\frac{a}{a} = 1$; and therefore $a^0 = 1$. In like manner $\frac{1}{a} = \frac{a^0}{a^1} = a^{-1}$; $\frac{1}{aa} = \frac{a^0}{a^2} = a^{0-2} = a^{-2}$; $\frac{1}{aaa} = a^{0-3} = a^{-3}$, ſo that the quantities a, 1, $\frac{1}{a}$, $\frac{1}{a^2}$, $\frac{1}{a^3}$, $\frac{1}{a^4}$, *&c.* may be expreſſed thus, a^1, a^0, a^{-1}, a^{-2}, a^{-3}, a^{-4}, *&c.*

This change of expreſſion is often of great uſe in the computation of fluxions and infinite ſeries.

When the quantity to be raiſed to any *power* is poſitive, all its *powers* muſt be poſitive. And when the radical quantity is negative, yet all its *powers*, whoſe exponents are even numbers, muſt be poſitive. For $- \times -$ gives $+$.

The *power* then can only be negative, when the exponent is an odd number. Thus the *powers* of $-a$ are $-a$, $+a^2$, $-a^3$, $+a^4$, $-a^5$, *&c.* Thoſe whoſe exponents are 2, 4, 6, *&c.* are poſitive, but thoſe whoſe exponents are 1, 3, 5, 7, *&c.* are negative. *Mac. Laur.* Algebr. p. 37, 38.

Hence if a *power* have a negative ſign, no root of it denominated by an even number, can be aſſigned; ſince no quantity multiplied into itſelf an even number of times can give a negative product. Thus the ſquare root of $-aa$ or $\sqrt{-aa}$ cannot be aſſigned, and is what mathematicians call an *impoſſible*, or *imaginary* quantity or *root*. See ROOT.

Obſerve, that every *power* has as many roots, real and imaginary, as there are units in the exponent of the *power*. This holds true of unity itſelf. *Mac. Laur.* Algebr. p. 128. See the article UNITY.

Imperfect POWER, in algebra, is uſed for a *power* that has a fractional exponent; thus $a^{\frac{1}{2}}$ $a^{\frac{2}{3}}$ $a^{\frac{3}{5}}$ $a^{\frac{7}{8}}$, *&c.* are imperfect *powers*. *Mac. Laur.* Algebr. p. 44.

Theſe are otherwiſe expreſſed by placing the given *power* within the radical ſign $\surd$, and placing above the radical ſign the number that denominates what kind of root is required. Thus, $a^{\frac{1}{2}} = \sqrt[2]{a}$; $a^{\frac{2}{3}} = \sqrt[3]{a^2}$; $a^{\frac{m}{n}} = \sqrt[n]{a^m}$.

Theſe imperfect *powers* are alſo called *ſurds*. See SURD, *Cycl.*

Negative POWER, in algebra. See NEGATIVE *power*.

POWTER, *or Engliſh* POWTER, the name of a peculiar ſpecies of pidgeon, called by Moore the *columba gutturoſa Anglica*.

It was firſt bred in England, and is of a mixed breed, between what is called the horſeman and the cropper. It is a very beautiful ſpecies, and is valued for its length of legs and body, neatneſs of crop, and ſlenderneſs in girth, added to the beauty of its feathers. This ſpecies is often eighteen, ſometimes twenty inches long from the end of the bill to the extremity of the tail. Its legs, from the upper joint of the thigh to the toe-nail, is ſometimes ſeven inches; the crop is large and round, eſpecially toward the beak, filling alſo behind, and making almoſt a perfectly orbicular figure. They are either blue-pied, black-pied, red-pied, or yellow-pied; the laſt colour is moſt valued. *Moor's* Columbarium, p. 35.

Pariſian POWTER, a ſpecies of pidgeon called by Moore *columba gutturoſa Pariſiorum*.

It was firſt bred at Paris, and thence ſent to Bruſſels, whence it was afterwards brought into England. It reſembles the Engliſh *powter*, but is ſhort-bodied, ſhort-legg'd, thick in the girth, and long-cropp'd. It is admired for the beauty of its feathers, which is peculiar to itſelf; it reſembling in this a fine piece of that ſort of needle-work which the ladies call the Iriſh ſtitch, being chequered with various colours in every feather, except the flight, which is white. It has generally a good deal of red intermixed with the other colours, and the more it has of this the more it is eſteemed.

Horſeman POWTING, a name given to a mixed breed of pidgeons, produced between thoſe two kinds known by the names of the *cropper* and the *horſeman*, according to the number of times that the young are bred over from the *cropper*. They are diſtinguiſhed by the names of the firſt, ſecond, or third breed.

Theſe are a very agile and nimble pidgeon; and by their continually flying up and down about the dove-houſe, are apt to bring in other ſtray pidgeons, which cannot find their houſes. They are obſerved to breed often, and take great care of their young ones. *Moore's* Columbarium, p. 38.

POX *(Cycl.)*—*Small* POX. Dr. Hahn endeavours to prove, that the *ſmall pox* was deſcribed by the old Greek phyſicians under the name of carbuncle.

Dr. Hahn's treatiſe on the antiquity of the *ſmall pox*, has been criticized by Dr. Werlhoff, who endeavours to ſhew, that Dr. Hahn's quotations from the old Greek writers concerning the carbuncle, cannot be underſtood of the *ſmall pox*, which is a diſeaſe we have no account of till the Saracens diſperſed it. Med. Eſſ. Edinb.

Dr. Hilſcher recommends cutting off the hair in the *ſmall-pox*, by which perſpiration may be increaſed. This method was practiſed on the king of Spain's ſon Don Carlos, and on a Saxon prince with ſucceſs. Med Eſſ.

Dr. Martin of Lauſaunne, recommends bathing the face and body with cloths dipped in tepid water every four hours during the eruption of the *ſmall pox*; aſſuring that it has excellent good effects. Hiſt. de l'Acad. des Sciences, 1737.

Dr. Haller tells us, that camphor aſſiſts greatly to fill the puſtules of the *ſmall pox* of the confluent kind with petechiæ. Commerc. Norimb. 1736. Hebd. 10. § 1.

Dr. Lobb diſapproves entirely of blood-letting in the *ſmall pox*, and thinks the diſeaſe may be prevented, or cured, without any eruption, and that a ſpecific may be found: he propoſes the Æthiops mineral as ſuch, and relates ſome examples of the diſeaſe being, in his judgment, prevented by the timely uſe of it. The biſhop of Cloyne ſeems to aſcribe the ſame virtues to tar-water. See TAR-*water*.

Dr. Wintringham ſays, he never obſerved antiphlogiſtic medicines, which open the belly, diluting clyſters or ſuch like, to have any bad effects in this diſtemper; but on the contrary, has always ſeen them ſerviceable to young, vigorous, plethoric patients; while too bound a belly frequently at laſt produces a dangerous diarrhœa. He propoſes in urgent caſes of the confluent *ſmall pox*, where from the reſorption of the variolous matter there is great danger of increaſing the ſecondary fever, that the puſtules ſhould all be opened, and treated as ſo many ulcers. See his Commentar. Noſologicum.

Bloody urine is looked upon as a forerunner of death in the *ſmall pox*; but we have inſtances of perſons recovering under ſuch ſymptoms. See Phil. Tranſ. N° 470. Sect. 11.

Great POX. For the cure of the *lues venerea*, Dr. De Sault, in his treatiſe on this diſeaſe, recommends frequent frictions with large quantities of mercurial ointment made with one third of quick-ſilver; to wit, from two or three drams to an ounce, or an ounce and an half every night, or every other night, taking care to keep the belly in a purging way, by clyſters, laxatives, or the ſtronger purgatives, if the mercury begins to affect the mouth. He ſays this method is ſure, and altogether ſafe, and he relates ſeveral hiſtories of cures performed by it, not only in the *lues venerea*, but in many other diſeaſes, particularly in obſtructed hardned glands, the liver, teſtes, *&c.* Med. Eſſ. Edinb.

Mr. Douglas greatly commends De Sault's method, and it is ſaid that it has been practiſed with ſucceſs in ſome of the hoſpitals in London. See A Letter on the cure of the venereal diſeaſe.

Dr. Werlhoff prefers frequently repeated ſmall doſes of mercury to a ſalivation, for the cure of the *lues venerea*. Commerc. Norimb. 1235. Hebd. 13. § 4.

Mr. Macky, profeſſor of hiſtory in the univerſity of Edinburgh, ſent the Royal Society a voucher for the grandgor *(lues venerea)* raging at Edinburgh in 1497. It is a royal proclamation, ordering all who had the diſeaſe, or who had attended people under it, to repair forthwith to an iſland in the Frith of Forth. Phil. Tranſ. N° 469. § 5.

PRACTORES, πρακτορες, among the Athenians, officers appointed to receive the money due to the city from fines laid upon criminals. *Potter*, T. 1. p. 81.

PRÆBIUM, a name uſed by medical authors to expreſs a doſe of any thing, or the quantity of a medicine to be exhibited at one time.

PRÆCIÆ, among the Romans, the ſame with *præclamitatores*; which ſee.

PRÆCIPE *(Cycl.)*—PRECIPE *in capite*, a writ iſſuing out of the chancery, for a tenant holding of the king *in capite*; *viz.* in chief, as of his crown. Magn. Chart. c. 24. Reg. Orig. 4. *Terms of law.*

PRÆCLAMITATORES, among the Romans, officers that went along the ſtreets of Rome before the *flamen dialis*, to oblige all people to give over their work on public holydays;

for if the *flamen* ſaw any one at work, the ſervice of the gods could not be performed. *Danet.* in voc.

PRÆCLAVIUM, among the Romans, was uſed to ſignify the *prætexta*. See PRÆTEXTA, *Cycl.*

PRÆCO, among the Romans, the public crier, an officer whoſe buſineſs it was in the aſſemblies of the people to call the claſſes and centuries according to their order, and to order ſilence to be kept in the temples during the time of ſacrificing.

The aſſiſtance of the *præco* or public crier, was uſed on many other occaſions, as at public ſales or auctions, funerals, games, in courts of juſtice, to publiſh things loſt, *&c.* *Pitiſc.* Lex. Ant. in voc. See CERYX.

PRÆCOCIA *mala*, *apricocks*. The method of cultivating and propagating the ſeveral ſorts of this fruit, is this: They are all to be propagated by grafting them on plumb-ſtocks, and will readily take with almoſt any ſpecies of plumb, provided that the ſtock be in a thriving condition. See GRAFTING.

The Breda and Bruſſels *apricocks*, are beſt to be made ſtandard trees, all the reſt are to be propagated againſt walls, and ſhould have an eaſt or weſt aſpect. The borders under theſe walls ſhould be four feet wide at leaſt, and ſhould be two feet deep in earth. If the place where they are planted be a loamy ſoil, the beds are to be raiſed pretty high above the level of the ground, and if chalk or gravel, it muſt be removed to a conſiderable width, to make room for freſh ſoil to be put in, but it need not be dug more than two feet deep. The beſt ſoil for them is freſh earth from a paſture ground, taken to ten inches deep, and laid with the turf among it to rot together, for a twelvemonth before it is uſed.

Such trees ſhould be choſen for planting as are but of one year's growth from the budding, and where the ſoil is dry or moderately ſo, October is the beſt ſeaſon for planting. For the manner of planting, ſee the article APPLE-*tree*.

No part of the head ſhould be cut off at this time, unleſs there are ſome foreright ſhoots which will not come near the wall. In a good ſtrong ſoil, or againſt a low wall, theſe trees ſhould be planted at eighteen feet aſunder; the ſtem is to be placed four inches from the wall, and the head inclined toward the wall, the branches ſhould be then nailed up to the wall, and the ſurface over the earth muſt be covered with rotten dung, to keep out the froſts. In February the dung is to be removed, and the tree being held very ſteady the top is to be cut off to about three eyes above the bud, leaving the ſloping ſide toward the wall. If the weather proves dry after this, they muſt be gently watered, and ſome turf or mulch laid round the root to keep off the ſun's heat; and what branches are produced muſt be nailed up, except ſuch as are produced foreright, which muſt be cut off.

At Michaelmas, when the trees have done growing, the branches muſt be again unnailed and cut off to a proper length, the ſtronger ſhoots being left of nine or ten inches long, the weaker five or ſix inches. After they are thus ſhortened, they muſt be again nailed up, and that as much in an horizontal direction as poſſible. The ſecond and third ſummer the ſame rules muſt be obſerved, all the foreright ſhoots muſt be diſplaced as they are produced, nailing in the others horizontally to the wall; ſo that the middle of the tree may be kept open; and never ſhorten any of the ſhoots in ſummer, unleſs to furniſh branches to ſome vacant ſpaces on the wall; and this ſhould never be done later than April. The *apricock* produces its bloſſom buds not only on the laſt year's wood, but alſo on the curſons or ſpurs from the two year old wood; great care muſt therefore be taken not to injure or diſplace theſe.

The Bruſſels and Breda *apricocks* being planted for ſtandards, require very little management, only in autumn or ſpring cut away all the dead wood, and ſuch branches as croſs one another. The Bruſſels *apricock* is the fineſt of all the kinds: it is ripe in the middle of Auguſt. *Miller's* Gardner's Dict.

PRÆCONISSUS, in natural hiſtory, the name given by Ludovicus Dulcis, and other writers of his time, to a gem famous for its imaginary virtues: it is deſcribed to have been of the nature of the ſapphire, but ſomewhat approaching to the colour of the chalcedony: this ſeems to make it the leucoſapphirus of other authors.

PRÆFECTURÆ, among the Romans, towns in Italy, which were neither municipal, nor had the privilege of chooſing magiſtrates of their own, like the colonies; but were governed by a magiſtrate ſent from Rome, who was called *prefectus*, and his government a *præfectura*. *Pitiſc.* in voc.

PRÆFERICULUM, among the Romans, a vaſe with a large prominent mouth uſed in the ſacrifices of Ops. *Pitiſc.* in voc.

PRÆFICÆ, among the Romans, were mourning women hired to attend funeral ſolemnities; where they praiſed the deceaſed, made a lamentation, beat their breaſts, and diſtorted their faces, to excite others to mourn. *Danet.* and *Pitiſc.* in voc.

PRÆFINE, in law, that fine which upon ſuing out the writ of covenant on levying *fines of lands*, is paid before the time is paſſed. 22 and 23 Car. 2. *Blount.*

PRÆFURNIUM, a word uſed by chemical writers to expreſs the anterior part of a furnace, by which the coals, or fuel are put in, and the aſhes taken out.

PRÆMORSUM *folium*, among botaniſts. See LEAF.

PRÆNOTION is uſed by Lord Bacon for breaking of an endleſs ſearch, which he obſerves to be one of the principal parts of the art of memory. For when one endeavours to call any thing to mind, without ſome *previous notion* or perception of what is ſought for, the mind exerts itſelf and ſtrives in an endleſs manner: but if it hath any ſhort notion before hand, the infinity of the ſearch is preſently cut off, and the mind hunts nearer home, as in an incloſure. Thus verſe is eaſier remembered than proſe; becauſe if we ſtick at any word in a verſe, we have a *previous notion* that it is ſuch a word as muſt ſtand in a verſe. Hence alſo, order is a manifeſt help to memory; for here is a *previous notion* that the thing ſought for muſt be agreeable to order. *Bacon's* Works, abrid. Vol. I. p. 136. and Vol. II. p. 474. See PRÆNOTION, *Cycl.*

PRÆPOSITUS *ſacri cubiculi*, among the Romans, an officer who was to take care of the emperor's bed-chamber. His office was the ſame with that of our lord chamberlain, and he had the privilege of marching next to the captain of the horſe-guards. *Danet.* in voc.

PRÆSALTOR, among the Romans, an appellation given to the chief director of the *ſalii*. *Pitiſc.* in voc. See SALII.

PRÆSEPIA, a word uſed by authors to expreſs the ſockets of the teeth.

PRÆSICIA, in antiquity, thoſe parts of the intrails of ſacrifices which were cut off, and offered to the gods. *Hofm.* Lex. Univ. in voc.

PRÆSUL, among the Romans, the name of the chief of the *ſalii* or prieſts of Mars. He was ſo called *a præſiliendo*; *i. e.* dancing at the head of the *ſalii*. *Hofm.* Lex. Univ. in voc. See SALII, *Cycl.*

PRAMNION, in natural hiſtory, the name of one of the ſemipellucid gems, ſo diſtinct from all the others as to make properly a peculiar genus of foſſils. It is called by many of the antients *morio* or *morion*, and by our lapidaries the *black agate*.

It is a ſtone of a very great concealed beauty. Our lapidaries, who know it by the name of the *black agate*, are very indeterminate in the application of that name, calling by it not only this, but every black ſtone capable of a good poliſh by the ſame name, and never looking for its great character, its hidden colour. It is found in the ſhape of our common flints and pebbles, but ſeldom larger than an egg; it appears on a ſlight inſpection, to be of a fine deep black, but held up againſt the ſun, or the light of a candle, it diſcovers itſelf to be of a fine ſtrong red, without the leaſt admixture of any other colour. It is moſt frequently of a purpliſh tinge, like the amethyſt, but is at times found of all the degrees of red, from the pale flower colour of the hyacinth to the deep red of the carbuncle. It is of great hardneſs, and capable of an elegant poliſh.

It is produced only in the Eaſt Indies; and we ſometimes have it thence among other ſtones, but it is not much regarded with us. The Romans were fond of it for engraving on, as we find by Pliny, and by a much more undeniable proof, many of the valuable antiques being cut on it. *Hill's* Hiſt. of Foſſ. p. 471.

PRAMNOS, a name given by the antients to a ſort of auſtere wine which looked of a black colour till held up againſt the light, and then appeared of a deep purple: it is recommended by Hippocrates in hæmorrhages.

PRASINUM *viride*, a word uſed by the antients for verdigreaſe.

PRASION. The antient Greek writers have expreſſed three very different plants by this name.

The moſt common ſignification of the word is the common *marrubium* or horehound. It is in many places uſed alſo to ſignify the leek, and often for that ſort of marjoram which we call *origanum onitis*, or pot-marjoram. Pliny deſcribes this plant, and ſays that it was called *onitis* and *praſius*, and had the appearance of hyſſop. This is but a bad deſcription of the plant, and much inferior to the Greek epithet, which calls it the *capitated*, or *corymbous praſium*, for it bears its flowers in a ſort of heads or corymbi.

Heſychius tells us, that the ſea-weeds of the fucus and alga kinds, the ſea-oaks, and ſea-wracks, are called by ſome of the Greek writers *praſia*; and Theophraſtus in one part of his works ſeems to have given this name to thoſe plants.

The antients having uſed the word *praſion* in this ſenſe, explains a paſſage in Galen which cannot otherwiſe be well underſtood, that is, where he calls the *empetrum marinum*, *praſioides*, like the *praſion*.

Dioſcorides had called it *fucoides*, like the ſea-fucus, and he was very well underſtood; but Galen coming after him, and expreſſing his ſenſe by the word *praſioides*, which was ſuppoſed to ſignify reſembling leeks, or horehound, or origanum, his readers were perplexed to find out what alliance the epithet he had choſen to uſe could have, either to the plant, or to the epithet of Dioſcorides; but when it is found that *praſion* ſignifies the ſame as *fucus*, the whole is very intelligible.

PRASIS, a word uſed by ſome authors to expreſs what they call green chalk, an earth uſed by the painters, and known among us by the name of *terre verte*.

PRASIUM, in botany, the name of a genus of plants, the characters of which are theſe: the perianthium conſiſts of one leaf, and is of a turbinated bell-like ſhape, and divided at the end into two lips; theſe ſtand erect, and are permanent; the upper

upper one is broad, and divided into three acute ſegments; the under one is ſomewhat ſmaller, and is divided only into two. The flower is compoſed of one petal, and is of the labiated kind. The upper lip is erect and hollow, of an oval figure and emarginated; the under lip is broad and reflex, and is divided into three ſegments, of which the middle one is the largeſt. The ſtamina are four ſubulated filaments preſſed cloſely under the upper lips of the flower; they ſtand expanded, one pair of them are ſhorter than the other, and the longeſt do not reach to the verge of the flower. The antheræ are oblong and lateral. The germen of the piſtil is ſquare. The ſtyle is ſlender, and is of the length and ſituation of the ſtamina. The ſtigma is acute and bifid, one of the ſegments being ſhorter than the other. The fruit conſiſts of four roundiſh berries, which lie in the bottom of the cup, and each contain one ſeed. *Linnæi* Genera Plant. p. 280.

PRASIUS, in natural hiſtory, the name of a gem much approaching to the nature of the emerald, but of a coarſer green, and wanting its hardneſs, and having in its green a caſt of yellow.

It is the ſtone which the antients called *praſites*; and when of a greater than ordinary admixture of yellow, the *chryſopraſus*, and of which the gem diſtinguiſhed by later authors under the name of the *ſmaragdopraſus*, is only one of the varieties.

The *praſius*, even in its moſt perfect ſtate, is much leſs beautiful than moſt of the other gems: it is found of various ſizes, and not unfrequently conſiderably large: it is ſeldom met with ſmaller than a pea; from that to the ſize of a horſe bean is its moſt uſual ſtandard, from this to the ſize of a nutmeg it is more rarely found; and the larger ſpecimens are coarſer and leſs frequent than theſe.

It is of various figures, but is never found in a columnar or cryſtal-like form; this is declaring againſt the ſenſe of our dealers in gems, indeed, who frequently buy and ſell columns of the ſhape of ſprig cryſtal, under the name of the *ſmaragdopraſus*; but theſe are all truly no other than cryſtals tinged to a coarſe and dead green, and without any mixture of yellow; ſo that they are more properly *pſeudoſmaragdi*, or baſtard-emeralds, than any thing of the *praſius* kind.

The *praſius* is frequently of an orbicular form, flatted on one ſide and convex on the other, and often oblong or oval; but more uſually it is of a perfectly irregular ſhape, made up of a number of flat faces, as we often ſee ſome of the coarſer nodules of the debaſed cryſtals from the German mines; and it is uſually of an obſcure or much leſs poliſhed ſurface than many other of the native gems. Its colour is a duſky green, with a mixture of yellow, and often of bluiſh; and its moſt valuable pieces are of the hardneſs of the garnet; and its worſt, which are truly *praſii*, are conſiderably harder than cryſtal; the columnar *praſii*, as they are called, are, on the contrary, often as ſoft, or ſofter than pure cryſtal. It is like the other gems, found in the different ſpecimens of all degrees of colour, from its uſual duſky green to the mere colour of water; it is at times found alſo with more or leſs yellowneſs in the different ſpecimens, or in the different parts of the ſame ſpecimen, and has ſometimes a milky caſt among the green: authors have diſtinguiſhed it according to theſe its different appearances, by four names.

1. The *praſius* or *praſites*, ſimply ſo called. This is the name given to the gem in its moſt perfect ſtate, in which it has a conſiderable ſhare of yellow with the green, and the green is of a more pure and graſſy colour.

2. The *ſmaragdopraſus*. This is the name given it when there is leſs yellow in the colour and ſome mixture of blue with the green.

3. The *chryſoberyllus*. This is the name given to the *praſius* when it has the ſame bluiſh caſt, with a greater admixture of yellow.

4. The *chryſopraſius*. This is the name given it when it has a large admixture of yellow, and its green is a pure but a very pale one.

And, finally, De Boot mentions another ſpecies, as he calls it, of *praſius*, which was more opake than the reſt, and had but little green, and a large admixture of white among the yellow; but this is in reality only a ſpecies of nephriticus.

The fineſt of the *praſii* are found in the iſland of Ceylon; but there are many of them in New Spain. We have them alſo from Sileſia and Bohemia; but theſe are very poor ones. *Hill*'s Hiſt. of Foſſ. p. 597.

PRECATORES, in church hiſtory, a ſect of heretics, who under the pretence of praying always, refuſed to work. *Hofm.* Lex. Univ. in voc.

PRECEDENCY. See the articles PRECEDENCE, *Cycl.* and CEREMONIAL, *Suppl.*

PRECIPITATION, *(Cycl.)* in aſſaying, is the ſeparation of any part of a compound body while melting in the fire, or when cooling from fuſion from the reſt of the maſs, in ſuch manner that it ſinks to the bottom, while the remainder continues at top and makes the ſurface. The heavy part thus *precipitated* from the reſt, is called the *regulus* of that body.

This is an operation which almoſt always requires the addition of ſuch ingredients as ſerve to take away the mutual connection and coherence of the parts of the body to be ſeparated; that is, ſuch as have a menſtrual virtue, and keep others in a ſtate of diſſolution. For inſtance, the regulin part of antimony, and mineral ſulphur, diſſolve each other mutually, and conſtitute crude antimony; nor can they be ſeparated from each other by fire alone without deſtroying the regulus; but if you add iron, copper, ſilver, *&c.* which are more thoroughly penetrated by ſulphur, and are thus reduced to the ſtate of ore, then the regulus of antimony is freed of its ſulphur, and ſinks to the bottom, as it is heavier than the additional bodies, when joined to the ſulphur.

Such a *precipitation by fuſion* happens in vitrifications, ſcorifications, and coppelings, while one part of the body turns into droſs, or *ſcoriæ*, and the other metallic part, if there be any, keeping ſtill its metallic form, is collected at the bottom of the ſpherical veſſel. Therefore ſilver and gold, which are hardly ſubject to a perfect vitrification, conſtantly remain and ſhew themſelves in their own form; and on this account, tho' they were in ever ſo ſmall a quantity in a *coppel*, they always ſhew themſelves very clearly to the eye when the *ſcoriæ* are abſorbed; whereas ſo ſmall a regulus of the other metals would have been as it were buried and hidden under ſo great a quantity of *ſcoriæ*.

Nor is *precipitation by fuſion* leſs neceſſary to obtain almoſt all the other metals, which on this account are called leſs perfect, unleſs perhaps you except a very ſmall quantity of native metal, which nevertheleſs can ſcarce be properly called pure. Beſide, they are all to be had either in form of earth, or of that of a ſolid ore. In the firſt caſe you may make a glaſs by a bare fuſion: in the ſecond, if the ſulphur and arſenic, which, together with the metallic part, conſtitute an ore, are diſſipated in roaſting; the ore deſtitute of the oily phlogiſton, becomes glaſs in a pure fire, which glaſs may be mixed with unmetallic ſtones and earths; but by adding a phlogiſton or inflammable principle to it, this metallic glaſs is again reduced to its metalline form; and ſo long as it keeps under this form it cannot be united with the glaſs of the other ſpecies, but ſinks to the bottom of it, except only a very ſmall quantity of it, which is detained by the clammineſs of the glaſs. The *precipitating* body in this caſe, therefore, is truly the phlogiſton, or inflammable principle: any body that takes away the connection, by the removal of which a *precipitation* is made, is properly called the *precipitating* body. *Cramer*'s Aſſ. p. 187.

Precipitation of ſolid bodies from fluid menſtrua, is performed either by extracting, or evaporating over a gentle fire the diſſolving menſtruum out of the diſſolved fixed body, or by adding ſuch a body, as is greedily diſſolved by that menſtruum: as if one metal diſſolved by an acid is *precipitated* by another metal, or by an alkaline ſalt: for inſtance, ſilver diſſolved in aqua fortis is *precipitated* by copper, copper by iron, iron by zink, and all metals and ſemi-meals, either partly or entirely by pot-aſhes, volatile, and urinous ſalts.

A *precipitation* is alſo made by pouring on a ſolution, ſuch things as either cannot diſſolve the body in hand, whether alone, or joined to a menſtruum that contains the ſaid body; or diſſolve it in another manner; or in a leſſer quantity than if the menſtruum had been uſed pure. In the firſt caſe a total *precipitation* is performed, as may be ſeen in the *precipitation* of ſilver out of aqua fortis, by means of ſpirit of ſalt. In the ſecond a great deturbation and *precipitation* is made, but a ſecond ſolution ſoon follows, as it happens when iron being diſſolved in aqua fortis, you add to it in a proper manner a liquor perfectly free from alkaline fixed ſalt; but then there remains uſually a certain part which is not perfectly diſſolved a ſecond time. In the third caſe there is but a partial *precipitation* made. You have an inſtance of this, if mercury diſſolved in aqua fortis, and the menſtruum thoroughly ſaturated with it, is *precipitated* either by common ſalt, or ſal armoniac, or by their acid ſpirit. A *precipitation* is alſo ſometimes made only by adding a large quantity of fair water to dilute; ſuch is that made on the regulus of antimony diſſolved in ſpirit of common ſalt, or in aqua regia, when a large quantity of cold water is poured on this ſolution; for theſe menſtrua do not diſſolve this ſemi-metal, unleſs concentrated.

All theſe *precipitations* are promoted greatly by a gentle heat, by means of which the *precipitating* body enters more eaſily into the menſtruum, and a conſiderable quantity of water is next neceſſary to dilute with, except in the *precipitations* of the firſt kind; for moſt commonly the more concentrated diſſolutions aſſume the conſiſtence of a paſte ſo ſoon as the *precipitating* body is added to them, which hinders this from mixing equally with the ſolution. Id. ibid. p. 196.

Boerhaave makes the following obſervations on the different manner in which *precipitation* is performed by ſeveral different agents.

Thus 1. By water poured on oils diſſolved in alcohol, where the liquor turns milky.

2. By water poured to ſolid reſins diſſolved in alcohol, where alſo the liquor turns milky.

3. By water in the diſtillation of oily ſpirits, if any water run after the ſpirit is drawn off.

4. By acids on acids; thus ſilver and mercury are *precipitated* out of ſpirit of nitre, in which they had been diſſolved by adding ſpirit of ſalt.

5. By metals with metals, and other bodies. Thus for example, dilute an ounce of ſilver diſſolved in ſpirit of nitre,

with twelve times the quantity of rain water; put poliſhed plates of copper into this liquor, and the ſilver will be precipitated and the copper diſſolved: then put this ſolution of copper into another glaſs, and add to it poliſhed plates of iron; the copper will be precipitated and caſe over the iron; finally the copper falls to the bottom, and the iron diſſolves. Pour this ſolution of iron into a freſh glaſs, and drop upon it oil of tartar, per deliquium; the diſſolved iron immediately falls to the bottom, and the alkali unites with the acid, and regenerates true nitre, after ſo many changes.

Thus does this ſalt travel from one body to another almoſt unaltered, tho' it is more attracted by one than another, till at length it reſts in that which in this reſpect is the ſtrongeſt, and is only thence expelled when oil of vitriol is poured upon the nitre thus regenerated. On theſe two principles *precipitation* depends, and is the true, and often abſtruſe cauſe of numberleſs wonderful operations, both in art and nature. Take a grain of white or red *precipitate*, rub it upon a poliſhed and heated copper-plate, and wherever the matter has paſſed the copper will immediately look like ſilver; for the copper attracts the acid of the nitre from the calx of the mercury, and thus preſently makes an amalgam upon the ſurface of the copper, and then acquires a ſilver colour.

6. Alkalies often *precipitate* things diſſolved by acids. This happens frequently, but not always, nor in perfection: alkali *precipitates* copper diſſolved by an acid, but the copper is afterwards diſſolved by a ſalt made of the two.

7. Acids generally *precipitate* things diſſolved by alkalies; but in this caſe alſo there are ſome proceſſes which ſhew us exceptions.

8. Sharp ſalts, without being changed, and lying perfectly concealed, have ſtrange and unexpected effects by means of *precipitation*. If an ounce of luna cornea, which is perfectly ſcentleſs, inſipid, and unactive, and affords no ſign of acrimony in the fire, be ground, and united in a ſtrong heat in a glaſs retort with half an ounce of inodorous and perfectly inſipid regulus of antimony, there inſtantly ariſes an extremely ſtrong poiſon, or an exceedingly corroſive butter of antimony, the exhalation of which proves mortal. We ſee in this one inſtance how dangerous the art of mixing is, and with what care we ought to go about the compounding of bodies. *Boerh.* Chem. P. II. p. 338.

PRECIPITATE *(Cycl.)*—The different abſorbent ſalts which are commonly uſed for the *precipitations* of metals, from their ſolutions in acid menſtrua have no effect upon thoſe metals as to the colour of the *precipitate*; but when the ſolution is clear and limpid, and the matter left on the evaporation of it would have been white, the *precipitate* in this caſe, by whatever ſalt it is made, will be white alſo. And when that ſolution has any particular colour, whether it be that of the metal alone, as in ſolutions of gold; or a colour that is the reſult both of the metal and menſtruum, as is the caſe in the ſolutions of copper and iron, the *precipitate* obtained from the ſolution will always be of the colour the ſolution was of, whatever was the ſalt employed to make it. Tho' this is, however, the caſe in regard to the metals in general, yet it is to be obſerved that mercury diſſolved in ſpirit of nitre, or reduced to the ſtate of corroſive ſublimate, and afterwards diſſolved in water, affords phænomena perfectly different from all theſe: for tho' it gives no colour to the menſtruum in which it is diſſolved, but lets it remain limpid; and if the ſolution be evaporated to a drineſs, leaves only a white reſiduum, in the manner of the ſolutions of ſilver, tin, or lead; yet inſtead of giving a white *precipitate*, in the manner of thoſe metals, it affords a differently coloured one, through a great many varieties, according to the nature of the ſalt uſed to make it. As mercury is ſoluble in more acids than one, and as the experiments made on one of the ſolutions of this metal often have different phenomena from the ſame experiments made on other ſolutions, Mr. Lemery, who has employed himſelf very nicely on this ſubject, choſe the ſolution in ſpirit of nitre as the baſis of a long ſeries of experiments.

As this ſolution was a mixture of two bodies, it was firſt neceſſary to conſider them ſeparately, as to their colours. In this examination it is to be obſerved,

1. That ſpirit of nitre, when firſt made, and while it yet contains a great quantity of fiery particles, is of a red colour; and that afterwards, as theſe gradually evaporate and fly off, the ſpirit by degrees loſes that colour.

2. That crude mercury, when expoſed a long time to the action of the fire, becomes of a red colour.

3. That when a ſimple ſolution of ſpirit of nitre is evaporated, and the matter which remains after the evaporation is calcined, it changes from its white colour, which it had at firſt, to red, after paſſing through all the ſhades of yellow. Now ſince, in the change of its ſtate from the white to the red colour, the mercury loſes a great part of the acid particles which it had carried away from the ſolution, we might at firſt be apt to conclude, that its change of colour proceeded from this; but on the contrary, experience proves, that of whatever quantity of its acids mercury is diveſted after ſolution, provided that no freſh particles are admitted in their room, it always continues white ſo long as it contains acid enough to preſerve it in this form, or keep it in the condition of a *precipitate*.

As we know that fire is itſelf a fluid of a peculiar nature, and which has a power like other fluids of inſinuating itſelf into the pores of the other bodies, and there, like them, preſerving its eſſential properties; and as we alſo know, that the mixture of the particles of fire, either ſingly with mercury, or with ſpirit of nitre, gives to either a red colour; it is very natural to conclude, that the quickſilver, when it has been penetrated by the acid of ſpirit of nitre, and afterwards acted upon by calcination, is not changed from white to yellow, and from yellow through all its changes to red, by any other means than by the particles of fire which introduce themſelves into the *precipitate* as they drive the acid particles out: and this is evinced the more clearly by this experiment, that if freſh acid be added to this *precipitate*, now become red, in ſuch proportion as to diveſt it again of the fiery particles, and lodge its own in their places, then the whole loſes its red colour, and either becomes colourleſs, or elſe white as it was before.

The common white *precipitate* acted upon by a ſlow fire, thus loſes its white colour, and advancing through all the degrees of yellow, becomes at laſt red, as in the former inſtance; but if, inſtead of this ſlow heat, there is a ſtronger fire employed, and that continued ſo long as to raiſe this *precipitate* in a matraſs into the form of a ſublimate, in this caſe it preſerves its white colour, notwithſtanding the violence of the fire and the loſs of its acid particles, which in this proceſs cannot but be very conſiderable; nay, and tho' the ſublimation be repeated ſeveral times, the whiteneſs of the matter will not be altered by it. From this obſervation it may be ſeen, that when nothing is added to the matter in the place of the acid particles which are driven off, it ſuffers no change of colour by their loſs; and that in caſes where larger fires are uſed, and conſequently the fiery particles are driven through the body of the *precipitate*, there is no change of colour made in it by them; but that in order to make this change of colour, the fire muſt be ſlow, and the particles muſt be driven in with a force that is not ſufficient to drive them out again, and conſequently muſt remain there. It is evident, that the deprivation of the acids alone, does not change the white *precipitate* red; becauſe in this caſe, where there is no ſuch change of colour, there is, however, a manifeſt deprivation of a great part of thoſe acids; ſince there are always many globules of revived mercury found among the maſſes of the ſublimate.

Experiment proves, that mercury becomes more or leſs able to reſiſt the force of fire, as it is more or leſs highly impregnated with acids: and hence the ſame degree of fire applied to two quantities of mercury, differently charged with acids, ſhall have different effects, and ſhall give a red colour to that which is ſo fated with acids that it will not be raiſed in ſublimation; and the other, which is leſs charged with them, ſhall be ſublimed and left white. The white *precipitate* made in the common way, is at the utmoſt only able to bear a much ſmaller degree of fire than that neceſſary to make the common red *precipitate*; and crude mercury itſelf can only bear a much weaker than either, as is ſeen in the making the common calcined mercury, improperly called *precipitate per ſe*.

There is this, however, very remarkable in the making this calcination, that after the mercury has been calcined ſome time with the neceſſary gentle heat, it becomes able to bear a much ſtronger degree than it could at firſt. This is exactly the contrary of what is found in making the common red *precipitate*; in doing which the fire muſt neceſſarily be gradually diminiſhed, for the ſame degree of fire which it at firſt bore, nay, which was neceſſary to it, if continued, would certainly ſublime and evaporate it. The explanation of this is, that in each caſe the mercury becomes able to reſiſt the force of the fire in proportion as it receives particles which increaſe its weight. This both fire and the acid are capable of doing to it; but the acid does it in ſo greatly ſuperior a degree, that while in the one caſe crude mercury, receiving particles of fire into its body, becomes by their means capable of reſiſting a ſtronger heat; in the other, theſe particles of fire being only received in the place of acid ones before diſſipated, which added much more to its weight than they, it becomes much leſs able to reſiſt a violent heat by the change, and gradually, as it receives the fiery in the place of the acid particles, requires the heat to be decreaſed, otherwiſe it muſt be evaporated.

In fine, we ſee that crude mercury requires a long time to be reduced into a red powder by means of calcination; whereas the ſame mercury, when loaded with acids, may be converted into this red powder in a few hours; the one bearing a tolerably ſtrong heat, the other only a very weak one.

It appears that the mercury loaded with acids yields, therefore, a more eaſy acceſs to the particles of fire than the crude; and what proves this, and evidently ſhews that the acids accelerate the effect of the fire on this body is, that if the common white *precipitate* be expoſed to the ſame gentle degree of heat with crude mercury, it becomes red much ſooner; and as the difference here is only, that the one is plain mercury, the other mercury penetrated by acids, there can evidently be no reaſon for the latter turning red ſooner, but its being ſo penetrated.

After thus examining the effects of fire on ſolutions of mercury, this author proceeds to examine the effects of the differ-

ent ſalts on the ſolution in aqua fortis; and in theſe diſquiſitions it appeared, that thoſe ſalts which gave the mercury a yellow or a red colour, only produced this effect, as they had been expoſed to a longer or a ſhorter calcination, by which their acids had been driven out, and particles of fire received in their places, and retained there, inſomuch that theſe all heat water on being put to diſſolve in it, as they contain a larger or ſmaller quantity of theſe particles. Now as it is evident that theſe ſalts give a heat to water, by no other means than by the fiery particles they contain, it is very naturally ſuppoſed, that they give the yellow or red colour to the diſſolved mercury, by the ſame means as we know that theſe are the colours that fire itſelf gives to this body. Theſe ſalts, before their calcination, make no ſuch change in mercury: and it appears, that they act upon it as alkalies only, or bodies which have paſſed a violent calcination; and that the fiery particles they contain make them act upon it as fire would; and upon the whole, that fire and alkalies produce the ſame effects on the ſolution of mercury in aqua fortis.

On the other hand, thoſe ſalts which have not been expoſed to the action of fire, and which cool, inſtead of heating the water they are diſſolved in, or ſuch as having been calcined have acquired but little of an alkaline nature by the proceſs; that is, have collected few particles of fire in the place of the few acid particles which they have loſt; theſe do nothing to the diſſolved mercury but carry off a part of its acids, its whiteneſs being not at all affected by them: nay, even ſalt of tartar, which is a very powerful alkali, if there be acids mixed with it to drive off the fiery particles it contains, and place themſelves in their room, becomes wholly like one of theſe ſalts, and makes no change in the colour of the mercury.

In fine, the volatile ſalts, if they are pure, always give a white *precipitate* from the ſolution of mercury; but as theſe ſalts uſually contain a large portion of oil, this generally becomes ſeparated from them in the operation, and mixing itſelf with the *precipitate*, makes it of a mixt colour between its own natural white and the natural colour of the oil. As theſe oils in the ſalts have paſſed a ſtrong fire, they are uſually burnt, and naturally of a blackiſh colour; and therefore the reſult of their mixture, with the white *precipitate*, is a dirty grey. On the other hand, when urine is uſed, as the oily matter attending its ſalts has not been burned by fire, and as it naturally, by becoming exalted, by fermenting with the ſolution, acquires a deep blood-red colour, the conſequence is, that the *precipitate* is of the middle colour between this blood-red and its own natural white, and ſhews itſelf of a pale damaſk roſe colour.

Theſe are the effects of the abſorbent ſalts, when added ſingly to the ſolution of mercury; the next thing to be enquired into is, how they act when added one after another to the ſame quantity of the ſolution? When we have given this ſolution a yellow colour, by adding ſalt of tartar, which, as an alkali, occaſions that effect; if we afterwards pour upon this ſpirit of ſal armoniac, or other volatile ſalt diſſolved in phlegm, and raiſed by diſtillation, the yellowiſh or reddiſh colour immediately diſappears, and the whole becomes of a dirty greyiſh colour, which afterwards becomes blackiſh; but if oil of tartar, per deliquium, or any other powerful alkali be added, it does not again deſtroy this colour, and produce what it naturally would, if ſimply mixt with the ſolution, but only extends the dark or blackiſh colour which the mixt matter before had received from the ſpirit of ſal armoniac.

If ſalt of tartar, or any other fixed alkali be added to a ſolution of mercury, which has before been rendered white by amixture of common ſalt, or any other ſalt that has little alkali in it, the liquor becomes immediately yellow, and that colour remains unalterable by any freſh addition of ſalt whatever. Salt of tartar is therefore in this caſe to the other ſalts what the ſpirit of ſal armoniac is to ſalt of tartar. If oil of tartar and ſpirit of ſalt be alternately added to a ſolution of mercury, the ſolution becomes alternately yellow and white, according to the laſt liquor that was added; ſo that theſe two oppoſite liquors ſeem to be of equal force, each making the ſolution of the colour it naturally gives, when ſuperior to the other in quantity. Thus far, however, only two different liquors have been mentioned; it is poſſible to employ ſeveral others in the ſame manner one after another, and by that means to produce many more changes of colour in the ſolution. All that is to be taken care of in this experiment is, that the weaker liquors be uſed firſt, ſince otherwiſe they cannot produce any change; and what is to be concluded from the whole is this: 1. That mercury when it is penetrated by acid ſpirits, is naturally of a white colour. 2. That when it is changed to a red or yellow colour, it is wholly owing to particles of fire introduced into it. 3. That it never changes from white to red, or from red to white again, otherwiſe than by receiving or parting with the fiery particles it had before received. 4. That when the ſolution acquires a colour, the mercury loſes its acids, or part of them. 5. That every time it changes its colour it either loſes it acids, or gains freſh ones; and that this loſing and gaining its acids, is a condition without which the mercury can neither admit, or throw off the particles of fire. 6. That when an abſorbent does nothing to the ſolution but take away the acids, without communicating any thing to the mercury in their place, it always gives a white colour to the *precipitate*, or to ſpeak more properly, it makes the *precipitate* appear in its proper colour. 7. That it makes ſome other colour appear, when in the place of the acids, of which it has robbed the mercury, it gives it other ſubſtances which colour it according to their nature and quantity. 8. That in ſeveral abſorbents calculated to produce ſeveral colours, that which is the moſt powerful alkali is always capable of deſtroying all the reſt; but that there does not neceſſarily follow a change of colour, on the liquor becoming altered from a leſs alkaline to a more ſtrongly alkaline nature. 9. That a liquor of a very ſtrongly alkaline nature, added to the ſolution after one which was a weaker alkali, will make no change in the colour of the liquor, if it have no other effect than the abſorbing more of the acids from the *precipitate*, and does not give it other particles in the room of thoſe acid ones which it takes away; and, finally, that weak acids are capable of changing the *precipitate* from red to white, but that ſtrong ones utterly deſtroy all colours. Mem. Acad. Par. 1714.

PREDY, a ſea word ſignifying the ſame as *ready*. Thus, *predy the ſhip*, or *predy the ordnance*, is as much as to make things ready for a fight. *Predy the hold*, is to lay or ſtow every thing there in its due order and proper place.

PREGNANCY, *graviditas*, *(Cycl.)* the ſtate of a woman going with child. This is a time in which women ſuffer many diſorders, which tho' no way to be cured abſolutely but by childbirth, yet may be greatly mitigated by medicines. Before any one venture to do any thing, however, in theſe or the like caſes, it is very neceſſary to be perfectly aſſured, whether the patient is with child or not; and this is known by the following ſymptoms, in caſes where there is no occaſion for diſſimulation, or no other diſtemperature joined with this; but when the woman chuſes to conceal it, and there is a complication of diſorders, the utmoſt proofs amount but to preſumptive ones.

The ſtoppage of the menſtrual diſcharges is the firſt ſign of it, provided that there be no other apparent cauſe. But this, tho' the moſt plain and obvious ſymptom, is by no means a certain one; for a ſuppreſſion of this kind may happen from latent cauſes. A ſecond ſymptom is, a particular nauſea at the ſight of meat, or even the ſmell of it, while the perſon is otherwiſe well in health, and can eat heartily of other foods. A third ſymptom is, a ſwelling of the belly; which appears regularly round or globoſe, not irregularly protuberant, as is the caſe in diſorders of the liver, and other viſcera. This ſwelling, alſo, increaſes placidly, and without the legs ſwelling, or any other ſymptom, if the perſon is otherwiſe in health. After this, the twentieth week of *pregnancy* gives the moſt certain of all the ſigns, the motion of the fœtus; but this is to be carefully diſtinguiſhed from motions of the bowels in flatulencies, which often ſo much reſemble it as to deceive the unwary.

If the mother has a mind to hide the ſymptoms, the thing may, however, uſually be found out at this period; for if a cold hand be laid upon the belly when warm, or a warm hand when it is cold, the fœtus uſually ſoon ſtirs, and the very figure and appearance of the belly will give very probable aſſurances to a perſon accuſtomed to ſuch inſpections. In caſes of a certain conception, a living fœtus is only to be diſtinguiſhed from a mole or falſe conception by its moving; therefore when a perſon grows toward the full time, without ever perceiving the child to ſtir, it is very much to be ſuſpected that it is a mole; which alſo is the more probable, if the menſtrual diſcharges have come on at times and irregularly, during the time, and the ſwelling of the belly be irregular, the woman ſubject to violent flatulencies, and eſpecially if ſhe go beyond the natural period of nine months.

Theſe ſymptoms are not all, however, to be expected in every *pregnant* woman; for many of the laborious people of the lower claſs of life, go thro' their whole time in the midſt of fatigue and trouble, and that without any of theſe ſymptoms; ſo that they are in a great meaſure to be attributed to the courſe of life, not the courſe of nature, in the *pregnant* women of better fortunes. Thoſe women are moſt ſubject to them who are of a tender and delicate frame, and thoſe who are of a plethoric habit, an idle life, or given to intemperance, or ſubject to paſſions of various kinds, fear, anger, grief, or the like.

Theſe are the more natural and leſs troubleſome ſymptoms of *gravidation*, but this time is frequently attended with others more troubleſome or hurtful, which art is able in ſome degree to mitigate. Some are ſubject to violent hæmorrhages at the noſe, which are to be treated in the common way, and are uſually as eaſily cured as any other complaints of that kind. In others the hæmorrhoidal diſcharges are very large during the time. Theſe are to be aſſwayed by giving powders of nitre, cinnabar and crab's eyes, once or twice a day. Some are alſo ſubject to an hæmorrhage of the uterus itſelf, but this very rarely happens; when it does it may be owing to two cauſes, and therefore appear in two manners. In the

firſt it flows as in the common way of the menſtrual diſcharges, during the firſt months of *pregnancy*, and by that means greatly diſturbs the regular calculation of the time. In the other caſe it ſtops during the firſt months, but comes on again about the middle of the time, or later than that, and in this caſe it uſually continues regularly to the time of delivery; both theſe caſes bring on great danger of miſcarriages. In theſe caſes nitrous cinnabarine and abſorbent medicines are to be given; to theſe are to be added corroborating ones, and bleeding in the arm muſt never be omitted.

Head-achs often alſo attend women during their *pregnancy*: theſe are principally owing to occaſional cauſes; ſuch as violent emotions either of the body or mind, an improper cooling of the lower parts of the body, or the drinking ſpirituous liquors. The method of taking off this troubleſome ſymptom is, by giving the attemperating and nitrous medicines, with laxatives of the moſt gentle kind, and externally the head ſhould be rubbed with ſpirit of wine and camphor, if the perſon can bear the ſmell of it, which often in this caſe they cannot.

A wearineſs and laſſitude of the limbs is another very common and very troubleſome accident attending *pregnancy*, and is to be remedied by proper bleedings and gentle exerciſe; and if theſe fail, the nitrous powders before given may be added to quiet the emotions of the blood, and this uſually takes effect.

A dry cough and difficulty of breathing are alſo not unfrequently attendant on this ſtate: theſe require the ſame methods; but when the difficulty of breathing comes on after meals, the ſaline and digeſtive powders may be given in ſmall doſes; ſuch as the vitriolated tartar, with the nitrous and abſorbent powders; and when it comes on only in the latter months, and ariſes merely from the preſſure of the diſtended uterus, there is no cure but patience till the time of delivery; when the ſymptom always goes off of itſelf on the ſubſiding of the womb. *Junk.* Conſp. Med. p. 701.

The French memoirs give us an account of a very unhappy ſtate of *pregnancy* in a young woman of ſeventeen, attended with ſymptoms not common to that ſtate. The child lay on the right ſide, and grew to ſo conſiderable a ſize that ſhe could not ſtir; it died ſoon after, and was taken from her dead and in ſeparate pieces. In the latter months of her *pregnancy* ſhe was troubled with a terrible oppreſſion in the breaſt and difficulty of reſpiration, attended with violent palpitations of the heart: her delivery gave her no eaſe as to theſe ſymptoms, but they continued increaſing in violence for five years. In this time, as ſhe was young ſhe grew in height, and had two children, which both lay on the right ſide alſo, and of which ſhe was delivered without any particular bad ſymptoms. After theſe five years the bad ſymptoms of her diſeaſe became at a ſtand, and in her thirty-ninth year ſhe died.

The body being opened after her death, the round and the broad ligament of the uterus were both found much ſhorter on the right ſide than on the other, and were more compact and thick on that ſhort ſide. The uterus was larger than uſual, and inclined a little to the right ſide; and the great lobe of the liver, which ought to be hollow behind, convex before, and narrow and ſtrait at the bottom, large and thick at the top, and wholly included in the cavity of the belly, was in this ſubject of a conic figure, nine inches long, and four inches broad at the baſe, which was its lower part, and two at the point; and half its quantity was depoſited in the cavity of the breaſt, and all the parts on the ſame ſide. The kidney, the diaphragm, and the lungs, appeared, as well in regard to one another as to the neighbouring parts, to have been all conſiderably puſhed upwards by the matrix. The too great force of the ligaments of the uterus on the right ſide, had drawn the uterus itſelf to that ſide, and determined the fœtus to that part; and unhappily that had been particularly large, and had extended the influence of its preſſure upon the viſcera above it, even to the lungs. The duration of the ſymptoms was owing to this, that the parts having been diſplaced for a long time together during the latter months of the firſt *pregnancy*, could not reſtore themſelves to their places again, even when the obſtacle was removed; ſo that the ſymptoms continued, even tho' the firſt cauſe was removed; and the growth of the young woman only increaſed them. Mem. Acad. Par. 1709.

The miſcarriage of *pregnant* women is principally owing to a plethora, and is moſt frequent with young plethoric women, in the firſt months of their firſt *pregnancy*. There are, however, ſeveral other cauſes which concur to it; ſuch are, any violent paſſions of the mind, as ſudden anger, fear, or the like; an habitual great diſcharge at the time of the menſes, a high-ſeaſoned diet, with much wine or other ſtrong liquors; the taking of ſtrong purges, or violent emetics; diarrhœas, eſpecially when of long continuance and of the aromatic kind, as they drain off the nouriſhment from the fœtus; a teneſmus, or violent motion to ſtool, and hence the uſe of ſtimulating glyſters may alſo bring on abortion; as alſo any commotions of the body, ſuch as running, leaping, the carrying heavy burthens, falls, or blows on the abdomen: a too frequent uſe of venery may alſo occaſion it, as may the effect of ſtrong emmenagogues, copious bleeding in the foot, the ſmell of burning oil or any other ſtinking ſubſtance, nephritic complaints, cachexies, a fluor albus, or other diſorder of the womb; the taking opiates, and the death or great debility of the fœtus while in the womb. The beſt methods of preventing abortion, are the uſe of the attemperating and particularly the nitrous medicines after every commotion of the blood; bleeding at proper times, corroborating medicines, and the milder carminatives; and to theſe are to be added a temperance in diet, and placid motion of the body. Egg-ſhells are by ſome greatly recommended, and by others the ſtones of reſins, which are, indeed, manifeſtly aſtringent.

Coſtiveneſs in the time of *pregnancy* is very common, and is uſually owing to the want of drinking and exerciſe; ſometimes, indeed, it is owing to the immediate preſſure of the womb upon the rectum; but this caſe is known from the others, as it is always attended with a teneſmus. This complaint is to be relieved by a lubricating diet, the drinking more liquids than before, and the uſing placid motion of the body, or gentle exerciſe. Gum ammoniacum is alſo found a very uſeful medicine in this caſe, and ſometimes gentle infuſions of ſenna are neceſſary; but theſe can only be given in very ſmall doſes. Some uſe ſuppoſitories that are not acrid or pungent, and others glyſters of water-gruel.

Flatulencies are another very frequent complaint with *pregnant* women: theſe are removed by the milder carminatives, ſuch as, orange-peel, pimpernel-root, and the ſeeds of aniſe, ſweet fennel, &c. taken in powders or in decoctions.

Diarrhœas, in *pregnant* women, are uſually from the ſame cauſes with thoſe in other perſons; but they require in this caſe a very peculiar regard, as they, when long continued and accompanied with a teneſmus, uſually bring on abortion. They are to be gently reſtrained, and finally ſtopped, in the following manner: ſtrengthening, carminative and ſtomachic medicines are to be given, ſuch as candied orange-peel, preſerved ginger, calamus aromaticus, galengals and zedoary, and the marmalade of quinces; and while theſe are taken internally, balſams and ſtomachic plaiſters applied to the ſtomach have alſo a very great effect.

The fluor albus. This is a complaint that very rarely affects women with child, eſpecially if their huſbands be honeſt; but when it does, it is very difficult of cure, becauſe the purging medicines neceſſary to be given in it are by no means to be allowed of in the time of *pregnancy*. In this caſe it can only be reſtrained by the uſe of correctives, depuratives, and carminatives: of this kind are infuſions of the bitter herbs, with pimpernel-root, balm, ſouthernwood, and white dead nettle-flowers; or theſe ingredients may be made into powders, and taken in red wine.

Beſides all theſe complaints, women in their *pregnancy* are ſubject to ſeveral others which depend upon the mere weight and preſſure of the uterus. Of this kind are:

Pains in the loins and back. Theſe are principally felt in the laſt months, when the belly is greatly ſwelled and drawn forwards; in others, at the ſame period, the belly itſelf is pained, and looks red in many places, as if it threatened to burſt. Theſe complaints are made worſe by all motion, and they admit of no cure but child-birth, which immediately takes off the whole pain.

Varicous tumors of the legs. Theſe are alſo very common and very troubleſome, and in phlegmatic habits have alſo very frequently œdematous tumors joined with them; and in other perſons livid marks appear upon them, ſuch as are ſeen in others after bruiſes. Theſe diſtemperatures of the legs attend *pregnant* women at all times from the ſecond month to the time of delivery, and are owing to the preſſure of the uterus upon the iliac or crural veſſels. Theſe always go off on delivery, but in many perſons return again at every *pregnancy*: in ſome caſes they are ſo ſlight as not to be worth regard in others they are very violent and painful; theſe are to be treated in the following manner: the common antiſpaſmodic powders are to be given internally once or twice every day, and externally, a moderate bandage, with camphorated medicines and friction; and if theſe fail, a liniment made of lime-water, oil of elder, and ſugar of lead, will be found of great ſervice; and when the perſon is delivered, gentle ligatures are to be uſed all up the leg, from the ankle to the knee. In order to prevent theſe tumors for the future, early in the time of *pregnancy* the perſon ſhould be blooded, the bowels are to be kept from coſtiveneſs; and it is a thing of the greateſt conſequence, that the perſon uſe herſelf to ſit upon a high ſeat, the low chairs in which *pregnant* women uſually love to ſit making the belly preſs greatly more on the crural veſſels than it would otherwiſe. Too much exerciſe alſo is to be avoided, and particular care taken that the womb is well cleanſed before the month of a former lying in is over.

Frequent deſire of voiding the urine often attends, and is very troubleſome to *pregnant* women; but eſpecially in the later part of their time, particularly in the laſt weeks: if it happen ſooner, as it ſometimes does, it is owing to the womb's hanging too much downward, from a laxity of the ligaments. This is a complaint of no ill conſequence, and therefore, tho' troubleſome, is to be borne with patience, delivery being its proper cure.

A Strangury and temporary ſuppreſſions of urine happen alſo frequently

quently to *pregnant* women. In theſe caſes powders of nitre and cinnabar are to be given internally, and externally emolient cataplaſms are to be applied warm till the diſorder ceaſes.

Hæmorrhoides. Theſe in *pregnant* women often ſwell into a ſort of bladders, and are attended with a violent burning pain, and ſometimes with an ulcerous eroſion, and are uſually a very troubleſome complaint to perſons of plethoric habits. They are to be cured by giving internally nitrous and other attemperating medicines, and applying externally the unguentum linariæ, made of the herb toad-flax, cut and boiled in lard. A decoction or extract of yarrow is alſo a good medicine.

Swellings of the feet are another of the troubleſome complaints that attend *pregnant* women. Theſe, when they are confined to the feet, or do not extend above the knees, are of no great harm; but they ſometimes reach up to the abdomen, and there leave the ſymptoms of an aſcites: but even in this caſe, it is beſt to let the tumor alone during the time of *pregnancy*, or at the utmoſt only to attempt mitigating and allaying its ſymptoms; for the cure requires ſuch medicines as cannot be ſafely given at that time. The patient muſt avoid ſtanding as much as poſſible, and after delivery the cure is to be attempted in the common way. When women in their *pregnancy* loſe their fleſh, and become extenuated and thin, the child is uſually found to be the luſtier and more robuſt for it: the woman in this caſe ſhould feed on jellies, and other the moſt nouriſhing foods, and ſhould uſe very little exerciſe, avoiding all fatigue of body and mind. Others, on the other hand, are ſubject to grow remarkably fat during their *pregnancy*: theſe generally bring forth ſmall and lean children. Women to whom their fat grows troubleſome in this time, ſhould bleed, uſe moderate exerciſe, a thin diet, and now and then take a very gentle doſe of ſome laxative medicine.

Many are very weak and ſubject to frequent faintings during *pregnancy*: theſe ſhould take at times a gentle doſe of ſome laxative medicine, and in the intermediate days, the ſtrengthening and ſtomachic medicines, with the milder carminatives.

A voiding of the waters too ſoon always threatens abortion, or an untimely delivery, which are to be guarded againſt by ſtrengthening medicines of all kinds. Many women during *pregnancy* are troubled with large brown ſpots, or lichenes, in the neck and face: theſe principally happen to perſons of bilious habits, and are in ſome attended with a continual paleneſs, in others with frequent fluſhings of heat and redneſs: the good women apply many remedies to theſe, but they are much better wholly let alone; for they always go off of themſelves after delivery.

The too great motion of the fœtus is a complaint not uncommon with *pregnant* women; but this is principally owing to themſelves, and is brought on by the violent paſſions of the mother, eſpecially thoſe of anger: the keeping the abdomen too hot will alſo occaſion this, and ſometimes it is owing to ſome indiſpoſition of the fœtus itſelf. If any medicines are to be given in this caſe, it muſt be the attemperating ones, and ſuch as can correct the acrimony of the bilious juices; nervous epithems may alſo be externally applied, and the perſon is to be kept in as tranquil a ſtate as poſſible, both as to bodily motion and the paſſions of the mind.

The child's kicking in the uterus is a complaint very frequent in the laſt months of *pregnancy*, and in perſons of tender habits it often occaſions tears, and ſometimes faintings. Some ſuppoſe that this threatens abortion; but this is wholly erroneous, for the fœtus has no power of contributing to its own birth. This is a ſymptom for which there is no remedy but patience, but it goes off before the time of delivery.

Weakneſs of the fœtus is known by its feeble motion in the womb, and uſually depends on the bad conſtitution of the mother, or elſe on her having been ſubjected to violent frights, or to great ſorrow. Internal medicines of the ſtrengthening kind are proper in this caſe, and externally, balſamic and aromatic plaiſters may be applied.

The ſecundines ſometimes concrete or grow to the uterus, out of their proper order and place: this is a diſorder we have but very ſlender opportunities of gueſſing at, and is principally cauſed by too much ſitting ſtill during the latter part of *pregnancy*. When this is ſuſpected to be the caſe, internal medicines are of no uſe; and the externals are only the fat of tender animals, or ſpirit of wine impregnated with oils of anniſe or caraway, frequently rubbed in on the belly.

The winding of the navel-ſtring about the neck of the child is often a very unhappy accident and proves fatal to it: the good women ſuppoſe this to be owing to the mother's reaching upwards, and ſtraining her arms above her head near the time of her delivery; but this is an idle opinion, and the caſe is owing to no ſudden accident, but is probably an unlucky turn of the ſtring from the beginning. *Junker*'s Conſp. Med. p. 708. See LYING-*in*.

PRENANTHES, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the compoſite kind; the common cup is of a cylindric figure, and has a wide mouth; there are five equal ſquammæ, and three unequal ones, which are ſmaller, and placed at the baſe. The flower is compound, not imbricated; it is compoſed of equal flowers of the hermaphrodite kind, placed in a ſingle circle; each ſingle flower is compoſed of one petal, and is ligulated, truncated, and divided into five ſegments at the edge; the ſtamina are five very ſhort and capillary filaments; the antheræ are cylindric and tubular; the germen of the piſtil is placed below the flower; it is ſmall; the ſtyle is capillary and longer than the ſtamina; the ſtigma is bifid and reflex; the cup, after the flower is fallen, joins its ſeveral ſegments lightly at the top; and the ſeeds are ſingle, of a cordated figure, and winged with a ſlender downy filament; the receptacle is naked. There is one ſpecies of this plant in which the down has a pedicle. *Linnæi* Gen. Pl. p. 374.

PREPARATION *(Cycl.)*—PREPARATION, in anatomy, is uſed for the art of preſerving the parts of animal bodies for anatomical uſes.

It is alſo uſed to ſignify the parts themſelves ſo preſerved. Mr. Monro has given us an eſſay on the method of *preparing* and preſerving the parts of animal bodies for anatomical uſes. Med. Eſſ. Edinb. Vol. III. Art. 10.

The manner of preſerving anatomical *preparations*, is either by drying them thoroughly in the air, or putting them into a proper liquor.

In drying parts which are thick, when the weather is warm, care muſt be taken to prevent puttefaction, fly-blows, inſects, *&c.* This is eaſily done by the uſe of a ſolution of corroſive ſublimate in ſpirit of wine, in the proportion of two drachms of ſublimate to a pound of ſpirit: the part ſhould be moiſtened with this liquor as it dries, and by this method the body of a child may be kept ſafe even in ſummer. Dried *preparations* are apt to crack and moulder away in keeping; to prevent this their ſurface ſhould be covered with a thick varniſh, repeated as often as occaſion requires. Med. Eſſ. Edinb. abr. Vol. II. p. 8.

Tho' ſeveral parts *prepared* dry are uſeful, yet others muſt be ſo managed as to be always flexible, and nearer a natural ſtate. The difficulty has been to find a proper liquor for this purpoſe. Mr. Monro ſays, the beſt he knows is a well rectified colourleſs ſpirit of wine, to which is added a ſmall quantity of the ſpirit of vitriol or nitre. When theſe are properly mixed, they neither change their colour nor the conſiſtence of the parts, except where there are ſerous or mucous liquor contained in them. The brain, even of a young child, in this mixture grows ſo firm as to admit of gentle handling, as do alſo the vitreous and chryſtaline humours of the eye. The liquor of the ſebaceous glands and the ſemen are coagulated by this ſpirituous mixture; and it heightens the red colour of the injection of the blood veſſels, ſo that after the part has been in it a little time, ſeveral veſſels appear which were before inviſible. If you will compare theſe effects with what Ruyſch has ſaid of his balſam, you will find the liquor above mentioned to come very near to it.

The proportion of the two ſpirits muſt be changed according to the part *prepared*: for the brain and humours of the eye, you muſt put two drachms of ſpirit of nitre to one pound of ſpirit of wine. In preſerving other parts which are harder, thirty or forty drops of the acid will be ſufficient; a larger quantity will make bones flexible, and even diſſolve them. The part thus preſerved ſhould be always kept covered with the liquor, therefore great care ſhould be taken to ſtop the mouth of the glaſs with a waxed cork and a bladder tied over it, to prevent the evaporation of the ſpirit; ſome of which, notwithſtanding all this care, will fly off; therefore freſh muſt be added as there is occaſion. When the ſpirits change to a dark tincture, which will ſometimes happen, they ſhould be poured off, and freſh put in their room; but with ſomewhat leſs acid than at firſt.

The glaſſes which contain the *preparations* ſhould be of the fineſt ſort, and pretty thick; for through ſuch the parts may be ſeen very diſtinctly, and of a true colour, and the object will be ſo magnified as to ſhew veſſels in the glaſs which out of it were not to be ſeen.

As the glaſs when filled with the liquor has a certain focus, it is neceſſary to keep the *preparation* at a proper diſtance from the ſides of it, which is eaſily done by little ſticks ſuitably placed; or by ſuſpending it by a thread in a proper ſituation. The operator ſhould be cautious of putting his fingers in this liquor oftener than is abſolutely neceſſary; becauſe it brings on a numbneſs on the ſkin, which makes the fingers unfit for any nice operation. The beſt remedy for this is to waſh them in water mixed with a few drops of oil of tartar per deliquium. Med. Eſſ. Edinb. abr. Vol. II. p. 9.

Dr. Chriſt. Jac. Trew prefers the rectified ſpirit of grain for preſerving anatomical *preparations* to ſpirit of wine, or compoſitions of alcohol, amber, camphor, *&c.* becauſe theſe ſoon change into a brown colour; whereas the ſpirit from malt preſerves its limpid appearance. When any part is to be preſerved wet, waſh it with water till it is no more tinctured. The water is next to be waſhed away with ſpirits, and then the *preparation* is to be put among ſpirits in a glaſs, the mouth of which is to be cloſely covered with a glaſs head, over which a wet bladder and leaf-tin are to be tied. Com. Lit. Norimb. 1731. Semeſt. 1. Specim. 9.

PREPARATION *of inſects*, in anatomy. See INSECTS.

PRESA, in the Italian muſic, is in general a character which ſhews when and where a performer in a concert is to begin to

ſing or play: but in particular, in fugues or canons it is thus marked + over the note at which the ſecond part, which is to follow or imitate the firſt, muſt begin. If the mark be repeated a ſecond time, it is to ſhew the place where the third part muſt begin, to imitate the ſecond; and ſo on through all the parts. See USUS.

PRESBYS, in zoology, a name uſed by many of the antient naturaliſts for the *regulus criſtatus*, or golden-crowned wren. *Ray*'s Ornithol. p. 163. See REGULUS *criſtatus*.

PRESERVATION *of Corn.* A ſucceſsful method of *preſerving corn*, for the uſe of armies, and againſt times of ſcarcity, is a moſt uſeful and curious object of enquiry.

It is well known that accident often preſerves *corn* very long, when all the care in the world ſuffers it to decay in a few years, the owner knows not why. One very remarkable inſtance we have recorded in the memoirs of the academy of ſciences at Paris, in 1708, of ſome *corn* laid up in the citadel of Metz, in the year 1578, which had kept good to that time without any particular care. It was on this occaſion that the ſubject of *preſerving corn* in general became the employment of the thoughts of the members of the academy, and Mr. Reneaume obſerved,

1. That *corn* can never be too dry when it is brought into the granary, if intended for long keeping; and that in order to keep, it muſt be preſerved quite dry and quite clean.

2. That tho' ſome have imagined that *corn* increaſes in ſize in the granary, and therefore ſhould be cut after a wet ſeaſon, and in dewy mornings; yet on the contrary, *corn* never ſwells, if well preſerved, but always ſhrinks and wrinkles up a little: and that the *corn* of dry ſeaſons is always obſerved to keep much better than that of wet ones, which uſually heats and decays. And that as to dewy mornings, they are never to be choſen for reaping, unleſs on particular occaſions; as when the ſeaſon has been ſo remarkably dry, that the *corn* is looſe in the ears: then, indeed, there is danger of its being loſt by falling out while the reaper cuts the ſtalk, and this is prevented by cutting it while the dew has wetted the huſks, or the grains of *corn*, and retains them in their places.

4. It is very certain, that any *corn* which is dry will, on laying it in a moiſt place, ſwell and increaſe in bulk, and will become larger by this means. The merchants generally are able to find this out, however, and do not care to buy ſuch *corn*, well knowing that it is very ſubject to mould and decay. There is another yet more artful method than this in too common uſe among the petty merchants, who buy up *corn* to ſell it to the larger dealers, which is this: they heat a large piece of freeſtone, and incloſing it in an iron box, they thruſt it under the heap of *corn*, and carefully remove it about to every part, at the ſame time gently moiſtening the *corn*; the effect of this is a very conſiderable ſwelling of the *corn*, inſomuch that what they buy as ſixteen buſhels, they ſell after this for ſeventeen; but there is no wonder that *corn*, treated in this manner cannot keep. This is an artifice often practiſed alſo on oats, and is more profitable in that, as the oats will gain at leaſt twice as much in quantity by it as wheat or barley.

5. If it is abſolutely neceſſary at any time to lay up *corn* in a place that is damp, it is beſt to lay it up in the ear, not in the looſe ſtate, ſince in that caſe the ſtalk and huſks will abſorb a great quantity of the moiſture, and preſerve the *corn* in ſome degree from it. The leaving the chaff with the *corn*; that is, the threſhing, but not fanning it, may alſo be of uſe in many caſes, and this takes up but little room in a magazine, and it is much the ſame thing to the proprietor, whether it be all fanned together, or be only fanned in quantities ſufficient for a certain number of days, as it is wanted to be uſed; but tho' the trouble is the ſame, the advantage is not ſo, but is greatly on the ſide of the latter practice: we all well know the uſe of chaff, and the like dry ſubſtances in preſerving fruits for the winter; and this might alone give a hint that *corn* might fare the better for it; but we have alſo this additional mark of its uſe in preſerving *corn*, that the zea or ſpelta, called ſpelt *corn* and white *corn*, and uſed for food in many parts of Germany, is always preſerved in the huſk, and is found the leaſt ſubject to decay of all *corns*.

From theſe conſiderations it is eaſy to learn, what are to be the principal objects of our care in the preſerving *corn* for the uſe of armies, *&c.* The granary muſt be a well choſen place; and according to Vitruvius's rules, ſhould always be at the top of a houſe, and have its openings only to the north or eaſt, that the *corn* may not be expoſed to the damp winds from the ſouth and weſt, which are very deſtructive to it; whereas the contrary ones are very neceſſary and wholeſome to it, ſerving to cool and to dry it from all external humidity, from whatever cauſe. There muſt alſo be openings in the roof to be ſet open in dry weather, partly to let in freſh air, and partly to let out the warm effluvia which are often emitted by the *corn*. The covering of the roofs ſhould always be of tiles, becauſe in the worſt ſeaſons, when the other openings cannot be ſafe, there will always be a conſiderable inlet for freſh air, and a way out for the vapours by their joinings, which are never cloſe. If there happen to be any windows to the ſouth, great care muſt be taken to ſhut them up in moiſt weather, and in the time of the hot ſouthern winds.

There muſt never be a cellar, or any other damp place under a granary, nor ſhould it ever be built over ſtables; for in either of theſe caſes the *corn* will certainly ſuffer by the vapours, and be made damp in one and ill-taſted in the other. Mem. Acad. Par. 1708.

The accidents that attend *corn* in public granaries, are of the utmoſt importance, and ought to be well underſtood and guarded againſt. See GRANARY.

Dantzic is the grand ſtorehouſe, or repoſitory of all the fruitful kingdom of Poland. The wheat, barley, and rye, of a great part of the country are there laid up in parcels of twenty, thirty, or ſixty laſts in a chamber, according to the ſize of the room; and this they keep turning every day or two, to keep it ſweet and fit for ſhiping. A thunder ſtorm has ſometimes been of very terrible conſequence to theſe ſtores. All the *corn* of the growth of former years having been found ſo much altered by one night's thunder, that tho' over night it was dry, fit for ſhiping or keeping, and proper for uſes of any ſort, yet in the morning it was found clammy and ſticking. In this caſe there is no remedy, but the turning all ſuch *corn* three or four times a day for two months or longer; in which time it will ſometimes come to itſelf, tho' ſometimes not.

This effect of thunder and lightning is only obſerved to take place in ſuch *corn* as is not a year old, or has not ſweated thoroughly in the ſtraw before it was threſhed out. The latter inconvenience is eaſily prevented by a timely care; but as to the former, all that can be done is carefully to examine all ſtores of the laſt year's *corn* after every thunder ſtorm, that if any of this have been ſo affected, it may be cured in time; for a neglect of turning will certainly utterly deſtroy it. Phil. Tranſ. N°. 96.

PRESERVATION *of other vegetables.* This is to be done ſeveral ways in the ſeveral kinds, and many more might certainly be invented; for we are not yet arrived at the perfect method of *preſerving vegetables* with their colours, odours, and all their ſenſible qualities, as well as their natural form for a number of years. Fruits may be long *preſerved* in ſpirit of wine, firſt well ſaturated with the ſkins and tinging parts of thoſe fruits; and many may be tolerably *preſerved* in perfectly fermented liquors, which generate no more air. The more ſolid *vegetable* ſubſtances may be *preſerved* by gently drying in the ſun ſhade, or other ſlack heat. Thus peas or beans may be dried young in a ſlack oven in their proper ſeaſon, and may afterwards be boiled in the winter, and will eat young and tender, as if juſt gathered. The ways of *preſerving* fruits both dry and moiſt, with ſugar, are now univerſally known; and there are in the ſeveral ways many ſecrets in the hands of particular artiſts, which it would be well to have generally known. *Shaw*'s Lectures, p. 196.

PRESS *(Cycl.)*—PRESS, in the manege. A horſe is ſaid to reſiſt, or *preſs* upon the hand, when either through the ſtiffneſs of his neck, or from an ardour to run too much a head, he ſtretches his head againſt the horſeman's hand, refuſes the aid of the hand, and withſtands the effects of the bridle.

If your horſe is too fiery, and *preſſes* upon the hand, endeavour to pacify him, by making him go more ſoftly, and pulling him backwards; and if it proceeds from a ſtiffneſs of the ſhoulders and neck, you muſt ſupply him with a caveſſon made after the Duke of Newcaſtle's way. See HEAVY.

PRESS is alſo uſed for puſhing a horſe forewards, by aſſiſting him with the calves of your legs, or even ſpurring him, in order to make him go on.

PRESS, or PRESSING, in the ſea language. See MANNING.

PRESTER, *(Cycl.)* a word uſed by ſome to expreſs the external part of the neck, which is uſually inflated in anger: with others it is a name for the ſerpent *dipſas*.

PRESTESSE, in the manege, is uſed to denote the readineſs and diligence of a horſe in working a manege.

PRESTISSIMO, in the Italian muſic, intimates to perform extremely quick, haſtily, and with fury.

PRESTO, in the Italian muſic, is uſed to ſignify that the part it is joined to ſhould be performed gayly, faſt and quick, yet not with rapidity.

Non tropo PRESTO, or *men* PRESTO, in the Italian muſic, ſignifies not too quick, or leſs than *preſto*.

Piu PRESTO, in the Italian muſic, is uſed to intimate that we ſhould ſing, or play the part to which it is annexed, a little briſker and quicker than the *preſto* alone requires. When *piu* is added to other words, as *adagio*, *grave*, *vivace*, &c. it adds in like manner to the ſlowneſs, or quickneſs of the movements, reſpectively.

PRESTO, PRESTO, in the Italian muſic, the ſame with *preſtiſſimo*. See PRESTISSIMO.

PRESUMPTION, *præſumptio*, in rhetoric, the ſame with *prolepſis*. See PROLEPSIS.

PRETERNATURAL *rains*. See the article RAINS.

PRIAPE *de mer*, in natural hiſtory, a name given by the French to a peculiar ſpecies of canalis, or tubulus marinus, called alſo by ſome authors of that nation, the *arroſoir*.

It is an oblong, and thick-ſhell of this kind, with a large head, which is pierced thro' with a great number of holes, ſo as at once to reſemble, in ſome ſort, the glans of the penis, and the head of a common gardener's watering-pot. This ſpecies is found at Amboina. See CANALIS.

PRIAPEIA, *(Cycl.)* in botany, a name given by John Bauhine and ſome other authors, to the ſmall ſpecies of tobacco called by Mr. Tournefort and others, *nicotiana minor*. See the article NICOTIANA.

PRIAPOLITHUS, a name given by ſome authors to a ſtone found about Caſtro in Italy, which very aptly reſembles the figure of the human penis.

PRICK *(Cycl.)*—PRICK, or PINCH, in the manege, is to give a horſe a gentle touch of the ſpur, without clapping them hard to him. To *prick* or *pinch*, is an aid; but to *appuyer*, or bear hard with the ſpur, is correction.

PRICKING *(Cycl.)*—PRICKING *of a horſe's foot*, in the manege, is the hurt received by a nail driven too far into the foot, ſo as to reach the quick, or preſs the vein in the horſe's foot when he is ſhod.

PRICKLE *back*, in natural hiſtory, a ſmall fiſh ſo called from the *prickles* on its ſides and back. Vaſt numbers of theſe little fiſh are to be found in almoſt all freſh waters, wherever it is poſſible for fiſh to live, as Mr. Arderon informs us, Phil. Tranſ. N°. 482. ſect. 15. who gives us ſome account of theſe creatures. They are very deſtructive to the ſpawn of all ſorts of fiſh; and they themſelves are tormented to death by a kind of louſe of an oval figure, with eight legs and a very tranſparent body. This louſe has little fins always in motion, whether it be ſwimming about or fixed on the fiſh.

PRIDE *of the Iſis*, a name given by Dr. Plot to the common lampern, from its being found very plentifully and very delicate in that river.

It is to be obſerved, that we diſtinguiſh between the lampern and lamprey, which, tho' words very nearly the ſame in ſound, are yet the names of two different fiſhes: what we call the lampern, is the *lampetra parva fluviatilis* of Willughby; this is the fiſh found in the Iſis. The lamprey is the *lampetra* of Willughby, and others: they are both ſpecies of the petromyzon of Artedi. See the articles PETROMYZON and LAMPETRA.

PRIDE *gavel*, a cuſtom in the manor of Rodely in the county of Glouceſter; by which to this day a rent is paid to the lord, by certain tenants, in duty and acknowledgement to him for their liberty and privilege of fiſhing for lampreys or lamprids in the river Severn. *Tayl.* Hiſt. Gavelk. 112. *Blount.*

PRIMIER *(Cycl.)*—PRIMIER *ſerjeant*, the King's firſt ſerjeant at law.

PRIMING *(Cycl.)*—PRIMING-*iron*, in gunnery, a ſmall ſharp iron, which is thruſt into the touch-hole of a great gun, and pierces into the cartridge that holds the powder, that ſo they may put in the *prime*-powder, or touch-powder, to fire off the piece.

PRIMO *(Cycl.)*—PRIMO, in the Italian muſic, is often abridged thus, P°. or I°. and added to other words, as, *primo canto*, the firſt treble; *alto primo*, the firſt counter tenor; *tenore primo*, the firſt tenor; *baſſo primo*, the firſt baſs; *fagotto primo*, the firſt baſſoon; *choro primo*, the firſt chorus, *&c.*

PRIMULA, *or* PRIMULA *veris*, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: the cup is a general involucrum, ſmall, compoſed of many leaves, and containing ſeveral flowers. The ſeparate perianthium of every flower is tubular, and of a pentagonal figure, compoſed of one leaf, divided into five ſegments, placed erect, and remaining when the flower is fallen. The flower is compoſed of only one leaf, in form of a cylindric tube, of the length of the cup, terminated by a ſmall hemiſphere neck. The margin is ſpread open, and divided into five ſegments, which are obtuſe, inverted in the ſhape of a heart at their ends, and have a rim round their edges. The ſtamina are five very ſhort filaments, ſituated within the tube of the flower. The antheræ are erect, pointed, and converge toward one another at their ends. The germen of the piſtillum is globoſe. The ſtyle is ſlender, and of the length of the cup, and the ſtigma is globoſe. The fruit is a cylindric capſule, nearly of the length of the cup, covered, containing only one cell, and ſplitting open. Its top is dented into ten ſegments. The ſeeds are numerous and round. The receptacle is of an oblong oval figure and free. *Linnæi* Genera Plant. p. 63.

The characters of this genus, according to Mr. Tournefort, are theſe: the flower conſiſts of only one leaf, which is expanded wide at the mouth, and divided into ſeveral ſegments. The cup is tubular, and from it ariſes a piſtil, which is fixed like a nail into the hinder part of the flower, and afterwards becomes a fruit, or an oblong caſe, cloſely ſurrounded by the cup, and containing ſmall roundiſh ſeeds, affixed to a placenta.

The ſpecies of *primula*, enumerated by Mr. Tournefort, are theſe: 1. The ſweet yellow-flowered ſingle *primula*, commonly called the *cowſlip*. 2. The taller ſingle *primula*, with a paler flower. 3. The ſcentleſs *primula*, which has no cup to the flowers. 4. The ſcentleſs *primula*, with double flowers. 5. The ſweet *primula*, with indented or diſſected cups. 6. The *primula*, with a foliaceous head inſtead of flowers. 7. The yellow, mountain, hairy *primula*. 8. The red-flowered *primula*. 9. The white-flowered *primula*. 10. The great ſcarlet umbellated *primula*, with a foliaceous ſtalk and foliaceous flower. 11. The leſſer yellow umbellated *primula*, with a foliaceous ſtalk and flower. 12. The garden umbellated yellow *primula*. 13. The garden white umbellated *primula*. 14. The garden red umbellated *primula*. 15. The ferrugineous umbellated garden *primula*. 16. The common wild many-flowered *primula*. 17. The double many-flowered ſpring *primula*. 18. The ſweet proliferous *primula*. 19. The large-flowered proliferous *primula*. 20. The white-flowered proliferous *primula*. 21. The purple-flowered proliferous *primula*. 22. The ferrugineous-flowered proliferous *primula*. 23. The great-flowered, pale, whitiſh, ſingle *primula*. 24. The pure white ſingle-flowered *primula*. 25. The green-flowered ſingle *primula*. 26. The double green-flowered *primula*. 27. The green and white ſingle-flowered *primula*. 28. The double-flowered ſeparately divided *primroſe*, called *Heſket's primroſe*. 29. The deep green-flowered *primula*, with fimbriated edges. 30. The Conſtantinople *primula*, with a pale purple flower. 31. The Conſtantinople *primula*, with a large purple flower. 32. The Conſtantinople *primula*, with ſmaller purple flowers. 33. The Conſtantinople *primula*, with a ſcarlet flower. 34. The Conſtantinople *primula*, with a ferrugineous flower with white ſpots. 35. The Conſtantinople *primula*, with white flowers. 36. The Conſtantinople *primula*, with pale fleſh-coloured flowers. 37. The Conſtantinople *primula*, with yellow flowers. 38. The Conſtantinople *primula*, with pale lemon-coloured flowers. 39. The Conſtantinople *primula*, with a ruſty whitiſh flower. 40. The Conſtantinople *primula*, with a browniſh flower.

The flowers of this plant are eſteemed greatly cephalic and nervine. They are recommended in palſies, apoplexies, and all nervous diſorders.

The *primula* may be known when not in flower, by their having rugged and wrinkled leaves of a thin conſiſtence. *Tourn.* Inſt. p. 124, 125.

PRIMUS *(Cycl.)*—PRIMUS *Brachii moventium*, in anatomy, a name given by Veſalius, and ſome others who have copied from him, to a muſcle generally known under the name of the *pectoralis*. See the article PECTORALIS.

PRIMUS *communium laryngis*, in anatomy, a name given by Caſſerius and ſome others to the muſcle more generally known by the name of the *ſternothyroidæus*, or *ſterno-thyroides*. See the article STERNOTHYROIDÆUS.

PRIMUS *hyoidis oſſis muſculus*, in anatomy, a name given by Fallopius and ſome others to the muſcle of the *os hyoides*, called by Albinus *ſternohyoidæus*.

PRIMUS *oculum movens*, in anatomy, a name given by Veſalius to one of the four *muſculi recti* of the eye, called by Albinus and others the *adductor*. It is called by Fabricius the *rectus interior*, and by ſome the *bibitorius*.

PRIMUS *propriorum auriculæ muſculus*, in anatomy, a name given by Caſſerius to one of the muſcles of the head, called by Albinus the *auriculam attollens*, and by Cowper and Winſlow *ſuperior auriculæ*, which ſee.

PRINCE *(Cycl.)*—PRINCE *of the Senate*. There was one member of the Roman Senate diſtinguiſhed always from the reſt by the title of *Prince of the Senate*. This title was given of courſe to that perſon whoſe name was called over the firſt in the roll of the Senate, whenever it was renewed by the cenſors. He was always one of conſular and cenſorian dignity.

After the inſtitution of the cenſors, it became a cuſtom to confer this title of *Prince of the Senate* on the oldeſt ſenator then living of cenſorian dignity. Yet there were no peculiar rights annexed to this title, nor any other advantage, except an acceſſion of authority, from a notion which it would naturally imprint of a ſuperior merit in thoſe who bore it. *Middleton* of Rom. Sen. p. 147, 149. See SENATE.

PRINCE *of pleaſantry*, *prince de plaiſance*, in the cuſtoms of Flanders. See SPORTS.

PRINCE *of the horſe-comb*, in the cuſtoms of Flanders. See SPORTS.

PRINCES *feather*, in botany, a name given to the amaranth. See AMARANTH.

PRINCES *metal*. Copper, tho' one of the leſs precious *metals*, yet has been found of ſo great uſe in the common affairs of life, that ſcarce any other has been ſubject to ſo many trials for its improvement, or the rendering it either more beautiful or more fit for certain purpoſes.

One of the firſt diſcoveries in theſe attempts was the making it into braſs, by means of an addition of lapis calaminaris; and tho' it was not at that time known to be a ſtone which contained any *metal*, yet the braſs was always found to weigh one third more than the copper which had been uſed in the proceſs.

This yellow metal gave many people hopes of making copper approach yet nearer to gold, and without knowing that zink was the ſeparated metalline part of lapis calaminaris, the experimenters ſoon found, by happy accident or repeated chance mixtures, that it would give copper a yet finer and purer yellow; but it was alſo found, that this mixed *metal* was much more brittle than braſs made in the common way. This, however, did not prevent the world from ſtill valuing it for ſuch works as were to be finiſhed by caſting, and did not require the hammer: and we, who firſt had it in perfection,

called

called it *princes metal*, from Prince Rupert, whom ſome ſuppoſed to have been the inventor of it; but the greateſt perfection this *metal* was ever brought to, was by two Frenchmen, Mr. La Croix and Mr. Le Blanc. Their methods of making the compoſition, tho' both beautiful, were very different. Mr. Le Blanc's was the brighteſt, and of the moſt elegant and lively colour; but Mr. La Croix's was greatly ſuperior to that in ductility and ſoftneſs, ſo that it was very eaſily malleable.

Mr. La Croix invented a ſort of varniſh or lacquer for his *metal*, which added a ſomewhat deeper tinge to it, as it was naturally rather too pale; and had this farther advantage, that while it remained on the *metal*, it preſerved it from ruſt or decay. This is a very material point in regard to a *metal* of which copper is the baſis, ſince that is, of all other *metals*, moſt ſubject to be injured by the air, or by the contact of liquids of almoſt any kind. Mr. Le Blanc's *metal* is of a deeper, yet equally lively colour, and remarkably bright; and is of ſuch a temper as to be admirably fitted for working. The whole hiſtory of theſe *metals* is certainly, that they are compoſed of zink and copper in different proportions the one to the other; but it is not eaſy, without the help of numerous experiments, to determine what is to be the true proportion for either.

The microſcope, however, ſhews a manifeſt difference, which may lead ſomewhat towards it; for the *metal* of La Croix is ſeen to be compoſed merely of a number of irregular ſtriæ, while the other is diſcovered to conſiſt of always two regular beds of them, which meet in the center of the piece; hence it is that this is always brittle, and will not well poliſh. The fabrick of theſe *metals* was long kept a ſecret; but it was always to be diſcovered by melting it in a crucible in a ſtrong fire, when it always ſent up plain flowers of zink, and the remaining *metal* appeared no other than copper altered by calamine; that is, common braſs. Mem. Acad. Par. 1732.

PRINCIPALIS, in ſome antient Latin writers of muſic, is uſed for the chord or note called ὑπάτη by the Greeks. See the articles HYPATE, TETRACHORD, and DIAGRAM.

PRINCIPIUM *recti abdominis*, in anatomy, a name given by Veſalius to a muſcle generally known at this time under the name of the *pyramidalis*.

PRINCIPLE *(Cycl.)*— Some antient philoſophers diſtinguiſhed between *principles*, ἀρχαὶ, and elements στοιχεῖα. *Principles* according to them, were neither compoſed nor produced; but the elements were complex or compounded beings. *Plutarch*, ap. Eller. in Mem. de l'Acad. de Berlin, 1746.

It would be endleſs to enumerate all the opinions of philoſophers concerning the elements of bodies. A late author has given us a ſummary of many of theſe opinions; and, laſtly, adds his own, that fire and water are the only things which properly deſerve the name of elements, or *principles* of natural bodies; fire being the active, and water the paſſive *principle*. According to him, water is convertible into air, and into earth, by means of fire. Hence the four, vulgarly called elements, may be reduced to two. He endeavours to eſtabliſh his doctrine on the experiments of Boyle, Hales, and Muſchenbroek. Vid. *Eller*, in Mem. de l'Acad. de Berlin, 1746.

Original PRINCIPLE, *principium originale*, a name given by Tachenius and ſome other authors, to ſalt, without conſidering it as acid, alkali, or of any other particular kind, or any mode of exiſtence. The ſalt of wood or vegetables, not being alkali till after burning, and ſo on; but ſalt that is the baſe of theſe, being evidently exiſtent in the bodies, and, in regard to wood, ſeeming indeed to conſtitute its character as ſuch, ſince the evaporation of it cauſes the wood to looſe all its ſtrength and to decay: for we find that in rotten wood there is no alkali at all; and the Venetians, who ſink their timber for ſhip-building into water while it is green, prevent, by that means, the evaporation of thoſe ſalts, and leave the wood little leſs durable than ſtone. On theſe and the like principles, Tachenius ſuppoſes ſalt to be the true *original principle* of bodies; but many others allow this name only to water, or at leaſt that water is, in almoſt all natural bodies, the moſt copious, the moſt active, and the moſt influencing part; yet even this is found to agree much better with ſome bodies than with others. The birch and elder feed more kindly on a thin uliginous moiſture; the elm, the pine, the fir, and cedar, chuſe a ſtronger liquor; yet theſe and many more, the moſt widely different that can be from one another, are often ſeen to draw their whole ſuſtenance and bulk, whether annual or perennial, from the ſame piece of ground, impregnated ſo far as is poſſible to be judged of with the ſame ſort of juices, and from the ambient air and dews, when as yet by our beſt diligence we cannot diſtinguiſh the liquors or ſalts approaching cloſely to their ſeveral roots; and if we wholly take away, and exchange all the earth from the roots of trees whoſe barks, ſap, and fruit, have very much differing ſalts, and are of very different kinds, yet we ſhall find each tree to proſper better by the exchange, inſtead of being injured by it.

Hence we may ſuſpect, that the very contextures of the bodies of plants, from the firſt germination of the ſeed, and as they form gradually from the inviſible *principles* of their ſeeds, are, however ſmall and imperceptible, the natural alembics, where the common water and air are changed into the different juices, gums, reſins, *&c.* as the animal organization in the body of the cow changes the juices of every ſort of graſs and eſculent vegetable, into one and the ſame milk.

The ſea-plants growing on ſhells, or affixed to yet harder ſtones, taking no nouriſhment from the thing they grow on, but being as it were all root, and taking the whole from the ambient water; yet that water giving to different ſpecies of them, tho' itſelf the ſame to all, the different textures of herbaceous to ſome; tough and horny to others; and to ſome, abſolutely ſtony; as to the corals, many of which have been eſteemed by the generality of authors, abſolute ſtones.

Trees of ſeveral different kinds are found in America growing out of the ſame dry and hard rock, and the various kinds of ſucculent plants; the poiſonous ones and their oppoſites, or remedies, as the euphorbium and the antieuphorbium; the moſt acrid and pungent, and the moſt ſoft and emollient, out of the ſame barren lands of Arabia, where it could not be expected that any plant could grow at all. Hence it is eaſy to apprehend, how the ſeeds in their time, and after them the roots, ſtems, and leaves of trees, may be the proper ſtrainers to ſeparate and prepare the ſeveral ſaps and juices, and to ferment the liquors into their ſeveral particular ſalts. See the article VEGETATION and SALT.

PRINCIPLE, in chemiſtry. It is impoſſible to diſcover the virtues of any body, or to find how mixed bodies of different kinds ſtand related to the human body, either for the preſervation of its functions entire, or the reſtoring them when loſt or impaired; or, finally, for the total deſtruction thereof; till we know the *principles* of which they conſiſt, and likewiſe the mixture and proportion of ſuch *principles* in bodies to which their effects are chiefly owing. Wherefore having diſcovered by various ways the parts into which a true chemical analyſis reſolves bodies, we muſt look upon ſuch ſimple parts into which all mixts are reſolvable, and of which they ſeem to be compounded, as their true and genuine *principles*.

The antient chemiſts having obſerved, that in analyſing all bodies whatever, they obtained a ſpirit, or mercury, ſulphur, ſalt, water, and earth, concluded the number of *principles* to be five. If wine, for inſtance, be diſtilled in a proper alembic, a burning water or ſpirit will firſt ariſe, and next an inſipid water, which they call phlegm; a thick viſcid maſs alone remaining in the ſtill; this put into another veſſel, or retort, and expoſed to a more intenſe and violent heat, a ſmall portion of phlegm comes over firſt, then an acid water, which according to them is ſtill ſpirit or mercury, and next a fat oily ſubſtance, called ſulphur: what remains ſtill in the retort is next burnt to aſhes in an open fire; theſe aſhes are thrown into an earthen veſſel, with a proper quantity of boiling water, which they impregnate with their ſalt; this water being filtred thro' cap paper, and afterwards evaporated, leaves the ſalt at the bottom of the veſſel; and the other part of the aſhes, which the water could not take up, or have any effect on, is termed the earth of the ſubſtance, or its caput mortuum.

Of theſe five *principles* the chemiſts have reckoned two to be paſſive, water and earth; and three to be active, ſpirit, ſulphur, and ſalt; and on theſe laſt they have thought the whole virtue of the mixed body depended. In this analyſis we may obſerve, that there is a twofold ſpirit; one oily and inflammable, which riſes firſt by a gentle heat, and is termed ſpirit of wine, another acid penetrating like that of vinegar. Beſide theſe, the chemiſts give the name of ſpirit to other penetrating volatile, or urinous liquors, obtained from the parts of animals; ſuch as the ſpirit of urine, hartſhorn, and ſuch like ſubſtances: but the later chemiſts have baniſhed theſe ſpirits from the number of their *principles*, as being nothing elſe than ſulphur and ſalt diſſolved in water. Thus ſpirit of nitre, and others of that kind, are only acid ſalts in water; ſpirit of hartſhorn, or urine, alkaline ſalts; and ſpirit of wine, or of turpentine, an æthereal attenuated oil.

Some of the moderns deny likewiſe, that either ſulphur or ſalt deſerve the names of *principles* or elements, as not being the moſt ſimple ſubſtances producible by chemiſtry. For ſulphur, when heated with due care, may be reſolved into ſalt, water, and earth; as is evident by diſtilling fetid diſtilled oils ſeveral times with quick-lime, which by this treatment yield in large quantities a volatile ſalt, diſſolved in phlegm, together with a caput mortuum or earth. Æthereal oils alſo are only fat thick oils, like that of olives, attenuated by ſalts and diſſolved in water; as may be proved by theſe two experiments. If oil of olives, or any other of that kind be mixed with a fermenting liquor, ſuch as a ſolution of honey in water; the whole may be converted into an inflammable ſpirit. And if a quart of ſpirit of wine, diluted with ſix quarts of common water, be expoſed in a cold place to the open air, the volatile ſalts will fly off and leave drops of oil ſwimming at top, which are in every reſpect the ſame with oil of olives or almonds.

Salt is no more a *principle* than ſulphur; becauſe it may, by proper management, be at length reduced to earth and water.

Thus

Thus nitre by diſtillation may be almoſt wholly reduced to an acid ſpirit; but if it be burnt with tartar, or charcoal duſt, it becomes an alkali ſalt, called fixed nitre: this, if ſuffered to run per deliquium, and afterwards filtred thro' cap paper, will leave a large quantity of earth behind; and if the ſame liquor be diſtilled to dryneſs, an inſipid water will come over, and the ſalt remaining at the bottom of the retort, will be found to have loſt a great part of its quantity; and if the operation be often repeated, nothing will at length remain but earth. Again, the vitrification of alkaline ſalts ſeems to be nothing but the converſion of them into earth; for glaſs has no qualities different from thoſe of earth.

What we have proved by experiments, in reſolving bodies, may be farther confirmed by others relating to the formation and compoſition of them; and particularly by Van Helmont's famous experiment of the willow. He took about two hundred pounds of earth dried in an oven, and put it into a veſſel covered with an iron-lid full of holes: in this earth he ſet a branch of willow, weighing about five pounds; which ſoon took root, and grew ſo much, that in eight years time it weighed one hundred and ſixty pounds; the earth it ſtood in having, during all this time, loſt only a few ounces; ſo that the whole increaſe of the tree muſt have been owing to rain water, with a very ſmall proportion of earth; and the ſalts and ſulphurs therein muſt have been compoſed of two elements alone. The experiments of this kind, made by the illuſtrious Mr. Boyle on ſmall ſprigs of mint, marjoram, balm, pennyroyal, *&c.* ſet in ſmall vials filled only with pure water, are yet more to be depended on. Theſe increaſe in a ſhort time to double their firſt weight; and being afterwards diſtilled, they yielded the very ſame principles they would have done, had they grown in the moſt proper ſoil. From all this it cannot but be allowed, that ſalt and oil owe their original to water and earth.

Water and earth do indeed, in the ſtricteſt ſenſe, deſerve the name of *principles*; but in the formation of mixed bodies a third *principle* muſt neceſſarily concur with them; for as they are of themſelves wholly unactive, ſomething muſt be ſuppoſed to give them their motion and activity: without this, water would immediately turn to ice; and as there are few bodies out of which fire may not be drawn, it is evdient that there muſt be ſome active, moveable *principle* in them all, to which the motion of the other parts is owing. Therefore, tho' this *principle* ſhould not fall under our ſenſes in the ſame manner as the others do, that can be no reaſon for doubting its exiſtence, ſince it muſt concur in the compoſition of all bodies; which, if they were made of water and earth alone, would remain for ever without any virtue or energy. This they muſt receive from another *principle*; and according to the different combinations of all the three, bodies are formed with different properties and powers. We acknowledge, therefore, three ſimple ſubſtances in bodies, which are properly elements or *principles*; one active, which may be termed fire; and two paſſive, water and earth. From the moſt ſimple union, or connection of theſe three, ſalt ariſes; which conſequently is to be looked upon as the moſt ſimple of all mixed bodies. The next to that in ſimplicity is ſulphur or oil, made by an union of theſe three *principles*, and of ſalt. *Geoffroy*, Tract. p. 5.

Elementary earth is the ſame with the *terra damnata*, or *caput mortuum* of the chemiſts; being a ſimple, friable, porous ſubſtance, without ſmell or taſte, conſiſting of particles of no regular figure, and altogether unfit for motion. The poroſity of earth ſeems to ariſe from the irregular figure of its particles; and as theſe particles oftentimes touch one another only by their angles, the whole maſs muſt neceſſarily be friable, and the want of taſte and ſmell may be owing to the inaptitude of the particles of earth to motion.

In any analyſis of bodies, the laſt thing is always this *principle* earth; and in their compoſition it ſeems to ſerve as a baſis or foundation to the other parts of the mixture, and to it the dryneſs, ſolidity, and hardneſs of bodies is in a great meaſure to be aſcribed. *Geoffroy*, Tract. p. 11.

Elementary water is a ſimple liquid, inſipid, inodorous, pellucid ſubſtance: its fluidity is owing entirely to the action of fire, and when that action is very great, its parts are actually divided, and the whole turned to vapours; but when it is very ſmall, they cohere ſtrongly, and turn to ice. This element ſome chemiſts call *phlegm*, and it may be conceived to conſiſt of ſmall ſmooth particles, of an oblong or oval figure, and perfectly rigid and inflexible. From the minuteneſs of its particles it eaſily penetrates the pores of almoſt all bodies. An oval figure ſeems more agreeable to the fluidity of waters, as alſo to its motion, than a ſperical one; and likewiſe to the ſolidity we obſerve in ice, the points of contact in ſpherical bodies being too few to form ſo ſtrong a coheſion. Were its particles angular and flexible, they would be too weak to penetrate and diſſolve ſalts, and would likewiſe be too much reſiſted; but as their ſurface is ſmooth, they can eaſily enter the ſubſtance of ſalts, and afterwards as eaſily ſeparate their parts, that is, diſſolve them by their rigidity and oval figure. The want of taſte and ſmell in water ſeems to be owing to the ſmoothneſs, obtuſeneſs, and ſmallneſs of its particles, which cannot vellicate the nerves of the tongue and noſtrils. The fluidity of the water ariſes from the ſmallneſs, ſmoothneſs and figure of its particles, and from their eaſy motion by the fire contained in their interſtices. Without the action of fire ſeparating theſe particles, and keeping them in continual motion, their fluidity would preſently be loſt, how much ſoever their natural figure may diſpoſe them to it, and they would become one ſolid maſs. On the other hand, if the action of fire upon them be very great, they are farther ſeparated from one another, and fly off in vapour and ſmoke. In fine, water is tranſparent, becauſe its pores are ſo diſpoſed, as readily to tranſmit the rays of light. *Geff.* Tract. p. 10.

We reckon elementary fire the firſt *principle* of bodies, as being that from whence all the reſt receive their activity: it is a ſimple and moſt ſubtle body, in a continual ſwift motion, filling and eaſily penetrating the pores of all other bodies. Its immenſe ſubtlety is evident from this, that it pervades all bodies whatſoever, and its ſwift motion from that rapidity which it is capable of communicating to them. Its force is in proportion to the quantity of it any where collected. In the ſun, which may be looked upon as a vaſt congeries of this ſubſtance, its motion is moſt violent. In culinary fires, the quantity and motion of it are not ſo great, but ſtill greater than in ſpirituous and volatile liquors, where it is hardly to be perceived, except when they are ſet on fire. Not only all motion, but alſo heat is owing to fire, which as it exiſts in bodies, is nothing elſe but the exceſſive motion of their parts. It is too ſubtle and active ever to be collected pure in chemical analyſes; wherever it is found it is always united with water and earth in ſalts and ſulphurs; and is ſometimes concentred in bodies in ſo great quantities, as conſiderably to increaſe their weight; as is evident in calcined antimony, in which there is in the operation an addition made of almoſt a fifth part. *Geoffroy*, Tract. p. 9.

What the chemiſts call oil or ſulphur, is not a ſimple ſubſtance, but a body compounded of earth, fire, water, and ſalt; but as it is uſually ſeparated entire in chemical analyſes, it has been uſually eſteemed a chemical *principle* or element of bodies; and is, indeed, tho' a real compound, yet not without conſiderable difficulty to be reduced to its *principles*. It may be defined to be a fluid, viſcid, inflammable, tranſparent body, without taſte or ſmell, (tho' by mixing it differently with ſalts theſe different qualities are produced) compounded of fire, water, earth, and ſalt; and it may be conceived to conſiſt of many flakes, or flocculi, each of which is again made up of very ſmall flexible filaments, formed of the four *principles* before mentioned, by fermentations, as well in the bowels of the earth, as in the bodies of vegetables and animals; thus an aromatic plant growing in water will, by diſtillation, yield an oil, which could never have been obtained from the water in which it ſtood; and all oils may by art be reſolved into water, earth, and ſalt: from theſe filaments variouſly concreted ariſe the flakes already mentioned, which are of different thickneſſes; and in the pores thereof is lodged the element of fire, which alſo runs in little ſtreams thro' their interſtices. On theſe depend the ſpecific levity, inflammability, and fluidity of oil; but as notwithſtanding the inteſtine motion cauſed by the element of fire, the flocculi ſtill adhere, in ſome meaſure, together; this fluid muſt neceſſarily be more viſcid than any other.

From what has been ſaid concerning the nature of alkaline ſalts, and the figure and ſtructure of the oily flocculi, it is eaſy to conceive why all alkalies diſſolve ſulphurs; for ſince the alkaline particles are ſpherical and prickly, they cannot enter the interſtices of theſe flocculi, without carrying away ſome of them from the reſt, and thus by degrees thoroughly diſſolving them. But the denſe, rigid, and pointed moleculæ of acids being laid into theſe interſtices, increaſe the denſity, and ſtrengthen the texture of the flocculi; and from the diverſity of theſe and of the acid ſpicula mixed with them, ariſe the different kinds of ſulphurs.

Sulphurs formed in the earth, of fire, acid ſalt, water, and a very fine earth, are termed ſimple bitumens, and theſe bitumens diſſolved in a large quantity of water, form the mineral oils or petrolea; but if they are mixed with earth and ſalt, the common ſolid bitumens are produced, differing from one another in degrees of purity, according to the quantity and groſsneſs of the earth, or different degrees of mixture. Thus foſſile or pit-coal, jet, amber, and the common bitumens, and bituminoſe earths are produced. If there be but a ſmall quantity of earth and much acid ſalt, the common mineral ſulphur or brimſtone is formed: if the mineral original bitumen is joined to a fuſible earth, capable of vitrification, it communicates to it a metallic form, that is the ſound, brightneſs, ſoftneſs, ductility, malleability, and all the other ſenſible qualities of metals.

This origin of mineral bitumens may be confirmed by many experiments. If a mixture of equal parts of oil of vitriol, and oil of turpentine, be digeſted together for a conſiderable time in a very gentle heat, and afterwards diſtilled in a retort, there will come over firſt a yelloviſh liquor reſembling petroleum both in ſmell and conſiſtence; and what remains in the retort is at firſt a ſoft bitumen, and afterwards turns into a hard black maſs, eaſily inflammable, and ſmelling in the burning exactly like foſſile coal. But if the diſtillation be continued, a white acid liquor will next be obtained, which

by ſtanding lets fall a grey powder, which is true common brimſtone; a yellow ſubſtance of the like nature adhering likewiſe to the neck of the retort; what is left behind being a black, ſhining, light, ſubſtance, diſpoſed in thin diſgregated ſtrata or plates, like ſome of the foliaceous talcs, and in theſe iron may be diſcovered by the help of the loadſtone. Thus therefore all theſe bitumens may be artificially produced; and the moſt accurate analyſes of the natural ones, confirm the manner of their formation.

Thus the chemiſts have ſhewn, that metals are nothing but bituminous ſubſtances, which have undergone a long digeſtion; for by depriving them of their ſulphur they are firſt reduced to aſhes, and afterwards to glaſs; this is eaſily ſeen in the imperfect metals; for if any of them be expoſed to a long heat, and eſpecially if to the rays of the ſun collected by a large burning glaſs, the ſulphureous *principle* flies off, and only a calx or aſhes will be left behind; which in a more vehement degree of fire are preſently vitrified, and by reſtoring the ſulphur this glaſs may be again reduced to metal.

The inflammable ſubſtances in animals and vegetables, conſiſt of a different combination of the *principle* of ſulphur and acid ſalt; for the oil or ſulphur in theſe is formed by a ſmall portion of earth joined to the elementary fire, water, and acid ſalt; this oil when joined to an acid ſalt produces gums; when joined to a fine acid, and a new acceſſion of fiery particles, it produces eſſential oils and inflammable ſpirits; but if the acids are more groſs, by reaſon of a larger quantity of earth joined to them, it forms reſins, as we learn from the artificial compoſitions of all theſe ſubſtances. By mixing ſpirit of wine with volatile ſpirit of urine, we obtain a mucilaginous concretion, or thin gum: oil of olives and ſalt of tartar melted together, make a kind of ſoap or thick gum; and if ſpirit of wine be digeſted for a long time with oil of vitriol, and then diſtilled, an inflammable oil is obtained, reſembling in ſmell and other qualities the eſſential oils of plants, a true reſin being left behind in the retort.

In animals this ſame oleaginous *principle* forms the fat and other glutinous or gelatinous ſubſtances; theſe laſt being compoſed of an acid volatile ſalt and oil, as appears from their analyſis: but fat is made of the ſame oil and acid ſalt; for, if oil of olives and ſpirit of nitre be mixed together, and digeſted, a ſubſtance will be formed in all particulars reſembling the fat of animals.

Sulphureous ſubſtances found in bodies are either fixed or volatile. The fixed ſulphurs are either ſolid, ſuch as, fat, reſin, and the bitumens; or fluid, as oils. Volatile ſulphurs are ſuch as fly off with a ſmall degree of fire, and have an appearance compounded of that of oil and water. Such are inflammable ſpirits obtained from the fruits and flowers of plants. *Geoff.* Tract. p. 17.

Tho' ſalt be in reality a mixed body, yet in the common analyſis of bodies it is obtained intire, and has therefore paſſed with many for a true chemical *principle*: a great deal of pains is neceſſary to decompoſe and reduce it to its natural *principles*, but with accuracy and caution it is reduced to water and earth. It is the ſole origin of taſte, ſmell, and many other of the moſt obvious properties of bodies, and may properly be defined to be a mixed body, formed by the concretion of fire, water, and earth, into a ſolid, rigid, ſubſtance, ſoluble in water, and fuſible by fire. As its particles may be conceived to cohere by large ſurfaces only, ſalt cannot be friable, like earth; but requires a conſiderable force to ſeparate its parts, which fly off from one another with a ſenſible noiſe like thoſe of glaſs. It becomes the cauſe of taſte and ſmell, becauſe its particles terminate in ſtrong points, which vellicate the nervous membranes of the tongue and noſe.

Salt is properly of three diſtinct kinds, acid, acrid or alkaline, and neutral, or ſal ſalſus, compounded of the other two. *Geoff.* Tract. p. 12.

Acid ſalt is a congeries of inflexible ſolid parts, of an oblong figure, pointed at both ends. That its particles are rigid and hard, appears from the force with which it divides and diſſolves ſolid bodies; and their ſharpneſs and pungency are evident from the effect they have on the tongue, different from the corroſion of the acrid or alkaline ſalts. Acid ſalt is eaſily diſſolved by water; and after this ſolution, its parts are equally diſperſed through that fluid, and have the ſame motion with it. Hence it appears, that the particles of both theſe ſubſtances have nearly the ſame ſpecific gravity; and likewiſe, that the motion of the aqueous parts is great enough to overcome the coheſion of the parts of the ſalt.

Concerning the manner in which the particles of acid ſalt are compounded of fire, water, and earth, nothing can with certainty be determined. It may be conjectured, however, that ſeveral particles of water being collected into one little maſs, are cemented together by ſome particles of fire and earth, lodged in the interſtices left between them; and that all theſe taken together are diſpoſed in one oval form, or that of two cones joined by their baſes. This configuration, however, is not the ſame in all acid ſalts; but the differences may all be reduced to three, the nitrous acid, the muriatic, and the vitriolic. *Geoff.* Tract. p. 13.

Salt alkali has its name from the Arabian *kali*, a plant, from whoſe aſhes a ſalt proper for glaſs-making was obtained; and from thence it came to be uſed for the fixed ſalts got from the aſhes of all plants, and afterwards for all ſalts and other ſubſtances whatever, that will ferment with acids.

Acrid or alkaline ſalt ſeems to be a congeries of ſpherical particles, with rough, prickly ſurfaces; becauſe of their great diſpoſition to motion, and their corroſive burning taſte. The points of their ſurfaces act on the nervous papillæ of the tongue like ſo many files; whereas acid ſalt is only pungent. But then by theſe points a larger ſurface is expoſed to the action of the fire than could otherwiſe be, and thus the particles of ſome alkaline ſalts are very volatile, or eaſily raiſed by a gentle heat. The origin of this ſalt is probably from a connection of acid points and terreſtrial particles; becauſe, in many operations in chemiſtry, ſuch ſalts ariſe from the mixture of acid ſalts and earth; as we ſee particularly in the preparation of fixed nitre and fermentation of urine.

Nitre being diſtilled, leaves a compound fixed ſalt behind, of the ſame nature with ſea-ſalt; out of which, by a nicer diſtillation, an acid liquor may be extracted without any volatile ſalt, or at leaſt but a very ſmall quantity: but if the ſame fixed ſalt be previouſly fermented, and then diſtilled, it yields a large quantity of volatile ſalt, and a very little fixed ſalt or acid; becauſe by fermentation or calcination, the acid and terreſtrial particles are intimately mixed, the acid ſpicula entering the pores of the earth, and ſo forming new molecules, which are denſe and cloſe toward the center, and prickly on the ſurface by the acid points ſticking out. Such are the particles of volatile alkalies, of which, if a great number be joined together, they muſt cohere very ſtrongly by means of their points, and form maleculæ of irregular figures; in the pores of which, watery, ſulphureous, earthy, or acid particles may be received and abſorbed.

Hence it is, that theſe ſalts are ſeldom pure; and as they are very often filled with particles of earth, they reſiſt the moſt violent degree of fire, and will ſooner melt than be raiſed by it. This is the true nature of fixed alkaline ſalt, ſuch as ſalt of tartar, or the ſalts got from the aſhes of plants, called lixivial ſalts. If they be impregnated with ſulphureous particles, they continue very volatile, and are raiſed by a ſmall degree of fire; as we ſee in ſalt of urine, hartſhorn, and others got from animals.

Acrid ſalts eaſily melt, when expoſed to a moiſt air, becauſe the particles of water contained in ſuch air readily enter their pores: when thus melted, they become properly lixivia, and are commonly termed oils, as oil of tartar per deliquium. Volatile alkaline ſalts, diluted with water, are called volatile urinous ſpirits; ſuch as the volatile ſpirit of urine, of hartſhorn, of blood, and others. *Geoff.* Tract. p. 14.

Neutral ſalt is a kind of ſalt compounded of acid and alkaline moleculæ united together, and the figure of its particles is chiefly owing to the kind of acid that enters its compoſition. The impreſſion theſe particles make on the tongue is more dull and languid than that made by acid or acrid particles alone; becauſe the moleculæ formed by the union of theſe are larger in bulk, and conſequently leſs diſpoſed for motion; and therefore, tho' there is a greater quantity of aculei, or points, in one of theſe moleculæ than in one of the former; yet their bulks make them leſs capable of entering the pores of the ſkin, and vellicating the nervous papillæ, than when they are in a disjoined ſtate. The taſte of theſe ſalts is termed ſaline, and varies according to the differences both of the acid and alkaline particles that compoſe them, according to the thickneſs of the ſpicula, their number, and the other parts that may be mixed with them. That this is the true original of this kind of ſalts, is evident from the artificial compoſition of ſuch a ſalt from acid and acrid particles blended together, and from the reſolution of them into the ſame. Thus by pouring ſpirit of nitre, of ſea-ſalt, or of vitriol, on ſalt of tartar, new ſalts are produced exactly of the ſame appearance with nitre, ſea-ſalt, and vitriol; and by analyſing theſe three ſalts, the eſſential ſalts of plants, ſal armoniac, and others of the neutral ſalts, an acid and an alkaline ſalt may be obtained, in ſome fixed, in others volatile. *Geoff.* Tract. p. 15.

PRINOS, in botany, the name of a genus of plants, the characters of which are theſe: the perianthium is very ſmall and permanent; it is compoſed of one leaf, lightly divided into ſix ſegments. The flower conſiſts of one petal, and is of the rotated kind; it has no tube, but its edge is divided into ſix oval ſegments. The ſtamina are ſix erect tubulated filaments, ſhorter than the flower. The antheræ are oblong and obtuſe. The germen of the piſtil is oval, and terminates in a ſtyle, which is ſhorter than the ſtamina. The ſtigma is obtuſe. The fruit is a roundiſh berry, containing ſix cells, and is much larger than the cup. The ſeeds are ſingle; they are very hard and obtuſe, convex on one ſide, and angular on the other. In ſome ſpecies the ſtamina are but five inſtead of ſix. *Linnæi* Gen. Pl. p. 151. *Plukenet*, p. 452. *Gronov.*

PRINTING *(Cycl.)*—The arts and ſciences, eſpecially ſtatuary and ſculpture, were arrived at ſo great perfection among the Romans, at the time when that empire was in its greateſt glory,

glory, that it is much to be wondered at that the art of *printing* was not found out among them; an art ſo nearly allied to that of the cutting ſeals and the dies of medals.

The making theſe dies, and the ſtamping their coins with them, was, in reality, no other than *printing* on metal; and their impreſſing their ſeals, cut in cornelians, agates, &c. on wax, was another ſpecies of *printing* on this ſubſtance. And finally, a third ſort of *printing* among them, was the impreſſing the name of the workman on their pieces of fine earthenware.

Mountfaucon, in his antiquities, gives the figures and deſcriptions of ſeveral very large ſigilla of the Romans, in which the names were all cut in hollow, in capital letters; and he imagines, that the uſe of theſe was to mark large earthen veſſels with, while the clay was ſoft, and particularly thoſe large veſſels in which the Romans kept their wines. It does not ſeem that this diligent enquirer into antiquity ever met with any of theſe ſigilla with the letters or characters in relief, or ſtanding out in the manner of our modern types for *printing*, ſince he mentions none ſuch; yet the remains of the Roman antiquities in terra cocta, or earthen-ware, ſhew that they had ſome ſuch, tho' they were leſs common than the others; theſe veſſels ſometimes being marked with letters going in, tho' in general they have them all ſtanding out, as muſt be the caſe when the impreſſion was given from a ſigillum cut in creux.

There is now, in the collection of the Duke of Richmond, a ſigillum of the other more rare kind, which brings the diſcovery very near to that of *printing*: on this all the letters are raiſed, as is alſo the verge or rim of the ſeal, in the manner of our types uſed this day in *printing*. The ſtamp is made of true antient braſs, and has on it the common green coat of ærugo which diſtinguiſhes the true antique medals. The plate is near two inches long, and near an inch in breadth, and has on the back part a ring for the convenience of holding it for making the impreſſion. The letters ſtand in two rows; they are the common Roman capitals, very well made, and their faces all ſtand exactly on the level with one another, and with the ſurface of the verge of the ſeal. This ſeal was exactly of the nature of our method of *printing* ſo many letters at once. It contains the name of one Caius Julius Cæcilius Hermias, ſome private man, as we have no account of any perſon of this name upon record. It ſerved him probably to ſet his name to any thing, to ſave him the trouble of writing; and the name being that of ſome private man ſeems alſo to prove, that theſe ſigilla were very common among that people. It was evidently made to be uſed on parchment, or ſome other ſuch thin ſubſtance; and the manner of uſing it muſt have been by firſt dipping it into ink, or ſome other coloured matter, not plunging it ſo far as to touch the ground, ſo that the letters only became marked, and gave their figures on the paper. The ground of this ſeal is very rough and uneven, and thence alſo it is plain, that the uſe of it was not to preſs down any ſoft ſubſtance, ſuch as clay, or the like; becauſe the imperfection of the ground would, in that caſe, have been ſeen, whereas in the uſe it was really intended for, the ground never gave any impreſſion, and therefore there was no reaſon for beſtowing any pains in the working it even.

The firſt uſe of *printing* among the later ages, was by wooden blocks in this very manner; and it was not till long after this invention, that we learned the way of uſing ſeparate types for the letters; and theſe were then called *typi mobiles*, in oppoſition to the blocks, where the whole page was contained together, which were called *typi fixi*. This ſignet of the Duke of Richmond's, which was found near Rome, is truly and properly one of thoſe *typi fixi*, and prints off its impreſſion on paper with our modern printer's ink, as well as any ſet of letters cut in this manner can be expected to perform. This ſeems, therefore, the moſt antient ſample of *printing* that we know of; for, by the appearance of the metal, it ſeems to be of the higher empire.

It is plain, by this ſtamp, that the very eſſence of *printing* was known to the Romans; for they had nothing to do, but to have made a ſtamp with lines three or four times as long, and containing twenty lines inſtead of two, to have formed a frame of types that would have *printed* a whole page as well as Coſter's wooden blocks, uſed in *printing* the book called *ſpeculum ſalutis*, which was the firſt book *printed*, in the year 1440, and conſiſted of pictures of ſtories out of the bible, with ſome of the verſes underneath each page; being *printed* from a block of wood, like a wooden cut. This was the firſt eſſay of the fixed types, from which the moveable, or common ſeparate types were ſoon deduced; and it ſeems ſtrange, that the Romans, who were as ſagacious a people as any in the world, ſhould not as eaſily have fallen upon the uſe of ſeparate types, in which the whole art of modern *printing* conſiſts, from ſuch ſignets as theſe, as the later ages from Coſter's wooden blocks, which were plainly no other than larger works of the ſame kind.

Cicero, in his book *de natura deorum*, has a paſſage from which Toland ſuppoſes that the moderns took the hint of *printing*. That author orders the types to be made of metal, and calls them *formæ literarum*, the very words uſed by the firſt *printers* to expreſs them. It is plain from Virgil, that brands, with the letters of the owner's name, were in uſe in his time for the marking of cattle. And we have an account of the ſame artifice that is now uſed for the painting of cards being uſed by the emperor Juſtin, who could not write. There was a ſmooth board, with holes cut through it, in form of the letters of his name; and when he had occaſion to ſign any thing, this was laid on the paper, and he marked the letters with a pen or ſtylus dipped in red ink and directed through the holes. Philoſ. Tranſ. N°. 479, p. 393.

PRINTS. To take off printed cuts, ſo that the outlines and principal ſtrokes may be exactly copied for graving, may be thus performed: if the *print* be not above a year or two old, the paper need only be moiſtened with water in the manner uſually practiſed for *printing* cuts; but if it be more antient, it ſhould be laid to ſoak all night in water, and afterwards hung in the air till it becomes dry enough for the preſs. The paper thus prepared, is to be laid with its *printed* ſide next the plate, thinly caſed over with white wax, which is thus to be committed to the rolling preſs, whereby an impreſſion of the cut will be obtained. *Boyle*'s Works abr. Vol. 1. p. 136.

PRIORITES, in botany, a name given by the antient Greeks to a plant which they recommend in medicine; but they do not clearly explain what it was. It is the ſame with the ceſtrum and pſuchrotrophon of the ſame writers; and they ſay it was called *betonica*, *ſerratula*, or *roſmarinus*, by the Romans. It is evident, from a ſtrict enquiry into their accounts, that the ſerratula was the plant they meant; for Pliny ſays, that the betonica was only a Gauliſh name for this plant, and the place of growth, which is deſcribed to be wet ſhady places, evidently excludes what we call *roſemary* from any title to the name.

Apuleius has greatly perplexed the cauſe by ſaying, that the *pioites*, or betony, has leaves like the docks; but he does not diſtinguiſh between the betonica and britannica, which laſt plant is the hydrolapathum, or great water dock, and has leaves like the other docks; and it is plain, that both Apuleius and Pliny borrow the account of the dock-like leaves from this paſſage, and attribute them to a plant the original author never meant them for.

PRISMATIC *antennæ*, in natural hiſtory, a term uſed to expreſs the horns or *antennæ* of a peculiar genus of butterflies. As thoſe of the common kind are ſlender and buttoned at the end, theſe become very thick a little way from their origin, and continue of that diameter through their whole length, till juſt at the extremity they turn a little and terminate in a ſharp point. The anterior part of theſe is rounded, as in the other kinds; but behind they are made up of two planes meeting in an angle, and each of theſe has a row of hairs on it: theſe meeting at their ſummits, form an angular vacant ſpace or alley below. *Reaumur*'s Hiſt. Inſ. See FEELERS.

PRISON *(Cycl.)—Breaking of priſon*, by the law of Scotland, is a puniſhable offence; but there are no particular laws againſt it in that country, ſo they are guided by the Roman laws in ſuch caſes. But tho' this law ſeems to make the puniſhment of this crime capital, yet this is thought too great ſeverity in Scotland, where an arbitrary puniſhment, greater or leſs, according to the circumſtances of the eſcape, and the violence with which it was accompliſhed, is thought ſufficient and adequate. *Math.* de Crimin. Carpz. Part 3. *Bayne*'s Crim. Law.

PRISTIS, the *ſaw-fiſh*, a fiſh of very large ſize, and armed with a very remarkable weapon like a ſaw, at his noſe, from whence he has his name. See Tab. of Fiſhes, N°. 5.

This fiſh, from its large ſize, is generally reckoned a kind of whale, but erroneouſly; for it is truly of the ſame genus with the galei or hound-fiſhes. It is aſh-coloured on the back, and white on the belly; its head is of a heart-like ſhape, and flatted; its mouth is placed far below the end of the ſnout, and in the under part of the head, as in the zygæna; its lips are rough and ſharp, like a file, but it has no other teeth; its head is terminated by a long and flat, bony ſubſtance, furniſhed on each ſide with jaggs or points like deep teeth of a ſaw. There are from twenty to thirty of theſe teeth on each ſide. The body is round, and grows ſmall towards the tail. The ſword of this fiſh is ſometimes five feet long. It is found in the weſtern ocean.

PRIVET, *liguſtrum*, in botany. See LIGUSTRUM.

The leaves and flowers of *privet* are cooling, drying, and aſtringent, and conſequently good in ulcers and inflammations of the throat and mouth, bleeding of the gums, and relaxation of the uvula.

PRIVET-*fly*, in natural hiſtory, the name of a ſpecies of *fly* very common on the ſhrub from whence it has its name. It is called the *erinopterus*, and is remarkable for having its wings deeply divided into ſegments, ſo that they ſeem compoſed of feathers like bird's wings. The creature as it ſits looks like a ſmall feather.

PRIZES *(Cycl.)*—The officers and ſeamen of the king's ſhips, and of other Britiſh ſhips having letters of marque, are intitled to the ſole intereſt, and property of all ſhips and goods by them taken, and adjudged lawful *prizes* by the court of admiralty. Stat. 13 Geo. II. c. 4. ſect. 1 and 2.

The *prize* is to be divided among the officers and ſeamen of the

the king's ſhips, as he ſhall appoint by proclamation. Among privateers, the diviſion is according to the agreement between the owners. *Ibid.*

The court of admiralty are to finiſh the examination of the perſons to be examined to prove the lawfulneſs of the *prize*, in five days after requeſt for that purpoſe made. The monition is to be executed in three days. And in caſe no claim of the capture be duly entered, giving twenty days notice after the execution of the monition; or if there be a claim, and the claimant does not give ſufficient ſecurity to pay double coſts to the captors, if the *prize* be adjudged lawful, then the court are to proceed to ſentence in ten days. *Ibid.* ſect. 3.

In caſe of doubt, or of witneſſes being remote, the court may releaſe the *prize*, on the claimant's giving good ſecurity to the captors for the payment of the full appraiſed value, in caſe the *prize* be adjudged lawful. *Ib.* ſect. 3. fin.

Judges and officers, on failure of their duty, in reſpect to the condemnation of *prizes*, forfeit 500 l. with full coſts of ſuit; one moiety to the king, and the other to the informer. *Ib.* ſect. 6.

The judges and officers of the court of admiralty in the king's plantations or dominions abroad, ſhall not receive above 10 l. in caſe the *prize* be under an hundred tons burthen; nor above 15 l. if it be of greater burthen. *Ib* ſect. 7.

Commiſſioners of appeals in cauſes of *prizes* are to be appointed under the great ſeal: and appeals may be made to them within fourteen days after ſentence. *Ib.* ſect. 8.

Agents for *prizes* are to be choſen by the captors. *Ib.* ſect. 10.

The treaſurer of the navy is to pay to the officers and ſeamen on board ſhips of war, or privateers, in any action where any ſhip of war, or privateer, ſhall have been taken from the enemy or deſtroyed, 5 l. for every man on board ſuch *prize* or ſhip deſtroyed, at the beginning of the engagement. *Ib.* ſect. 15.

The captures of Flota ſhips, or galleons, or regiſter ſhips bound from Buenos Ayres, or Honduras, can be tried only in the high court of admiralty. *Ib.* ſect. 17.

This ſtatute enacts ſeveral penalties and forfeitures for taking *prizes* by colluſion. Privateers forfeit the *prize*, half to the king, and half to the informer; and the commander of a man of war forfeits 1000 l. to be divided between the king and the informer. *Ib.* ſect. 19.

PRO *(Cycl.)*—PRO *partibus liberandis*, in law, an antient writ for the partition of lands between co-heirs. Reg. orig. 316. *Blount*, *Cowel.*

PROBOLIUM, among the Romans, a kind of ſpear, which hunters uſed in hunting boars. *Pitiſc.* in voc.

PROBOSCIPLECTANUS, in natural hiſtory, a name given by ſome authors to a peculiar and very elegant ſpecies of penicillus marinus, which has ſomewhat of a funnel-like ſhape, and has its mouth ſurrounded by a number of thin hair-like filaments. See PENICILLI *marini*.

The firſt who has deſcribed this particular ſpecies, is the accurate Fabius Columna, from whom Klein has engraved a figure of it. *Klein* de Tub. Mar. p. 1.

PROBOSCIS, *(Cycl.)*—PROBOSCIS *of flies*. See the article TRUNK.

PROBULEUMA, προβεβλευμα, among the Athenians, a decree or vote of the Areopagus, or ſenate of Athens.

It was ſo called becauſe agreed upon by the ſenate, with a deſign to have it afterwards propounded to an aſſembly of the people, that it might receive from them a farther ratification, without which it could not be paſſed into a law, nor have any force or obligatory power after the end of that year, when the ſenators and other magiſtrates laid down their commiſſions. *Potter*, Archæol. Græc. l. 1. c. 18. T. 1. p. 100.

PROCERS, in glaſs-making, iron inſtruments hooked at the extremity, uſed to ſettle the pots in their places, whether ſet too near or too far off. *Neri*'s Art of Glaſs, Append.

PROCESSUS *(Cycl.)*—PROCESSUS *majoris muſculus*, in anatomy, a name given by ſome of the writers of the ear to one of the muſcles of that part, called by Cowper and others the *internus auris*, and by Albinus, more properly, the *tenſor tympani*.

PROCESSUS *minimi muſculus*, in anatomy, a name given by ſeveral authors to one of the muſcles of the ear, called by Cowper and others *obliquus externus*, and by Albinus *tranſverſus auriculæ*. See TRANSVERSUS *auriculæ*.

PROCESTRIA, among the Romans, buildings adjoining to camps, eſpecially winter quarters or ſtanding camps, where ſutlers, ſtrangers, traders, and others that followed the army, reſided; for they were not permitted to mix with the ſoldiers, unleſs when the enemy was near. *Pitiſc.*

PROCHARISTERIA, προχαριστηρια in antiquity, a ſolemn ſacrifice which the Athenian magiſtrates yearly offered to Minerva, when the ſpring firſt began to appear. *Potter*, Archæol. Græc. T. 1. p. 427.

PROCHEILA, a word uſed by ſome authors to expreſs the extremities of the lips.

PROCHYMA, a word uſed by the antients to expreſs that kind of muſt which flows ſpontaneouſly from the grapes without their being preſſed.

PROCICADA, in natural hiſtory, a name given by ſome to the inſect which the French call *procigale*. It reſembles the cicada in moſt reſpects, but it has not the power of making the noiſe that inſect does. See PROCIGALE.

PROCIDENTIA *(Cycl.)*—PROCIDENTIA *uteri*. The firſt ſtep towards a cure of a *procidentia uteri*, or falling down of the womb, is to reduce it to its natural ſituation, and to keep it there by means of peſſaries. But as ſome diſadvantages attend the uſe of common peſſaries, Dr. Thomas Simſon has contrived one, and given us the deſcription and figure of it in the medical eſſays of Edinburgh, Vol. III. art. 18. See alſo the abridgment of this work, Vol II. p. 224.

PROCIDENTIA *ani*. See the article TENESMUS, under which this is treated of.

PROCIGALE, in natural hiſtory, a name given by Reaumur, and from him by all the French naturaliſts, to a ſpecies of four-winged fly, greatly reſembling the cigale, or cicada, but wanting its power of making a noiſe.

This creature has a trunk of the ſame form with that of the cicada, very long, and laid cloſely upon the belly, and contained in a caſe or ſheath of the ſame ſtructure with that of this inſect. The female alſo has the ſame inſtrument at its tail, prepared for boring holes in wood, and called in that creature the *piercer*, and it uſes it to the ſame purpoſe, depoſiting its eggs by means of it in the branches of trees.

There is alſo another very ſmall inſect mentioned by Reaumur, as reducible to this claſs, if properly of the fly-kind; but its ſmallneſs makes the ſtructure of its wings ſcarce diſtinguiſhable with any degree of accuracy; and it is hard to determine whether it has four wings, or two wings, and two caſes of wings: this little fly is extremely common on roſe-trees; its wings are yelloviſh, and its body white; and it can hop as well as fly. It is hardly poſſible to find a roſe-tree in the ſummer-months that is not loaded with theſe inſects, and they are principally found about the extremities of the young branches. The trunk of this ſmall fly is of the ſame kind with that of the cicada, and its buſineſs on the roſe-tree is the laying its eggs, in the ſame manner as the cicada, in the wood of the branches. This operation, however, is performed by a very different inſtrument; for inſtead of the piercer which the female cicada has at the end of her body, this little fly has a ſaw placed on the third ring of the body, and as much differing in ſhape as in poſition from the ſaw of the ſerrate roſe-fly, for it is leſs elegantly faſhioned; it is pointed, however, at the end, and the creature preſſing upon it with the whole weight of its body, forces it into the wood, by which means it makes a cavity, in which to depoſite its eggs. Theſe eggs are ſo ſmall and ſo tender, that they are not to be taken out of their place without breaking them. They finally produce ſmall worms, of a white colour and tenderer nature than the eggs themſelves: theſe, after they have fed a proper time on the juices of the branch, leave their holes, and become transformed into nymphs, which yet have the power of moving and feeding, and greatly reſemble the nymphs of the cicada in that they perfectly ſhew the lineaments of the fly contained within them, differing ſcarce in any thing from it, except that they have caſes over their wings, which are ſo ſmall as to leave the rings of the body almoſt entirely bare. *Reaumur*'s Hiſt. Inſ Vol. IX. p. 241.

PROCINDYNEUONTES, προκινδυνευοντες, among the Romans, a deſignation given to the Velites, becauſe they were moſt expoſed to danger. The term anſwers to what we call the *forlorn-hope*. See VELITES and FORLORN-HOPE, *Cycl.*

PROCONNESIUM *marmor*, a name given by the antients to a ſpecies of marble called alſo *neuris* and *elaphoneſus*, and by ſome *Cyzicus*, from the works of a famous ſtatuary of that name, many of which were made of it. It was of a bluiſh white, lightly variegated with black; this colour uſually running in ſmall veins, and not unaptly reſembling in many inſtances the courſe of the veins of a human body in the naked ſtatues. It was alſo uſed in the ſumptuous buildings of the Romans.

PROCUBITORES, among the Romans, an appellation given to the Velites, becauſe when the enemy was near, they always formed the outguard. *Pitiſc.*

PROCYON, in aſtronomy, a fixed ſtar of the ſecond magnitude, in the conſtellation canis minor.

PRODUCTION *(Cycl.)*—*Marine* PRODUCTIONS. To inveſtigate the nature of *marine productions*, Count Marſigli moiſtened in ſea-water ſome branches of coral, newly taken up, and found that the tubercles ſo frequent on its branches, after a little time all opened themſelves into regular flowers, each terminated by eight points. Theſe were white, and were ſuſtained by a cup divided into the ſame number of ſegments; and on the taking the branches again out of the water, he found theſe flowers all immediately cloſe themſelves up again, and only make red irregular tubercles; and the vigorous branches of coral retained this property of opening and cloſing their flowers for ſeven or eight days after they were taken out of the ſea. The tubercles, when wounded, yield a milky juice, in which, doubtleſs there is contained the ſeed of the coral.

When this curious naturaliſt had found coral to be a true plant in its organizations, it appeared a very deſirable thing to enquire whether it would yield vegetable principles, or thoſe of another kind, in a chemical analyſis. This experiment

ment he carefully tried, not only on coral but on many other of the ſtony plants, and found all of them yielded the ſame principles with vegetables. All of them yielded on this trial, a phlegm, a volatile urinous ſpirit, with always more or leſs of a ſea-water ſmell, and a thick reddiſh black fœtid oil; and the remainder in the retort being calcined, always yielded a fixt alkaline ſalt like that of plants.

The ſea *productions* all afforded more or leſs of every one of theſe principles; but thoſe of which ever kind that had been kept a long time after they were taken out of the ſea, afforded always much leſs fluid matter than thoſe which were freſh. Mr. Geoffroy was very deſirous of following the Count in theſe reſearches; and as he had no opportunity of procuring any freſh coral from the ſea, he put into a retort a pound of the common red coral, ſold by the druggiſts, which is what wants the outer bark, and has uſually been a long time out of the ſea. This yielded two drams and ſix grains of a reddiſh volatile urinous ſpirit, and two or three grains of a fœtid oil, and the remainder in the retort by the common treatment, yielded afterwards near two drams of a lixivial ſalt of a ſaline taſte: the matter remaining after the lixiviation appeared a ſort of lime.

The ſpirit appeared to Mr. Geoffroy to be wholly the ſame with that which the Count had himſelf ſent to the academy under the title of the ſpirit of old coral; and it appeared ſcarce at all different from ſpirit of hartſhorn. It turned ſyrup of violets green, and made a white coagulation with the ſolution of corroſive ſublimate. Tho' this was much the ſame with the Count's ſpirit, the ſalts drawn from the caput mortuum were, however, different; that made by Mr. Geoffroy making a white coagulation with a ſolution of corroſive ſublimate, and that of Count Marſigli having no ſuch effect; both the ſalts, however, turned the ſyrup of violets green, and Mr. Geoffroy judged the difference in the other trial to be only from the Count's ſalt having been leſs carefully made, and containing ſome quantity of earth which weakened its power and prevented this effect from it. It follows from all this, that the corals and all the other ſea *productions* of that claſs are properly plants, tho' of the hardneſs of ſtones: and in the internal uſe of coral it may be proper to conſider it not as a mere abſorbent, but as a ſubſtance which contains alſo a volatile ſpirit and oil, which may well be ſuppoſed to poſſeſs virtues above thoſe of mere abſorbent earth; and that there is great difference between the virtues of ſuch coral as has been long kept, and ſuch as is newly taken up from the ſea. The Count, after analyſing coral in this manner, tried the ſame proceſs on ſeveral parts of the rocks on which the coral grew; but he found this to yield none of theſe active principles; ſo that altho' the hardneſs of corals and of ſtones ſeems the ſame, there is great difference between them in their principles, their nature, and effects.

There is yet one queſtion remaining to be determined in this point, which is, what is the nature of this milky juice contained in the tubercles or flowers, and perhaps not leſs in the other parts of coral. The Count has ſaid nothing as to its qualities, but Boccone ſays it is hot, acrid, and almoſt cauſtic; whence perhaps it is the natural ſap of the plant, and is analogous to the milky juice of the ſpurges and ſome other plants. It were to be wiſhed that this liquor could be tried with acids and alkalies, and in other ways, and its analyſis known: this perhaps would make our knowledge of the nature of this ſtony vegetable perfect. Mem. Acad. Par. 1708.

PROEDRI, Προεδροι, among the Athenians, magiſtrates whoſe buſineſs it was to propoſe to the people the things they were to deliberate upon and determine at every aſſembly, after which their offices expired. *Potter*, Archæol. Græc. l. 1. c. 17. T. 1. p. 93.

They were ſo called from the privilege they enjoyed, of always having the firſt ſeats at aſſemblies.

PROEROSIA, Προηροσια, in antiquity, the ſame with *preroſia*. See PREROSIA.

PROFUNDUS, in anatomy, a name given by Albinus, Hunaud, and others, to a muſcle of the wriſt, generally known by the name of the *perforans*. Theſe authors called, in the ſame manner, the *perforatus* of others the *ſublimis*.

PROGALL-INSECT, an animal nearly approaching to the gall-inſect claſs, but differing from it in ſome reſpects, and called by this name from its reſemblance to thoſe creatures; as the creatures ſomewhat approaching to the ſcarab or beetle claſs, but not regularly of it, are called *proſcarabs*.

This claſs of animals paſs a great part of their lives in the ſame manner with the gall-inſects, faſtened to the bark of a tree, and there remaining motionleſs; ſome of them alſo in the manner of the gall-inſects cover their young brood with their bodies; but they are eaſily diſtinguiſhable as animals, in all the ſtages of their lives, and in that they differ from the others. The annular depreſſions of their bodies may in all their ſtates be diſtinguiſhed, eſpecially with the help of a magnifying glaſs; whereas thoſe of the gall-inſects all diſappear as they grow towards their utmoſt bulk.

If the gall-inſects are worthy of obſervation on account of the great value of one ſpecies of them, the kermes; the *progall-inſects* are at leaſt equally ſo on the ſame account, ſince the cochineal belongs to this claſs.

The moſt common and obſervable ſpecies of the *progall-inſect* claſs, is that of the elm, and a deſcription of that alone may give a ſufficient light into the hiſtory of the whole claſs, and ſhew what characters are to be found in the inſects properly reducible to it.

This inſect is principally found in the forked branches of the elm, and commonly in thoſe of one, or at the utmoſt of two years growth; it is ſometimes found in other parts of the branches and twigs, but that is much leſs frequently. It is in the months of June and July that this inſect is at its full growth; at this time, however, it appears to the naked eye only as a ſmall oval convex maſs, of a dirty browniſh red colour, ſurrounded with a ſmall downy white thread. This reddiſh oval maſs is the back of the animal, and by the help of glaſſes we may ſee the annular ridges and depreſſions that characterize the inſect claſs. This is all that gives an idea of its being an animal; for it is at this time in a ſtate of perfect immobility, and ſhews neither head, legs, or any other part that might give a proof of what it is; all theſe parts are enveloped and hid by the cottony band that ſurrounds it, which ſuffers no part but the convex ſurface of the back to be ſeen.

It is giving but a very imperfect idea of this downy rim, to call it only a border or pad laid round the body of the animal. This matter, in reality, makes a kind of neſt in form of a baſket, in which the body of the inſect is in a great meaſure lodged. Its belly, which is placed on this neſt, is ſeparated by it from the bark of the tree, and lodged on a ſort of downy bed; the threads of this down are ſomewhat thick and ſtrong. The principal uſe this bed or neſt ſeems deſtined for, is, the reception of the young, which are produced in the end of June or in July. If the animal be removed from its bed at this ſeaſon, a vaſt number of ſmall living animals are found in the bottom and ſides of the neſt. Theſe are of a yellowiſh white, and have two ſmall horns; their ſhape much reſembles that of the young gall-inſects; their hinder part is more ſharp than their fore part, and they run about very ſwiftly on ſix very ſhort legs.

At whatever time however the *progallinſect* is removed from its neſt, there are never found any eggs; the creature is viviparous, and the young animal ſeems to be born with its head foremoſt, which is contrary to the manner of the pucerons and ſome other ſmall animals.

If the body of the parent *progall-inſect* be cruſhed in the month of June, a great number of ſmall oblong bodies are always protruded; theſe are probably the embryo animals, tho' all that the niceſt attention can in this ſtate diſcover in them, is, two ſmall black ſpecks, which afterwards prove to be the eyes.

The neſts of theſe inſects are ſeldom found ſo full of young ones as might be expected; but that is probably owing to the length of time taken up in bringing forth ſo great a number, probably eight or ten days, and the young ones in a day or two are perhaps fit to eſcape and run away; ſo that one finds only the laſt born there.

The branches of the elm examined with the help of glaſſes at this ſeaſon, ſhew us multitudes of the young *progall-inſects* running about them; theſe, however, continue in this ſtate but a little while, they ſoon chooſe their place for fixing for life, and there remain without motion afterwards. They do not loſe the power of moving, however, till the month of April following; for till that time, if the branch on which they are be cut off, when it becomes dry, and furniſhes them no more juices, they will leave it and go in ſearch of another; but after April, if the branch be cut off, they die upon the place when it dries, being no longer able to remove themſelves.

Theſe inſects, like the gall-inſects, do not grow much till after the winter is over: toward the end of April they have uſually arrived at their deſtined bigneſs; their bodies in the beginning of this month, and in ſome part of March, are ſomewhat reddiſh; but this colour is the leſs to be diſtinguiſhed, as the rings are all bordered with ſhort grey hairs. Theſe hairs are conſiderably thick, but the animal is found abſolutely without them again, when it has its cottony bed under it, having then diveſted itſelf of them in quitting its ſkin, which it changes for one whoſe pores are more proper to give paſſage to the matter of which that bed is to be made. At all ſeaſons their belly is of a redder colour than their back; and that is in a great meaſure owing to the belly being always free from thoſe grey hairs. The legs are very ſmall and ſlender, in proportion to the ſize of the animal; they are ſix in number. Its trunk or ſucker is not eaſily diſcovered, but is placed however in the ſame manner with that of the gall-inſect, and is like it in ſhape.

The cottony matter forming itſelf by tranſpiration from the ſeveral parts of the animal, forms by degrees the neſt, and as this increaſes, the animal itſelf increaſes alſo in bulk, and becomes gradually more and more red. No obſervation has yet been able to determine the manner of the fecundation of theſe inſects; they are never ſeen to couple one with another, and moſt probably the male of this claſs, as of the gall-inſects, is a ſmall fly. *Reaumur*'s Hiſt. of Inſects, Tom. 4. p. 83.

PROGALL-INSECT, otherwiſe called COCHINEAL. There have been many conjectures about *cochineal*; but the moſt probable ſeems to be, that it is an animal of the *progall-inſect* claſs.

The *cochineal*, in the ſtate in which it is brought to us, is in ſmall bodies of an irregular figure, uſually convex, and ridged and furrowed on one ſide, and concave on the other. The colour of the beſt is a purpliſh grey, powdered over with a ſort of white duſt. All that the world knew of it for a long time, was, that it was gathered from certain plants in Mexico, and therefore it was naturally ſuppoſed to be a ſeed. *Reaumur*'s Hiſt. of Inſects, Tom. 4. p. 88.

In the year 1692, Father Plumier gave Pomet, the French author of a hiſtory of drugs, an account of its being an animal: this, however, was diſregarded; but Meſſrs. Hartſoeker, De La Hire, and Geoffroy, afterwards evidently proved it to be one; and after this there were printed the depoſitions in form of a number of perſons upon the ſpot, who all declare it to be a viviparous animal, and that it paſſes a great part of its life fixed to the vegetable body on which it feeds; and that it was a creature ſubject to no change, nor ever appearing in any other ſtate. Theſe and many other qualities found in the *cochineal*, all analogous to thoſe of the claſs of *progall-inſects*, give great room to believe that it is truly and properly an inſect of this claſs.

There are two kinds of *cochineal*, the finer called *meſtique*, the other termed the wild *cochineal*. The firſt is gathered from ſuch plants of the opuntia as are prepared and managed properly on purpoſe for the production of the animal, the other is found wild on the wild plant, and is much inferior to the *meſtique* in value. The *meſtique* has its name from the name of the place, where it is propagated in the greateſt quantity, Meſtique, in the Province of Honduras. As to the other, it is not yet determined whether it be another ſpecies of the animal, or whether the ſame ſpecies in a leſs thriving condition. Ibid. p. 91.

The Indians plant about their habitations the opuntias, on which they propagate and raiſe the *cochineal*; they gather ſeveral quantities of it in the year, and what they are moſt afraid of in regard to it, is, a cold or a wet ſeaſon. In ſuch caſes they cut off the leaves of the plant ſtored with the inſects, and take them into their habitations. Theſe are of ſuch a nature as not to dry and wither immediately, like the leſs ſucculent plants, but often keep their juices long enough to furniſh the creatures a ſufficient nouriſhment, till the dangerous ſeaſon is over. The inſects are at this time in a ſtate to produce their young; and the Indians place them in a ſort of little neſts, twelve or fourteen together, on different parts of the opuntias of their plantation. Ibid. p. 93.

The animal is ſeldom more than three or four days in this condition, before it produces its young ones; each produces many thouſands, each ſcarce ſo large as the ſmalleſt mite; the young brood ſoon quit their neſt, and like the other gall and *progall-inſects*, wander about the plant for a little time, and then fix themſelves upon it in ſeveral places. They do not eat the plant, but only introduce their trunks and ſuck the juice, and wherever they fix themſelves, which is uſually in the more ſucculent parts of the plant, there they remain till they have acquired their full growth, and are in a condition themſelves to produce young ones. Ibid. p. 94.

The figure of this inſect is oval, and its utmoſt ſize is that of a ſmall pea. It has ſix legs armed with claws, two eyes, and a trunk by which it ſucks its nouriſhment. Ibid. p. 95.

The ants, and many other little animals, are very fond of eating the *cochineals*; and it is with great difficulty that the Indians defend the young brood from thoſe devourers. Ibid.

The firſt of the gatherings of the *cochineal*, is at the time the Indians carry the parent animals to the plants; when theſe have produced their young they die in the neſts, and the Indians take down the neſts and take them out. The ſecond gathering is three or four months after this, a little ſooner or later, according to the ſeaſon. The young ones produced from the former crop, have now acquired their full growth, and are ready to produce their young. In this ſecond gathering they take care not to take off the whole generation, but leave enough on the plant to multiply and give them a new crop afterwards. About three or four months after this, they have another gathering from theſe. Soon after this the rainy ſeaſon comes on, and the young ones produced from what are left on the plants from this gathering, are what the Indians houſe, for the parents of the next year's crops. The laſt of theſe crops is the leaſt valuable, being generally foul and full of ſmall inſects of the new brood, among the right and full grown ones. Ibid. p. 96.

After the Indians have gathered the *cochineal* they kill it, otherwiſe they would looſe a great part of their harveſt; for the parent race would live ſome days after their being taken from the plant, and would produce their young, which would be nimble enough to run away in great numbers. Some to kill the creatures plunge them in hot water, and afterwards dry them in the ſun; others kill them by a proper degree of heat. Ibid. p. 97.

The living *cochineals* are covered, like all other inſects of this kind, with a kind of white powder; but in the water uſed to kill them they looſe much of this powder, and are therefore of a different colour from thoſe killed by heat. Ibid. p. 98.

The accounts from the place where the *cochineal* is produced, give us all theſe particulars; but to decide the long diſputed point, whether they are of the animal or vegetable kingdom, we have the means in our own hands even in this part of the world. We need only moiſten and ſoak in water, or in vinegar, a number of *cochineals* till they are ſwelled and diſtended, to know that every one is the more or leſs perfect body of an inſect; the moſt imperfect and mutilated ſpecimens always ſhew the rings of the body, and from obſerving others it will be eaſy to find the number and diſpoſition of the legs; parts, or even whole ones being left on ſeveral, and often compleat pairs. Ibid. p. 100.

People of warm imaginations no ſooner knew it to be an inſect, but before they were perfectly acquainted with its form, they were for alloting it its proper claſs. Some would have it to be a worm, others a ſpider, and others a beetle. Petiver is of the number of the laſt, and has been ſanguine enough to figure it in all the ſtates he ſuppoſed it to have paſſed, the hexapode worm, the nymph, and the perfect beetle; tho' we now find by poſitive accounts from the place, that it undergoes no change at all, and from its whole figure and hiſtory, that it is properly of a claſs of animals then not known. Many have alſo been of opinion, that it was only a part of an animal, but a cloſer and repeated obſervation would have ſhewn them that it comes to us often more perfect than is imagined, and frequently wants only its horns and a leg or two, of being a perfect animal.

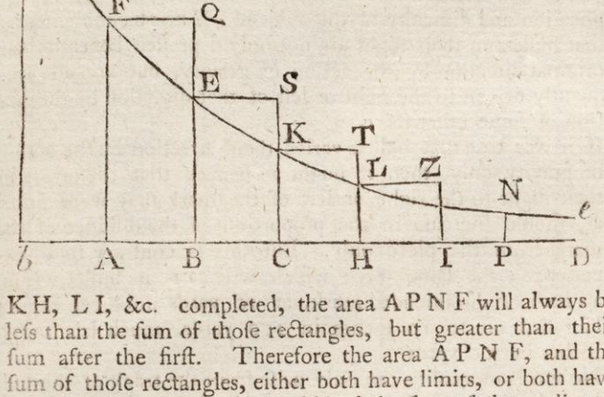
It is eaſy to ſee in ſome of theſe the head, and ſometimes a tubercle on each ſide of it, which may very naturally be ſuppoſed the eyes, or elſe the roots of the antennæ or horns. The firſt pair of legs are thus found to be very near the head of the animal, and placed exactly as in all the gall-inſect and *progall-inſect* claſs; a little above theſe one may diſtinguiſh alſo the remainder of the trunk ſituated exactly as in the gall-inſects and *progall-inſects*; the anus is alſo eaſily diſtinguiſhed. Ibid. p. 101.

As the manner of the fecundation of the gall-inſects was ſo long unknown in Europe, it is no wonder that that of the *cochineal* ſhould not be very early diſcovered in Mexico: but we have an account among Mr. Ruyſche's pieces from whence almoſt all the true hiſtory of this animal is had, that at the ſeaſon of the *cochineals* becoming big, there is ſeen continually among them a ſmall butterfly, which is bred upon the ſame plants, and by means of which the *cochineals* conceive. This is ſo ſtrictly analogous to the manner of the gall-inſect claſs, that there is no room to doubt the fact; and it is a farther great proof, how little truth was before in the gueſſes concerning the claſs of animals this belonged to. Ibid. p. 103.

It would be an eaſy miſtake for any one not profeſſedly a naturaliſt to miſtake the male gall-inſect for a butterfly, as it has white opake wings; and aſſuredly the male *cochineal* is an animal of the ſame ſpecies, a true two winged fly.

If a full grown *cochineal* be ſoaked a conſiderable time in water or vinegar, and afterwards gently preſſed, there will frequently be protruded from its hinder part a number of ſmooth oblong bodies, which might be eaſily miſtaken for eggs; but a good microſcope will ſhew in theſe the traces of the legs and other lineaments ſufficient to prove it to be a true embryo fœtus. Ibid. p. 104.

The wild *cochineal* differs from the *meſtique* in being leſs pure, and conſiſting of animals of all ages and ſizes, as being gathered with leſs care, and without the intent of propagating future crops; the larger ſpecimens in this ſometimes exceed the finer *cochineal* in ſize, and when moiſtened and ſqueezed, ſend forth vaſt numbers of the ſame oblong bodies. Ibid. p. 105.



Duhamel, while he reſided at St. Domingo, found in that iſland the ſame animal which Father Plumier had before obſerved there, and accounted the ſame creature with the *cochineal* inſect; he gathered ſome of theſe animals from off the opuntias there, and ſent them over to Paris; they were found to have all the exterior marks of *cochineal*; but it is much to be feared they are really no more than that to the *cochineal*, which the common peach and vine gall-inſects are to the kermes of the ilex. Poſſibly, however, a proper care and attention, and the bringing over the very creatures from Mexico to other parts of the world, might, with many tryals to determine what ſpecies of the opuntia it is that they moſt thrive on, be a means of propagating them to vaſt advantage. Ibid. p. 108.

Joſſelin, in his account of the products of New England, mentions a particular kind of ſun-flower, called by ſome a ſpecies of *golden-rod*; the ſtalks of which are covered about the knots in the ſummer months with inſects of the ſize of large fleas. Theſe preſerved in a proper manner, yield a very elegant ſcarlet colour, and the author thinks might be made to ſupply the uſe of *cochineal*.

PROGRESSION *(Cycl.)*—As a right line, or figure, may increaſe continually, and never amount to a given line or area; ſo there are *progreſſions* of fractions which may be continued at pleaſure, and yet the ſum of the terms be always leſs than a given number. If the difference between their ſum and this number decreaſe in ſuch a manner, that by continuing the *progreſſion* it may become leſs than any fraction how ſmall ſoever, that can be aſſigned; this number is the limit of the ſum of the *progreſſion*, and is what is underſtood by the value

of the *progreſſion*, when it is ſuppoſed to be continued infinitely. Theſe limits are analogous to the limits of figures, and they mutually aſſiſt each other. The areas of figures can, in many caſes, be no otherwiſe expreſſed than by ſuch *progreſſions*; and when the limits of figures are known, they may ſometimes be advantageouſly applied for approximating to the ſums of certain *progreſſions*.

Thus, for inſtance, let the terms of any *progreſſion* be repreſented by the perpendiculars A F, B E, C K, H L, &c. ſtanding at a given diſtance on the baſe A D; and let P N be any ordinate of the curve, F N *e* paſſing over the extremities of thoſe perpendiculars. Suppoſe A P to be produced; then according as the area, A P N F, has a limit to which it may approach continually, but never exceed, or may be produced till it exceed any given ſpace; there will alſo be a limit of the ſum of the *progreſſion*, or it may be continued till it exceed any given number. For ſuppoſing the rectangles F B, E C,

K H, L I, &c. completed, the area A P N F will always be leſs than the ſum of thoſe rectangles, but greater than their ſum after the firſt. Therefore the area A P N F, and the ſum of thoſe rectangles, either both have limits, or both have none. The ſame is to be ſaid of the ſum of the ordinates A F, B E, C K, H L, &c. and of the ſum of the terms of the *progreſſion* repreſented by them. If the curve, F N *e*, for example, be the common hyperbola, *b* its center, *b* P the aſymptote; and A B being equal to *b* A, if A F repreſent unity, the ſeries of ordinates will repreſent the *progreſſion* 1, $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, $\frac{1}{5}$, $\frac{1}{6}$, &c. which may therefore be continued till it exceed any given number, as the hyperbolic area may be produced till it exceed any given ſpace[a]. But if F N *e* be an hyperbola of any higher order, ſo that the ordinate P N be reciprocally as any power of the baſe *b* P, whoſe exponent is greater than unity, the area A P N F[b], and the ſum of the *progreſſion* repreſented by the ſeries of ordinates, will have limits. Hence there is always a limit of the ſum of the fractions that have unity for their common numerator; and the ſquares, cubes, or any other powers of the numbers, 1, 2, 3, 4, &c. whoſe exponents exceed unity for their ſucceſſive denominators[c]. [[a] See HYPERBOLA. [b] Ibid. [c] See *Maclaurin*'s Fluxions, B 1. p. 290.]

When the area A P N F has a limit, we may not only conclude, that the ſum of the *progreſſion* repreſented by the ordinates has a limit; but when the former limit is known, we may by it approximate to the value of the latter: and *vice verſa*, when the limit of the *progreſſion* is given, the limit of the area may be found. See *Maclaurin*, Lib. cit. Art. 352, 353.

Progreſſions of fractions may be found at pleaſure, that ſhall have aſſignable numbers equal to the limit of the ſum of the terms. Thus a ſeries or *progreſſion* of any number of quantities continually decreaſing being given, their ſucceſſive differences form a new ſeries of terms, the ſum of which from the beginning is always equal to the exceſs of the firſt term of the firſt ſeries above its laſt term. For inſtance, if A, B, C, D, E, &c. be the terms of the firſt ſeries, it is manifeſt that the ſum of the difference of A and B, B and C, C and D, D and E, is the exceſs of A above E. If the terms of the firſt ſeries decreaſe in ſuch a manner, that by continuing the *progreſſion* they may become leſs than any quantity that can be aſſigned, then the firſt term of the firſt ſeries is the limit of the ſum of the ſecond ſeries. In like manner, the difference of the alternate terms of the firſt ſeries, as of A and C, B and D, C and E, &c. form a new *progreſſion* of terms, the ſum of any number of which is equal to the exceſs of the ſum of A and B, the firſt and ſecond term of the ſeries, above the ſum of the laſt and penultimate terms; and the ſum of A and B is the limit of the ſum of the new ſeries. In general, if a *progreſſion* is formed by taking the difference of the firſt term A, and the term whoſe place in the ſeries is expreſſed by any number n; of the ſecond term B, and that whoſe place is $n+1$; of the third term C, and that whoſe place is $n+2$, and ſo on; then will the limit of the ſum of this new *progreſſion* be equal to the ſum of the terms A, B, C, D, &c. which precede that term whoſe place is expreſſed by n. In this manner *progreſſions* may be found at pleaſure, which may be continued without end, and have given numbers for the limits of their ſums.

For example, let the firſt ſeries be 1, $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, $\frac{1}{5}$, &c. the ſucceſſive differences of the terms of which are $\frac{1}{2}$, $\frac{1}{6}$, $\frac{1}{12}$, $\frac{1}{20}$, &c. and the limit of the ſum of this *progreſſion* will therefore be 1. If we multiply each term of this laſt ſeries by 2, that the firſt term may be unit, we ſhall have 1, $\frac{1}{3}$, $\frac{1}{6}$, $\frac{1}{10}$, &c. the denominators of which are the triangular numbers, unity being the common numerator, and the limit of the ſum of this *progreſſion* is 2. The ſucceſſive differences of the terms of this latter ſeries being each multiplied by $\frac{3}{2}$, that the term of the new ſeries may be unity, give 1, $\frac{1}{4}$, $\frac{1}{10}$, $\frac{1}{20}$, &c. which have the pyramidal numbers for their ſucceſſive denominators; and the limit of the ſum of this *progreſſion* is $\frac{3}{2}$. In the ſame manner, the limit of the ſum of the fractions having unity for their common numerator, and the figurate numbers of any order denoted by m for their ſucceſſive denominators, is found to be $\frac{m-1}{m-2}$.

The ſame ſeries 1, $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, $\frac{1}{5}$, &c. being again aſſumed, the differences of the alternate terms are $\frac{2}{3}$, $\frac{2}{8}$, $\frac{2}{15}$, $\frac{2}{24}$ &c. the limit of the ſum of which *progreſſion* is $1\frac{1}{2}$. Dividing each term by 2, the limit of the ſum of $\frac{1}{3}$, $\frac{1}{8}$, $\frac{1}{15}$, $\frac{1}{24}$, &c. is $\frac{3}{4}$. If we take the differences of the firſt term, and that whoſe place is m, the ſecond term and that whoſe place is $m+1$, &c. the common numerator of thoſe differences will be $m-1$; and their ſucceſſive denominators, the products of $1\times m$, $2\times m+1$. $3\times m+2$, &c. and the limit of the ſum of this *progreſſion* is the ſum of as many terms $1+\frac{1}{2}+\frac{1}{3}+\frac{1}{4}$, &c. as there are units in $m-1$. Now if each term of the new *progreſſion* be divided by $m-1$, that unity may be the common numerator, the terms $\frac{1}{m}$, $\frac{1}{2\times m+1}$, $\frac{1}{3\times m+2}$, &c. will ariſe, the limit of which is equal to the ſum of the fractions 1, $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, &c. (continued till their number be $m-1$) divided by $m-1$. In like manner, by aſſuming other alternate, or any equivalent terms of the ſeries 1, $\frac{1}{2}$, $\frac{1}{3}$ $\frac{1}{4}$, &c. we may form new *progreſſions*, the value of which may be found. Thus, if we take the terms 1, $\frac{1}{5}$, $\frac{1}{9}$, $\frac{1}{13}$, &c paſſing over three terms, and divide the ſucceſſive differences of theſe terms by 96, we ſhall have the ſeries $\frac{1}{5.24}$, $\frac{1}{5.9.24}$, $\frac{1}{9.13.24}$, $\frac{1}{13.17.24}$, &c. which is equivalent to the ſeries C, given by Monſ. de Monmort, in the philoſophical tranſactions, N°. 353, p. 651. viz. $C=\frac{1}{1.2.3.4.5}+\frac{14}{5.6.7.8.9}+\frac{55}{9.10.11.12.13}+\frac{140}{13.14.15.16.17.}$ + &c. The ſum of which will therefore be $\frac{1}{96}$. And if we take the alternate terms of the ſeries $\frac{1}{2}$, $\frac{1}{12}$, $\frac{1}{30}$, $\frac{1}{56}$, &c. above mentioned, and divide the ſucceſſive differences of the terms by 2, we ſhall have the ſeries $\frac{5}{2.12}$, $\frac{9}{12.30}$, $\frac{13}{30.56}$, &c. which is equivalent to the ſeries $\frac{5}{1.2.3.4.}$, $\frac{9}{3.4.5.6}$, $\frac{13}{5.6.7.8}$, $\frac{17}{7.8.9.10}$, &c. mentioned in the ſaid philoſophical tranſactions, and marked A, the ſum or limit of which, by the foregoing rule, will be $\frac{1}{4}$. So the limit of Mr. Monmort's ſeries $B=\frac{1}{1.2.3.4.5}+\frac{4}{4.5.6.7.8}$, &c. will be $=\frac{1}{108}$ See *Maclaurin*'s fluxions, art. 356, where there is an error of the preſs, in p. 296. l 11. and 15. for the ſeries which in line 11. is ſaid to be Mr. Monmort's ſeries B, is the ſeries A, p. 651. of the philoſophical tranſactions, N°. 353 aforeſaid; ſo in line 15, for A, read B.

This may ſuffice to ſhew how the ſums of *progreſſions* ſo derived may be found. We refer for the farther application of theſe principles to the aforeſaid treatiſe of fluxions, art. 357, &c. Mr. Stirling's [a] treatiſe of the ſummation of ſeries, ought alſo to be conſulted, as he has improved the method of approximating to the value of *progreſſions*, which often ariſe in the ſolution of problems. See alſo Mr. de Moivre's *miſcellanea analytica*, and particularly the ſupplement to that work. [[a] *Methodus differentialis*: ſive *tractatus de ſummatione et interpolatione ſerierum infinitarum*. Lond 1730. 4°.]

PROGYMNASMATA, Προγυμνασματα, in antiquity, certain preparatory exerciſes performed by all thoſe who offered themſelves to contend in the Olympian games. *Potter*, Archæol. l. 2. c. 22. T. 1. p. 448.

PROHIBITO, in the Italian muſic, is a term applied to ſuch parts of a piece as are not proper, or according to juſt rule. Thus *intervallo prohibito* is every interval in melody that does not paſs the ear eaſily or naturally, to give it ſome pleaſure; ſuch are the tritone, the ſixth major, the ſeventh, ninth, &c. though under certain circumſtances, even theſe have pleaſing effects, in that by their harſhneſs they render the ſubſequent concords more agreeable.

PROJECTILE *(Cycl.)*—The theory of *projectiles*, as delivered under this head in the Cyclopædia, and by almoſt all writers on gunnery ſince Galileo, proceeds on the ſuppoſition, that the flight of ſhot or ſhells is nearly in the curve of a parabola. Galileo, indeed, has ſhewn, that independently of the reſiſtance of the air, all *projectiles* would in their flight deſcribe a parabola; and did propoſe ſome means of examining what inequalities would ariſe from that reſiſtance. So that it might have been expected, that thoſe who came after him would have tried how far the real motions of *projectiles* deviated from a parabolic tract, in order to have decided how far

far the reſiſtance of the air was to be attended to, in the determinations of gunnery. But inſtead of proceeding thus cautiouſly, ſubſequent writers have boldly aſſerted, that no conſiderable variation could ariſe from the reſiſtance of the air, in the flight of ſhells and cannon-ſhot; and it is now become an axiom almoſt generally acquieſced in, that the flight of theſe bodies is nearly in the curve of a parabola.

This hypotheſis was ſupported by Anderſon in his Treatiſe *of the genuine uſe and effects of the gun*, publiſhed in 1674; alſo by Monſ Blondel in his *Art de jetter les Bombes*; and the ſame ſubject being treated of by Dr Halley in the Phil. Tranſactions, N°. 216. this learned gentleman, ſwayed by the conſideration of the great diſproportion between the denſity of bullets and of the air, thinks it reaſonable to believe, that the reſiſtance of the air to large metal ſhot is ſcarcely diſcernible, although in light ſhot he acknowledges it ought to be accounted for. But though this hypotheſis was readily admitted by thoſe who contented themſelves with ſpeculation only, yet Anderſon himſelf found it impoſſible to reconcile it to experience, without ſome modification. This led him to ſuppoſe that a bullet at its firſt diſcharge, flew a certain diſtance in a right line, from the end of which line only it began to bend into a parabola. By this means he defended, as he thought, the hypotheſis of a parabolic motion: but ſo ſtrange a ſuppoſition as that of the ſuſpenſion of the action of gravity, needs no confutation. Anderſon was deceived, by his not knowing how greatly the primitive velocity of the heavieſt ſhot is diminiſhed in the courſe of its flight by the reſiſtance of the air.

Practical gunners alſo unanimouſly agree, that every ſhot flies in a ſtreight line to a certain diſtance from the piece, which imaginary diſtance they call the extent of the point-blank ſhot. This flight in a ſtreight line, indeed, ſuppoſing it fact, would be not only a refutation of the parabolic hypotheſis, but a moſt unaccountable difficulty in itſelf, as implying a ſuſpenſion of the action of gravity. But the great velocity of cannon-ſhot, aſſigned by Mr. Robins, ſeems readily to clear up this affair. We need only ſuppoſe, that within the diſtance thus determined by practical gunners, the deviation of the path of the ſhot is not very perceptible in their way of pointing. Now as a ſhot of 24 lb. fired with two thirds of its weight in powder, will, at the diſtance of five hundred yards from the piece, be ſeparated from the line of its original direction, by an angle of little more than half a degree; thoſe who are acquainted with the inaccurate methods often uſed in the directing of cannon, will eaſily allow, that ſo ſmall an aberration as this, may, by the generality of practitioners, be unattended to, and the path of the ſhot may conſequently be deemed a ſtrait line, eſpecially as other cauſes of error will often intervene, much greater than what ariſes from the incurvation of this line by gravity. See new princip. of Gunnery, p. 82.

How raſh and erroneous the opinion of the inconſiderable reſiſtance of the air is, will eaſily appear from what is eſtabliſhed by that ingenious author, who has ſhewn that this reſiſtance to a cannon ball amounts to more than twenty times the weight of the ball. What errors may not be expected from an hypotheſis which neglects this force as inconſiderable? In effect, it will not be difficult to ſhew, that the track deſcribed by the flight of ſhot or ſhells, is neither a parabola nor nearly a parabola. For by that author's experiments it appears, that a muſket ball of three fourths of an inch diameter, fired with half its weight of powder from a piece 45 inches long, moves with the velocity of near 1700 feet in a ſecond. Now, by the common parabolic theory if this ball flew in the curve of a parabola, its horizontal range at 45°, would be found to be about 17 miles. But from practical writers, as Diego, Uſano, and Merſennus, it appears, that this range is ſhort of half a mile; ſo that a muſket ſhot at 45° elevation, with a reaſonable charge of powder, flies not the $\frac{1}{34}$ part of the diſtance it ought to do if it moved in a parabola.

Nor is this great diminution of the horizontal range to be wondered at, when it is conſidered that the reſiſtance of the air to this bullet, when it firſt iſſues from the piece, amounts to 120 times its gravity.

Again, if the flight of the heavieſt ſhot, in common uſe for land ſervice, as of iron bullets of 24lb. weight, be examined, it will appear, that ſuch a ſhot made with a full charge of powder has a velocity of 1650 feet in 1″. And the horizontal range at 45° of this ſhot, would, according to the parabolic hypotheſis, be about 16 miles; but by the experiments of St. Remy it appears, that the range is really ſhort of three miles; which is not one fifth of the diſtance it ought to fly, if it deſcribed the curve of a parabola

And this deviation from the parabola, happens not only in theſe great velocities, but in ſuch as are much leſs; thus in velocities of about 400 feet in 1″; by ſeveral experiments it appears, that the range of a leaden bullet of three fourths of an inch in diameter, fired at different elevations with this velocity, did not at all anſwer the common theory. So that it ſufficiently appears that this theory, or the ſuppoſition of the inconſiderableneſs of the air's reſiſtance to *projectiles*, is falſe.

Indeed the falſeneſs of this hypotheſis almoſt appears at ſight, even in *projectiles* ſlow enough to have their motion traced by the eye; few there are who do not deſcend thro' a curve manifeſtly ſhorter and more inclined to the horizon than that in which they aſcended, and the higheſt point of their flight, or the vertex of the curve, is much nearer to the place where they fall on the ground than from whence they were at firſt diſcharged. Theſe things cannot be a moment doubted of by any one, who in a proper ſituation views the flight of ſtones, arrows, or ſhells, thrown to any conſiderable diſtance. See new princip. of Gunnery, Part 2. Prop. 6.

What is here advanced may be confirmed from the conſtant obſervation of all who are converſant in the practice of throwing bombs, *viz.* that the ranges at elevations below 45°, conſtantly exceed the ranges at elevations above 45°, which are reſpectively at an equal diſtance from 45°. Thus the range of ſhells at 15°, will go farther than one at 60°, and ſo a range at 20° exceeds one at 65°, &c. but it is known that in the parabolic hypotheſis theſe ought to be equal, which hypotheſis is therefore falſe.

There is an odd phænomenon in the motion of bodies projected with conſiderable force, which ſhews the great complication and difficulty of this ſubject. The phænomenon is, that bullets in their flight are not only depreſſed beneath their original direction by the action of gravity, but are alſo frequently driven to the right or left of that direction by the action of ſome other force.

If it was true that bullets varied their direction by the action of gravity only, then it ought to happen that the errors in their flight to the right or left of the mark they were aimed at, ſhould increaſe in the proportion of the diſtance of the mark from the piece only. But this is contrary to all experience; the ſame piece which will carry its bullet within an inch of the intended mark, at 10 yards diſtance, cannot be relied on to 10 inches in 100 yards, much leſs to 30 inches in 300 yards.

Now this inequality can only ariſe from the track of the bullet being incurvated ſideways as well as downwards; for by this means the diſtance between the incurvated line, and the line of direction, will increaſe in a much greater ratio than that of the diſtance; theſe lines being co-incident at the mouth of the piece, and afterwards ſeparating in the manner of a curve from its tangent, if the mouth of the piece be conſidered as the point of contact.

This is put beyond diſpute from the experiments made by Mr. Robins; who informs us, that having taken a barrel carrying a ball of three fourths of an inch diameter, and fixing it on a heavy carriage, he ſatisfied himſelf of the ſteadineſs and truth of its direction, by firing at a board one foot and a half ſquare, and miſſing it but once in 16 ſucceſſive ſhot. Now the ſame barrel being fixed on the ſame carriage, and fired with a ſmaller quantity of powder, ſo that the ſhock on the diſcharge would be much leſs, and conſequently the direction leſs changed, he found that at 760 yards diſtance the ball flew ſometimes 100 yards to the right of the line it was pointed on, and at other times 100 yards to the left. He found too that its direction in the perpendicular line was not leſs uncertain, it falling one time above 200 yards ſhort of what it did at another; altho' by the niceſt examination of the piece after the diſcharge, it appeared not to have the leaſt ſtarted from the poſition it was placed in. New principles of Gunnery, Part. 2. Prop. 7.

If it be aſked what can be the cauſe of a motion ſo different from what has been hitherto ſuppoſed? It may be anſwered, That the deflection in queſtion muſt be owing to ſome power acting obliquely to the progreſſive motion of the body, which power can be no other than the reſiſtance of the air. And this reſiſtance may perhaps act obliquely to the progreſſive motion of the body, from inequalities in the reſiſted ſurface; but its general cauſe is doubtleſs a whirling motion acquired by the bullet about its axis; for by this motion of rotation, combined with the progreſſive motion, each part of the bullet's ſurface will ſtrike the air in a direction very different from what it would do if there was no ſuch whirl; and the obliquity of the action of the air ariſing from this cauſe will be greater, according as the rotatory motion of the bullet is greater in proportion to its progreſſive motion.

PROLAPSUS *oculi*, in ſurgery, a diſtemperature of the eye, in which it is ſo violently inflamed and ſwelled, that it cannot be retained in its orbit or ſocket, but protrudes itſelf out of its natural ſeat. This diſorder is not only attended with great deformity, but alſo intenſe pains, blindneſs, and too often an obſtinate cancer are the effects of it. This is ſometimes ſo violent in degree, that the eye burſts out of its coats.

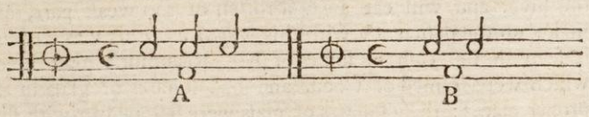
This diſorder ſometimes ariſes from inflammations, or redundancy of humors; and ſometimes from external violence, or from a cancer. Sometimes, when the diſorder is recent, and but in a moderate degree, it may be carried off by bleeding, bliſtering, and purging, with external applications, as fomentations and the like. When it will give way to none of theſe, the tumor muſt be opened, and the humors diſcharged, and this repeated as often as neceſſary; after every dreſſing, binding on a plate of lead hollowed in a proper degree.

When the natural figure of the eye, and its office of viſion are wholly deſtroyed by this diſeaſe, and the pains become more

more intenſe, there is no way left but to make a large inciſion and let out the humors of the eye, and afterwards cut away ſo much of it, that the remainder may be covered with the eye-lid. *Heiſter*'s Surg. p. 427.

PROLAPSUS *uvulæ*. The *uvula* is ſometimes ſo much enlarged and elongated, as to reach the larynx and pharynx, and obſtruct the actions both of reſpiration and deglutition, as well as of ſpeech. If it proceed from a recent inflammation, the patient may be relieved by bleeding and cooling gargles, with ſal armoniac and alum; ſcarifications are alſo very uſeful in this caſe, to prevent its ſpreading and inflammation.

When, on the other hand, this part is too much enlarged and elongated by phlegmatic humors, it appears white and free from pain and inflammation, and is moſt relieved by a gargle of ſpirit of wine and water warm, or a decoction of red roſes, or the like aſtringent ſubſtances with ſpirit of wine, or ſpirit of ſal armoniac added in ſmall quantities to them.



A powder of ginger, pepper, and pomegranate peel, may alſo be applied; but when all theſe methods prove ineffectual, the only remaining one is, to take off as much of the *uvula* as is neceſſary, either by ligature or by the ſciſſars. This latter is much the eaſier and better way; and the great caution neceſſary in it is, neither to take off too much nor too little of the *uvula*. For if too much be taken off, the patient's voice will be the worſe for it afterwards; and if too little, he will be very little the better for the operation.

This is a very common diſorder among the peaſants in Norway, and they have invented a machine with a hole in it, to let thro' a proper portion of the *uvula* when the whole is thruſt into the mouth, and a ſpring knife, which cuts off juſt as much as is let thro'. The ſurgeons have copied and improved on this invention. *Heiſter*'s Surg. p. 470.

PROLATION, *(Cycl.)* in muſic. The ſigns by which the modern antients uſed to ſignify a *prolation* to be made on any note, was a point in a circle or ſemi-circle, thus, ⊙, ☾. This point was the length of a ſemi-breve and minim.

Prolation was either *perfect* or *imperfect*. *Perfect prolation* was marked after the cleff as above, and then the ſemi-breve contained three minims, for which reaſon they placed the figure 3, or $\frac{3}{2}$, or $\frac{3}{1}$, after the circle, to ſignify that three ſuch notes were required to a bar. See example A.

Imperfect prolation was marked with the ſame characters, but without points, and then the ſemi-breve contained but two minims. See example B.

Theſe characters are almoſt entirely diſuſed in the modern practice; but as they are often met with in antient muſic, 'tis therefore neceſſary that a muſician ſhould have ſome knowledge of them. Tho' even now the Italians have two ſorts of *prolation* in muſic, which are ſignified by characters reſembling thoſe above deſcribed in the example A. The firſt they call *prolatione maggiore perfetta*, and it is marked thus, ⊙ and $\frac{3}{2}$. The ſecond they call *prolatione minore perfetta*, the characters of which are, ☾, or $\frac{3}{1}$, or $\frac{3}{2}$, but oftener C and $\frac{3}{2}$; but in both caſes the ſemi-breve contains a whole bar, and its pauſe the ſame; the minim one third of the bar, and its pauſe the ſame; and ſo of the reſt in proportion.

Prolation is alſo uſed for a ſeries of ſeveral ſounds or notes on the ſame ſyllable or vowel.

PROLECTATIO, a word uſed in chemiſtry to expreſs an extraction of the finer ſubſtances of a mixed body by the attenuation of the ſubtler particles; ſo that theſe being rarefied, ſeparate ſpontaneouſly from the reſt, and leave the groſſer and leſs valuable part in form of a reſiduum behind.

PROLEPTICOS, an epithet uſed by the antients to expreſs a fever the fits or exacerbations of which were apt to return before their regular time.

PROLOGIA, Προλογια, in antiquity, a feſtival celebrated by the inhabitants of Laconia, before they gathered their fruits. *Potter*, Archæol. Græc. T. 1. p. 427.

PROMACHIA, Προμαχια. in antiquity, a feſtival in which the Lacedæmonians crowned themſelves with reeds. *Potter*, Archæol. T. 1. p. 427.

PROMALACTERION, the name of the firſt apartment in the hot baths of the antients; this was a hot and cloſe room, in which the perſon was kept a while before he plunged at once into the warm water.

PROMETHEIA, Προμηθεια, in antiquity, an Athenian ſolemnity celebrated in honour of Prometheus, with torch-races, in remembrance that he was the firſt that taught men the uſe of fire. *Potter*, Archæol. Græc. T. 1. p. 427.

PROMYTHION, Προμυθιον, in rhetoric. See FABLE, *Cycl.*

PRONATOR *(Cycl.)*—PRONATOR *quadratus, ſive tranſverſus*, a ſmall fleſhy muſcle nearly as broad as it is long, lying tranſverſely on the inſide of the lower extremity of the fore arm. It is fixed by one ſide or edge in the long eminence, at the lower part of the internal angle of the ulna, and by the other in the broad concave ſide of the lower extremity of the radius. It is wholly fleſhy, without any mixture of tendinous fibres. It is ſituated tranſverſely, but that extremity which lies on the radius is nearer the carpus than that on the ulna. It is of a moderate thickneſs; the fibres neareſt the ſurface are longeſt, the reſt decreaſing in proportion as they lie nearer the interval between the two bones, and the interoſſeous ligament. It has a ligamentary or tendinous frænum belonging to it, one end of which is fixed in the interoſſeous ligament, the other in the inner edge of the baſis of the radius. *Winſlow*'s Anatomy, p. 190.

PRONATOR *teres ſive obliquus*, a ſmall muſcle broader than it is thick, ſituated on the upper part of the ulna, oppoſite to the ſupinator brevis, with which it forms an angle like the letter V.

It is fixed to the internal condyle of the os humeri, partly by fleſhy fibres, and partly by a tendon common to it with the ulnaris internus; from thence it paſſes obliquely before the extremity of the tendon of the brachiæus, and reaches to the middle part of the convex ſide of the radius; where it becomes flat, and is inſerted below the ſupinator brevis, by an extremity almoſt wholly fleſhy.

It is called *teres*, to diſtinguiſh it from the quadratus; but the name of *pronator ſuperior* is much more proper; but that of *pronator obliquus* is certainly propereſt of all. *Winſlow*'s Anatomy, p. 190.

PRONG-*hoe*, in huſbandry, a term uſed to expreſs an inſtrument uſed to *hoe* or break the ground near, and among the roots of plants.

The ordinary contrivance of the *hoe* in England is very bad, it being only made for ſcraping on the ſurface; but the great uſe of *hoeing* being to break and open the ground, beſide the killing the weeds, which the antients, and many among us have thought the only uſe of the *hoe*, this dull and blunt inſtrument is by no means calculated for the purpoſes it is to ſerve.

The *prong-hoe* conſiſts of two hooked points of ſix or ſeven inches long, and when ſtruck into the ground will ſtir and remove it the ſame depth as the plough does, and thus anſwer both the ends of cutting up the weeds and opening the land. The antient Romans had an inſtrument of this kind, which they called the *bidens*; but they were afraid of its uſe in their fields and gardens, and only uſed it in their vineyards. The *prong-hoe* comes into excellent uſe even in the horſehoing huſbandry; in this the *hoe*-plough can only come within three or four inches of the rows of the corn, turneps and the like; but this inſtrument may be uſed afterwards, and with it the land may be raiſed and ſtirred, even to the very ſtalk of the plant. *Tull*'s Huſbandry.

PRONOMÆA, a word uſed by ſome naturaliſts to expreſs what is uſually called the trunk, or proboſcis in inſects; an inſtrument ſomewhat reſembling the trunk of an elephant, which moſt of thoſe ſmall animals are provided with for the extracting the juices of plants, &c. deſtined for their food.

PRONTIA *lapis*, a name given by the writers of the middle ages to a foſſile of which they relate ſeveral extraordinary things; but their reſembling it to the head of a tortoiſe, and giving it the virtue of preſerving people from injuries by lightning, ſeem to make it plain that the word is only a corrupt ſpelling of the *brontia* of the antients, of which Pliny has related the ſame things.

This was a ſpecies of echinites, ſuppoſed to fall from the clouds in thunder ſtorms. See BRONTIA.

PROOF *(Cycl.)*—PROOF, in the ſugar trade, a term uſed by the refiners of ſugar for the proper ſtate of the diſſolved ſugar when it ſhould be ſet to harden.

The proceſs in the bringing ſugar to this ſtate may be underſtood by performing the whole work in little in this manner: Take ſix pounds of coarſe, or unrefined ſugar, diſſolve it over the fire in ſix pints of lime water; add to this the whites of four eggs beat up to a froth, ſtir the whole together; then boil the liquor to a higher conſiſtence than a ſyrup, or till, when expoſed to the cold it will concrete into grains. This is what the ſugar-bakers call *proof*. Pour this ſyrup into an earthen mould, with a hole at its bottom, ſtop the hole and ſet the veſſel in a moderately warm place.

The ſugar in a few days will ſet and harden, then open the hole at the bottom, and lay over the top of the ſugar ſome tobacco-pipe clay, made into a ſoft pap with water. The clay muſt be afterwards weted at times, and the water from among it will gradually be ſoaked up by the ſugar, and running thro' it will waſh away the treacle, without diſſolving the grained part. And thus all the treacle will by degrees be drained out of the maſs, and a loaf of white ſugar procured. *Shaw*'s Lectures, p. 149.

PROOF *ſpirits*, among diſtillers. See SPIRITS.

PROPAGATION *(Cycl.)*—PROPAGATION *of plants*. The number of vegetables that may be *propagated* from an individual, is very remarkable, eſpecially in the moſt minute plants.

It has been recorded, that in ſo large a plant as the common mallow, the annual product of one ſeed was no leſs than 200,000; but it has been ſince proved, by a ſtrict examination into the more minute parts of the vegetable world, that ſo deſpiſed a plant as the common wall maſs produces a much more numerous offſpring. In one of the little heads of this

plant there have been counted 13824 ſeeds. Now alloting to a root of this plant eight branches, and to each branch ſix heads, which appears to be a very moderate computation, the produce of one ſeed is 6×13824=82944; and 8×82944, gives 663552 ſeeds, as the annual produce of one ſeed, and that ſo ſmall that 13824 of them are contained in a capſule, whoſe length is but one ninth of an inch; its diameter but one twenty third of an inch, and its weight but the thirteenth part of a grain. Phil. Tranſ. N°. 478. ſect. 12.

PROPEMPTICON, προπεμπτικον, in poetry, a poem wherein are expreſſed ardent wiſhes and ſolemn vows for the ſafety of a perſon going upon a journey or voyage. Such is that of Horace, L. 1. Od. 3. addreſſed to Virgil on his ſetting out for Athens. It was otherwiſe called *apopemptic*on. *Hofm.* Lex Univ. in voc. See APOPEMPTIC, *Cycl.*

The word is derived from προπεμπω, I ſend forward, or accompany on the way.

PROPHECY *(Cycl.)*—The *prophecies* in the Old Teſtament, particularly thoſe relating to the Meſſiah, are allowed by all Chriſtians to have been accompliſhed in Jeſus Chriſt; but the diſpute is, as to the ſenſe or manner wherein they have received their accompliſhment.

Oppoſite ſyſtems have been framed on this head; Grotius, Vitringa, Le Clerc, Whiſton, Collins, Chandler, *&c.* Some hold the *prophecies* to have been accompliſhed in one ſenſe, ſome in another, and ſome in both. Mr. Whiſton's opinion is mentioned in the Cyclopædia.

A modern learned advocate for Chriſtianity ſhews, that it was the cuſtom of Jewiſh writers to ſay a thing was accompliſhed when they only made alluſions to it, more or leſs remote; that however there are ſome formal *prophecies* which literally relate only to the Meſſiah; other typical *prophecies* which are alſo to be applied in a literal ſenſe to the Meſſiah; and that others are only cited as accompliſhed allegorically, by way of *argumentum ad hominem*, to the Jews only who admitted this way of reaſoning. *Chandler*'s Defence of Chriſtian. paſſim. Bibl. Angl. T. 12. p. 458, ſeq.

Grotius's method is to look for a literal accompliſhment in the Jewiſh affairs about the time when the prophets wrote; or in the affairs of the neighbouring nations with whom they had wars. This method, diſapproved by Vitringa and many others, is defended by Le Clerc, Maſſon, L'Enfant, *&c.* who even carry it further, ſo as to maintain that there is no *prophecy* in the Old Teſtament which has not had a literal accompliſhment, and that if there be any wherein this is not known, 'tis thro' the defect of hiſtory. Vid. Hiſt. Crit. Rep. Lett. T. 6. Art. 2. p. 43, ſeq.

Grotius allows that the *prophecies* applied to the Meſſiah in the New Teſtament, tho' they had a literal accompliſhment before, had another more ſublime and peculiar accompliſhment in Chriſt. This appears from his notes on Matthew and Iſaiah, where he ſays expreſly, that what he interprets literally of Jeremiah, agrees in a more ſublime manner, and even more literally to Jeſus Chriſt. See alſo his notes on Pſalm XXII. 1. and his Treat. de Veritat. Relig. Chriſt. l. 5. c. 14. §. 17.

This opinion touching the double ſenſe of *prophecies* is not new. The greateſt allegoriſts, even thoſe among the Jews who make uſe of this manner of interpreting, have allowed a double ſenſe, as is ſhewn by Surenhuyſius; nor does Vitringa himſelf reject it. In lib. Conciliat. Vid. Bibl. Choiſ. T. 25. p. 411.

The diſpute then between Grotius and his adverſaries, is not whether there are two ſenſes in the *prophecies*, but whether ſeveral *prophecies* of the Old Teſtament, which relate to Chriſt, had a literal, leſs ſublime, and leſs perfect accompliſhment before they were accompliſhed in Chriſt. The affirmative is maintained by him, the negative by them. Vid. Le Clerc. Bibl. Choiſ. T. 27. p. 391, ſeq

As to the accompliſhment of particular *prophecies*, we find endleſs diſputes among critics and interpreters, concerning thoſe of the conception of a virgin, the ſeed of a woman, the ſceptre's departure from Juda, the root of Jeſſe, out of Egypt have I called my ſon, he ſhall be called a Nazarine, Daniel's ſeventy weeks, the Babyloniſh captivity, the diſperſion and reſtoration of the Jews. Matth. xxii. 23. *Surenhuſ.* Liber Conciliat. Bibl. Choiſ. T. 25. p. 414. *Jaquelot* Diſſ. ſur le Meſſie. Ouv. des Scav. Dec. An. 1698. p. 538. *Marſhal* Tabul. Chron. Jour des Scav. Iſrael.* Hope of Iſrael, Sect. 29. p. 36.

Few modern events of any conſiderable note, but one interpreter or other finds to be the accompliſhment of ſome Scripture *prophecy*. The late war and death of the king of France, and numerous others are pretended to be found in Holy Writ.

The viſions in the Old and New Teſtament, have been more tortured for accompliſhments than the *prophecies* themſelves. Such is the caſe of Ezechiel's temple, the temporal reign of Chriſt on earth, the deſtruction of antichriſt, the looſening the great dragon, the opening of the ſeals, and many others. *L'Enfant* and *Beauſobre* Verſ. du Nouv. PROPOLIS, *(Cycl.)* a name given by authors to a certain ſubſtance more glutinous and tenacious than wax, with which the bees ſtop up all the holes or cracks in the ſides of their hives. Beſide the wax and the honey which the bees gather in their daily travels, they have occaſion for this third ſubſtance at times, and that eſpecially when they are placed in a new hive.

They very well know that it is neceſſary to their well being, that they ſhould be kept perfectly warm in their hives, and ſtrongly defended againſt the injuries of weather: to keep out wind and rain they ſtop every little chink in the ſides of their habitations with this matter; nor is this the only reaſon for it, they have other enemies of the inſect tribe, which are on different occaſions eternally ſeeking a way into their habitations; ſome of them feed on their honey, others on the wax, and others on their young offspring. To be guarded againſt theſe, they as firmly as poſſible block up all the accidental holes or cracks in the hive, and guard the principal opening, which ſerves as the gate of their city, by numbers which are always placed round about it, ſo that no enemy can come in that way. *Reaumur*'s Hiſt. of Inſects, V. 10. p. 76.

Theſe wary animals not only ſtop up in this manner all the cracks they can find, but even examine all the weak places of the hive, and will eat away a rotten or too weak part, and make up the deficiency with this *propolis*. This was elegantly ſeen in the caſe of ſome of Mr. Reaumur's glaſs hives, which were framed of wood, and had ſquares of glaſs in the proper places: theſe ſquares of glaſs were faſtened in with ſlips of paſted paper. The bees finding this a much weaker part of the hive than any other, and capable of being eaten thro' by their enemies, ſoon gnawed to pieces all the paper and paſte, and covered thoſe parts with the *propolis* in the place of that matter.

It might ſeem that the bees might uſe wax on this occaſion; but this would be no defence againſt thoſe of their enemies, which devour and feed on wax; and nature has guarded them againſt theſe, by ſupplying them with a matter which ſpreads more eaſily, is of greater tenacity, and fixes itſelf much more ſtrongly in the ſmall crevices than wax could do. It has been known from the earlieſt times, that the bees made uſe of this ſubſtance; Pliny mentions it, and tells us, that the authors of his time diſtinguiſhed three kinds of it, the firſt they called *metys*, the ſecond *piſſiceron*, and the third *propolis*. The laſt of theſe names is only retained among the later writers, and ſeems to have ſtood with the antients for the pure ſubſtance, the other kinds differing from it only as they were more or leſs mixed with wax.

The *propolis* itſelf is a ſubſtance perfectly different from wax; it is found to be ſoluble in ſpirit of wine, or in oil of turpentine; and is ſoft when laid on by the bees, but grows hard afterwards; it may, however, even in its hardeſt ſtate, be ſoftened by heat. By all theſe obſervations it appears very plainly, that the *propolis* is a true genuine vegetable reſin, of the nature of many others which we have in common uſe. The authors who have treated of this ſubſtance, have deſcribed it very differently; George Pictorius, who has written of bees, ſays, that it is of a yellow colour and an agreeable ſmell, like that of ſtorax, and that it would ſpread when warmed properly. Pliny and the old authors deſcribe it as being of a rank and ſtrong ſmell, and being uſed as a ſuccedaneum for galbanum; and at preſent we uſually find it of an aromatic and agreeable ſmell, inſomuch that ſome rank it among the perfumes. The apothecaries, in ſome places, keep it as a medicine in their ſhops; but it is to be obſerved, that it is very various in its nature; for according to the deſcriptions of authors, it is ſometimes ſweet and ſometimes ſtinking. The truth is, that the bees who collect it as a thing to be uſed for a cement, not for food, are not over curious of what plants they gather it from; and hence in different hives it is found of very different colours and conſiſtences. In general, the *propolis* is of a browniſh red colour on the ſurface; the red ſometimes predominating, ſometimes the brown; but when broken it is yelloviſh, or approaching to the

the colour of wax. It very readily diſſolves in ſpirit of wine or oil of turpentine, and this ſolution is of a fine gold colour, and will ſerve extremely well as a varniſh to colour ſilvered picture-frames, or other the like work, into the appearance of gold. It gives a fine gold-like appearance, indeed, to any white metal of a poliſhed ſurface; all that it wants is a little more brilliancy, which is eaſily given it by mixing a ſmall quantity of maſtich, or of ſandarach in the ſolution. *Reaumur*'s Hiſt. Inſ. Vol. X. p. 77.

The bees having much leſs frequent occaſion for this ſubſtance than for wax, are very ſeldom to be met loaded with it; they never bring any of it home, except when they are eſtabliſhed in a new hive, or when there happens ſome crack or flaw in an old one. The morning is the time of their gathering the matter of which they make their wax; but the evening is the time of their going out for the *propolis*. When there is occaſion for this ſubſtance in the hive, the bees will be found to return loaded with it in lumps placed upon the third joint of their hinder legs, in the very ſame manner in which they carry their wax. It differs greatly from the rough wax which they carry, as that is made up of ſmall round or oval granules; and this is one uniform ſubſtance of the nature of a ſoft reſin or gum. This ſubſtance is not to be eaten firſt, in the manner of the rough wax, in order to its being rendered fit for uſe; but is of immediate readineſs for ſervice. It is one of the moſt troubleſome offices of the bees, to bring it home and apply it to the places where it is wanted. It is ſo tough and viſcous, that it muſt be with infinite difficulty that the poor bee gets it upon her leg; but the getting it off again, is a taſk left to others. As ſoon as one of the ſwarm enters the hive loaded with this, ſeveral others immediately gather about her, and bite out pieces of a very minute ſize from the lumps ſhe is loaded with. This is a work of great trouble and difficulty for them; for their teeth are ſo faſtened in by the tenacity of the matter, that it is with the utmoſt labour that they get off the little portion they have thus ſeized upon. This piece draws out, in the pulling it away, into a long thread, as any of the ſoft gum-reſins would do. Often the matter is ſo tenacious, that the bee which ſeizes on it, in order to ſeparate a piece, is not able to do it; but remains hung faſt by the teeth to the leg of the other. Often two bees are at work at a time, one at the lump of *propolis* attached to each leg of the bee that brought it in: as ſoon as they have any of them diſlodged a piece, tho' ever ſo ſmall, they immediately fly with it to ſome place where there is a crack to be ſtopped, and the moment theſe are gone, others ſupply their place at the lumps; ſo that both legs of the bee who brought in the load are very ſoon perfectly cleared of it, when the whole is employed to the proper purpoſe. The great trouble of working and ſeparating this matter, and the ſmall quantity that one bee is able to bring at a time, might ſeem to prove, that it would be an endleſs work to ſtop the large holes ſometimes found in the hives with it: but the great number of bees employed in this work at the ſame time, are what makes it go off tolerably well, tho' each has unqueſtionably a very hard taſk to perform in it.

It is the general opinion of thoſe who have ſtudied bees, that the willow and the poplar are the trees which principally furniſh them with this reſin, which, when it has paſſed through their management, we call *propolis*. It is very certain, however, that theſe are not the only trees which afford it, ſince the bees are not found to want this neceſſary material for their work, in places where there are no trees of that kind in the neighbourhood of the hives. *Reaumur*'s Hiſt. Inſ. Vol. X. p. 80.

Mr. Reaumur was very deſirous of ſeeing the manner in which the bees collected this tenacious matter; but watched them in vain in the fields and upon the trees: although an accident gave him an opportunity of obſerving them at their work on this occaſion. He had taken off the cover of one of his glaſs hives on ſome occaſion, and as there was much of the *propolis* ſticking to its edges, which the bees had uſed to ſtop the crevices when it was fixed in, the bees of a neighbouring hive ſoon found that here was this ſubſtance ready for them in large quantities together, and that they could have it at a very eaſy rate: they therefore immediately detached a party to bring it off; and in conſequence of this, it was eaſy to obſerve any one of them, during the whole courſe of his work. The manner of ſeparating it from the ſubſtance it lay upon, was by detaching very ſmall pieces at a time with the teeth; theſe, when they had been with great labour looſened from the reſt, were delivered to the foot of one of the fore-legs: they were here moulded into a roundiſh lump, and, after a little working, delivered to the foot of a ſecond leg; and finally, by this to the flat triangular piece which makes the third joint of the hinder legs, the part deſtined in their common labours to receive the lumps of rough wax. It is here preſſed down with ſome violence, and afterwards fixed in its place by three or four ſtrokes from the ſame foot; and then another is ſeparated by the teeth in the ſame manner, and by the ſame means carried to the ſame place, and added to the firſt piece; and ſo on till the whole work is finiſhed. The bees which found this treaſure loaded themſelves to an immenſe degree, carrying of a lump larger than a pea on each leg, and the time to take up theſe large parcels was at leaſt half an hour: after carrying this load to the hive, and being relieved from it by the joint labours of ſeveral others, the bee which has been at all the pains of collecting it, joins a cluſter of others in ſome quiet part of the hive, where it reſts for the remainder of that day.

The *propolis* is not only uſed by theſe animals for ſtopping up holes and cracks in the ſides of their hives; they often cover with it the ſurface of thoſe croſs pieces which ſupport the combs, and when they can find it in ſufficient plenty, they cover over the whole inner ſurface of the hive with it, to defend it from the entrance of enemies of any kind which might eat their way through the ſhell of the hive. The antients who obſerved this lining of the hives, ſuppoſed that the bees uſed the *propolis* to faſten their combs to the hive; but later obſervation has proved this to be an erroneous opinion, the combs being always faſtened with lumps of wax only.

Beſides the uſes of the *propolis* already mentioned, there is another very ſingular one, which muſt by no means be paſſed over in ſilence: this is the embalming and preſerving, by means of it, certain bodies which they know not to diſpoſe of otherwiſe. Notwithſtanding the care that the bees take to guard the entrances of their hives, enemies of one kind or other will often get in: theſe uſually fare very ill; for the bees ſting is a weapon very capable of puniſhing ſuch an intruſion, and the ſwarm is ſo numerous, that it is not eaſy for the intruder to eſcape repeated wounds. When a creature of ſmall ſize has thus entered, and thus been killed for it, the bees with great care and pains carry him out; for they will bear no ſort of foulneſs in the hive. It ſometimes happens, however, that an unlucky ſnail, particularly of the large naked kind, crawls into the hive; in this caſe he never ceaſes crawling over the combs ſo long as he lives. It is no wonder that ſo cleanly creatures as the bees are highly enraged at this naſty viſiter: they ſoon ſurround and kill him with their ſtings; but then as he is a load too heavy to allow a poſſibility of their carrying him out, they prevent the miſchiefs attending the ſtinking of the carcaſe, by covering it over with a thick coat of this *propolis*, which perfectly well preſerves it from putrefaction. *Reaumur*'s Hiſt. Inſ. Vol. X. p. 84.

The common garden ſnail, with the ſhell, ſometimes alſo viſit theſe induſtrious and cleanly animals; and this creature they ſecure in a different manner, and that at the expence of only a very ſmall quantity of the *propolis*: but Reaumur had an opportunity of obſerving their method of deſtroying this enemy in a very accurate and eaſy manner, in one of his glaſs hives. The ſnail had entered the hive early in the morning, and after crawling about for ſome time, had fixed itſelf to one of the glaſs ſquares by the ſame glutinous matter by means of which it is frequently found fixed to old walls and trees; when the bees found their enemy thus fixed, they ſurrounded him, and in a few minutes formed a border of *propolis* round the verge of the mouth of the ſhell: this they continually added more and more to, till they had formed ſo thick a coat round it, that the ſnail could never move from the place again.

The ſnail is eaſily able to looſen the faſtening which it gives itſelf to any place, becauſe this is done by means of a gum, which water will diſſolve; therefore the firſt ſhower of rain, or the moiſture which the animal is able to ſecrete from its own body, releaſes it in this caſe; but the faſtening which the bees uſe to fix the ſhell to the glaſs being a reſin, this remains untouched by water, and muſt keep the animal fixed in its place till death, and even long afterwards.

It ſeems probable, that the bees are not over curious in the choice of the matter of the *propolis*; but that many vegetable reſins indifferently ſerve for this purpoſe: it has been tried, however, whether they would uſe common turpentine, and ſome other of the reſins in uſe among us, by laying them before their hives; but without ſucceſs. This is an experiment, however, that requires frequent repetition; ſince there are many ſeaſons at which the bee has no occaſion for this matter. *Reaumur*'s Hiſt. Inſ. Vol. X. p. 80.

PROPOMA, a name given by the antients to a potion prepared of honey and wine boiled together: the proportions were four parts of wine to one of honey.

PROPTOSIS, in ſurgery, a name by which ſome authors have called that diſtemperature of the eye commonly called a *prolapſus oculi*. *Heiſter*'s Surg. p. 427. See PROLAPSUS *oculi*.

PROSCHÆRETERIA, Προσχαιρήτηρια, in antiquity, a day of rejoicing, kept when a new-married wife went to cohabit with her huſband. *Potter*, Archæol. Grec. T. 1. p. 427.

PROSCLYSMA, a word uſed to expreſs an irroration, or ſprinkling of any part with a fluid, as the throwing water in the face in caſes of fainting, &c.

PROSECUTION. To make men liable to criminal *proſecutions* by the law of England, it is required that they have the uſe of reaſon, and that they be *ſui juris*. On the firſt account the law indulges infants under the age of diſcretion, ideots, and lunatics, whatever the nature of the fact may be; and even againſt the perſon of the king, as it has been held of late: neither will it ſuffer one who becomes *non compos*, after he has committed a capital offence, to be either arraigned or executed. See LUNATIC and INFANT, *Cycl.*

As to an offender's being *ſui juris*, it is to be obſerved, that neither a ſon, nor a ſervant, nor any other perſon, except a feme covert, is excuſed on the account of acting by command or coercion of another. *Hawk.* P. C. B. 1. c. 1. See the article FEME *covert*.

PROSERPINA, in botany, a name given by ſome authors to chamemile *Ger.* Emac. Ind. 2.

PROSEUCHE, in antiquity, properly ſignifies prayer; but it is taken for the places of prayer of the Jews, and was pretty near the ſame as their ſynagogues. But the ſynagogues were originally in the cities, and were covered places; whereas, for the moſt part, the *proſeuches* were out of the cities, and upon the banks of rivers, having no covering, except, perhaps, the ſhade of ſome trees, or ſome covered galleries. *Calmet.* Diction. Bibl.

The word is Greek, Προσευχη. petitio, precatio, oratio. Vid. *Hederic.* Lex. Man. Græc. in voc. Juv. Sat. 3 v. 296. In qua te quæro *proſeuchâ*.

PROSLAMBANOMENOS, in the antient Greek muſic, was the firſt note of their ſcale, whether aſcending or deſcending. Phil. Tranſ. N°. 481. p. 269.

It was uſual among the Greeks to conſider a deſcending as well as an aſcending ſcale; the former proceeding from acute to grave preciſely by the ſame intervals as the latter did from grave to acute. The not diſtinguiſhing theſe two ſcales has led ſeveral learned moderns to ſuppoſe, that the Greeks, in ſome centuries took the *proſlambanomenos* to be the loweſt note in their ſyſtem; and in other centuries to be the higheſt. But the truth of the matter is, that the *proſlambanomenos* was the loweſt or higheſt note, according as they conſidered the aſcending or deſcending ſcale [a]. The learned author of this remark [b], thinks this diſtinction of the aſcending or deſcending ſcales conducive to the variety and perfection of melody; but he ſays, he never met with above one piece of muſic, where the compoſer appeared to have any intelligence of that kind: and this piece was above 150 years old. [a Phil. Tranſ. ibid. b Dr. *Pepuſch*, ibid.]

The *proſlambanomenos* was one of thoſe ſounds which the antients called *ſtabiles*, from their remaining fixed throughout all the genera and ſpecies. Phil. Tranſ. N°. 481. p. 270.

PROSODIA, Προσοδια, in antiquity, a ſacred ſong, or hymn, ſung in honour of the gods. It differed from the *proſodia* with an omega, προσωδια, which was a ſong ſung in concert with ſome muſical inſtrument. Mem. Acad. Inſcript. Vol. 14. p. 352.

PROSTATES, Προσταλες, among the Athenians, was uſed to ſignify any patron to whoſe protection ſojourners in that city committed themſelves.

He was allowed to demand ſeveral ſervices of them, in which, if they failed, or neglected to chooſe a patron, an action was commenced againſt them before the polemarchus, and their goods were confiſcated. *Potter*, Archæol. Græc. l. 1. c. 10. T. 1. p. 56. See SOJOURNERS.

PROSTYPA, Προστυπα, in the ſculpture of the antients, images carved in ſuch a manner as to be only half raiſed above the ground, or plain, on which they were formed.

They ſeem to adhere to it, and have only one ſide expoſed to view. To *proſtypæ* is oppoſed *ectypa*. *Hoffm.* Lex. in voc. See ECTYPA.

PROTEA, in the Linnæan ſyſtem of botany, a genus of plants which takes in the lepidocarpodendron, and the hypophyllocarpodendron of Boerhaave.

The characters of this are, that the calyx is a common perianthium, containing ſeveral flowers; it is made up of ſeveral little leaves laid in a looſe manner over one another, and the inner ones very long, expanded, coloured, and remaining when the flowers are fallen. The flower is monopetalous, or made of one leaf, in form of a ſimple tube, divided at its ſummit into four ſegments, each as long as the tubular part, and all ſtrait, obtuſe, and bent backward. The ſtamina are four extremely ſhort filaments, inſerted on the ſegments of the flower, near its ſummit; the antheræ are laid cloſely on theſe. The germen of the piſtil is below the proper receptacle of the flower. The ſtyle is ſlender and very long, and the ſtigma ſimple. The fruit is one common large receptacle, which is flat and divided by hairy ſcales. The ſeeds are ſingle. *Linnæi* Gen. Plant. p. 22.

PROTELARII, among the Romans, were the poorer ſort of citizens, whoſe eſtate did not exceed fifteen hundred pieces of ſilver. They were diſtinguiſhed from thoſe who were worth little or nothing; theſe laſt being called *capite cenſi*. *Pitiſc.* in voc. See CAPITE *cenſi*.

PROTHESIS, Προθεσις, among the Greeks, the ceremony of laying the dead near the door till the time of their interment, with their feet outwards; on which account the Romans called them *poſiti*. *Hoſm.* Lex. in voc. See POSITI.

The word is derived from προτιθημι, *I expoſe to view*.

PROTIPULA, in natural hiſtory, a name given to a ſpecies of fly reſembling the tipula, or long-legs, in many reſpects; but differing in regard to the eſſential character, which, in the tipula, is the having two beards growing on the anterior part of the head, and occaſionally falling over the mouth, and cloſing its aperture; theſe the *protipula* wants. See the article TIPULA.

PROTOGALA, the term uſed by the antients for what we call *beeſtings*, the firſt milk of a cow or other animal after her having brought forth young.

PROTOMEDIA, in botany, a name given by ſome authors to the pimpinella or burnet. *Ger.* Emac. Ind. 2.

PROTOPASCHITÆ, Πρωτοπασχιται, in church hiſtory, Hereties, who after the manner of the Jews, celebrated the feaſt of Eaſter with unleavened bread. They were likewiſe called *Sabatiani*. *Hoffm.* Lex. univ. in voc. See SABATIANI.

PROTRUSORIS *ordo exterior*, in anatomy, a name given by Santorini to certain faſciculi of the great zygomatic muſcle, running under the fleſhy part of the lower lip. See the articles ZYGOMATICUS *major*, and LABIORUM *attollens*.

PROTRUSORIS *interior ordo*, in anatomy, a name given by Santorini to a muſcle of the face, called by Albinus *orbicularis oris*; and by Cowper and Douglaſs *conſtrictor labiorum* and *ſphincter labiorum*.

PROTRYGIA, Προτρυγεια, in antiquity, a feſtival in honour of Neptune, and of Bacchus, ſurnamed Προτρυγης, or Προτρυγαιος, απο της τρυγος, *i. e.* from new wine. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 427.

PROVER, *(Cycl.)* among jewellers, an inſtrument by which they examine the ſize and depth of diamonds. It is a ſpring in ſhape not unlike a pair of caliber compaſſes, kept at the proper diſtance by means of a ſpring. *Jeffreys* on diamonds, p. 18, and plate 6.

PROX, in natural hiſtory, a name given by Ariſtotle to the *cervus platyceros*, or broad-horned ſtag. The modern Greeks have called it *platonia*, and the interpreters of the oldeſt writers have rendered the word by *dama*; but this we are to underſtand as meant of the dama of our times, for the dama of the antients was our iſarus, or ſarrius, a kind of goat, whoſe ſkin affords us the true chamoy leather. This has no title to the name platonia, or the platyceros; nor is the creature that Ariſtotle deſcribes under the name *prox*, nor of the ſtag kind, as that certainly was.

PRUNELLA, or BRUNELLA, in botany, the name of a genus of plants, the characters of which are theſe: the flowers conſiſt of one leaf, which is of the labiated kind. The upper lip is galeated, and the lower is divided into three ſegments, the middle one being hollowed like a ſpoon. The piſtil ariſes from the cup, and is fixed in the manner of a nail to the hinder part of the flower, and ſurrounded by four embryos, which afterwards become four ſeeds, ripening in an open capſule which was the cup of the flower.

To theſe characters it may be added, that the ſtamina have not that reſemblance of the os hyoides that thoſe of ſage, clary, and the reſt have; and that the flowers are always arranged in cloſe ſpikes. See Tab. 1. of Botany, Claſs 4.

The ſpecies of *prunella*, enumerated by Mr. Tournefort, are theſe: 1. The broad-leaved Italian *brunella*, with fleſh-coloured flowers. 2. The common blue-flowered *brunella*, with undivided leaves. 3. The common *brunella*, with undivided leaves and purple flowers. 4. The common *brunella*, with undivided leaves and white flowers. 5. The great flowered *brunella*, with blue flowers. 6 The great flowered *brunella*, with fleſh coloured flowers. 7. The great flowered *brunella*, with white flowers. 8. The greateſt Pyrenean *brunella*, with very large flowers. 9 The Portugal *prunella*, with a larger flower and ſpike. 10. The narrow-leaved, or hyſſop-leaved *brunella*. 11. The *brunella* with diſſected leaves. 12. The cut-leaved *brunella*, with white flowers. 13. The leaſt white-flowered cut-leaved *brunella*. 14. The cut-leaved *brunella*, with roſe-coloured flowers. *Tourn.* Inſt. p. 182.

PRUNUS, the *plum*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the roſaceous kind, being compoſed of ſeveral petals, arranged in a circular form. From the cup of the flower there ariſes a piſtil, which finally becomes a fruit of a roundiſh or oval figure. This is ſoft and fleſhy, and includes a ſtone pointed at each end, within which is the kernel. *Tourn.* Inſt. p. 622.

The ſpecies of *plum* enumerated by Mr. Tournefort, are theſe: 1. The double-flowered *plum* tree. 2. The *plum* with large, ſweet, bluiſh black fruit. 3. The *plum* with ſmall ſweet, bluiſh black fruit. 4. The *plum* with large fleſhy and ſoweriſh fruit. 5. The *plum* with oblong blue fruit. 6. The *plum* with hard black fruit. 7. The *plum* with very large bluiſh-red, ſweet, and ſugar-like fruit. 8. The *plum* with the large, bluiſh red, late ripening fruit, called by the French the *imperatrice*. 9. The *plum* with large, oval, red fruit, called the *red imperial plum*. 10. The *plum* with a large, oval, yellow fruit, called ſimply the *imperial plum*. 11. The *plum* with a very large, oval, yellow fruit. 12. The wax-coloured *plum*. 13. The *plum* with large, round, red fruit. 14. The *plum* with a large, round, yellow, ſweet-taſted fruit. 15. The almond *plum*. 16. The *plum* with oblong, white, acid fruit. 17. The ſweet-taſted Brignole *plum*. 18. The *plum* with a remarkably red and ſweet fruit. 19 The *plum* with large, round, blackiſh, and very ſweet fruit. 20. The *plum* with ſmall, round, blackiſh, and very ſweet fruit. 21. The *plum* with a ſmall auſtere fruit. 22. The *plum* with ſmall and early ripe fruit. 23. The *plum* with ſmall, yellowiſh green fruit. 24. The common wild *plum*. 25. The tall,

early

early ripe, wild *plum*. 26. The wild *plum*, with large white fruit. 27. The wild *plum*, with red, harſh, and unpleaſant fruit, called in England the *hedge-plum*, or *horſe-plum*. *Tourn.* Inſt. p. 612. See PLUM.

PRUSSIAN *blue*. In a paper of Dr. Woodward's, communicated to the royal ſociety from another hand, there is given a ſhort way of making the *Pruſſian blue*, which when tried over again by Mr. Brown the chemiſt, was found to anſwer perfectly well; and gave hints and occaſions to ſeveral experiments which gave great light into the true nature of the bodies uſed in that preparation.

The method was this: four ounces of blood dried, and four ounces of ſalt of tartar were calcined together; two hours after which, a black ſpungy ſubſtance remained in the crucible, weighing four ounces; a ſolution of which being made in rain water, and afterwards filtered, left a remainder which when dried weighed nine drachms. An ounce of Engliſh vitriol was diſſolved in ſix ounces of rain water, and eight ounces of crude alum in two quarts of water. Theſe being mixed hot with the blood, became green; and on adding two or three ounces of ſpirit of ſalt, they became of a fine blue, which will ſubſide, and leave the water clear at top. Mr. Brown found the proceſs exactly anſwer, and the product was an ounce of a very fine colour, and perfectly fit for the painter's uſe.

Among the ſeveral experiments which were made by mixing, in different manners and proportions, the ſeveral liquors of which this colour was to be prepared, all produced a blue; but that in different degrees, ſome being deeper, and others much paler. In one experiment the alum was wholly left out, and a very pale blue was produced; in another, the alum and vitriol were uſed in equal quantities, and then the product was an extremely deep blue.

Upon the whole, the preſcription ſeems given after repeated trials, and appears to be that very combination of the ſeveral ingredients, which muſt give the very fineſt colour they are capable of giving.

It would be curious to know what gave the firſt hint for the production of ſo fine a colour from a combination of ſuch materials, eſpecially when we come to conſider, that the blood has the principal ſhare in this ſurpriſing change. Blood of any kind, or fleſh of any kind, would produce the ſame effects; but it is probable that fleſh would not yield ſo ſtrong or fine a colour. Beef has been tried, and found to yield a *blue*, but not ſo fine as the blood. Phil. Tranſ. N°. 381. p. 17.

The ſolution of alum, mixed with that of vitriol, produces no change of colour. If to theſe the ſpirit of ſalt is added, there is ſtill no change; but as ſoon as ever the blood is added, the blue is produced. If inſtead of the lixivium with blood, there be added to theſe ingredients, a lixivium with ſalt of tartar only, there follows a precipitation, indeed, but of no colour; and when the ſpirit of ſalt is added to this, it clears up, and the precipitation is received again into the liquor.

The very ſame effect will follow if any volatile alkaline ſpirit is made uſe of as a precipitant, or any volatile ſalt diſſolved in water; nor can the blood itſelf be ſuppoſed to communicate this change from any ſuch properties, the heat of the fire it undergoes in calcination being ſufficient to drive them off. In the calcination of the dried blood and ſalt of tartar it was obſerved, that there was a loſs of juſt one half. It is difficult to determine with certainty, what quantity of either was loſt in this operation; but it will eaſily be granted, that a much greater quantity of blood was loſt than of the ſalt: and this is confirmed by experiment; for the ſame quantity of ſalt of tartar, calcined alone in the ſame heat, has been found to loſe only one eighth part; whereas, when dried blood was calcined by itſelf, it loſt more than ſix eighths. It appears that the blood in calcination parts with its tinging quality to the ſalt, or that quality is extracted from it by the ſalt, and paſſes with it in its diſſolution with the boiling water.

To prove this, ſome dried blood was calcined alone, and a ſtrong decoction of it made in water, and afterwards filtered: this, when mixed with the former ſolutions, produced little or no alteration; and on the addition of the ſpirit of ſalt, the whole became of an amber colour, without any precipitation. When this, mixed with oleum tartari, was added to the former ſolutions, it cauſed a precipitation, but no colour; and the ſpirit of ſalt being added to the liquor, made it clear again; but of no other colour than the amber tinge it had before.

The change of colour is not effected in any of the materials, except in that of the ſolution of the vitriol; ſo that the alum ſeems only to be of uſe in fixing the colour, as it is often uſed by dyers to that purpoſe: and the ſpiritus ſalis gives it a deeper dye; for if the lixivium with blood be poured to a ſolution of alum alone, there will fall a ſediment a little inclining to the purple; which on adding ſome ſpirit of ſalt, changes to a brown. Much the ſame changes will alſo be produced if you pour the ſpiritus ſalis to the lixivium; but not the leaſt appearance of *blue*: but when the lixivium is poured to a ſolution of vitriol, there is immediately a deep *blue* produced, and this is ſtill heightened by the ſpirit of ſalt.

In all the recipes which have been given for making the *Pruſſian blue*, the liquors are ordered to be mixed together boiling hot, except the ſpirit of ſalt; and experience ſhews, that the colour is moſt readily and beautifully made that way: but in experiments made with all the liquors cold, the colours have been very well produced, only in leſs beauty; and they have required waſhing ſeveral times in freſh water, to bring them to their beauty.

If after the lixivium has precipitated the *blue* colour, on mixing with the ſolutions of alum and vitriol, a little more of the blood lixivium be added afterwards, the whole loſes its *blue*, and becomes brown; but on adding ſome more ſpirit of ſalt, the matter becomes of a fine *blue* again.

As it appears from ſome of the before mentioned experiments, that the ſolution of vitriol is the only thing which makes the colour with the blood; and as this vitriol is no other than iron diſſolved by a liquor running from the pyrites when long expoſed to the weather, it ſhould ſeem that the iron was the only ſubſtance that really produced the colour: and experiments confirm this to be the caſe. Phil. Tranſ. N°. 381. p. 20. See the article BLOOD.

PRYTANITIDES, in antiquity, a name given to thoſe widows who at Athens, and throughout all Greece, had the ſacred fire of Veſta committed to their care. The cuſtom of the Greeks, in this reſpect, differed very much from that of the Romans; who allowed none but virgins to tend this ſacred fire, whence they were called *veſtals*. See VESTALS, *Cycl.* They had the appellation of *prytanitides* from Πρυτανειον, a name common to all places ſacred to Veſta. *Hoffm.* Lex. univ. in voc.

PSALMIST, in the church of Rome, one of the leſſer eccleſiaſtical order, the ſame with what among us is called *clerk*, *precentor*, or *ſinger*. *Hoffm.* Lex. in voc.

PSEGMA, a name given by ſome of the antients to the flos æris, or flowers of braſs.

PSELAPHIA, a word uſed by the antient medical writers to expreſs friction with the hands, in caſes where the diſtempered parts required it. This was always eſteemed a part of the buſineſs of a phyſician, and was done with his own hand.

PSEN, Ψην, the name given by naturaliſts to the fig-gnat, a ſmall ſpecies of gnat bred in figs while growing on the tree, and always remaining on the leaves of the ſame tree, and feeding on its juices. See CAPRIFICATION.

PSEPHISMA, Ψηφισμα, among the Athenians, a decree of the ſenate; the ſame with *probuleuma*. See PROBULEUMA.

PSEPHOMANTIA, Ψηφομαντεια, in antiquity, a ſpecies of divination, the ſame with *cleromancy*. See CLEROMANCY, *Cycl.*

PSEPHOPHORIA, in antiquity, the art of uſing the *pſephi*, Ψηφοι, or counters. This was the firſt arithmetic taught children of every condition. Capitolinus, in his life of Pertinax, ſays, *Puer literis elementariis & calculo imbutus.* Thoſe who taught this art were called *calculones*, if ſlaves, or lately made free; but thoſe of better condition were called *calculatores* and *numerarii*. Every family, anywiſe conſiderable, had one of theſe maſters, the title of whoſe charge was *a calculis*, *a rationibus*. See the next article.

PSEPHOS, Ψηφος, in antiquity, a name given to ſeveral things, as ſmall ſtones, ſhells, and beans, uſed among the Greeks in giving their ſuffrages, and in their computations. Their origin is, by Mr. Mahudel, aſcribed to the ſons of Noah, who uſed this kind of calculation to aſſiſt their memory in numbering their flocks. Joſephus aſſures us, that the Egyptians borrowed this method of counting from Abraham; and Herodotus relates, that theſe ſmall ſtones were uſed both by the Egyptians and Greeks, only with this difference, that the latter placed them and cyphers from left to right, and the former from the right to the left. The art of uſing them in calculations was called *pſephophoria*. See PSEPHOPHORIA.

Pſephi were in uſe too among the Romans, who called them *calculi*. Whatever materials they conſiſted of, they were all of the ſame colour when uſed in calculations; whereas thoſe uſed in giving ſuffrages were partly black and partly white. Lucky days were denoted by white, and unlucky by black ones. In paſſing of laws, there were characters engraved on them, as V. R. i. e. *uti rogas*; and A. i. e. *antiquo*. Thoſe marked with V. R. approved, and thoſe with A. rejected the law in queſtion. Judges made uſe of calculi marked with the letter A. i. e. *abſolvo*, when they abſolved the accuſed perſon; but if they were for condemning him, they uſed ſuch as were marked with the letter C. i. e. *condemno*: and if the evidence for and againſt the accuſed perſon was equal, ſo that they could neither condemn nor abſolve him, they made uſe of calculi marked with N. L. i. e. *non liquet*. There was another kind of calculi uſed at public games, which were marked with figures: thus, if there were twenty athletæ ready to engage, they threw into a ſilver urn twenty calculi, every two of which were marked with the ſame figures, from 1 to 10. Then upon drawing, thoſe who got the ſame numbers were obliged to engage together; on which account they were called *calculi athletici*.

The Greeks and antient Romans made uſe of very ſimple materials for their calculi, ſuch as ſmall ſtones, ſhells, and beans; and even in the time of the firſt Roman emperors, it was thought a piece of luxury to uſe any of ivory. It is queſtioned whether the Romans ever uſed any of ſilver or gold; becauſe the

the paſſage of Petronius, which is the only one that can be alledged for their having done ſo, may be underſtood of the current coin or money, which Trimalcio, in the time of Nero, employed for calculi, *notari rem omnium delicatiſſimam, pro calculis albis aut nigris, aureos argenteoſque habebat denarios*. If this is the true meaning of the author, the firſt gold and ſilver calculi muſt have been made in France, in the fourteenth century, under Charles VIIth. whoſe name, together with the arms of France, is found inſcribed on the oldeſt ſilver counters in that king's cabinet.

PSETA, in ichthyology, a name given by Athenæus to the fiſh we call the *plaiſe*, the *paſſer lævis* and *plateſſa* of authors. See the articles PASSER and PLEURONECTES.

PSETITES, in natural hiſtory, a name given by authors to a ſtone, having in it the figure of a turbot. There are ſtones found in ſome parts of Germany having the impreſſions of ſeveral kinds of fiſh as perfect as if drawn by a pencil, and it is not to be doubted, but that they in reality owe them to the fiſh themſelves; which at ſome time, perhaps while the earth was overflowed at the univerſal deluge, were received into beds of the matter of ſtone, yet unhardened, which taking its conſiſtence while they were in it, muſt cruſh them, and retain the marks of their bodies. They are uſually found in a whitiſh flaty ſtone.

PSEUDO-ACACIA, *baſtard acacia*, in botany, the name of a genus of trees, the characters of which are theſe: the flower is of the papilionaceous kind, and from its cup there ariſes a piſtil, ſurrounded by a fimbriated membrane. This finally becomes a flat pod, which burſts into two parts, and contains kidney-ſhaped ſeeds. To this it is to be added, that the leaves are placed in ſeries over againſt one another, on a middle rib, the end of which is terminated by a pod leaf.

The ſpecies of *pſeudo-acacia*, enumerated by Mr. Tournefort, are theſe: 1. The common prickly *pſeudo-acacia*, called the *common acacia*, and by ſome the *lotus tree*. 2. The broad-leaved American *pſeudo-acacia*, with roſe-coloured flowers. And, 3. The aſh-leaved American *pſeudo-acacia*, with violet-coloured flowers. *Tourn.* Inſt. p. 649.

PSEUDO-APIOS, in botany, a name given by ſome authors to the roots of the *bulbocaſtanum*, or earth-nut.

The peaſants in Burgundy, and other parts of France, turn up theſe in great quantities with the plough, and eat them. They call them *arnottas*, and ſome of the writers of the adjacent places, not diſtinguiſhing what they truly were, have avoided the common name, by giving them this of *pſeudo-apios*, formed of the name of a root to which they have no alliance, and taking away a name by which they would have been much better known; *arnotta* being only a corruption of the Dutch name *ertnote*, or earth-nut, a name by which they are called almoſt every where.

PSEUDO-ARGYRON, in mineralogy, a word uſed by the antients in two very different ſenſes; ſome make it the name of what Virgil calls *orichalcum album*, white braſs; and others of a mineral with which the common braſs was made.

It is very evident, from the joint teſtimony of the old Greeks and Romans both, that they had in uſe a kind of white metal made of copper, and they eſteemed it greatly above the yellow, or braſs.

Ariſtotle tells us of this white metal, and gives it great encomiums; he ſays, it was very white and very bright; and that it was made by melting copper together with a certain earth: but this he does not deſcribe, ſo that we are left in the dark as to what it was.

This ſhining white metal might very naturally be called *pſeudo-argyron*, or baſtard-ſilver; but beſide this, there is another native mineral ſubſtance, called by the ſame name by Strabo and others: and this is ſaid by Strabo to be uſed in making copper into braſs. Many authors have been much perplexed in endeavouring to make out what this latter kind of *pſeudo-argyrum* was; ſome have ſuppoſed it the molybdæna, others ſome of the brighter lead-ores, and others the micæ argenteæ, or ſilvery talcs, and ſome the ſilvery mundicks: all theſe might in ſome degree anſwer to the name, as to their outward appearance, but they could none of them have the effect of turning copper into braſs.

We are to look for ſomething that will do this firſt, and then find the reſemblance in the colour to ſilver. We well know, that nothing will turn copper yellow but calamine, which is the ore of zink, or zink itſelf. Zink is a metal that comes neareſt the appearance of ſilver of any other, and is ſometimes found native, and in its proper form. If any of the mines wrought by the antients afforded this native metal, there is no doubt but it was the thing called *pſeudo-argyros*, its colour and qualities all anſwering to the name; but if not, it is probable that no more was meant by the name than the common calamine found in their ſilver mines.

Many of the ores of ſilver are found to be very like the common calamine, and in the ſame mines one might be taken for the other at firſt ſight: this reſemblance might very naturally lead people to call the calamine found there *pſeudo-argyros*, or baſtard-ſilver; and the properties of this being the ſame with thoſe of all other calamine, it cannot but anſwer in the ſame manner in making braſs.

PSEUDO-CARPASUM, in botany, a name given by ſome authors to the plant called by the generality of writers *libanotis*.

This is a plant of a very ſtrong ſmell; and the *carpaſum*, or *carpaſium* of the antients, being a poiſonous gum, and the ſmell of the libanotis approaching to the ſame odour, occaſioned its being called the *baſtard-carpaſum*.

PSEUDO-DICTAMNUS, *baſtard-dittany*, in botany, the name of a genus of plants, the characters of which are theſe: the flower conſiſts of one leaf, and is of the labiated kind. The upper lip is of an arched form, and uſually is bifid; and the lower is divided into three ſegments. The cup is of the ſhape of a funnel, and from it there ariſes a piſtil, which is fixed in the manner of a nail to the hinder part of the flower. The four embryos which ſurround this afterwards become four oblong ſeeds, which ripen in the funnel-faſhioned caſe, which was the cup of the flower.

The ſpecies of *pſeudodictamnus*, enumerated by Mr. Tournefort, are theſe: 1. The *pſeudodictamnus*, with cups like thoſe of Molucca. 2. The *pſeudodictamnus*, with curled and wrinkled leaves. 3. The Spaniſh *pſeudodictamnus*, with very large, hoary, and whitiſh leaves. 4. The Spaniſh *pſeudodictamnus*, with very large, hairy, and blackiſh leaves. 5. The Spaniſh *pſeudodictamnus*, with fig-wort-like leaves. 6. The ſcentleſs, verticillated *pſeudodictamnus*. 7. The ſmaller, alpine, verticillated *pſeudodictamnus*. And, 8. The ground ivy-leaved African *pſeudodictamnus*. *Tourn.* Inſt. p. 188.

PSEUDOGELSEMINUM, in botany, a name given by Rivinus to a genus of plants, the ſame with the *bignonia* of authors. *Rivin.* 1. 151.

PSEUDO-*ipecacuanha*, in botany, the name by which ſome authors have called a poiſonous kind of American apocynum, the root of which ſomething reſembles the true *ipecacuanha*, and has ſometimes been unfortunately collected and uſed in its place. *Dale*, Pharm. p. 178.

PSEUDO-*pulex arboreus*, in natural hiſtory, the name of a genus of inſects deſcribed by Mr. Reaumur, and ſomewhat approaching in their form to the *pulex aboreus*; but having their wings covered with a ſquammoſe caſe, which thoſe creatures have not, and having broader and flatter bodies.

Theſe principally live upon the fig-tree and the box; they paſs through a ſort of metamorphoſis into a hopping fly, ſuppoſed by ſome of the nature of a graſs-hopper; but erroneouſly, for that animal has a caſe for its wings, and the other not.

It has not yet been determined by obſervation, whether theſe creatures are oviparous, as moſt other of the known winged inſects, or viviparous, as the *pulex arboreus*. That ſpecies which lives upon the box throws out a ſort of glutinous matter from the anus, with which it faſtens the leaf when curled up: this curled leaf, on being opened, always diſcovers the animal, with a long train of connected globules dragging after it, and forming, as it were, a ſort of tail; but when examined more carefully, this is found only to be a train of excrements ſticking together by means of their glutinous quality, and of a ſweet taſte, like that of manna. Theſe, like the others, are at length changed into a ſort of fly, remarkable for its manner of hopping, like the flea. *Reaumur*'s Hiſt. Inſt. T. 1.

PSEUDO-*ſaliva*, in botany, a name by which ſome authors call the *phlomis*.

PSEUDO-*ſantalum*, *baſtard-ſaunders*, a name given by ſome botanical writers to the *lignum Braſilianum*, or Braſil wood. *C. Bauhin.* Pin. p. 393.

PSEUDO-*ſenna*, *baſtard-ſena*, in botany, a name uſed by ſome authors for the common *colutea veſicarica*. It is called alſo by ſome *ſena pauperum*. *Boerhaave*, p. 468.

PSEUDO *theca*, in natural hiſtory, the name of a ſpecies of two-winged fly, approaching to the nature of the common waſp, but having no ſting. It has a blackiſh head, with two ſhort antennæ, or horns; large, black, reticulated eyes; a long forked mouth, and prominent ſhoulders. The body is long and ſlender, and conſiſts of many joints. The legs are rough and hairy. It is found about dirty ditches, being bred of a water-worm that loves muddy places.

This is, according to the later diſtinctions in the hiſtory of inſects, properly called a *waſp-fly*. There are bee-flies, as much reſembling the bees as this does the waſp.

PSEUDO-*tinea*, in natural hiſtory, the name of a very remarkable ſpecies of inſect deſcribed by Mr. Reamur, approaching to the nature of the *tinea*, or cloaths-moth, while in the worm-ſtate; but not making themſelves coats of the ſubſtance of leaves, cloath, &c. tho' they form a ſort of caſes for their defence againſt a very terrible enemy.

Theſe creatures are truly of the caterpillar kind, and have, in the manner of any of theſe inſects, ſixteen legs. They feed on wax, and for food enter the bee-hives; where they boldly engage the bees, and are not to be prevented by them from feeding, tho' at the expence of their habitations and the cells of their reſervoirs of honey: ſo that it is no uncommon thing for a ſwarm of bees to be forced to change their place of habitation, and make new combs elſewhere; leaving the old ones to this contemptible victor, whom they know not how to drive out or diſpoſſeſs.

Virgil and Ariſtotle, and all the authors who have written on bees, have complained of this deſtructive animal. It never

eats the honey, but feeds only on the wax; attacking principally thoſe waxy cells where the female bee depoſits her eggs for the future progeny.

The bees, who are a match for moſt other creatures, by means of their ſtings, would eaſily deſtroy theſe weak creatures, were it not for the impervious armour they are covered with. They form themſelves a coat of armour of a double matter; the firſt, which immediately covers the body, is of a kind of ſilk of their own ſpinning; and the outer covering over this is of the bees wax: this is laid conſiderably thick, and the creature juſt thruſting out its head to feed, goes on devouring the cells undiſturbed, while a whole army of the inhabitants are in vain buzzing about him, and attempting to pierce him with their ſtings. He never forſakes his covering, but lengthens and enlarges it as he goes; and gnawing down the ſides of the cells in his march, without ſtaying to eat them one by one, the havock and deſtruction he occaſions are ſcarce to be conceived. When the time of the change of this creature approaches, it contracts its body within its double covering, and there changes into the nymph ſtate; whence, after a proper time, it comes forth in form of a moth, with granulated horns and a crooked proboſcis.

The bees have cunning enough to know their deſtructive enemy in this new form, and as this is a weak and defenceleſs ſtate, they attack and deſtroy all the moths of this ſpecies they can meet with. They ſeldom are ſo fortunate, however, as to kill the whole race as ſoon as produced; and if only one eſcapes, it is able to lay a foundation of revenge for the death of its brethren. All the flies of the moth kind lay a vaſt number of eggs, and this is behind-hand with none of them in that particular: the young ones produced from the eggs of one ſurviving female of this ſpecies, are ſufficient to deſtroy many honey-combs; nay, many hives of them. The moth produced by this caterpillar flies but little, yet is very nimble in avoiding danger by running, which it does with great ſwiftneſs.

There are a ſpecies of theſe *pſeud-tineæ*, or wax-eating caterpillars, which infeſt the ſubterranean hives of waſps, and other creatures which make wax: the manner of living, feeding, and defending themſelves from their enemies, is the ſame in all theſe ſpecies. Theſe laſt, if they are at any time diſtreſſed for food, will eat their own dung; the wax having paſſed almoſt unaltered through their bodies, and being ſtill wax, and capable of affording them more nouriſhment on a ſecond digeſtion. Theſe ſpecies, tho' they naturally live on this ſoft food, yet if by any accident they meet with harder only, they know how to live upon it; and can eat a way into the covers and leaves of books, and make themſelves caſes and coverings of the fragments of theſe ſubſtances. The accurate author of theſe obſervations deſcribes alſo a kind of *pſeudo-tineæ* which feed on wool, and another that eats leather; both making themſelves houſes alſo on the materials they feed on.

There is alſo another kind, very deſtructive of corn: theſe make themſelves a covering by faſtening together a great number of the grains, and there living and eating in ſecret. All theſe creatures, whatever be their food or habitation, finally become *phalenæ*, or moths; and may be diſtinguiſhed, even in this ſtate, from the other ſpecies, by having granulated horns of a remarkable ſtructure, and all of them a proboſcis, or trunk, more or leſs incurvated. *Reaumur*'s Hiſt. Inſ. T. 1.

PSIDIUM, in botany, the name by which Linnæus calls a genus of plants, named *guajava* by Tournefort and others. *Linnæi* Gen. Pl. p. 211. See GUAJAVA.

PSILOCITHARISTA, among the antients, one who plays on the cithara, without ſinging in concert to it. *Pitiſc.* Lex. Ant. in voc.

PSITTACUS, the *parrot*, in the Linnæan ſyſtem of zoology, makes a particular and diſtinct genus of birds, of the order of the hawks; the diſtinguiſhing characters of which are, that the feet have two toes before and two behind. *Linnæi* Syſt. Natur. p. 44.

The *parrot* is a very well-known bird, of which there are ſeveral very beautiful ſpecies.

Its head is large, and beek and ſkull extremely hard and ſtrong. It might ſeem a wonder why nature has deſtined to this, which is not naturally a bird of prey, but feeds on fruits and vegetable ſubſtances, the crooked beak allotted to the hawk and other carnivorous birds; but the reaſon ſeems to be, that the *parrot*'s being a heavy bird, and its legs not very fit for ſervice, it climbs up and down trees by the help of this ſharp and hooked bill, with which it lays hold of any thing and ſecures itſelf, before it ſtirs a foot; and beſides this, it helps itſelf forward very much, by pulling its body on with this hold.

Of all animals, the *parrot* and crocodile are the only ones which move the upper jaw; all creatures elſe moving the lower only. As ſome particular animals beſide are fond of particular foods, ſo the *parrot* loves nothing ſo much as the ſeeds of the carthamus, or baſtard-ſaffron; and eats them without any hurt, tho' they are a purge when given to other creatures.

The *parrots* are common both in the Eaſt and Weſt Indies: they are a very briſk and lively bird in the warmer countries; but with us loſe much of their vigour. They lay two or three eggs in the hollow of a tree.

In all the known *parrots* the noſtrils are round and placed very high upon the beak, and very near one another.

Parrots are divided into three kinds: 1. The larger, which are as big as a moderate fowl, called *macaos* and *cocketoons*; theſe have very long tails. 2. The middle ſized ones, commonly called *parrots*, which have ſhort tails, and are a little larger than a pigeon. And, 3. The ſmall ones, which are called *paroquets*, and have long tails, and are not larger than a lark or blackbird. *Ray*'s Ornithol. p. 72.

PSOAS *(Cycl.)*—PSOAS *major*, called alſo *lumbaris internus*, a long and thick muſcle, ſituated on the abdomen, on the *lumbar* region, adhering to the vertebræ of the loins, from the poſterior part of the os ilium to the anterior part near the thigh.

It is fixed above to the laſt vertebræ of the back, and to all thoſe of the loins; that is, to the lateral parts of the bodies of theſe vertebræ, and to the roots of their tranſverſe apophyſes. The inſertions in the bodies of the vertebræ are by a kind of digitations, and are very little tendinous: from thence the muſcle runs down laterally over the os ilium, on one ſide of the iliac muſcle; and paſſes over the ligamentum Fallopii, between the anterior inferior ſpine of the os ilium, and that eminence which, from its ſituation, may be called *iliopectinea*. Before it goes out of the abdomen it unites with the iliacus, and afterwards covers the foreſide of the head of the os femoris. It is ſometimes accompanied by a ſmall muſcle, called *pſoas parvus*. *Winſlow*'s Anatomy, p 204.

PSOAS *parvus*, a long ſlender muſcle lying upon the *pſoas major*: it is ſometimes wanting; but tho' ſome have imagined it wanting in one ſex more than the other, the conjecture ſeems without foundation. It is fixed above by a ſhort tendon, ſometimes to the laſt tranſverſe apophyſis of the back, or higher; ſometimes to the firſt of the loins, and ſometimes to both: from thence it runs down wholly fleſhy, and more or leſs complex on the great *pſoas*, in a direction a little oblique; and having reached the middle of the regio lumbaris, it forms a ſlender flat tendon, which gradually increaſing in breadth like a thin aponeuroſis, runs over the *pſoas major*, and *iliacus internus* at their union; and from thence down to the ſymphyſis of the os pubis and os ilium, and is inſerted chiefly in the criſta of the os pubis, above the inſertion of the pectinæus. *Winſlow*'s Anatomy, p. 250.

Beſide this *pſoas parvus*, there is another, ſtill ſmaller, between it and the vertebræ.

PSORA, *(Cycl.)* in botany, a name by which Aëtius and ſeveral others of the later Greek writers have called the *pſorice* of the antient Greeks, that is, the *ſcabioſa* of the Latins, and our common ſcabious. It has been ſuppoſed by ſome, that the antient Greeks were not acquainted with our ſcabious; but that is an erroneous opinion, both the deſcription and virtues of the pſorice being the ſame with thoſe of the ſcabious. See PSORICE.

PSORALIA, in botany, the name of a genus of plants of the leguminous kind, the characters of which are theſe: the perianthium is one-leaved, and is dotted with a ſort of tubercles, and is divided into five acute ſegments, the under one being twice as long as any of the others. The flower is of the papilionaceous kind, and is compoſed of five petals. The vexillum is roundiſh, emarginated, and riſes upwards. The alæ are lunulated, obtuſe and ſmall. The carina is dipetalous, lunulated, and obtuſe. The ſtamina are diadelphous filaments, and the antheræ are roundiſh. The germen of the piſtil is ſlender. The ſtile is pointed, and of the length of the ſtamina. The ſtigma is obtuſe. The fruit is a pod of the length of the cup; it is of a compreſſed figure and pointed. The ſeed is ſingle and kidney-ſhaped. It is very ſingular in this plant, that the cup is always dotted with tubercles, and the petals of the flowers are full of coloured veins. *Linnæi* Gen. Pl. p. 358. *Ray*'s Lugd. p. 372.

PSORAS, in zoology, a name by which ſome authors have called a fiſh of the turdus kind, remarkable for the variety and beauty of its ſpots, and more uſually known by the name *lepros*. *Willughby*'s Hiſt. Piſc. p. 320. See LEPROS.

PSORIASIS, a peculiar ſpecies of itch affecting the ſcrotum.

PSORICE, or PSORICE-*poa*, a name given by the botanical writers among the antient Greeks to the plant we call *ſcabioſa*, or *ſcabious*.

They have ſo well deſcribed this plant, that there is no room to doubt its being our ſcabious; and they have attributed the ſame virtues to it, and given it in the ſame diſtempers that we do. Yet ſome botaniſts of the later ages, having overlooked their deſcriptions of the *pſorice*, have ſuppoſed that our ſcabious was wholly unknown to the antients: and others have thought that the ſtæbe of thoſe writers was this plant. But this is as erroneous as the former opinion, for the ſtæbe of the antient Greeks was the name of the phleos, a kind of marſhy gnaphalium, or cudweed; and with ſome, the name of the pheos or hippopheos, called by Dioſcorides *hippophaes*, a prickly ſhrub, growing on the ſandy ſhores of the iſland of Crete, and uſed by the fullers in dreſſing their cloths.

Pelagonius recommends the herb *pſorice*, among ſeveral other known antiſcorbutics, in a compound medicine, intended for the itch, or any other virulent eruption. Aëtius preſcribes the ſame plant under the name of *pſora*, and the modern Greeks call it *campiuſa* or *ſcampiuſa*; a name which, tho'

Fuch-

Fuchſius confeſſes he does not underſtand, yet is plainly no other than a barbarous term formed by theſe Grecians on the word ſcabioſa, the Latin name of the plant.

The change between ſcabioſa and ſcampiuſa is ſcarce any thing, for the common cuſtom of the Greeks of theſe times, was to change the Roman b into mp, in the words which they adopted from that language. *Pelagonius*, c. 300.

PSOROPHTHALMIA, *(Cycl.)* a name given by the antients to a ſcorbutic diſorder of the eye-lids, very troubleſome to the patient, and cured with difficulty.

PSUCHAGOGICA, a word uſed by the antients to expreſs ſuch medicines as were uſed in apoplexies and faintings, to recal life.

PSUCHROTROPHON, in the materia medica of the antients, a name given to a plant often recommended, but not perfectly underſtood as to what ſpecies it means. It is the ſame plant called *ceſtrum* by the Greeks, and has this firſt name only becauſe of its growing in moiſt places; the word being formed of the Greek Ψυχρος, moiſt, and τρεφω, to nouriſh or cauſe to grow.

Dioſcorides has opened a way to great perplexity, by ſaying that this is the plant which the Romans in his time called the *betonica*, or *ſerratula*, and ſometimes *roſmarinus*. The Romans ſeem from this to have been at that time very indeterminate in their names; but by the deſcription it appears clearly, that the roſemary which we know by that name, could not be meant; and the queſtion lying wholly between the betony and ſerratula, is decided in favour of the latter by the deſcription, which, as it ſtands in Dioſcorides, gives the plant the leaves of the oak. This may ſeem at firſt ſight not to make much in favour of the ſerratula; but the reſemblance is explained, as this author expreſly does, to conſiſt only in their being very deeply ſinuated, and finely notched, or ſerrated, all round. The ſerratula of our times ſeems plainly meant as the plant. So that this plant we are to obſerve, is the ceſtrum and *pſeuchrotrophon* of the Greeks, and the betonica, or vettonica, as well as the ſerrata of the Romans; and is ſometimes called *roſmarinus*. Apuleius ſeems to perplex the whole affair in a ſtrange manner, by ſaying, the betonica has leaves like the docks, and very large; but we are to obſerve, that he miſtakes the betonica and britannica for the ſame plant, and ſays, that the betonica, or britannica, was called *ceſtrum*, &c. by the Greeks. The reaſon of his ſaying the leaves are like thoſe of the dock, is eaſily ſeen after this; for Dioſcorides ſays ſo of the britannica, and that very juſtly; it being only the common great water-dock, or hydrolapathum. Pliny has ſomewhere run into the ſame error, of giving leaves like the dock to the betonica; but the ſource of his error is plainly the ſame. We may obſerve from this, however, that very little dependence can be had on the accounts theſe authors give us of plants.

PSYCHROLUSIA, a word uſed by medical writers to expreſs cold bathing.

PSYCTICA, a term uſed by medical writers to expreſs cooling remedies.

PSYDRACIA, a term uſed by medical writers to expreſs ſmall tubercles on the head, which reſemble puſtules, and after a little time corrode and eat through the ſkin.

PSYGMATA, a name given by phyſicians to all refrigerating medicines, external and internal.

PSYLLIUM, *fleawort*, in botany, the name of a genus of plants, the flowers and fruit of which are like thoſe of the plantain's, but the ſtalks are ramoſe and foliaceous.

The ſpecies of *pſyllium*, enumerated by authors, are theſe: 1. The *pſyllium* of Dioſcorides, or Indian *pſyllium*, with jagged leaves. 2. The great upright *pſyllium*. 3. The larger procumbent *pſyllium*. 4. The leſſer *pſyllium* of Caſpar Bauhine. *Tourn.* Inſt. Bot. p. 128.

The ſeeds of *pſyllium* are recommended by many in jaundices and dyſenteries; but the preſent practice receives it only as a mucilaginous ſeed.

PSYLON, in ichthyology, a name given by Ariſtotle, and many other of the old Greek writers, to the tench, or cyprinus niger. See CYPRINUS and TINCA.

PTARMICA, *ſneezewort*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the radiated kind, the diſk being compoſed of floſcules, and the outer circle of ſemi-floſcules; theſe are placed upon the embryo-ſeeds, and are contained in a ſquammoſe cup. The embryos afterwards become ſlender ſeeds. To this it is to be added, that the leaves are either only denticulated at the edges, or elſe divided into large broad ſegments, wholly different at firſt inſpection from the leaves of yarrow.

The ſpecies of *ptarmica*, enumerated by Mr. Tournefort, are theſe: 1. The common *ptarmica*, with long ſerrated leaves and white flowers. 2. The common *ptarmica*, with double flowers. 3. The Alpine *ptarmica*, with leaves partly whole, and partly ſerrated. 4. The low dwarf *ptarmica*, with leaves divided in the manner of thoſe of wormwood. 5. The Cretric ſhrubby *ptarmica*, with the appearance of the ſantolina. 6. The purple-flowered tawny-leaved Alpine *ptarmica*. 7. The yellow-flowered ſweet ſcented *ptarmica*. 8. The yellow ſweet *ptarmica*, with long and thick tufts of flowers. 9. The Alpine *ptarmica*, with deeply divided leaves. 10. The feverfew-leaved Alpine *ptarmica*. 11. The tall Alpine *ptarmica*, with yellowiſh white flowers. 12. The other Alpine *ptarmica*, with leſs compact flowers. 13. The elecampane-leaved Virginian *ptarmica*. *Tourn.* Inſt. p. 496.

The common *ptarmica* is frequent in our meadows, and flowers in June and July. The leaves are of an acrid taſte, and are ſometimes added to ſallad inſtead of creſſes, or the garden-tarragon. When dried and rubbed to powder, they are a good ſternutatory; they are not over ſtrong, but occaſion a continued ſneezing, which draws out a great deal of phlegm by the noſe. The root has the ſame virtue more ſtrongly.

PTELEA, in the Linnæan ſyſtem of botany, the name of a diſtinct genus of vegetables, the characters of which are theſe: that the cup is the perianthium, divided into four ſmall ſegments. The flower is compoſed of four petals, which are of an oval figure, and pointed at the ends; theſe are flat, larger than the ſegments of the calyx, and ſpread wide open. The ſtamina are four pointed filaments. The antheræ are roundiſh. The germen of the piſtil is orbicular, but ſomewhat compreſſed. The ſtyle is ſhort. The ſtigmata are two, and are acute. The fruit is a circular membrane, placed perpendicularly, with a cavity in the middle, which contains the ſeed, which is ſingle and oblong. The fruit of this genus is extremely like that of the elm, but the ſtamina are wholly different. *Linnæi*, Gen. Pl. p. 49.

PTERIDION, in botany, a name uſed by ſome authors for a ſmall kind of fern common in damp places. *Ger.* Emac. Ind. 2.

PTERIS, in botany, the name of a genus of ferns, the characters of which, according to Linnæus, are theſe: the fructifications are diſpoſed into a line, which ſurrounds the whole margin of the under part of the leaf. In this diſpoſition the *pteris* evidently differs from all the other capillary plants.

PTEROPHŒNICUS *Indiarum*, in zoology, a name under which Nieremberg has deſcribed a bird, which he ſays is called by the Spaniards there *commendadoza*, remarkable for the redneſs of the upper part of its wings.

It is of the ſhape and ſize of the ſtarling, and not unlike it in colour, but for the ſingularity of the upper part of their wings, which in one part of their lives are of a yellowiſh or orange colour, and in the reſt red. They are kept in cages and learn to imitate the human voice: they feed on vegetables, principally Indian corn, and are common as well in the colder as in the hotter climates; flying in large flocks, and often doing great damages to the people. They build in trees and are eaten there; but are no very valuable bird. *Ray's* Ornithology, p. 302.

PTEROSPERMADENDRON, in botany, the name of a genus of plants, eſtabliſhed by Dr. Amman.

The name is derived from the Greek πτερον, a wing, σπερμα, ſeed, and δενδρον, a tree, to expreſs a tree with alated ſeeds.

The characters of the genus are theſe: the flower is of the roſaceous kind, conſiſting of ſeveral petals arranged in a circular order. From the cup of the flower there ariſes a piſtil, with an embryo fruit, which finally becomes a woody ſeed-veſſel of the ſhape of a pod, which, when ripe, opens at the end, and is ſeen to be divided into five cells, containing alated ſeeds.

Of this genus the author deſcribes two ſpecies. The firſt has leaves like the cork-tree, angulated and hoary underneath, and white flowers: the other has auriculated leaves, and a large flower and fruit. The firſt of theſe is mentioned in Petiver's muſeum, N°. 349. under the name of a tree from Champana, with a woody fruit, containing alated ſeeds: and the other ſeems to be the tree called *ſolda*, in the Hortus Malabaricus, Vol. VI. T. 58.

Beſides theſe two ſpecies, the author ſuſpects there are four others, which have not yet been ſufficiently examined in their various ſtates, to determine whether they are properly of it or not. Theſe are,

1. The poplar-leaved tree alcea, called the *green ebony* at St. Helena, and by the Engliſh *blackwood* and *ebony*, Pluk. mant. T. 333. 2. The tree alcea, with large red flowers, and with leaves like the black poplar, hoary underneath, called by the Engliſh *redwood*, *ejuſd.* 3. The quinquecapſular alcea of Florida, with bay-like leaves, lightly crenated, and with alated ſeeds. And, 4. a tree with pentangular fruit, and alated ſeeds, collected by Dr. Houſton, at La Vera Cruz. Act. Petropol. Vol. VIII. p. 218.

PTERYGIUM, *(Cycl.)* in anatomy and ſurgery, a preternatural membrane, formed externally upon the coats of the eye, and extending itſelf over the cornea and pupil, and obſtructing the ſight. Sometimes this pellicle or membrane appears red, and is then called *pannus*.

It uſually ariſes in the angles of the eyes from the temples toward the noſe, and ſometimes from above or below, extending itſelf by degrees over the pupil. Sometimes it only adheres to the cornea by a few ſlender fibres, and ſometimes it is extended over the whole eye, and is every where firmly and intimately attached to it; and in this caſe the cure is rendered very difficult.

If the patient's conſtitution, or a beginning inflammation require it, bleeding and bliſtering are proper in this caſe; and when the membrane is but thin, gentle eſcharotics may per-

form a cure, ſuch as burnt alum, vitriol, &c. mixed into a powder with ſugar; or a ſolution of half a ſcruple of white vitriol in two ounces of celandine or other water.

If theſe methods prove ineffectual, the aſſiſtance of a ſurgeon muſt be called in; who ſeating the patient before him, with his head bent backwards upon his lap, while an aſſiſtant holds open the eyelids, takes hold of the thickeſt or looſeſt part of the pellicle with a hook, and elevating it a little, paſſes a threaded needle through it; and taking hold of both ends of the thread, makes a gentle elevation of it; then ſeparates its upper and lower margin with a lancet, that he may afterwards cut off the reſt immediately in a ſtrait line near the lachrymal caruncle, with a ſtrait and fine pair of ſciſſars; then he draws back the thread and membrane towards the cornea, and if it adheres any where to the eye, frees it by degrees with the ſcalpell, or ſciſſars, not wounding the cornea, nor leaving any of the membrane behind to give riſe to a new production of it. *Heiſter*'s Surg. p. 420.

PTERYGOIDÆUS *major (Cycl.)*—This muſcle lies on the inſide of the lower jaw, almoſt in the ſame manner that the maſſeter does on the outſide, and is of the ſame figure with that muſcle, only ſmaller and narrower.

It is fixed above chiefly to the inſide of the external ala of the apophyſis *pterygoides*. This inſertion is wholly fleſhy, and from hence it runs down obliquely toward the angle of the lower jaw, and is inſerted a little tendinous in the inequalities on the inſide thereof, oppoſite to the inſertion of the maſſeter. *Winſlow*'s Anat. p. 253.

PTERYGOIDÆUS *minor*, an oblong ſmall fleſhy muſcle, ſituated almoſt horizontally between the outſide of the apophyſis *pterygoides*, and the condyloide apophyſis of the lower jaw, the ſubject being conſidered in an erect poſture.

It is fixed by one extremity to the outſide and edge of the outer ala of the *pterygoide* apophyſis, filling the foſſula which is at the baſis of this apophyſis, near the baſis of the temporal apophyſis of the ſphenoidal bone; from thence it runs backward and a little outward into the void ſpace between the two apophyſes of the lower jaw, and is inſerted anteriorly in the condyloide apophyſis, at a ſmall foſſula immediately under the angle of the inner condyle. It is alſo fixed to the capſular ligament of the joint. *Winſlow*'s Anat. p. 253.

PTOSIS, a diſtemperature of the eyelids, occaſioned by a relaxation or tumor of thoſe parts, the ſame as the phalangoſis. *Heiſter*'s Surg. p. 367. See PHALANGOSIS.

PTYALAGOGA, a word uſed by phyſicians to expreſs ſuch medicines as promote a copious diſcharge of the ſaliva, ſuch as pellitory-root and the like.

PTYSMA, a word uſed to expreſs whatever is brought up from the lungs by ſpitting.

PTYSMAGOGA, medicines which promote a copious diſcharge by ſpitting.

PUBERTY *(Cycl.)*—Dr. Kramer obſerves, that all boys at the time of *puberty*, between twelve and fourteen years of age, complain of uneaſineſs at their breaſts, which are ſwelled and itchy, the nipples and areolæ round them inflaming with pain, and ſometimes excoriation and exulceration of ſome of the lactiferous ducts. The beſt remedy for which, he ſays, is to preſs out the white ſerum then contained in them, after which they cure with a bit of plaiſter. Commerc. Norimb. 1735. Hebd. 30. ſect. 2.

By the law of Scotland, perſons under *puberty*, or under the years of diſcretion, are capable of committing the higher crimes, which being contrary to the law of nature, are obvious. But they are not chargeable with ſmaller offences ariſing from poſitive law or ſtatute.

PUBIS *(Cycl.)*—The *os pubis* is the leaſt of the three portions of the oſſa innominata; the two together form the forepart of the pelvis, and anatomiſts diſtinguiſh in each, the body, the angle, and the branch.

The body of the *os pubis* is its upper part, ſituated tranſverſely before the inferior part of the os ilium. Its poſterior extremity is very thick, and by its union with the oſſa ilium forms the oblique eminence which diſtinguiſhes theſe two portions of the oſſa innominata. It likewiſe contributes to the formation of the cotyloide cavity. Its anterior extremity ends in a ſmall eminence, or tuberoſity, called the *ſpine* of the *os pubis*, which is ſometimes double. The upper edge has on its inner part an oblique ridge, which may be called the *criſta* of the *os pubis*, and is continuous with that ridge which diſtinguiſhes the margin and the bottom of the pelvis. Before this criſta is a broad, oblong, and oblique ſlope. The lower edge is obliquely notched, and forms the upper part of the foramen ovale.

The angle of the *os pubis* is its anterior portion, and makes part of that connexion called the *ſymphyſis* of the *oſſa pubis*. This portion is flat, and not very thick; and in ſome ſubjects toward the upper part of the fore-ſide, near the angular curvature, it has an eminence, which increaſes the ſize and extent of the ſpine already mentioned. The two *oſſa pubis* connected together by this portion, form, on the foreſide, an unequal convexity; but on the backſide a pretty even concavity.

The branch of the *os pubis* is a flat thin apophyſis, which running downwards, unites with the branch of the os iſchium by a cartilaginous ſymphyſis; of which, however, there remain only ſome light marks in adults. It compleats the formation of the foramen ovale. The branches of the two *oſſa pubis* form, on the foreſide, a pointed arch; which, however, in a natural ſtate, is much more round than in a dried ſkeleton. *Winſlow*'s Anatomy, p. 71.

PUCELAGE, *(Cycl.)* in natural hiſtory, a name by which ſome authors among the French have called the porcellane-ſhells. See the article PORCELLANA.

PUCERON, the name given by naturaliſts to a ſmall inſect of a peculiar nature frequently found on the young branches of trees and plants, and that often in ſuch cluſters as wholly to cover them. See Tab. of Inſects.

The *puceron* is a ſmall animal, but very numerous in the ſeveral genera and ſpecies; inſomuch, that Reaumur has obſerved that there is ſcarce a vegetable to be found, either in the fields or gardens, that has not its peculiar ſpecies of *puceron* to feed on its juices. Mr. De la Hire, of the Paris academy, has left many curious particulars in regard to theſe animals in the memoirs of the year 1703; and Mr. Lewenhoek, and others ſince, have given figures and deſcriptions of ſeveral of the ſpecies.

Pucerons are all viviparous animals, and that after a very ſingular manner. It is to be obſerved, that the name is ſcarce more expreſſive of the creature, than ſome of the others given of late to inſects; that of the polype to a creature which has no legs or feet at all, is very improper; and that of the *puceron* hardly leſs ſo, as it would naturally lead us to imagine, that the creature thus called was able to hop like a flea, whereas, in reality, it is very ſlow in its motions, and ſeldom ſo much as walks.

Theſe creatures have ſix legs, which are extremely ſmall and ſlender; and which, when the animal is at its full growth, are loaded with a weight ſo large, that they ſeem ſcarce able to ſupport it. Some of the ſpecies arrive at a tolerable bigneſs for common obſervation; but the greater number are too ſmall to be accurately ſeen without the aſſiſtance of glaſſes. Among theſe inſects there are great numbers that in their full perfection have wings, and become a ſort of little flies: theſe are diſtinguiſhed from the others by the name of *alated pucerons*. *Reaumur*'s Hiſt. Inſ. Vol. VI. p. 9.

Thoſe ſpecies which never become winged, have nothing of the appearance of the caterpillar kind; having not long, but ſhort bodies, and much reſembling flies whoſe wings had been taken off. All the ſpecies have antennæ or horns; but theſe in the ſeveral kinds are very different from one another, ſome being very ſhort, and others as remarkably long: and of theſe laſt kinds, ſome carry them ſtrait before the head, as is the uſual cuſtom, and others carry them laid along over their backs; in ſome of theſe the horns are longer than the body. But beſide theſe antennæ, the greater number of theſe creatures have two other horns or ſpines placed in a very ſingular manner behind them, near the tail. They are placed at ſome diſtance at their origin, but they become more diſtant as they go out from the body. Theſe are much thicker and much ſhorter than the antennæ; and there are among the various kinds of them, ſome which actually want them, and others which appear to want them, tho' they have them in reality; and others have in the places of them certain round ſpots, which ſtand juſt where they ſhould, and ſeem deſtined to perform their functions.

The ſeveral kinds of *pucerons* differ greatly in colour. The greater number of them are green; but many are brown, ſome yellow, and ſome are black. In Auguſt the roſe-trees afford a vaſt number of them of a pale red, and ſome exactly of the colour of the damaſk roſe; in ſome other months of the year we find green ones on the roſe-trees. The ſycamore and ſeveral other plants afford green ones in the ſummer, and red ones in November; and there ſeems no doubt, but that theſe are the ſame individual animals which change colour, the leaves and juices of the plants being not capable of affording them the ſame ſort of nouriſhment at ſome times that they do at others. Some of them alſo are of a duſky colour, and others bright and ſhining, as if varniſhed over. Thoſe of the willow, of the poppy, and ſome other plants, are of a cloth-like appearance, and ſome reſemble velvet; others, as thoſe of the apricot, and of the catch-fly, are ſhining as if covered with the fineſt lacquer. Some appear of the colour of browſe metal, when it has its higheſt poliſh; ſuch are thoſe of the tanſy, and ſome other plants. The largeſt kind are found on the oak and other trees. The gooſeberry buſh affords a ſpecies that are of the colour of mother of pearl; and in general, the ſkin or covering of thoſe ſpecies which are thus bright and ſhining, is much harder and firmer than that of the others. The more uſual ſpecies are all over of one colour, but there are ſome others which are ſpotted; that of the common wormwood is prettily ſpeckled with black and brown; thoſe of the ſorrel are green in the middle, and black at each extremity; and there are ſeveral others, as of the willow, &c. that are variegated with theſe two colours.

It is not certain, however, that all the ſpecies are peculiar to the plants that they are found upon; for it has been obſerved, that when a plant of the common wormwood has been full of them, by ſome accident they have all left it to fix themſelves upon plants in the neighbourhood, which had juices of a leſs diſagreeable taſte. Theſe creatures always live in companies; we never find them ſingly on plants, and very ſeldom other-

wiſe than in extremely great numbers. In plants they faſten themſelves on every part; but in trees, they only ſeize upon the leaves and young ſhoots, and they uſually cover theſe entirely, leaving no part to be ſeen. *Reaumur*'s Hiſt. Inſ. Vol. VI. p. 13.

The elder is the tree on which they are of all others the moſt plentifully produced, and on which they are obſerved in their ſeveral ſtages with the greateſt accuracy and eaſe. They often cover the thick green roots of this tree for many inches together, and ſometimes for many feet; and they are always placed ſo cloſe together, that they touch in every part, and ſometimes they lie two beds, one over another. Theſe are of a greeniſh black. If they are obſerved on the branches undiſturbed, they are always found to be perfectly quiet, and ſeem to paſs their whole lives in inaction; but they are all this time doing the moſt neceſſary buſineſs of life, that is, ſucking in their nouriſhment from the juices of the tree. They do this by means of a fine ſlender trunk, which eaſily eſcapes the naked eye; but is always found by the microſcope, and it is by means of this that they pierce the bark of the tender parts of the vegetables, and get at their juices. The trunk is uſually of two thirds of the length of the body; but when they are moving on, it is always applied ſo cloſely under the belly, that it is not ſeen.

When there are two ſeries of theſe inſects placed one over another, they are always more looſly placed in the upper ſeries, and theſe are uſually the larger and the nimbler in all their motions. In this caſe they have no power of ſucking the plant; for beſide that it is cloſe covered with the other ſeries, their trunks are not long enough to reach and penetrate it from the heighth at which they ſtand above it. Theſe, therefore, are ſuch as have no farther need of nouriſhment, but are employed in propagating their ſpecies. Mr. De la Hire thought, that when theſe animals arrived at their winged ſtate, they laid eggs on the ſtalks and leaves of thoſe plants on which we find them afterwards hatched without wings. The reaſon of his ſuppoſing this, was doubtleſs the opinion of an analogy between theſe creatures, and the butterflies and flies, with the other animals of the winged claſs: but obſervation and facts agree but very ill with that analogy; for if the plants on which they abound be obſerved nicely from day to day, their numbers will be found daily to increaſe on the leaves and branches, and this without the leaſt appearance of eggs: on the other hand, as the new-produced animals are of very different ſizes, this ſpeaks their being of different ages; and from hence it appears evident, that they are not produced in the manner of other inſects, which, when perfect, have wings; but, on the contrary, that they are really produced alive from the parent. Mr. Reaumur ſaw them brought forth; and, indeed, the obſervations of Mr. Lewenhoek long before, made it evident that this was the caſe; for he ſaw, by the help of microſcopes, the young animals perfectly formed, tho' extremely minute, in the bodies of the full-grown females.

If the large and full-grown *pucerons* are watched on their native places, with moderately powerful magnifiers, there will ſoon be ſeen ſome of them that have a ſmall greeniſh body ſtanding out from near the anus. This is the moſt plainly viſible in the elder *puceron*, which is itſelf uſually blackiſh. This in its firſt appearance is an oblong body, reſembling an egg flatted a little; but as it more nearly approaches to its delivery from the body of the parent, there appear legs upon it, and it is clearly ſeen to be a perfect and very lively animal. The legs by degrees fly off from the ſides and belly, along which they were laid, and the creature then makes ſeveral motions to aſſiſt the getting out of its head from the body of the parent; for theſe inſects are always brought into the world with the hinder part foremoſt. The parent is wholly paſſive all the time of the birth, all her efforts being internal; ſo that the body ſtirs not out of its place, nor is the young one able to help itſelf till its whole body is very near out, as the legs are attached to the breaſt at a ſmall diſtance from the head: and even when the head is out, the antennæ require the repeated motion of the young one, for a minute or two, to ſeparate them.

The whole operation of the delivery of one young one uſually takes up about ſeven minutes. Mr. Reaumnr obſerved the delivery of the *pucerons* of all kinds to be in the ſame manner. He found it very eaſy to make the obſervation, as the female *pucerons* are eaſily diſtinguiſhed from the male by their being much thicker in the body, and by their ſkin ſeeming always much diſtended, and by the furrows which ſeparate the rings of the body being obliterated. They are a ſort of animal which propagates ſo quickly, that uſually there are many females on the ſame leaf or branch of a plant in labour at the ſame time; and their fœcundity is ſo great, that when they have once begun to bring forth young ones, they ſeem to continue it inceſſantly for a long time together. They will often bring forth fifteen or twenty ſucceſſively, and if their bodies be a little ſqueezed afterwards, there are forced out of it a vaſt number of others leſs mature; yet even in theſe the eyes may be diſtinguiſhed: and after theſe, there follow long chains, as it were, of leſs perfect ones, which ſeem like the beads of a necklace, and are oblong, and much reſemble eggs. Theſe young ones are of different maturity, therefore, in the bodies of the parent; and in that reſemble the eggs in hens and other birds, they always growing to a proper ſtate for excluſion in this manner, one after another: whereas, in the quadrupeds, which are viviparous, the young ones of the ſame brood, if ever ſo numerous, always grow to their ſtate of maturity for the delivery together, and are all excluded at the ſame period. The young *pucerons*, when firſt brought forth, are always paler coloured than the parent; but are of the ſame ſhape and ſtructure, except that their bodies are ſomewhat flatted.

We ſee that they are able to move their legs before they are perfectly excluded from the parent, and as ſoon as they are ſo, they walk and ſeek a place where they may fix their little trunk into the plant, for the receiving nouriſhment. This they always chooſe to do as near to ſome others of their ſpecies as they can, always loving to live in communities. The young one always places its head as near as poſſible to the hinder part of the next to it, and thus they continue enlarging their bodies at every new birth. Thoſe which live upon the leaves of trees and plants, always fix themſelves on the under ſide, being there moſt ſheltered; and as their number is always very great, they frequently much alter the plant whoſe juices they ſuck; tho' ſome ſpecies, both of trees and plants, bear this much better than others. Id. ibid. p. 15.

Theſe little inſects are extremely plentiful on many different trees, and are very eaſily obſerved in their ſeveral ſtages and progreſſions by a curious ſearcher after them; but if at any time they are not ſo eaſily found, the perſon who ſeeks after them may be conducted to them by the ants, which he will find moving in great numbers on the trees and plants where they are, and pointing out the way to them.

Mr. Lewenhoek, Hartſoeker, and others, have obſerved this, and have ſuppoſed that the ants fed on them, by their frequenting the places where they are found; but that is far from being the caſe, the ants, on the contrary, ſeem to love them as friends. Goedart judged better of the matter, and eſteemed the ants of great benefit to the nation of *pucerons*, in deſtroying many of their bloody enemies. Goedart, however, erred greatly in ſuppoſing the ants to be the mothers of the *pucerons*; yet this is an error that has place among our gardiners to this day, they all ſuppoſing that the ants leave a ſlime behind them, out of which, according to the opinion of this laſt author, they judge them to be produced. We may, however, eaſily find out the reaſon of the ants following the cluſters of *pucerons*, without doing them any injury, when we conſider that the ants love ſugar and all ſweet things, and the places about which the *pucerons* are have uſually the cavities filled with a thick ſaccharine matter, formed of the juices of the plant, extravaſated by the wounds they make in it, and dried up to this conſiſtence by the heat of the ſun.

The bladders of the leaves of the elm always contain a large quantity of a ſaccharine juice; but thoſe of the black poplar have always a much ſweeter and more delicious fluid in them; and very often on other trees, the extravaſated ſaccharine juice may be ſeen among the cluſters of theſe animals, and the ants crawling over their backs to feed upon it.

This liquor of the elm has not eſcaped the obſervation of the ſearchers after remedies from the vegetable world; but tho' great virtues have been attributed to it by many, none have yet given any true account of its origin. The moſt natural opinion would ſeem, that it was the juice of the tree ſimply extravaſated; but experience ſhews that it has another origin: it is really the excrement of theſe *pucerons*; they receive no ſolid food into their bodies, all that is conveyed into them coming through their trunk, which is an extremely fine pipe; and as none but a very thin and pure juice can be received through ſuch an organ, it is no wonder that the creature which lives wholly upon it ſhould void no ſolid excrements. If a parcel of the *pucerons* be watched, it will not be long before one or other of them will be found voiding a ſmall round drop of this liquor by the anus, and after that, ſeveral more; which all falling upon one another, form the viſible drop on which the ants feed. The creature ſeems in ſome pain on the voiding this, and very often the hinder legs may be obſerved aſſiſting in removing it from the anus.

Mr. Reaumur obſerved, that it was common to find ſeveral drops of this liquor on the leaves of ſome trees; and that, tho' they were fluid and limpid, when firſt evacuated from the animal, they became more and more thick afterwards, reſembling honey after a few days, and after that drying up ſo as not to be eaſily removed from the leaves: and Mr. Geoffroy obſerved, that the liquor of the bladder of the elm became, when dried, as hard as the gum of the cherry-tree. The drops of this liquor is not ſo frequently found on the leaves of plants as might be expected, and that becauſe many of them are immediately devoured by the ants, and many others are dried up by the ſun; but they may always be found collected in ſome quantity in the bladders of the elm, and other trees inhabited by theſe creatures, as there the liquor is defended from the heat of the ſun, and is ſafe from being devoured. *Reaumur*'s Hiſt. Inſ. Vol. VI. p. 49.

The two horns which are placed on the hinder part of the body of this inſect are as ſingular in their uſe as in their appearance; they are hollow, and they at times excrete alſo a li-

quor

quor as limpid and clear as that of the anus. This ſtands in round drops at the end of one or both of them at once, and reſembles heads upon pins. This liquor, tho' limpid in ſome ſpecies, is, however, reddiſh and thick in others; as particularly in thoſe of the willow: and as this ſeems plainly to be an excrement, the creature is very ſingular in having its different paſſages for thoſe of different kinds. The liquor voided by the aperture at the extremity of the body, which reſembles the anus in other animals, appearing to be the urine; and this by theſe two horns, the fæces of the bowels. At any time when there is not a drop to be ſeen upon either of the horns, if the body of the animal be gently ſqueezed, a drop will always be forced out either from one or both.

The *puceron*, like moſt other inſects, changes its ſkin three or four times before it arrives at its full growth. Theſe exuviæ perfectly reſemble the animal in its natural ſtate, the legs and other parts being all in their proper places; but whatever is the colour of the ſpecies of *puceron*, theſe ſkins which it caſts are whitiſh. They lie in great numbers about the leaves where the creatures are, and among them there is uſually found a cottony matter. This at firſt ſight might be miſtaken for the ſkins, reduced to a kind of powder; but on a cloſer examination, it appears to be truly filamentous, and on a nice inſpection is found to be the natural produce of many ſpecies of the animal. All thoſe kinds of *pucerons* which are not ſmooth and gloſſy, as if varniſhed, have more or leſs of this cottony matter about them: in ſome the whole roughneſs of the ſurface is made of it; and in others, it ſtands in white ſpots on ſeveral parts of the body.

Thoſe *pucerons* which inhabit the bladders or leaf-galls of the elm and other trees, and thoſe which live in the folded leaves of the black poplar, are all of the nature of thoſe which produce the largeſt ſhare of this matter: they have it hanging in long ſtrings in an odd manner from their bodies, and often are ſo compleatly covered with it, that they look as if they had been wetted, and then rolled in meal.

On examining the leaves of ſome plants and trees inhabited by theſe animals, there is ſeen a ſort of collection of this down into parcels, ſo that they reſemble the white feathers of a bird in miniature. The leaves of the beech-tree afford theſe plumes in the greateſt perfection, and frequently they cover its leaves in whole cluſters, and are an inch or more in length. Theſe plumes, or cluſters of plumes, ſeem all to grow out of the leaf, and are much thicker at their baſe than at their extremity; a great number of the plumes that compoſe them being ſhorter than the reſt, and not running to the extremity. The longer plumes divide themſelves into two cluſters near their origin, and theſe never unite again afterwards: when examined by the microſcope, each plume appears to be compoſed of ſeveral other plumes or threads, like thoſe of cotton, which are undulated, but not twiſted together. Tho' theſe cluſters of plumes ſeem to be fixed to the leaf, yet when more cloſely examined, that is found not to be at all the caſe; but that they really proceed from the body of a *puceron*. The different threads or plumes ariſe from the different parts of the body of the animal, and altogether they hide it abſolutely from ſight as it ſtands on the leaf. When the bottom of the tufts are examined, however, there are always found either the bodies of the *pucerons*, or their exuviæ; for when they quit their ſkins, they quit theſe filaments with them.

Tho' theſe long threads might ſeem a conſiderable load for ſo ſmall an animal, yet when the creature is touched it always moves very briſkly, and as it creeps along, generally leaves ſome of its plumes in the way; but in its motion, no other part of it than the head, and the foremoſt pair of legs are ſeen. *Reaumur*'s Hiſt. Inſ. Vol. VI. p. 53.

The young brood of this ſpecies are green, and only by degrees acquire this white down; which at firſt appears only in form of a farinaceous powder, and by degrees lengthens out as we ſee it. The old ones alſo, when they have newly changed their ſkins, have it not at all; and when it afterwards grows upon them, it is by theſe degrees, and in this manner. The leaves of the common bramble alſo afford this remarkable ſpecies of *puceron*; and the common meadow crowfoot is frequently covered with cluſters of them at its lower part, reſembling a white mouldineſs. The filaments that cover the bodies of this ſpecies of *puceron*, are not at all of the nature of the ſilky matter ſpun by other animals; but ſeem to be produced from every pore of the body, and to iſſue thence in form of ſmall round globules of a liquid matter, which harden with the air, and adhering to one another as they iſſue out, form this ſort of plume, a congeries of which make the tufts we ſee.

The male and female *pucerons*, as they are uſually ſuppoſed to be, differ greatly from one another in form, even in their time of growing; but much more eminently at the time of their maturity, the male having then wings, which the females never have. Lewenhoek and others, who have treated of theſe animals, have ſuppoſed that they all became at length little flies, that is, were winged; but this is a great error.

The young male *pucerons* may be diſtinguiſhed from the females by having a ſort of eminence on their ſhoulders, of a ſquare form; which is owing to the young wings. The ſeveral changes of the ſkin which theſe animals have, make no great difference in their form till the laſt, when the males appear with their wings at liberty. A little before this laſt caſting off the ſkins, the males are ſeen to have a ſort of tuberoſity alſo on each ſide, which is owing to the wings, folded up there within the ſkin; but the females, tho' much larger than theſe, have no ſuch protuberance.

The winged *pucerons*, when they have caſt off their laſt ſkin, and have their wings looſe, do not, however, ſhew them immediately; for they are folded cloſely together, and the creature then appears like what it was before, being all over green, and having only two eminences on the ſide: but in a quarter of an hour, the head and ſhoulders change from their green colour to a fine ſhining black, and the wings unfold and expand themſelves, and then cover a large part of the body, and extend themſelves to a conſiderable length beyond it.

Theſe now appear animals wholly different from what they were before, and many of the flies which we ſee in our gardens are of this kind: the animal, however, tho' it appear ſo very different from its fellow inſects, is much more like them, when cloſely examined, than could be imagined. It ſtill carries the great character of the genus, which is the having two horns growing out from the hinder part of the body, and ſtill has its trunk, and lives by ſucking the juices of plants. *Reaumur*'s Hiſt. Inſ. Vol. VI. p. 57.

Notwithſtanding, however, the general opinion, that the winged *pucerons* are all males, and the unwinged ones females, it appears that their manner of generation is yet unknown to us. This opinion was founded too haſtily by ſome from a ſuppoſed analogy of theſe and other inſects; but later obſervations prove, that this is not ſtrictly the caſe: for that the winged ones, as well as the others, bring forth young ones. Some have ſuppoſed, that theſe winged and naked *pucerons* were the offſpring of different families of ſeveral ſpecies living together; but the contrary is proved by this, that the winged ones are found to produce ſome winged and ſome naked ones; and the naked to produce both kinds in the ſame manner. Some have imagined, that they found the male *pucerons* among the others, obſerving ſome of a flatter ſhape, in whoſe bodies there were never found any young ones, as there always were in the others, even when they were very young; but theſe have been ſince found to be only ſuch females as had already brought forth their offſpring.

The young *pucerons* being themſelves filled with embryos, and that in every individual, ſo that all that have been ever examined appear mothers, has given many ſtrange ideas of the manner of their generation: many have imagined them all to be hermaphrodites; and as no copulation has ever been obſerved among them, they are by ſome ſuppoſed to be able to impregnate each itſelf. The later opinion, however, is, that when a female is once impregnated by a male, ſhe will bring forth young ones already impregnated with others, and thus to the third or fourth ſucceſſion; ſo that copulation is only neceſſary to theſe animals once in three or four generations, and the children and childrens children of an old *puceron* that has had congreſs with a male, will bring forth young ones without having ever had any ſuch congreſs. *Reaumur*'s Hiſt. Inſ. Vol. VI. p. 59. See the articles WOOD-*puceron*, OAK-*puceron*, &c.

Bladder PUCERON, a ſort of *puceron* that lives in bladders on the leaves of trees. See PUCERON, *ſupra*.

We often obſerve on the leaves of different trees, a ſort of roundiſh bladders, which only adhere to the leaf by a ſhort pedicle: theſe are a ſort of ſmall galls, and their figure varies much in the different kinds; ſome are leſs round than others, and many are very rough on the ſurface; and ſometimes they are long, terminating in a point, and being broader at the baſe than in any other part, and ſuſtained by no pedicle, but fixed immediately to the leaves.

The elm and aſh afford us more frequent inſtances of theſe than any other trees, and very often on the firſt of theſe they grow to the bigneſs of a nut, and ſometimes much larger; and when they are grown to their full ſize, they often take up the whole ſurface of the leaf. When theſe bladders are opened, they are found to contain a large number of *pucerons*.

If theſe bladders are examined at the time when they are but newly riſen, which uſually is in the beginning of June, on opening them there is uſually found in them only one *puceron*, and that always a female big with young; and in others more advanced, the parent inſect is found ſurrounded with different numbers of her young ones. Theſe bladders have all of them at firſt only one female *puceron*; but afterwards they have more, as they become larger; and the largeſt of all are uſually found filled with a prodigious number of young ones. The newly riſen bladders are always found cloſe and firm in every part, the aperture at which the female *puceron* had entered, being uſually neatly and cloſely ſtopped up. The queſtion is, how this bladder was formed?

We very well know, that winged inſects of ſeveral kinds prick holes in the leaves and branches of vegetables, and depoſit their eggs in them; and that thence ariſe all the various ſpecies of galls, the eggs hatching within thoſe tumors into worms or maggots, and theſe finally becoming winged inſects like their parents.

Malpighi has given an excellent account of the ſeveral ſpecies of

of theſe galls; but he has not mentioned any of them being produced by a viviparous inſect, for the bringing up her numerous family: he has not omitted the bladders on the leaves of trees among the numbers of galls, but he has had no true idea of their origin; nor could this, indeed, have been any way found out, but by the obſervation that the creatures contained within them were of the ſame nature and origin with thoſe on the ſurface of the ſame or other leaves.

There ſeems no doubt, but that each of the female *pucerons* found in the bladders of theſe leaves, has been herſelf the occaſion and the maker of that bladder in which ſhe is found ſo cloſe ſhut up.

It would be natural to ſuppoſe, that the creature formed herſelf this lodgment when ſhe found herſelf loaded with young, and under a neceſſity of being delivered of them: but this is not the caſe; for a female *puceron* taken in this ſtate, and placed upon a leaf, makes no attempt towards the making herſelf ſuch a lodging; and there are taken out of the new-riſen bladders many ſingle animals of this kind, which are ſo far from being about producing their young, that they are not full grown. Theſe, however, are always females.

The method of the formation of them ſeems to be this: as ſoon as the female *puceron* is produced, ſhe fixes her trunk into the leaf to ſuck its juices; the conſequence of this in all the *pucerons* is, that the ſurface of the leaf ſeparates a little from the nervous part: in the common caſes the creature takes no advantage of this, but only continues ſucking the juices; but in this kind, the female, as ſoon as ſhe has made the ſeparation between the parts of the leaf, gets into the cavity that is formed there, by enlarging the orifice firſt made by the trunk, till it will admit her body. When once in, ſhe works forward in a ſtrait line, and the hole behind her ſoon cloſes up, as there was no rupture, but only a ſtretching open of the parts of the leaf. The female thus finds herſelf in a ſecure place, and the elevation ſhe makes in the leaf is ſcarce perceivable, only appearing as an oblong ſmall ſpecies of gall. The mark of the aperture at which ſhe made her way in, is always to be ſeen at ſome diſtance behind her, tho' uſually very neatly cloſed up: thus the whole continues till the creature produces her young. But then the ſcene is quite altered; the young ones begin to ſuck as ſoon as produced, and as they uſually ſeize upon the ſides of the ſmall gall, already formed for that purpoſe, this derives more juices than otherwiſe would flow into it; and it begins to elevate itſelf much higher, and forms a tubercle of the ſhape of a nut or pear.

Its growth in this caſe is entirely analogous to that of the common galls on the branches of trees, *&c.* and all the difference in the ſhape of the ſeveral bladders, is owing to the manner of the young *pucerons* ſucking: for if they ſuck much at its baſe, that enlarges and becomes the broadeſt part, as is the caſe in the conic and pointed ones; but if they let this alone, and ſuck only the ſides and upper part, they ſwell while this does not, and conſequently this forms a ſort of pedicle to the growing bladder. *Reaumur*'s Hiſt. Inſ. Vol. VI. p. 33.

Baſtard-PUCERON. See FIG-*inſect*, and GRUB *of the box*.

Earth PUCERON. See EARTH.

Grub PUCERONS. See GRUB.

PUCERON-*eater*, or *Lion* PUCERON. See LION *puceron*.

Oak PUCERON. See OAK.

Ver PUCERON. See VER *puceron*.

Wood PUCERON. See WOOD.

PUCKAUN *beady*, in natural hiſtory, a name given by the people of the Eaſt Indies to a peculiar ſpecies of orpiment, which they uſe in medicine.

They find it on the hills and on the banks of rivers. It is prepared by ſeveral tedious proceſſes, and then is given with ſucceſs in a diabetes.

PUDDINGS, in a ſhip, are ropes nailed to the arms of the main and fore yards, near the ends, and then at three or four due diſtances inwards one from another, in order to keep the robbins from galling or wearing aſunder upon the yards, when the top-ſail ſheets are haled home.

They call alſo thoſe ropes which are wound about the rings of anchors, to ſave the clinch of the cable from being galled with the iron, by this name; ſo that when the ring is ſo ſerved, it is called the *pudding of the anchor*.

PUDDING-*ſtone*. See the article OCULATUS *lapis*.

PUDENDA *(Cycl.)*—It is remarkable, that among the fiſh-tribe all that are oviparous have no *pudenda*, properly ſpeaking; that is, they have no penis or vulva, unleſs the ovaria of the females and the vaſiculæ ſeminales of the males may be called by that name.

The viviparous fiſhes, on the other hand, as the cetaceous fiſhes in particular, and many kinds of the cartilagineous, have the penis and vulva, diſtinctly and properly ſo called. *Artedi* Ichthyolog.

PUDIANO, called alſo *pædiano*, and by others *vermelho*, *apaimixira*, and *tetimixira*, a fiſh of the ſize of a middling pearch, but not ſo broad as that fiſh.

Its head is ſmall, its noſe pointed, and the upper part of its mouth furniſhed with very ſharp teeth; its lower part with others extremely minute. Its eyes are prominent, and the rays of its back fin are rigid and prickly. Its ſcales are extremely ſmall, and ſo cloſely laid, that it ſeems ſmooth to the touch. Its whole body is of a gold-yellow; but that the upper part of its head, and its back to the end of the back-fin, are of a very beautiful purple. The rim or edge of the belly-fin is alſo purple, and the reſt of a gold-yellow. It is a wholeſome and well taſted fiſh. *Ray*'s Ichthyol. p. 339. *Marggrave*'s Hiſt. Braſil.

PUDIANO *verde*, in zoology, the name of an American fiſh of a very remarkable colour, and very well taſted and wholeſome. See Tab. of Fiſhes, N°. 60.

It is of an oblong ſhape, and its uſual ſize is about ten fingers long, and three broad in the broadeſt part; for towards the tail it is but about half that breadth. Its mouth is ſmall, and its upper jaw furniſhed with two long teeth, and a great number of ſhort ones; and its under one with four long ones, and a like number of ſmall ones. Its back-fin is very long, and is ſupported by prickly rays. It is of a yellow colour, and variegated with longitudinal ſtreaks of blue. Its tail is not forked, and is of a reddiſh brown, variegated with a bluiſh green, and has a border of green at the end. Its ſcales are broad, and are ſo diſpoſed, as to repreſent ſo many cubes. Theſe are all of a fine yellow, and each has a rim of a bright blue all round its edges; and the whole fiſh is very elegantly variegated with blue, yellow, green, and white ſtreaks. *Marggrave*'s Hiſt. Braſil. *Willughby*'s Hiſt. Piſc. p. 340.

PUFF-*ball*, the common Engliſh name for the *fungus pulverulentus*, or lycoperdon. See LYCOPERDON.

The duſt contained within this body, (which, when it is cruſhed, flies out in an inconceivably fine powder, in form of a cloud of ſmoak) when examined by the microſcope, appears to be a multitude of regulary figured, tho' extremely ſmall bodies. Theſe require the moſt powerful magnifiers to diſtinguiſh them, and are found to be little globules of an orange colour, and ſomewhat tranſparent; and ſo ſmall, that the cube of the diameter of a hair, would be equal to an hundred and twenty-five thouſand of them. In other ſpecies of this muſhroom, the globules are evidently ſeen to be ſo many *puff-balls*, being of a darker colour, and having each a little ſtalk or tail: by means of theſe ſtalks they penetrate into the ground, when ſhed from their parent plant.

The duſt of theſe muſhrooms is very hurtful to the eyes, and we have had inſtances of perſons being blinded for a long time by it, with violent pain, ſwelling, and inflammation; and this is probably owing to the ſharpneſs of theſe almoſt inconceivably minute ſtalks or tails. *Baker*'s Microſcope, p. 255.

PUFFIN, in zoology, a name by which ſome call the anas arctica Cluſii. See PUFFINUS, *infra*.

PUFFINET, in zoology, the name of a bird known among authors by that of the *columba Groenlandica*, or the Greenland or ſea turtle-dove.

It is common on the northern coaſts, and is black all over, except two ſmall ſpots on its head: but it is pretended by ſome, that in winter it turns white. *Ray*'s Ornithol. p. 245.

PUFFINUS, in zoology, the name of a water fowl, with its three fore-toes connected by a membrane; but its hinder ones looſe, and with a ſharp and crooked beak. It is called in Engliſh the *puffin*.

It is larger than the tame pigeon: its head, neck and back are black: its breaſt and belly white: its beak is two fingers breadth long, and its baſe covered by a naked membrane, and has on each ſide a furrow, running from thence to the end of it: its wings are very long, and its tail a hand-breadth long, and black: it is extremely common in the Iſle of Man, but is ſo fat, that its fleſh is accounted unwholeſome unleſs it is ſalted: it is alſo common in the Scilly iſlands. They breed only in the culf of Man, an uninhabited part of the firſt mentioned iſland, and each female lays only one egg.

They lay in rabbit holes, and as ſoon as the young are hatched, they follow their parents all day to ſea, returning only in the evening. The people take them early in the morning, about the time of their going out, and that every man may remember how many he takes, he always cuts off one of the legs, and keeps it in his pocket; hence the vulgarly obtained opinion, that *puffins* have but one leg. *Ray*'s Ornithol. p. 252.

PUGNAX *avis*, in zoology, the name of the bird called in Engliſh the *ruffe*, and the female of which is the *reeve*. It has its Latin name from its quarrelſome diſpoſition, the males being always fighting. See the article RUFFE.

PUGNITIUS, in zoology, the name of the common ſtickleback, or barnſticle, called alſo from its ſpines *aculeatus*, and by ſome authors *ſpinachia*, *turonilla*, and *centiſcus*.

It is a very well known fiſh, and is found every where in new dug ditches, *&c.* where no body can perceive how it comes. Hence the vulgar have an opinion, that it breeds there equivocally and of itſelf, without the help of parents of its own kind; and that from it all other fiſhes are bred.

Theſe are idle opinions: the ſmalleſt animalcule is not produced in putrid matter otherwiſe than by the egg of a parent animal; this origin will, therefore, hardly be believed of larger, and, as they are called, more perfect animals. Theſe ſmall fiſh are ſo far from peopling ponds with other fiſh, that they are very great devourers of the ſpawn of larger fiſh, and do infinite miſchief in ponds.

There are two ſpecies of this little fiſh, the one larger, of two inches or more in length, and conſiderably thick. This has but five prickles, three on the back and two on the belly: this laſt is fixed to a penniform bone, very hard and ſtrong; for inſtead of belly-fins, this has two triangular bony laminæ. It has no ſcales, but its ſides are defended with a bony armature, reaching from the ſpines on the back to thoſe on the belly. It can raiſe or depreſs its ſpines at pleaſure. This ſpecies is common in our ditches; and they ſometimes ſwim in immenſe ſhoals together in the ſea.

The other is the ſmaller kind: this is ſhorter and much ſlenderer than the former, ſo that it appears proportionably of a longer figure. It has ten or eleven ſpines on its back, and theſe not ſet in an even row, but alternately bending one to the right, the other to the left; and it has bony laminæ inſtead of belly-fins, and two ſpines or prickles on them; and one behind the anus. This ſpecies has not the bony armature on its ſides that the larger has. It is common in our ditches. *Ray*'s Ichthyol. p. 341. ſeq.

PUGNITIUS *longus*, in zoology, the name of a Weſt Indian ſea-fiſh, caught about Chili and in ſome other places, and approaching in many particulars to the European *pugnitii*.

It is a ſmall animal; its body is ſquare, and of a tender conſtruction; of the thickneſs of a finger, and of five, ſix, or ſeven inches long, becoming gradually ſmaller towards the tail: its ſkin is ſmooth, and its back is black; its belly yellow: its head reſembles that of the pike, but that the noſe is ſomewhat longer: it has two fins at the gills, one of a triangular ſhape on the back; and from this to the neck there are placed a row of fifteen prickles, which bend a little backward, and are not connected by a membrane. On the middle of the belly it has alſo two ſpines at the two ſides, and one behind the anus: behind this there is a fin anſwering to that on the back, and the body is terminated by a fine ſmall tail. *Schonefeldt*'s Hiſt. Piſc. *Ray*'s Ichthyol. p. 340.

PULCHER *piſcis*, in ichthyology, a name given by Gaza to the fiſh commonly known by the name of the *uranoſcope*, or ſtargazer. See URANOSCOPUS.

It is a ſpecies of the trachinus, and diſtinguiſhed by Artedi by the name of the *trachinus*, with many beards on the lower jaw. See TRACHINUS

PULEGIUM, *penny-royal*, in botany, *&c.* a name given by authors to the common water-mint. Vid. *Linnæi* Gen. Pl. p. 271. *Tourn.* Inſt. Bot. p. 189. *Rivin.* Vol. I. p. 31, 32. See alſo the article MENTHA.

Penny-royal is among the firſt plants in eſteem in the preſent practice, as well as in former ages, as an attenuant and uterine. It promotes the menſes, and forwards delivery. It is good in flatulencies and ſuppreſſions of urine, and by many is greatly recommended in dropſies, jaundices, and other chronic diſtempers. It communicates its virtues very readily to water in infuſion, and its ſimple water drawn by the alembic, has, perhaps, more virtue than any other kept in the ſhops. Its eſſential oil is ſometimes, tho' rarely, uſed in the ſame intentions with the water.

PULEX, the *flea*. It is to Signior Redi that we owe the true hiſtory of the generation of this common and troubleſome animal.

The *flea* lays its eggs, and from each egg is hatched a ſmall worm: this worm ſpins itſelf a bag of ſilk, in the ſame manner that the ſilk-worm does; and out of this bag it comes at laſt in the perfect form of a *flea*, as the other does in its winged ſtate.

The *flea* depoſits its eggs on the bodies of dogs, cats, and other animals, and on the clothes of men, or the beds, and other places where they ſleep. Theſe eggs being round and ſmooth, ſlip eaſily down till they come into ſome fold of the clothes, or ſome other place, where they are hatched. In this place each egg produces a ſmall white worm of a ſilvery appearance; theſe worms feed on the white ſcurfy matter which is found in great plenty on the ſkins of dogs and other animals; and they are alſo found among the folds of linnen in drawers and other places: they are a fortnight in arriving at the full bigneſs of the worm ſtate, and will roll themſelves cloſe up into a ball, in the manner of the wood-louſe, when touched.

They ſoon after this ſpin themſelves their web, in which they lie a fortnight, and then come out perfect *fleas*.

The *flea*, if examined a day or two before its full growth in the bag, is found to have all its parts and lineaments; but it is ſoft and white. After this it gradually becomes hard and coloured, and when it comes out of the bag, is as ſtrong and large as it ever is to be.

PULEX-*eaters*, a name given by naturaliſts to a ſort of worms frequently found on the leaves of trees, where they devour the animals called *pulices arborei*. Vid. infra.

Of theſe there are ſeveral ſpecies, which owe their origin to the eggs of different creatures; for they are none of them in their ultimate ſtate in this their time of feeding. According to the different animals whoſe eggs they are hatched from, theſe are of different form and ſtructure: ſome are hexapodes, or endued with ſix feet; theſe belong to the beetle tribe, and finally change into beetles like the parent animal from whoſe eggs they ſprung: others have no legs, and are produced from the eggs of flies of various kinds: and finally, others are genuine caterpillars, tho' ſmall; but theſe are the moſt rare of all.

The two general kinds are the hexapodes, or beetle-worms, and the apodes, or fly-worms. The fly which gives origin to the laſt of theſe is a four-winged one, and takes care always to depoſit her eggs in a place where there are plenty of the *pulices*, uſually on the ſtalk or young branches of a tree in the midſt of large families of them. The worm, as ſoon as hatched, finds itſelf in the midſt of abundance of food, preying at pleaſure on theſe animals, which are wholly defenceleſs. The ſtalk of the elder and woodbine are frequently found covered over with theſe *pulices*, and among them there may uſually be found one or more of theſe deſtroyers feeding at will, ſucking in the juices from their bodies, and then throwing away the dry ſkins. Beſides the worms of this four-winged fly, there is one of a two-winged waſp-fly, very deſtructive of theſe animals. *Reaumur*'s Hiſt. Inſ. T. 1.

PULEX-*arboreus*, in natural hiſtory, the name given by Mr. Reaumur to a very large genus of ſmall animals. They are a kind of half-winged creatures; they have granulated antennæ, and ſome of them, in their moſt perfect ſtate, have complete wings. Theſe are diſtinguiſhed from the others by the name of *muſca pulex*, or the *winged-pulex*.

The ſeveral ſpecies of theſe creatures are of different colours; ſome are brown, others yellow; but the moſt frequent are green. They all feed upon the leaves of trees, which become withered and curled up on their eroding them; and they are ſo common, that wherever a leaf of a tree is found curled up, or of a different form from the others, it is highly probable theſe animals are on it, or that it is their work. Among trees the willow and the roſe are the moſt infected by them; and among plants, the bean and the poppy. They live a ſocial life, multitudes of males and females being found together. The females are eaſily diſtinguiſhed from the males, by their being thicker in the body, and having larger bellies.

It is very wonderful, that of all the known animals of the winged kind, theſe are the only ones which are viviparous. This is eaſily ſeen beyond a poſſibility of doubt; for on examining a cluſter of them together, it is a common thing to ſee, by the help of a ſmall magnifier, a female in the act of parturition; and the author of this account frequently ſaw the young *pulex* protruded out, from a paſſage near the anus of the female, perfectly formed. He had ſuſpected this from the total want of eggs among ſo numerous a tribe of animals, and from their remarkably ſpeedy propagation, and was thus convinced of it by ocular demonſtration.

They are armed with a tender and flexile proboſcis, with which they ſeize hold of the young ſhoots of the tree: they live upon twiſting the proboſcis round it. Theſe creatures are always ſeen naked and expoſed, ſtanding on the outſide of the ſtalks and leaves, and ſucking in their juices for nouriſhment with their proboſcis. But there is another ſpecies of them, which are alike viviparous, and agree with them in all reſpects, except in their manner of living. Theſe get into the inner ſubſtance of the leaves, like the worms called *aſcarides*, and feed on the parenchyma, being defended from all injuries by living between the integuments. In this caſe, the leaves they bury themſelves in become ſcabrous and deformed, and produce a ſort of galls: ſo that Malpighi erred in ſuppoſing all the galls of trees to be produced by the animals hatched of the eggs of ichneumon flies; ſince theſe animals which are viviparous, and are of a very different kind from the worms of the ichneumon flies, equally produce them. A female of the ſpecies here treated of has been ſeen to bring forth ſeven young ones in one day; and thus, from reſiding alone in the tubercles which ſhe had formed on a leaf, ſhe in a little time becomes the mother of a numerous family; each of which raiſes its own tumor or gall on the leaf, which at firſt are ſmall and round, and of a beautiful red like kermes.

Such of theſe as are of the male ſpecies have a certain time of reſt, in which they lie buried in a ſilky matter, and afterwards become winged, flying nimbly about; whereas the females never are able to fly, but remain always half-winged. It is to be obſerved, however, that there is a different ſpecies of winged inſects frequently found flying about the female *pulices*, as well as their own males; ſo that all the ſmall-winged inſects about them are not to be thought of their own ſpecies. Theſe do not greatly differ in figure; but the one are harmleſs, and the others have ſtings, and hurt any part of the body on which they fix. *Reaumur*'s Hiſt. Inſ. T. 1. See PSEUDO-*pulex*.

Locuſta-PULEX. See CICADULA.

PULMONARIA, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: the cup is a cylindric, pentagonal, perianthium, conſiſting of one leaf divided into five ſegments at the edge, and remaining after the flower is fallen. The flower conſiſts of one petal, in form of a cylindric tube, of the length of the cup, with its edge ſlightly divided into five ſegments, and its mouth open. The ſtamina are five very ſhort filaments, ſituated in the opening of the flower. The antheræ are erect, and converge one toward another. The piſtillum has four germina. The ſtyle is ſlender and ſhorter than the cup, and the ſtigma is obtuſe and emarginated. The cup, without ſuffering any changes, ſerves in the place of a fruit, containing in its bottom four roundiſh-leaved obtuſe ſeeds. *Linnæi* Gen. Pl. p. 59.

The characters of *pulmonaria*, according to Mr. Tournefort,

are theſe: the flower conſiſts of one leaf, and is funnel-faſhioned, and divided into many ſegments at the edges. The mouth is wide, and reſembles a ſort of baſin. The cup is tubular, and uſually of a pentangular form, and divided into five ſegments. From this ariſes a piſtil, which is fixed in the manner of a nail to the lower part of the flower, and is ſurrounded by four embryos, which afterwards ripen into ſo many ſeeds, which are contained in the enlarged cup. *Tourn.* Inſt. p. 136

The ſpecies of *pulmonaria*, enumerated by Mr. Tournefort, are theſe: 1. The common ſpotted-leaved *pulmonaria*, reſembling bugloſs. 2. The common broad-leaved white-flowered *pulmonaria*. 3. The blue-flowered Alpine *pulmonaria*, with ſoft and roundiſh leaves. 4. The plain-leaved not ſpotted *pulmonaria*. 5. The echium-leaved *pulmonaria*. 6. The white-flowered *pulmonaria*, with echium leaves. 7. The red-flowered echium-leaved *pulmonaria*. 8. The blue-flowered, echium-leaved *pulmonaria*. 9. The narrow-leaved Alpine *pulmonaria*. 10. The ſoft *pulmonaria*, with the ſtrawberry ſmell. 11. The annual Cretic *pulmonaria*, with bladder cups. 12. The *pulmonaria*, with roundiſh, plain, green, not ſpotted leaves.

The figure of the flower-cup is what principally diſtinguiſhes the *pulmonaria* from the bugloſs, *&c.* and the plants of it may be uſually known when not in flower, by their long, rough, and not divided leaves, which in almoſt all the ſpecies are ſpotted, ſo as to reſemble the tabid lungs of an animal, whence it had its name. *Tourn.* Inſt. p. 137.

The common ſpotted *pulmonaria*, or, as we vulgarly call it, *ſage of Jeruſalem*, is eſteemed an excellent medicine in many of the diſorders of the lungs. It has been known to do great ſervice in ſpittings of blood, and ſtands greatly recommended, externally uſed, as a conſolidator and healer of old ulcers, as well as freſh wounds.

PULSATILLA, *paſque-flower*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the roſaceous kind, conſiſting of ſeveral leaves diſpoſed in a circular form. The piſtil ariſes from the center of the flower, and is ſurrounded by ſtamina. The piſtil becomes at length a fruit, to which there are fixed a number of ſeeds, each of which terminates in a ſlender filament. The *pulſatilla* has, like the anemone, a regular ſet of leaves growing from one part of the ſtalk under the flower; but differs from it in having its ſeed naked, and terminated by the long filament juſt mentioned.

The ſpecies of *pulſatilla*, enumerated by Mr. Tournefort, are theſe: 1. The purple *pulſatilla*, with thick leaves and a large flower. 2. The double violet-coloured *pulſatilla*, with fimbriated flowers. 3. The marſh *pulſatilla*, with more finely divided leaves and ſmaller flowers. 4. The finely divided-leaved or marſh *pulſatilla*, with paler coloured flowers. 5. The *pulſatilla* with ſmall blackiſh flowers. 6. The ſmallage-leaved ſpring *pulſatilla*, with larger flowers. 7. The ſmallage-leaved ſpring *pulſatilla*, with ſmaller flowers. 8. The ſmallage-leaved autumnal *pulſatilla*. 9. The roundiſh-leaved *pulſatilla*. 10. The *pulſatilla* with red, obtuſe-leaved flowers. 11. The white-flowered *pulſatilla*. 12. The double white Pyrenean *pulſatilla*. 13. The celeri-leaved yellow-flowered *pulſatilla*. 14. The wild parſnep-leaved yellow *pulſatilla*. 15. The yellow rough-leaved Alpine *pulſatilla*. *Tourn.* Inſt. p. 284.

PULSATOR, a name given by ſome writers to that ſpecies of beetle, commonly known among us by the name of the *death-watch*, and about which ſo many ſuperſtitious fancies prevail.

The manner of the creature's making its noiſe is this: it lifts itſelf up on its hind legs, and ſomewhat extending, or rather inclining its neck, ſtrikes down its face with great ſtrength and agility, upon any ſubſtance on which it happens to be placed. It is often found on the matted bottoms of old chairs, and ſeems to uſe the motion which makes this noiſe, in order to get its food. It is uſually found ſtanding on a part of the ſedge where the outer covering is off, and the pithy part expoſed; and it uſually works at the ſide or edge of this place, in order to the getting off more of the outer bark. Where it is found there are uſually ſeveral of theſe bald places in the ſedge, which ſeem to have been places where it was before employed in getting its food. Every ſtroke the creature gives may be ſeen to have a ſenſible effect upon the ſedge, and where it ſtrikes a ſound part, the impreſſion is ſeen to be a dent as large as a ſilver penny.

The creature is called by ſome *ſcarrabæus galeatus*, from a ſort of galea, or helmet, which it wears. It is about a quarter of an inch long, and is of a duſky brown colour. Its helmet is very broad in compariſon of its bulk, and when the creature is at reſt, it draws in its head under this covering.

PULSE (*Cycl.*)—It is certain that the climate will alter the *pulſe* of perſons, and on this is founded the obſervation of *pulſes* being naturally various in the people of different nations. The *pulſes* of Frenchmen are ſaid to be more equal and quick, and thoſe of the Britiſh, Dutch, and Germans, more irregular and uncertain; and this is to be jointly attributed to the air of the country, and to the manner of living.

In general, the higher and nearer the ſun is, the quicker is the *pulſe*; and the lower and farther off, the ſlower. In rainy ſeaſons, the *pulſe* is more free and quick, becauſe of the ſmaller preſſure of the atmoſphere. It is more impetuous in the ſpring; more equal after a quiet ſleep; weak and uncertain in men very intent upon buſineſs.

Melancholy renders the *pulſe* extremely inconſtant, probably through the great thoughtfulneſs of ſuch men: in bilious tempers it is high and ſtrong; in ſanguine, more equal and regular than in any: in the phlegmatic, equal enough; but more ſlow: in children, eſpecially infants, the *pulſe* is very ſmall; and in old men it is extremely uncertain: in glutonous people it is dull and ſlow, unleſs by drinking it is made ſtumbling and vertiginous: this ſort of *pulſe* alſo frequently foretells ſudden death By too ſparing a diet it becomes ſmall and ſlow, and always abates upon faſting. By the paſſions the *pulſe* may be alſo greatly altered; but moſt of all by fear, joy, and anger. In fevers the *pulſe* is varied according to the beginning, heighth, and declination. In ſcorbutic and hyſteric perſons it is very uncertain: in hydropical perſons it is much ſtopped and interrupted by ſtagnant humors: in the gout it is free and expedite: in the plague, as in the aſthma, it is mightily oppreſſed, unleſs freed by the hot fit. In general, any variation of the *pulſe* certainly denotes ſome alteration in the habit of the body.

The *pulſe* is unequal either in regard to time or ſtrength; that is, it either ſtrikes quicker and ſlower, or ſtronger and weaker. The firſt is common in moſt acute diſtempers, and does not threaten any immediate danger; but the latter, both in acute and chronic caſes, is always a dangerous ſymptom: very often it is the forerunner of death, which happens two or three days after this is firſt obſerved. It is ſaid to be interrupted when the ſtrokes are much ſmaller and weaker than at other times, or their intervals much greater. This firſt ſhews a great decay of ſtrength; and the latter, which is, as it were, a ceſſation for a time, denotes approaching palſies, apoplexies, and the like terrible diſtempers, and ſometimes death itſelf.

The intenſe *pulſe* is when the ſtroke is very hard, the parts being, as it were, upon the bent; or elſe this ſtrength is made up by the multiplicity and frequency of leſs mications, as in the heighth of acute fevers.

The remiſs *pulſe* has ſtrokes leſs quick and ſtrong, and in ſickneſs ſhews more danger than the other. The ſuperficial *pulſe* ſhews an exact temperament of body, as alſo a free and eaſy temper of mind.

The deep *pulſe* ſhews a diſpoſition to melancholy, aſthmas, and lethargies, and is more frequent in the aged than in young people.

The leaping *pulſe* often ſhews no great danger, but the trembling *pulſe* is uſually a fatal ſymptom, after which very few people recover.

But of all others the wandering *pulſe* is the moſt terrible and fatal; this is felt ſometimes in one part of the artery, and ſometimes in another, and ſometimes in no part at all. This is a certain fore-runner of death, and that uſually very ſpeedily following; and if great power in nature gives a ſhort reprieve after this, it is only a very ſhort relief. *Abercromb.* de variat. Pulſus.

The *pulſe* has been obſerved to beat faſter in perſons electrified. Phil. Tranſ. N°. 478. p. 59. See ELECTRICITY, *Cycl.*

PULSILOGIUM, a name given by authors to a pulſe-watch, or inſtrument to meaſure the celerity of the pulſe. Sanctorius was the firſt inventor of this machine; but ſeveral have ſince ſpoke very largely in praiſe of it, and Sir John Floyer wrote a treatiſe on this ſubject.

PULSUS *latus*. See LATUS *pulſus*.

PULVERATICUM, in Roman antiquity, the fee paid to ſurveyors for their trouble; alſo a ſum exacted from the provincial cities by their garriſons. *Pitiſc.* in voc.

PULVILLUS, in ſurgery, a term uſed to expreſs a little pledget-bolſter, or compreſs.

PULVINARIA, in Roman antiquity, cuſhions upon which the ſtatues of the gods were laid in the temples, at the time that thanks were given for ſome ſignal victory. *Danet* in voc.

PULVIS (*Cycl.*)—PULVIS *e bolo compoſitus*, a powder preſcribed in the late London pharmacopœa, and intended to be uſed in the place of the *confectio Fracaſtorii* or *diaſcordium*. It being ſuppoſed that this medicine was by its author meant as an alexipharmic, and being now principally uſed as an aſtringent, it was thought neceſſary to make this ſeparate medicine.

This powder is compoſed of bole armenic, half a pound; cinnamon, four ounces; and tormentill-root and gum arabic, of each three ounces, made together to a powder. *Pemberton's* Lond. Diſp. p. 311.

PULVIS *bezoarticus*, the name given in the late London diſpenſatory to the powder commonly called *Gaſcoign's powder*.

This is now ordered to be made only of crab's claws, one pound; prepared pearls and red coral, of each three ounces; and oriental bezoar, an ounce. The amber and hartſhorn are left out of the compoſition, as improper or inefficacious ingredients; and the whole ordered to be kept alſo without the bezoar, and called by the name of *pulvis e chelis cancrorum compoſitus*, the name the Gaſcoigne's powder uſed to be known by. *Pemberton's* Lond. Diſp. p. 313.

PULVIS *e ceruſſa*, a medicine preſcribed in the late London pharmacopœa, in the place of the white troches of Rhaſes or Razi. See TROCHE.

The late compoſitions of that medicine had been much more com-

complex than the original receipt of that author, and the college have therefore retrenched the number of ingredients in them; and as the medicine is always to be powdered for use, it is now ordered to be kept in the form of powder.

It is thus prescribed there: take cerus, five ounces; sarcocolla, an ounce; gum tragacanth, half an ounce; make the whole into a fine powder. *Pemberton*'s Lond. Disp. p. 312.

PULVIS *contrayervæ compositus*, the name given in the late London dispensatory to the composition usually called *lapis contrayervæ*.

The preparation is also there made much less complex, by leaving out the less powerful absorbent powders, and using the compound powder of crabs claws in the place of all.

This is now ordered to be made only of the compound powder of crab's claws, a pound and half; and contrayerva-root, five ounces. *Pemberton*'s Lond. Disp. p. 313.

PULVIS *e myrrha*, a form of medicine prescribed in the late London dispensatory, to supply the place of the troches of myrrh.

The composition is the same but for the omission of one or two of the ingredients, supposed not of the same virtues with the rest, or very disagreeable to the taste.

It is ordered to be made thus: take of dried leaves of rue, of dittany, of crete, of myrrh, each an ounce and half; of assafœtida, sagapenum, Russia castor, and opopanax, each an ounce, beat altogether to a fine powder. *Pemberton*'s Lond. Pharm. p. 314.

PULVIS *e scammonio*, a name given in the late London dispensatory to the purging powder commonly called the *Earl of Warwick's powder*.

It is, however, wholly altered here, the crystals of tartar and diaphoretic antimony being left out, and the medicine ordered to be made only of four ounces of scammony, and three ounces of burnt hartshorn reduced together to a fine powder. *Pemberton*'s Lond. Disp. p. 315.

PULVIS *e succino*, *amber-powder*, a form of medicine prescribed in the late London pharmacopœa, to stand in the place of the troches of amber, or *trochisci de carabe* of former dispensatories.

The composition of the powder is this: take prepared amber and gum arabic, of each ten drachms; juice of hypocistus, balaustines, and Japan earth, of each five drachms; olibanum, half an ounce; strained opium, a drachm; mix all together into a fine powder. *Pemberton*'s Lond. Disp. p. 316.

PULVIS *fœcundans*, in natural history, a name given by late writers to that fine powder which is contained in capsules upon the stamina or threads in the flowers of plants, and is called by some English writers the *maleduſt*, and in general the *farina* of flowers.

This dust was for many ages looked upon as a recrement of the plant; but it has of later times been found to consist wholly of organical bodies, which are in reality the embryo plants; and entering into the seeds in the capsules, while yet buried in the style, they fœcundate them, and put them in a state to vegetate and produce their species. On the most accurate examination, however, with microscopes, the farina, or *pulvis fœcundans* of plants, has never been found to carry any likeness to a *plantula seminalis*, or the rudiments of the plant which was to be produced by it. All that the microscope does in this case, is but increasing the apparent magnitude of the particles of the powder; but they are found, when thus viewed, to be no other than a congeries of globules, which are all alike in the same species, and composed of fibres and vasicules wrought together in such a curious manner, to the keeping whole as long as necessary, and bursting when necessary, that it appears evident they are destined for some very great uses. See Tab. of microsc. Obj Class 2.

Verdresius, in the Acta eruditorum, has given a very curious detail, and has figured and described fifty kinds of this dust, most of which are considerably different from one another; tho' some are nearly alike. He observes, that in all the number of flowers he examined, he found no farina, or *pulvis fœcundans*, that did not resemble one of these fifty; and that, therefore, whoever engages in this curious research, should first observe these, and then refer the others to one or other of them, as they next approach them, and mention their differences, if any, by way of characters, by which they might always be known. Act. Erudit Ann. 1724. p. 410.

The author of this curious treatise, from a multitude of experiments, seems to think these globules of dust rather to represent the testicles of male animals, than any other part of the organization of any known body. The numerous fibres they are composed of, which are convoluted and twisted in a most remarkable and intricate manner, and the vesicles contained in their substance among these fibres, shew a great resemblance to the testes in structure, and in their apparent uses.

The principal farinæ he describes, are those of the yellow water iris, or flag-flower, which are of an oval figure, somewhat hairy, and covered either in part or entirely with a thin membranous coat. The tulip farina, which is flat, broad, and somewhat angular at one end, tho' rounded at the other. The honey-suckle farina, which is broad and truncated at one end, and roundish, but somewhat pointed at the other. The farina of the iris-leaved yellow lilly, which is oblong, pointed at one end, and rounded at the other; and when separated perfect from its capsule, has a tail at the rounded or largest end. The farina of the hypericum, which is oblong and slender, truncated at both ends, and marked with a deep longitudinal furrow on one side, resembling the channel in the midst of the seeds of corn or oats, and serving to the same purpose, the opening of the granule. The marshmallow farina, which is like the mallow and holy oak, a very beautiful object, being round granules, surrounded with a regular circle of spines or prickles. The Indian cress has a farina, which in most lights appears of a triangular figure. The lysimachia, or willow-herb, has a farina resembling that of the hypericum, but shorter and thicker, truncated at both ends, and with a longitudinal furrow, tho' but a slight one. That of the scabious is smoother than most others, and approaches most of all to a globular figure. That of wormwood is also globular, and small, and when separated entire, has a stalk or pedicle like that of the yellow lilly. The farina of the clematitis is very singular, it being of a globular figure, but consisting of one globule enclosing another; or of a pale-coloured globule, contained in a thick browniſh husk, which opens in one determined part, and lets out the globule it contained. That of the white jessamine consists of half globules, or a sort of hemispheres, flat on one side, and regularly rounded on the other.

The farina of tobacco is oblong and slender, and pointed at both ends, sometimes very sharply, sometimes more obtusely, according to its state of ripeness. This has also an oblong furrow running from end to end on one side, which is the place where it is to open, as the hypericum and some others have. The farina of the passion flower consists of very large dusky-coloured globules, which, when separated entire, have tails or pedicles; but those very short. That of the gourd is a more elegant object than almost any other: it is round, and surrounded with a row of flat and obtuse rays, resembling the mallow farina, except that they are not pointed. The cucumber, tho' a plant nearly allied to this, yet produces a simple, small, and roundish farina. The cabbages of some kinds have farinæ composed of simple, oval bodies; in others these globules are more oblong, and resemble very perfectly the naked grains of wheat, having the same sort of furrow running longitudinally from end to end. The dust of the hyacinth is very long and slender, often crooked, and always obtuse at one end, and pointed at the other. The farina of some of the species of clary is very large, perfectly round and smooth, and has the mark of an opening in one part. It is probably like that of the clematitis, one globule contained within another, and this the opening thro' which the inner one is to pass. The author of these curious observations has given good figures of these and of the other of the fifty of his farinæ, to which we refer the reader. Act. Erudit. Ann. 1724. p. 411.

Puteolanus PULVIS, in natural history, the name of a fossile substance, found in form of powder, and famous for its consolidating under water. The accounts of it seem, however, to be a little erroneous.

The substance itself is a pale greyish powder, composed of particles so extremely minute, as to escape the distinction even of the best glasses, and appear, when viewed by the microscope, only a loose, very fine, irregular powder. It has among it a few small spangles of talc, and being shook up in a vial of water, leaves a whitish muddiness in it, which is very long in subsiding. If wetted with salt-water, it immediately dries into a firm solid mass, like a stone. It does the same also in common water; but the mass is less firm.

The antients were well acquainted with this substance and its properties. It is said, indeed, that on running down into the water, it becomes a hard stone, while it remains under it; but this is probably a mistake, arising from this, that the powder was continually running down the hills into the sea, and lodging on their sides in large quantities in many places; when these masses became wet with the waves, in storms or high tides, and afterwards deserted by them, they naturally hardened into so many masses of a sort of stone: and these were probably what authors have seen and described, for they never, probably, searched for these masses under water. The principal use of this powder among the antients, was in mixing with their cements for buildings sunk into the sea. It is at present well known in France and Italy, as an ingredient in that sort of plaister they call *pozzolane*.

The remarkable quality of its coalescing on its being mixed with water, is probably owing to its having in its composition a quantity of a certain earth known in almost all ages and countries for coalescing into a kind of plaister without previous burning. The antients knew this earth by the name of *gypsum tymphaicum*; and we, by that of *calx nativa*. It is very common on the sides of hills in many parts of Italy. *Hill*'s Hist. of Foss. p. 573.

PUMICE *(Cycl.)*—There have been many different conjectures about the nature and origin of this substance; but the very earliest writers of antiquity, and the most judicious of the later ages, agree, that it is no native fossile, nor in its original condition but a mere cinder, or remainder of some other fossile body, calcined by a violent fire.

This may have been either subterranean and unseen, or perhaps since extinguished; or that of the well-known burning

mountains, on and about which *pumices* are conſtantly found, and that in vaſt abundance. The more violent exploſions of theſe may alſo, at one time or other, have toſſed vaſt quantities of *pumices* to places ſo diſtant as to make people forget from whence they came; or into ſeas, whoſe tides and ſtorms may have carried them to other ſhores, near which no ſuch repoſitories of *pumices* are ſituated; and this might very much puzzle and miſlead people about its true nature and origin.

The great quantities of *pumices* found in this manner, far from fires by which they might have been formed, floating on the ſurface of the ſea, thus thrown on it, or perhaps raiſed by the burſting of vulcanos from its bottom; and ſomething altered from their original form and colour, by being waſhed and rounded by the motion of the waves, and by rolling againſt one another, gave riſe to an opinion in ſome, that theſe were of another kind, and were different from thoſe *pumices* found on the burning mountains, and that they were formed by the concretion of the froth of the ſea. Many have ſuppoſed, that the authors who have favoured this opinion ranked the alcyonia among the bodies they call *pumices* ſo formed; and Theophraſtus has been very unjuſtly cenſured of the ſame fault, tho' not guilty of it. *Hill*'s Theophraſtus, p. 48.

There are whole mountains in the principality of Heſſe, which conſiſt of rocks of the *pumice*-ſtone, as it is there vulgarly called. This is a ſpungy and cavernous ſtone, of a grey colour, and very much reſembles the *pumices* in external appearance; but on examination, proves to be a very different ſubſtance, and there is not the leaſt ground for ſuppoſing, that it owes its preſent appearance to the action of fire, as the common *pumices* thrown out of the burning mountains certainly do. It is very neceſſary, in order to treat accurately of the nature of the *pumice*-ſtone, to diſtinguiſh rightly between theſe ſtones and ſuch as have been burnt into their ſpungy ſtate. Yet this is generally neglected, and theſe are called *pumices* as well as the reſt, and all are ſuppoſed to be of the ſame origin.

PUMPING *at ſea*, is uſually done by ſpells, that is, by relieving the men with freſh ones, and counting how many ſtrokes they *pump* each watch. By this means they know if the ſhip be ſtanch, or how her leaks increaſe.

When all the water is drawn up, and there comes up nothing but wind and froth, they ſay the *pump ſucks*.

PUMPKIN. See the article PEPO.

PUNARU, in zoology, the name of a ſmall fiſh of the alauda kind. It has an oblong body, and a thick head, obtuſe at the ſnout. The mouth is ſmall, and in the lower jaw there are only two oblong teeth, which are ſharp and pointed like needles. The eyes ſtand high in the head, the pupil is black, and the iris yellow; and over theſe there are two ſhort red filaments. The gills are large, and have two oblong fins placed behind them. The back fin reaches from the head to the tail, and is prickly at the edge. The belly-fin reaches from the anus to the tail. The ſkin and fins are all brown.

Beſides this, there is another ſpecies, variegated on its ſides with lines of a duſky purple. Its jaws beſet with very ſmall teeth, and its fins not prickly. Both kinds are found among the rocks about Braſil, and ſometimes get into the ſhells of the larger ſhell-fiſh. *Marggrave*'s Hiſt. Braſil.

PUNAY, in natural hiſtory, a name given by the people of the Philippine iſlands to a very beautiful ſpecies of turtle, common in their woods.

It is of the ſize of a ſmall parrot, and is of a fine green colour; but the extreme feathers of its wings are tipped with white, and the lower part of its belly is of a ſaffron colour. Its beak is yellow.

PUNCH *(Cycl.)*—PUNCH, in the manege, a well ſet, well knit horſe, called in French *gouſſaut*. He ſhould be ſhort-backed, and thick ſhouldered, with a broad neck, and well lined with fleſh.

PUNCTICULARIS *febris*, a name given by ſome authors to a fever attended with ſmall eruptions.

PUNCTURE *(Cycl.)*—Among the number of the moſt ſimple wounds are reckoned thoſe which are made by *puncture*, or ſtabbing on the external parts, and not penetrating to a very great depth. In theſe wounds, after the blood has been ſtopped at the firſt dreſſing, by the application of dry lint, the common digeſtive, or *linimentum Arcæi*, is to be ſpread upon a pledget and applied once every day; or if the diſcharge is but ſmall, every other day, covering the dreſſings with a plaiſter and compreſs, and ſecuring the whole with a proper bandage. At each dreſſing, care muſt be taken to remove every thing that will give way readily; the pus or ſanies is to be gently wiped off with fine raggs; and unleſs a great diſcharge of matter make it neceſſary, too frequent dreſſings do rather harm than good. The firſt dreſſings that have been applied, eſpecially when there has been a flux of blood, ſhould by no means be removed forcibly; but be left till they will fall off of themſelves, which they will do after a ſuppuration is formed: and by this caution, much pain, and, perhaps, a freſh hæmorrhage, are avoided.

When a *puncture*, however, penetrates very deep, the cure is attended with many difficulties; eſpecially if it is made perpendicularly down, and has no depending orifice: for, in this caſe, the blood and matter are eaſily collected at the bottom, and protract the cure, and frequently form fiſtulæ. To prevent theſe conſequences, it will be proper to preſs the wound from the bottom upwards, to apply a compreſs toward the bottom of the wound externally, and to apply a bandage over all, which preſſes much tighter upon the lower than upon the upper parts. If all this precaution, however, prove of no effect, which, indeed, is too often the caſe, it is the moſt proper method to make a large opening at the bottom of the wound, before any fiſtulæ are formed there. In order to make this opening to the greater advantage, it will be proper to get a particular ſort of probe or needle, very blunt at top, and at the other end provided with a large eye, or hole, through which a linnen rag may be paſſed. This probe is to be paſſed to the bottom of the wound, and the blunt end of it preſſed outwards toward the ſkin, till you can feel it with a finger: when you can feel it, cut down upon it if you can ſafely, and make a large opening; ſpread the rag that you have run through the eye of the probe with ſome vulnerary balſam, and draw it through the wound after the manner of a ſeton, and leave it there, dreſſing up both the orifices with the ſame balſam, and covering the whole with compreſſes and the proper bandages. In every ſucceeding dreſſing, that part of the rag that is left out of the wound is to be ſpread with freſh ointment, and the lower part drawn down till this takes place in the new wound. This method is to be continued till the wound is well cleanſed, the diſcharge greatly diminiſhed, and all in a readineſs to heal: the ſeton is then to be removed, and the wound healed as uſual. *Heiſter*'s Surg. p. 35.

PUNICA, the *pomegranate*, in botany, the name of a genus of trees, the characters of which are theſe: the flower is of the roſaceous kind, being compoſed of ſeveral petals, arranged in a circular form. The cup is of the ſhape of a bell, and divided into ſeveral ſegments at the edges; this finally becomes a fruit of a roundiſh figure, coronated at the end, and divided into many cells within, which contain many kernels full of juice, affixed to a placenta, and ſeparated from one another by very fine membranes: theſe contain ſeeds of an oblong figure.

The ſpecies of *pomegranate*, enumerated by Mr. Tournefort, are theſe: 1. The common cultivated *pomegranate*. 2. The common wild *pomegranate*. 3. The cultivated *pomegranate*, with ſweet fruit. 4. The cultivated *pomegranate*, with fruit of a middle taſte between ſweet and ſour. 5. The large fruited *pomegranate*, with large, criſp, amathyſtine kernels. 6. The great double-flowered *pomegranate*, or balauſtine. 7. The *pomegranate* with a double variegated flower. 8. The *pomegranate* with ſmall double flowers. And, 9. The low dwarf American *pomegranate*. *Tourn.* Inſt. p. 636.

PUNICUS *lapis*, a name given by the writers of the middle ages to a ſtone of a ſpungy texture, the powder of which was good in diſeaſes of the eyes.

This ſeems to have been no other than the pumice, the writers of theſe times having been ſtrangely incorrect in their orthography; and all the virtues aſcribed to this ſtone, as alſo the places where it was found, which are the Æolian iſlands, *&c.* ſeeming to have been copied from Pliny's account of the pumice.

PUNK, in natural hiſtory, the inward part of the excreſcence or exuberance of an oak. It is uſed by the Indians in Virginia for medicinal burning, as the Eaſt Indians uſe moxa. Phil. Tranſ. N°. 454, ſect. 1. See MOXA.

PUPIL *(Cycl.)*—PUPIL *contracted*. The diſtemper of the eye called by ſurgeons a *contraction of the pupil*, is ſo total or cloſe a contraction of that part as will not let it tranſmit light enough to the bottom of the eye, to enable the patient to ſee objects diſtinctly. Sometimes this diſorder is from infancy, and ſometimes it ariſes from an intenſe inflammation of the eye, or other cauſes.

The cure of this is extremely difficult; but Mr. Cheſelden has invented a method by which he has often proved very ſucceſsful in his attempts to relieve it. The method is this: the eyelids being held open by a ſpeculum oculi, he takes a narrow ſingle-edged ſcalpell, or needle, almoſt like that uſed in couching for a cataract, and paſſing it through the ſclerotica, as in couching, he afterwards thruſts it forward through the uvea or iris, and in extracting it cuts through the iris.

If the diſorder is not accompanied with a cataract, it will be beſt to cut through the iris in the middle; otherwiſe, when there is a cataract, the inciſion ſhould be made a little higher in the uvea, that the cataract may not obſtruct the ingreſs of the rays of light. The cataracts that accompany this diſorder are uſually very ſmall, and ſometimes their adheſion to the iris is ſo firm, as to render it impracticable to couch or ſuppreſs them. *Heiſter*'s Surg. p. 417.

PUPPETS, in natural hiſtory, the name given by Swammerdam to the nymphæ of animals, which he diſtinguiſhes from the chryſaliſes by this ſimple name, calling theſe the *gilt puppets*, from their golden colour.

It has been a general diſtinction eſtabliſhed by writers between the nymph and chryſalis, that in the former the limbs and lineaments of the future animal might be ſeen, but in the latter not. But Swammerdam has proved, that the lineaments of every trace, and every part of the animal, is to be ſeen under the

the chryſalis as well as under the nymph ſtate, with proper attention in the examination, and that therefore the diſtinction is founded on a very vague and uncertain baſis. The far greater part of the inſect kingdom are hatched from the egg in the worm ſtate, and become, after a time, changed into theſe chryſaliſes and aureliæ; but ſome are hatched perfect, and in their own form, from the egg. Among thoſe which undergo the change into the chryſalis ſtate, the principal diſtinction is into worms that have legs, and worms that have not any. The breaſt of thoſe worms which have no feet is never changed at all, and among thoſe worms which have many feet, the ſix fore feet are never changed, but ſerve the animal as well in its flying ſtate as in its creeping one. The wings, the horns, the feet, &c. grow up under the ſkin by degrees.

In all worms, of whatever kind, theſe parts may be diſtinguiſhed more or leſs plainly under the ſkin, at the different times of their growth, in different degrees of forwardneſs. Even the frog may be thus traced, by proper care, in the tad-pole, and all its changing from the tad-pole ſtate to that of the perfect animal, is no other than as in the butterfly, the developing and unfolding its parts, as they require a proper age, conſiſtence, and maturity.

Mouffet, and other writers on inſects, call the aurelia a ſeparate and peculiar thing, and expreſly neither an egg nor an animal. Harvey alſo miſtakes the matter as groſly, in calling the aurelia an egg, and ſaying, that the bloodleſs animalcules are produced by transformation; but theſe are expreſſions much to be lamented in the works of ſuch great men, and have been the means of darkening and perplexing the knowledge of the aurelia ſtate in inſects, and muſt be overthrown before any true judgment can be formed of that ſtate.

All the change happening in the *puppets*, or nymphæ, which was ſuppoſed by Harvey to be the production of one animal from another, is in reality no more than the exſudation of a certain abundant moiſture which leaves the animal dry, and all its parts firm and capable of expanding and extending themſelves, and bearing the weather.

Goedartius has alſo propagated another groundleſs error, which, by its conſequences, tends to overthrow all the true knowledge of theſe changes. This is, that the caterpillar may change before its time, and that in this caſe it becomes a very different animal in the winged ſtate. This tends wholly to overthrow the conſtant and uniform law of nature, according to which, all the lineaments of the perfect animal are formed even in the egg, and have only to grow and enlarge in the worm and chryſalis ſtate; and can therefore be ſubject to no change in either.

What has led Geodartius into this error, was real obſervation, only not carried ſo far as it ſhould have been. In ſome of the inſects which ſuffer the chryſalis ſtate, the males are winged and the females not. In theſe the courſe and order of nature is as invariable as in the reſt, all the males being of the winged, and all the females of the reptile kind; but this author, not knowing this great difference in the ſexes, when he had been uſed to ſee a winged creature come out of the chryſalis of a worm he knew very well, and found inſtead of it a creeping animal without wings, ſuppoſed the creature, which was only of a different ſex, to be of a different ſpecies.

Some difference alſo is found in the ſize of the fly produced from the chryſalis of the ſame ſpecies of caterpillar, according to its changing ſooner or later into that ſtate. All the difference, however, is, that if the caterpillar eats its fill firſt, the fly is the larger and the fairer; and if it goes into the chryſalis earlier, then the fly is the leſs perfect: and of whatever ſize the fly is when produced out of the chryſalis, in that it remains; for it can grow no more after it has paſſed this latter change.

From the knowledge of the propagation of this ſort of animal, this author goes up to that of larger creatures, and is firm in the opinion, that there is properly no ſuch thing as generation at all; that all that our blindneſs calls ſo, is only a ſenſible production by the growing of parts at firſt very minute. All the parts of the butterfly may be ſeen, by a proper inſpection, in the caterpillar; and as to the imaginary tranſformation of the caterpillar into the chryſalis, it may be retarded and made to come on ſo eaſily, as to become the object of the ſenſes, and finally ſtopped in the progreſs, ſo as to appear half caterpillar, half chryſalis. *Swammerdam*'s Hiſt. Inſect.

PUPPIS OS, a name given by ſome authors to the os frontis. The future in this bone is alſo called by many anatomiſts the *ſutura puppis*.

PUPULÆ, a name uſed by ſome to expreſs the extremities of the fingers.

PUR *autre vie*, in our law-books, is uſed where lands are held for the life of another.

PURCHASE-*book*, among traders, is the name given to a book which is a kind of journal, containing an account of all the purchaſes made, or things bought in the day.

Purchaſe, in the ſea-language, is the ſame as *draw in*: thus when they ſay, *the capſtan purchaſes apace*, they only mean it draws in the cable apace; alſo when they cannot draw or hale in any thing with the tackle, they ſay, *the tackle will not purchaſe*.

PURETTA, a name given by ſome writers to the common ſhining black ſand, uſed to ſtrew over writing, and erroneouſly called by ſome *ſteel-duſt*.

It is a natural mineral ſubſtance, found on the ſhores near Genoa and in other places.

PURGATIVE *(Cycl.)*—We have had attempts of adjuſting the doſes of *purgative* medicines ſcientifically. Dr. Cockburn endeavoured at the ſolution of this problem; but, it is ſaid, on wrong principles. Dr. Balguy has alſo given us an eſſay on this ſubject in the Med. Eſſ. Edinb. Vol. IV. art. 5.

He aſſumes, that part of the medicine is ſpent on the firſt paſſages, where it acts as a ſtimulus; and that the other part is carried into the blood, and has its effect there by thinning and rarifying it. This being premiſed, 1ſt. If the medicine acts only in the firſt paſſages, the doſe will be as the ſize of the perſon into the conſtitution. 2d. If the whole medicine paſſes into the blood, the doſe will be as the ſize into the ſquare of the conſtitution; and therefore, 3d. You are to doſe ſo much of the medicine as is ſpent on the ſtomach and inteſtines directly, as the conſtitution; and ſo much as is carried into the blood, as the ſquare of the conſtitution, and the ſum into the perſon's ſize, is the quantity required.

The ſame rules hold in vomits. How far in either caſe the practice of phyſic may be thereby improved, we leave to the judgment of the learned. The ſolution of the problem ſuppoſes a great poſtulatum, no leſs than the art of meaſuring a perſon's conſtitution!

PURGATION, *purgatio*, in rhetoric, is uſed for that kind of defence which takes place when the accuſed perſon owns the fact, but denies that he did it with deſign, or with any bad intention. *Voſſ.* Rhet. l. 1. p. 148.

PURIFICATION, in pharmacy. See TRYING.

PURPURA, the *purple-fiſh*, in natural hiſtory, the name of a genus of ſhell-fiſh, the characters of which are theſe: it is a univalve ſhell, jagged and beſet from head to tail with ſpines, tubercles, umbos, or ſtriæ. The mouth is ſmall and roundiſh; the tail is ſhort, and uſually the baſe runs out into a long beak.

It has been uſual with moſt authors to confound together the genera of the murex and *purpura*, and to uſe the words as ſynonymous: but tho' there is ſome external reſemblance between many of the ſhells of the two genera, yet they are eaſily diſtinguiſhed by this, that the mouth of the *purpura* is leſs long, and is leſs dentated and alated than that of the murex. The body and the head of the ſhells of this genus are not ſo elevated as thoſe of the murex kind, and are not covered with points or buttons at the mouth. If a ſhell is therefore found to have a ſmall, ſmooth, and round mouth, and a body covered with undulated leaves, as it were, like thoſe of ſavory or endive, and ſometimes with long points, and its tail, whether long or ſhort, be hollowed and ſomewhat bent, this may be called a *purpura* and not a murex.

The antients diſtinguiſhed three kinds of *purpura*, one which had a long and crooked tail, made hollow like a tube or pipe; a ſecond which had either no tail at all, or at the moſt a very ſhort one; and a third which had no ſpiral head, or, as we ſhould expreſs it, no clavicle.

On examining the whole family of the *purpuræ*, we may diſtinguiſh four remarkable ſpecific differences among them. The firſt of theſe comprehends thoſe *purpuræ* which have the body of the ſhell garniſhed with a ſort of undulated foliage in clouded ridges, and have a ſhort and crooked tail. The ſecond comprehends thoſe which have the body of the ſhell covered with acute points, and have a long tail. The third comprehends thoſe which have as long a tail as the former, but have a ſmooth body, or at the utmoſt have only a few ſlight protuberances and wrinkles on it. And the fourth takes in thoſe which are ſmall, and have an elevated clavicle, a ſhort crooked tail, and the body of which is covered either with ſlender ſpines or hairs. See Tab. of Shells, N°. 14.

This ſpecies of fiſh, as well as the murex, ſerved among the antients to dye the fine purple colour they were ſo fond of, and ſome of the buccina have been of late found to have the ſame juice. The *purpura* and murex are both fiſhed up in great plenty in the gulph of Tarentum; but the ſmall quantity of the coloured juice which each fiſh contains, and the neceſſity of uſing it before the animal dies, makes it impoſſible to bring it to any regular article of traffick. The antients uſed this colour only on cotton and woollen ſtuffs, whereas our cochineal, which was unknown to the antients, ſtrikes equally well on ſilks and ſtuffs.

The *purpura* lives on other fiſh. It uſually hides itſelf at a ſmall depth in the ſand, ſometimes even in freſh-water rivers, and as it lies hid, it thruſts up a pointed tongue, which wounds and kills any thing that comes over it. We frequently find ſea-ſhells with round holes bored through them, as regularly as if made with a boring inſtrument: theſe are generally allowed to be made by the tongue of the *purpura*, in order to its feeding on the fiſh within.

The *purpura* has two horns like that of a ſnail; and Fabius Columna ſays, that they have eyes in theſe, not placed at the ends, as in the ſnail, but in the middle of each horn.

Of the ramoſe, or branched *purpuræ*, with ſhort tails, we have the following ſpecies preſerved in cabinets. 1. The rough *purpura*, with a fleſh-coloured lip, armed with three rows of branches. 2. The yellow *purpura*, with three rows of high branches. 3. The tribulus, or whitiſh *purpura*, with three rows of leſs jagged branches. 4. The fine armed *purpura*, with the branches jagged in the manner of the foot of a toad, with a diſtinct clavicle. 5. The leſs rough *purpura*, with ſix rows of branches. 6. The curled lettuce *purpura*, jagged from the head to the baſe, and having ſix rows of branches.

Of the ſpinoſe *purpuræ* with long tails, we have theſe: 1. The great ſpinoſe *purpura*, with very long ſpines. 2. The ſmall ſpinoſe *purpura*, with three rows of ſhorter ſpines. 3. The ſmall rough *purpura*.

Of the *purpuræ* covered with tubera, having a long beak and long tail, we have the following: 1. The woodcock *purpura*, with a long tail and no ſpines. 2. The leſs ſpotted woodcock *purpura*. 3. The ſmall brown woodcock *purpura*.

Of the thick coſtated, or ribbed *purpuræ*, with crooked beaks, we have the following ſpecies: 1. The marble coſtated and tuberous *purpura*, with blue faſciæ. 2. The ſpinoſe marbled *purpura*.

Of the hairy *purpuræ*, with long clavicles, we have the following ſpecies: 1. The grey *purpura*, with three rows of ſpines or hairs, with an erected clavicle and ſtrait beak. 2. The crooked beaked hairy *purpura*, with ſeveral ſetoſe fimbriæ.

Of the thin oculated *purpuræ*, with compreſſed clavicles and ſhort beaks, we have the following ſpecies: 1. The ſea-porcupine, or oculated *purpura*. 2. The porphyry *purpura*. Hiſt. Nat. Eclairc. p. 298.

The *purpura* is a ſhell-fiſh very well known, and has been known alſo in almoſt all times to afford a purple liquor; but as there has been no method diſcovered of bringing this liquor into uſe in dying, the fiſh has been neglected, and its juice never attempted to be brought into uſe.

The juice which gives this beautiful purple colour is, while it remains in the body of the animal, and while that is in health, wholly white; but no ſooner is it expoſed to the ſun, than it begins to change colour, and in leſs than five minutes goes through the ſeveral changes of pale green, yellowiſh, and a beautiful emerald green: after this it becomes of a deeper and duſkier green, then bluiſh, reddiſh, and finally a deep and very beautiful purple. Sometimes the juice is found naturally green in the animal; this is probably from the creature's being in a diſeaſed ſtate: but when it is naturally thus, it immediately becomes red, and afterwards purple, on being expoſed to the ſun, its ſeveral preceding changes ſeeming to have been made already in the body of the animal.

If a piece of linnen be rubbed over with this juice, and part of it expoſed to the ſun, part not, that only will turn red which is ſo expoſed, the other remaining green without any alteration; and it is obſerved, that the ſtronger the ſun ſhines, the quicker the change appears, and probably the colour is in proportion alſo the more beautiful and lively. And it is very remarkable, that if a needle, or any other opake body, be laid upon the linnen which is yet green, and is to become red on being expoſed to the ſun; after ſuch an expoſure the whole ſhall be changed red or purple, excepting only that ſmall ſpot which is covered by the needle, which will ſtill remain green.

A plate of glaſs, tho' it be three inches thick, will not prevent the colour from changing purple by being laid over it; but the thinneſt piece of metal will keep it wholly green. The one being opake, and the other pellucid, are evidently the only reaſons for this difference.

If the coloured linnen be ſucceſſively covered by three pieces of paper, the one blacked with ink, the other in its natural ſtate, and the third rubbed over with oil, it will change colour on being expoſed to the ſun in different degrees; and that exactly in proportion to the degree of tranſparence in each of the papers: moſt of all in that which was covered with the oiled paper, ſomething leſs than that covered by the paper in its natural ſtate, and leaſt of all in that which was covered with the blacked paper, as that is leaſt tranſparent.

The common heat of a fire, or that of a red hot iron, produce no change at all in the colour when green. The vapour of burning ſulphur produces a little; but the green which had not changed to purple by theſe experiments, immediately changed to it on being expoſed to the rays of the ſun.

Theſe experiments were all made in the months of January and February, by Mr. Du Hamel, in Provence; and the ſun having power to change the colour ſo ſpeedily there in theſe cold months, probably in a warmer climate or ſeaſon the air would have been ſufficient for the purpoſe, without the open ſun; ſince it ſeems, from experiment, that both the ſolar rays, and the light alone in a cloudy day, can act upon this colour. The light and heat of the ſun both act on this colour: light is always ſufficient to produce the effect; but the heat may eaſily be too great, or too little, and to do the whole in perfection it muſt be at a certain middle degree.

This beautiful purple, if it can ever be brought into uſe in dying, will have one very great advantage from its viſcoſity The pieces of cloth that had been ſtained by it retained their colour, in ſpite of ſeveral boilings in different liquors, which Mr. Du Hamel made them paſs through; and the colour, on examination, was found not to be ſuperficial, but penetrated the whole body of the ſtuff which was tinged by it. There are many inconveniences which muſt naturally attend the uſe of this ſubſtance as a dye, but they may, perhaps, all be got over by care and application. It is very certain, that it is of too viſcid a nature eaſily to penetrate many ſubſtances; but it is alſo certain, that this might be obviated by diſſolving it in ſome proper liquor. It appears very plainly, that the antients had a method of thus diſſolving their purple; but we neither know what was their purple, nor what was its diſſolvent; nor, which would be of much more conſequence to us at preſent, what is the proper diſſolvent for our own. Mem. Acad. Scien. Par. 1736.

Perſian PURPURA, the ſame with the Perſian-ſhell, a ſpecies of dolium. See DOLIUM.

PURPUREA *febris*, the *purple fever*, in medicine, the name given by authors to a ſpecies of *fever*, called alſo by ſome a *miliary fever*.

It is an acute, continual, and exanthematous *fever*, in which nature ſeems to be endeavouring to drive out the ſubtle morbific matter to the ſurface of the body, by increaſing her ſecretory and excretory motions. *Junker*'s Conſp. Med. p. 325.

This *fever* is divided into two kinds; of the which, one is called *purpura rubra*, or the *red purple fever*; and the other by a very odd form of expreſſion, the *purpura alba*, or *white purple fever*.

The white *purple fever* is uſually malignant; it is eaſily complicated with the petechial *fevers*, and in ſome places has of late years been found often to affect lying-in women.

The red *purpura* is much more benign and mild than this, and, indeed, often is attended with no danger.

Theſe two ſpecies of *purpura* ſeem to differ as much as the ſmall-pox and meaſles do from one another, the white *fever* of this kind being uſually as much more fatal than the red, as the ſmall-pox is more fatal than the meaſles; but as there are caſes in which the ſmall-pox is mild and benign, and the meaſles are ſometimes dangerous, ſo in theſe diſeaſes, out of the natural courſe, the white is ſometimes mild, and attended but with a ſlight *fever*, while the red is fatal, and attended with a very high one. As the ſmall-pox alſo has white puſtules, and the meaſles only protuberances on the ſkin; ſo the white *purple fever* has alſo regular white puſtules, while the red has only ſuch protuberances as thoſe of the meaſles. *Junk*'s Conſp. Med. p. 327.

Signs of theſe diſeaſes. The white kind ſeizes the patient with a general ſhivering and coldneſs, and a ſtraitneſs of the præcordia, with great anxiety of mind, and afterwards ſhews itſelf in alternate changes of heat and cold; and before the appearance of the eruptions, the patients are worſe in reſpect of their anxiety and other ſymptoms, and complain of a troubleſome itching under the ſkin. The puſtules uſually firſt appear on the fourth day, ſometimes later; and at their approach, there is firſt perceived a general redneſs of the ſkin, and after this the redneſs is collected into ſpots, in the middle of each of which there appears a white puſtule; and theſe are often ſo copiouſly ſpread over the body, that they almoſt touch one another. Theſe puſtules are pellucid, and contain only a clear water, and their eruption is uſually attended with an acute fever; when theſe puſtules have ſtood four days, they dry away, and the places appear ſcaly, and the diſeaſe terminates. Sometimes in people of humid habits, and ſuch as have no *fever*, theſe puſtules ſweat out a white water.

The red *purple fever* ſeizes the patient in nearly the ſame way with the white, that is, with ſhiverings and heat ſucceeding one another. It is alſo attended with a tenſion and pain in the back, and with a ſtraitneſs of the breaſt and a cough. The *purple* eruptions appear on the fourth, or on the ſeventh day, or later even than that, in form of ſmall protuberances, like millet-ſeeds; and are attended at the time of their eruption, with an itching within the ſkin: the *fever* is not violent, and the ſweat is copious, and of an ill ſmell. In ſome caſes this diſeaſe is attended with no *fever* at all, and people go about their buſineſs with it, only complaining of an itching all over them. Some have violent pains of the head at the time, and are ſleepy and anxious they know not why; but theſe ſymptoms uſually go off as ſoon as the eruptions appear properly: theſe remain fully out a few days, and then die away of themſelves, and the perſon finds himſelf as well as before.

The *purple fever* of both kinds ſeems to have been more frequent of late than in the times of the earlier writers on medicine. The white kind in particular, ſome years ago, was in a manner epidemic in Saxony, and carried off great numbers, and particularly ſeized the lying-in women. Wherever the petechial *fevers* are frequent, there the white *purple fever* is uſually alſo common. It often alſo mixes itſelf with the ſmall pox, and makes the caſe always greatly worſe, and all the ſymptoms more violent. The red *purple fever* is moſt frequent with young men, and ſuch as lead ſedentary lives, and are ſubject to violent paſſions; labouring people are ſcarce ever found affected with this diſeaſe Among women, thoſe of tenderer conſtitutions are moſt ſubject to it, and eſpecially ſuch

as have been before ſubject to hyſteric complaints. And the perſons moſt ſubject of all others to it, are thoſe of both ſexes who live at eaſe and within doors, and by this means always are ſending off the humours to the ſurface of the body.

Cauſes of it. Theſe are, a bad quality in the air, contagion from perſons who have the diſeaſe, the driving back of ſweats, and even the forcing them too violently by hot medicines; this too often happens to women in child-bed, and to perſons in petechial *fevers*. To theſe are to be added alſo, the curing the rheumatic and catarrhal diſorders by a too cold regimen and method, and an omiſſion of habitual bleedings, or by ſuppreſſion of the menſes, or diſcharges by the hæmorrhoidal veins.

Prognoſticks in it. The going back of the eruptions in the white *purpura* is very often fatal, and in the mildeſt circumſtances is uſually attended with aphthæ, alienations of the mind, and terrible anxieties; and, if by means of medicines, the eruptions appear again, and yet the ſymptoms occaſioned by their going in do not diſappear, there is great reaſon to ſuſpect danger. The white *purpura* attending the petechial *fever* is very dangerous when the eruptions appear on the fourth day, but is leſs ſo when they appear later. The white *purpura*, when not attended with a *fever*, is leſs dangerous than otherwiſe; but it is uſually attended with terrible anxieties of mind, and with ſpaſtic motions.

The red *purpura*, when the eruptions are ſtruck back, is not attended with ſuch ſudden danger as the white; but people uſually have ſome convulſive motions attending it, and a great languor and debility of motion, and ſometimes with inflammations of the fauces, and with dangerous quinſeys; ſometimes with a dry cough, ſometimes with a heat of urine, or with arthritic complaints, or a ſpurious pleuriſy, or a hemicrania; but all theſe ſymptoms go off as ſoon as the eruptions appear again.

Method of cure. This is to be the ſame both in the red and the white *purpura*, and is not different from that in other inflammatory *fevers*, namely, a gentle but continual perſpiration muſt be kept up, and this alone will often cure the diſeaſe. On the days before the eruption of the ſpots, powders are to be given of nitre, diaphoretic antimony, and the abſorbents, as crabs-eyes, and the like; and when the eruptions are out, which uſually happens on the fourth day, the ſame powders muſt be given interchangeably, with gentle ſudorific draughts, from all which, fumitory water, however, is to be carefully excluded. This method is to be continued, only giving the doſes leſs frequently in the decline of the diſeaſe; and when it is wholly gone off, gentle purges, with ſome mercurial admixture, are to be given, thoroughly to cleanſe the primæ viæ; and the patient is by degrees to be hardened to the air. It is to be obſerved, that all irritations of the bowels are as bad in theſe caſes as in the ſmall-pox or meaſles, and that even the uſe of the moſt gentle clyſters is ſcarce to be allowed. Great care is to be taken that no cold air be admitted to the patient during the time the eruptions are out, and he ſhould not be removed, nor have the bed made in all that time. People who are often ſubject to returns of the red or white *purpura*, would be right to uſe cupping with ſcarification frequently, by way of prevention; and when the cauſe of the diſeaſe is the ſuppreſſion of ſome habitual evacuation, great care is to be taken to ſupply the place of that by bleedings, if it cannot be recalled in the accuſtomed way. This is to be done at different times, to prevent relapſes; and in general, a method of uſing gentle exerciſe, ſo as to promote a moderate ſweat, is greatly preferable to the method uſed by ſome of cloathing too warm, which rather promotes the diſeaſe by inviting the humors to the ſurface. *Junker*'s Conſp. Med. p. 329.

PURPURINA, a name uſed by Caneparius, and ſome other authors, for the *aurum moſaicum*, or *aurum muſivum* of the ſhops, the preſent preparation of which differs from that of that author only in the proportions of the ingredients. *Pemberton*'s Lond. Diſp. p. 221. See AURUM *muſivum*.

PURPURISSUS, in the antient writers, both Greek and Roman, the name of a compound colour or fucus of a fine purpliſh red, uſed to paint womens cheeks.

It ſeems by the compoſition to have been ſomewhat like our roſe-pink, as it is called by the colourmen. It was made of the *creta argentaria*, or fine white kind of chalk, diſſolved in a ſtrong purple tincture of ſome of the roots or woods which dyed red; and when the coarſer part was ſubſided to the bottom of the veſſel, the liquor, while yet thick, was poured off into another veſſel; and what ſubſided from this, which was as fine as flour, was of a beautiful pale purple, and was the *purpuriſſus* ſaved for uſe.

PURSE *(Cycl.)*—PURSE, in the Turkiſh dominions, is a term appropriated to a certain ſum of money. When the Turks ſpeak of large ſums, they always count by *purſes*. In this, however, there is ſome difference; for the *purſe* in Egypt is twenty-five thouſand medines, and in other parts of Turky it is only twenty thouſand. *Pocock*'s Egypt. p. 175.

PURSLAIN, in botany. See PORTULACA.

PUS *(Cycl.)*—A very ſmall portion of *pus* abſorbed into the blood-veſſels, raiſes a putrid fever as certainly as yeſt does a fermentation in wort. This fever is not owing to its ſtimulating the ſolids to quicker and greater vibrations, but to its increaſing the inteſtine motion and accelerating the animal proceſs, haſtening the change of the juices to that ſubtle acrid ſtate which renders them unfit to be retained in the body, and diſpoſes them to run off in colliquative evacuations, ſuch as ſweating and purging, which conſtantly attend theſe putrid or hectic fevers, or riſing to internal ulcers. Med. Eſſ. Edinb. Vol. V. art. 77. See PUTREFACTION.

When *pus* is laudable and mild, it is one of the moſt powerful digeſters, ſuppurants, and incarners; when it ſtagnates too long, or when the liquors and veſſels are faulty, it may become an acrid, ſtimulating, eroding ſanies; when abſorbed into the blood, it affects all the liquors, ſtimulates the veſſels, and is capable of producing violent diſorders.

PUSHERS, a name given to Canary birds when new flown. See BRANCHER, CANARY, and PASSERES *Canarienſes*.

PUSILLATUM, a word uſed by ſome medical writers to expreſs a coarſe powder, or any medicinal ſubſtance, beat into ſmall pieces for infuſion, or the like purpoſes.

PUSU, in botany, the name of a famous plant growing in China, and greatly eſteemed there. This and the ginſeng theſe people a long time kept to themſelves; but at length it was diſcovered, that the one was eſteemed a certain prolonger of life, and the other a preſervative againſt all diſeaſes.

They, in their manner of ſpeaking, ſay, that the *puſu* gives immortality: we have not been ſo happy to obtain any of this famous plant for the trial, but the ginſeng having been brought over, and found not to poſſeſs thoſe great virtues they aſcribe to it, and the people in China, who are poſſeſſed of the *puſu*, dying, as well as thoſe who have it not, we find, that the virtues of both are ſo greatly exaggerated by the Eaſtern dialect, that there is not much to be expected from them. *Redi*'s Exper.

PUT, in the manege, called in French *mettre*, is uſed for the breaking or managing of a horſe: thus,

To put a horſe to corvets, or caprioles, is to teach him thoſe parts of the manege.

To put a horſe upon his haunches, called in French *aſſeoir*, is to make him bend them handſomely in galloping in the manege, or upon a ſtop. See HAUNCHES.

To put a horſe to the walk, trot, or gallop, is to make him walk, trot, or gallop.

To put a horſe upon the button. See BUTTON.

PUTEAL, among the Romans, a ſmall kind of edifice, raiſed in the place where a thunder-bolt had fallen. Mem. Acad. Inſcript. Vol. III. p. 85, ſeq. See BIDENTAL.

PUTICULI, among the Romans, ditches or holes in the earth, a little without the Eſquiline gate, in which the poorer ſort of people were buried. *Pitiſc.* in voc.

PUTORIUS, in zoology, the name by which authors call the polecat; a creature of the weaſel kind, but larger than the common weaſel, and of a blackiſh colour, and remarkable for its ſtinking ſmell.

The whole circumference of the face is white, at the extremity of the angles of the mouth there begins a broad line of a yellowiſh hue, which ſurrounds the head, and is white in ſeveral parts. Its long hairs are black, its ſhort ones yellowiſh; and the throat, the feet, and the tail, are blacker than any other part of the body. The upper jaws ſtand out a little beyond the lower. The ears are broad and ſhort, and are fringed, as it were, with white. Its ſtink is occaſioned by an extremely fetid matter, ſecreted by two glands, which it has in common with all the creatures of this kind, within the anus.

It feeds on fleſh, frequently ſtealing hens and other poultry, and ſometimes contenting itſelf with their eggs. *Ray*'s Syn. Quad. p. 199.

PUTORIUS *ſerpens*, in zoology, a name given by ſome to that ſpecies of ſerpent called by others *dryinus*. See DRYINUS.

PUTREFACTION *(Cycl.)*—In *putrefaction* there is a great inteſtine motion; when carried to a height, and when the *putrefying* ſubſtance is much compreſſed, it is accompanied with heat and ſmoke, and ſometimes flame. Air is neceſſary to it; and the viſible texture of the *putrifying* maſs is changed.

Putrefaction is the moſt ſubtle of all diſſolvents. It effectually disjoins and ſeparates all the component parts of *putrifying* bodies, except ſea-ſalt. In this powerful ſolution, the inteſtine action of the minute particles of bodies creates, collects, or is by ſome way or other the cauſe and means of heat.

The fluids of the human body are much diſpoſed to *putrefaction*, and out of the body become highly *putrid*, even in cool air, and without any ſtirring or agitation; and our blood and ſome of our juices, out of the circulation, but within the body, change to *putrid* matter.

The changes wrought in bodies by *putrefaction*, are no where more remarkable than in the *putrefaction* of vegetable ſubſtances, which by means of this change are brought nearly into the condition and nature of animal ſubſtances.

To prove this by an eaſy experiment, take a large quantity of cabbage-leaves, and preſs them hard down with weights in an open tub, with holes bored in its ſide; ſet them in a warm place, and the leaves will ſoon conceive a heat in the middle, and at length the whole, or nearly the whole, will be converted into a ſoft pappy ſubſtance. This ſubſtance diſtilled in a glaſs retort, yields the ſame kind of volatile ſalt and oil as

animal ſubſtances do: neither is it particular to this plant, but all equally do this; the acid and the alkaline, the ſweet and the bitter, the aſtringent and emolient. Hence we may learn, how it is that nature, in our bodies, converts vegetable into animal ſubſtances; and it is very remarkable, that not a grain of fixed ſalt can be procured from this *putrified* maſs. *Shaw*'s Lect. p. 134.

PUTREFACTION *of water*. It is ſaid to be the peculiar quality of the Thames water, that it will ſtink and yet be wholeſome; and after this will recover itſelf again. Many ſailors have been obliged to drink it ſtinking, ſo that they held their noſes while they poured it down their throats, yet no ſickneſs enſued from it. It generates a ſort of ſpirit alſo in this ſtinking ſtate, which will take fire at the approach of a lighted candle as if ſpirit of wine were touched by the ſame.

PUTTOCKS, or PUTTOCK-*ſhrouds*, in a ſhip, are ſmall ſhrouds which go from the ſhrouds of the main-maſt, fore-maſt, and mizen-maſt, to the top-maſt ſhrouds; and if there be any top-gallant-maſts, there are *puttocks* to go from the top-maſt ſhrouds into theſe. Theſe *puttocks* are at the bottom ſeized to a ſtaff, or to ſome rope which is ſeized to a plate of iron, or to a dead-man's eye, to which the lanniards of the fore-maſt ſhrouds do come.

PUWAKHAGA, in botany, the name by which ſome authors call the faufel-tree, of whoſe fruit the expreſſed juice called *terra Japonica*, or Japan earth, is made. *Herm.* Muſ. Zeyl. p. 51.

PYANEPSION, Πυανεψιων, in the Athenian chronology, a month of thirty days, in which the feſtival *pianepſia* was celebrated. *Potter*, Archæol. Græc. T. 1. p. 464. See the article PYANEPSIA, *Cycl.*

PYCIELT, in botany, a name given by Hernandez, and ſome other authors, to a peculiar ſpecies of tobacco, diſtinguiſhed by Mr. Tournefort by the name of *nicotiana major lato et rotundo folio*, the broad roundiſh leaved great tobacco. See the article NICOTIANA.

PYCNI, πυκνοι, in the antient muſic, was uſed for ſuch ſounds or chords of a tetrachord as might enter the ſpiſſum, or πυκνον.

Theſe were the hypatæ [a], the parypatæ [b], and the lichani [c], of the ſeveral tetrachords. The hypatæ were called *barypycni*, βαρυπυκνοι; the parypatæ *meſopycni*, μεσοπυκνοι; and the lichani *oxypycni*, ὀξυπυκνοι: becauſe the firſt were the loweſt notes; the ſecond, the middle notes; and the third, the higheſt of the ſpiſſum [d]. Such chords as could never enter the ſpiſſum were called *apycni*, απυκνοι. [a ὑπατοειδεις. b παρυπατοειδεις. c λιχανοειδεις. d *Wallis*'s Append. ad Ptolem. Harm. p. 165.]

Hence in the Greek ſcale or diagram [a], containing eighteen chords, there were five *barypycni*, as many *meſopycni*, and an equal number of *oxypycni*, together with three *apycni*. The *apycni* and *barypycni* were ſtabiles or fixed chords; but the *meſopycni* and *oxypycni* were moveable, or mobiles [b]. [a See DIAGRAM. b *Wallis* ibid. p. 165, 166.]

PYCNON, πυκνον, in the antient muſic. See SPISSUM.

PYE, in mechanics. See the article CRABB.

PYGAIA, in the materia medica, a name by which ſome authors have called the ipecacuanha, or vomiting Indian-root. *De Laët* Ind. Occid. 566. *Purchas*. Pilgr. Vol. IV. p. 1311.

PYGARGITES, in natural hiſtory, a name given by Pliny and ſome other of the old writers to the eagle-ſtone, when it was variegated with white, in the manner of the tail of the eagle called *pygargus*.

Some have called this ſtone *pygarus*, and others have applied the name to a ſtone very different from the aëtites, and only reſembling the colour of the eagle. From hence it has happened, that two very different ſtones have been confounded together; but the virtues of both being merely ideal and imaginary, the world is not greatly the worſe for the want of the neceſſary diſtinctions.

PYGARGUS, a ſpecies of eagle, called alſo by ſome authors *albicilla*, and *ilianularia*.

It is a large and fierce bird, of the ſize of a common turkey. Its beak is yellow, and covered with a yellow membrane at its baſe. It has large hazel-coloured eyes. Its feet are yellow, and its claws extremely ſtrong and ſharp. The head is white, and there are no feathers, but ſome fine hairs between the eyes and noſtrils. The upper part of the neck is of a reddiſh brown, and the rump black: all the body beſides this is of an obſcure ruſt colour, and its wings are partly black, partly grey. Its tail is long, and the upper half of it is white, and the reſt black. It is from this white part that it has its name *albicilla*.

Authors who have written on this ſubject ſeem not all agreed to call the ſame bird by this name. The *pygargus* of Aldrovand ſeems different from this, and the *pygargus prior* of Bellonius ſeems no other than the male of that kind of hawk called in Engliſh the *hen-harrier*. *Willughby*'s Ornithol. p. 31.

PYGARGUS *accipiter*, in zoology, a name by which many authors have called the ſubbuteo, a bird of the hawk kind; the male of which is called in Engliſh the *hen-harrier*, and the female the *ringtail*. *Ray*'s Ornithol. p. 40. See HENHARRIER and RINGTAIL.

PYKER, or PYCAR, in our writers, a ſmall ſhip or herring-boat. 31 Edw. III. c. 2. *Blount. Cowel.*

PYLÆA, Πυλαια, in antiquity, a name given to the aſſembly of the Amphictyons, as well when they met at Delphi as at Thermopylæ. The concourſe of people at theſe aſſemblies was ſo great, that the term *pylæa* came to be uſed for any very numerous aſſembly, or croud of people. Mem. Acad. Inſcr. Vol. IV. p. 287, 290.

PYLAGORE, Πυλαγορες, in antiquity, a name given to the Amphictyons, becauſe they aſſembled at Thermopylæ, or Pylæ. See AMPHICTYONS, *Cycl.* and *Suppl.*

PYLORUS *(Cycl.)*—Kerkring gives us an account from his own knowledge of the entire ſtoppage of this part, by a Dutch ſtiver accidentally ſwallowed, the conſequence of which was the death of the patient in a few days. On the other hand, he mentions an inſtance of another perſon's ſwallowing a copper coin, which without any other effect than violent nauſeas and ſickneſs, was, at the end of about a month, diſcharged by purges; but ſo corroded by the juices of the ſtomach, that it was ſcarce to be known, all the letters and marks being eaten down to the ſame common ſurface on both ſides. *Kerkring*'s Specileg. Anat.

PYNANG, in botany, a name by which ſome authors call the faufel, or areca tree; a kind of palm, from the expreſſed juice of which the drug commonly, but improperly, called *Japan-earth* is made. *Bont.* p. 90.

PYRACANTHA, in botany, a name given by ſome authors to the lycium, or box-thorn.

PYRALIS, the *fire-fly*, a name given by authors to a ſuppoſed inſect, which they ſay is produced in the violent fires of the glaſs and metal furnaces. Plin. l. 2. c. 36.

PYRAMIDALIS *(Cycl.)*—PYRAMIDALES *abdominis*. Theſe are called *ſuccenturiati* by Fallopius; they are ſituated on the lower part of the recti, and ſeem only a portion or appendix of it. They are partly incloſed within the vagina of the recti, running cloſe by each other along the linea alba, to which they are fixed at different diſtances by oblique tendinous indentations, the uppermoſt of which was ſometimes very long.

When theſe muſcles are wanting, the lower extremities of the recti are always thicker than uſual: often there is only one found, and ſometimes, tho' rarely, three. *Winſlow*'s Anat. p. 168.

PYRAMIDALIS *oculorum*, in anatomy, a name given by Molinet and ſome others to one of the muſcles of the face, called by Douglaſs and Cooper *aperiens palpebram*, and by Albinus *levator palpebræ ſuperioris*.

PYRÆIA, or PYRETHEA, among the Eaſtern nations of antiquity, were great incloſures uncovered, and dedicated to the ſun, in which a perpetual fire was kept up in honour of this luminary, which was worſhipped by moſt of them. *Calmet*. Dict. Bibl. See CHAMANIM.

PYRENE, in natural hiſtory, the name of a ſtone found always in the ſhape of the ſtone of an olive. It is of the lapis judaicus kind, being no other than the petrified ſpine of ſome ſpecies of echinites. See ECHINUS *marinus*.

PYRETHRUM *(Cycl.)*—PYRETHRUM, in the materia medica, a root of which the druggiſts ſell us indiſcriminately two kinds; the one the root of a corymbiferous plant, called by authors *pyrethrum flore Bellidis*, or the daiſy-flowered pellitory of Spain; the other, the *pyrethrum umbelliferum*, or umbelliferous pellitory: and it is a diſpute among the learned, which of the two is the genuine and proper kind. The deſcription left us of it by Dioſcorides, as it is differently written, ſerving as well to prove the one ſo as the other.

The roots of the daiſy-flowered pellitory are what we moſt frequently meet with. They are of three or four inches long, of the thickneſs of one's little finger, greyiſh and wrinkled without, and whitiſh within, and of an acrid and burning taſte. Thoſe of the umbelliferous pellitory are of the ſame length, but ſomewhat thinner, of a browniſh grey without, and white within, and are furniſhed with a ſort of beard at top, ſomewhat like the roots of the meum. It is of an acrid taſte, and much reſembles the other in its virtues. They are both uſed in the tooth-ach, and are preſcribed by ſome in diſeaſes of the head and nerves, and are found to be diuretic and violently ſudorific, but they are very ſeldom given.

PYRGUS, among the Romans, a dice-box of the ſhape of a modius, open above, and having a great many ſhelves or partitions within it; ſo that when the dice were thrown into it out of the frittillum, they were thereby overturned many times before they could reach the bottom, in which there was an opening for them to fall through upon the table. *Pitiſc.* in voc. See FRITTILLUM.

PYRHOPOECILOS, in the natural hiſtory of the antients, a ſtone ſo called from its having a great many ſpots of the colour of fire. *Pitiſc.* in voc.

PYRIATERION, a word uſed by the antients to expreſs a ſweating room.

PYRIATOS, a word uſed by ſome authors to expreſs a brick when heated, in order to be applied to the body wrapped up in a cloth by way of a dry fomentation.

PYRICAUSTUM, a word uſed by medical writers to expreſs a burn or ſcald.

PYRICUBIUM, in natural hiſtory, the name of a genus of foſſile bodies, uſually comprehended, with many others of very different figure and ſtructure, under the general name *pyrites*. See Tab. of Foſſils, Claſs 5.

The

The distinguishing characters of the *pyricubia* are these: they are compound, inflammable, metallic bodies, of a cubic figure, or resembling a die, being composed of six sides.

Of this genus there are only two known species: 1. The great *pyricubium*, of a foliaceous structure; and, 2. The smaller solid *pyricubium*. See Tab. of Foss. Class 5.

The first of these is a very elegant fossil, and is so regularly shaped, and so highly polished by nature, that it has been often supposed to be wrought by art. It is but moderately hard, but is very heavy, and is of a foliaceous structure. It is exactly of the figure of a die, being composed of six regular sides, placed at right angles; but tho' ever thus regular in shape, it is not at all so in size: the most common specimens of it are about a third of an inch in diameter; but it is found much larger, even to three inches, and so small as to the tenth of an inch. It is perfectly polished and smooth on all its surfaces, and is of a very beautiful whitish green, with a faint admixture of yellow. It is found in the German and Hungarian mines, and in the East Indies.

The second sort, or the small solid *pyricubium*, is a fossil of much less beauty, tho' equally regular in its shape and appearance. It is very heavy, and extremely firm and hard, and is not of a foliaceous or flaky structure; but of one regular and uniform mass, and when broken appears very bright and glossy. It is ever found in the regular form of a cube, or regular solid body, made up of six flat sides placed at right angles. Its usual size is about the eighth of an inch diameter, but it is found smaller than a pin's head, and sometimes so large as to be near an inch. It is perfectly smooth on all its surfaces, and is naturally of a pale yellowish green, and as bright on the outside as within; but very often it is found of a ferrugineous or dusky surface, owing to a sort of rusting, which is an accident to which the several species of naturally bright pyritæ are most of them also subject.

It is very common in Germany and Italy, and in some parts of America, as also in our own country. With us it is commonly found immersed in slate, such as we cover houses with; but in Germany and other places it is usually found loose among the earth of mountains. With us it is usually of a bright surface, in Germany it is more frequently dusky. *Hill*'s Hist. of Foss. p. 619.

PYRIFORMIS (*Cycl.*)—This is also called *pyramidalis*, and is a small oblong muscle, of the figure of a flat pear, or *pyramid*, whence it has its names.

It is situated almost transversely between the os sacrum and ischium, being covered and hid by the first two glutæi. It is fixed to the interior lateral part of the os sacrum by fleshy fibres, and to the neighbouring part of the anterior or concave side of that bone, by three digitations lying between the anterior holes. It is also fixed by a small insertion to the ligamentum sacro-sciaticum, and edge of the great sinus of the os ilium. From thence it runs transversely toward the joint of the hip, its fibres contracting in breadth; it terminates in a short tendon, which is inserted in the middle of the internal labium of the upper edge of the great trochanter, by two or three branches. The upper part of this tendon receives several fibres from the glutæus medius, and its lower part is united to the gemellus superior, and tendon of the obturator internus. Sometimes there are two *pyriformes*, separated only by the nervus sciaticus. *Winslow*'s Anat. 209.

PYRIPHLEGES, a word used by the old writers in medicine to express a person labouring under an extreme degree of a febrile heat.

PYRIPLACIS, in natural history, the name of a genus of pyritæ, the characters of which are these: they are compound, inflammable, metallic bodies, found in loose detached masses of a simple and uniform, not striated internal structure, and are covered with an investient coat or crust.

Of this genus of fossils there are three known species: 1. A flatted kind, with a scabrous coat. 2. A globose one, with a cracked and furrowed coat. And 3. A flatted one, with a very thick, browniish-white crust. See Tab. of Foss. Class 5.

The first of these is a dusky browniish-green mass, surrounded and every way covered by a ferrugineous coat, of the thickness of a shilling or more, which is rendered very rough and scabrous, by having received multitudes of small pebbles and particles of sand into its substance while yet moist, which are become firmly bedded in it, and make a part of its substance. This is common in the gravel-pits about London.

The second is of an orbicular figure, and is of a very coarse structure, being composed of visible granules, and is of a pale yet dusky green colour. It is covered with a browniish yellow or ferrugineous coat, of the thickness of half a crown, or sometimes much more. This is usually somewhat irregularly raised in tubercles on the surface, which are divided by a sort of fine lines: these are truly so many cracks in the superficies, all which, when the body has been some time exposed to a damp air, fly more asunder at their edges, and become deeper, opening into the body of the mass. This species is found of all the intermediate sizes between an ounce and eight or ten pounds in weight. It is very common in the chalk-pits of Kent, and in many other parts of the kingdom; and tho' most frequently found in chalk, yet is sometimes met with among gravel, or lying loose upon the surface.

The third is a very singular species, yet from its unpromising appearance has been overlooked by all the enquirers into these subjects; having never been described in the writings, nor preserved in the museums of the late collectors of fossils. It is very hard, and moderately heavy, and is usually of a flatted, orbicular, or oval figure; and its most frequent size is between two and three inches in diameter. It is of an irregular, uneven, and rough surface, full of small prominences, very harsh and rough to the touch, and looks merely like a lump of greyish hard clay. When broken, it is found, however, to consist of a nucleus of the same shape with the whole body, and every way equally surrounded with a crust of a thickness equal to its whole diameter, or nearly so.

The nucleus is of a deep and dusky browniish-green colour, and of a plain simple structure; being composed of no visible moleculæ. The crust is of a pale, greyish-brown, earthy substance, appearing like an indurated earth, and glittering in some few places with small glossy particles. This is found in great plenty in some of the clay-pits about London. *Hill*'s Hist. of Foss. p. 613.

PYRIPOLYGONIUM, in natural history, the name of a genus of fossils, the characters of which are, that they are compound metallic bodies, of a regular figure, consisting of twelve planes. See Tab. of Foss. Class 5.

There is only one known species of this genus, tho' subject to great varieties in its appearance; and this has been by authors hitherto confounded, with many other bodies of very different nature and figure, under the general name pyrites.

The *pyripolygonium*, when perfect, is an extremely elegant and beautiful fossil; but this is a state it is very rarely found in. It is moderately firm, of a compact texture, and very heavy; tho' its natural figure be a regular body, composed of twelve planes, yet it is subject to great imperfections and irregularities. It often seems to want one or more of its sides, and not unfrequently, from the accidental breaking of some of its angles, to have more than its number; and very often has a great many other smaller and less perfect bodies of its own kind, growing to its larger and less perfect specimens. It is found from the twentieth part of an inch, to four inches in diameter; but its most common size is about a third of an inch. It is naturally of a polished and shining surface, and of a pale whitish yellow; but sometimes it is browniish, or of an iron colour.

It is not unfrequent in Cornwall and Devonshire; but is much more common in Germany. *Hill*'s Hist. of Foss. p. 621.

PYRITES, *(Cycl.)* in natural history, a name used by Dr. Hill as the classical term for the less regularly figured bodies of the number of those usually called, too indeterminately, by that name. See Tab. of Foss. Class 5.

According to this distinction *pyritæ* are compound, inflammable, metallic bodies, found in detached masses, but of no determinately angular figure. Of this class there are two general orders of bodies; the first, those which are of a plain and simple internal structure; and the second, those which are regularly striated within: and of each of these there are two genera. Those of the first are:

1. The *pyriplaces*. These are *pyritæ* of a simple internal structure, and covered with an investient coat or crust.

2. The *gymnopyres*. These are *pyritæ* of a simple internal structure, and naked, or not covered by any investient coat or crust.

The genera of the second order, or the striated *pyritæ*, are,

1. The *pyritricha*. These are the *pyritæ* of a simply striated structure.

And, 2. The *pyritrichiphylla*. These are the *pyritæ* whose surfaces are covered with foliaceous flakes, made by a continuation and expansion of the ends of the striæ. *Hill*'s Hist. of Foss. p. 612.

The several species of each of these genera, see under the several generical heads, PYRITRICHUM, *&c.*

Dioscorides mentions only one kind of *pyrites*, which is the common yellow species. Avisenna and the other Arabians mention two yellow sorts, a white one, and a ferrugineous one. None of these authors made any distinction between the marcasites and *pyritæ*, but this sort of matter, whether formed into small nodules, or continued strata, was called indifferently by one or other of these names.

The four kinds of this stone mentioned by the Arabians are called from their colours, the golden, the silver, the brassy, and the ferrugineous *pyrites*. The oldest authors are of the opinion of Dioscorides, and mention only one kind, deducing them all from the same principles, and supposing their variety of colours to be only owing to accidents. Aristotle and Theophrastus thus mention the *pyrites* as one thing, under the name *mylia*, which having been translated *molaris lapis*, has been understood by some to mean some sort of mill-stone, or other coarse stone fit for such purposes; and by that means the whole sense of the authors has been perverted and misunderstood.

Pliny mentions two kinds of the *pyrites*, the gold and the silver kind: he tells us, there is a stone, with some resemblance of brass in its appearance, which is found in Cyprus, and about Acarnania; and that it is of two kinds, yellow and white. It is clear from this, that this author had consulted

ſulted ſome other of the Greeks beſides Dioſcorides and Theophraſtus, from whom he principally furniſhes himſelf with theſe accounts; but he makes no mention of the ruſt-coloured or ferrugineous *pyrites*, which is as common as any of the others, even in the country where he wrote: and thence it is evident, that he did not write from his own obſervation, tho' in ſome places we are not able to trace him up to his originals, which may be loſt. Aviſenna tells us, that cadmia was made of the *pyrites*, that is, the cadmia fornacum, or tutty. Pliny and Dioſcorides do not in all reſpects agree as to the ſeveral kinds of factitious cadmia; and tho' Pliny does not mention this particular kind of it, Dioſcorides tells us of ſuch a ſort made in ſome places by burning the ſtone called *pyrites*.

The principal contents of *pyritæ* may be in general gueſſed at from their colour. The white *pyrites* uſually contains arſenic, the yellowiſh contains ſulphur and iron, and the fully yellow ſulphur and copper. The colours, therefore, make a very eſſential mark for the diſtinction of the ſeveral kinds of this foſſil. The yellowiſh *pyrites*, that is, ſuch as contains iron and ſulphur, is found in the ſtrata of ſeveral kinds of ſtone, in clay, and in the earth lying over the mines of ſeveral metals. The white, or arſenical *pyrites*, and the fully yellow, are leſs common, but are uſually met with about mines. *Agricola* de Metall.

It is a matter of great difficulty to aſcertain the time of the formation of foſſils. Many of them ſeem to have remained in their preſent ſtate, unaltered, from the beginning of the world; but many have alſo been formed in later times, and continue to be formed to this day. Of the number of theſe laſt the ſtalactitæ, or ſtony icicles, hanging down from the roofs of grottos are known to be; and it is equally certain, that the *pyritæ* alſo are ſo formed, for many of the ſtalactitæ in the caves dug by the German miners are found to be coated over in ſeveral parts with *pyritæ* [a]; and even in our own kingdom, pieces of wood buried in clay that contains *pyrites*, ſuch as is commonly dug to make tiles, if taken up again after a number of years, is always found impregnated with this ſubſtance, forming veins in it, and ſometimes nodules on its ſurface. [[a]Act. Erudit. Ann. 1726. p. 273.]

The *pyritæ* affixed to ſtalactitæ are finer than the other kinds, and it appears very evident to ſuch as have thoroughly conſidered the proceſs of nature in them, that they are not formed of particles brought together by water, in the manner of the *pyrites*, in wood buried under clay, or in the manner of theſe ſtalactitæ themſelves; but are compoſed of infinitely minute particles, brought together by their mutual attractions on a proper baſis, and which had been before floating in the air. The antients in general ſuppoſed, that copper was contained in the *pyrites*; but they had no opinion that iron was a part of it, tho' it is certain that iron is the baſis of almoſt all of them, and copper has a part only in a very few: but this was the effect of judging from appearances, inſtead of having recourſe to experiments. Our own Liſter has the honour of being the firſt author who has treated properly of them, and found out their true and general baſis to be iron; but he carries it too far when he ſuppoſes them to be all properly iron ores: for this is not the caſe, many of them, which contain no other metal beſide iron, yet holding it in ſmall quantity, and in ſuch a combination of other principles, that it is ſcarce extricable from them, and ſome kinds contain no iron at all. *Liſter* de Font. Medic. Angliæ.

Berger, who has written on the Caroline baths, has taken up the ſubject, and improving upon Liſter's plan, has given a much more juſt account of them. He allows that iron ſeems the baſis of great numbers of the *pyritæ*, and that this is evident from the obſervation, that the remaining matter of many, of them, after burning away the ſulphur, is found to be attracted by the magnet; but he obſerves alſo, that in many copper is mixed with the iron, and that tho' iron is in general found in even thoſe kinds which give the moſt obvious proofs of copper, yet there are ſome in which there can no iron be found.

This author obſerves alſo, that beſides the metalline particles, whether iron or copper, there is alſo contained in the *pyritæ* an unmetallic earth, which is in the compoſition of this ſtone moſt equally mixed and perfectly blended with the particles of theſe metals, and with thoſe of the ſalts and ſulphurs contained alſo in the maſs. Sulphur alſo he acknowledges to make a great part of many of the *pyritæ*, particularly of all the yellowiſh and full yellow kinds. The white or ſilvery *pyrites* contains leſs ſulphur than any of the others, and the yellow or venereal *pyrites*, tho' it contain much arſenic, yet does not fail to contain ſulphur alſo in conſiderable quantity. *Berger* de Font. Carolin.

The mention of gold and ſilver in the *pyrites* is very common among authors, but the colour of theſe ſtones ſeems principally to have given ground for that opinion. In reality theſe metals are very ſeldom found naturally making parts of the *pyrites*, and when they are, it is only in a very inconſiderable quantity. But in thoſe ſpecimens found about the mines of gold and ſilver, the particles of thoſe metals aſſembled into viſible maſſes are ſometimes found unbedded in lumps of the *pyrites*; and ſuch pieces of this ſtone may then well be ſaid to contain thoſe precious metals. The occaſion of this accident, however, is no more than this, that the *pyrites* is formed in mines and other places at this day; which is plain from its being in ſome places found adhering to the ſides of ſtalactitæ, as has already been mentioned: and in like manner it might adhere to particles of gold and ſilver, and thereby give ground to the ſuppoſition of their being parts of it.

The common *pyritæ* of our clay-pits and ſea coaſts are uſed in the making of coperas or vitriol; but among theſe there is found a very great difference, ſome of them turning themſelves very eaſily to vitriol, when only expoſed to moiſt air; others doing it with more difficulty; and ſome not at all, tho' expoſed many years. Some alſo yield all their vitriol at once, on pouring warm water on them; while others muſt lie expoſed to the air at ſeveral different times, and roaſted in the mean while in order to obtain it. The ſettled obſervations on this ſubject, as collected from experiments, are theſe:

No *pyrites* which contains any copper, or any arſenic, will of itſelf turn into vitriol, but requires a previous roaſting.

The ſulphureous iron *pyrites*, void of copper or arſenic, all turn to vitriol on being only expoſed to the air; and that the ſooner or later, as they are of a more or leſs compact ſubſtance. The fibrous or radiated *tyritæ* are uſually of this kind; but this is no general rule, for there are ſome radiated ones which remain whole years unaltered in the air.

Copper and arſenic always reſiſt the ſhooting of the ſalts of the *pyrites*, or its turning to vitriol; but theſe are not the only agents that reſiſt this change, for in ſome merely ferreous and ſulphureous *pyritæ* the change is not made but with much time and difficulty. *Henkell*, Pyritol.

It is remarkable alſo, that vitriol is found in ſome *pyritæ*, if water be poured upon them immediately after the roaſting; while others will not yield any till they have been afterwards expoſed to the air. It even ſeems, that we are to look into the air for the cauſe of the appearance of vitriol in the copperas ſtones. This it may greatly aſſiſt in effecting, as it carries a quantity of moiſt vapours in it: for it is well known, that the acid of ſulphur has not the power to reſolve iron into the form of a ſalt without the addition of water; nay, oil of vitriol, or of ſulphur, being moderately concentrated, tho' it be then diluted with much more water than it is united with while yet in ſulphur, does not even diſſolve filings of iron unleſs there be four times or ſix times as much water poured to it. Water alone, however, tho' a great and neceſſary agent, cannot be ſuppoſed to effect the whole change; for tho' there are ſome of the *pyritæ* that yield their vitriol by means of it, yet there are others that do not; and ſome *pyritæ* are preſently turned into vitriol, when expoſed to the air, which had before remained for many years under water unaltered. Of this kind there are many on the ſhores of the ſea in moſt parts of Europe. In England particularly we have them in great plenty in Sheppey Iſland in Kent. Theſe *pyritæ* will long reſiſt the change into vitriol, when in the air, and yet they evidently contain no copper nor arſenic.

There is alſo a kind very common on the ſhores, which reſembles wood in texture and appearance; and has probably once been wood, but has now its pores filled with the *pyrites*: of theſe many lie buried a foot or more deep in the ſand under the ſea water; and in that ſtate they never ſhoot into vitriol, but are of a firm texture and conſiderable hardneſs, and when broken look very bright within, and have no taſte of vitriol, nor give any mark that they contain any: yet theſe, if they are taken up and expoſed to the air for a fortnight, loſe all their brightneſs and their hardneſs, and moulder-ing to pieces, become ſo rich in vitriol, that it forms itſelf into regular cryſtals on their ſurfaces. Now if moiſture alone was ſufficient to produce this effect, there is no reaſon why they ſhould not have been reſolved into vitriol under a very moiſt ſand. The great cauſe we are able to aſſign, appears to be the vague acid, ſo common in the foſſile world, and filling alſo the region of air; but an ingenious reaſoner will ſtill own, that tho' this may do much, yet there muſt be ſome other cauſe, yet undiſcovered, for the production of vitriol in theſe foſſils; ſince this, as well as the moiſture of the air, ought to act more equally than we find by experience it does on theſe ſtones, if all were owing to it. *Henkell*, Pyritol.

In the expoſing theſe copperas ſtones to the air, if it be a moiſt ſeaſon, no farther care need be taken of them than the piling them up in a heap; but moiſtening them now and then is a neceſſary circumſtance in dry ſeaſons, and in this caſe the water ſhould be ſprinkled on them in ſmall quantities at a time, and the heaps now and then turned and new made. Much depends on this management, the ſame quantity of ſtones yielding twice as much copperas, with proper care, as they would without it

When the matter of the *pyrites* is mixed with the lead ores, the method of ſeparating the metal by aſſaying is this: roaſt two centners of the ore, as in the uſual method, and keep a ſtronger fire than when the ore is pure. The *pyrites*, eſpecially when it is merely iron, hinders an ore from eaſily growing clammy, or turning into large lumps, or entirely melting. When the ore is ſufficiently waſhed, let it cool, beat it to powder, and repeat the roaſting to a third fire, till when it is red hot in the fire, there is no ſmell of ſulphur: then mix the

ore with six centners of the black flux, and two of sandiver, and finish the work in the common way, only making the fire greater, and continuing it longer, toward the end of the operation. *Cramer*'s Art of assaying, p. 292. See the article LEAD-*ore*.

PYRITICUM *liquamen*. See LIQUAMEN *pyriticum*.

PYRITRICHIPHYLLUM, in natural history, the name of a genus of fossils of the class of the pyritæ, the characters of which are these: they are compound, inflammable, metallic bodies, found in loose masses not of any regularly angular figure, and of a striated texture, with foliaceous ends to the striæ, appearing on the surface or within the mass. See Tab. of Foss. Class 5.

Of this genus there are only two known species; one having the foliaceous ends of the striæ on the outer surface of the mass, and the other having a smooth external surface, and the foliaceous ends of the striæ covering the sides of internal hollows. *Hill*'s Hist. of Foss. p. 617.

The first is a fossil of great beauty, of a very firm texture, remarkably heavy, and usually found in large masses of an orbicular or oblong figure: these masses are sometimes composed wholly of the matter of the pyrites, and in others they are only coats of that substance surrounding stones.

It is of a very closely striated texture, and the striæ are broad, but unequally so, and their extremities at the surface of the mass are beautifully formed into several series of thin foliaceous plates, which usually cover all the superficies, and stand up to several heighths and in different angles, but mostly leaning one way; they are of unequal thicknesses, being composed of different numbers of plates, and are usually notched at the ends. The whole is of a somewhat deep green, with a cast of olive or amber colour, and when it is fresh broken, is very bright and glittering.

The second is a fossil of equal beauty with the former, tho' of a very different appearance; it is very hard and very heavy, and is always found in detached masses; but those of a very singular kind, for they are always more or less hollow. These masses are of various figures and appearances, sometimes round and like pebbles, but more frequently full of odd protuberances, like the flints in our chalk pits; and sometimes the masses of it are found running over the surfaces of stones in form of crusts, which are variously protuberant in different parts, and rise into frequent beautiful tho' irregular tubercles.

The outer surface of this species is usually very bright and glossy, and perfectly smooth, as if wrought by art, even on the tubercles themselves. It is usually a sort of crust even in its most solid masses, seldom being above half an inch thick, and of a very beautifully striated texture, the striæ being remarkably fine and slender. These, tho' they unite so at their superficies as to form a very smooth surface, yet at their other ends, where they terminate at the hollows of the masses, are expanded into very elegant series of foliaceous plates, usually approaching to a square figure, and not standing erect, as in the other species, but lying horizontally and almost perfectly flat over one another: these are composed of flakes not thicker than those of many of the foliacious talcs. The whole is usually of a gold yellow, and very bright and beautiful; but the outer surface often contracts a dull brownish hue on being long exposed to the air.

The first of these is found in many of the English and German mines, the other has been yet only found in the mines on Mendip hills in Somersetshire, but there in considerable plenty. *Hill*'s Hist. of Foss. p. 618.

PYRITRICHUM, in natural history, the name of a genus of pyritæ, the characters of which are these: they are compound, inflammable, metallic fossils, always found in detached masses of no regularly angular figure, and of a simply striated internal structure. See Tab. of Foss. Class 5.

Of this genus of pyritæ there are three known species, 1. A globose one, with an irregular surface. 2. A globose one covered with angular tubercles. 3. A silver-coloured globose one, with a smooth surface.

The first is considerably hard, and very remarkably heavy, and is usually of a roundish form, tho' sometimes oblong; sometimes it is full of irregular prominences on the surface, and sometimes is a complex mass, consisting of a great number of roundish masses of smoother or rougher surfaces joined together. It is very various in size; the more common specimens of it are of six or eight ounces weight, tho' there are others of less than an ounce, and some of several pounds. The prominences on the surface are usually broad and depressed, and these are frequently marked with irregular short lines, and raised in ridges. When broken, it is found to be of a very regular striated structure; the striæ are not very broad, and usually run from the center to the circumference. It is of a pale whitish green within, and is covered with a brown or ferrugineous crust.

The second is a very firm and hard body, usually of an orbicular figure, and sometimes, tho' rarely, oblong; it is of a very remarkably rough surface, being covered with pyramidal tubercles, with very obtuse ends. These are of a quadrangular figure, and have very broad bases: they sometimes incline, or bend a little; but more usually they stand perfectly upright, and are placed so close together, that they croud and injure one another's figure at their bases. The whole is of a ferrugineous or rust colour without, and of a yellowish colour within, beautifully striated, and very bright and glittering.

The third is an extremely elegant and beautiful species, it is but moderately hard, tho' remarkably heavy, and is usually of a regularly orbicular form, tho' sometimes it varies from it like the other pyritæ. Its most frequent size is about an inch and half in diameter; but it is sometimes found as small as a nut, or a schoolboy's marble, and sometimes of more than two pounds weight. Its surface is usually smooth and even, and it is never covered with any coat or crust. It is of a very regularly striated internal structure, and of a beautiful silvery green colour: the striæ are moderately broad and run very evenly from the center to the circumference; and very often there is a small and firm central nucleus, which is much harder than the rest of the mass, and is of a plain not striated structure.

All the three species are found plentifully in different parts of the kingdom: the first in all sorts of strata, and often loose on the ground; the second, principally in the chalk pits of Kent and Sussex; and the last in Essex and Hampshire, and very frequently in the German mines. *Hill*'s Hist. of Foss. p. 617.

PYRMONT-*waters*. The country all about where these springs are, abound with materials which give virtue to the waters; and the quarries of stone, wherever they are dug, send up spirituous and martial exhalations as well as the springs that run from them, and the water among them has in general a vitriolic taste. Iron is found all about the place also, under the appearance of a yellowish earth or ochre, which contains so much of that metal, that it may be worked as an ore of it to great advantage. Ferrugineous stones are also found in great abundance in the neighbourhood of the place; these may be also worked as iron ores, and the selenites is found in the strata of earth that make up the hills thereabout, in great abundance, and in beautiful perfection.

The waters themselves, tho' they shew evident marks of an alkali, yet have also an acid principle in them, of the nature of the common acid of sulphur, except in this, that in these waters the acid carries with it a subtle mineral oil or fattiness; and mixing with the common alkali salt, which is found in all mineral waters, these together form a neutral salt: but as in the composition of this salt there is much more alkali than acid, it is necessary that the water should shew alkaline rather than acid qualities. The analysis shews also, that the waters contain a stony matter embodied in them, which is pure, insipid, colourless and tasteless, and seems to be in nothing different from common crystal. The earth about the springs contains also a great number of lumps of a clayey matter, of the size of a walnut, and of a yellowish colour; in all of which, when broken, there is found pure crystal in small shoots, sometimes in its own regular figure, and sometimes irregular and mutilated.

A water containing these principles thus combined, cannot but possess those virtues we find so eminent in this; these are, the opening obstructions, correcting the sharpness of the humors, and restoring the solids to their due state. *Seipp*, Nova Descrip. Font. Pyrm.

The history of these waters is accurately given by Hoffman in his observations on them, both in their natural state and in mixture with other bodies.

He first observes, that they contain a volatile and subtle principle, greatly more penetrating and strong, as well as in larger quantity, than any other mineral water; but that this is not to be expected in them any where but upon the spot, for those who transport them to other places are constrained to let a part of this fly off to preserve the rest. If either glass or earthen vessels be filled at the spring, and immediately corked and fastened down, the consequence is, that they will burst on the first motion or heat of the weather. They are, therefore, forced to fill them only in part at first, and let them stand a while for this subtle spirit to exhale, and then a while after the filling them up, to cork and fit them for carriage.

2. If they are drank upon the spot in a morning on an empty stomach, they affect the nose with a pungent tingling, and disturb the head for many hours afterwards.

3. If they are taken at the spring, they purge but very little; but if taken in another place, after transportation, they purge considerably more, and render the stools black. It is observable also, that if they are left in an open vessel a few days, their virtue wholly exhales, and they no longer purge nor render the stools black.

4. If tea-leaves, balaustine-flowers, or galls, are put into this water, they first change it to a blue, from that to a purple, and finally to a black. This is a ready proof, that black is only a deep purple, and purple only a deep blue: a little spirit of vitriol added to this liquor destroys all the colour, and renders it limpid as before.

5. If any acid be mixed with *Pyrmont water*, there is raised an effervescence, and bubbles of air are carried up in great quantity; and this whether the stronger acids, such as spirit of vitriol, or aqua fortis, be used; or the weaker, as vinegar, lemon-juice, or Rhenish wine.

6. If an alkaline liquor be added, whether it be volatile, as the spirit of sal armoniac; or fixed, as the oil of tartar, there

is no ebullition raiſed, but the liquor becomes turbid and milky. If ſpirit of vitriol be afterwards added to this, to ſaturate the additional alkali, the liquor becomes limpid again.

7. Cow's milk mixed in equal quantity with *Pyrmont water* does not coagulate, but, on the contrary, becomes thinner than before, and is preſerved from turning ſower ſo ſoon as it otherwiſe would in hot weather. This is a proof that there is no predominating acid in theſe waters.

8. If ſyrup of violets be added to *Pyrmont water*, it turns it to a beautiful green. This is a proof of the alkaline nature of theſe waters; and it is farther proved by adding ſpirit of vitriol, or any other acid, to this green liquor, which on that becomes limpid again.

9. Four pints of this water evaporated over a gentle fire, yield no more than two ſcruples of a dry reſiduum. Oil of vitriol being poured on this, acid efferveſcence ariſes, and with it an acrid and pungent vapour, like that produced by mixing oil of vitriol and common ſalt. If ſpirit of vitriol be uſed inſtead of the oil, the efferveſcence is in a leſs degree, and the ſalt is in part changed to a bitter ſaline maſs, the remainder ſeparated from which proves to be a calcarious earth no longer fermenting with the ſpirit of vitriol.

10. If a quantity of *Pyrmont water* be expoſed twenty four hours to the open air in a baſon, it will at the end be found to have loſt all its virtues, taſting wholly inſipid, and being turbid inſtead of the fine clearneſs it had before, and a yellow ochreous earth is precipitated to the bottom; after this the liquor will no longer ſhew any of thoſe qualities which were before its diſtinguiſhing characters, it will no longer ferment with acids, nor turn black with galls, nor green with ſyrup of violets.

It appears from the whole, that the *Pyrmont waters* poſſeſs a pure, extremely penetrating, and elaſtic mineral ſpirit, and that in a very large proportion; and to this their virtues are principally to be attributed. This mineral ſpirit, while it remains engaged in a calcarious earth, imitates the properties of an alkaline ſubſtance; and when joined with a ſubtile martial earth, it emulates the properties of vitriol, giving the ſtools a black colour, and turning a tincture of galls into ink: and while this remains in the water in theſe forms of an alkaline or vitriolic principle of ſo great ſubtilty, it cannot but give them very great virtues in ſtrengthening the tone of the viſcera, opening obſtructions, and ſtimulating in a proper manner the excretory ducts, ſo as to make them duly perform their office; but as ſoon as by the ſtanding of the water open, or by any other accident, this ſubtle element is evaporated, all the virtues of the water muſt be gone with it.

The great quantity of this powerful ſpirit contained in the waters makes them more fit for the robuſt and ſtrong conſtitutions, when depraved by illneſs, than for the weak and tender ones; but even the tendereſt people may take them, only obſerving to take but a ſmall doſe, or to dilute them with an equal quantity of common water immediately before the taking them.

Hoffman alſo recommends the *Pyrmont water* mixed with equal quantities of milk, on his own experience, in ſcorbutic and gouty caſes. *Hoffm.* Opera, T. 5. p. 143, ſeq.

Near the famous well at *Pyrmont*, is a ſtone-quarry under ground, from ſome parts of which a ſulphureous ſteam comes out, which commonly riſes to a ſmall height. Animals held in this ſteam are ſoon ſuffocated, but recover if quickly taken out. When a man ſtands in this ſteam, but with his head over it, it proves an excellent ſudorific. Dr. Seip propoſes to perform cures in ſeveral diſeaſes with it. See Phil. Tranſ. N°. 448. ſect. 4. and Miſc. Berolin. Tom. V. part. 2. ſect. 4.

Imitation of PYRMONT *water*. This medicinal water may be imitated very nicely by art in the following manner: take a quart of the pureſt and lighteſt water, add to it thirty drops of a ſtrong ſolution of iron made in ſpirit of ſalt, a drachm of oil of tartar per deliquium, and thirty drops of ſpirit of vitriol, or a little more or leſs, as is found neceſſary, not to let the alkali of the oil of tartar prevail too ſtrongly, tho' it muſt prevail a little. Shake all briſkly together, and on taſting it will be found extremely to reſemble the true *Pyrmont water*.

The baſis on which this is founded is the analyſis and trial of the true *Pyrmont water*, by which it is found to contain a ſubtle aqueous fluid, a volatile iron, and a predominant alkali, all joined together into one briſk pungent ſpirituous water. The artificial *Pyrmont* thus made, if the proportions are carefully minded, will extremely reſemble the natural, and will have the ſame effects as a medicine. *Shaw's* Lectures, p. 90.

PYROBOLUS, in natural hiſtory, a name given by many authors to the ſtone more generally called *pyrites*; others have called it *ſiderites*, *pyrobalanus*, *pyropus*, and *othonna*, and the Greeks *mylias*. Among the tranſlators and interpreters of the works of authors who have treated on theſe ſubjects, there has been great confuſion concerning this ſtone, few of them underſtanding any thing of the ſubject, and rendering its deſcriptions ſo injudiciouſly, that they may rather be thought to belong to other ſtones. See PYRITES.

PYROCTOGONIUM, in natural hiſtory, the name given by Dr. Hill to a genus of foſſils uſually comprehended by authors, with many other bodies of a different figure and ſtructure, under the general name pyrites.

The characters of the *pyroctogonium* are theſe: it is a compound, inflammable, metallic body, of a regular octohaedral figure, or compoſed of eight planes.

There is only one known ſpecies of this genus, which is a very ſingular and elegant foſſil, being compoſed of eight triangular planes; theſe being the ſides of two quadrilateral pyramids, with broad baſes, which being joined baſe to baſe, conſtitute the *pyroctogonium*. See Tab. of Foſſ. Claſs 5.

This figure is very regular and determinate in the perfect ſpecimens of this body, but there is ſcarce any foſſil which is more ſubject to imperfections and accidental variations. Its moſt perfect ſtate is when the two pyramids of which it is compoſed are placed evenly one over againſt the other; but this is but rarely the caſe, they are often placed unevenly, or ſlanting; their planes are frequently of very irregular lengths and breadths, and not unfrequently the ſpecimens are found mutilated and imperfect, and very often a number of them cohering in a cluſter one with another, and very much mutilating or injuring one another's figure. They are found of all the ſizes between that of a pin's head, and an inch in diameter; but the large ones are ſcarce, and the moſt uſual ſtandard is a third of an inch. They are naturally of a ſmooth and poliſhed ſurface, and of the colour of wrought iron; when broken they are bright and ſparkling, and of a paler colour than without. When nicely examined as to their internal ſtructure, they are found to be compoſed like the marcaſites, of a number of irregularly arranged foliaceous flakes or plates.

It is found very frequently in Cornwall, Devonſhire, and moſt other of our counties where there are mines. It is ſometimes met with looſe in the earth, ſometimes lodged in the bodies of marcaſites, or in the ſolid foſſils, and varies ſometimes from its iron colour to a duſky yellow. It is ſometimes alſo found with many ſpecimens connected into a maſs; theſe are ſeldom uniform in ſize, and cohere in various directions, often greatly injuring one another's figure. Sometimes alſo, as in the caſe of the cryſtals, they form a large maſs, of which the outer ſurface only is concreted into or covered with regular figures, the whole inner part being a confuſed ſubſtance.

Maſſes of this kind are not unfrequently found of a regularly orbicular figure, and beſet all over with regularly figured *pyroctogonia* of various ſizes. *Hill's* Hiſt. of Foſſ. p. 620.

PYROLA, *winter-green*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the roſaceous kind, conſiſting of ſeveral petals arranged in a circular form. The piſtil ariſes from the flower-cup, and ends in a ſort of proboſcis: this afterwards becomes an umbilicated and ſtriated, roundiſh, quinque capſular fruit, uſually containing a number of very ſmall ſeeds.

The ſpecies of *pyrolæ*, enumerated by Mr. Tournefort, are theſe: 1. The larger round-leaved *pyrola*. 2. The ſmaller round-leaved *pyrola*. 3. The *pyrola* with ſharp-pointed and ſerrated leaves. And 4. The ſhrubby *pyrola*, with flowers reſembling thoſe of the arbutus. *Tourn.* Inſt. p. 256.

PYROLAMPIS, the *glow-worm*, a ſmall inſect remarkable for its ſhining in the night.

The male and female differ greatly in this ſpecies of inſect. The male has wings, and is a ſmall fly; the female has no wings, but is a large crawling worm.

The body of the male is oblong, and ſomewhat flatted; the wings are ſhorter than the body; the head is broad, dun, and flat; the eyes are large and black. This has no light iſſuing from it, and is not commonly ſuppoſed to be at all of kin to the *glow-worm*. See Tab. of microſcopical Objects, Claſs 1. voc. *Cicindela volens*.

The female is what we expreſly call by this name. This is a very ſlow-paced animal, without wings, and ſomewhat reſembling a caterpillar; the head is ſmall, flat, hard, and black, and ſharp towards the mouth; it has ſhort antennæ, and ſix moderately long legs; the body is flat, and is compoſed of twelve rings, whereas the body of the male conſiſts only of five; it is of a duſky colour, with a ſtreak of white down the back. It is often ſeen in the day-time, but is not known till in the dark; at which time it is eaſily diſtinguiſhed by the glowing light, or lambent flame, that is ſeen near the tail, iſſuing from the under part of the body.

PYROMACHUS, a name given by ſome to antimony when reduced to a ſtony hardneſs; and by others to copper, when fuſed with ſulphur, and thus rendered leſs ductile.

PYRONOMIA, a term uſed by the chemical writers to expreſs the art of regulating fire, ſo as to make it ſubſervient to all their proceſſes in a determinate degree.

PYROPHAGI, *fire-eaters*, a name given by ſome to thoſe juglers and mountebanks who deceive people into a belief that they ſwallow fire.

PYROPHORUS, the name uſually given to that ſubſtance called by ſome the *black phoſphorus*. See PHOSPHORUS.

It is made in this manner: take four or five parts of alum, and one part of wheat-flour, calcine this together to a brown or blackiſh maſs; powder this and put it into a vial, ſtop it looſly with a paper, and ſet it in a ſand heat, ſo as to make it continue glowing hot for ſome time; after this, remove the

whole from the fire, ſuffer it to cool gradually, and finally ſtop the bottle very cloſe down.

A little of this powder being poured out of the bottle, and expoſed to the open air, immediately takes fire, and appears like a glowing coal; but the powder muſt be freſh made to have a good effect, for the ſun's rays, or the moiſture of the air being admitted to it, gradually take away its virtue.

Almoſt any animal or vegetable ſubſtance may be ſubſtituted inſtead of wheat-flour in this proceſs, and it will ſucceed equally well; but no other ſalt will do in the place of alum. *Shaw*'s Lectures, p. 406.

PYROPHYLACIA, a term uſed by Kircher and ſome others to expreſs thoſe magazines of fire which are placed in the cavities of mountains and other hollows of the earth, and ſerve to ſupply the ſeveral volcanos in the different parts of the world. See VOLCANO.

PYROSCOPIA, among the Greeks, a kind of divination, being the ſame with pyromancy and igniſpicium. See the article PYROMANCY, *Cycl.*

PYROSIS, a word uſed to expreſs an intenſe heat and redneſs in the face, ſuch as that of perſons who travel in extremely hot weather, and the like.

PYRRHALA, in zoology, the name of a bird well known in England by the name of the *bulfinch*, and called by ſome authors *rubicilla*.

It is a beautiful bird, and ſings very ſweetly; but does great miſchief in gardens and orchards, deſtroying the buds of the fruit-trees.

PYRRHOCORNIX, in zoology, a name given by authors to a bird of the crow-kind, deſcribed by ſome authors as a diſtinct ſpecies; but Mr. Ray, and other very judicious naturaliſts, eſteem it the ſame with the coracias, or Corniſh chough, or only differing in age or by other accidents. *Ray*'s Ornithol. p. 86. See CORACIAS.

PYRROPŒCILOS, in the natural hiſtory of the antients, the name by which they call the granite of Arabia, commonly known to this day under the name of the *oriental granite*.

The name is derived from the Greek πῦρ, fire, or fire-coloured, and ποικιλος, ſpotted; and the antients having uſed the epithet fiery to yellow, as well as red, ſome have imagined the granite muſt be a yellow ſtone; but it is evident that red is the colour meant by it here. *Hill*'s Hiſt. of Foſſ. p. 500.

PYRSEPHORUS, πυρσηφορος, in the Athenian feſtival, hephæſtia, the ſame with lampadephorus. See LAMPADEPHORUS.

PYRUS, the *pear-tree*, in botany, the name of a genus of trees, the characters of which are theſe: the flower is of the roſaceous kind, and is compoſed of ſeveral petals arranged in a circular form. The cup finally becomes a fleſhy fruit, uſually of a turbinated ſhape, umbilicated, and divided within into cells which contain oblong ſeeds. *Tourn.* Inſt. p. 629.

The ſpecies of *pear*, enumerated by Mr. Tournefort, are theſe: 1. The double-flowered *pear*. 2. The ſmall, branched, very ſweet-ſcented ſummer-*pear*. 3. The ſummer-*pear*, with very ſmall and ſweet-ſcented fruit. 4. The ſweet-flavoured ſummer-*pear*, partly of a deep red, and partly of a yellow colour. 5. The ſmall, yellowiſh, ſweet-flavoured *pear*. 6. The round, ſeſſile, ſweet-flavoured ſummer-*pear*, variegated with black ſpots. 7. The round, ſeſſile, ſweet flavoured, ſugar-taſted ſummer-*pear*, of a purpliſh green colour. 8. The oblong, iron-coloured, ſweet-flavoured ſummer-*pear*, with tender pulp. 9. The ſmall ſummer-*pear*, of a whitiſh green colour. 10. The greater whitiſh ſummer-*pear*. 11. The whitiſh, ſugar-taſted, very ſweet-flavoured, ſummer-*pear*. 12. The whitiſh ſummer-*pear*, with a long pedicle. 13. The oval ſummer-*pear*, variegated with iron-coloured ſpots. 14. The oblong, reddiſh, ſugar-taſted, ſummer-*pear*. 15. The ſmall, roundiſh, vinous, ſummer-*pear*, of a reddiſh yellow colour. 16. The ſugar-taſted turbinated ſummer-*pear*, with tender pulp. 17. The oblong, ſmall, aſh-coloured ſweet-flavoured ſummer-*pear*. 18. The globoſe, ſeſſile, ſugar-taſted, ſummer-*pear*, of a whitiſh yellow colour. 19. The ſugar-taſted, globoſe, whitiſh ſummer-*pear*. 20. The globoſe, ſeſſile, ſweet-flavoured ſummer-*pear*. 21. The turbinated, ſeſſile, red-coloured, and punctated ſummer-*pear*. 22. The turbinated, ſeſſile, ſweet-flavoured, ſummer-*pear*, partly yellow, and partly variegated with red ſpots and veins. 23. The long, red, ſummer-*pear*, of a ſomewhat acid taſte. 24. The globoſe, greeniſh purple, ſummer-*pear*. 25. The globoſe, ſugar-taſted, ſweet-flavoured, ſummer-*pear*, of a yellowiſh colour, blended with red and white. 26. The great oblong ſummer-*pear*, partly red and partly white. 27. The long ſummer-*pear*, of an extremely bitter taſte. 28. The autumnal-*pear*, with very ſweet fruit, which diſſolves in the mouth. 29. The ſeſſile, ſugar-taſted, ſweet-flavoured, autumnal-*pear*, of a greeniſh yellow colour, and diſſolving in the mouth. 30. The turbinated autumnal-*pear*, of a green colour, variegated with blood-coloured veins. 31. The roundiſh autumnal-*pear*, of a reddiſh iron colour, ſometimes ſpotted. 32. The long, green, ſweet-flavoured autumnal-*pear*, which diſſolves in the mouth. 33. The tuberous, ſeſſile, autumnal-*pear*, of a greeniſh yellow colour, variegated with black ſpots, with ſugar-taſted tender pulp. 34. The tuberous, ſeſſile, ſugar-taſted, autumnal-*pear*, with hard pulp. 35. The globoſe, iron-coloured, very ſweet-taſted autumnal-*pear*, with tender pulp. 36. The turbinated, ſeſſile, autumnal-*pear*, with yellowiſh fruit, diſſolving in the mouth. 37. The globoſe, iron-coloured, autumnal-*pear*, with viſcid pulp. 38. The Engliſh *pear*, with long fruit, variegated with iron-coloured ſpots. 39. The very ſweet-flavoured, ſugar-taſted, pale-red, oblong, autumnal-*pear*. 40. The great aſh-coloured, oblong, autumnal-*pear*. 41. The roundiſh, ſweet-flavoured, red, autumnal-*pear*. 42. The ſmall, globoſe, punctated, autumnal-*pear*, of a greeniſh red colour. 43. The ſmall, tuberous, ſeſſile, darkiſh-coloured, autumnal-*pear*. 44. The tuberous, turbinated, punctated, autumnal-*pear*, of a yellowiſh or whitiſh colour. 45. The turbinated, yellow, or ſtriated, ſubacid, autumnal *pear*. 46. The turbinated, fading yellow, and ſomewhat bitter, aromatic taſted, autumnal-*pear*. 47. The turbinated, ſeſſile, yellow, autumnal-*pear*, with a ſomewhat bitter aromatic taſte. 48. The turbinated, ſeſſile, yellow, autumnal-*pear*, with ſtriated ribs. 49. The tuberous, angular, autumnal-*pear*, of a yellowiſh, fading green colour. 50. The tuberous autumnal-*pear*, with a thin, pellucid ſkin, partly red, and partly yellow. 51. The oval, ſomewhat angular, autumnal-*pear*, with a very tender ſkin of a faint yellow. 52. The large winter-*pear*, of a reddiſh yellow colour, and ſhaped like a pyramid. 53. The pyramid like winter-*pear*, partly purple, variegated with black ſpots, and partly yellow. 54. The great oblong, turbinated, iron-coloured, Windſor-*pear*, umbilicated on both ſides. 55. The great quince like winter-*pear*, partly yellow, and partly purple. 56. The very ſweet-flavoured, yellow, winter-*pear*, with a thick pedicle. 57. The great ſeſſile, winter-*pear*, of a yellowiſh grey colour. 58. The globoſe, ſeſſile, winter-*pear*, of an aſh-colour, variegated with large dark ſpots. 59. The long yellow winter-*pear*. 60. The ſmall winter-*pear*, of a yellow colour, variegated with red ſpots, and a bitter taſte. 61. The oval, ſugar-taſted, winter-*pear*, of an iron colour, with a faint admixture of purple. 62. The citron-ſhaped, hard, and very ſweet-flavoured, winter-*pear*. 63. The globoſe, ſeſſile, ſugar-taſted, ſweet-flavoured, winter-*pear*. 64. The turbinated and unequally tumid winter-*pear*, partly purple, and partly yellow. 65. The great globoſe winter-*pear*, of a yellow colour, variegated with red ſpots. 66. The turbinated, ſeſſile, winter-*pear*, of a ſubacid taſte, a yellow colour, and covered with a multitude of ſharp points. 67. The turbinated, ſeſſile, yellow, ſugar-taſted, winter-*pear*, of a ſweet ſmell, and diſſolving in the mouth. 68. The tuberous, turbinated, greater ſugar-taſted, winter-*pear*, diſſolving in the mouth. 69. The oblong, ſugar-taſted, ſweet-flavoured, winter-*pear*, of a partly deep and partly faint iron colour. 70. The oblong, winter-*pear*, of a very pale red colour. 71. The oblong, yellowiſh green, winter-*pear*, of an auſterely ſweetiſh taſte. 72. The oblong, tuberous, ſubacid, winter-*pear*, of a punctated yellow colour. 73. The tuberous, ſugar-taſted, punctated, yellowiſh green, winter-*pear*. 74. The long, whitiſh green, winter-*pear*, diſſolving in the mouth. 75. The long, yellowiſh green, winter-*pear*, diſſolving in the mouth. 76. The ſeſſile, yellowiſh green, winter-*pear*, ſpotted, umbilicated on both ſides, and diſſolving in the mouth. 77. The globoſe, pale green, tuberous, punctated, winter-*pear*, diſſolving in the mouth. 78. The great pyramidal, whitiſh, ſugar-taſted, ſweet-ſcented, winter-*pear*, diſſolving in the mouth. 79. The ſeſſile, iron-coloured, very ſweet-ſcented, winter-*pear*, diſſolving in the mouth. 80. The globoſe, citron-ſhaped, punctated, yellow, winter-*pear*, diſſolving in the mouth, and very ſweet-ſcented. 81. The long, ſugar-taſted, yellowiſh green, winter-*pear*, diſſolving in the mouth. 82. The ſeſſile, winter-*pear*, partly purple, and partly yellow. 83. The great, double-headed, winter-*pear*. 84. The tuberous and angular winter-*pear*. 85. The oval, paler green, winter-*pear*, with a very long pedicle, and beſet with tubercles. 86. The wild *pear*. 87. The great wild *pear*. *Tourn.* Inſt. Bot. p. 628, ſeq. See the article PEAR.

PYULCUM, a word uſed by the antients to expreſs an inſtrument uſed in their times to draw out the pus from the bottom of deep ſinuſes, probably a ſort of canula.

Q.

QUACHILTO, in zoology, the name of a very beautiful Braſilian bird, of the moorhen kind, called alſo *yacacintli*, and *porphyrio Americanus*.

It is of a fine blackiſh purple colour, variegated with white. Its beak is white, while young; but becomes red as it grows older, and has a naked ſpace at its baſis, reſembling, in ſome ſort, the coot. Its legs are of a yellowiſh green. It lives about the waters, and feeds on fiſh; yet is a very well taſted fiſh. It imitates the crowing of a common cock, and makes its muſic early in the morning. *Marggrave*'s Hiſt. Braſil.

QUADRANGULARIS *piſcis*, the *ſquare-fiſh*, in zoology, the name of a fiſh, which in its moſt uſual ſize, is about fifteen inches long, four inches high in the middle, and three inches and an half over. The forehead is ſquare, a little hollow, and, by the eminency of the eyebrows, two inches and an half over. The noſe blunt, and not very ſteep, with two holes in the place of noſtrils, and the mouth very ſmall. The back is a little convex toward the tail, and on the ſides a little obtuſely angled; as is alſo the belly, which is plain and flat, and a little riſing toward the tail. It has five fins, two near the gills, two near the tail, and the tail-fin, which is conſiderably long. Part of the head and tail are covered with a ſoft ſkin, the reſt of the body with a kind of cruſt, adorned all over with little round knots, reduced for the moſt part into hexagonal figures, and ſubdivided into equilateral triangles. *Grew.* Muſ. Reg. Soc. p. 110.

QUADRANS, *(Cycl.)* a word uſed by ſome authors to expreſs a fourth part of a pound, that is, three ounces Troy weight, or four of the averdupois.

QUADRATING *of a piece*, in gunnery, is examining whether the piece be duly placed in its carriage, and that the wheels be of an equal height.

QUADRATO, or QUADRO, in the Italian muſic, is a name given to the note B, when it comes in the natural or diatonic order, and is thus marked ♮. It is a ſemitone minor higher than the B mol, or ♭, and in reſpect of that may be called *ſharp*. See FLAT and SHARP, *Cycl.* and *Suppl.*

QUADRATULUS, in ichthyology, a name given by Rondeletius to the fiſh called by other authors the *plateſſa*, and *paſſer lævis*, in Engliſh the *plaiſe*.

This is properly a ſpecies of the pleuronectes, and is diſtinguiſhed from the reſt of that genus by Artedi, by a name expreſſing that it has the eyes and ſix tubercles on the right ſide of the head, and ſmooth ſides, and a ſpine at the anus. See the article PLEURONECTES.

QUADRATURE *of the hyperbola*. See HYPERBOLA.

QUADRATUS *(Cycl.)*—QUADRATUS, in zoology, a name by which ſome authors have called the flat fiſh, called *paſſer* by moſt writers, and in Engliſh the *plaiſe*. *Rondelet.* de Piſc. p. 331.

QUADRATUS, in anatomy, a ſmall, flat, fleſhy muſcle, of the figure of an oblong ſquare, ſituated tranſverſely between the tuberoſity of the iſchium and the great trochanter. It is fixed by one extremity along that obtuſe line which runs from under the acetabulum, toward the lower part of the tuberoſity of the iſchium; from whence it runs directly towards the great trochanter, and is inſerted in almoſt all the lower half of the oblong eminence in that apophyſis, but chiefly in the ſmall riſing or tuberoſity in the middle of that eminence. *Winſlow*'s Anat. p. 211.

QUADRATUS *lumborum*, *ſive lumbaris externus*, a ſmall, oblong, flat muſcle, irregularly ſquare, narrower at its upper than at its lower part, lying along the ſides of the vertebræ lumborum, between the laſt falſe rib and the os ilium. It is fixed below to the external labium of almoſt all the poſterior half of the criſta of the os ilium, to the ligamentum ſacro-iliacum, and a little to the os ſacrum, by a fleſhy plane, the fibres whereof run obliquely backward; from thence it runs up between the ſacro-lumbaris and pſoas, by both which it is partly hid, and is inſerted in the extremities of all the tranſverſe apophyſes of the loins by oblique tendinous digitations. It is alſo fixed by a broad inſertion in the twelfth rib, on the inſide of the ligament which lies between it and the longiſſimus dorſi, by which that rib is connected to the firſt vertebra of the loins. *Winſlow*'s Anat. p. 249.

QUADRATUS *muſculus*, in anatomy, is alſo a name given by Winſlow to the muſcle of the lips called by Albinus and Cowper *depreſſor labii inferioris*.

QUADRIGÆ, among the Romans, chariots drawn by four horſes, which were harneſſed all a-breaſt, and not two and two. *Pitiſc.* in voc.

QUADRISETÆ, the *four-haired fly*, a term uſed by the writers in natural hiſtory to expreſs thoſe flies of the ſeticaude or hair-tailed kind, which have four hairs or briſtles growing from the tail, as the others have three, two, or one.

QUADRULA, in natural hiſtory, a word ſometimes uſed in the ſame ſenſe as teſſela, and ſpoken of the cubic pyrites. Sometimes it is uſed alſo as the name of thoſe little ſpangles of ſhining matter that are mixed among ſand. Theſe are generally fragments of talc, and are of various colours, white, yellow, and blackiſh.

Solinus has uſed the word *quadrula* to expreſs the fragments of yellow talc that are found in that ſand called *ammochryſos*, or golden ſand. He miſtakes theſe ſhining particles for maſſes of real gold, and makes the ſand itſelf a kind of precious ſubſtance ranked among the gems, and brought from Perſia; but in this he does not agree with the reſt of the antients.

QUADRUPEDS, *(Cycl.)* in natural hiſtory. The eſſential character of *quadrupeds* is, that they have a hairy body and four feet, and that the females are viviparous, and give ſuck to their young. *Linnæi* Syſtem. Natur. p. 33.

Alated QUADRUPEDS. Among the many fabulous things with which natural hiſtory has been loaded, ſtories of flying *quadrupeds* ſeem to claim a very high rank; the gryphon, the *quadruped* dragon, and a great many other imaginary animals, having been introduced ſo ſeriouſly among the deſcriptions of real animals, that too many have been taught to believe them. Scheuchzer, in his *Phyſica ſacra Jobi*, has done much toward diſcountenancing ſuch relations, and Hyacinthus Gemma, who has written expreſly de fabuloſis animalibus, has added much on the ſame occaſion: yet all is not done. The world have late hiſtories of lemmas and baſiliſks, which never exiſted but in the imagination of the relator, or in the ſubtle contrivances of the fabricator; as is evidently the caſe in the baſiliſks, which we find in the muſæums of the curious, and which are all made out of the wray-fiſh. And the generality of readers are ſo fond of any thing that is marvellous, that theſe things are ſure to be remembered, while perhaps all the truths in the book are forgotten.

Tho' moſt of the ſtories of *alated* or flying *quadrupeds* are falſe, yet there are evidently ſome animals which ſhew, that this property is not denied to all *quadrupeds*. We have bats in every part of this kingdom, and the Eaſt and Weſt Indies are not without them; and whoever accurately examines this creature, will find that it has nothing of a bird but that one property of flying; and that what are called its wings, and ſerve it in the office of wings, are in reality only its fore-feet extended, and webbed with a peculiar kind of membrane.

There is a ſpecies of flying lizard very common in Java, and called by many the *flying dragon*. Bellonius had led the world into a great error in regard to this animal, having miſtaken it for a two-legged creature, and deſcribed and figured it as ſuch; but Bontius, and others ſince his time, have ſet us right about it from their own obſervation, and Piſo, as well as many others, have deſcribed it truly as a *quadruped*.

Theſe creatures are properly enough called flying animals, as they can ſuſpend themſelves a long time in the air, and move about in it at pleaſure; but leſs accurate writers have added to the numbers of flying *quadrupeds* the common ſquirrel, and ſeveral other creatures which live in woods, and being very light in their bodies, and very ſtrong in their legs, can leap or throw themſelves forward to a great diſtance, and by this means paſs from one tree to another. Of this kind the moſt eminent is that ſpecies called the *flying ſquirrel*, which has a ſort of membrane which it expands on each ſide to catch the air, and ſupport it from falling in its leaps; which by this means it makes very long, and ſeems to fly, eſpecially when it throws itſelf from the top of a very high tree to a low ſhrub.

Upon the whole, the ſtandard of the flying or *alated quadrupeds* ſeems to be properly enough reducible to this: that the words flying and *alated* are not ſynonymous terms, and that there are three kinds of flying among the *quadruped* claſs. The firſt abſolute and ſwift, flying as perfect as in birds; this peculiarly belongs to the bat, which is the only *alated* or winged *quadruped*, properly ſpeaking. 2. An imperfect flying by means of certain membranes ſerving as wings, but imperfectly, and not turning quick, or enduring long flights; ſuch is the flying of the lizard, which is not properly an *alated* animal. And laſtly, the imperfect flying of the ſquirrel kind, which even in that ſpecies called, by way of eminence, the *flying ſquirrel*, is not properly flying, but only long leaping; the creature being able to turn but very little out of a right line, and only to ſuſpend itſelf during a ſhort time in a leap from a high place to a lower. Phil. Tranſ. N°. 427. p. 34.

QUADRUPLATORES, among the Romans, were informers, who had the fourth part of the confiſcated goods for their pains. *Pitiſc.* in voc.

QUÆRENS *non invenit plegium*, a return made by the ſheriff upon a writ directed to him with this clauſe, viz. *Si A. fecerit B. ſecurum de clamore ſuo proſequendo*, &c. F. N. B. 38. *Blount*, *Cowel.*

QUÆSTOR,

QUÆSTOR, among the Romans. See QUESTOR, *Cycl.* and *Suppl.*

QUAHVITLA, in botany, a name uſed by ſome authors for the tree from which the reſin commonly called *gum copal* is procured. *Hernand.* p. 46.

QUAIL, *coturnix*, in ornithology, a bird of the gallinaceous kind. See COTURNIX and GALLINACEOUS.

The *quail* is a bird of paſſage, and with us frequents the corn-fields, and ſometimes the meadows. They begin to ſing in April, and they make their neſts in the month of May, building on the ground.

Quails are to be taken by means of the call, during their whole woing time, which laſts from April to Auguſt. The proper times for uſing the call are at ſun-riſing, at nine o'clock in the morning, at three in the afternoon, and at ſun ſet; for theſe are the natural times of the *quail*'s calling. The notes of the cock and hen-*quail* are very different, and the ſportſman who expects to ſucceed in the taking them, muſt be expert in both; for when the cock calls, the anſwer is to be made in the hen's note; and when the hen calls, the anſwer is to be made in the cock's. By this means, they will come up to the perſon ſo that he may, with great eaſe, throw the net over them and take them. If a cock-*quail* be ſingle, on hearing the hen's note he will immediately come; but if he have a hen already with him, he will not forſake her. Sometimes, tho' only one *quail* anſwers to the call, there will three or four come up; and then it is beſt to have patience, and not run to take up the firſt, but ſtay till they are all entangled, as they will ſoon be.

The *quail* is a neat cleanly bird, and will not run much into dirty or wet places: in dewy mornings they will often fly inſtead of running to the call; and in this caſe, it is beſt to let them go over the net, if it ſo happens that they fly higher than its top, and the ſportſman then changing ſides, and calling again, the bird will come back, and then will probably be taken in the net.

The calls are to be made of a ſmall leather purſe, about two fingers wide, and four fingers long, and made in the ſhape of a pear; this is to be ſtuffed half full of horſe-hair, and at the end of it is to be placed a ſmall whiſtle, made of the bone of a rabbit's leg, or ſome other ſuch bone: this is to be about two inches long, and the end formed like a flageolet, with a little ſoft wax. This is to be the end faſtened into the purſe, the other is to be cloſed up with the ſame wax, only that a hole is to be opened with a pin, to make it give a diſtinct and clear ſound. To make this ſound, it is to be held full in the palm of the hand, with one of the fingers placed over the top of the wax, then the purſe is to be preſſed, and the finger is to ſhake over the middle of it, to modulate the ſound it gives into a ſort of ſhake. This is the moſt uſeful call, for it imitates the note of the hen-*quail*, and ſeldom fails to bring a cock to the net, if there be one near the place.

The call that imitates the note of the cock, and is uſed to bring the hen to him, is to be about four inches long, and above an inch thick; it is to be made of a piece of wire turned round and curled, and covered with leather; and one end of it muſt be cloſed up with a piece of flat wood, about the middle of which there muſt be a ſmall thread or ſtrap of leather, and at the other end is to be placed the ſame ſort of pipe, made of bone, as is uſed in the other call. The noiſe is made by opening and cloſing the ſpiral, and gives the ſame ſound that the cock does when he gives the hen a ſignal that he is near her.

QUALIFICATIONS *of members of parliament.* A knight, baronet, or any other under the degree of a baron, may be elected knight, citizen, or burgeſs. 4 Inſt. 46, 47.

An alien, tho' made a denizen, cannot ſit in parliament[a]; even perſons naturalized by act of parliament are uſually reſtrained from ſitting as members[b]. Perſons under the age of twenty-one years are not capable of being elected members of parliament. The election is void, and minors, tho' choſen, preſuming to ſit and vote, are under the ſame penalties as if they had ſat and voted without being choſen[c]. [[a] 4 Inſt. 47. [b] Vid. Stat. 12, 13 Will. III. 4 Ann, c. 8. and 1 Geo. I. [c] 7 and 8 Will. III. c. 25.]

None of the judges of the king's-bench, common-pleas, or barons of the exchequer, that have judicial places, can be choſen knights, citizens, or burgeſſes of parliament. 4 Inſt. 47.

None of the clergy can be elected knight, citizen, or burgeſs of parliament; becauſe they are of another body, the convocation. 4 Inſt. 47. Moor 783.

A perſon attainted of treaſon or felony is not eligible; for he ought, according to the writ, to be *idoneus, diſcretus & ſufficiens.* 4 Inſt. 48.

The king cannot grant a charter of exemption to any man, to be freed from election of knight, citizen, or burgeſs of the parliament. 4 Inſt. 49.

For the incapacities of ſheriffs, mayors of towns, and the reaſons why they may or may not be elected knights, citizens, or burgeſſes, vid. 4 Inſt. 48. *Bro.* Abr. Tit. Parliament. *Cromp.* Juriſd. 3. 16. *Ruſhw.* Collect. Vol. I. p. 684. *Townſh.* Coll. 185.

QUALITY *(Cycl.)*—QUALITY *of curvature*, in geometry, is uſed to ſignify its form, as it is more or leſs inequable, or as it is varied more or leſs in its progreſs through different parts of the curve. *Newton*'s Meth. of Flux. and Inf. Ser. p. 75. *Maclaur.* Flux. Art. 369. See CURVATURE, Appendix.

QUAMOCLIT, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the monopetalous or one-leaved kind, and is funnel-ſhaped and divided into ſeveral ſegments at the end. From the cup there ariſes a piſtil, which is fixed in the manner of a nail to the lower part of the flower; this afterwards changes into an oblong fruit, containing ſmall ſeeds, uſually of an oblong figure. See Tab. 1. of Botany, Claſs 2.

The ſpecies of *quamoclit*, enumerated by Mr. Tournefort, are theſe: 1. The finely divided pennated-leaved *quamoclit*. 2. The purple-flowered American *quamoclit*, with fingered leaves. 3. The ſix-leaved American *quamoclit*, with purple umbellated flowers. 4. The American *quamoclit*, with large heart-like leaves. 5. The purple-flowered American *quamoclit*, with large angular leaves. 6. The trifid, or ivy-leaved American *quamoclit*. 7. The pale red American *quamoclit*, with leaves like thoſe of nightſhade. *Tourn.* Inſt. p. 116.

Quamoclit differs from bindweed, or convolvulus, in the ſhape of the flower.

QUANDROS, a name given by the writers of the middle ages to a ſtone, to which they attribute great virtues, and which, they ſay, is found in the head of a vulture.

QUANTITY *(Cycl.)*—QUANTITY *of curvature* at any point of a curve is determined by the circle of curvature at that point, and is reciprocally proportional to its radius. *Newton* Meth. of Flux. and Inf. Series, p. 60. *Maclaurin*'s Fluxions, B. 1. ch. 11. See CURVATURE, Appendix.

QUANTITY *of action.* See ACTION.

QUANTITY { *impoſſible*, / *imaginary*, } See the article ROOT.

QUAPACHTOTOTL, in zoology, a name under which Nieremberg has deſcribed a bird, which, he ſays, imitates the human laugh. He ſays its body is eight inches long, and the tail as many; the beak of a bluiſh black, and bent and crooked; the breaſt grey and the belly black; the tail of a browniſh black, and the wings, neck, and head of a yellowiſh brown. *Ray*'s Ornithol. p. 298.

QUARRY *(Cycl.)*—In many parts of England we find ſea-ſhells buried in hard ſtone, and under great beds of earth.

Near Broughton, in Lincolnſhire, all the *quarries* abound with them. At the eaſt end of this town there is a *quarry* of a ſoft ſtone, which they dig through to get at a bed of clay, which is of a peculiarly glutinous quality, and hardens like mortar in drying: this is uſed for cementing other ſtones together, and in this are innumerable fragments of ſhells of cockles, ſcallops, ſea-echini, and corals; and among theſe fragments there are found ſome whole ſhells of their natural colours, and often wholly unhurt; tho' ſome of them are bruiſed and preſſed quite flat by the great weight of earth that lies upon them. On the ſouth ſide of the town there is a *quarry* of a blue ſtone, which was doubtleſs in the times before the deluge a blue clay, of the ſame nature with that juſt mentioned. This contains in its body vaſt numbers of the ſame ſorts of ſhells, and of many other kinds; but they are all ſo firmly bedded in the ſtone, that it is not eaſy to get them out whole: but there is this very remarkable, that they only lie in the ſuperficial part of the ſtone, the ſtratum being very thick, but not one ſhell found in it beyond the depth of two foot from the ſurface.

The ſurface of this ſtratum of ſtone is not even and ſmooth, but is waved and ridged irregularly, like a bed of ſnow, or like the waves of the ſea in the time of a ſmall wind. This has juſt the appearance that the ſurface of a maſs of half hardened matter muſt have, if the wind blew fiercely upon it from one quarter; and by the direction of theſe undulations, it is eaſy to ſee from what quarter the wind blew at that time. In that part of the ſtone which forms this undulated roughneſs, there are as many ſhells as any where elſe; and theſe lie partly buried and partly ſtanding out of the ſtone, juſt as we ſee the freſh water ſhell-fiſh lie half in and half out of the mud of the bottom of a pond or river that is dried up in ſummer.

It is very obſervable, that in this caſe, as much of the ſhell as is within the ſtone is perfectly well preſerved, and as hard as ſtone; whereas that part which ſtands out is either wholly decayed, or at the beſt of the nature of a rotten ſhell, which falls to pieces on being touched with the hands. The part of the ſhell within the ſtone is uſually converted into a maſs different from the ſhell in all things but figure; but that which ſtands out always preſerves the true texture of the natural ſhell, and is made up of many flakes and cruſts as the natural ſhells of the kind to which it belongs are.

Among the ſhells buried in the ſubſtance of the ſtone, ſome have their ſhell perfect on them, others have only a thin cruſt of a whitiſh ſtony matter in the place of it, and others are wholly naked, and have no ſhell nor any covering at all: theſe are properly only caſts of ſtone in the places where ſhells once were, all the matter of the ſhells themſelves having been diſſolved and waſhed away. In ſome of theſe there is a thick white ſubſtance in the place of the ſhell, between the caſt and the bed of ſtone: theſe come out the moſt eaſy and perfect of

of any, and the matter which ſupplied the place of the ſhell remains faſtened to the bed of the ſtone; others ſeparate themſelves very perfect after froſty nights.

Some of the cockles and other bivalves are found cloſed, others are found half open, as ſhell-fiſh naturally open their ſhells when deſerted by the water. In theſe the cavity is always filled with the matter of the ſtratum, and both petrified together. In ſome places they lie in heaps together in the ſtone, and there they uſually enter into and injure one another. Some are found ſhut ſo cloſely, that the matter of the ſtone-bed could not get into their cavity; and of theſe, ſome are at this time wholly empty, others are filled, or partly filled, with cryſtals and ſpars: theſe bodies muſt have been found in them only from the cryſtaline and ſparry matter riſing through the earth in vapour, and penetrating the very ſubſtance of the ſhells after their being lodged in the ſtone.

In this *quarry* there is alſo found a very remarkable ſhell, reſembling a ram's horn, bent in the ſame manner, and with the ſame lineations. This is wholly different from the common cornu ammonis claſs, and has an operculum to cloſe its mouth with, in the manner of the wilks and other ſuch ſhells. This operculum is often found entire with the ſhell, or near it, in the ſame bed of ſtone.

This ſpecies of foſſile ſhell is found in prodigious numbers together, and uſually lies near the ſurface of the bed of ſtone, a part being buried in the ſtone, and a part ſtanding out of it; many of them ſtand more than half way out, and the ſhell of theſe is ſo much more durable than that of the common kinds, that it is uſually very firm and ſtrong, even in ſuch places where the other kinds moulder all away. Theſe are uſually found entire, but in ſome places they are cruſhed flat, and otherwiſe bruiſed and injured.

From theſe and the like obſervations made on the whole ſurface of the earth, and to great depths in its bowels, where ever men have dug on any occaſion, ariſe plain proofs of the univerſality of the deluge; and from many of theſe obſervations it ſeems very plain, that in the time of the deluge the earth ſuffered great violence in many parts, that the bottoms of ſeas were in ſome places raiſed into mountains, and in others the tops of mountains ſunk into ſeas, and the beds of ſhells ſtill preſerved in the foſſile world were very often cruſhed and bruiſed by large maſſes of earth and pieces of rock thrown upon them.

Some think that it appears from the conſideration of the *quarries* and ſtrata of earth, *&c.* in the preſent world, that the antediluvian earth had ſeas and ſhores, mountains and plains, rivers and vallies, as ours has; and that waters from within the earth were let out upon its ſurface, and the whole cruſt of the then world ſubſided under theſe; that the contents of the ſeas, ſuch as ſhells, corals, and the like, were after this toſſed variouſly about over the ſurface of this drowned world, and left in different parts of it; and that this preſent earth afterwards partly aroſe out of the common flood, as iſlands are now formed in ſome ſeas, and partly was deſerted by the waters, when called off again by the ſame almighty hand that brought it on: and as the ſtrata of the earth were at that time ſoft, it is no wonder that matter then ſoft enough to let in the ſhells, *&c.* afterwards hardened, together with the ſhells it had received, into ſtone; and that in proceſs of time, the ſtony particles eternally floating in the air and waters that pervade all the ſtrata, depoſited their ſmall parts in the interſtices of theſe ſhells, and finally the whole became ſtone.

It is no wonder that all ſorts of marine productions, ſhells, parts of ſea-fiſhes, corals, and the like, are found at this time in beds and *quarries*, in hills and mountains, and alſo in the bowels of the earth; for it is certain that they were produced in the antediluvian ſea, and were either elevated with the hills and mountains in the time of the deluge, or they fell into holes, clifts, and chaſms in the earth, which muſt be formed in vaſt numbers during the time of that terrible cataſtrophe, and in theſe they remain buried to this time; while others lodged on what was then the ſurface, became afterwards covered with more ſtrata, depoſited from what was ſtill ſuſpended in the waters, and ſo were buried at great depths from the preſent ſurface; when others rolling about among the laſt ſediments of the ſame waters, while yet ſo unfixed as to be carried away with their violence, were finally left on or near the ſurface.

The *quarries* about Broughton ſeem to have been but little diſturbed; and to have been originally the mud which formed the bottom of ſome large freſh water lake; for the ſhells found in greateſt plenty of all there, are freſh water ſhells. Theſe ſeem to have remained in their original mud while turned to ſtone; and the other ſhells, natives of the ſea, which are buried there among them, ſeem to have been ſome of that immenſe number and variety that muſt have rolled along the bottom of that bed of waters; and the viſcid nature of the clay detained many of theſe among its own proper inhabitants, and preſerved them together in its ſtrong ſtate.

Beſide the parts of animals, theſe *quarries* have vegetable matters alſo in them: the leaves and branches of whortles are not uncommon, and pieces of wood turned black and reſembling charcoal are alſo found there. Theſe have been preſerved in the ſame manner with the leaves of fern on the ſlates of our coal-pits, and the plants and fiſhes found in hard ſtone in many of the German mines. Many of theſe vegetable remains are alſo found in looſe nodules of ſtone reſembling pebbles: theſe are not leſs eaſily accounted for than the reſt; for it is not ſtrange to conceive, that leaves and pieces of plants might be, in that general confuſion, received into lumps of clay, which might afterwards be rolled into roundneſs by the motion of the water, and finally received into chaſms of the earth, and there petrified. Phil. Tranſ. N°. 266, p. 685.

QUARTAN, (*Cycl.*) in medicine, the name of a ſpecies of intermitting fever, which returns upon the patient every fourth day, including the days of both the paroxyſms, with a cold fit ſucceeded by a hot one. In this nature is endeavouring to relieve herſelf from ſome noxious matter adhering to ſome of the hypocondriac viſcera, and to prevent the injury that might thence happen to the part, the *quartan* is, by authors, diſtinguiſhed into the ſimple and the continual.

The ſimple *quartan* is the moſt regular of all the ſpecies of intermitting fevers: it almoſt conſtantly ſeizes the patient about four or five in the afternoon with a cold fit; but this is not ſo violent as in the quotidian or tertian, nor does it occaſion any of the ſhaking of the limbs: it is, however very ſenſible, and uſually laſts about two hours. This is preceded and accompanied by a general languor or faintneſs; but is not ſo frequently attended with vomitings as the other intermittents in the time of their cold fit, nor is there any tendency to a diarrhœa; but, on the contrary, the bowels are uſually coſtive, not only on the day of the fit, but on the intermediate ones. The hot fit ſlowly ſucceeds the cold one, and is not ſo violent as in the tertian; but rather is troubleſome from the ſenſation of drineſs it brings on, and is ſeldom ſucceeded by any ſweating. The hot fit uſually continues about four hours, ſometimes ſix, and ſometimes much longer than that in the firſt fits. During the heat the head is vertiginous, and afflicted with a heavy pain, not a very acute one. When the fit is over, the patient returns to tolerable good health again, and remains in that ſtate for the two ſucceeding days, ſaving that he has a foreneſs in the limbs, and a wearineſs and general laſſitude. The fit afterwards returns at the very hour it firſt came on at, and rarely varies at all from this: when it is obſerved to anticipate its uſual time, there is juſt reaſon to fear its becoming continual. The perſons moſt ſubject to *quartans* are thoſe of a middle or advanced age; it rarely happens to young people unleſs epidemic, and of all other perſons, thoſe are moſt ſubject to it who live a ſedentary life, and are of a melancholy diſpoſition.

Cauſes of it. The general cauſe of a *quartan* is a morbid viſcous matter, lodged in the hypocondriac viſcera, and having communication by that means with the vena portæ. The liver, ſpleen, and glands of the meſentery are frequently the ſeats of this, rarely the primæ viæ. That theſe viſcera are affected in *quartans*, is evident from the connection theſe diſeaſes have with their other affections, ſuch as dropſies, jaundice, and the like. The occaſional cauſes are very frequently a quotidian or tertian fever improperly treated, obſtructions or omiſſions of habitual diſcharges of blood, whether by bleeding, or by the menſes, or hæmorrhoids; a heavy diet, without ſufficient drink; a ſudden chilling of the abdomen in a humid air, after the body has been violently heated. The principal time for theſe fevers is the autumn, whence they have been called by ſome *autumnal fevers*; and nothing more endangers their frequent return, than the abuſe of ſtrong liquors, or of acids, which coagulate the blood.

Prognoſtics. The tenacity of the morbific matter in theſe fevers, tho' in but a very ſmall quantiy, yet renders them very difficult of cure. They often laſt many weeks or months, in ſpite of all medicines, and in ſome ages have been accounted the greateſt ſcandal to phyſicians. When it ſeizes a perſon in the ſpring ſeaſon, it is naturally of ſhorter duration; but when it comes on in its more uſual ſeaſon, the autumn, it generally holds the patient till the ſpring. *Quartans* are very apt to return upon people at the ſame ſeaſon of the year at which they firſt ſeized them, eſpecially when they have been but injudicially treated in the cure. It is often, indeed, rather ſuppreſſed than cured, and then returns uſually at ſhorter periods, and often almoſt immediately on feeding heartily, which is commonly the caſe with thoſe who have been freed from it by the bark injudiciouſly given.

It has been already obſerved, that this diſeaſe does not naturally tend to any ſort of evacuation, and when ſuch diſcharges are unnaturally provoked by medicines, as by vomits, purges, and violent ſudorifics, it is eaſily changed into a hectic, or ſome other dangerous chronic malady. A *quartan*, when properly cured, uſually carries off with it all tendency to hypocondriac complaints, to which the patient may before have been ſubject; but, on the contrary, when improperly ſuppreſſed, it too often brings on ſchirroſities of the liver and ſpleen, and of the meſariac glands, with œdematous ſwellings, hectics, aſthmas, and other complaints.

A violent appetite after the fit of a *quartan*, or a tertian fever, is a ſign that the diſeaſe will be very difficult of cure. Eruptions on the ſkin in the time of *quartans*, uſually preſage the going off of the diſeaſe; and ſometimes hard tumors, and bad ulcers in the legs and feet, come on during the time of the ill-

illneſs; theſe generally preſage the going off of the original diſeaſe, but they have in themſelves a worſe complaint in the place of it: and it is obſerved alſo, that œdematous tumors, which have their riſe from ill-cured *quartans*, are much more obſtinate and difficult of cure than any others.

Method of cure. The uſe of the bark is now univerſal in all intermittents, and the ignorant as well as the judicious give it; but there are many authors who are greatly againſt the ſole uſe of it in *quartans*. Stahl ſays, that in this caſe the mucous matter lodged in the hypocondric viſcera, which is the cauſe of the diſeaſe, ſhould be firſt attenuated and incided by the neutral and digeſtive ſalts, as vitriolated tartar and the like; and with the gums, as ammoniacum and ſagapenum, with the roots of arum and pimpernel; and by diluents, which would alſo take off the obſtinate coſtiveneſs of the bowels. That when the matter is by this means fitted for evacuation, it ſhould be thrown off by purges and diuretics, ſuch as black hellebore, mercurius dulcis, and the tartar pills; and afterwards the cure to be compleated by reſtoring the viſcera to their due tone, by means of bitters and ſubaſtringents, as gentian, centaury, and the jeſuit's bark given in ſmall quantities. By this means cures are much more regularly and happily effected than by bark alone. *Junker*'s Conſp. Med. p. 373--376.

Bartholine, in his medical obſervations, gives us a very remarkable inſtance of a cure performed on a perſon long afflicted with a *quartan*, and who had tried all the common methods in vain. He was adviſed by ſome body to drink plentifully of very new beer; he did ſo, and going to bed, ſweat very largely upon it, and was abſolutely cured by it.

Quartans have ſometimes been cured by mercurials. Med. Eſſ. Edinb. abr. Vol. 2. p. 317.

The *quartan* ague is ſaid to be cured by a medicine compoſed of euphorbium, reſin of jalap, merc. dulc. and ſugar.

Continual QUARTANS, in medicine, the name given to a ſpecies of compound fever, which has the paroxyſms of a common *quartan*; but in which the heat never goes wholly off, but continues till the time of the ſucceeding fit. In all reſpects, except the regular returns of the paroxyſms, this diſeaſe greatly reſembles a hectic.

Signs of it. Every fourth day there is a regular paroxyſm, which begins with a coldneſs and ſhivering: this, however, does not return exactly to an hour, as the ſimple *quartan* does in its fits; but uſually the ſucceeding fit anticipates the time of the former. When the cold fit is over, there comes on a violent day-burning; the heat is much greater the firſt day than the ſucceeding ones, but continues in ſome degree till the fourth day, when the cold fit returns again, and the patient is ſeldom able to keep long together out of bed in the whole time. There is a continual thirſt and drineſs of the mouth, and the ſaliva is very little in quantity and very frothy; the appetite is bad, and the patient uſually has more inclination to ſalted and cold foods than any other; the head is diſordered rather than aking, and there is a continual deſire to ſleep, but what ſleep the patient has is troubled and unſound, and gives very little refreſhment; the urine during the whole courſe of the diſeaſe, reſembles that of hectical patients, and is reddiſh and turbid, depoſiting, after a time, a roſe-coloured ſediment.

Perſons ſubject to it. This diſeaſe is frequently brought upon perſons who have had a common *quartan*, by the injudicious treatment of that diſtemper, and particularly by the taking hot medicines in it before the approach of the fit; the too free uſe of aſtringents has alſo in many caſes changed that diſeaſe into this. People of a middle or more advanced age are more ſubject to it than youth; and of theſe, ſuch are principally ſeen to be afflicted with it as are of a melancholic habit and ſedentary life.

Prognoſtics in it. This diſeaſe, tho' in itſelf leſs dangerous than many others, yet very eaſily changes, under improper management, into a hectic, and ſometimes into a dropſy. This is the caſe not unfrequently when it is treated with large repeated doſes of aſtringents; on the other hand, when it is treated with vomits and a hot regimen, it eaſily paſſes into an acute and dangerous inflammatory fever.

Method of cure. Toward the time of the fit there ſhould be given powders compoſed of the digeſtive ſalts, ſuch as vitriolated tartar, with crabs-eyes, ſaturated with lemon juice. So long as the heat continues violent, the perſon is to be kept quiet, and to drink plentifully of warm and weak liquors; and in the following days, when the heat is obſerved to be decreaſed, gentle purges are to be given, with gentle aperitives, and reſolvents, ſuch as the decoctions of dandelion and ſuccory roots; and toward evening, a gentle doſe of ſome anodyne, as the ſtorax pill and the like. The common violent methods by vomits, bleeding, ſtimulating purges, and hot alexipharmics, have no place in the cure of this diſeaſe; but, on the contrary, violently diſturb nature, and add to the complaints. Abſorbents in large quantities are alſo to be avoided, leaſt the viſcid matter which is the cauſe of the diſeaſe ſhould be increaſed by their effects: and when the patient is happily cured, he is not immediately to abſtain from medicines, ſince relapſes are very frequent. Digeſtives and ſtomachics taken for ſome weeks after, is the way to prevent them. *Junker*'s Conſp. Med. p. 209, 401.

QUARTARIUS, a meaſure among the antients, being the fourth part of a ſextary, and nearly equal to a quarter of a pint of our wine-meaſure.

QUARTATION, (*Cycl.*) in metallurgy, is the ſeparation of ſilver from gold by means of aqua fortis; which is an operation that has ſomething ſingular in it.

If ſilver and gold are mixed together into a maſs, and the gold is not leſs than one third part of the maſs in weight, the beſt aqua fortis poured upon it is not at all capable of diſſolving the ſilver; but if you add more ſilver to this maſs, by melting it again in the fire, with ſuch a neceſſary addition of that metal alone as ſhall bring the gold in the maſs to the proportion of leſs than one third of the whole, and ſuffer it to cool, then aqua fortis poured on it will corrode the ſilver from it: this is alſo by ſo much the more ſtrongly performed, as the quantity of gold is leſs than in the proportion of one third of the whole maſs; but experience has taught us, that aqua fortis diſſolves ſilver mixed with gold quickly enough when the gold conſtitutes but one, and the ſilver three parts of a mixed maſs of them: and in this caſe, if the ſolution is not too impetuouſly performed, the gold uſually remains in ſuch a proportion, in the ſame figure that the whole maſs had before the ſeparation of the ſilver by this menſtruum; ſo that in this caſe, there is no reaſon to apprehend the gold's being torn into minute particles, and diſſipated in ſome meaſure; tho' this can hardly be prevented when the ſilver exceeds the three quarter proportion, in regard to the gold in the maſs. The artificers, therefore, always make it their ſtudy to obſerve very exactly this proportion of the gold being one fourth part of the mixture; and thence it is that the operation itſelf has been called *quartation*.

From this operation we may learn how fallacious the examination made with aqua fortis alone of the gold rubbed on the touchſtone, muſt neceſſarily prove. *Cramer*'s Art. aſſ. p. 195.

QUARTER *(Cycl.)*—QUARTER, in corn meaſure, ſeems to have ſignified originally the fourth part of a ton in weight, or capacity. See WEIGHT.

QUARTER-*chord*, in mining, is ſeven yards and a quarter, which the miner hath croſs-ways of his vein on either ſide, for liberty to lay his earth, ſtones, and rubbiſh on, and to waſh and dreſs up his ore. *Houghton*'s compl. Miner in the Explan. of the Terms.

QUARTER *of a ſhip*, is that part of the ſhip's hull which lies from the ſteerage-room to the tranſom.

Cloſe QUARTERS, in a ſhip, thoſe places where the ſeamen *quarter* themſelves, in caſe of boarding, for their own defence and clearing the decks, *&c.*

Fat QUARTER, in a ſhip. See FAT, *Cycl.*

QUARTER-*maſters*, or QUARTEERS, in a man of war, thoſe officers whoſe buſineſs is rummaging, ſtowing, and trimming the ſhip in the hold; to overlook the ſteward in his delivery of victuals to the cook; and in pumping or drawing out beer, or the like. They alſo are to keep their watch duly, in conding the ſhip, or any other duty.

QUARTER-*point* of the compaſs. See POINT, *Cycl.*

QUARTER-*wind*, at ſea, that which comes in abaft the main-maſt ſhrouds, even with the *quarter* of the ſhip.

QUARTER, in the manege. To work from *quarter* to *quarter*, is to ride a horſe three times in end upon the firſt of the four lines of a ſquare; then changing your hand to ride him three times upon the ſecond; and ſo to the third and fourth, always changing hands and obſerving the ſame order.

QUARTERS *of a ſaddle*, are the pieces of leather or ſtuff made faſt to the lower part of the ſides of a ſaddle, and hanging down below the ſaddle.

QUARTERS *of a horſe*, are the ſhoulders and fore-legs, called *fore-quarters*; and the hips and hinder legs, called *hind-quarters*.

QUARTERS *of a horſe's foot*, are the ſides of the coffin, comprehended between the toe and the heel on one ſide and t'other of the foot. The inner *quarters* are thoſe oppoſite to one another, facing from one foot to the other; and theſe are always weaker than the outſide *quarter*, which lie on the external ſides of the coffin.

QUARTER-*caſt*. A horſe is ſaid to be *quarter-caſt* when, for any diſorder of the coffin, we are obliged to cut one of the *quarters* of the hoof; and when the hoof thus cut grows anew, it is called *new quarter*.

Falſe QUARTERS, a cleft in the horn of a horſe's *quarters*, extending from the cronet to the ſhoe, which voids blood, and occaſions a great deal of pain, and makes the horſe lame.

QUARTERING *the men*, in the ſea language, the diſpoſing of the ſhip's company at the time of an engagement in ſuch a manner, that each may readily know where his ſtation is, and what he is to do: as, ſome to the maſter, for the management of the ſails; ſome to aſſiſt the gunners, to traverſe the ordnance; ſome for plying the enemy with ſmall ſhot; ſome to fill powder in the powder-room; others to carry it from thence to the gunners in cartridges, *&c.*

QUARTUM *par conſtringens*, in anatomy, a name given by Spigelius and ſome others to the muſcle called by Albinus and Riolanus *orbicularis oris*; and by Cowper and ſome others, *conſtrictor labiorum*.

QUARTUS *hyoidis muſculus*, in anatomy, a name given by

Veſalius, Fabricius, and many other anatomiſts, to a muſcle now generally called the *coracohyoidæus*.

QUARTUS *oculum movens*, in anatomy, a name given by Veſalius to one of the muſcles of the eye, called by ſome *rectus inferior*, and by others *humilis*.

It is the *depreſſor oculi* of Albinus, being one of the *quatuor recti oculi* of that author.

QUATERNA *folia*, among botaniſts. See LEAF.

QUATOTONI, in zoology, the name of an American bird of the wood-pecker kind, having a red creſt on its head, and two white lines running down the ſides of the neck to the breaſt. It is called by Nieremberg *picus imbrifœtus*.

QUATRICHROMA, in the Italian muſic, is what we call a *demi-ſemi-quaver*, thirty-two whereof make a bar in common time. See TIME, TRIPLE, and BISCHROMA.

QUAVITL, in botany, a name given by ſome authors to the cocoa-tree. *Hern.* p. 79.

QUAUHAYQHUATLI, in botany, a name by which ſome authors have called the tree whoſe fruit is the caſſia fiſtula of the ſhops. *Hern.* p. 87.

QUAUHTZONECOLIM, in zoology, the American name for a bird called by moſt a *quail*, but eſteemed by Nieremberg a ſpecies of partridge.

It is of the ſize of the European partridge, and of a browniſh colour, and ornamented with a creſt upon its head. There are alſo in America two other ſpecies of partridge much allied to this, the one with a yellow body, and black and white head; the other ſmall and brown, and without a creſt. *Ray*'s Ornithology, p. 304.

QUEEN *(Cycl.)*—QUEEN-*bee*, a term given by late writers to what uſed to be called the *king-bee*, or king of the bees; a large and long-bodied bee, of which kind there is only one found in every ſwarm, and which is always treated with the greateſt reſpect by the reſt.

This is, indeed, the parent of the ſwarm, and from the fœcundity of this one female, a whole hive is eaſily and ſoon repeopled.

It is to be obſerved, that the autumn and winter ſeaſons deſtroy a great number of the bees; ſo that a hive, which was full in the ſummer, is often found ſo thinly peopled before the end of winter, that the bees ſeem only a few inhabitants in a very large city: by midſummer again this ſame hive ſhall, however, be found ſo well filled with inhabitants, that there ſhall be a neceſſity of ſending out a colony in the name of a new ſwarm, and yet the hive will remain as full as it can well hold. This increaſe might well appear very amazing, if all the remaining bees of the hive were ſuppoſed to be females, and to join in it; but how much more ſo when it muſt be acknowledged, that it is all owing to one female, and that this *queen-bee*, or bee-mother, alone, has given origin to ſuch an immenſe progeny?

The form of this bee, and there being only one ſuch in a hive, naturally led all who ſaw it into an opinion of ſomething ſingular in its nature, and the antients determined that it muſt be the king over the reſt: they made it an abſolute monarch, and have ſuppoſed that all the buſineſs of the hive was done by its immediate orders; and that the ſeveral parties of bees allotted to work in the making the combs, in the filling their cells, in the ſtopping the crevices of the hives, and in carrying away the filth, *&c.* had all their ſeveral ſtations allotted them by this wiſe and provident monarch. This was giving great talents to the monarch-bee; but this was mere fancy, and it is plain, that if this creature rules, it is over a people who all perfectly well know their ſeveral buſineſs: but it rather appears, that there is no ſovereignty at all, but that this creature is reſpected in a very high degree by the reſt as the common parent of the whole nation.

There were not wanting among the antients, however, ſome who believed this large bee to be a female, and theſe pretend that ſhe brought forth only females like herſelf, which ſucceeded her in her reign. They had a very different opinion as to the origin of the common bees, not ſuppoſing them generated of animal parents like themſelves, but produced out of corruption, and born of the fleſh of a bull or cow. Among the later writers this opinion, notwithſtanding the ſanction of the poet Virgil, has been laughed out of the world; yet it was long before the true origin of bees, even after this, was known. The author of the female monarchy, tho' well apprized of this great bee being of the female ſex, yet ſuppoſed that ſhe only produced young ones like herſelf; and pretended that the common bees copulated together for the production of other bees like themſelves: this, however, has been ſince found to be wholly erroneous, the female, or *queen-bee*, giving birth to all, and theſe common bees being of no ſex at all.

Many of the authors who have not given into the idle opinion of the bees being bred of putrid fleſh, have yet given them an origin not leſs idle and ridiculous. They pretend that the bees are exempted from the pain of producing either eggs or young; and that their offſpring are formed of the juices of flowers, the different kinds, as the drones, females, *&c.* owing their riſe to juices of different kinds. Theſe, and a number of other falſe notions, have been propagated in regard to bees; but their true origin could not well be found till we were in a condition to ſee what paſſes at certain times within the receſſes of the hive, which is done by the uſe of that excellent invention the glaſs hive. By this, and by the help of diſſections, we may eaſily inform ourſelves perfectly of the true ſtate of the caſe.

The parts of generation are the ſubjects of our enquiry for this purpoſe, and tho' the bodies of theſe animals are ſo ſmall, theſe are uſually ſufficiently large to be diſtinguiſhed, often taking up more room in the abdomen than all the other parts together. Thus, if the large long-bodied bee be opened, the abdomen will be found to contain vaſt numbers of oblong bodies, which any one acquainted with inſects will eaſily diſtinguiſh to be eggs: vaſt numbers of theſe are large enough to be obſervable by the naked eye, but when the aſſiſtance of glaſſes is called in, there are diſcerned a vaſt number of other ſmaller eggs, which exceed all computation. It is eaſy to determine from this, that this creature, ſo long eſteemed a male, is in reality a female, and is in condition to give birth to a very numerous poſterity.

In order to diſtinguiſh this, however, a proper time muſt be choſen for the diſſection, and the moſt proper of all is when the creature is juſt ready to depoſit her eggs. This is in the months of April and May, and the moſt certain time of all is when ſhe is in a hive where a new ſwarm have been received about ten days before: if ſhe be diſſected at other times, the eggs are leſs viſible; and particularly in winter, there requires a good glaſs to ſhew the rudiments of them. This is a diſagreeable experiment, indeed, becauſe it is always the deſtruction of a future ſwarm; all the eggs we ſee in the diſſected female being what would have produced bees to labour for our benefit.

When the body of one of the drones is opened, there is found, inſtead of theſe vaſt numbers of eggs, a part ſeeming proper for a male organ of generation; and in the abdomen a number of veſſels running in ſeveral windings and contortions, and filled with a milky humour. Theſe ſeem deſtined for the important uſe of impregnating the eggs in the belly of the female, and it is very natural to determine from this that theſe are the males.

The common bees, when diſſected, at whatever time of the year, never ſhew the leaſt marks of any ſex at all. The inteſtines of theſe bees are found at times to be more or leſs diſtended with honey, and with rough wax; but there are never diſcovered any eggs, nor any of the winding ſeminal veſſels, ſo that it is plain they have no ſhare in propagating the ſpecies: and the obſervation of the ſwarms from time to time, with the aſſiſtance of glaſs hives, gives proof to what the diſſections ſeem to make ſufficiently certain without this evidence.

The female bee reſides within the center of the hive, always living in one of the ſpaces between the combs; if ſhe occaſionally comes out to the ſurface, and is ſeen walking over the edge of a comb, ſhe is to be well obſerved at thoſe times; for her only buſineſs is the laying her eggs in ſome of the empty cells of that part of the comb, which done, ſhe always retires again.

In order to ſee the female, or mother bee, employed in this operation, we are to obſerve in the morning hours, between ſeven and ten, what paſſes in a glaſs hive into which a ſwarm have been received a few days before. The ſpeed with which the common bees labour in making their combs on this occaſion is almoſt incredible, and they ſeem not only to labour to have cells to depoſit their honey in, but to know that the parent bee is at this time loaded with eggs for the production of a numerous progeny, and that ſhe has an immediate neceſſity of cells for the depoſiting them in. This neceſſity is ſo urgent, that ſhe is often forced to depoſit them in cells not yet finiſhed; tho' the bees labour ſo vigorouſly, that they often will erect a whole large comb in one day. If the hive be narrowly watched at theſe times in the morning hours, the female bee will be ſoon found employed in her work, and will be ſeen dropping her tail by turns into ſeveral cells every day. If the combs be examined a day or two after this, they will alſo be found to contain the eggs; one of theſe is placed in each cell, and appears in form of an oblong white body, fixed either to the ſolid angle of the baſe, or to one of the angles compoſed by the rhombs which form the triangular baſe of the cell, and is always attached in ſuch a manner, that it lies nearly in an horizontal poſition.

The flat glaſs hives are the moſt favourable for the making theſe obſervations, ſince in thoſe the combs are ſo narrow and ſo numerous, that the whole is taken in view at a time, from one ſide or the other; and there are always ſeveral combs to be made choice of for the operation; in the morning hours of April and May, the female mother bee will be uſually ſeen walking very ſoberly over one or other of theſe combs, attended by a guard of about twenty of the common bees, all placing themſelves in ſuch a manner, that their faces are turned toward her, and all paying her the greateſt marks of homage and adoration. As ſhe walks along in this ſtate, ſhe examines every cell as ſhe paſſes over, and ſuch as ſhe finds yet empty, and fit for her purpoſe, ſhe reſts at; and introducing the hinder part of her body at the top, plunges it ſo deep in that her tail touches the bottom. Then ſhe depoſites one egg and no more,

more, and this is at that time covered with a glutinous matter, which faſtens it to the place where it is laid: from this cell the female paſſes to ſeveral others, where ſhe depoſits her eggs in the ſame manner.

Some authors who have written of the polity of bees, have repreſented the time of the female bee's laying her eggs as a ſeaſon of feſtivity and rejoicing in the hive; but this does not at all appear to be the caſe, the few bees which attend her on this occaſion ſeem the only ones that know any thing of the matter, and their behaviour ſavours more of homage and reſpect than of joy: they are continually ſtroking and bruſhing her clean with their legs and with their trunks, and offer her from their own mouths the fineſt honey, when ſhe has occaſion for food. The reſt are all employed in their proper offices, and the work of the hive goes on as uſual; and, indeed, it is well that it does ſo, for this time of rejoicing would be of very bad conſequence to the affairs of the hive, if carried on as ſuppoſed, ſince the female bee is thus employed, more or leſs, during the whole ſummer months.

When the female bee has laid ſix or ſeven eggs, ſhe always takes a time of reſpite or repoſe; and during this time, the bees which form her levee are doubly buſy in their careſſes, ſome bruſhing her head and breaſt with their trunk, but ſeveral being always employed together to cleanſe the hinder rings of the body, which have been fouled by being thruſt into the cells. When this is done, ſhe begins again; but Mr. Reaumur obſerves, that he never could ſee a female lay more than ten or twelve eggs at one time: he ſuppoſes that his preſence diſturbed the creature, and finally drove her into the inner parts of the hive, where ſhe might continue her works in cells leſs expoſed. It is not difficult to compute the number of eggs which the female lays every day, from the ſwarm which is ready to leave the hive at the end of May: this ſwarm uſually amounts to at leaſt twelve thouſand, and as the hive out of which theſe depart is not the leſs peopled by their loſs, it is evident that they were all the produce of the eggs depoſited by the female in the preceding months of April, with a part of March, and a few of the firſt days of May. On a moderate computation on theſe principles it will appear, that the female bee cannot lay leſs than two hundred eggs every day, for a long ſpace of time together; and this, tho' ſeemingly a monſtrous increaſe, is yet much leſs than that of ſome other of the winged inſects, in one of which, a two-winged fly, that author counted no leſs than twenty thouſand living worms, all ready to be depoſited by the parent, and to become flies of the ſame kind.

It has been ſtrongly objected againſt this ſyſtem, that tho' the female bee lays eggs, ſhe is not the only one that lays; and many will not give up the opinion of the common bees alſo laying ſome eggs, tho' but a few in number; obſerving, that if each of theſe lay only four or five eggs, it would be enough to give birth to a whole ſwarm, without ſuppoſing that this prodigious fœcundity belonged to the female bee alone: but this is running into the old error of the female producing only females like herſelf; whereas if we obſerve the cells in which we ſee the female depoſit her eggs, we ſhall in the ſequel find the common bees produced from theſe eggs, and iſſuing out of theſe cells: this is a ſufficient proof to any fair reaſoner, ſince it appears very plain, that if the female produces them, they do not produce one another. It is alſo evident, that not only theſe common, or working bees, but alſo the drones, or male bees, are produced from the eggs of this ſame female; and there is this remarkable forecaſt in the female, that ſhe always depoſits the eggs which are to give origin to theſe, in peculiar cells, proper for the reception of the worms which are to be hatched from them. It is to be obſerved, in examining a hive, that there are always ſome combs, or ſome parts at leaſt of combs, the cells of which are much larger than thoſe of the other parts or combs: theſe large cells are deſtined for the reſidence of the larger worms, which are to produce the drones or male bees It has been obſerved as a miraculous ſingularity by ſome, that the female bee always knows before hand, whether the egg ſhe is going to lay will produce a male or a common bee; and that according to this knowledge, ſhe never depoſits the eggs for a male in a ſmaller cell, nor that of a common bee in a large one; but there is, in reality, leſs wonder in this than is ſuppoſed, for the eggs of which the drones are to be hatched are much larger while in the body of the female than thoſe of which the common bees are to be produced, and the whole occaſion of this choice in regard to the placing of them is, that when the creature finds a large egg coming forth, ſhe ſeeks one of the large cells to depoſit it in; and when the common ſmall eggs are coming, ſhe contents herſelf with the common cells.

It is very natural to believe, that the female bee lays a third kind of eggs; and that beſides producing many thouſand common, or working bees, and many hundreds of the males or drones, ſhe ought to lay one egg at leaſt capable of producing a female like herſelf, which is to be the mother of a future progeny, and the *queen* of the preſent race; ſince without ſuch a one for their leader, the young brood would never leave the hive in nature of a colony, and ſettle themſelves elſewhere.

What we thus perceive ought to be the caſe, is alſo found in reality to be ſo, and the female, beſides the other kinds of eggs, is found by a ſtrict obſervation to lay alſo eggs of this kind. We might perhaps only expect one female bee to be produced for each ſwarm, but as nature has ſeemed every where prodigal in the manner of the increaſe of her works, ſo it is in this caſe alſo. What millions of ſeeds are produced on a common elm-tree, for one that ſtrikes and ſucceeds ſo well as to grow up to be a tree? And of the number of young produced from the ſpawn of a carp, how few live to the ſize of a parent? Thus it alſo is in regard to the female bees; nature, tho' it has allotted only one of this kind, as abſolutely neceſſary to the new ſwarm, yet has given abundance of chances for that one to ſucceed, by the female's uſually laying at leaſt ten eggs for the production of the female offſpring, and often not leſs than twenty: there are, indeed, ſome ſeaſons when not one female is produced; but in theſe ſeaſons there is no ſwarm going out from the old hive, the creatures being informed by nature, that they have no buſineſs for combs and cells when they can have no offſpring to rear in them.

The working bees are not only very obedient to, and very careful of their *queen*, or female parent; but they are alſo very ſolicitous about her progeny. This is very evident in the ſtructure of the cells, which they prepare for the reception of thoſe eggs which are to be hatched into females. It has been before obſerved, that they prepare larger cells for the eggs which are to become drones, or male bees, than for thoſe which are to produce workers like themſelves. The large cells deſtined for the drones are, however, of the ſame ſhape and figure with the others, differing only in ſize; but this is not the caſe with thoſe deſtined for the female offſpring: theſe are not only very large, but very clumſily contrived, for the ſake of ſtrength; their ſides being much thicker than thoſe of the reſt, and their figure oval. The bees are extremely ſparing of their wax on all other occaſions, but for the conſtruction of theſe royal cells, as they may not improperly be called, they are as remarkably profuſe: one of the royal cells will weigh more than an hundred and fifty of the common kind. The bees are no more ſparing of the room than of the materials in the conſtruction of theſe royal habitations: they are often placed near the center of a comb, and a vaſt number of other cells are deſtroyed for their baſe; often alſo they hang down from the reſt of the comb, in form of ſtalactitæ from the roofs of ſubterraneous caverns.

A cell of this kind, when firſt formed, repreſents an acorn cup; but it is ſoon lengthened beyond the poſſibility of retaining that figure, and it remains thus till the creature is hatched from the chryſalis or nymph ſtate, and comes out of it; after which the bees, to loſe no room in the hive, form other common cells upon it, and the only remaining mark of the female cell, is the appearance of a knot in the place where it once ſtood.

The number of cells deſtined to receive the eggs which are to produce female bees are ſo few, and they are commonly placed in ſuch cloſe parts of the hive, that there is no great probability of the ſeeing the female employed in laying her eggs in them: there is no reaſon to doubt the fact, however, ſince when we know that ſhe lays eggs for the production of the male and the working bees, there is no wonder that ſhe ſhould alſo lay ſome for the production of females like herſelf.

It might ſeem much harder to conceive how ſo vaſt a number of bees ſhould be produced from this one, as we know are produced from her; but when one of the females is opened, the vaſt number of eggs diſcovered in each of her ovaries makes the prodigious increaſe no way wonderful.

Swammerdam obſerved, that the number of veſicles in the ovary of the female bee, was aſtoniſhingly great; he eaſily counted an hundred and fifty in each ovary, and could count about ſeventeen eggs in each veſicle large enough to be diſtinctly viſible; each ovary contains, therefore, two thouſand five hundred and fifty eggs, and both ovaries five thouſand one hundred. When we find ſo many eggs at once diſtinguiſhable by their ſize, it will be eaſy to conceive, according to the common courſe of nature in the propagation of inſects, that there may be more than as many too ſmall to be yet diſtinguiſhable; and at that rate, the number of twelve thouſand bees, which is the quantity that compoſes a moderate ſwarm, is not wonderful for the product of the eggs of one female for one ſeaſon. *Reaumur*'s Hiſt. Inſ. Vol. X. p. 111--126.

QUEI, in natural hiſtory, a name given by the Chineſe to a peculiar earth found in many parts of the Eaſt.

It is of the nature of an indurated clay, and in ſome degree approaches to the talcs, as our ſteatites and the galactites do. It is very white and abſterſive, uſed by the women of China to take off ſpots from the ſkin, and render it ſoft and ſmooth, as the Italian ladies uſe talc of Venice. They ſometimes uſe the fine powder of this ſtone dry, rubbing it on the hands and face after waſhing. Sometimes they mix it in pomatum. *Kircher*'s China Illuſtrat.

QUEM *redditum reddit*, in law, an old writ which lay where a rent-charge, or other rent, which was not rent-ſervice, was granted by fine holding of the grantor. If the tenant would not attorn, then the grantee might have had this writ. Terms of law.

QUEMI, in botany, a name uſed by ſome authors for the nigella, or geth. *Ger.* Emac. Ind. 2.

QUERCERA, in medicine. See EPIALOS.

QUERCUS, the *oak*, in botany, the name of a genus of trees, the characters of which are theſe: the flower is of the catkin kind, and is compoſed of a great number of apices affixed to an axis by ſlender capillaments, and ſtanding in thick cluſters. Theſe are male or barren flowers, and the embryo fruit grows in other parts of the ſame tree: theſe finally ripen into acorns ſurrounded with their cups, and containing a kernel which readily ſplits into two parts. To theſe characters it is to be added, that all the *oaks* have ſinuated leaves.

The ſpecies of *oak*, enumerated by Mr. Tournefort, are theſe: 1. The broad-leaved *oak*, with ſhort pedicles, called by authors the *male-oak*. 2. The broad-leaved *oak*, with longer pedicles, called by authors the *female-oak*. 3. The ever-green broad-leaved *oak*. 4. The common *oak*, with very long pedicles. 5. The ſmall *oak*, called the *phagus* and *eſculus* by the old writers. 6. The *oak*, with large acorns and echinated cups. 7. The *oak* with ſmall acorns and rough cups. 8. The Burgundy *oak*, with rough acorn cups. 9. The dwarf *oak*, which ſeldom grows to more than a foot high. 10. The woolly-leaved *oak*. 11. The ſmall gall-bearing *oak*. 12. The *oak* with prickly, not woolly leaves, producing ſmall galls. 13. The ſmaller prickly-leaved *oak*. 14. The dwarf gall-*oak*, with cluſtered galls. *Tourn.* Inſt. p. 82. See OAK.

QUERCUS *marina*, the *ſea-oak*, in botany, the name of one of the broad-leaved dichotomous ſea-fucuſes.

It is not agreed among the late botaniſts what was the *ſea-oak* of Theophraſtus; and the moſt antient botaniſts, Cluſius and Cæſalpinus ſuppoſe it to have been a ſpecies of the ſhrubby coraline; but that ſeems by no means to have been the caſe, ſince Theophraſtus ſays his *ſea-oak* had a long, thick, and fleſhy leaf, whence we may much more naturally conclude it to have been of the fucus claſs. *Park.* Herb. 294. Gen. 1378, *&c.* *Dale*, Pharmac. p. 56.

QUERFAA, in the materia medica of the Arabians, a name given by Aviſenna and others to cinnamon, when gathered with the wood of the young branches.

It was a common practice in the early times not to ſtrip the ſmall bark from medicinal trees, but to cut off the little boughs and uſe them bark and wood together. This the Greeks called *xylo-cinnamomum*, or woody cinnamon, and the Arabians *querfaa*, *querfe*, or *kerfe*.

QUERQUEDULA, in zoology, the name by which authors call the teal.

This is the ſmalleſt of all the duck kind. Its beak is black, and its head and the upper part of its neck of a reddiſh brown; but there runs on each ſide of the head a green ſtreak from behind the eyes quite to the back part, and between theſe there is a black ſpot under the eyes; there is a white line which ſeparates the reddiſh colour from the green. The lower part of the neck, the ſhoulders, and the ſides are very beautifully variegated with black and white ſtreaks. The breaſt and belly are of a duſky greyiſh white. The wings have ſome white in them, and the legs are of a pale brown. There is a black ſpot on the rump in the male, which is wanting in the female. The head alſo in that ſex is leſs beautifully coloured. *Ray*'s Ornithol. p. 290.

QUERQUEDULA *criſtata*, the *creſted teal*, a name given by Bellonius and ſome others to a ſpecies of duck, remarkable for a tuft of feathers of an inch and an half long, hanging down from the back part of its head, and thence called the *tufted duck*; but more known among authors by the name *capo negro*. *Bellonius* de Avib. See CAPO *negro*.

QUESTOR *(Cycl.)*—The *queſtorſhip* was called the firſt ſtep of honour, and the *queſtors*, who were generally employed in the provinces abroad, aſſigned to them ſeverally by lot, no ſooner returned from their provincial adminiſtration, than they took their places in the ſenate; and from that time forward, from the rank of equeſtrians, or what we commonly call knights, became ſenators for life. *Middleton* of Rom. Senate. p. 6, 7. See SENATE and SENATOR.

QUI *tam*, in law, is uſed where an information is exhibited againſt any perſon on a penal ſtatute at the ſuit of the king, and the party who is informer, when the penalty for breach of the ſtatute is to be divided between them; and the party informing proſecutes for the king and himſelf. *Finch* 340.

QUICKSILVER *(Cycl.)*—This mineral is frequently found native in the earth, in its own fluid form; ſometimes lying in large quantities together in the accidental cavities of ſtone, and running out in a ſtream as the miners break the maſſes: but this is leſs frequent; its more common appearance being in ſmall parcels, and often in ſingle globules, ſcarce large enough to be ſeen by the naked eye, lodged in great abundance in the pores of a ſoft foſſile ſtone, of a pale bluiſh colour, from which it is eaſily ſeparated by pounding and waſhing. It is alſo found in ſome places lodged in the ſame manner in ſome of the harder ſtones, and in various ſpecies of earths.

Tho' *quickſilver* be, however, often found native, yet we much more frequently find it in the form of an ore; its particles being penetrated by, and intimately mixed with ſulphur, and the concrete being by no means to be known for *quickſilver* to the naked eye, but being a red maſs of a ſtony hardneſs, called *cinnabar*: and we are very ſure that it is *quickſilver* penetrated by ſulphur that makes this ore, ſince we are not only able to ſeparate *quickſilver* eaſily from it; but by a mixture of *quickſilver* and ſulphur, we are able to make a red ſtony maſs perfectly the ſame with this.

The cinnabar is of a different form and appearance, according to the quantity of ſulphur it contains, being uſually ſtriated, and that ſometimes with broader, ſometimes with finer ſtriæ; and the quantity of *quickſilver* in this is very great, the richeſt maſſes containing ſix parts *quickſilver* to one of ſulphur; and the poorer uſually half. It is ſometimes found in large and pure maſſes, and ſometimes in ſmaller particles, lodged in different earths and ſtones. Theſe are ſometimes few in number and placed ſeparately, and ſo of little value; but in other maſſes they are placed very thick in congeries, and are then ſeparated by pounding and waſhing, and worked for *quickſilver*.

Beſide this pure ore of *quickſilver*, there is another much leſs rich; but which is worked in ſome places to conſiderable advantage: as the former is a mixture of *quickſilver* and ſulphur alone, this is a mixture of thoſe two, and of many other ſubſtances, and appears in form of a moderately hard ſtone, uſually of a duſky orange colour; but not rarely of a greeniſh brown, and ſometimes blackiſh. This has very little brightneſs, and nothing of the ſtriated texture of the cinnabar.

The manner of ſeparating *quickſilver* from its ores, is by pounding them, and waſhing off the ſuperfluous matter by repeated affuſions of water; then adding iron filings to the remainder, the whole is diſtilled in large iron retorts, and the mercury comes over pure into the receiver. In ſome places where the ore is very rich, they only powder it, and put it into long-necked earthen veſſels, which they ſtop with bundles of moſs: theſe they invert into other veſſels buried in the ground, and then making a fire about them, the *quickſilver* becomes ſeparated and drains through the maſs into the underpots. *Hill*'s Hiſt. of Foſſ. p. 627.

It is very difficult to bring *quickſilver* to the great teſt of the burning-glaſs, by which all the other imperfect metals are eaſily tried; but with proper cautions ſomething is to be learned of it by this means:

If *quickſilver* be expoſed to the focus on a piece of charcoal, on a tile, or in a coppel, the effect is the ſame, it very ſoon is wholly diſſipated in form of a thick ſmoak; but if precipitate *per ſe*, that is, mercury calcined alone by a long digeſtion on a ſlow fire, be placed in the focus, it ſeems at firſt to melt and run, but immediately after is diſſipated in a thick ſmoak, leaving a ſmall quantity of an extremely fine powder upon the tile, in form of a ſhort down. This powder, on being continued in the focus, finally runs together into a yellowiſh glaſs; in ſeveral parts of which there may be diſtinguiſhed ſmall white, ſhining, metalline particles, which ſeem to be *ſilver*.

If the precipitate *per ſe* be expoſed to the focus on a piece of charcoal, it is ſeen to melt and run into ſmall globules of pure mercury, which ſoon after begin to fume and are diſſipated entirely. It appears, therefore, upon the whole, that there is in *quickſilver* an oil, which may be ſeparated by long digeſtion over a ſlow fire; and that the matter diveſted of that, is no longer mercury, but a mere calx or a red earth, this being properly the baſis of this metal; that this calx does not vitrify in the manner of the other calxes of the metals, being too volatile for that, and eaſily flying off in the fire; and finally, that this oil of mercury is not different from the other oils, even thoſe of the vegetable kind, ſince common charcoal could ſupply its place by means of its oil, and reſtore the calx to running mercury again. As to the ſmall remainder of earth, after the diſſipation of the calx of mercury, which run into glaſs with metalline ſpecks, it is much to be queſtioned whether it be not owing to ſome impurity in the mercury. Mem. Acad. Par. 1709.

The mines of Friuli afford at preſent very large quantities of *quickſilver*, ſome native, or virgin, which they call *jung-frau*, and obtain either out of natural beds in the rocks, or by waſhing the ore in which it lies diſperſed in ſmall globules; but the far greateſt part is not viſible to the eye in the form of *quickſilver*, nor can be ſeparated from the ore without the help of fire. Kircher, in his Mundus ſubterraneous, gives a moſt frightful deſcription of this mine; but it is not more terrible than others of the ſame kind. It is remarkable, that the entrance into it is not high up in the hills, as is uſually the caſe; but upon a level ground, and in the ſtreets of the town. This ſubjects them to great inconveniences from water, but they have admirable machines for the draining it out again. The deſcent is by ladders near ninety fathoms down.

There are no damps in theſe mines, but the miſchiefs of the mercury itſelf getting into the bodies of the workmen are much greater and more general, tho' not ſo ſudden, as the effects of the damps in our lead and coal mines, and the like places.

The elaboratory belonging to theſe mines has furnaces capable of working fifty retorts at a time. There are generally ſixteen of theſe furnaces at work at once, ſo that eight hundred retorts are the general number in conſtant uſe.

The retorts ſtand in double rows on each ſide the furnace, a row of thirteen below, and a row of twelve above.

The antients all eſteemed *quickſilver* a poiſon, and it muſt be allowed to have diſmal effects; the unhappy people employed in preparing it ſeldom live more than three or four years, and then die miſerably: and ſuch as take it internally, or by way of unguents, without great care, often ſuffer for their imprudence.

Under proper regulation, however, it is a moſt powerful and noble medicine, opening obſtructions, and attenuating viſcid humors in the very remoteſt parts of the body.

The preparations of *quickſilver* now in uſe are, 1. Æthiops mineral. 2. Factitious cinnabar. 3. Corroſive ſublimate. 4. Mercurius dulcis. 5. Mercurius calcinatus, commonly called *precipitate per ſe*. 6. White precipitate. 7. Red precipitate, or red corroſive mercury. 8. Coralline mercury. 9. Turbith mineral. See MERCURY, *&c.*

Water in which *quickſilver* has lain for ſome time, tho' inſipid, is ſaid by Van Helmont to deſtroy worms; and Mr. Boyle ſeems to recommend it as an innocent and effectual coſmetic. Works abr. Vol. III. p. 345.

QUID *juris clamat*, in law, a writ that lies where I grant the reverſion of my tenant for life by fine in the king's court, and the tenant will not attorn; then the grantee ſhall have this writ to compel him. Terms of Law.

QUIJUBATUI, in zoology, the name of an American ſpecies of peroquette.

It is of the ſize of a lark, and in general of a yellow colour. Its eyes are black, and its beak grey. The edges of its wings are of a duſky green, and its tail long and yellow. It is a very beautiful bird, and very eaſily tamed. *Marggrave*'s Hiſt. Braſil.

QUIL, in zoology, the name of a ſmall animal of the ferret kind, frequent in the Weſt Indies, and famous for its combat with ſerpents. See the article QUIRPELE.

QUILAQUIL, in natural hiſtory, the name given by the people of the Phillipine iſlands to a very beautiful ſpecies of parrots, which is commonly found wild in the woods there. It is all over of a fine green colour, and is ſmaller than the common parrots, and has a broad black bill and black legs. It is a very wild bird, and will not learn any thing.

QUILLOBO, in botany, a name given by ſome to a ſpecies of ketmia, called alſo *quingombo*. See QUINGOMBO.

QUINA *folia*, among botaniſts. See LEAF.

QUINCE, *cydonia*, in botany, *&c.* See CYDONIA.

The fruit of the *quince* is aſtringent and ſtomachic, but its chief uſe in the ſhops is in the *ſyrupus cydoniarum*, or ſyrup of *quinces*, prepared from its juice with ſugar, which is a very pleaſant ſyrup.

QUINGOMBO, in botany, the name given by the people of Congo to a ſpecies of ketmia, diſtinguiſhed by Mr. Tournefort by the name of the *ketmia Braſilienſis folio ficus fructu pyramidato ſulcato*, the fig-leaved Braſilian ketmia, with a pyramidal ſulcated fruit. See KETMIA.

QUINNET, in mining, the name of a tool uſed in the cleaving rocks by means of gunpowder. This is a ſort of wedge fitted to the flat ſide of what is called the *gun*; that is, a cylindric piece of iron, only flatted in one part, to receive this, and drilled through. When a proper hole has been made in the rock by the borer, the powder is put in, and then the orifice being ſtopped by the gun, and that wedged in by this *quinnet*, the powder being fired by a train communicating with the hole drilled through the gun, exerts all its force on the rock, and ſplits it in ſeveral directions at one exploſion. Philoſ. Tranſ. N°. 167. See MINING.

QUINQUANGULAR-*leaf*, among botaniſts. See LEAF.

QUINQUEFOLIUM, *cinquefoil*, in botany. See CINQUEFOIL.

QUINQUENNES, in ſome old hiſtorians, a name given to a certain people of India, among whom the women began to bear children at five years old, and ſeldom lived to more than eight years. Pliny gives us this account, and Solinus, who repeats it from him, increaſes the miracle by telling us, that they were a nation of women who had no men among them.

QUINQUEPRIMI, among the Romans, the five principal men in the ſenate of every municipal town. *Pitiſc.* in voc.

QUINQUEREMIS, in the naval architecture of the antients, a name given to a galley which had five rows of oars. They divided their veſſels in general into monocrota and polycrota; the former had only one tire of rowers, the latter had ſeveral tires of them, from two or three, up to twenty, thirty, or even forty; for ſuch a veſſel we have an account of in the time of Philopater, which required no leſs than four thouſand men to row it.

Meibom has taken off from the imaginary improbability of there ever having been ſuch a veſſel, by reducing the enormous height ſuppoſed neceſſary for ſuch a number of rows of oars and men to work them, by finding a better way of placing the men than others had thought of. The *quinqueremes* of the antients had four hundred and twenty men in each, three hundred of which were rowers, and the reſt ſoldiers. The Roman fleet at Meſſina, conſiſted of three hundred and thirty of theſe ſhips; and the Carthaginian, at Lilybœum of three hundred and fifty of the ſame ſize. Each veſſel was an hundred and fifty foot long. Thus an hundred and thirty thouſand men were contained in the one, and an hundred and fifty thouſand in the other, with the apparatus and proviſions neceſſary for ſuch expeditions as they were intended for. This gives ſo grand an idea of the antient naval armaments, that ſome have queſtioned the truth of the hiſtory; but we find it related by Polybius, an hiſtorian too authentic to be queſtioned, and who expreſſes his wonder at it while he relates it. *Meibom* de Trirem.

QUINQUEPARTITE-*leaf*, among botaniſts. See LEAF.

QUINQUERTIONES, among the Romans, an appellation given to thoſe who had gained the victory in the *quinquertium* or *pentathlon*.

QUINQUERTIUM, among the Romans, was the ſame with the Grecian *pentathlon*, comprehending the five exerciſes of running, leaping, throwing, darting, and wreſtling. See the article PENTATHLON, *Cycl.*

QUINQUINA *(Cycl.)*—The moſt accurate account we have ever received of the tree which produces the *quinquina*, or Peruvian bark, is from Mr. de la Condamine, who in travelling through ſome parts of America, choſe the route of Loxa, where the fineſt bark is gathered, and where the greateſt number of the trees are found; and taking inſtructions from Mr. de Juſſieu, as to what enquiries were moſt neceſſary to be made, informed himſelf very much at large about it.

The fineſt bark, and the greateſt quantity, he informs us, was gathered on Cajanuma, ſituated two leagues and an half to the ſouth of Loxa; and this is the very place where the firſt bark that was ſent into Europe was gathered. He found means to remain a night on his journey on this mountain, and in his return took a branch from one of the trees which had both flowers and ripe fruit on it, as is the caſe with this tree throughout the whole year, and this branch was the ground of his figures, as the obſervations he made in the journey were of his accurate account of the tree.

The natives reckon three ſpecies of bark, the reddiſh, the yellowiſh, and the white. The laſt of theſe has very little virtue, and the other two are nearly equal in goodneſs, tho' the world gives it in favour of the red. Theſe two are the barks of trees which have no difference in their leaves, fruits, or flowers; and which even the people who are continually employed in the ſervice cannot diſtinguiſh at ſight, but pierce the bark with a knife, to ſee the difference, the yellowiſh being thus found to be tenderer and paler coloured than the other. The trees which produce theſe two ſorts grow indiſcriminately one by another, and the bark is gathered indifferently from both; and in drying the diſtinction between them becomes yet leſs viſible, ſince both acquire a browniſh colour.

The tree which produces the white *quinquina* has rounder and rougher leaves, the flower alſo is whiter, and the fruit larger, and its outer covering whitiſh. This tree uſually grows near the top of the mountain, and is not found among the other kinds; they uſually being found about the midway of the height, and principally in hollows, or in the more cloſe or ſheltered places. Some have ſuſpected, that this difference of the trees which produce white, and the other barks, was only owing to the more cold and expoſed ſituation it had on the top of the mountain; and thus much is well known as to the bark in general, that the warmer the place is where it grows, the greater are its virtues.

The *quinquina* tree never grows in the plains; it is a conſtant inhabitant of the mountains, and is eaſily known from the trees it grows among by its erect growth, and its height when of any conſiderable age, as it always carries its head above the reſt. Theſe trees are never found in clumps or cluſters together, but always ſeparate and ſingle among other kinds. They grow to a very conſiderable ſize, when ſuffered to remain long enough; ſome are as thick as a man's body, but the more uſual are about nine inches in diameter.

It is very rare, however, to find any large ones at this time on the mountain where the bark is gathered, the great demand for it having made them bark all the trees, and theſe having all periſhed by it; for the old trees never recover the barking, tho' the young ones frequently do.

They uſe no other inſtrument for barking the trees than a common knife, which the workman thruſts through the bark at as great a height as he can reach, and then bearing hard upon it, brings it down to the bottom, cutting all the way. If there be any difference, as ſome have pretended, between the bark that was at firſt imported, and that which we now receive, it muſt be wholly owing to the different ages of the trees it was then and is now procured from; that having been the bark of old trees, and there being now none but young ones: this gentleman having ſcarce ſeen any there that were thicker than a man's arm, or above twelve or fifteen feet high; and thoſe which they cut young always throw out new ſhoots from the bottom.

In the times when the bark was firſt brought into uſe, the world preferred the thickeſt pieces, now they ſet the greateſt value on the thinneſt; but the latter preference is moſt reaſonable; ſince it is not founded on fancy, but on the experiments made by the Engliſh and other nations of the different virtues, and the reſult of chemical analyſes.

There was once an opinion, that there were certain ſeaſons to be obſerved for the gathering the bark, and that it ought always to be done in the decreaſe of the moon; but expe-

rience has ſhewed theſe to be idle opinions, and it is now gathered at all times if the weather be dry. When the bark is taken off, it is laid in the ſun till perfectly dry; the omitting this circumſtance, and packing up the bark while moiſt, has occaſioned it often to become mouldy, and ſpoil, and the merchants have attributed this to the taking it off in a wrong time of the moon, when it was wholly owing to its being put into the ſkins while too moiſt.

The leaves of the *quinquina*-tree ſtand on pedicles of about half an inch long: they are very ſmooth and gloſſy, and of a beautiful green; but ſomewhat paler on the under ſide than the upper. They are perfectly ſmooth at the edges, and are of an oblong figure, pointed at the end, and rounded at that part which joins to the ſtalk. They are from two and an half to three inches in length, and from an inch and an half to two inches in breadth. The middle rib of the leaf is rounded on the upper ſide, and is uſually of a reddiſh colour, eſpecially towards the pedicle; and the whole leaf often becomes red, when perfectly mature. All the ſmall branches towards the top of the tree terminate in one or more cluſters of flowers, which, before they are open, reſemble in their ſhape and their bluiſh grey colour, thoſe of the common lavender. Mem. Acad. Scienc. Par. 1738.

When theſe open, they change their colour: each ſtalk that ſuſtains one of theſe cluſters of flowers ariſes from the ala of one of the leaves, and divides into a great number of ſmall branches, each of which is terminated by a cup divided into five parts, which ſuſtains a flower reſembling that of the hyacinth. It is compoſed of a pipe of three quarters of an inch long, which at the end is divided into five, and ſometimes into ſix ſegments. Theſe are of a beautiful deep red within, and are ſerrated round the edges in a very elegant manner. From the bottom of the tube of the flower there ariſes a white piſtil, terminated by a long green head; this ariſes above the level of the ſegments of the flower, and is ſurrounded by five ſtamina, which ſuſtain apices of a pale yellow colour: theſe remain hid within the flowers. The tube is of a dirty red, and is covered with a ſort of whitiſh down. When the flower is fallen, the cup ſwells in the middle into the form of an olive, which by degrees grows into a fruit divided into two cells, which in drying become ſhorter, and the whole fruit rounder than in its natural condition.

This fruit finally opens longitudinally into two capſules, ſeparated by a membranaceous ſeptum, and coated by a thin yelloviſh ſkin; the ſeeds are of a reddiſh colour, and in ſhape are flattiſh, and, as it were, foliaceous; they are not more than a twentieth part of an inch in diameter, and are thickeſt in the middle, becoming thinner at each ſide. The plantula ſeminalis lies in the very center of the ſeed, between two pellicles: theſe ſeeds, which reſemble in ſome degree thoſe of the aſh in miniature, are faſtened in the manner of ſo many ſcales to a placenta of an oblong figure, pointed at the two extremities, ſo as ſomewhat to reſemble a ſeed of the common oat, but that it is longer and flatter. This is joined to the ſeptum, and has on that part a longitudinal furrow; but on the other ſide is convex, and ſomewhat rough all over. Mem. Acad. Scienc. Par. 1738.

By this deſcription it appears, that they were very ignorant of the nature and characters of this tree, who, in its firſt knowledge among us, called it a ſpecies of ſebeſten.

The uſe of this febrifuge ſeems to have been very long known to the natives, and their manner of taking it was by pounding the bark, and laying it to infuſe in water, and drinking the infuſion; their hatred to the Spaniards, their conquerors, made them keep it a long time a ſecret from them; and when the thing became known among the inhabitants of Loxa, it ſtill remained a ſecret to the reſt of the world, and its great value was never generally known till the year 1633; when the lady of the viceroy of Peru, the counteſs de Chinchon, being long ill of an intermittent fever, which would give way to none of the known remedies, the corregidor of Loxa ſent to the viceroy a quantity of the *quinquina* bark, which he aſſured him would cure the lady, tho' all other means had failed. Upon this the corregidor was ſent for to Lima, and after having given the medicine to many other perſons with ſafety and ſucceſs, the lady at length took it, and was cured. She immediately on this ſent for a large quantity of the bark, had it powdered, and herſelf diſperſed it to thoſe who had occaſion for it; whence it obtained the name of the *counteſs's powder*: but this lady being ſoon tired of the office, gave it in charge to the jeſuits; and they continuing to give it to the ſick with the ſame ſucceſs, it then was called the *jeſuits powder*. Theſe reverend fathers ſoon found means to ſend a quantity of it to Cardinal Lugo, who diſperſed it with the ſame ſucceſs at Rome; and after him the apothecary to the college gave it gratis to the poor with the ſame good effects, and under the name of the *jeſuits* or the *cardinal's powder*: afterwards the better ſort were made to pay its weight in ſilver for it, to defray the expences of its importation, while the poor ſtill had it gratis. Lewis XIV. at that time dauphin of France, was cured by it of a fever which had not given way to other medicines.

In the year 1640, the count and counteſs of Chinchon being returned to Spain, their phyſician, Juan de Vega, who brought a great quantity of it over with him, ſold it at a conſiderable price; and ſoon after this, large quantities were ſent over by the galleons, but the great demands from Europe cauſing the inhabitants of Loxa to adulterate it with other barks, it had like to have loſt part of its juſt praiſe. The *quinquina*-trees are found at this time on all that chain of mountains adjoining to Cajanuma, and in many other parts of America.

QUINTAIN, (*Cycl.*) the name of an old Engliſh ſport, intended for a trial of the agility of men on horſeback. It is loſt in many parts of the kingdom, but was ſtill in uſe at Deddington, in Oxfordſhire, in the time of Dr. Plot. The method of performing it is this:

They firſt ſet up a poſt perpendicularly in the ground, and then place a ſlender piece of timber on the top of it, on a ſpindle, with a board nailed to it at one end, and a bag of ſand at the other. Againſt this board they antiently rode with ſpears, but afterwards only with ſtaves, which violently brought about the bag of ſand; ſo that if they did not make good ſpeed away, it ſtruck them on the neck or ſhoulders, and ſometimes knocked them down. The great point aimed at was always the breaking of the board, and he that did that, was accounted the greateſt maſter.

It ſeems to have had its name from the Latin *quintus*, fifth, as one of the antient ſports uſed every fifth year among the Olympian games; or becauſe it was the ſport of the fifth or laſt day of theſe games. *Plot*'s Oxford. p. 204.

QUINTESSENCE *(Cycl.)*—QUINTESSENCE *of wine*, a term uſed by Glauber to expreſs an eſſential oil of wine, which he directs to be made by a careful diſtillation, and which he is very fond of, as having a power to meliorate, improve, and even to ſpecificate the poorer wines into the nature of thoſe from which it was obtained.

This is one of the ſchemes of Glauber, generally eſteemed an impracticable one, tho' very plauſible in theory; but tho' in general there is a diſagreeable flavour in the *quinteſſence* drawn after his method, which is different from the true flavour of the wine, and ſpoils the liquor it is added to; yet by proper care there is a poſſibility of ſucceeding ſo far as to render this extraneous flavour almoſt imperceptible, and produce an oil that will mend poor wines extremely, and give a truly vinous flavour to ſuch as are in themſelves taſteleſs: but whatever may be done by this method, may alſo be done with much more certainty, and much leſs trouble, by the concentration of wines by freezing. This may be eaſily practiſed in the wine countries; and by this means Burgundy, Champaign, and other the moſt valuable wines, may be reduced into thick extracts and robs, by the means of which wines may be made in England; a very ſmall quantity of theſe concentrated wines being ſufficient to convert the whole of any of the poor taſteleſs and inſipid wines, which are of themſelves of little or no value, into the very wine from which the rob was made, and that in ſuch perfection, that the niceſt judge cannot find out the difference.

Theſe robs of wine made and preſerved upon the ſpot, would alſo be of infinite uſe in the wine countries, as they might be kept to improve the wines of bad years. *Stahl*, de Concentr. Vin. *Shaw*'s Chem. Eſſ.

QUINTUS *femoris*, in anatomy, a name given by Fallopius and many others to one of the muſcles of the thigh, now called the *pſoas magnus*. See PSOAS.

QUINTUS *oculorum*, in anatomy, a name given by Veſalius and ſome others to one of the muſcles of the eyes, more expreſſively called by others *obliquus ſuperior oculi*, and *opifex circumgyrationis oculi*.

QUINVA, in botany, a name by which ſome authors have called the amaranth, or cockſcomb. *Moriſon*, Hiſt. Vol. II. p. 602.

QUINZY, or ANGINA *(Cycl.)*—This is defined by medical writers to be an inflammatory ſtaſis of the blood about the throat, in which nature ſeems to have aimed at the diſcharging part of the load of a plethora, either by an hæmorrhage of the noſe, or by ſpitting of blood; but effecting neither, the *quinzy* is produced.

Authors have divided the *quinzy* in general into two kinds, the true and the ſpurious. The true *quinzy* is that in which the tumor is internal, and is attended with a fever. The ſpurious is that in which the tumor ſhews itſelf more outwardly, and is not attended with a fever.

The antients alſo divided the *quinzy* into four other kinds, which they called by as many names.

1. The *cynanche*. In this the tumor neither manifeſts itſelf outwardly nor inwardly, but is attended with a very violent fever.

2. The *paracynanche*. This was the name given it when the tumor appeared externally in the muſcles of the larynx, and was highly inflammatory.

3. The *ſynanche*. In this kind the tumor appears externally alſo, and there is a leſs difficulty of breathing; but a greater of ſwallowing than in the other kinds.

4. The *paraſynanche*. This name denoted an inflammation of the muſcles of the pharynx, attended with a fever.

We at this time diſtinguiſh alſo the *quinzy* into the idiopathic and ſymptomatic. The firſt, where it is itſelf the diſeaſe, and owes its origin only to a plethora. The ſecond, where it

is but the accidental ſymptom of an inflammatory fever, or ſome other diſeaſe about the time of its criſis.

Signs of a quinzy. The firſt ſymptom of this diſeaſe is a difficulty of ſwallowing, joined with a tumor in the throat, and a ſenſation of a pricking pain; to theſe ſymptoms there ſucceeds an inflammation and violent heat in the fauces: and in a few hours theſe ſymptoms increaſe to ſo great a degree, that the patient becomes unable to ſwallow; the tongue ſwells violently, and the veins appear black and tumid under it, the face becomes red and tumid, and the temporal veſſels are diſtended, and the eyes become ſwelled and ſeem as if they would ſtart out of the head; then reſpiration becomes very painful, and there is danger of abſolute ſuffocation. The hands become pale and cold to the touch; and the fleſh is at times very hot, and ſoon after very cold again; and in the progreſs of the diſeaſe the patient is uſually found to be very low ſpirited.

The idiopathic *quinzy* ſeldom happens to any except young people of a remarkably plethoric habit of body; and people are moſt ſubject to it who have been uſed to frequent bleedings at the noſe, and who live ſedentary lives, and feed high. The moſt frequent cauſes of this diſeaſe are a ſuppreſſion of hæmorrhages by the noſe, a ſudden cooling of the body after exceſſive heat, drunkenneſs, an improper uſe of ſtrong ſternutatory powders, violent and loud calling, and finally, luxations of the neck.

As to the ſymptomatic *quinzy*, the moſt common of all cauſes of it is the improper uſe of bleeding in acute fevers and other inflammatory diſeaſes.

Prognoſtics in quinzies. The more violent the attack of this diſeaſe is, the greater is the danger with which it is attended. The ſpurious *quinzy* is always more favourable than the true one, and the mildeſt of all the kinds is the paracynanche, as the cynanche is of all others the moſt fatal. Thoſe who die of this diſeaſe rather die of convulſions than of ſuffocation. When the matter cannot be diſcuſſed, there uſually happens a ſuppuration; and in this caſe the event is very dubious and uncertain.

Method of cure. Immediately on the attack of the diſeaſe, a clyſter is to be given. Warm urine or brine will ſerve the purpoſe, or, if equally ready, the pulp of colocynth, or aloes ſhould be boiled in the liquor. After this there muſt be a large quantity of blood taken from the arm, or foot, which is by ſome eſteemed much better; and if the ſymptoms do not then remit, the raninæ venæ are to be opened ſoon afterwards. In a milder attack it is not neceſſary to bleed in the time of the fit, but the common remedies for allaying the inordinate emotions of the blood take place; ſuch as powders of nitre, crabs-eyes, and cinnabar, and on occaſion a gentle anodyne or opiate may be added to theſe; as a ſmall doſe of the ſtorax pill, or the like. Theſe things are alſo to be given in the more violent caſes, and through the whole courſe of the diſtemper, provided that the difficulty of ſwallowing does not prevent it. After bleeding and theſe powders, the uſe of gargariſms is very great: of theſe there are three kinds; 1. The reſolvent or nervine and diſcutient: theſe are prepared of orrice and elecampane-root, hyſſop, chamæmile flowers, and anniſe and caroway ſeeds, and the like. 2. The lenient, or demulcent, which ſerve to allay the inflammatory heat: theſe are prepared of the mucilaginous and cooling things, as quince-ſeeds in red roſewater, with ſyrup of raſpberries, mulberries, and nitre, with jews-ears and album græcum, which two laſt are looked upon by many as ſpecifics. And, 3. The aſtringents: theſe are made of the traumatic herbs, ſuch as mouſe-ear, ſelf-heal, and the like, with biſtort and comfry-root, pomegranate rind, galls, terra Japonica, and alum.

The gentle aſtringents are to be firſt uſed, and it muſt be with great caution that we proceed from thoſe to the more powerful ones. While theſe are uſed internally, the external uſe of emolient and diſcutient plaiſters is alſo to be brought in; ſuch are melilot and diachylon with the gums: and in caſes where the heat is violent, inſtead of plaiſters, linnen-cloths wetted with ſpirit of wine and camphor, with a little ſaffron, are to be applied. If all theſe things fail, and the ſwelling riſes and breaks, the patient is always relieved by the breaking, and is to uſe afterwards, by way of gargariſm, wine ſweetened with honey of roſes. The bowels are always to be kept looſe by glyſters, or gentle purges; and finally, where the danger of ſuffocation is imminent, bronchotomy is the laſt relief. *Junker*, Conſp. Med. p. 154, ſeq.

Beſide the common occaſions of this diſeaſe, we have in the philoſophical tranſactions an account of a ſtone breeding at the root of the tongue, and cauſing one. The patient was almoſt choaked, and the tumor, which was large outwardly, tho' not tending to ſuppuration, yet was ready to break within, and ſhewed matter ready to be diſcharged. On breaking it with the finger, there iſſued out above a quarter of a pint of matter, and with it a ſmall ſtone, very hard, and of the ſame nature and ſubſtance with thoſe formed in the kidneys.

In this diſtemper, beſides high bleeding, ſome recommend a gargariſm compoſed of ſublimate mercury, half a drachm; cream of tartar, two drachms; diſſolved in a pint of ſpring water. Med. Eſſ. Edinb abr. Vol. II. p. 431.

We have the hiſtory of an uncommon *angina*, or *quinzy*, by Mr. Monro in the medical eſſays of Edinburgh abridged, Vol. II. p. 400.

QUIRICIA, a name given by ſome to the ſtone called *quiris* by the generality of writers. See QUIRIS.

QUIRINACIUM *opium*, in the materia medica, a name given by ſome to the gum we know by the name of aſſa fœtida.

It is a barbarous phraſe of the middle ages, and is founded on the name ὄπον κυρενιακον of the Greeks, which expreſſed the Cyrenean gum, that being the name they gave to the original aſſa, which was a ſweet-ſcented gum, not the ſtinking aſſa-fœtida. We call both theſe aſſa, but the Greeks diſtinguiſh the ſtinking kind by the name *ſcordolaſaron*. See the article ASA.

QUIRINUS *lapis*. See QUIRIS.

QUIRIS, a name given by the writers of the middle ages to a ſtone famous among them for its imaginary virtues, but of which they have left us no deſcription.

They call it alſo *quirinus* and *quiricia*, and pretend, that if put under any one's pillow, it will cauſe them to divulge all their ſecrets by talking in their ſleep.

QUIRPELE, in zoology, the name of a ſmall animal, called by ſome authors the *Indian ferret*, *viverra Indica*, and by others *quil*.

Garcias and ſome authors give very remarkable accounts of the enmity this creature has to ſerpents of all kinds. They tell us, that when this little creature intends an attack upon one of theſe animals, it firſt prepares againſt danger by gnawing a quantity of the root of the *lignum colubrinum*, or ſnake-wood; and when it has thoroughly impregnated its *ſaliva*, it wets with it firſt its fore-feet, and with them daubs over its head and its whole body; and that thus prepared, it boldly attacks the ſnake, and never leaves off till it has killed it. Garcias aſſures us, that many of the Portugueſe have been eye-witneſſes of theſe combats.

It is probable enough, that this creature may attack a ſnake when thoroughly hungry, knowing its fleſh to be good food; but I fear the ſtory of the antidote is to be ſuſpected. *Ray*'s Syn. Quad. p. 197.

QUITY, in botany, a Braſilian name uſed by ſome authors for the ſapindus, or ſoap-berry tree of the Weſt Indies. *Margg.* Hiſt. Braſil. p. 113.

QUOD *(Cycl.)*—QUOD *ei deforceat*, in law, a writ for tenant in tail, tenant in dower, by the courteſy, or for term of life, having loſt their lands by default againſt him that recovers, or his heir. Reg. orig. 171. Stat. Weſtm. 2. c. 4. *Cowel*, Terms of Law.

QUOD *permittat*, in law, a writ that lies where a man is diſſeiſed of his common of paſture, and the *diſſeiſor aliens*, or dies ſeiſed, and his heir enters; then if the diſſeiſee die, his heir ſhall have this writ.

QUOIL *(Cycl)*—*Weather*-QUOIL, at ſea. See WEATHER.

QUORUM *(Cycl)*—QUORUM *nomina*. In the reign of King Henry VI. the king's collectors, and other accomptants, were much perplexed, in paſſing their accounts, by new extorted fees, and forced to procure a then late invented writ of *quorum nomina*, for the allowance and ſuing out their quietus, without the allowance of the king. *Blount.*

QUOTIDIAN, *(Cycl.)* in medicine, the name of a ſpecies of fever which attacks the patient every day, at firſt with a chilneſs, and with a febrile heat ſucceeding this, by which nature commonly attempts to eaſe herſelf of the load of ſome morbific matter which uſually adheres in the primæ viæ. This differs greatly from the continual *quotidian* fever. See the article *Catarrhal* FEVER.

It is diſtinguiſhed from the double tertian by this, that the *quotidian* regularly obſerves its times of attack and of duration every day; but in the double tertian, the ſingle fits do not correſpond one with another, but only the alternate ones, that is, the paroxyſm of the third day correſponds with that of the firſt, that of the fourth with that of the ſecond, and ſo on.

Signs of it. This fever uſually attacks the patient in a morning, and moſt frequently about ſix or ſeven o'clock. The firſt ſymptom is a very violent chilneſs or coldneſs, which uſually laſts about an hour, and is attended either with a vomiting, or with a diarrhœa, or both. This cold fit is ſucceeded by a violent hot one, in which there is an intolerable thirſt and pain of the head. The whole duration of the fit is uſually ſix hours, and when the heat remits a little of its violence, then ſweats uſually come on. This returns regularly at the ſame hour the next day, and ſo on, unleſs diſturbed by any means; in which caſe, it anticipates or poſtpones the accuſtomed time.

Perſons ſubject to it. This is the leaſt frequent of all the intermittent fevers. Perſons of phlegmatic habits are more ſubject to it than thoſe of any other temperament; and it ſeizes old people oftner than young, and women much more frequently than men.

Cauſes of it. The firſt cauſe of this diſeaſe is a viſcous and mucous matter lodged in the primæ viæ. This is often attended with a ſpiſſitude of the blood in the vena portæ. The occaſional cauſes which bring on this ſpiſſitude of the blood and foulneſs of the primæ viæ, are a coarſe and thick diet, a ſedentary

dentary life, and a natural turn to melancholy. The cauſes of this, and of the tertian, ſeem to be the ſame, only that in this they are ſtronger.

Method of cure. The general cuſtom of curing intermittents by vomits and the Peruvian bark alone, is cenſured by Stahl, and many other writers, as being faulty in two extremes; the vomiting throwing off the offending matter with too much violence, and the bark locking it up in the body. Vomits, when injudiciouſly given, often give violent reachings, without bringing up any part of the matter of the diſeaſe; and the bark, and other aſtringents, bring on obſtinate coſtiveneſs, flatulencies, ſtraitneſs of the breaſt, and many other diſorders; ſuch as, the jaundice, dropſy, œdematous ſwellings, and many other the like complaints, which often ſucceed the too large or injudicious uſe of it: for this reaſon, theſe authors prefer a regular method, by inciding the tough matter in the primæ viæ, with tartarum vitriolatum, and the like, then the giving a gentle emetic; after this, gentle diaphoretics and diluents, ſuch as all warm and weak liquors; and afterwards ſtrengthening the ſtomach and bowels by bitters and ſubaſtringents, among which the bark has its place, tho' in ſmaller quantities than when truſted to alone in the uſual way. *Junker's* Conſp. Med. p. 360.

R.

RABBIT, *cuniculus*, in zoology, a well known animal of the hare kind. See the article LEPUS.

The female, or doe *rabbit* goes with young thirty days, and then ſhe kindles; and if ſhe take not buck preſently ſhe loſes her month, or at leaſt a fortnight, and often kills her young and eats them.

In England they begin to breed at a year old, but in ſome places much ſooner; and they continue breeding very faſt from the time when they begin, four, five, ſix, or ſeven times a year being common with them. They have uſually from four to ſeven in a litter, and hence it is that a ſmall number at firſt will ſoon ſtock a whole warren, if left to breed a little while undiſturbed. The does cannot ſuckle their young till they have been at buck again; this therefore is to be done preſently, elſe there is a fortnight loſt of the time for the next brood, and the preſent brood alſo probably loſt. When the buck goes to the doe, he always firſt beats and ſtamps very hard with his feet, and when he has copulated with her he falls backwards, and lies as it were in a trance; in this ſtate it is eaſy to take him, but he ſoon recovers from it.

The buck *rabbits*, like our boar cats, will kill the young ones, if they can get at them; and the does in the warrens prevent this, by covering their ſtocks, or neſts, with gravel or earth, which they cloſe ſo artificially up with the hinder part of their bodies, that it is hard to find them out. They never ſuckle the young ones at any other time than early in the morning, and late at night, and always, for eight or ten days, cloſe up the hole at the mouth of the neſt, in this careful manner, when they go out. After this they begin to leave a ſmall opening, which they encreaſe by degrees, till at length, when they are about three weeks old, the mouth of the hole is left wholly open, that they may go out; for they are at that time grown big enough to take care of themſelves, and to feed on graſs.

People who keep *rabbits* tame for profit, breed them in hutches, but theſe muſt be kept very neat and clean, elſe they will be always ſubject to diſeaſes. Care muſt be taken alſo to keep the bucks and does apart till the latter have juſt kindled, then they are to be turned to the bucks again, and to remain with them till they ſhun and run from them.

The general direction for the chuſing of tame *rabbits* is, to pick the largeſt and faireſt, but the breeder ſhould remember that the ſkins of the ſilver haired ones ſell better than any other. The food of the tame *rabbits* may be colewort and cabbage leaves, carrots, parſneps, apple rinds, green corn, and vetches, in the time of the year; alſo vine leaves, graſs, fruits, oats, and oatmeal, milk-thiſtles, ſow-thiſtles, and the like; but with theſe moiſt foods they muſt always have a proportionable quantity of the dry foods, as hay, bread, oats, bran, and the like, otherwiſe they will grow pot-bellied, and die. Bran and grains mixed together have been alſo found to be very good food. In winter they will eat hay, oats, and chaff, and theſe may be given them three times a day; but when they eat green things, it muſt be obſerved that they are not to drink at all, for it would throw them into a dropſy. At all other times a very little drink ſerves their turn, but that muſt always be freſh. When any green herbs, or graſs, are cut for their food, care muſt be taken that there is no hemlock among it, for though they will eat this greedily among other things, when offered to them, yet it is ſudden poiſon to them.

Rabbits are ſubject to two principal infirmities. Firſt, the rot, which is cauſed by the giving them too large a quantity of greens, or from the giving them freſh gathered with the dew or rain hanging in drops upon them. It is over moiſture that always cauſes this diſeaſe, the greens therefore are always to be given dry, and a ſufficient quantity of hay, or other dry food, intermixed with them, to take up the abundant moiſture of their juices. On this account the very beſt food that can be given them, is the ſhorteſt and ſweeteſt hay that can be got, of which one load will ſerve two hundred couples a year; and out of this ſtock of two hundred, two hundred may be eat in the family, two hundred ſold to the markets, and a ſufficient number kept in caſe of accidents.

The other general diſeaſe of theſe creatures is a ſort of madneſs: this may be known by their wallowing and tumbling about with their heels upwards, and hopping in an odd manner into their boxes. This diſtemper is ſuppoſed to be owing to the rankneſs of their feeding; and the general cure is the keeping them low, and giving them the prickly herb, called *tare-thiſtle*, to eat.

The general computation of males and females is, that one buck *rabbit* will ſerve for nine does; ſome allow ten to one buck; but thoſe who go beyond this always ſuffer for it in their breed.

The wild *rabbits* are to be taken either by ſmall cur dogs, or by ſpaniels bred up to the ſport; and the places of hunting thoſe who ſtraggle from their burrows, is under cloſe hedges, or buſhes, or among corn-fields and freſh paſtures. The owners uſe to courſe them with ſmall greyhounds, and though they are ſeldom kill'd this way, yet they are driven back to their burrows, and are prevented from being a prey to others. The common method is by nets, called *purſe nets*, and ferrets. The ferret is ſent into the hole to force them out, and the purſe net being ſpread over the hole, takes them as they come out. The ferrets mouths muſt be muffled, and then the *rabbit* gets no harm. For the more certain taking of them, it may not be improper to pitch up a hay net or two, at a ſmall diſtance from the burrows that are intended to be hunted: thus very few of the number that are attempted will eſcape. The method by the dog, called the *lurcher* and *tumbler*, is alſo a very good one. See FERRET and LURCHER.

Some who have not ferrets ſmoak the *rabbits* out of their holes with burning brimſtone and orpiment. This certainly brings them out into the nets, but then it is a very troubleſome and offenſive method, and is very detrimental to the place, as no *rabbit* will, of a long time, afterwards come near the burrows which have been fumed with theſe ſtinking ingredients.

The teſticle of a *rabbit* is a very good object for examining the ſtructure of this part of generation in animals. The whole ſubſtance of the teſticle in this animal is made up of veſſels, which lie in round folds in the manner of the ſmaller inteſtines, but then both ends of each roll meet at their inſertion, which ſeems to be made into the *ductus nervoſus*; and every one of theſe little rolls is curiouſly embroidered with other veſſels, which, from their red colour, appear to be arteries and veins. The ſeveral little rolls lie in ranges, diſpoſed with an uniformity which is very agreeable to the eye. Every one of theſe rolls is not a ſingle and entire tube, but each conſiſts of ſeveral tubes, beſide the veins and arteries which embroider it. This is beſt diſtinguiſhed by the cutting one of the rolls tranſverſely, and then examining the cut end with a glaſs, which will then appear to be made up of the cut and open ends of four, five, or more parallel tubes, which together form the roll, or ſingle tube, as it appears to the eye, being all wrapped up in one common and very thin membrane. Theſe are ſo tender that they cannot be explicated and viewed diſtinct, as De Graeff tells us thoſe of the teſticles of a rat, and of ſome other animals, may. Theſe however, as well as the others, are only made up of a congeries of veſſels, and the liquors, which are their contents, without any intermediate ſubſtance, or any thing of that parenchyma, which many authors have talked of. The teſticles of a bull have the greateſt appearance of a fleſhy texture of thoſe of any known animal, yet even theſe afford no particle of parenchyma, or fleſh, when examined by glaſſes in any ſort of preparation, whether boiled, raw, ſoaked in ſpirits, or in whatever other ſtate. The teſticles of various animals are very variouſly compoſed, but all in this general manner of veſſels variouſly rolled and folded together; and even the human teſticles are of the ſame ſort, being compoſed ſolely of rolls of veſſels, without any intermediate ſubſtance, be it called by whatever name, but only conſiſting of veſſels and their liquors. Philoſ. Tranſ. N° 52.

RABCHORCADO, in zoology, the name of an American bird, deſcribed by Nieremberg with many fabulous circumſtances. All that ſeems certainly known is, that its tail is very remarkably forked. *Ray*'s Ornithol. p. 305.

RABEBOIA, a name given by ſome to the roots of the flammula major.

RABICH, a name given by Leo Africanus to a tree or ſhrub growing very plentifully in many parts of Africa, the fruit of which is much eſteemed by the natives. He ſays that the tree *rabich* is prickly, and that the fruit is round and like a cherry, but ſmaller, and of the taſte of the jujube. *Leo Africanus*, lib. 3.

RABIEL, a name given by ſome authors to dragons blood. See SANGUIS *draconis*.

RABIRA, a word uſed by ſome of the chemical writers to expreſs tin. See TIN.

RABOLANE, in zoology, a name given by many to the lagopus, a bird found on the ſnowy mountains, and called by ſome the *white partridge*. *Ray*'s Ornitholog. p. 127. See the article LAGOPUS.

RABRI, a name given by ſome authors to bole armenic.

RACE, in natural hiſtory. See CIBDELOPLACIA.

RACHISAGRA, a term uſed by ſome phyſicians for the gout in the ſpine of the back.

RACING, the riding heats for a plate or other premium.

The firſt thing to be conſidered in this ſort of gaming is the chuſing a rider; for it is not only neceſſary that he ſhould be very expert and able, but he muſt alſo be very honeſt.

He muſt have a very cloſe ſeat, his knees being turned cloſe to the ſaddle ſkirts, and held firmly there, and the toes turned inwards, ſo that the ſpurs may be turned outward to the horſe's belly. His left hand governing the horſe's mouth, and his right the whip. During the whole time of the *race* he muſt take care to ſit firm in the ſaddle, without waving or ſtanding up in the ſtirrups. Some jockies fancy this is a becoming feat; but, it is certain, that all motions of this kind, do really incommode the horſe. In ſpurring the horſe, it is not to be done by ſticking the calves of the legs cloſe to the horſe's ſides, as if it were intended to preſs the wind out of his body; but, on the contrary, the toes are to be turned a little outwards; that the heels being brought in, the ſpurs may juſt be brought to touch the ſides. A ſharp touch of this kind will be of more ſervice toward the quickening a horſe's pace, and will ſooner draw blood than one of the common coarſe kicks. The expert jockey will never ſpur his horſe until there is great occaſion, and then he will avoid ſtriking him under the fore bowels between the ſhoulders and girth; this is the tendereſt part of a horſe, and a touch there is to be reſerved for the greateſt extremity.

As to whipping the horſe, it ought always to be done over the ſhoulder on the near ſide, except in very hard running, and on the point of victory; then the horſe is to be ſtruck on the flank with a ſtrong jerk; for the ſkin is moſt tender of all there, and moſt ſenſible of the laſh.

When a horſe is whipped and ſpurred, and is at the top of his ſpeed; if he claps his ears in his pole, or whiſks his tail, it is a proof that the jockey heats him hard, and then he ought to give him as much comfort as he can, by ſawing the ſnaffle backwards and forwards in his mouth; and by that means forcing him to open his mouth, which will give him wind, and be of great ſervice. If there be any high wind ſtirring in the time of riding; the artful jockey will let his adverſary lead, holding hard behind him, till he ſees an opportunity of giving a looſe; yet, in this caſe, he muſt keep ſo cloſe behind, that the other horſe may keep the wind from him; and that he ſitting low, may at once ſhelter himſelf under him, and aſſiſt the ſtrength of the horſe. If the wind happen to be in their back a juſt contrary method is to be taken with it; the expert jocky is to keep directly behind the adverſary, that he may have all the advantage of the wind to blow his horſe along, as it were, and at the ſame time intercept it in regard to his adverſary.

When running on level carpet ground, the jockey is to bear his horſe as much as the adverſary will give him leave, becauſe the horſe is naturally more inclined to ſpend himſelf on this ground: on the contrary, on deep earths, he may have more liberty, as he will there ſpare himſelf.

In riding up hill the horſe is always to be favoured, by bearing him hard, for fear of running him out of wind; but, in running down hill, if the horſe's feet and ſhoulders will bear it, and the rider dares venture his neck, he may have a full looſe. If the horſe have the heels of the reſt, the jockey muſt always ſpare him a little, that he may have a reſerve of ſtrength, to make a puſh at the laſt poſt.

A great deal depends on the jockey's knowing the nature of the horſe that is to run againſt him, for by managing accordingly, great advantages are to be obtained: thus, if the oppoſite horſe is of a hot and fiery diſpoſition, the jockey is either to run juſt behind him, or cheek by joul with him, making a noiſe with the whip, and by that means forcing him on faſter than his rider would have him, and conſequently ſpending him ſo much the ſooner: or elſe keep juſt before him, in ſuch a ſlow gallop, that he may either overreach, or by treading on the heels of the fore horſe, endanger tumbling over.

Whatever be the ground that the adverſary's horſe runs worſt on, the cunning jockey is to ride the moſt violently over; that by this means, it will often happen, that in following, he either ſtumbles or claps on the back ſinews.

The ſeveral corrections of the hand, the whip, and the ſpur, are alſo to be obſerved in the adverſary, and in what manner he makes uſe of them; and when it is perceived, by any of the ſymptoms, of holding down the ears, or whiſking the tail, or ſtretching out the noſe like a pig, that the horſe is almoſt blown; the buſineſs is to keep him on to this ſpeed, and he will be ſoon thrown out or diſtanced. If the horſe of the opponent looks dull, it is a ſign his ſtrength fails him; and if his flanks beat much, it is a ſign that his wind begins to fail him, and his ſtrength will ſoon do ſo too.

After every heat for a plate, there muſt be dry ſtraw, and dry cloths, both linnen and woollen, ready to rub him down all over, after taking off the ſweat with what is called a ſweat knife; that is, a piece of an old ſword blade, or ſome ſuch thing. Some adviſe the ſteeping the cloths in urine and ſalt-petre the day before, and letting them be dried in the ſun for this occaſion. After the horſe has been well rubbed with theſe, he ſhould be chafed all over, with cloaths wetted in common water till the time of ſtarting again. When it is certainly known that the horſe is good at the bottom, and will ſtick at the mark, he ſhould be rid every heat to the beſt of his performance; and the jockey is, as much as poſſible, to avoid riding at any particular horſe, or ſtaying for any, but to ride out the whole heat with the beſt ſpeed he can. If, on the contrary, he has a fiery horſe to ride, and one that is hard to manage, hard mouthed, and difficult to be held, he is to be ſtarted behind the reſt of the horſes with all imaginable coolneſs and gentleneſs; and when he begins to ride at ſome command, then the jockey is to put up to the other horſes; and if they ride at their eaſe, and are hard held, they are to be drawn on faſter; and if it be perceived, that their wind begins to rake hot, and they want a ſob, the buſineſs is to keep them up to that ſpeed: and when they all are come within three quarters of a mile of the poſt, then is the time to puſh for it, and uſe the utmoſt ſpeed in the creature's power.

When the race is over, the horſe is immediately to be cloathed up, and rode home, and immediately on his coming into the ſtable the following drink is to be given him. Beat up the yolks of three eggs, and put them into a pint and half of new milk made warm; let there be added to this three pennyworth of ſaffron, and three ſpoonfuls of ſallad oil, and let the whole be given with a horn. After this he is to be rubbed well down, and the ſaddle place rubbed over with warm ſack, and the places where the ſpurs have touched, with a mixture of urine and ſalt, and afterwards with a mixture of powder of jet and Venice turpentine; after this he ſhould have a feed of rye bread, then a good maſh, and at ſome time after theſe as much hay and oats as he will eat. His legs after this ſhould be bathed ſometimes with a mixture of urine and ſalt-petre.

RACK (*Cycl.*)—RACK, or *Arrack*, is properly a ſpirit procured by diſtillation, from the fermented juice of certain trees in the Eaſt Indies. See ARAC, *Cycl.*

Various and contradictory accounts have been delivered, as to the real ſubject that gives origin to this fine ſpirit. The vulgar ſuppoſe it to be rice; ſome the juice of the Eaſt Indian ſugar canes; and others a mixture of the juice of this cane and of the toddy tree; finally, ſome affirm, that it is prepared from the fleſh of animals, and other more coſtly ingredients.

The juice of the cocoa trees, and palm trees, are what afford us the fineſt *arracks*; but there are many other juices diſtilled into the ſame kind of liquors, though wanting the fine flavour of what is made from theſe. *Shaw*'s Eſſay on Diſtillery.

The manner of making the *arrack* is this. The juice of the trees is not procured in the way of tapping the trees, as we do; but the operator provides himſelf with a parcel of earthen pots, with bellies and necks, like our ordinary bird bottles; he makes faſt a parcel of theſe to his girdle, and any way elſe, that he commodiouſly can about him. Thus equipped, he ſwarms up the trunk of a cocoa tree; and when he comes to the boughs, he takes out his knife, and cutting off one of the ſmall knots, or buttons, he applies the mouth of the bottle to the wound, faſtening it to the bough with a bandage; in the ſame manner he cuts off other buttons, and faſtens on his pots, till the whole number is uſed; this is done in the evening, and deſcending from the tree, he leaves things to themſelves till the next morning, when climbing up again he takes off the bottles which are moſtly filled, and empties the juice into the proper receptacle. This is repeated every night, till there is a ſufficient quantity produced, and the whole being then put together, is left to ferment, which it ſoon does.

When the fermentation is over, and the liquor, or waſh, is grown a little tart, it is put into the ſtill, and a fire being made, the ſtill is ſuffered to work, as long as what comes over has any conſiderable taſte of ſpirit.

The liquor thus procured is the low wine of *arrack*, and this is ſo poor a liquor, that it will ſoon corrupt and ſpoil, if not diſtilled again, to ſeparate ſome of its phlegm; they therefore immediately after pour back this low wine into the ſtill, and rectify it to that very weak kind of proof ſpirit, in which ſtate we find it. The *arrack* we meet with, notwithſtanding its being of a proof teſt, according to the way of judging by the crown of bubbles; holds but a ſixth, and ſometimes but an eighth part of alcohol, or pure ſpirit; whereas our other ſpirits, when they ſhew that proof, are generally eſteemed to hold one half pure ſpirit. Ibid.

This ſhews how very uncertain a way of judging of the ſtrength of ſpirits, this by the bead or bubble proof is. And

we may from this learn, that it would be much better to have the *arrack* rectified to the pure alcohol in the Eaſt Indies, in which caſe it would be brought over in one ſixth, or one eighth part of the room, and might be lowered to its ſtandard with common water here. All that it contains beſide this ſixth or eighth part of ſpirit, being only a poor phlegm, or an acidulated water, valuable only for having been brought from Goa or Batavia. It may appear ſtrange to ſome, that this ſpirit ſhould be proof, according to the way of judging by the bead or bubble, and yet be ſo far below the ſtrength, which we uſually underſtand to be in proof ſpirit. But the truth is, that this ſtanding crown of bubbles, may be owing only to the tenacity of the oil that is held in the ſpirit. Our malt diſtillers know very well, that the more oil they work over with the ſpirit, the ſtronger proof it will hold, at a ſomewhat weaker ſtandard of ſtrength than it ought to have, and this caſe of the *arrack* ſhews the fallacy of the other. The finer and more ſubtile any oil is, the leſs it refuſes to mix with any aqueous menſtruum: thus we ſee that the eſſential oils of ſome vegetables, or at leaſt ſome portion of them, is ſo fine and ſubtile, as to mix without turning milky, even with water itſelf, which is the caſe in many of our ſimple diſtilled waters. Hence, it is no wonder, that ſo ſubtile an oil, as is contained in that thin and dilute vegetable juice of which *arrack* is made, ſhould readily mix with ſuch a mixture, as that of one part alcohol, and ſix or eight of water, which tho' weak, conſidered as a ſpirit, is much more likely to retain and embody an oil, than ſimple water alone. The oil of the cocoa is thus ſuſpended imperceptibly in the ſpirit; and that in ſuch quantity, as to give a tenacity to the whole, that diſpoſes it to form a froth or lather at the top when ſhook, and the bubbles of that froth to hang well together. Sometimes indeed there come over into England, and more frequently into Holland, *arracks* that are of the ſtrength of brandy and rum: theſe chiefly come from the Dutch ſettlements, and are a piece of frugality of the Dutch to ſave freight: it is a wonder the ſaving ſpirit had not gone a little farther, and the method of reducing *rack* to alcohol been found out on the ſame plan.

Beſide the common ſorts of Goa and Batavia *arrack*, there are two others leſs generally known; theſe are the bitter *arrack* and the black *arrack*. The bitter *arrack* is ſuppoſed to have been impregnated with ſome kind of bezoar, as that of the porcupine or monkey, which being not generated in the ſtomachs, as thoſe of other animals, but in the gall bladder, are of a very ſtrongly bitter taſte, and very readily communicate it to other things.

Some, on the contrary, are of opinion, that there is nothing added to this, but that the taſte is owing to the juice of the trees, from which the *arrack* is made; and many think that it is obtained from the juice of that tree which bears the fruit, whoſe inſpiſſated juice is what we call terra Japonica.

The black *arrack* is a very coarſe ſpirit, and is uſually drawn higher than any of the finer kinds are, being not drank like them, but employed for coarſer purpoſes. The Turkiſh *arrack*, or as it is uſually called *rackee*, ſeems to be of this kind. The finer, and better kinds of *arrack*, though ever ſo good, when put on board, are apt to grow foul, and black in the carriage; if the leager, or caſk, in which they are brought over, be decayed on the inſide, or the liquor come to touch any nails, or ruſty iron of any kind; for the ſpirit preſently diſſolves a part of the ferrugineous matter; and thence, upon account of the tincture of the oak, which it had before obtained from the wood of the caſk, it will appear inky. *Arrack*, that is thus accidentally tinged black, is not to be confounded with ſuch *arrack* as is originally black, and of the coarſe kind named before. This, which has obtained the colour by accident, is not the worſe in taſte for it, and the tinge may be taken off, and the liquor recovered by putting into the caſk a large quantity of new or ſkimmed milk; and working it well about, as the vintners do, in order to whiten their brown wines. When the bottoms are large, they are to be committed to a conical filter of flannel, through which the *arrack* runs fine. This art of purifying foul *arracks* with milk, would be very pardonable, if our dealers only impoſed that upon us: but they have a ſhameful way of lowering this ſpirit with water, and that to ſuch a degree as is ſcarce credible.

The weakneſs of ſome genuine *arracks* greatly contributes to the countenancing this cheat. This is the principal deceit uſed in regard to this commodity; for it is not eaſy to find any other ſpirit taſteleſs enough to mix with it, without diſcovering the cheat with us; and in Holland they are not only more deſtitute of clean ſpirits than here, but the price of *arrack* itſelf is ſo low there, that it is hardly worth while to do it if they had proper materials.

The extravagant price that *arrack* bears in England, has given great occaſion to the diſtillers to endeavour the counterfeiting it. All the attempts which, for cheapneſs ſake, have been made with malt ſpirit, have naturally proved unſucceſsful: but the thing is not impracticable, though theſe methods have failed. The firſt requiſite muſt be the making a perfectly taſteleſs ſpirit, and the next the treating the juices of vegetables, ſo as to obtain their flavour, to add to it, or elſe the obtaining a pulverable dry ſubſtance, which would at once mix with the ſpirit, and prevent the trouble of a ſecond proceſs of diſtillation. It is poſſible, alſo, that the Engliſh juices of trees, which will bleed freely, ſuch as the birch, maple, ſycamore, and the like, may, on proper trials, be found to afford this ſort of ſpirit in ſome degree of perfection.

RACKOON, in zoology, the name by which we commonly know an American animal, called *coati* by the Braſilians. It is ſomething ſmaller than the beaver, and is of the ſhape of the beaver in its body, and its legs are as ſhort as in that creature. Its hair is like that of a fox, very long, ſoft, and placed thick together, and black at the ends, and brown toward the body. Sometimes from this mixture of colour the back appears plainly grey; and Marggrave mentions another ſpecies, which is of a deep yellow or ochre colour. *Ray*'s Syn. Quad. p. 179.

The head is very like that of the fox in ſhape; but that the ears are ſhorter, roundiſh, and naked, and therefore has a black line drawn acroſs the eyes. The eyes are large, the noſe is black, and rounded at the extremity, like that of a dog; its tail is longer than its body, and is very like that of a cat, having annular marks of different colours. Its feet are each divided into five ſlender toes; by the help of which it climbs trees as expertly as a monkey, and uſes the fore feet as hands, to reach up its food to its mouth. It is a very cleanly animal; and if there be water any way near, it always waſhes its food, be it what it will, before it eats it. It feeds on vegetables, but is alſo very fond of eggs, and will even ſeize birds if it can catch them. It is very common in many parts of the Weſt Indies, and is a creature eaſily tamed.

RADAINUS, among the writers of the middle ages, the name of a black ſtone ſomewhat tranſparent, and ſaid to be found in the head of a cock; and, by others, in the head of a ſea fiſh. They ſay the method of finding the ſtone was to put the creature's head into an ant-hill, where theſe inſects having eaten away the fleſh, the ſtone was eaſily found among the bones.

RADIALIS (*Cycl.*)—RADIALIS *externus primus & ſecundus*, two muſcles cloſely united together; appearing, at firſt ſight, like one muſcle, lying along the external angle of the radius, between the os humeri and the carpus, being fleſhy near the former, and tendinous near the latter.

In many ſubjects we find theſe two muſcles entirely diſtinct from one end to the other; and they may, in that ſtate, be named *radialis externus primus*, and *radialis externus ſecundus*, regard being had to the inſertion of their tendons. Sometimes the two fleſhy portions adhere cloſely together, appearing to make but one body, but the tendons are always diſtinct and ſeparate. The firſt is inſerted above in the criſta of the external condyle of the os humeri, below the inſertion of the ſupinator longus. The ſecond is inſerted in the ſame condyle below the inſertion of the firſt, and in the neighbouring articular ligament. From thence the two fleſhy bodies run down very cloſe together, and having reached the middle of the outſide of the radius, each of them terminates in a long tendon.

The two tendons accompany each other to the extremity of the radius, and having paſſed under a particular annular ligament; they are divided as it were into two cornua, from whence the antients, who looked upon them as but one muſcle, called it bicornis. One of theſe tendons is inſerted anteriorly in the baſis of the firſt metacarpal bone, the other nearly in the ſame part of the ſecond bone, and the tendon of the firſt is ſometimes double, appearing like another bicornis. *Winſlow*'s Anatomy, p. 193.

RADIALIS *internus*, a long muſcle, very like in ſhape to the ulnaris externus, but ſituated more obliquely. Its fleſhy portion is fixed by a ſhort tendon to the outer and upper ſide of the inner condyle of the os humeri, from thence it paſſes obliquely toward the radius, and running along about two thirds of that bone, it forms a long tendon, which continues in the ſame courſe; and at the lower extremity of the radius, paſſes under a particular annular ligament, and under the inſertion of the muſculus thenar. This tendon is at length inſerted chiefly in the inſide of the baſis of the firſt metacarpal bone, and alſo often in the ſecond, and a little in the firſt phalanx of the thumb; having firſt paſſed through the channel of the os trapezium which ſuſtains the thumb. *Winſlow*'s Anatomy, p. 191.

RADIATED *flowers*, (*Cycl.*) in botany, a term uſed by Mr. Tournefort, and others, to expreſs flowers, like that of the great daiſy, ſun flower, *&c.*

A *radiated* flower has two parts; its middle part which is called the diſk, and which is wholly made up of floſcules; and the outer part, which is called the circle or border, which is wholly made up of ſemi-floſcules, or elſe of plain flat leaves; but that is leſs common. The floſcules and ſemi floſcules both uſually adhere to the embryos, and to the thalamus of the flower, being contained in one general cup. Theſe embryos finally ripen into ſeeds; ſometimes furniſhed with down, ſometimes with foliaceous heads, and ſometimes without either, and ſometimes marginated. Of theſe ſeeds ſome are wrapped round with a kind of caſe or capſule, others are ſeparated from

one

one another by ſmall perpendicular leaves. See Tab. I. of Botany, Claſs 1. *Tourn.* Inſt. p. 480.

RADIATED *leaf*, among botaniſts. See LEAF.

RADICAL (*Cycl.*)—RADICAL *numbers*, *numeri radicales*, in the Italian muſic, are 2, 3, 4, 5, 6, 7, 8, 9, and ſometimes 10, which are often met with in muſical compoſitions, to denote the accords of the thorough baſſes. 2 ſtands for the ſecond and its duplicates; 3 for the third; 4 for the fourth, *&c.*

RADICAL *leaf*, among botaniſts. See LEAF.

RADICATUM *folium*, among botaniſts. See LEAF.

RADII (*Cycl.*)—RADII *pinnarum*, in ichthyology, the little ſlender bones ſupporting the membrane, forming the fins in fiſhes, and called by Artedi *oſſicula radiata pinnarum*, from their running from the baſe to the ſummit in the form of rays. See FIN.

Of theſe *radii* ſome are prickly, others not. The prickly ones are always hard and rigid, the others are always ſoft and flexile, whether they terminate ſingle, or are ſplit into two or more branches at the extremity. The prickly ones are always formed of ſingle bones; the others always of two bones, each applied cloſely and evenly to one another. When the fiſh is alive, it is not always eaſy to ſeparate theſe, but when it is boiled, they are eaſily parted at the baſe, and ſometimes all the way up. The fiſh, which have the ſingle and prickly fins on their back, belly, or at the anus, are theſe: the percæ, the ſpari, the labri, the amiæ, the trachuri, the mugiles, the ſudes, the trachini, the zei, the mulli, the ligyri, the gaſteroſtei, the ſcorpœnæ, the capriſci; in theſe the *radii* are all ſingle, and are more or leſs prickly. In the mackrel, the *radii* of the firſt fin of the back, and thoſe of the belly fins, are abſolutely ſimple, but they are ſcarce obſervably prickly.

The following genera of fiſhes are thoſe which have the *radii* of the fins all double at the baſe, and ſoft and flexile: the ſyngnathi, the cobitides, the cyprini, the clupeæ, the coregoni, the oſmari, the eſoces, the pleuronecti, the gadi, and the congers. The ſofter and the more flexile theſe bones are, the more numerous, tranſverſe, and lucid internodia they have in them. The cyprini give us many inſtances of this, as alſo the clupeæ, the coregones, and the eſoces. Thoſe which have fewer of theſe internodia, or tranſverſe lines, are ſomewhat more rigid, though not aculeate, or prickly: this we ſee in the pleuronecti and gadi. Beſide theſe *radii*, there are certain other ſmall bones which are of an oblong figure, and ſerve to ſuſtain the baſes of the back fins, and the fin at the anus. The back fins, and thoſe at the anus, are not joined by their rays to ſome one large muſcle, or large bone, as the pectoral and ventral fins are; but every *radius*, or bone in theſe fins, is affixed to an oblong bone, erected perpendicularly between the apophyſes of the vertebra and the back of the fin. The rays are joined at their baſe to theſe bones by an articulation, and faſtened in by means of a cartilage; and theſe bones do not adhere to the apophyſes of the vertebra, but are placed regularly between them. Theſe bones are always ſingle, and in many kinds of fiſh, as in the pleuronecti, they are hollow at the bottom. Between theſe bones, and the firſt rays of the back fin, in mackrel, there are found certain other little bones, placed ſemicircularly and tranſverſely, but their apices are ſtriated, and turn a little upwards. This is an obſervation yet made only in a few fiſh, but it is worth while to examine whether it is found in thoſe other fiſh alſo, which have ſulci at the back fins. *Artedi*'s Ichthyolog.

RADISH, *raphanus*, in botany. See RAPHANUS.

There are ſeveral varieties of the root of the common garden *radiſh*, which is the only ſpecies cultivated by our gardners: theſe are called by them the ſmall top'd *radiſh*, the deep red, and the ſtriped *radiſh*, &c. All theſe are only varieties ariſing from the culture. The ſmall topped is the kind, the ſeed of which is moſt ſaved, and which is moſt valued about London, becauſe it does not take up much room. They are ſown at various ſeaſons, but the earlieſt is generally at the latter end of October; if theſe are not deſtroyed by froſts, they become fit to eat in March. Theſe are commonly ſowed about walls, pales, or hedges, where they may have ſome defence againſt the cold. The ſecond ſowing is commonly about Chriſtmas, if the weather be mild enough to let the ground be worked. Theſe are alſo to be ſown under a ſhelter, and, if they are not deſtroyed, will be fit to eat in April; and to have a conſtant ſupply, there ſhould be a new ſowing every fortnight, from the middle of January to the beginning of April. The later crops ſhould be ſown on a moiſt ſoil, and in an open ſituation. *Miller*'s Gard. Dict.

RADIUS (*Cycl.*)—RADIUS *of curvature*, or *Radius of the curvature of a curve*, is the *radius* of a circle that has the ſame curvature in a given point of the curve, that the curve has in that point.

RADIUS, among the Romans, a name given to the iron rod with which the boys rolled the trochus. See the article TROCHUS.

RADIUS, in anatomy. The *radius* is nearly of the ſame length with the ulna, bigger at one end than at the other, irregularly triangular, a little bent, and ſituated ſideways along the ulna, and has its name from the reſemblance it bears to the *radius*, or ſpoke of a wheel. Anatomiſts deſcribe in this bone a middle portion, and two extremities. One extremity is ſmall, and like a kind of head ſet upon a neck; the other is large, reſembling a pedeſtal, or baſis; and the bone might therefore be very properly divided into the head, body, and baſis.

The head, or ſmall extremity of the *radius*, is very ſhort or low, the top of it is concave, and the circumference cylindrical, and both the glenoide cavity, and whole circumference, are covered with the ſame ſmooth ſhining cartilaginous cruſt, and about one quarter of the circumference is broader than the reſt. The neck is ſmall, and its ſituation a little oblique; it ends by a lateral tuberoſity, which lies directly under the broad part of the head, being rough in the middle, and on one ſide, and ſmooth and ſuperficially cartilaginous on the other.

The baſis, or great extremity of the *radius*, is much broader than it is thick, and has two broad ſides, and one narrow one. One of the broad ſides is a little hollow, and pretty even; the other is unequally convex, and divided by longitudinal eminences, or bony lines, into three or four longitudinal channels; but theſe are much more diſtinct in freſh bones, than in the dried ſceleton. The narrow ſide is hollowed lengthwiſe, and between it, and the other two, are formed two angles, by which the three ſides are diſtinguiſhed; and oppoſite to it, the other two meet in a third angle. This narrow ſide ends in a ſemilunar cavity, bordered by a ſmooth cartilage, and lying almoſt in the ſame direction with the tuberoſity. The broad ſides end at their common angle by an obtuſe point, or production, which has been called the *ſtyloide apophyſis* of the *radius*, and is in reality a continuation of one of the bony lines already mentioned. The whole baſis ends in an oblong, triangular glenoide cavity, the cartilage of which is continued over the hollow edge of the narrow ſide. This is an articular cavity, reſembling an arch, and ending on one ſide at the ſtyloide apophyſis, and hollowed on the other by the cavity of the narrow ſide. It appears divided into two portions by a ſmall tranſverſe line, and in the natural ſtate, the hollowed ſide is lengthened out by a cartilaginous production, which is loſt in the dried ſceleton.

The middle, or body of the *radius*, is a little incurvated, the concavity lying between the tuberoſity in the head, and the ſemilunar cavity in the baſis. It has three ſides; one rounded, which is the convex ſide of the curvature, and two concave; three angles, two of which are obtuſe, diſtinguiſhing the two concave ſides from the convex, and the third acute, lying between the concave ſides, oppoſite to the convex ſide. In each of theſe ſides there are ſeveral muſcular impreſſions. The head and baſis of this bone are epiphyſes in children, and in ſome ſubjects remain ſuch for a long time afterwards. The *radius* is connected with the ulna, os humeri, and carpus. It is articulated with the ulna, at its two extremities, by a double lateral ginglymus, the cartilaginous ſubſtance of the head turning in the ſmall ſigmoide cavity, and the ſemilunar cavity in the baſis turning upon the ſmall head at the lower extremity of the other bone, and thus the ſmall extremity of one of theſe bones is joined to the great extremity of the other. It is articulated with the os humeri by the application of the cavity in the top of its head to the ſmall head at the lower extremity of the other bone: by this conformation it would be capable of moving in all directions; but as it is tied to the ulna at both extremities, its motions on the ſmall condyloide head, at the lower extremity of the os humeri, are confined to two kinds; that of rotation, when it turns on the ſides of the extremities of the ulna; and that of flexion and extenſion in common with the ulna; and both theſe motions may be performed at the ſame time. *Winſlow*'s Anatomy, p. 80.

Cartilages of the RADIUS. At the baſis of this bone there is a particular cartilage, or triangular production, very thin, longer than it is broad, and rather flat than concave. It is fixed by the baſis, or ſhorteſt ſide, to the lateral ſigmoide notch of the baſis of the *radius*; the other ſide touches the flat extremity of the ſmall head of the ulna, but is not affixed to it. This may properly enough be called the inter-articular cartilage of the wriſt. It is tied to the *radius* by very ſhort ligaments, and ſliding on the ſmall head of the ulna, it follows all the motions of the *radius*. It is therefore a ſort of articular production of the lower ſide of the baſis of the *radius*, and in the natural ſtate fills the void ſpace which, in the ſceleton, appears between the end of the ulna and neighbouring bone of the carpus. *Winſlow*'s Anatomy, p. 140.

Ligaments of the RADIUS. Many of the ligaments of the bones of the fore arm are common to them, and to the os humeri, and others to them, and the bones of the head: two however there are which are proper to this part of the arm, the one called the interoſſeous ligament of the fore arm, the other the coronary ligament of the *radius*; and

and to these may be added the annular ligaments, which serve only for the passage of tendons, and other ligamentary expansions, which may be called muscular ligaments. The interosseous ligament of the fore arm is like that of the leg; it is fixed by one edge along the sharp angle of the *radius*, the other along that of the ulna. It is principally made up of two very strong planes of fibres, which cross each other at oblique angles, and leave holes at different distances for the passage of blood vessels. This ligament ties the two bones closely together, and the two planes serve for the insertion of several muscles. The coronary ligament of the *radius* is a sort of ligamentary hoop, surrounding the circular circumference of the head of that bone. It is very strong, and comes near the solidity of a cartilage, and the side next the *radius* is very smooth. The capsular ligament of the joint of the elbow runs down from its insertion in the os humeri, and is fixed in the olecranum, round the edge of the great sigmoide cavity, including both the apex of the olecranum, and of the coronoide apophysis.

The true common ligaments, by which the os humeri is connected to the bones of the fore arm, called lateral ligaments, are the two fasciculi, which, after being inserted in the condyles of the os humeri, are expanded like a goose's foot; that which is fixed in the inner condyle is called the brachio-cubital, the other the brachio-radical.

Of the ligaments by which the bones of the fore arm are connected to those of the hand, one is like a roundish cord fixed in the styloide apophysis of the ulna, and from thence passes over the os cuneiforme of the carpus; and another pretty broad ligament is fixed on the point of the *radius*, and by its other extremity in the bones of the carpus. From this styloide ligament of the *radius*, along each edge of the basis of that bone, are ranks of ligamentary fibres, lying much in the same direction with the ligament itself, and continued all the way to the styloide ligament of the ulna. There are also several small annular ligaments placed at different distances on the convex side of the basis *radii*, from its styloide apex to its articulation with the extremity of the ulna; these are at least six in number, and some of them are double or triple. The first of these is fixed in the styloide apex; the second in the groove near that apex; the third in the small, narrow, or middle groove; the fourth in the groove next the former; the fifth in the corner of the notch of the basis, at its articulation with the ulna; and the sixth in the extremity of the ulna, near the styloide apophysis. These are all almost wholly covered by the great oblique ligament, and are fixed as strongly in it on one side, as they are in the bones on the other. *Winslow*'s Anatomy, p. 141. seq.

RADIUS *articulatus*, in natural history, a name given by Mellius, Gmelin, and some other authors, to a kind of figured fossils, of which there are a great many very different species, some of which have been described by authors among the belemnitæ, under the names of *alveoli belemnitarum*. Mr. Gmelin, who has taken great pains to inform himself, as well of the nature and figure of these stones, from the subjects themselves, as of their history, and the various accounts of them from other authors, observes, that the place where they are most frequent is Sweden, and that there they are no where so common as in the isle of Oeland. Volkman figures some also which he found in Silesia, and Helwing others which he collected in Prussia: he also found great numbers of them himself in Russia.

They are usually immersed in lime stone, and though at first sight they may all appear alike, yet, on a careful examination, they will be found to differ very greatly. The most obvious general distinction, established by Mr. Gmelin, is, that some of them are strait, and others crooked.

The strait ones may be divided into two genera. The first of these comprehends, according to this gentleman, two species: the first smooth, and with a converging alveolus. This consists of several patellæ of a roundish figure, and disposed in a parallel manner over one another. Each of these patellæ is convex on one side, and concave on the other; and the convex part of one is in the articulation, which joins them into one body, always received into the concave part of another, whose convex part is again received into the concave of a third, and so on throughout the whole body. The diameter of the largest of this species is about two inches, and that of the least an inch. The circumference is not perfectly circular, but in one part is cut in manner of a crescent. This hollow is made for the reception of another cylindric stone, which is not articulated, and which Mr. Gmelin calls an *alveolus*. This alveolus runs through all these crescents in a strait and continued course, and standing out beyond the patellæ, of which the body is composed, is surrounded with a series of fasciæ, more or less elate: these answer to so many of the patellæ, and from these indeed it seems to have obtained this figure; but when this alveolus has, by any accident, been disengaged from its *radius*, it is easily rendered smooth by attrition and other accidents, and is usually found smooth when loose. Acta Petropol. Vol. 3. p. 248.

These are general characters, and are observed in all the specimens of this species; but there are other accidental varieties found in the different ones. Some have the patellæ and the alveolus standing out beyond them, all covered with a thin crust of a matter plainly testaceous, and in some the shelly matter is also found between the junctures of the patellæ. Sometimes also there are seen, at every junction of the patellæ, certain little forked bodies, standing upon the outer part of the alveolus, and seeming to join the several patellæ together. Sometimes the *radii* are found without the alveolus, but then there is always a cavity, or the remains of a cavity, in form of a canal, answering to every lineament of the alveolus; and this is ever covered with a shelly crust on its inner surface. Many of these *radii* are found remarkably compressed, bent, or distorted, which is an accident accounted peculiar to the fossils formed in animal moulds, and shews, with the shelly matter, that the whole must be the remains of some sea fish. Often also, when the whole substance is not injured in its form, the alveolus alone is oddly bent and distorted, whence it appears that it was originally of a tenderer texture than the rest, and there are also evident marks of its having been once hollow.

These are the characters and varieties of this species of *radius*, and there do not seem to be any distinct species under this, unless we are to account for such, those in which the patellæ are a little thicker, or a little thinner, or where they stand closer, or farther asunder. They are found from twelve to eighteen inches in length, but never seem to have been found with the posterior extremity perfect. They all lose themselves in the stone, keeping through their whole extent, as far as they can be traced, the same cylindric figure, without tapering toward either end. It is true, that in some of the stones where they are immersed, and which are polished for various uses, they often seem to grow gradually smaller, so as to terminate in a point; but this may be owing to their being cut in a slanting, not a truly horizontal position, and the bodies themselves may be truly cylindric all the while. Possibly, however, there may be of these, as of the belemnitæ, some cylindric, and others conic; or perhaps all may be conic, but that we have not been able perfectly to trace them.

The second species of the first genus, is the strait articulated *radius* which contains an alveolus, and is of a striated texture. This is composed of patellæ, which stand close, and are firmly joined together. These are convex on one side, and concave on the other, and their several diameters sensibly decrease toward one end. These contain also an alveolus. The patellæ, of which this species is composed, are of an elliptic figure, and each is surrounded with numbers of circular striæ. Ibid. p. 256.

The second genus of the *radii* comprehends those which are strait, and which have a siphunculus running all the way through their middle. These are composed of patellæ of equal diameters, laid parallel on one another, and are convex on one side, and concave on the other; and by this shape are adapted mutually to receive, and be received by one another. The siphunculus in these may often be traced very fairly, and seen to have been once hollow, though in this fossile state it is filled up with the matter of the stone in which the body is lodged; but sometimes they are almost obliterated, either in the whole length of the *radius*, or in one part or other of it. Another species of this is sometimes found, which seems only composed of circular rings, or segments of cylinders, not patellæ: this also has a siphunculus running its whole length, and both this, and the former, have often the remains of a thin coat of a shelly matter upon them.

These are the genera, and subordinate distinction of the first class of the articulated *radii*, that is the strait ones. The second class contains those which are crooked or twisted. The bodies of this class are much more rare than those of the former. They consist of patellæ, which are nearly round, only a little inclining to an elliptic figure; they are convex on one side, and concave on the other, and are each bored through with a small aperture, through which a siphunculus passes, running through the whole length of the body. Sometimes this is placed regularly in the middle, sometimes nearer to one side. There seem to be two species of this; the one composed of very thin patellæ, and the other of considerably thick ones.

The regular and nice configuration of these bodies, shews very plainly that they cannot be of mineral origin, but the several patellæ of which each is composed, the siphunculus of communication, obvious in several, and the shelly matter yet found remaining on many, prove them to have been once shell-fish of the univalve or tubular concamerated kind; the description of which, so far as it can be gathered from these remains, must have been this. The shell must have been either cylindric or conic in figure, of a smooth surface, and divided into several chambers or cells; but this so, that the septa which form the concamerations are not continued, and whole, but in some part of the periphery are cut in, in the shape of a crescent. Through these crescents, which

ſtanding all together, make a continued canal, there has paſſed another ſhelly body of a cylindric or conic figure, alſo divided into concamerations; and that in ſuch a manner, that the ſepta which form the cells are pierced with a ſmall aperture on one ſide, which grows gradually ſmaller as the ſhell extends in length; and finally, through theſe apertures in the concamerations, there paſſes another ſhell pointed at the end, and like the reſt divided into its concamerations, and pierced along its middle with a ſiphunculus. Mem. Acad. Petrop. Vol. 3. p. 263.

This ſhell is therefore a compages of three ſhelly bodies, incloſed one within another; and it muſt be ſuppoſed, in order to carry an analogy with other ſhell-fiſh, that theſe three ſhelly bodies have communications with one another, by means of certain ſlits or perforations. The communication of theſe, one with another, ſeems alſo evident, from their being all found in their foſſile ſtate, filled with the ſame ſtony matter; this has, doubtleſs, been all received in at the ſiphunculus of the inner ſhell, and thence has been thrown into the ſecond, and from this into the third ſhell, ſo as to fill up all the concamerations of the outer, as well as of the inner parts. This muſt have been the caſe with theſe; and the ſeveral various ſpecies that are at this day found foſſile, muſt have owed their origin to as many different ſpecies of the ſhells. The crooked, and twiſted, or wreathed kinds, which have the ſiphunculus, uſually placed near the ſide, greatly approach in their ſtructure to ſome of the cornua ammonis.

RADIX (*Cycl.*)—RADIX *entrochorum*, the *root of the entrochi*, a name given by ſome authors to a foſſile ſubſtance, uſually found among the entrochi, and ſeeming to have been the baſis from which they have grown. It is plainly a part of the *ſtella marina arboreſcens* petrified, as thoſe ſtones alſo are: but people, who from a proper examination of the animal world, had miſſed the true origin of theſe ſtones, and called them rock plants, have eſteemed this part of the fiſh the bulbous root of the plant. This foſſil is rarely found whole, but the fragments of it are very common. When entire, it is about the ſize of a walnut; the top of it being flat, and in ſome degree reſembling the end of an entrochus, with a central hollow, but not having the leaſt appearance of the rays of thoſe ſtones. Theſe foſſils, though not properly judged of as to their origin, have yet been deſcribed by a great number of authors. Agricola, in particular, compares the form of them to a wheel. The body of this kind well reſembles indeed the nave of a wheel, the ſhape of it being conical toward one end, till you come to the top, and then a little flatted, with a hole in it. There is alſo a like hole in the oppoſite broad end of the ſame foſſil, ſeeming fit for an axle to paſs through; and there are five hollow ſtirts, or feet, iſſuing ſideways, at equal diſtances from the broad bottom, and equally carried on in the ſame direction, ſo as not amiſs to repreſent the ſpokes. At the end of each of theſe rays, or ſpokes, there is a hollow, of the ſame nature with thoſe in the middle of the common entrochi, but this is cut acroſs by a ſeam, or ſtreak of the ſame ſtone, which paſſes directly over its center, and covers about a third part of it; this goes no farther than the mouth of the hole, but it cuts it into two, and ſhews it in the form of two eyes. Theſe radii, or ſpokes, are very ſeldom found ſo perfect as here deſcribed. Liſter mentions them as being formed like creſcents at the end, which may very eaſily happen from the breaking off a part of the terminating part. Phil. Tranſ. N° 129.

The *radix entrochorum* is never of a ſmooth ſurface, but is wrought all over with trigonal, tetragonal, pentagonal, and hexagonal plates. The uſual ſtructure is this: the upper part of the conical end is wrought round with ſix large hexagonal plates. Theſe reach half way of the ſtone, then follow a ſecond round made up of eleven pentagonal plates; theſe are pretty large, and reach almoſt to the broad bottom, which is a little convex. The bottom itſelf and the feet contain plates of all the ſhapes, but they are uſually very ſmall. The ſubſtance of this foſſil is always a whitiſh opake ſpar, of the ſame nature with the trochites. It has outwardly a ruſty coat, and is blueiſh within, like ſmall ſhells. It is generally found in clay, and is ſo filled up with it, as to appear ſolid; but on the picking this out with a pointed inſtrument, the whole appears to be only a hollow ſhell, of about the thickneſs of a half crown piece.

The ſmall ſcales of pentangular and other figures, which make up theſe bodies, are often found looſe in the clay where the entrochi are alſo found; but they have ſo little reſemblance to any thing of the entrochus kind, that few have thought of referring them to that foſſil, till they have met with the *radix* entire. There are a vaſt variety of theſe plates, ſome are convex, others concave; ſome have edges plain and ſmooth, others ſerrated, and ſome have, on the convex parts, the figure of a ſtar, conſiſting of ſix emboſſed rays, with a ſtud between every two of them, in the manner of the wires, or appendiculæ, growing from the aſteriæ, which are a ſort of foſſils, evidently very nearly allied to the entrochus kind in all reſpects.

RADIX *alba*, a word uſed by Dioſcorides, to expreſs the root of the dracunculus.

RADULA, the *raſpatory*, a chirurgical inſtrument uſed to cleanſe foul bones.

RAERS *of a cart*. See the article CART.

RAGS. In ſome counties of England, particularly in Oxfordſhire, it is a common thing to uſe old woollen *rags* by way of manure upon land. Taylors ſhreads anſwer this purpoſe, in ſome degree; but the old *rags* of cloaths, which have been worn by men and women, are much better, which is owing to the ſalts they have imbibed from the perſpiration of the body they uſed to cover. *Plot*'s Oxfordſhire, p. 250.

RAG-*bolts*, in a ſhip, are ſuch as have jags or barbs on each ſide, to keep them from flying out of the hole wherein they are driven.

RAG-*ſtone*, a name given by our artificers to a kind of ſtone, which they uſe for ſetting an edge upon knives, chiſels, and other tools. It is a greyiſh coloured ſtone, containing a large quantity of talcky particles, and ſplits eaſily into thin flakes. It is a ſoft ſtone, and is uſed only to finiſh the ſetting an inſtrument after the edge has been prepared by grinding or rubbing the tool upon ſome other ſtone of a coarſer texture. We have this from Newcaſtle and many other parts of the north of England, where there are very large rocks of it in the hills.

RAG-*wort*, *jacobæa*, in botany. See JACOBÆA.

There are two or three ſpecies of this plant cultivated in the gardens of the curious; and one very common in moſt places, which is the maritime kind, remarkable for its white leaves. This had been long uſed to be nurſed up, with great care, in our green houſes; but of late ſome ſtraggling ſeeds of it having propagated themſelves on a wall, and there ſtood the winter's cold without hurt, we were taught that the plant did not require the care it had been uſed to be treated with.

All the kinds may be propagated by ſowing their ſeeds in March, on a bed of light earth, watering it frequently in dry weather. In May the plants may be taken up, and planted in pots, and ſet in a warm ſituation till October, when the tenderer kinds are to be taken into a green-houſe. Theſe require much pruning in ſummer to keep them in ſhape, for they grow very faſt, and in winter will die if they are not often watered. *Miller*'s Gardners Dict.

The grey, or white leaved kind, is eaſily propagated by cuttings, planting them in light earth, and frequently watering them till they have taken root, and then the plants are to be removed into a warm ſituation. This method is vaſtly better in regard to this particular plant, than the raiſing from ſeeds; becauſe, when ſo raiſed, it is very apt to degenerate, and loſe the whiteneſs of its leaves, which are its principal beauty. See JACOBÆA.

RAHAS, in ichthyology, a name given by ſome authors to the *torpedo*, or cramp fiſh. It is a ſpecies of the ray fiſh, diſtinguiſhed by Artedi, by the name of the *raia tota levis*, the wholly ſmooth ray. See TORPEDO, *Cycl.*

RAIA, in the Linnæan ſyſtem of zoology, the name of a diſtinct genus of fiſhes of the general order of the chondropterygii. The diſtinguiſhing characters of this genus are, that the body is flatted, and the apertures of the gills are five on each ſide. *Linnæi* Syſt. Natur. p. 51.

In the Artedian ſyſtem of ichthyology, the characters of this genus of fiſhes are theſe. They are of the chondropterygious kind. The apertures of the bronchia are five on each ſide, and are ſituated on the breaſt a little below the mouth. The head and the whole body are of a remarkably depreſſed or flatted figure. The ſides are terminated in broad fins, which are in the place of pectoral ones in other fiſhes. The eyes are placed in the upper ſide of the head, and the mouth generally in the lower. There is on each ſide of the head a foramen behind the eyes. And the tail is generally long and ſlender.

Of thoſe *raiæ* which have obtuſe or granulous teeth, the following are the ſpecies. 1. The oblong *ray* with one row of ſpines, along the middle of the back. This is the *rhinobatus* and *ſquatino-raia* of authors. 2. The prickly *ray*, with teeth like tubercles, and a tranſverſe cartilage in the belly. This is the *raia clavata* of authors, and our *thornback* and *maid*. 3. The ſmooth bodied *ray*, with a long ſpine ſerrated on one ſide in the tail, which has no fin. This is the *paſtinacha marina* of authors. 4. The ſmooth bodied *ray*, with generally two ſpines ſerrated behind in the tail, without a fin. This is the *altavela* of the Italians. 5. The ſmooth bodied *ray* with a ſingle long ſerrated ſpine in the tail, with a fin on it. This is the fiſh, called by authors the *aquila marina*.

Of the *rays* with ſharp teeth, the following are the known ſpecies. 1. The *ray* with the whole back armed with ſpines, with two rows of them on the tail, and a ſingle row about the eyes. This is the *ray* called the white horſe *ray*, or *raja tota aſpera* of authors. 2. The *ray* with the back and belly ſmooth, but with a row of ſpines about the eyes, and three rows of them upon the tail. This is the *raja lævis oculata* of authors. 3. The variegated *ray* with two prickly tubercles on the middle of the back. This is the *raja oxyrhincos major* of authors. It ſometimes has two fins,

ſome-

ſometimes only one on the tail. 4. The *ray* with the middle of the back ſmooth, and with only one row of ſpines on the tail. This is the *ſkate* fiſh or *flair*. It is of a greyiſh colour, variegated with blackiſh ſpots, and grows very large. 5. The wholly ſmooth *ray*. This is the famous *torpedo*, or cramp fiſh. See the article TORPEDO, *Cycl.*

Rays are generally divided by authors into the ſmooth and the prickly. The ſmooth are what we call the *ſkates* and *flairs*: the prickly we call *thornbacks*, and the young ones of both kinds *maids*. But Willughby thinks they are more regularly divided into two orders, the one containing thoſe which have teeth, the other thoſe which have none. *Willughby*'s Hiſt. Piſc. p. 68.

RAJANIA, in botany, a name given by Linnæus to a genus of plants. The different ſpecies of which are made to compoſe two genera in Plumier, under the names of *jan-raia* and *bryoniæ* ſpecies. The characters of the genus are theſe. It produces ſeparate male and female flowers; in the male flower the perianthium is divided into ſix ſegments, which are oblong, and pointed, and ſtand cloſe in the baſis, ſo as to form a ſort of bell, and expand more at their points. There are no petals, and the ſtamina are ſix briſtly filaments ſhorter than the cup, and terminated by ſimple apices. In the female flower the perianthium is one leaved, campanulated, and ſtands upon the germen, but afterwards withers away. This alſo is divided into ſix ſegments at the edge. There are no petals, and the germen of the piſtil is compreſſed, and edged, with a membrane on one ſide. The ſtyles are three in number, and are of the length of the cup. The ſtigmata are ſimple and obtuſe. The fruit is roundiſh, and has a membrane growing on one ſide, which, in fine, ſpreads almoſt round it; in this is contained a ſingle ſeed of a roundiſh colour. *Linnæi* Gen. Pl. p. 479. *Plum.* 29 and 98.

RAIL (*Cycl.*)—RAIL, or *water* RAIL, in zoology, the name of the *rollus aquaticus* of authors, a bird of the moorhen kind, but ſmaller than the common moorhen. See ROLLUS.

Fife RAILS, in a ſhip. See FIFE.

RAIN (*Cycl.*)—Vehement *rains* in many countries are found to be attended with barrenneſs and poorneſs of the lands, and miſcarriage of the crops in the ſucceeding year: and the reaſon is plain; for theſe exceſſive ſtorms waſh away the fine mould into the rivers, which carry it into the ſea, and it is a long time before the land recovers itſelf again. The remedy to the famine, which ſome countries are ſubject to from this ſort of miſchief, is the planting large orchards and groves of ſuch trees, as bear eſculent fruit; for it is an old obſervation, that in years, when grain ſucceeds worſt, theſe trees produce moſt fruit of all. It may partly be owing to the thorough moiſtening of the earth, as deep as their roots go, by theſe rains, and partly to their trunks ſtopping part of the light mould carried down by the rains, and by this means furniſhing themſelves with a coat of new earth. Phil. Tranſ. N° 90.

Preternatural RAINS. We have numerous accounts in the hiſtorians of our own, as well as other countries of *preternatural rains*, ſuch as the *raining* of ſtones, of duſt, of blood, nay, and of living animals, as young frogs, and the like. We are not to doubt the truth of what thoſe who are authors of veracity and credit relate to us of this kind, ſo far as to ſuppoſe that the falling of ſtones and duſt never happened; the whole miſtake is, the ſuppoſing them to have fallen from the clouds; but as to the blood and frogs, it is very certain that they never fell at all, but the opinion has been a mere deception of the eyes. Men are extremely fond of the marvellous in their relations; but the judicious reader is to examine ſtrictly whatever is reported of this kind, and is not to ſuffer himſelf to be deceived.

There are two natural methods by which quantities of ſtones and duſt may fall in certain places, without their having been generated in the clouds, or fallen as *rain*. The one is by means of hurricanes; the wind which we frequently ſee tearing off the tiles of houſes, and carrying them to conſiderable diſtances, being equally able to take up a quantity of ſtones, and drop them again at ſome other place. But the other, which is much the moſt powerful, and probably the moſt uſual way, is for the eruptions of volcano's, and burning mountains, to toſs up, as they frequently do, a vaſt quantity of ſtones, aſhes, and cinders, to an immenſe height in the air; and theſe being hurried away by the hurricanes and impetuous winds, which uſually accompany thoſe eruptions, and being in themſelves much lighter than common ſtones, as being half calcined, may eaſily be thus carried to vaſt diſtances, and there falling in places where the inhabitants know nothing of the occaſion, they cannot but be ſuppoſed by the vulgar to fall on them from the clouds. It is well known, that in the great eruptions of Ætna and Veſuvius, ſhowers of aſhes, duſt, and ſmall cinders, have been ſeen to obſcure the air, and overſpread the ſurface of the ſea for a great way, and cover the decks of ſhips; and this at ſuch a diſtance, as it ſhould appear ſcarce conceivable that they ſhould have been carried to; and probably, if the accounts of all the ſhowers of theſe ſubſtances mentioned by authors be collected, they will all be found to have fallen within ſuch diſtances of vulcano's; and if compared, as to the time of their falling, will be found to correſpond in that alſo with the eruptions of thoſe mountains. We have known inſtances of the aſhes from Veſuvius having been carried thirty, nay forty leagues, and peculiar accidents may have carried them yet farther. It is not to be ſuppoſed that theſe ſhowers of ſtones and duſt fall for a continuance, in the manner of ſhowers of *rain*, or that the fragments or pieces are as frequent as drops of water; it is ſufficient that a number of ſtones, or a quantity of duſt, fall at once on a place, where the inhabitants can have no knowledge of the part from whence they come, and the vulgar will not doubt their dropping from the clouds. Nay, in the canton of Berne in Swiſſerland, the inhabitants accounted it a miracle that it rained earth and ſulphur upon them, at a time that a ſmall vulcano terrified them; and even while the wind was ſo boiſterous, and hurricanes ſo frequent, that they ſaw almoſt every moment the duſt, ſand, and little ſtones torn up from the ſurface of the earth in whirlwinds, and carried to a conſiderable height in the air, they never conſidered, that both the ſulphur thrown up by the vulcano, and the duſt, *&c.* carried from their feet muſt fall ſoon after ſomewhere. It is very certain that in ſome of the terrible ſtorms of large hail, where the hail-ſtones have been of many inches round, that on breaking them there have been found what people have called ſtones in their middle; but theſe obſervers needed only to have waited the diſſolving of one of theſe hail-ſtones, to have ſeen the ſtone in its center diſunite alſo, it being only formed of particles of looſe earthy matter, which the water, exhaled by the ſun's heat, had taken up in extremely ſmall moleculæ with it; and this only having ſerved to give an opake hue to the inner part of the congelation, to which the freezing of the water alone gave the apparent hardneſs of ſtone.

The *raining* of blood has been ever accounted a more terrible ſight, and a more fatal omen than the other *preternatural rains*, already mentioned. It is very certain that nature forms blood no where but in the veſſels of animals, and therefore ſhowers of it from the clouds are by no means to be credited. Thoſe who ſuppoſe that what has been taken for blood, has been actually ſeen falling through the air, have had recourſe to flying inſects for its origin, and ſuppoſe it the eggs or dungs of certain butter-flies, diſcharged from them as they were high up in the air. But this ſeems a very wild conjecture, as we know of no butterfly whoſe excrements, or eggs, are of ſuch a colour, or whoſe abode is ſo high, or their flocks ſo numerous, as to be the occaſion of this.

It is moſt probable that theſe bloody waters were never ſeen falling, but that people ſeeing the ſtanding waters blood coloured, were aſſured, from their not knowing how it ſhould elſe happen, that it had *rained* blood into them. A very memorable inſtance of this there was at the Hague in the year 1670. Swammerdam, who relates it, tells us, that one morning the whole town was in an uproar on finding their lakes and ditches full of blood, as they thought, and having been certainly full of water the night before, they agreed it muſt have *rained* blood in the night; but a certain phyſician went down to one of the canals, and taking home a quantity of this blood coloured water, he examined it by the microſcope, and found that the water was water ſtill, and had not at all changed its colour, but that it was full of prodigious ſwarms of ſmall red animals, all alive, and very nimble in their motions, whoſe colour, and prodigious number, gave a red tinge to the whole body of the water they lived in, on a leſs accurate inſpection. The certainty that this was the caſe, did not however perſuade the Hollanders to part with the miracle; they prudently concluded, that the ſudden appearance of ſuch a number of animals was as great a prodigy, as the *raining* of blood would have been; and are aſſured to this day, that this portent foretold the ſcene of war and deſtruction which Lewis the fourteenth afterwards brought into that country, which had before enjoyed forty years uninterrupted peace.

The animals which thus colour the water of lakes and ponds, are the *pulices arboreſcentes* of Swammerdam, or the water fleas with branched horns. Theſe creatures are of a reddiſh yellow, or flame colour; they live about the ſides of ditches, under weeds, and among the mud, and are therefore the leſs viſible, except at a certain time, which is in the end of May or beginning of June; it is at this time that theſe little animals leave their receſſes to float looſe about the water, to meet for the propagation of their ſpecies, and by that means become viſible in the colour they give the water. This is viſible, more or leſs, in one part or other of almoſt all ſtanding waters at this ſeaſon; and it is always at this ſeaſon that the bloody waters have alarmed the ignorant.

The *raining* frogs is a thing not leſs wonderful in the accounts of authors who love the marvellous, than thoſe of blood or of ſtones, and this is ſuppoſed to happen ſo often, that there are multitudes who pretend to have been eye-

witneſſes

witneſſes of it. Theſe *rains* of frogs always happen after very dry ſeaſons, and are much more frequent in the hotter countries than the cold ones. In Italy they are very frequent, and it is not uncommon to ſee the ſtreets of Rome ſwarming both with young frogs and toads in an inſtant, in a ſhower of *rain*; they hopping every where between the people's legs as they walk, though there was not the leaſt appearance of them before. Nay, they have been ſeen to fall through the air down upon the pavements. This ſeems a ſtrong circumſtance in favour of their being *rained* down from the clouds, but when ſtrictly examined, it comes to nothing; for theſe frogs that are ſeen to fall, are always found dead, lamed, or bruiſed by the fall, and never hop about as the reſt; and they are never ſeen to fall, except cloſe under the walls of houſes, from the roofs and gutters of which they have accidentally ſlipped down. People, who love to add to ſtrange things yet ſtranger, affirm that people have had the young frogs fall into their hats in the midſt of an open field, but this is idle and wholly falſe.

People, who cannot agree to their falling from the clouds, have tried to ſolve the difficulty of their ſudden appearance, by ſuppoſing them hatched out of the egg, or ſpawn, by theſe rains. Nay, ſome have ſuppoſed them made immediately out of the duſt; but there are unanſwerable arguments againſt all theſe ſuppoſitions. Equivocal generation, or the ſpontaneous production of animals out of duſt, being now wholly exploded. The fall from the clouds muſt deſtroy and kill theſe tender and ſoft bodied animals; and they cannot be at this time hatched immediately out of eggs; becauſe the young frog does not make its appearance from the egg in this form, but has its hinder legs enveloped in a ſkin, and is what we call a tadpole; and the young frogs are at leaſt an hundred times larger at this time of their appearance, than the egg from which they ſhould be hatched.

It is a certainty that the frogs, which make their appearance at this time, were hatched, and in being long before, but that the dry ſeaſons had injured them, and kept them ſluggiſhly in holes, or coverts, and that all the *rain* does, is the enlivening them, giving new ſpirits, and calling them forth to ſeek new habitations, and enjoy the element they were deſtined, in great part, to live in. Theophraſtus, the greateſt of all the naturaliſts of antiquity, has affirmed the ſame thing. We find that the error of ſuppoſing theſe creatures to fall from the clouds was as early as that author's time, and alſo that the truth, in regard to their appearance, was as early known; though, in the ages ſince, authors have taken care to conceal the truth, and to hand down to us the error. We find this venerable ſage, in a fragment of his on the generation of animals which appear on a ſudden, bantering the opinion, and aſſerting that they were hatched and living long before. The world owes, however, to the accurate Seignior Redi the great proof of this truth, which Theophraſtus only has affirmed; for this gentleman diſſecting ſome of theſe new appearing frogs, found in their ſtomachs herbs, and other half digeſted food, and openly ſhewing this to his credulous countrymen, aſked them whether they thought that nature, which engendered, according to their opinion, theſe animals in the clouds, had alſo been ſo provident as to engender graſs there alſo for their food and nouriſhment.

To the *raining* of frogs we ought to add the *raining* of graſshoppers and locuſts, which have ſometimes appeared in prodigious numbers, and devoured the fruits of the earth. There has not been the leaſt pretence for the ſuppoſing that theſe animals deſcended from the clouds, but that they appeared on a ſudden in prodigious numbers. The naturaliſt, who knows the many accidents attending the eggs of theſe, and other the like animals, cannot but know that ſome ſeaſons will prove particularly favourable to the hatching them, and the prodigious number of eggs, that many inſects lay, could not but every year bring us ſuch abundance of the young, were they not liable to many accidents, and had not provident nature taken care, as in many plants, to continue the ſpecies by a very numerous ſtock of ſeeds, of which perhaps not one in five hundred need take root, in order to continue an equal number of plants. As it is thus alſo in regard to inſects, it cannot but happen, that if a favourable ſeaſon encourage the hatching of all thoſe eggs, a very ſmall number of which alone were neceſſary to continue the ſpecies, we muſt, in ſuch ſeaſons, have a proportionate abundance of them. We had lately in London ſuch a prodigious ſwarm of the little beetle, we call the *lady cow*, that the very poſts in the ſtreets were every where covered with them. But thanks to the progreſs of philoſophy among us, we had no body to aſſert that it *rained* cow ladies, but contented ourſelves with ſaying that it had been a favourable ſeaſon for their eggs. The late prodigious number of a ſort of grub which did vaſt miſchief among the corn and graſs, by eating off their roots, might alſo have been ſuppoſed to proceed from its having *rained* grubs by people fond of making every thing a prodigy; but our knowledge in natural hiſtory aſſured us, that theſe were only the hexapode worms of the common hedge beetle, called the *cock chafer*.

The *raining* of fiſhes has been a prodigy alſo much talked of in France, where the ſtreets of a town at ſome diſtance from Paris, after a terrible hurricane in the night, which tore up trees, blew down houſes, *&c.* were found in a manner covered with fiſhes of various ſizes. No body here made any doubt of theſe having fallen from the clouds; nor did the abſurdity of fiſh, of five or ſix inches long, being generated in the air, at all ſtartle the people, or ſhake their belief in the miracle, till they found, upon enquiry, that a very well ſtocked fiſh-pond, which ſtood on an eminence in the neighbourhood, had been blown dry by the hurricane, and only the great fiſh left at the bottom of it, all the ſmaller fry having been toſſed into their ſtreets.

Upon the whole, all the ſuppoſed marvellous *rains* have been owing to ſubſtances naturally produced on the earth, and either never having been in the air at all, or only carried thither by accident.

In Sileſia, after a great dearth of wheat in that country, there happened a violent ſtorm of wind and rain, and the earth was afterwards covered, in many places, with ſmall round ſeeds. The vulgar cried out that providence had ſent them food, and that it had *rained* millet; but theſe were, in reality, only the ſeeds of a ſpecies of veronica, or ſpeedwell, very common in that country, and whoſe ſeeds being juſt ripe at that time, the wind had diſlodged them from their capſules, and ſcattered them about. In our own country, we have hiſtories of *rains* of this marvellous kind, but all fabulous. It was once ſaid to *rain* wheat in Wiltſhire, and the people were all alarmed at it as a miracle; till Mr. Cole ſhewed them, that what they took for wheat was only the ſeeds, or kernels of the berries of ivy, which being then fully ripe, the wind had diſlodged from the ſides of houſes, and trunks of trees, on which the ivy which produced them crept.

And we even once had a *raining* of fiſhes near the coaſt of Kent in a terrible hurricane, with thunder and lightning. The people who ſaw ſmall ſprats ſtrewed all abouts afterwards, would have it that they had fallen from the clouds; but thoſe who knew how far the high winds have been known to carry the ſea water, did not wonder that they ſhould be able to carry ſmall fiſh with it ſo ſmall a part of the way. Philoſ. Tranſ.

RAINS, in the ſea language, that tract of the ſea to the northwards of the equator, between four and ten degrees of latitude, and lying between the meridian of Cape Verde and that of the eaſtermoſt iſlands of the ſame name. They call this tract the *rains*, becauſe there are almoſt continual calms, conſtant *rains*, and thunder and lightning to a ſtrange degree there; and the winds, when they do ever blow, are only ſmall uncertain guſts, and ſhift about all round the compaſs; ſo that ſhips are ſometimes here detained a long while, and can make but very little way.

RAIN *fowl*, an Engliſh name given by many to the common green wood-pecker, or *picus viridis*, from an obſervation that it is always moſt clamorous when *rainy* weather is coming on. The Latins have, for the ſame reaſon, called it the *pluvialis avis*. See the article PICUS.

Animalcules in RAIN-*water*. The accurate Mr. Lewenhoek has obſerved, that there are no living creatures to be diſcerned in freſh *rain-water*, but that after it has ſtood ſome days, it will be found to abound with great numbers of animalcules, ſo ſmall, that they are to a mite what a bee is to a horſe. In ſome days more animalcules much larger are diſcovered.

Another very remarkable kind is diſcovered in *rain-water*, after ſtanding ſome time; theſe have two little horns, which are in continual motion. The ſpace between the horns is flat, though the body is round, but tapering a little toward the end, where there is a tail four times as long as the body, and of the thickneſs of the thread of a ſpider's web. Theſe are ſo ſmall, that many hundred of them are not equal to a grain of ſand; and if they meet with any little filament in the water, they are uſually entangled in it, and uſe great efforts to diſengage their tails.

Another animalcule there alſo is in *rain-water*, of an oval figure, with the head at the ſmaller end. Theſe have ſeveral feet extremely minute and fine, and they can, at pleaſure, contract their bodies into a round ſhape, which they uſually do as the water dries away. A third ſort Mr. Lewenhoek obſerved alſo, twice as long as broad, and eight times ſmaller than the laſt; theſe alſo had ſmall feet, and were very nimble. But the briſkeſt of all were a yet greatly ſmaller kind; theſe were not of a thouſandth part of the ſize of a louſe's eye, and they moved round with incredible ſwiftneſs. *Baker*'s Microſcop. p. 82.

RAISE, in the manege, is uſed for working; thus to *raiſe* a horſe upon corvets, caprioles, and peſades, is to make him work at corvets, caprioles, *&c.*

RAISE is likewiſe uſed for placing a horſe's head right, and making him carry well, and hindring him to carry low, or to arm himſelf.

RAISINS (*Cycl.*)—RAISIN *brandy*, a name given by our diſtillers to a very clean and pure ſpirit, procured from *raiſins*

fermented only with water. Thus treated, they yield a ſpirit ſcarce at all diſtinguiſhable from ſome of the wine ſpirits; for there are as many kinds of wine ſpirits, as there are of grapes. The coarſer the operation of diſtilling is performed in this caſe, the nearer will be the reſemblance of the wine ſpirit; that is, there will be moſt of this flavour in the ſpirit, when as much as can be of the oil is thrown up with a galloping heat.

The diſtillers are very fond of the wine ſpirit, with which they hide and diſguiſe the taſte of their nauſeous malt, and other ſpirits; and in defect of that ſpirit, this of *raiſins*, made in this coarſe manner, will go almoſt as far. It is indeed ſurpriſing how extenſive the uſe of theſe flavouring ſpirits is, ten gallons of *raiſin* ſpirit, or ſomewhat leſs of the wine ſpirit, being often ſufficient for a whole piece of malt ſpirit, to take off its native flavour, and give it an agreeable vinoſity. It is no wonder, therefore, that the diſtillers, and ordinary rectifiers, are ſo fond of this, as it is a good cloak for their defects, and the imperfection of their proceſſes.

When *raiſin brandy* is intended for common uſe, the fire ſhould be kept ſlower and more regular in the diſtillation, and the ſpirit, though it hath leſs of the high flavour of the grape, will be more pleaſant and more pure. *Shaw*'s Eſſay on Diſtillery.

RAKE (*Cycl.*)—RAKE, in the manege. A horſe *rakes*, when being ſhoulder-ſplait, or having ſtrained his fore-quarter, he goes ſo lame, that he drags one of his fore legs in a ſemicircle; which is more apparent when he trots, than when he paces.

RAKE, in mining, is the ſame with a vein. See VEIN.

RAM, (*Cycl.*) *aries*, in zoology, the male of the ſheep kind. See the article OVIS.

RAM *head*, on board a ſhip, the name of a great block belonging to the fore and main halliards. It hath in it three ſhivers, into which the halliards are put, and at its head the tyes are reeved into an hole made there for that purpoſe.

RAMADAN (*Cycl.*)—The *ramadan* happens at different ſeaſons of the year, and when it is in the ſummer, is very hard on the labourers, who are not allowed to drink, but only to waſh their mouths. This month once in thirty-three years is in every ſeaſon of the year, the Turkiſh month being lunar, and they beginning at the day they can ſee the moon; whereas the Jews begin their account from the day the moon makes, which is a day before the Turks. *Pocock*'s Egypt, p. 184.

RAMAG, a word uſed by ſome of the chemical writers to expreſs aſhes.

RAMAGE *falcons*. See the articles BRANCHER and FALCON.

RAMAI, in natural hiſtory, a name given by many old writers to bole armenic.

RAMALIS *vena*, a name given by ſome anatomical authors to the *vena portæ*.

RAMED, a name given by ſome chemical writers to rhubarb.

RAMESAN, an oriental term for a month of faſting, very religiouſly obſerved among the Turks. See RAMADAN.

RAMEX, a word uſed by ſome as a name for a hernia, or rupture.

RAMIGRI, a word uſed by ſome writers as a name for colophony.

RAMINGUE, in the manege. A horſe gets this name that is reſty, and reſiſts or cleaves to the ſpurs; that is, defends himſelf with malice againſt the ſpurs; ſometimes doubles the reins, and frequently yerks to favour his diſobedience. See the articles TICKLISH and DOUBLE.

RAMOSE *leaf*, in botany. See LEAF.

RAMPIN, in the manege. See TOE.

RAMPION, in botany. See RAPUNCULUS.

RAMULOSE *leaf*, *ramuloſum folium*, among botaniſts. See the article LEAF.

RAMUS, (*Cycl.*) in the anatomy of plants, a name given to the firſt or lateral branches, which go off from the petrolium, or middle rib of a leaf. The ſubdiviſions of theſe are called *furculi*, and the final diviſions of theſe, into the moſt minute of all, are by ſome called *capillamenta*; but in general, both theſe kinds are comprehended under the name of *furculus*. Act. Erudit. 1722.

RAN, in our old writers, is uſed for open or public robbery, ſo manifeſt that it cannot be denied. Ran *dicitur aperta rapina quæ negari non poteſt. Lamb.* 125. Leg. Canut. c. 58. Hence it is to this day vulgarly ſaid of one, who takes the goods of another injuriouſly and violently, that he has taken or ſnatched all he could *rap* and *ran*. Terms of Law. *Blount*, *Cowel*.

RANA, the *frog*, in zoology, a very well known animal of the amphibious kind, the characters of it are; that the body is naked, and is in one part of its life furniſhed with a tail.

The feet of the *frog* are webbed, for the better ſwimming, and it has very ſtrong muſcles in the hinder part of its body to aſſiſt it in leaping. The lungs of the *frog* are different from thoſe of all other animals; they are only a ſort of membranaceous bladders, with ſeveral tubercles, by means of which they reſemble the fruit of the firs, or pines: theſe, when once inflated, do not immediately become flaccid, as in other animals, but remain in that ſtate as long as the creature pleaſes. The creature can remain a long time under water, and has been kept ſo for ſeveral days by tying it down, and received no hurt from it. It is a very long lived animal; and even if its belly be opened, and the inteſtines, and all the viſcera, taken out, it will continue its leaping, and all its other motions, as if nothing had happened to it, for a conſiderable time; but if the nerve of one of the hinder legs be cut, it loſes all power of uſing that limb on the inſtant. *Ray*'s Synop. Quad. p. 247.

The *frog* differs from all creatures in the manner of its generation. It no way reſembles any of the quadrupeds in this particular, and though in ſome ſort it approaches to the nature of fiſhes, yet it differs from them alſo in many things. The egg of the *frog* is a ſmall black ſpot, enveloped in a mucilaginous ſubſtance; in this egg is contained the embryo *frog*, which, on the breaking of the egg in hatching, comes forth in form of a tadpole. This young animal is for ſome time nouriſhed by the gelatinous matter which envelops the eggs, but it does not conſume the whole of it; for the particles of water making way by degrees into it, divide its parts, and it ſoon becomes expanded, frees itſelf from the living animals, and floats on the ſurface of the water, or at a ſmall depth in it, in form of a thin cloud: this, though it now no longer ſerves for food to the young creature, is however of ſome ſervice to it, ſerving it as an aſylum, or place of reſt and ſafety, when tired with ſwimming.

The egg of the *frog* therefore is, in ſome degree, analogous to that of an inſect of the winged kind, which is to go through a metamorphoſis before it arrives at its perfect ſtate; for it hatches into the tadpole, as the egg of a butterfly into a caterpillar, and arrives at that its ultimate ſtate, after a determinate time ſpent in the other. In this it differs from the generation of fiſhes, the eggs of whoſe ſpawn hatch into perfect fiſhes, which go through no change; and it differs from all in the gelatinous ſubſtance, which envelops the egg, and ſerves as the firſt food to the fœtus.

The eggs are indeed, when nicely examined, found to be encloſed in a double liquor, a more pellucid and thin one within the gelatinous one, which ſerves as the general covering to the whole ſeries of eggs; and it is this thin one which it principally feeds on when firſt hatched, and which ſerves to the ſame purpoſes as the white of an egg in the fowl kind.

There is alſo an opinion that the male ſperm of the *frog* is depoſited on the ſpawn of the female after it is laid. *Ray*'s Syn. Quad. p. 249.

RANA *arborea*, the *tree frog*, in zoology. See RANUNCULUS *viridis*.

RANA *piſcatrix*, the *toad fiſh*, *frog fiſh*, or, as it is called by ſome, the *ſea devil*, a very remarkable ſpecies of fiſh, of a middle nature between the cartilagineous and bony fiſhes. In ſhape and figure it reſembles a tadpole. Its head is extremely large, being equal, or more than ſo, to the reſt of the body, and of a circular figure. The opening of its mouth is ſurpriſingly great, and its lower jaw is above a finger longer than the upper. Both jaws, but particularly the under one, are armed with a great number of long and ſharp teeth, and the longer ones of the under jaw are all moveable inwards. The back is flat, and of a blueiſh green colour, mottled with a few white ſpots. The eyes are pearly in the iris, and a tranſverſe ſtreak of white is drawn acroſs the pupil. In the upper part of the head, at half a finger's breadth diſtance from the angle of the upper jaw, are placed two briſtles, the fore one is ſix fingers long, the hinder one four; and in the middle of his back, lower down, are three more, which ſerve in the place of fins. Over the upper jaw there are, on each ſide, two ſharp thorns, and there are thorny tubercles all about the eyes; and on the middle of the back, not far from the tail, there is a fin with ten rays. The tail is not forked, but the rays are branched, and all ſtand out a little beyond the fin, and are hooked. In the under part of the body, juſt under the throat, there are two fins like a mole's feet, each compoſed of five rays, or fingers. There are two others on the edge of the body, and the extremity of all theſe, as alſo of the tail, is black. It has only three bronchiæ on one ſide. It has either no noſtrils, or elſe they are hid within the head, and has a ſort of membranous rim running all round the commiſſures of its ſides and belly. Its fleſh, when boiled, taſtes like that of the *frog*. See Tab. of Fiſhes, N° 8. and *Willughby*'s Hiſt. Piſc. p. 85.

RANCE, in natural hiſtory. See CIBDELOPLACIA.

RANGIFER, the *rein deer*, an animal very common in all the northern nations, and called by ſome authors *tarandus* and *machlis*. It is of the ſhape of a ſtag, but its body is thicker, and its whole make much more robuſt and ſtrong. The breaſt is thick, covered with very long hairs. The legs very

very hairy and the hoofs moveable, for the creature expands and opens them in going; it is an extremely ſwift, as well as ſtrong animal; its horns are very long, and finely branched, and particularly run out immediately from the forehead into two fingered branches; in the middle there is a little branch, like the joints in the ſtalks of ſome plants; and thence again they are divided into broad fingered ſegments. They differ from the horns of the elk in their length, and from thoſe of the ſtag or red deer in their breadth, and from both, in the multitude of branches, and in their colour which is white. The lower branches, which fall very near the forehead, are ſaid to be uſed by the creature to break the ice, when the waters are frozen over, that he may get drink. It feeds on ſhrubs and plants, and on the moſs, which it finds on the earth and upon the barks of trees.

It is of prodigious uſe, as a beaſt of carriage to the Laplanders, and almoſt all the other nations far north. Scheffer alledges from Tornæus, that the *rein deer*, though a cloven footed animal, and plainly of the deer kind, does not chew the cud. This, however, is wholly diſbelieved by the more accurate naturaliſts. *Ray*'s Sept. Quad. p. 88.

RANINÆ *venæ*, a name given by anatomiſts to the larger veins under the tongue.

RANIO, in natural hiſtory, a name given by ſome writers to bole armenic.

RANK (*Cycl.*)—RANK *keel*, in a ſhip. See KEEL, *Cycl.*

RANUNCULUS, *crowfoot*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, conſiſting of ſeveral leaves diſpoſed in a circular order, and uſually ſtanding in a many leaved cup. The piſtil ariſes from the center of the flower, and finally becomes a fruit of a roundiſh, oval, or ſpiked ſhape, to the axis of which there grow, as to a placenta, a great number of ſeeds, which are uſually naked.

The ſpecies of *ranunculus* enumerated by Mr. Tournefort are very many, and for the ſake of order, in ſo large a number, they are divided into ſeveral ſections. 1. Thoſe which have the appearance of the anemonies. 2. Thoſe which have roundiſh leaves. 3. Thoſe uſually known by the name of the Aſiatic *ranunculuſes*. 4. The ſmooth leaved *ranunculuſes*. 5. The aconite or geranium leaved *ranunculuſes*. 6. The fine leaved *ranunculuſes*; and 7. The long leaved *ranunculuſes*. *Tourn.* Inſt. p. 285.

The ſpecies of the *anemony ranunculuſes* are theſe. 1. The yellow wood *ranunculus*. 2. The ſingle yellow flowered wood *ranunculus*, with ſmaller and more deeply divided leaves. 3. The common white wood *ranunculus*, called the white wood anemony. 4. The purple flowered wood *ranunculus*, commonly called the purple wood anemony. 5. The purpliſh red wood *ranunculus*. 6. The double purple wood *ranunculus*. 7. The double white wood *ranunculus* with a border of leaves. 8. The common double white wood *ranunculus*. 9. The trifoliate white wood *ranunculus*, commonly called the trefoil wood anemony. 10. The large leaved blue flowered wood *ranunculus* of the Apennine mountains. 11. The ſmaller leaved Apennine blue wood *ranunculus*. 12. The wood *ranunculus* with ſmall blue flowers. 13. The double violet coloured wood *ranunculus*. Ibid. p. 286.

Of the roundiſh leaved *ranunculuſes*, the ſpecies are theſe. 1. The round leaved wood *ranunculus*, commonly called Tragus's ſweet *crowfoot*. 2. The ſpring wood *crowfoot* with marſh marygold or thora leaves. 3. The Virginian wood *crowfoot* with ſoft leaves and ſmall flowers. 4. The large *crowfoot* with aſphodel roots, and ſowbread leaves. 5. The ſmaller *crowfoot* with aſphodel roots and ſowbread leaves. 6. The larger round leaved ſpring *crowfoot* called little celandine or pilewort. 7. The ſmaller round leaved ſpring *crowfoot* called the common pilewort. 8. The ſmaller round leaved ſpring *crowfoot*, or celandine, with ſpotted leaves. 9. The ſmaller round leaved ſpring *crowfoot*, or little celandine, with double flowers. 10. The ſmaller round leaved ſpring *crowfoot*, or celandine, with two rows of petals. 11. The mountain *crowfoot* with leaves like thoſe of the parnaſſia. 12. The alpine *crowfoot* with water caltrop leaves. 13. The ivy leaved water *crowfoot* with very ſmall white flowers. 14. The American water *crowfoot* with aſarabacca leaves, and flowers in umbels at the joints of the ſtalks. 15. The little ſmallage leaved rock *crowfoot* with tuberoſe reticulated roots. 16. The ground ivy leaved knotty rooted Portugal *crowfoot*. 17. The round leaved creeping *crowfoot* with echinated ſeeds. 18. The marſh *crowfoot* with echinated ſeeds. 19. The cretic echinated ſtarry *crowfoot*. 20. The broad leaved bullated aſphodel rooted *crowfoot*. 21. The ſmall flowered round leaved Portugal *crowfoot*. 22. The double flowered broad leaved autumnal *crowfoot*. 23. The trifoliate ſpring *crowfoot* with ſingle blue flowers. 24. The trifoliate ſpring *crowfoot* with violet coloured flowers. 25. The trifoliate ſpring *crowfoot* with pale purpliſh flowers. 26. The trifoliate ſpring *crowfoot* with ſingle bright red flowers. 27. The trifoliate ſpring *crowfoot* with ſingle fleſh coloured flowers. 28. The trifoliate ſpring *crowfoot* with ſingle greyiſh flowers. 29. The trifoliate ſpring *crowfoot* with ſingle large white flowers. 30. The trifoliate ſpring *crowfoot* with ſmaller ſingle white flowers. 31. The trifoliate ſpring *crowfoot* with ſingle white flowers edged with red. 32. The trifoliate ſpring *crowfoot* with double blue flowers. 33. The trifoliate ſpring *crowfoot* with double purple flowers. 34. The trifoliate ſpring *crowfoot* with double fleſh coloured flowers. 35. The trifoliate ſpring *crowfoot* with double variegated flowers. Theſe plants, properly named trifoliate *crowfoots*, are the ſpring garden flowers, commonly called *hepaticas*.

Of the third ſet of *ranunculuſes*, commonly called the Aſiatic *ranunculuſes*, the ſpecies are theſe. 1. The knobby rooted Aſiatic *ranunculus* with very ſmall ſingle ſcarlet flowers. 2. The branched knobby rooted *ranunculus*. 3. The knobby rooted *ranunculus* with yellow flowers, being variegated with red. 4. The knobby rooted *ranunculus* with white flowers. 5. The knobby rooted *ranunculus* with ſnow white flowers. 6. The knobby rooted *ranunculus* with pale yellow flowers ſtreaked with red. 7. The knobby rooted *ranunculus* with ſingle yellow flowers. 8. The knobby rooted *ranunculus* with ſingle flowers, of a deep yellow, with red bottoms and red edges. 9. The ſingle whitiſh flowered Aſiatic *ranunculus*. 10. The ſingle *ranunculus* with a red lead coloured flower with yellow edges. 11. The roſe coloured *ranunculus* with white edges, and ſtreaks of white in the flower. 12. The butterfly *ranunculus* with yellow flowers ſpotted with red. 13. The ſingle crimſon ſweet ſcented *ranunculus*. 14. The piony *ranunculus*, or the large bloody purple flowered kind. 15. The Aleppo *ranunculus* with flowers ſtreaked with yellow and red. 16. The *ranunculus* with a very wide, open, red lead coloured flowers. 17. The lemon coloured and red *ranunculus*. 18. The white proliferous *ranunculus* with crimſon ſtamina. 19. The aſphodel rooted *ranunculus* with blood coloured flowers. 20. The aſphodel rooted *ranunculus* with a reddiſh purple flower. 21. The aſphodel rooted *ranunculus* with yellow flowers with red veins. 22. The double *ranunculus*, variegated with yellow and red, called by the French the *ſeraphique*. 23. The proliferous aſphodel rooted *ranunculus* with red coloured flowers. 24. The aſphodel rooted *ranunculus* with a very large blood coloured flower. 25. The aſphodel rooted *ranunculus* with yellow flowers ſtreaked with red. 26. The aſphodel rooted *ranunculus* with double greeniſh white flowers. 27. The aſphodel rooted *ranunculus* with ſmall double white flowers ſtreaked with red. 28. The aſphodel rooted *ranunculus* with great double white roſe-like flowers. 29. The aſphodel rooted *ranunculus* with great double violet coloured flowers. 30. The great Conſtantinople *ranunculus* with ſcarlet flowers. 31. The great Conſtantinople *ranunculus* with elegantly variegated flowers. 32. The Roman giant *ranunculus* with a red lead coloured flower. 33. The giant Roman *ranunculus* with very double flowers, variegated with red and yellow. *Tourn.* Inſt. p. 288.

Of the ſet of tender leaved *crowfoots*, the ſpecies are theſe. 1. The late flowering rue leaved *ranunculus* with double gold yellow flowers. 2. The early rue leaved *ranunculus* with bright red flowers. 3. The tender leaved aſphodel rooted mountain *ranunculus*. 4. The horn like leaved *ranunculus* with foliated ſeeds, collected into ſpikes, called by many the ſmaller cow wheat. 5. The common corn *ranunculus* with echinated ſeeds. 6. The greater narrow leaved woolly *ranunculus* with aſphodel roots. 7. The leſſer narrow leaved woolly grumoſe rooted *ranunculus*. 8. The ſmallage leaved aſphodel rooted woolly *ranunculus*. 9. The fumitory leaved Alpine *ranunculus*. 10. The purple mountain *ranunculus* with hairy cups. *Tourn.* Inſt. p. 289.

Of the ſet of aconite or crane's bill leaved *crowfoots*, the ſpecies are theſe. 1. The upright acrid meadow *crowfoot*. 2. The upright acrid meadow *crowfoot* with ſpotted leaves. 3. The ſingle many flowered meadow *crowfoot*. 4. The upright *crowfoot* with pale hairy leaves. 5. The upright or ſweet or not acrid meadow *crowfoot*. 6. The great ſallad *crowfoot*. 7. The common hairy creeping field *crowfoot*. 8. The common hairy creeping meadow *crowfoot* with leaves variegated with white. 9. The round rooted meadow *crowfoot*. 10. The leſſer round rooted meadow *crowfoot*. 11. The little field *crowfoot* with trifid leaves. 12. The annual hairy field *crowfoot* with extremely ſmall flowers. 13. The double flowered erect garden *crowfoot*. 14. The great hairy creeping double flowered *crowfoot*. 15. The garden *crowfoot* with bending heads. 16. The double flowered ſweet *crowfoot*. 17. The double flowered round rooted *crowfoot*. 18. The tuberoſe rooted proliferous double *crowfoot*. 19. The grumoſe rooted *crowfoot* with leaves like thoſe of the common round rooted kind. 20. The Cretic aſphodel rooted *crowfoot*. 21. The round leaved procumbent alpine *crowfoot* with ſmall flowers. 22. The low round leaved alpine *crowfoot* with larger flowers. 23. The tall hairy white flowered mountain *crowfoot*. 24. The low hairy mountain *crowfoot* with Narciſſus flowers. 25. The purple flowered hairy mountain *crowfoot*. 26. The aconite leaved moun-

mountain *crowfoot* with large white flowers. 27. The aconite leaved mountain *crowfoot* with ſmaller white flowers. 28. The aconite leaved mountain *crowfoot* with double white flowers. 29. The aconite leaved mountain *crowfoot* with large ſingle yellow flowers. 30. The *crowfoot* with leaves like thoſe of the knotty rooted crane's bill. 31. The hairy mountain *crowfoot* with very broad leaves. 32. The crane's bill leaved downy mountain *crowfoot*. 33. The yellow flowered fine leaved mountain *crowfoot*. 34. The woolly mountain *crowfoot* with leaves like thoſe of the common meadow *crowfoot*. 35. The rock *crowfoot* with large flowers. 36. The roundiſh leaved rock *crowfoot*. 37. The very hairy Montpelier *crowfoot*. 38. The ſmallage leaved hairy marſh *crowfoot*. 39. The ſmooth ſmallage leaved marſh *crowfoot*. 40. The purple flowered ſmallage leaved marſh *crowfoot*. 41. The water *crowfoot* with ſome of the leaves roundiſh, and others capillaceous. Ibid. p. 290.

Of the capillaceous leaved *ranunculuſes*, the ſpecies are theſe. 1. The capillaceous or fine leaved water *crowfoot*. 2. The white flowered floating water *crowfoot* with peucedanum leaves. 3. The fennel leaved *crowfoot* with roots like thoſe of black hellebore, called by authors the fine leaved black hellebore. The *conſiligo*, the *hellebore* of Hippocrates, and the *buphthalmum*, or ox eye. 4. The ſmaller or lower fennel leaved *crowfoot* with very large flowers, and jointed ſtalks. 5. The camomile leaved red flowered field *crowfoot*, commonly called the adonis flower, the pheaſant's eye, or red maithes. 6. The longer leaved chamomile *crowfoot* with orange coloured flowers. 7. The chamomile *crowfoot* with ſmall yellow flowers. 8. The betony leaved mountain *crowfoot*. Ibid. p. 291.

Of the ſet of long leaved *crowfoots* the ſpecies are theſe. 1. The graſſy leaved mountain *crowfoot*. 2. The double flowered graſſy leaved mountain *crowfoot*. 3. The bulboſe rooted graſſy leaved *crowfoot*. 4. The ſingle flowered hairy graſſy leaved *crowfoot*. 5. The many flowered hairy graſſy leaved *crowfoot*. 6. The white flowered dwarf Alpine *crowfoot* with graſſy leaves. 7. The plantain leaved mountain *crowfoot*. 8. The marſh *crowfoot* with very large plantain like leaves, commonly called the water plantain. 9. The marſh *crowfoot* with narrow plantain like leaves, called the narrow leaved water plantain. 10. The low procumbent plantain leaved water *crowfoot*, called the narrow leaved procumbent water plantain. 11. The plantain leaved water *crowfoot* with very narrow leaves. 12. The American plantain leaved water *crowfoot* with white flowers and purple cups. 13. The American water *crowfoot* with arrow head leaves. 14. The *water plantain* with very large arrow headed leaves, commonly called the great water arrow head. 15. The arrow headed *water plantain* with narrower leaves. 16. The great long leaved marſh *crowfoot*. 17. The broad plantain leaved ſpearwort with hairy edges. 18. The leſſer long leaved water *crowfoot* or ſpearwort. 19. The ſpearwort, or long leaved water *crowfoot*, with ſerrated leaves. 20. The *Bayonne ſpearwort* of Parkinſon. 21. The white flowered ſmall *ſpearwort*. 22. The graſſy leaved *crowfoot* with caudated flowers, and ſeeds arranged into long and ſlender heads, commonly called mouſe tail. Ibid. p. 292.

Several of the more beautiful ſpecies of this plant have long been cultivated in the Engliſh gardens, and are moſt of them hardy plants, and will thrive very well againſt hedges, and in ſhady borders, where they require no other care than to take up their roots every other year when their leaves decay, and part them, planting out the off-ſets into other borders.

Beſide thoſe we have been long uſed to, there have been ſome of late times brought from Turkey and from Perſia, which produce ſemi-double flowers of great beauty, and annually ripening their ſeeds; there are numbers of varieties, or as the gardeners call them new flowers continually raiſed from them. Many of theſe are finely ſcented; and the roots, when ſtrong, produce eight or ten flowers on each. The double flowered *ranunculuſes* not producing ſeeds, they are only to be propagated by parting their roots, taking off the off-ſets, which they uſually produce in great plenty.

The proper ſeaſon for planting their roots is in October. The beds in which they are planted are to be of good light ſandy earth, at leaſt a foot deep. Common paſture land is the beſt for this uſe, to which if it prove too clayey, there ſhould be added a proper quantity of ſea ſand. This mixture ſhould be turned often, and the larger ſtones and clods taken out; but it muſt not be ſkreened, or ſifted very fine, for that has been the occaſion of the loſs of many roots, both of this and other plants, by cohering into a hard clod with the wet, and rotting the roots.

The beds being prepared, ſhould lie about a fortnight to ſettle, and then drawing ſtrait and tranſverſe lines over the beds, the plants muſt be planted regularly at four inches diſtance, about an inch below the ſurface and the earth, carefully drawn over them with a rake. In November the heads will appear, and then about half an inch depth of freſh earth ſhould be added, which will greatly ſtrengthen the plants. And if it ſhould be very ſevere weather, when the heads appear above this ſecond covering, they ſhould be defended with mats laid over arched hoops. In the beginning of March the flower ſtones will appear; and when the flowering is paſt, and the leaves are decayed, the roots are to be taken up, and laid by for the October following. *Miller*'s Gard. Dict. in voc.

RANUNCULUS *viridis*, in zoology, the name of an animal common in many parts of the world, and uſually known by the name of the *tree frog*, or *rana arborea*.

The creature is eaſily diſtinguiſhed from the common frog, by its being much ſmaller, and of a green colour: it uſually ſits upon the leaves of trees and ſhrubs, and makes a great noiſe in an evening, but that is rather like the ſinging of a ſmall bird than the croaking of a frog.

Theſe creatures have been kept alive many years together in glaſs veſſels, giving them flies and other ſmall inſects; and in winter, when theſe are ſcarce, they uſually become very lean and feeble; but in ſummer, when they are plentiful, they will grow fat again, as if at their liberty. This is eſteemed a poiſonous creature. *Ray*'s Syn. Quad. p. 251.

RAPA, *turnep*, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of four leaves, which are diſpoſed in form of a croſs. The piſtil ariſes from the cup, and is at length changed into a long pod, divided into two cells, by an intermediate membrane, and ending in a long fungous horn, both of which contain roundiſh ſeeds. To this, it may be added, that the root is large, fleſhy, and eſculent.

The ſpecies of *turnep*, enumerated by Mr. Tournefort, are theſe. 1. The round white rooted *turnep*. 2. The round blackiſh rooted *turnep*. 3. The round green rooted *turnep*. 4. The round red rooted *turnep*. 5. The round rooted *turnep*, yellow both on the outſide and within. 6. The long rooted manured *turnep*. *Tourn.* Inſt. p. 228. See the article TURNEP.

RAPAX, in ichthyology, a name given by Schoneveldt to the *corvus piſcis* of ſome writers, a ſpecies of chub or cyprinus, called *rappe* by the Germans, and by Geſner and others *capito fluviatilis rapax*. See the article CYPRINUS.

Broom RAPE. See OROBANCHE.

RAPHA, in anatomy, the ridge or line which runs along the under ſide of the penis, and reaching from the frænum to the anus, divides the ſcrotum and perinæum in two.

This line is not uſually cut in the grand operation of cutting for the ſtone, becauſe it is both harder than the reſt of the ſkin thereabouts, and alſo becauſe you muſt then cut upon the interſtices of the muſcles, which will make the re-union the more difficult.

RAPHANIS, in botany, the name by which the Attics, among the Greeks, called the radiſh; for the word *raphanos raphanus* with them, does not expreſs the radiſh, but the cabbage. The Greeks, of all other places, concurred in calling the radiſh *raphanos* and the cabbage *crambe*; and it is owing to this, that we have many authors who confound together theſe two plants, though ſo very unlike one another in appearance and uſe. It is generally to be underſtood, that wherever Theophraſtus mentions the word *raphanos*, he means by it the cabbage; and the ſame being obſerved, in regard to all the other Attic writers, the whole danger of confuſion and error will ceaſe.

A moderate knowledge either in the language or the ſubject might have prevented errors on this occaſion; yet Pliny, in his account of the radiſh, has been miſled by the word *raphanos* in Theophraſtus, which is that author's name for the cabbage, and has tranſlated all his account of the cabbage, and given it as part of the hiſtory of the radiſh. Theophraſtus ſays, that the Greeks diſtinguiſhed three kinds of the cabbage; the ſmooth leaved, the curled leaved, or criſp cabbage, and the wild cabbage: and Pliny has tranſlated this verbatim, and made it a part of his hiſtory of the radiſh. To this he has added ſome accounts from the Latin writers of their *raphanus*, which is the common radiſh; and putting theſe together, he has compoſed an account wholly unintelligible to all, but thoſe who ſee through the occaſion of the error. The virtues of the radiſh he has alſo intermingled with thoſe of the cabbage, interſperſing among the accounts he took from the Latin authors of the *raphanus*, the virtues and qualities of Theophraſtus's *raphanos*, that is the cabbage. The opinion of the cabbage and the vine being enemies to one another, and not growing any where together, is as old as Theophraſtus, and has a place in his account of that plant; but Pliny has perplexed the caſe, by tranſlating this quality as belonging to the radiſh, which no other author ever gave it; though ſcarce any, who have read the antients, have omitted it in the hiſtory of the cabbage.

RAPHANISTRUM, in botany, the name of a genus of plants, the characters of which are theſe. The flower is compoſed of four leaves, placed in the manner of a croſs. The piſtil ariſes from the cup, and is at length made a long pod, jointed in ſeveral places, and reſembling a faſciated column, and containing roundiſh ſeeds, one lodged in every joint of the pod. See Tab. 1. of Botany, Claſs 5.

The ſpecies of *raphaniſtrum*, enumerated by Mr. Tournefort, are theſe. 1. The common *raphaniſtrum*, with ſmooth, larger,

larger, and ſmaller jointed pods. 2. The *raphaniſtrum* with white ſtriated flowers, and ſmall articulated ſtriated pods. 3. The white flowered field *raphaniſtrum*. 4. The yellow flowered field *raphaniſtrum*; and 5. The *raphaniſtrum* with the largeſt ſtriated and articulated pods. *Tourn.* Inſt. p. 230.

RAPHANUS, *radiſh*, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of four leaves, diſpoſed in form of a croſs. The piſtil ariſes from the cup, and becomes at length a long horn-like pod, very thick and ſpungy, and filled with two rows of roundiſh ſeeds, ſeparated by a very thin intermediate membrane.

The ſpecies of *radiſh*, enumerated by Mr. Tournefort, are theſe. 1. The great orbicular or round *radiſh*. 2. The white flowered great orbicular or round *radiſh*. 3. The black *radiſh*. 4. The ſmaller or common garden *radiſh*. *Tourn.* Inſt. p. 229.

The Athenians expreſſed the cabbage by the word ραφανος, *raphanus*, but all the other Greeks called the *radiſh* by that name. Pliny not obſerving this has run into ſtrange errors. See the article RAPHANIS.

RAPISTRUM, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of four leaves, and is of the cruciform kind; and the piſtil which ariſes from the cup, finally becomes an unicapſular huſk of a ſomewhat globoſe figure, which contains a ſingle ſeed.

The ſpecies of *rapiſtrum*, enumerated by Mr. Tournefort, are theſe. 1. The ſingle ſeeded *rapiſtrum* of Caſpar Bauhine. 2. The greateſt round leaved ſingle ſeeded *rapiſtrum* of Cornutus; and 3. The field *rapiſtrum*, with pointed, auriculated leaves. *Tourn.* Inſt. p. 211.

RAPPE, in zoology, a name given by ſome to the *capito fluviatilis* rapax of Geſner, more frequently known by the name of the *corvus piſcis*. *Willughby*'s Hiſt. Piſc. p. 256. See the article CORVUS *piſcis*.

RAPUNCULUS, *rampion*, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of only one leaf, and is of the bell ſhape, but very wide open at the mouth, and ſo deeply divided into ſegments, that it appears a ſtar faſhioned one. The piſtil is divided into two horns, and the cup afterwards becomes a membranous ſeed veſſel, divided into three cells, and containing a number of very ſmall ſeeds.

The ſpecies of this plant, enumerated by Mr. Tournefort, are theſe. 1. The blue ſpiked *rampion*. 2. The deep violet coloured flowered *rampion* with ſpotted leaves. 3. The white flowered ſpotted *rampion*. 4. The yellow flowered ſpiked garden *rampion*. 5. The round headed long leaved *rampion*. 6. The Cretic pyramidal *rampion*, called by many authors *petromerula*. 7. The alpine horned *rampion*. 8. The graſs leaved *rampion*. 9. The ſcabious headed blue flowered *rampion*, called by ſome *ſheeps ſcabious*. 10. The white flowered ſcabious headed *rampion*. *Tourn.* Inſt. p. 113.

RAPUNTIUM, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of one leaf, and is of a tubular form, ſulcated, and divided into ſeveral long and narrow ſegments, in the manner of fingers. The piſtil is encloſed in the cup, which afterwards becomes a dry fruit, divided into three cells, and containing numerous, and uſually very ſmall ſeeds affixed to a placenta divided into three parts.

The ſpecies of *rapuntium* enumerated by Mr. Tournefort are theſe. 1. The great ſpiked ſcarlet flowered *rapuntium*, called the red cardinal flower. 2. The great ſcarlet American *rapuntium* with white lines in the flowers. 3. The blue flowered American *rapuntium*. 4. The white flowered American *rapuntium*. 5. The golden red leaved American *rapuntium* with a ſmall blueiſh flower. 6. The talleſt American *rapuntium* with Cirſium leaves and greeniſh flowers. 7. The ſhining Cirſium leaved American *rapuntium* with double ſcarlet conglobated flowers. 8. The purple flowered American *rapuntium* with throatwort leaves. 9. The ſmall violet coloured burning *rapuntium*. 10. The purpliſh blue burning *rapuntium*. 11. The white flowered burning *rapuntium*. 12. The leſſer narrow leaved African *rapuntium* with violet coloured flowers. 13. The pinaſter leaved Æthiopian *rapuntium* with hooded, violet coloured flowers. 14. The coronopus leaved Æthiopian *rapuntium* with hooded blue flowers. 15. The blue hooded flowered Æthiopian *rapuntium* with dentated leaves. 16. The low Canada *rapuntium* with toad flax leaves. *Tourn.* Inſt. p. 163.

RARUM, *non-ſpiſſum*, in the antient muſic. See the article APYCNON, απυκνον.

RASA, a word uſed by ſome authors to expreſs reſin of any kind. See RESIN.

RASAKETI, a name given by ſome of the chemiſts to *æs uſtum*, or burnt copper.

RASCETA, a word uſed by the Arabian phyſicians to expreſs the wriſt or ankle.

RASE, *raſarium*, in our old writers, ſeems to have been a meaſure of corn now diſuſed: toll ſhall be taken by the *raſe*, and not by the heap or cantel. *Ordin. for bakers*, &c. c. 4. Pat. 12 Ed. 3. *Blount*.

RASE, in the manege. To *raſe* or glance upon the ground, called in French *razer le tapis*, is to gallop near the ground, as our Engliſh horſes do.

RASILIS *erugo*, in the materia medica of the antients, one of their kinds of verdigreaſe. It was prepared in the following manner: they ſet ſome ſharp vinegar over the fire in a ſtrong earthen veſſel, and covered it with a braſs pot inverted, well cleaned, and without any vent hole. And after ſome time the veſſels were to be ſeparated, and the verdigreaſe which was found concreted on the inſide of the braſs pot, was ſcraped off, and put up for uſe.

RASPBERRY, in botany, the Engliſh name of a ſpecies of *rubus*. See the article RUBUS.

The *raſpberry* buſh is often found wild in ſome of our northern counties, but is cultivated in gardens throughout England for the delicacy of its fruit. We have three kinds common about London. 1. The common. 2. The late red; and, 3. The white *raſpberry*.

Theſe ſhrubs ſend up great plenty of ſuckers from their roots, and are very eaſily propagated by them, they ſhould be taken up in October, and before they are replanted their fibres ſhould be ſhortened; but the buds, which are at a ſmall diſtance from the ſtem of the plant, muſt not be cut off, becauſe theſe produce new ſhoots the next ſummer. They ſhould be planted two feet aſunder, and ſet in rows, which ſhould be five feet diſtant from one another. The ſoil they thrive in beſt is in a freſh ſandy loam, which ſhould neither be too moiſt nor over dry. The time for dreſſing them is in October, when all the old wood which produced fruit the preceding ſummer ſhould be cut down to the ground, and the young ſhoots ſhortened to about two feet in length. The ſpaces between the rows ſhould then alſo be dug up, and ſome other rotten dung buried in them. In the ſummer they muſt be kept clean from weeds, and once in three or four years there ſhould be new beds made, and the old ones deſtroyed, for they ſeldom bear well after that time. *Miller*'s Gardners Dict.

RASPECON, in ichthyology, a name given by ſome to the uranoſcope or ſtargazer. It is properly a ſpecies of the trachinus; and is diſtinguiſhed by Artedi, under the name of the trachinus, with ſeveral cirri or beards growing from the lower jaw. See TRACHINUS.

RASSE *coronde*, in natural hiſtory, a name given by the Ceyloneſe to a peculiarly fine kind of cinnamon, which is the bark of a tree, growing no where but in that iſland. The name they give it ſignifies ſharp or biting cinnamon. This choice kind is exported annually, in conſiderable quantity, by the Dutch Eaſt-India company, who prohibit the mixing any other kind of cinnamon with it under a very ſevere penalty. Phil. Tranſ. N° 409.

RASTIS, a word uſed by ſome chemical writers as a name for tin. See TIN.

RASTOL, or RASOES, a name given by ſome of the chemical writers to copper.

RASTUL, a word uſed by ſome of the chemical writers to expreſs ſalt in general.

RASURA; a word uſed by the pharmaceutic writers, to expreſs the ſhaving woods, or other hard ſubſtances, to make them readily yield their virtues by decoction. Phyſicians alſo uſe it to expreſs the corroſion of acrid humours.

RAT, in zoology. See the article MUS.

RAT, in the ſea language, is uſed to expreſs a part of the ſea, where there are rapid and dangerous currents, or counter currents.

RAT-*gooſe*, in zoology, the name of a ſmall ſpecies of wild *gooſe*, common in ſome of the northern counties of England. See the article GOOSE.

Muſk RAT. See MUSK.

RAT-*tails*, or ARRESTS, in the manege, ſignify callous hard ſwellings upon the hinder legs under the hough, running along the ſinew. See the article ARRESTS.

RAT-*tailed*. A horſe is thus called that has no hair upon his tail. See HORSE.

RAT-*tailed worms*, in natural hiſtory, a ſpecies of fly-*worms*, with long tails, reſembling thoſe of *rats*, whence they have their name. They are of ſeveral ſizes, and found alſo in different places, but all change into two winged flies, having very much the reſemblance of bees, and commonly called bee flies. See Tab. of Inſects, N° 49. and *Reaumur*'s Hiſt. Inſ. Vol. 4. p. 439. See the article DRONE-*fly*.

RATIO (*Cycl.*)—When a *ratio* is given, expreſſed in large numbers, it is often very uſeful to find an approximated value of it, in ſmaller numbers. Mr. Huygens and Dr. Wallis have given methods for this purpoſe, but that of Mr. Cotes, being the moſt convenient in practice, we ſhall here inſert it. Suppoſe the *ratio* 2,718281828495 to 1, or of 1 to 0,367879441171 were propoſed to be reduced to ſmaller terms, ſo that no leſs numbers ſhall expreſs it nearer. The operation may be as follows:

Ratios greater than the true.		*Ratios* leſs than the true.	
1	0×2	0	1
2	1	2	0
3	1×2	2	1×1
8	3	6	2
11	4×1	8	3×1
76	28	11	4
87	32×1	19	7×4
106	39	87	32
193	71×6	106	39×1
1264	465	1158	426
1457	536×1	1264	465×1
21768	8008	1457	536
23225	8544×1	2721	1001×8
25946	9545	23225	8544
49171	18089×10	25946	9545×1
&c.	&c.	&c.	&c.

Divide the greater term 2.71828, &c. by the leſſer 1, or the greater 1 by the leſſer 0,367879, &c. and again the leſſer by the remainder, and this again by the laſt remainder, and ſo on: the quotients ariſing will be 2, 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8, 1, 1, 10, 1, 1, 12, 1, 1, 14, 1, 1, 16, 1, 1, &c. Theſe being found, two rows or columns of *ratios* muſt be made, the one containing the *ratios* greater than the true, and the other ſuch as are leſs; beginning the computation from the *ratio's* 1 to 0, 0 to 1, which are moſt remote from the truth, and from thence proceeding to ſuch as approach continually nearer. Let then the terms 1 and 0 be multiplied by the firſt quotient 2, and write the products 2 and 0, under the terms 0 and 1; then adding, there will ariſe the *ratio* 2+0 to 0+1, or 2 to 1. Multiply the terms of this *ratio* by the ſecond quotient 1, and add the products 2 and 1 to the terms 1 and 0 in the firſt column, there will ariſe the *ratio* 2+1 to 1+0 or 3 to 1. The terms of this *ratio* being multiplied by the third quotient 2, and the products 6 and 2 added to the terms 2 and 1 of the ſecond column, will give the *ratio* 8 to 3. Theſe multiplied by the fourth quotient 1, and the products 8 and 3 added to the preceding terms 3 and 1 in the firſt column, will give the *ratio* 11 to 4. Whoſe terms multiplied by the fifth quotient 1, and the products 11 and 4 added to the *ratio* 8 to 3 give the *ratio* 19 to 7; whoſe terms being multiplied by the ſixth quotient 4, and the products 76 and 28 being added to 11 and 4, give the *ratio* 87 to 32. And thus we may go as far as we think fit; proceeding alternately from one column to the other. This being done, we ſhall find *ratios* greater than the true, to be 3 to 1, 11 to 4, 87 to 32, 193 to 71, 1457 to 536, 23225 to 8544, 49171 to 18089, &c. And the *ratios* leſs than the true will be, 2 to 1, 8 to 3, 19 to 7, 106 to 39, 1264 to 465, 2721 to 1001, 25946 to 9545, &c. And theſe are the principal and primary *ratios*, which continually approximate to the *ratio* propoſed.

But if the whole ſeries of *ratios* greater than the true, be required, ſo that no *ratios* greater than the true, and expreſſed in ſmaller terms, ſhall come nearer the truth; and if alſo the whole ſeries of *ratios* leſs than the true, and ſuch, as that no *ratios* leſs than the true, and expreſſed in ſmaller terms, ſhall approach nearer to the truth, be deſired, then other ſecondary *ratios* muſt be inſerted between the primary already found. And theſe take place where the quotients ſurpaſs unity. They may be found by changing the multiplication by the quotient as above directed, into a continual addition of the terms, as often as there are units in the quotient. Thus, the firſt quotient being 2, the terms 1 and 0 are to be twice added to the terms 0 and 1. The ſums will give the *ratios* 1 to 1 and 2 to 1. Theſe laſt terms 2 and 1, the ſecond quotient being 1, muſt be once added to the terms 1 and 0, and the ſum will give the *ratio* 3 to 1. Alſo the terms 3 and 1, the third quotient being 2, are to be twice added to the terms 2 and 1; and the ſums will give the *ratios* 5 to 2, 8 to 3. Theſe laſt terms 8 and 3, the fourth quotient being 1 muſt be once added to the terms 3 and 1, and the ſums will give the *ratio* 11 to 4. Theſe terms 11 and 4, the fifth quotient being 1, muſt be once added to the terms 8 and 3, and the ſums will give the *ratio* 19 to 7. Laſtly, theſe terms 19 and 7, the ſixth quotient being 4 muſt be four times added to the terms 11 and 4. The ſums will give the *ratios* 30 to 11, 49 to 18, 68 to 25, 87 to 32. And ſo we may proceed as far as we think fit. The operation being performed, we ſhall find the whole ſeries of *ratios* greater than the truth to be 1 to 0, 3 to 1, 11 to 4, 30 to 11, 49 to 18, 68 to 25, 87 to 32, &c. and in like manner, the whole ſeries of *ratios* leſs than the truth will be 0 to 1, 1 to 1, 5 to 2, 8 to 3, 19 to 7, &c.

Example of the operation.

Ratios greater than the true.		*Ratios* leſs than the true.	
1	0×2	0	1
2	1	1	0
3	1×2	1	1
8	3	1	0
11	4×	2	1×1
19	7	3	1
30	11	5	2
19	7	3	1
49	18	8	3×1
19	7	11	4
68	25	19	7×4
19	7	87	32
87	32×1	106	39×1
&c.	&c.	&c.	&c.

See *Cotes* harmonia menſurarum, p. 7, &c.

The ingenious author has not given the demonſtration of his method; but Dr. Saunderſon has ſhewn the reaſon of it, in the fifth book of his algebra, to which we refer the reader.

By means of this method, the approximated values of the *ratio* of the circumference, to the diameter of a circle, may be found in ſmall terms. Thus the proportion of the circumference of a circle to its diameter, being according to Van Ceulen's numbers, when abridged, 314159265359 to 100000000000; dividing the greater by the leſſer, &c. as before directed, we ſhall find the quotients 3, 7, 15 and 1, which will give the following *ratios*, 3 to 1, 22 to 7, 333 to 106, and 355 to 113; the ſecond is that of Archimedes, and the fourth that of Adrian Metius.

This proportion of 113 to 355 approaches very near the truth, only erring by 2 in the ſeventh decimal, when reduced to that form, for 355 : 113 :: 3, 1415129 : 1 now it ought to be 3,1415927 to 1. To remember this proportion the better, we may make uſe of the following artifice. Take the three firſt odd numbers 1, 3, 5, and write each twice, thus 113355, then will the three firſt figures of this number 113, be the diameter, and the three laſt, 355 the circumference. Theſe approximations are of uſe in many practical parts of mathematics. See inſtances thereof in Huygen's *deſcriptio automati planetarii* among his poſthumous works, tom. 2. p. 174. Edit. Amſt. 1728, where he deſcribes his method, and demonſtrates it. In muſic, it is the foundation of the different ſchemes of geometrical temperatures. See the article TEMPERAMENT.

RATIO *modularis*. See LOGARITHM.

RATIONIS *os*, a term uſed by ſome anatomical writers to expreſs the *os ſincipitis*.

RATIONARIUM, among the Romans, a book which contained the accounts of the empire. *Pitiſc.* Lex. Ant. in voc. It was otherwiſe called *breviarium*. See BREVIARY.

RATSBANE. See the article ARSENIC.

RATTLE *ſnake*, a very dreadful ſpecies of ſerpent, whoſe bite is fatal, if not timely remedied, and which is diſtinguiſhed from all other ſerpents by the *rattles* in its tail. This is compoſed of ſeveral ſcaly ſubſtances, and is ſaid to encreaſe by the creature's age; every year adding one ſcale to it. It moves over the rocks and mountains with prodigious ſwiftneſs, but is leſs nimble on even ground, than many other ſnakes.

It grows to four or five feet long, and ſometimes, though rarely, more; and one of more than four feet long, having been diſſected, and accurately deſcribed by Dr. Tyſon, the account that gentleman gives of it may not be unacceptable to the reader. The body where largeſt, which was near the middle, meaſured ſix inches and a half round. Its neck only three inches. Its head was flat, as that of the viper; and as the jaws are very broad and protuberant, and the noſe ſharp, it ſomewhat reſembles the head of an arrow. At the end of the noſe are placed the noſtrils, and between theſe and the eyes there are two other holes which may be miſtaken for ears; but they only go into a hollow of the bone of the ſkull, without any perforation into the brain. The viper has nothing of theſe holes. The eyes are round, and wholly reſemble thoſe of the viper. The whole body of the creature greatly alſo reſembles the viper, but for the ſingularity of the *rattle*; and over the eyes there are two large ſcales, looking like eye-brows.

The ſcales which cover the head are very ſmall, thence they become gradually larger as they reach toward the middle of

of the body, and from the middle to the tail they grow leſs and leſs again; and all in ſhape much reſemble the broad and flat ſeeds of the common garden parſnip. There is ſome variety in the colours of this creature, whether according to the difference of age or ſex, or from leſſer accidents. The moſt uſual colours are theſe: the ſcales are of a duſky greeniſh, like the feathers of the back of the green-finch, and are variegated with ſmall black ſpots in great number; there alſo are four large ones of the ſame colour. *Ray*'s Syn. An. p. 291. *Tyſon*'s Nat. Crotaph.

The back is of a mixt colour, of a dead yellowiſh brown, variegated with blotches of black and yellow, and with a number of ſmall dots of the ſame colours; the larger blotches being laid in great regularity, and making a very beautiful teſſelated figure; the ſcales become darker as they approach the tail, where they are almoſt black; and thoſe on the ridge of the back, all along, are raiſed into a ſort of ſharp prominence in their middle, like the ſcales of a crocodile; thoſe on the ſides are plain and flat. The belly is all along covered with oblong parallellogram ſcales, laid tranſverſely; theſe are very bright and gloſſy, and are yellow, ſpotted with black.

The head is ſmall, in proportion to the body, but the mouth is capable of opening to a prodigious width. The tongue is wholly like that of the viper, compoſed of two oblong portions, joined toward the baſes, but ſeparate as they approach the end. The teeth are of two kinds, the ſmaller ones deſigned for its eating with, the larger and longer for biting and poiſoning what it ſeizes. Theſe are only placed in the upper jaw, but all the teeth of the mouth are of the canine kind, as the creature, never chewing its prey, has no uſe for dentes molares, or grinders.

The poiſonous teeth are ſituated on the outſide of the jaw, in the anterior part of the mouth; not fixed in the ſockets of the jaws, as the others, but fixed to two bones. Theſe, in their natural ſtate, are not viſible, even when the creature's mouth is opened, unleſs it be with an intent to wound; for they lie back under a membranaceous covering, and the creature has a power of erecting, and wounding with them at pleaſure, as the lion and cat kind can retract, or thruſt out their claws. Theſe teeth are crooked, and have a hollow at their bottom, and at their point a very plain and evident ſlit, looking like the neb of a writing pen. The teeth are hollow all the way from this ſlit to their bottom, and on preſſing the gums in a dead *rattle-ſnake*, the poiſonous juice may be ſeen to aſcend by degrees up the tooth, and at length to be diſcharged out of the ſlit at the point. This makes it very plain in what manner the poiſon is conveyed into the fleſh, when the creature bites.

The *rattle* is affixed to the laſt vertebra of the tail, and is compoſed of a ſeries of ſmall bones; that next the tail is uſually of a blueiſh grey colour, the reſt of a pale brown. Theſe bones are hollow, very thin, hard, and dry, and of a brittle texture, and very ſonorous. They are all of the ſame figure, repreſenting, in ſome degree, the os ſacrum in the human ſceleton, and all are nearly of the ſame ſize. The laſt of theſe is ſeen to have a rigid extremity, in manner of a tail, and all the others have the ſame, though it is not diſtinguiſhable in them, as in the joining it runs under two others; and by means of this ſtructure they are all moveable with the ſmalleſt force, and the ſound is the more vigorous, as each of theſe tails ſtrikes on two of the hollow joints, when put in motion.

The age of the creature is known by the number of joints of this *rattle*, which are found to be from one to twenty, or more. The uſe of this ſeems not to the creature, but to other animals, that they may be alarmed at the approach of ſo terrible an enemy, and get out of its way in time. Piſo, and ſome others, affirm, that this *rattle* put up a man's fundament, is as fatal a thing as the creature's bite. The power of doing miſchief, which nature has allotted to this animal, ſeems not only by its bite, but, according to the joint accounts of almoſt all authors, it appears to have a power of deſtroying even by a look. *Ray*'s Syn. Anim. p. 322.

The charming, or faſcination of the *rattle-ſnake*, as this is uſually called, has exerciſed the wits of many naturaliſts in vain, and many have diſbelieved the fact. Sir Hans Sloan mitigates the matter, by ſuppoſing the creature firſt to ſeize or bite its prey, which it then ſuffers to eſcape, as far as the poiſon will let it, watching its death, that it may devour it without trouble; and that it is in this poiſoned ſtate that people have ſeen the ſquirrels, *&c.* dancing about before the *rattle-ſnake*, and dying convulſed; all which they have attributed to the power of charming in the eye of the *ſnake*, not conceiving that it was the effect of the creature's having before bitten them. This, though a very plauſible account, yet however wants experience to confirm it, and the general teſtimony of people, who have ſeen the facts, makes againſt it.

The ſame author gives us, however, from Colonel Beverley, the whole proceſs of the charm. The colonel acquaints us, that ſome company he was with once ſaw a hare, about half grown, ſiting quietly in an orchard, and ſtriking at her, ſhe only removed a few yards; when wondering at the cauſe, they ſaw a *rattle-ſnake*, at about ten feet diſtance, eying the hare as his deſtined prey. The poor creature was, by this time, in agonies and convulſions, often getting up on its legs, as if intending to run away, but always immediately falling down again, and growing worſe and worſe, ſoon loſt the uſe of its hinder legs, and panting vehemently, fell on its ſide. In about half an hour more the hare ſeemed to have done with all ſtruggles, and to be dead, on which the *ſnake* uncoiled itſelf, and moved gently towards it, but the poor hare ſtarting again, he ſtopt; but when all was again quiet, he moved up to it, and, raiſing his head, looked all over his prey; his colours looking at that inſtant more beautiful than before, and his eyes ſparkling. The hinder part of the hare had been toward the *ſnake* all this time, and it had periſhed without much looking at its enemy. The *ſnake* wetted the body all over with his ſlaver; and then, with great difficulty, taking firſt the head into his mouth, ſwallowed that, and afterwards the whole body, ſucking it gently down, and not getting in the ſhoulders without great difficulty.

It is certain, upon the whole, that there is much in this account to favour Sir Hans Sloan's opinion of the hare's having been firſt bitten, though that was not ſeen, ſince the convulſions, and loſs of the uſe of the hinder legs, ſeem a very natural effect of poiſon; but we are aſſured, by perſons who have been eye-witneſſes to the fact, that a bird hopping about in all this agony and terror, has, on the frightning the *rattle-ſnake* away, flown off without any difficulty; ſo that the whole ſeems yet not underſtood. *Sloan*'s Hiſt. Jamaica. *Beverley*'s Virginia.

RAUCA *avis*, in zoology, the name of a bird deſcribed by Nieremberg, as common about the lakes and rivers of America, and of the king-fiſher kind, but nearly as large as a duck, and black on the crown, and white on the breaſt and belly. Its neck is naturally very long in proportion to its body, yet it can occaſionally contract and ſhorten it in a very wonderful manner. It is a native of Mexico, and is eſteemed very good for the table. Mr. Ray has placed this among the birds, the accounts of which he is diſtruſtful of. *Ray*'s Ornitholog. p. 300.

RAUCEDO, *hoarſeneſs*, in medicine, the name of a diſeaſe which conſiſts in the conſtriction of the glandulous coat, and other glandular parts, near the top of the wind-pipe, by means of which the due quantity of lymph, deſtined to lubricate the wind-pipe, is not ſuffered to flow to its place. This diſtemper differs in degree, being milder when from external cauſes, and greatly more obſtinate and troubleſome when from internal.

Signs of it. The *hoarſeneſs* of the voice in ſpeaking ſufficiently manifeſts this complaint, but it is uſually alſo attended with a ſlight cough in the milder kind; and when of the ſeverer ſort, is not unfrequently accompanied with catarrhal and ſcorbutic effects; and not uncommonly, in its worſt ſtates, with a complication of venereal taints. The perſons moſt ſubject to *hoarſeneſſes* are young and middle-aged men, and ſometimes women, who have for ſome time been afflicted with obſtructions of the menſes.

Cauſes of it. The general cauſe of an *hoarſeneſs* is an interception of the lymph deſtined to lubricate the wind-pipe; and the occaſional cauſe of this is uſually an obſtruction of the glandular parts, toward the top of that organ, in the ſimple *raucedo*; but in the complicated kind, in which there is a ſcorbutic or venereal taint, an eroſion of the epiglottis is very often the cauſe. Beſide theſe, there are many accidental and external cauſes, which will bring on a *hoarſeneſs*; ſuch as the falling of any ſmall particle of extraneous matter, if it be only a grain of duſt, into the wind-pipe; a vehement cough will alſo bring it on, as will a frequent loud ſpeaking, and too fat foods, and acrid or bilious humors ſtagnating about theſe parts. It is eaſy to conceive, that the more complicated this diſeaſe is, the more difficult will be the cure; and accordingly *hoarſeneſſes*, which have ſcorbutic or venereal taints for their baſis, are with great difficulty removed.

Method of cure. Lubricating medicines are firſt to be given, to obtund the acrimony of the humors, and relax the ſtrictures of the glandular parts. To this purpoſe are properly taken oil of almonds, and the pectoral ſyrups, with barley water, mucilaginous broths, and decoctions of the pectoral herbs, or infuſions of them drank in the manner of tea. When there is a coryza, or cough attending it, theſe are to be treated in the uſual way, and the *hoarſeneſs* will uſually go off with them. When acrid and bilious humors are in the caſe, the abſorbents and nitrous medicines are to be given, with gentle diaphoretics; powders compoſed of crabs eyes, nitre, and diaphoretic antimony, are of great uſe in this caſe. The bowels, in all theſe caſes, are to be kept gently relaxed; and where there is a ſcorbutic, or venereal taint for the baſis, thoſe diſeaſes muſt be attacked in the common way, and then the *hoarſeneſs* will be regularly taken off. A relaxation of the wind-pipe is uſually accuſed as being the cauſe of a *hoarſeneſs*, and that not without

ſome foundation; ſince where the humors are collected, there will be ſuch a relaxation; but when we conſider all the circumſtances of the diſeaſe, and obſerve that relaxing medicines are the only cure for it, we muſt acknowledge, that though a relaxation of ſome part of the aſpera arteria may be in the caſe, yet that the origin of the complaint is from a conſtriction of ſome part of it; and it appears, that the longer this complaint remains with people, the greater the conſtriction becomes; ſo that after a courſe of years, the voice is not only *hoarſe*, but is in a manner ſuppreſſed ſo, that it can ſcarce be heard. *Junker*'s Conſp. Med. p. 505.

RAVEL *bread*, a ſort of *bread*, called alſo *blackwhytlof*, as being of a middle fineneſs betwixt white and brown.

RAVEN, *corvus*, in ornithology. See CORVUS.

It is rare to find this creature white, yet it happens ſometimes. Boyle[a] mentions one. There was alſo one ſhewn to the Royal Society not long ago.—[[a] Works Abr. Vol. 2. p. 46.]

Night RAVEN, an Engliſh name for a heron which flies in the night, and makes a very odd and hoarſe noiſe. It has been applied by ſome to the bittern, or *ardea ſtellaris*, but improperly, belonging of right to the *ardea cinerea minor*, or ſmaller grey heron, called *nyćticorax*. *Ray*'s Ornithol. See NYCTICORAX.

RAVIS, the ſame with *raucedo*. See RAUCEDO.

RAUTY *mummy*, or RAUTY *muddum*, *ſtone mummy*, a name given by the people of the Eaſt-Indies to a kind of foſſile ſubſtance, much valued for its medicinal virtues. It is of the nature of the ſelenites, and is found upon the high rocks, and ſuppoſed to be generated of the dew which falls from the heavens; but this is an idle opinion, and the formation of it is evidently the ſame with that of the European rhomboidal ſelinites. They beat it to powder, and after boiling it in milk, they give it in caſes of the venereal kind. In a common clap, they give half a ſcruple night and morning. *Woodward*'s Cat. Foſſ. Vol. 2. p. 9.

RAY, *raia*, in ichthyology. See RAIA.

RAY, in our old writers, a word appropriated to cloth never coloured, or dyed. 11 Hen. IV. c. 6. *Blount*, *Cowel.*

RAY (*Cycl.*)—RAY *of curvature*, in geometry, is uſed to ſignify the ſemi-diameter of the circle of curvature. See CURVATURE, *Appendix*.

RAYCHE, in ichthyology. See RAYTE, infra.

RAYTE, or RYCHE, in ichthyology, a name given by Joannes Cuba, Albertus, and others, to the common ſkaite, or flaire. See the article RAIA.

RAZE, in the manege. A horſe is ſaid to have *razed*, whoſe corner teeth ceaſe to be hollow; ſo that the cavity, where the black mark was, is filled up; that is, even, ſmooth, and *razed*, or ſhaven, as it were, and the mark diſappears. See the articles TEETH and MARK.

RAZOR *bill*, in zoology, the common Engliſh name of the alka, a web-footed bird with no hinder toes, common on our ſea ſhores. See ALKA.

RAZOR-*fiſh*. See the article DACTYLUS.

REAR (*Cycl.*)—REAR *half files*, in the military art. See FILE *leaders*.

REAR *up*, in the manege, called in French *cabrer*, is ſaid of a horſe that riſes upon his hinder legs, as if he would come quite over.

REARED, or *Wale*-REARED. See WALE-*reared*.

REBUS, (*Cycl.*) a word uſed by the chemical writers ſometimes to ſignify ſour milk, and ſometimes for what they call the ultimate matter, of which all bodies are compoſed.

RECEIVER (*Cycl.*)—It is to be obſerved, that a very ſmall crack in the *receiver*, uſed in pneumatical experiments, does not render them uſeleſs; for, upon evacuating the internal air, the external preſſing the glaſs on all ſides, brings the edges of the glaſs cloſer together. But in caſe of conſiderable flaws, a plaſter may be applied, made of quick lime, finely powdered, and nimbly ground, with a proper quantity of the ſcrapings of cheeſe, and water enough to bring the mixture to a ſoft paſte; which, when the ingredients are well incorporated, will have a ſtrong and fetid ſcent; and then it muſt be immediately ſpread upon a linnen cloth, and applied, leſt it begin to harden. *Boyle*'s Works Abr. Vol. 2. p. 417.

RECEIVERS, in chemiſtry, veſſels of earth, glaſs, *&c.* for receiving any diſtilled liquor. See Tab. of Chemiſtry, N° 22, 23, and 34.

RECEPTACULUM (*Cycl.*)—RECEPTACULUM *ſeminum*, in botany, the name given by authors to the baſe of the flowers and ſeeds in the ſyngeneſiæ, or compound flowered plants. This is alſo called, by ſome writers, *thalamus floſculorum*. The flowers ſtand on this in conſiderable numbers, and without any pedicles. The diſk of the *receptacle* is of various ſhapes in the various plants; in ſome it is flat, in others concave, in others convex; in ſome globular, and in many pyramidal. Its ſurface is ſometimes naked, and ſometimes paleaceous. In thoſe plants, in which the ſurface is naked, it is either abſolutely ſmooth, or furniſhed with ſmall tubercles, or with a few hairs. In thoſe in which it is paleaceous, it is all over beſet with narrow pointed paleæ, which are erect, compreſſed, and ſtand between the flowers.

RECEPTARII, a term of reproach uſed to ſuch phyſicians as write pompous receits for loads of medicines, more conſulting the good of the apothecary than the patient; as alſo for ſuch as give receits for general medicines, to be uſed at the diſcretion of people wholly unacquainted with the nature of diſeaſes.

RECESSUS, (*Cycl.*) a word uſed by ſome medical writers to expreſs an abſceſs, or apoſthumation.

RECIMUS, among the Romans, a kind of ſquare mantle, or veil worn by women on their head. Salmaſius will have it to have been a ſort of gown uſed by the Roman ladies, and tucked up before with a ſquare pin, of a purple colour. *Danet.* in voc.

RECIPROCAL, (*Cycl.*) in mathematics, is applied to quantities, which multiplied together produce unity[a]. Thus $\frac{1}{x}$ and x, y and $\frac{1}{y}$ are *reciprocal* quantities. And $\frac{1}{x}$ is ſaid to be the *reciprocal* of x, which, *vice verſa*, is the *reciprocal* of $\frac{1}{x}$.—[[a] Maclaurin de Lin. Geom. propriet. general. p. 10.] See the Appendix to his Algebra.

RECITANTE. See FAVORITO.

RECLASSE, *auricula*, in botany. See AURICULA.

The characters of a good flower of this ſort are theſe. 1. The ſtem of the flower muſt be lofty and ſtrong. 2. The foot-ſtalk of the flower muſt be ſhort, that the umbel may be regular and cloſe. 3. The pipe, or neck of each flower ſhould be ſhort, and the flowers large and regularly ſpread, being no ways inclinable to cup. 4. The colours muſt be very bright, and well mixed. 5. The eye of the flower muſt be large and round, and of a good white or yellow, and the tube or neck muſt not be too wide.

Theſe are to be raiſed from ſeeds; to procure which the beſt flowers ſhould be made choice of, and theſe muſt be expoſed to the open air, and to ſhowers, that the ſeeds may be perfect. The time of their ripening is June, and they are known to be ripe by the ſeed veſſel becoming brown and opening. This ſeed may be ſown any time between Auguſt and Chriſtmas; and the beſt ſoil for it is good freſh light ſandy mould, mixed with very rotten cow dung, or tanners bark. With this the boxes or pots muſt be filled, and the ſeeds lightly ſcattered on it, and covered an inch deep with rotten willow mould. Cover the ſurface with nets, or otherwiſe, to preſerve the ſeed from birds, and give the boxes half the day's ſun. In March the young plants will appear, and they muſt then only have the morning ſun till ten o'clock. They muſt be carefully watered after this, a little at a time, and in July they will be ready to tranſplant. They muſt be ſet in the ſame ſort of earth, at three inches diſtance, and ſhaded carefully, till they have taken root. The ſpring following theſe young plants will flower, and then the fineſt of them ſhould be marked, and each removed into a pot of the ſame earth, in which they are to be kept till the next ſpring, when it will appear what they truly are.

The fine flowers, thus obtained, may afterwards be propagated from ſlips, or off-ſets taken from the old roots in April when they are in bloom; and theſe muſt be managed juſt as the young plants from ſeed, and the ſecond year will produce perfect flowers.

Theſe are the rules for the propagating theſe plants; but in order to have them flower in perfection, the following rules muſt alſo be obſerved.

1. The plants muſt be preſerved from too much wet in winter, and muſt have free air, and not too much ſun. 2. In the beginning of February, if the weather be mild, the earth in your *auricular* pots muſt be taken off as far as may be, without diſturbing the roots, and new freſh earth laid in its place. 3. The pots muſt be covered with matting in the night, to defend them from froſts while the plants are budding. 4. When the ſtalk begins to be long, they muſt be defended from haſty rains, yet not kept too much under cover, which draws up the ſtalk too long, and makes it weak; and they muſt be watered frequently, a little at a time, and none of the wet muſt be ſuffered to fall on the plant. Laſtly, when the flowers begin to open, the pots ſhould be removed to a ſtage of ſhelves, one over another, placed under cover, open to the morning ſun, but ſheltered from the midday's ſun. Here they may remain till their flowers are paſt, and then they muſt be ſet out to have the benefit of the rains and free air, for the ripening of the ſeed, which muſt be ſaved carefully, and ſpread on papers, and laid to dry. *Miller*'s Gardners Dict.

RECLINATE *ſtalk*. See the article STALK.

RECOGNITORS, *recognitores*. The jury impanelled upon an aſſize are called *recognitors*, becauſe they acknowledge a diſſeiſin by their verdict. *Bract.* lib. 5. *Cowel.*

RECOLATION, a method of fining the decoctions of vegetables, *&c.* by repeated percolation, or ſtraining them ſeveral times ſucceſſively through a linnen or woollen bag.

RECOMPOSITION, in chemiſtry, the compounding of bodies from their ſeparated parts, or principles, ſo as to compoſe

compoſe the original whole again. This is extremely difficult to effect univerſally, but in ſome caſes it may be done, and that ſo perfectly, that the *recompoſed* body ſhall not be diſtinguiſhable by the ſenſes from that which never had been ſeparated by the fire. If the art of chemiſtry were perfect, we ſhould thus be able, at leaſt in ſome degree, to *recompoſe* all the bodies we divide; but this is far from being the caſe at preſent. We can by no means do this in vegetable and animal bodies, where there is a vaſcular ſtructure, and therefore we are carefully to diſtinguiſh between the regeneration of organized, and that of unorganized bodies. *Shaw*'s Lectures, p. 168.

RECONCILIATION *of penitents*, in church hiſtory. See PENITENTS, *Cycl.*

RECRUITS, in the military art, new men raiſed to ſupply the places of ſuch as have loſt their lives in the ſervice, or are rendered unſerviceable by age or wounds.

RECRUIT *horſes*, are the *horſes* brought up for compleating the regiments of horſe or dragoons every year.

RECTIFICATION (*Cycl.*)—That the *rectification* of ſpirits may, in all caſes, proceed with the greateſt exactneſs, a due regard to it muſt be had even from the firſt fermenting the ſubſtance from which they are to be made, and continued through all the ſtages of diſtillation, the low wines, proof ſpirit, and alcohol. The management of the fermented liquor, to this purpoſe, is principally the letting it ſtand to ſubſide after the fermentation is over, and the drawing it off clear and thin, not too rich for the ſtill. The ſtill is not to be overfilled with this. Great care muſt be taken to prevent its burning, and the faints that run laſt muſt be kept ſeparate, not mixed with the reſt of the liquor diſtilled, which is now called the low wines. In the *rectifying* theſe into proof ſpirit, great caution muſt be uſed that the fire be kept regular, not raiſed by ſudden ſpirits, which always throw up the oil in large quantities, which is to be left behind. In the ſucceeding *rectification* of the proof ſpirit into alcohol, the ſame cautious management of the fire is neceſſary; and, in both this and the laſt, the faints are not to be ſuffered to run in among the ſpirit, but to be ſaved ſeparate. They may be all mixed together at laſt, and reduced to a ſpirit fit for burning in lamps; but the keeping out of the *rectified* liquor will keep away the coarſeſt and moſt ſtinking part of the oil of the ingredients.

By theſe eaſy means, without any additional trouble or charge, we might be furniſhed with a ſpirit greatly exceeding what we commonly meet with. And in general, the art and myſtery of our ſellers of the ſeveral ſorts of Engliſh brandies, ſeem to conſiſt in this prudent management, and in the adding a little of the *oleum vini*, or oil of wine lees, to the ſpirits thus procured pure: this gives the flavour of foreign brandies, and is ſo extenſive in its uſe, that half an ounce of it is ſufficient for a hogſhead of pure ſpirits.

Malt ſpirit is that which principally requires all this care in the *rectification*, becauſe its oil is more nauſeous and offenſive than that of any other ſpirit; but all others will be greatly the better for being treated in the ſame manner, and it is indeed neceſſary that they ſhould for ſome particular uſes.

It is remarkable, that no one method of combinatory *rectification*; that is, of the *rectification* performed by means of ſalts, and other additions, is ſuited to all the ſeveral kinds of ſpirits, ſcarce indeed will any one way ſerve for any two ſpirits; but this method, by ſimple and careful diſtillation, is equally ſuited to all. Melaſſes ſpirit, cyder ſpirit, wine ſpirit, or brandy, rum, and arrack, are all improved by it, and all of them are then known to be perfectly *rectified*. When in the ſtate of alcohol, they not only prove totally inflammable in a little veſſel floating upon cold water, but when poured into the pureſt ſpring water, they have not the leaſt power of making any change in it, nor leave any marks of oilyneſs, or that unctuoſity, which, on the mixture of the leſs pure ſpirits, floats on the top, and in certain lights gives the rainbow colours. *Shaw*'s Eſſay on Diſtillery.

RECTIFYER, (*Cycl.*) in the diſtillery, the perſon whoſe employment it is to take the coarſe malt ſpirit of the malt ſtiller, and re-deſtill it to a finer and better liquor. The art of the *rectifyer* might be entirely ſet aſide, if the malt ſtiller could make his ſpirit perfect at a ſecond operation; which ſeems very practicable, if the malt ſtillers could be got to forſake their old track. The great things to be recommended for the improvement of their art, would be firſt the brewing in perfection, and ſecondly the keeping their waſh after the manner of ſtale beer, till it has entirely loſt its malt flavour, and required a pungent acid vinoſity; and then thirdly leaving out the lees, to diſtil with a well regulated fire. It is ſcarce to be thought how pure a ſpirit is to be obtained from malt this way; but the great art would be, the finding a way to make malt liquors artificially ſtale, bright, and flavourleſs, though otherwiſe vinous. *Shaw*'s Lectures, p. 223.

RECTUS (*Cycl.*)—RECTI *abdominis*. Theſe are long narrow muſcles, thicker than the oblique; they lie near each other, like two large bands from the lower part of the thorax to the os pubis, the linea alba coming between them. Their breadth diminiſhes, and their thickneſs increaſes gradually from above downward. The ſuperior extremity of each of theſe muſcles is fixed to a part of the lower extremity of the ſternum, to the three loweſt true ribs, and to the firſt falſe rib, by the ſame number of digitations, of which that which is fartheſt from the ſternum is the broadeſt.

The body of the muſcle lies in the vagina formed by the aponeuroſis of the broad muſcles of the abdomen: exteriorly it is divided into ſeveral portions, reſembling diſtinct muſcles placed end-wiſe, by tranſverſe tendons termed enervations, which commonly are all above the umbilicus, very ſeldom below it, and adhere very cloſely to the vagina. Theſe inſertions are pretty irregular: they do not always penetrate the whole thickneſs of the muſcle; and, in that caſe, they do not at all appear, or but very little, on the inner ſurface. Sometimes thoſe which are ſeen on the ſurface do not run quite croſs the whole breadth of the muſcle. The lower extremity of this muſcle ends in a thin tendon, fixed in the internal labium of the upper edge of the os pubis near the ſymphyſis, and there it touches the tendon of the other *rectus*. Above the umbilicus, theſe muſcles are at ſome diſtance from each other, according to the breadth of the linea alba, but below it they come nearer the linea alba, being there narrower, and near their lower extremity, that line is almoſt entirely hid by their thick edges. *Winſlow*'s Anatomy, p. 168.

RECTUS *anterior*, a muſcle called alſo *gracilis anterior*, as long as the os femoris, and lying directly along the foreſide of the thigh. The greateſt part of it is fleſhy, and its middle is broader than the two extremities. It has its name *rectus* from the ſtrait diameter in which it lies, and its other *gracilis* from its thinneſs and flatneſs. It terminates above by a pretty ſtrong tendon, which is divided into two branches, one ſhort and ſtrait, the other long and bent; the ſhort branch running up in a ſtrait line, is inſerted in the anterior inferior-ſpine of the os ilium. The long branch is inflected backward over the ſupercilium of the acetabulum, and runs in the direction of it from the ſpine, toward the great iſchiatic ſinus: it is ſtrong and flat, adhering very cloſely to the bone, and covered by the orbicular ligament and the glutæus minimus; and, according to the common method of diſſecting, is therefore uſually cut off, and the ſmall branch of the tendon only left obſervable. From hence the muſcle runs down wholly fleſhy, and partly penniform, ſome of its fibres meeting above and ſeparating below. It is narrow at the upper extremity, and grows gradually broader towards the middle, afterwards contracting in the ſame manner, and at the lower extremity of the os femoris, ending in a flat tendon. Through its whole courſe it lies between the two vaſti, and covers the crureus; and its inferior tendon is inſerted in the upper edge of the patella, from whence it ſends down a ſmall plane of tendinous fibres, which adhere very cloſely to the convex ſide of that bone, and having reached the great ligament ſeem to be loſt therein. *Winſlow*'s Anatomy, p. 212.

RECTUS *muſculus*, in anatomy, a name given by Fabricius, in his treatiſe of the eyes, to the muſcle, which ſerves to elevate the upper eye-lid, called by Cowper and others *aperiens palpebram*, and by Albinus *levator palpebræ ſuperioris*.

RECTUS *internus major*, in anatomy, a name given by Winſlow to one of the muſcles of the head, deſcribed by Fallopius, under the name of the *muſculus nonus capitis*; and by Winſlow, the *muſculus rectus anterior longus*.

RECTUS *capitis major*, a ſmall, flat, ſhort muſcle, broad at the upper part, and narrow at the lower, and ſituated obliquely between the occiput and ſecond vertebra of the neck. It is fixed below the branch of the bifurcated ſpine of the ſecond vertebra of the neck, at a tuberoſity, which is often found at the upper part of the branch; from thence it aſcends a little obliquely outward, and is inſerted in the poſterior part of the inferior tranſverſe line of the os occipitis, at a ſmall diſtance from the criſta, being a little covered by the obliquus ſuperior. *Winſlow*'s Anatomy, p. 236.

RECTUS *minor capitis*, this muſcle has a ſmall inſertion below in the poſterior eminence of the firſt vertebra; from thence it aſcends laterally, and is inſerted immediately under the poſterior part of the inferior tranſverſe line of the os occipitis, in a ſuperficial foſſula on one ſide of the criſta occipitalis. Ibid. p. 237.

RECTUS *capitis anticus brevis*, a ſmall flat muſcle, about the breadth of one finger, ſituated laterally on the part of the body of the firſt vertebra. It is fixed below to the baſis or root of the tranſverſe apophyſis of that vertebra, near the anterior eminence; from thence it runs obliquely upward, and inward, to a tranſverſe impreſſion in the lower ſide of the apophyſis baſilaris of the occipital bone immediately before the condyle on the ſame ſide, being covered by the anticus longus. Ibid.

RECTUS *capitis anticus longus*, a muſcle in ſome degree of a pyramidal figure, lying along the anterior and lateral parts of the vertebræ of the neck, all the way up to the baſis cranii. It is fixed to the anterior parts of the tranſverſe apophyſis,

apophyſes, of the third, fourth, fifth, and ſixth vertebræ in a digitated manner, from thence it runs up obliquely inwards, and towards the lateral parts of the bodies of the vertebræ, paſſes on the foreſide of the firſt and ſecond, without being inſerted in them, and approaching gradually toward the ſame muſcle, on the other ſide, it is inſerted near it in the fore part of the lower ſide of the apophyſis baſilaris. Id. Ibid.

RECTUS *capitis poſticus major*, in anatomy, a name given by Albinus, in his hiſtory of the muſcles, to a muſcle called *magnus rectus capitis* by Winſlow, and deſcribed by Veſalius by the name of the *tertius capitis moventium*; and by Spigelius, and others, under that of *rectus major*.

RECTUS *capitis poſticus minor*, a name given by Albinus to a muſcle of the head, called by Riolanus and others *poſticus minor*, and by Winſlow *rectus parvus*; Veſalius has deſcribed it under the name of *quartus caput moventium*.

RECTUS *exterior oculi*, in anatomy, a name given by Fabricius and others to one of the muſcles of the eye, called by Riolan and others the *ſuperbus*, and by ſome the *elevator oculi*; it is the *abductor* of Albinus, one of his *quatuor recti*.

RECTUS *inferior oculi*, in anatomy, a name given by Fabricius, and ſome others, to one of the muſcles of the eye, called by others *humilis*, and by Albinus the *depreſſor*. It is one of the *quatuor recti oculi* of that author.

RECTUS *interior oculi*, in anatomy, a name given by Fabricius to one of the muſcles of the eye, called by Molinet the *bibitorius*; and by Cowper, Albinus, and others, the *adductor oculi*. See ADDUCTOR, *Cycl.* and *Suppl.*

RECTUS *ſuperior oculi*, in anatomy, a name given by Fabricius to one of the muſcles of the eye, called the *attollens* by Albinus, and by others the *elevator oculi* and the *ſuperbus*. See the article ELEVATOR *oculi*.

RECUPERATORES, among the Romans, were commiſſioners, appointed to take cognizance of private matters in diſpute, between the ſubjects of the ſtate and foreigners, and to take care that the former had juſtice done them.

It came at laſt to be uſed for commiſſioners, to whom the prætor referred the determination of any affair between one ſubject and another. *Pitiſc.* in voc.

RECURVIROSTRA, in zoology, the name of a very remarkable bird, ſo called from the remarkable bending upwards of its beak, and named *avoſetta* by the Italians.

It is a little larger than the common lapwing, weighing uſually about ten ounces; its beak is three fingers breadth long, very ſlender, black, and flatted, and bending upwards, which is peculiar to it alone. Its head is moderately large and very round, and both that and the upper part of the neck is black, only that there is a ſmall variegation of grey juſt behind the head. Its breaſt, belly, and throat are all of a ſnowy whiteneſs, and its back is variegated with black and white; its wings are alſo variegated with black and white; its tail is all white; its legs very long and blueiſh, and feathered half way down below the knees. It is very common in Italy, and is not unfrequently ſeen about the eaſtern ſhores of England. *Ray*'s Ornithol. p. 241.

RED (*Cycl.*)—To make a deep *red* in glaſs, the following method is that moſt practiſed by the glaſs-men. Take cryſtal fritt twenty pounds, broken pieces of white glaſs one pound, calcined tin two pound, mix theſe well together, and put them into a pot to melt and purify; when theſe are melted, take ſteel calcined, ſcales of iron from the ſmith's anvil, both powdered very fine, of each an equal quantity; put leiſurely an ounce of this mixed powder to the beforementioned metal, mix all well together, and let them ſtand ſix or eight hours in fuſion, to incorporate; take out a proof after this, and if there be too little of the powder, it will appear of a duſky yellow; then more of the powder muſt be added, and then add three quarters of an ounce of calcined braſs ground to a fine powder; mix them thoroughly together, and the maſs will be of a blood *red*; continue ſtirring the whole together, and frequently taking out proofs of the colour; when it is right, work it immediately, otherwiſe it will loſe its colour and become black. The mouth of the pot muſt in this proceſs be left open, elſe the colour will be loſt. *Neri*'s Art of Glaſs, p. 100.

Blown RED, in the porcelain manufacture, a name given to a peculiarly coloured china ware of a ſpangled *red*, or to the colour alone that ſpangles it. It is an ornament eaſily introduced into uſe in our own manufactories of porcelain ware, and is done in the following manner. The colour is to be prepared of common copperas, calcined to a *red* colour in a charcoal fire, in a crucible, with another luted on the top of it inverted, and with a hole in its bottom. The ſignal of the calcination being finiſhed, is, when the black clouds ceaſe to come up through the hole, and a fine white thin vapour ariſes in their place. The veſſels are to be then ſuffered to cool, and the *red* matter in them is to be reduced to a fine powder; while the veſſels to be coloured with this are yet wet. The operator is to provide a glaſs pipe, and covering one end of it with a piece of fine gawſe; he is to dip this into the powder, and taking it carefully out, with what little is ſticking to it, he is to blow againſt the veſſel at ſome diſtance from it: thus the fineſt part of the powder only will reach the veſſel, and will be laid on in form of glittering ſpangles, very ſmall, but all diſtinct. This is a ſort of colouring much eſteemed by the Chineſe themſelves, and they have a way of uſing the common blue in the ſame manner; but few of the veſſels, thus painted, come over to us. Obſerv. de l'Aſie.

RED *game*, an Engliſh name of a bird, common in the mountainous parts of Yorkſhire, and ſome other of our northern counties. It is of the ſhape of a partridge, but much larger, and of a mixed colour of red and black, and is feathered down to the ends of the toes. See the article GOR-*cock*.

Indian RED, a name uſed by the colourmen and painters for a kind of purple ochre, brought from the iſland of Ormus in the Perſian gulf, and uſed as a red colour. It is called among the authors on theſe ſubjects *terra perſica*. *Hill*'s Hiſt. of Foſſ. p. 58.

RED *land*, in agriculture, a term much uſed by huſbandmen, to expreſs a ſandy ſoil of a reddiſh hue, interſperſed for the moſt part with pieces of ſand ſtone of the ſame colour, or ſomewhat deeper.

There are ſeveral varieties of this ſoil, one of which is almoſt entirely made up of ſand; another with an admixture of clay with the ſand, the whole making a looſe loamy earth; and a third, full of fragments, of a poor ſandy iron ore, and often containing ſhining ſpecks of ſelenitæ. *Moreton*'s Northamp. p. 40.

RED-*lead*. See the article MINIUM.

RED-*ſhank*, in zoology, the name of a water bird, called by authors *gallinula erythropus*, and *callidrys*. It is about the ſize of the common plover. The back is of a greyiſh or browniſh green, uſually ſpotted with black; its neck grey, and its throat variegated with black and white; the breaſt is white, with a few looſe ſtreaks of black. The wing feathers are variegated with black, brown, and white; the breaſt is two fingers breadth long, ſlender, and ſhaped like the beak of the woodcock; reddiſh at the baſe, and blackiſh lower down. Its legs are of a fine beautiful red, and the hinder toe is very ſhort and ſmall. *Ray*'s Ornithol. p. 221.

RED *ſtart*, in zoology, the Engliſh name of the *ruticilla*, a very beautiful bird, with a white ſpot on his head and a red tail. See the article RUTICILLA.

RED *weed*, in botany, a name given to a plant common in Bermudas, and ſome other places; and called by our firſt travellers to that part of the world the *ſummer iſland redweed*. Its berry is of a fine red colour, and affords a tincture little inferior to that of cochineal, and poſſeſſing all its virtues in medicine; the only misfortune of this, and ſome other very fine vegetable colours, is, that they fade ſoon. The juice of the fruit of the opuntia, or prickly pear, is as fine a dye as can be procured from the cochineal, but it will not ſtand; the inſect feeding on this, however, we find affords a colour of the ſame nature, that will ſtand. The fruit of the *red weed* is in the ſame manner liable to be eaten by inſects as that of the prickly pear, and it is worthy a trial, whether its colour obtained at ſecond hand from thoſe inſects, will not ſtand as well as the cochineal does, and whether the inſects may not be propagated in a ſufficient abundance to ſerve the markets in the ſame manner. Phil. Tranſ. N°40.

RED *wing*, in zoology, the name of a bird of the turdus, or thruſh kind, called alſo in ſome places the *wind thruſh*, or *ſwine pipe*, and by authors the *turdus iliacus*, or *tylas*.

It is a little ſmaller than the common thruſh, and is leſs ſpotted. Its back, neck, and head are of the ſame colour with thoſe of the common thruſh; but its ſides, under the wings, and the feathers which line the wings, are of an orange colour, or duſky red; its belly and breaſt are whitiſh, and its throat yellowiſh, with brown ſpots: the wings are of a ſort of cheſnut colour, a little variegated. It feeds on inſects, as worms, and the like; and is a bird of paſſage, coming to us at the ſame time with the fieldfare, and leaving us alſo when that bird does. It is not well known where they breed, though ſome have gueſſed it to be in the mountains of Germany and Bohemia. They have a bitteriſh taſte, and are leſs valued than the fieldfare. *Ray*'s Ornithol. p. 139.

REDDLE, (*Cycl.*) the common Engliſh name for the ſubſtance, called in Latin *rubrica*, and uſed in painting, and for marking ſheep, &c. *Hill*'s Hiſt. of Foſſ. p. 48. See the article RUBRICA.

REDIMICULUM, among the Romans, a girdle, which going about the neck, divided on the breaſt, and paſſing down each ſide, went round, and kept the robe tight to the body. See *Pitiſc.* in voc.

REDUCTION, (*Cycl.*) in metallurgy, is the bringing back metalline ſubſtances, which have been changed into *ſcoriæ* or aſhes, or otherwiſe diveſted of their metallic form, into their natural and original ſtate of metals again. *Cramer*'s Art of Aſſaying, p. 185.

All metals and ſemi-metals may be reduced by proper management, whatever have been their changes, except only zink, which having been burnt to aſhes, admits of no *reduction*. But the mixture of gold, and ſilver, was never yet

yet radically diſſolved by any experiment, whatever ſome may have imagined. Even ſome earths will turn into metals by the admixture, and intimate union of a phlogiſton, or inflammable principle; but theſe metals never need any ſuch principle to aſſiſt their *reduction*. Ibid. p. 186.

REDUNDANT (*Cycl.*)—REDUNDANT *interval*, in muſic, is uſed for an interval exceeding the truth by a comma. See INTERVAL.

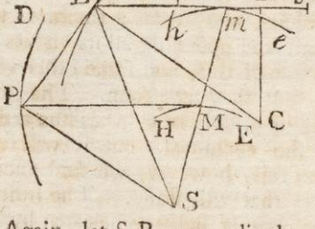
Some apply *redundant* to an interval exceeding a diatonic interval by a ſemitone minor; but this is more uſually called a ſuperfluous interval. See the articles SECOND, *Cycl.* and, INTERVAL, *Suppl.*

REDUVIA, in medicine, a word uſed by ſome for a whitlow, and by others for a painful crack, or other diſorder about the nails, either of the fingers or toes.

REED, *arundo*, in botany. See ARUNDO.

REED, *calamus*, likewiſe denotes a ſort of meaſure, otherwiſe called *canna*. See CANNA.

REED *ſparrow*, the Engliſh name of a bird by many eſteemed of the picus, or wood-pecker kind, having ſhort legs, and climbing up *reeds*, &c. as the other upon trees; but it wants the great character of that genus of birds, having its toes placed only one behind, and three before, as in the generality of other birds. There are two ſpecies of this bird, a greater and a leſſer; the firſt called by authors *junco*, and *cinclus*, and the other *cannevarola*, and by ſome *paſſer arundinaceus minor*. *Ray*'s Ornitholog. p. 99. See the articles JUNCO and CANNEVAROLA.



REEN *moſſa*, a name uſed by ſome for the mountain coralloides, or rein deer moſs.

REEVE (*Cycl.*)—REEVE, in zoology, the name of a bird which is the female of the *avis pugnax*; the male of which, from his long feathers round his neck, is called the *ruffe*.

REFLECTING *teleſcope* (*Cycl.*)—See TELESCOPE.

REFLEX *leaf*, among botaniſts. See LEAF.

REFLEXION (*Cycl.*)—*Cauſtic by* REFLEXION. Rays of light being ſuppoſed to iſſue from a given point, and to be *reflected* by a given curve, ſo as to make the angle of *reflexion* equal to the angle of incidence; a curve that touches all the *reflected* rays is called the *cauſtic by reflexion*.

Thus, let S be the given point from whence the rays iſſue, S L any incident ray, P L *p* the tangent at L, L C the radius of curvature at L, L *m* the *reflected* ray conſtituting the angle C L *m*, equal to C L S; then if the *reflected* rays always touch the curve *h m e*, it is the cauſtic by *reflexion*.

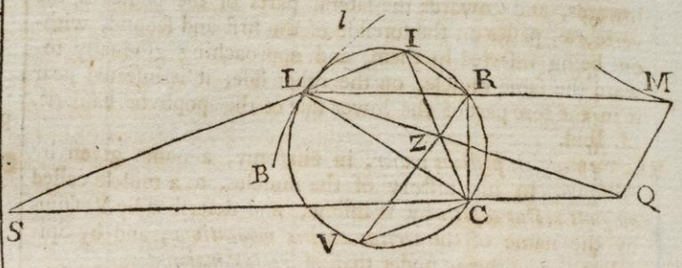
Again, let S P, perpendicular to the tangent L P, meet it always in P, a point of the curve D P; let H M E be the curve, by the evolution of which D P is deſcribed, and let P M touch H M E in M; join S M, and produce it to *m*, ſo that S *m* be equal to 2 S M: then will *m* be a point in the cauſtic of the curve B L, when S is the radiating point.

Hence, if perpendiculars be always drawn from the radiating point to the tangents of the *reflecting* curve, and a new curve be ſuppoſed to be the locus of the interſections of the perpendiculars and tangents, then will the evoluta of that new curve be ſimilar, and ſimilarly ſituated to the cauſtic by *reflexion* of the propoſed *reflecting* curve. See *Mac Laurin*'s Fluxions, Art. 409.

The point *m* may be thus found. Let C R be perpendicular to L R, the *reflected* ray, and let L *s* = L S; then if L R be biſected in *q*, *q m* will be a third proportional to *q s* and *q* R; that is, *q s* : *q* R :: *q* R : *q m*, or *s q* × *q m* = *q* R² = *q* L². Id. Art. 410.

Mr. de l'*Hopital*, in his Analyſe des Inf. Petits, Sect. 6. has treated of cauſtics by *reflexion*.

Point of REFLEXION, in geometry. See POINT *of reflexion*.



REFRACTED (*Cycl.*)—REFRACTED *angle*, in optics, the angle contained between the *refracted* ray and the perpendicular.

REFRACTION (*Cycl.*)—REFRACTION *to the perpendicular*, in optics, is when a ray falls from a leſs denſe into a more denſe medium, and ſo approaches nearer the perpendicular.

REFRACTION *from the perpendicular*, in optics, is when a ray falling inclined from a more denſe medium into one leſs denſe, in breaking departs further from the perpendicular.

Cauſtics by REFRACTION. When rays of light, iſſuing from a given point, are *refracted* at any curve, ſo that the ſine of the angle contained by the *refracted* ray, and the perpendicular to the curve, is always to the ſine of the angle contained by the incident ray, and that perpendicular, in one conſtant ratio, the curve that touches all the *refracted* rays, is called the *cauſtic by refraction*.

Let S be the radiating point, S L any incident ray on the curve B L *l*, L R the *refracted* ray, C the center of the curvature at L, C I perpendicular on the incident ray in I, C R perpendicular to the *refracted* ray in R; join S C

and I R; let R Z, perpendicular to R I, meet C I in Z; join L Z, meeting S C in Q; and let Q M, parallel to R Z, meet the *refracted* ray L R in M; then will the point M be in the cauſtic. See *Mac Laurin*'s Fluxions, Art. 413.

The point M may alſo be determined, by deſcribing a circle L I R C on the diameter L C, and by drawing V C parallel to S L; then applying R C in this circle, ſo that it may be to C I, in the given ratio of the ſine of *refraction*, to the ſine of incidence, joining V R, that meets C I perpendicular from C to the incident ray in Z, joining L Z that meets S C in Q, and drawing Q M parallel to V R. When L Z is parallel to S C, the *refracted* ray is the aſſymptot to the cauſtic. Ib. Art. 414.

The Marquis de l'Hopital has treated of *cauſtics by refraction*, in his Anal. des Inf. Pet. Sect. 7.

REFRANGIBLE, whatever is capable of being refracted. See REFRANGIBILITY, *Cycl.*

REFRIGERATORY, (*Cycl.*) a term uſed for a veſſel of cold water, through which the worm of the alembic paſſes in the common method of diſtillation, by means of which the vapours are condenſed. It is alſo uſed for the bucket head of the common ſmall alembic, containing water for the ſame purpoſe.

REFUTATION, *refutatio*, in rhetoric, that part of the anſwer made to an opponent, which diſproves what had been advanced by him. *Voſſ.* Rhet. l. 5. p. 382.

REGENERATED *tartar*. See TARTARUS *regeneratus*.

REGERENDARIUS, among the Romans, an officer who ſubſcribed and kept a regiſter of all petitions preſented to the præfect. *Pitiſc.* in voc.

REGESTOLA, in zoology, a name uſed by ſome authors for the mattageſs, or larger butcher bird, a very ſmall hawk, not exceeding the ſize of a common thruſh, but very fierce and voracious. *Aldrovand*, de Avib. See MATTAGESS and LANIUS.

REGIMEN, (*Cycl.*) in medicine, a regulation of diet, with intent to reſtore, or to preſerve health. In chemiſtry, it ſignifies the due regulation of fire.

REGINA *aurarum*, in zoology, a name given by Nieremberg to a bird called by the Mexicans *cozeacoauhtli*. It has obtained its name from its being able to fly againſt the ſtrongeſt winds. It is of the bigneſs of an eagle, and its whole body is of a blackiſh purple, variegated with a browniſh yellow, and a deep black. Its wings are variegated with black, yellow, and grey. Its legs are red. Its claws very ſtrong and ſharp; and its beak like that of the parrot. It has ſome rugoſe ſkin on the forehead, and about the beak, and its tail is black above, and grey underneath. It feeds on ſnakes, rats, and other vermin, but will alſo eat human dung. It flies very high. It is a native of Mexico, and breeds in ſpring. Its feathers are ſaid to be a remedy for many diſeaſes. But the truth of this account is much to be doubted. *Ray*'s Ornitholog. p. 302.

REGION (*Cycl.*)—REGIONS *of the ſea*. As the naturaliſts, in their deſcriptions of the ſubterranean parts of the globe, diſtinguiſh the earth into three regions of different depths, in which different temperatures are obſerved; ſo in deſcribing the ſea, they allow it two regions; the one extending from the ſurface of the water, down ſo low as the rays of the ſun can pierce, and extend their influence; and the other, from the loweſt bounds of that to the bottom. It is eaſy to ſee, that theſe regions rather regard quality than ſpace, and that their boundaries are far from being regular, or equal in all places, and at all times. The places expoſed to the hotteſt ſunſhine will have the largeſt upper *region*; thoſe where the ſun has leaſt power, will have the ſmalleſt; and the ſame part of the ſea will have its upper *region* more or leſs deep, according to the ſeaſon of the year. This upper *region* of the ſea is always more or leſs hot; the lower *region*, except in ſome few particular places, is every where cold; and the water, where the upper *region* is large, is always remarkably ſtill and quiet in the lower. *Boyle* of Coſmical Qualities.

Subterranean REGION. The earth is not only divided on its ſurface into *regions* and countries, but philoſophers, who have had occaſion to diſcourſe of its inner parts, have alſo divided them into three diſtinct *regions*, according to their different depths from the ſurface. The temperature of the ſubterranean parts of the globe is diſtinguiſhed according to the diviſion of theſe *regions*, but is not ſo regular and

preciſe

preciſe as ſome have ſuppoſed. The firſt *region* of the earth is very variable, both as to bounds and temperature. The ſecond *region* ſeems for the moſt part cold, in compariſon of the other two; but in ſeveral places, which, by reaſon of their diſtance from the ſurface of the earth, it would be natural to call the middle *region*, the temperature of the air is very different at the ſame ſeaſons of the year, which ſhews that it depends on ſomething more than bare depth from the ſurface. The third *region* of the earth is univerſally obſerved to be warm, but by no means regularly, or uniformly: the ſame depth in ſome places, giving only a moderate warmth, while in others it gives a very conſiderable heat. Borrichius tells us of a certain abbe fond of chemiſtry, and particularly curious in the matter of long digeſtions by regular heat, who found a way of making a furnace perpetually warm, by piercing the earth to a certain depth, and uſing the heat of this third *region* of it. His method, we are told, was to bore a hole with a pike twenty feet deep, and pour into it ten or twelve pounds of quickſilver; this made its way into the ſtrata, and through them in a body into the chambers of heat in this third *region*, where the heat having a vent upwards, made by this opening, never failed to aſcend in a perpetual and regular ſtream, and gave that regular digeſting heat that no artificial fire could equal. But this is an alchemical ſtory. *Boyle* of Coſmical Qualities. *Borrich.* de Ortu Chem.

REGION, in antient Rome, a part or diviſion of the city. They were only four in number till Auguſtus's time, who divided the city into fourteen *regions*, over each of which he ſettled two ſurveyors, called *curatores viarum*, who were made annually, and took their diviſions by lot. Theſe fourteen *regions* contained 424 ſtreets, 31 of which were called great or royal ſtreets, which begun at the gilt pillar that ſtood at the entry into the open place in the middle of the city.

The extent of theſe diviſions varied greatly, ſome being from 12000 or 13000 to 33000 feet and upwards in circumference. Authors, however, are not agreed as to the exact limits of each. See *Kenn.* Rom. Antiq. Not. l. 1. c. 2. p. 34. ſeq. *Pitiſc.* Lex. Antiq. in voc. *regio*. *Danet*, Dict. in voc. *Pancirol.* Deſcript. Urb. Rom. T. 3. p. 283.

REGRADATION, *regradatio*. See DEGRADATION, *Cycl.*

REGULAR *leap*, in muſic. See LEAP.

REGULUS (*Cycl.*)—The ſeparation of ſilver out of the *regulus*, made from the ſilver ore by means of lead, is to be performed in this manner. Put two coppels of the ſame bigneſs, perfectly dry, and capable of containing at leaſt one third more than the *regulus*, under a muffle in an aſſay-furnace; make a ſtrong fire, and let them be red hot for a quarter of an hour, then free the *regulus* from its ſcoriæ, by ſtriking it gently with a hammer, and put it carefully into one of the hot coppels, and into the other put, at the ſame time, the ſame quantity of granulated lead alone, as was uſed in the making the *regulus*. When the *regulus* boils and ſmoaks diminiſh the fire a little, and let the coppels be kept moderately, but not violently red hot. When it has ſtood ſo long, that the ſkin of litharge, continually produced from the lead, and covering the ſurface of the *regulus*, diſappears, and the coppel ſhews the ſcoriæ only of the lead with the pure ſilver, either in fuſion, or hard and bright in the middle, let the coppel continue only a minute or two longer on the fire; then take it out with a pair of tongs, take away the metal in grains, and if any ſcoriæ, or fragment of the coppel adhere to it, wrap it together in a paper, and ſqueeze it between the cheeks of a vice, or a pair of tongs, to break off that brittle matter without hurting the *regulus*. If this *regulus* be pure ſilver, it will now be very white, but if it contain any gold, it will ſhew it by its yellowneſs.

To determine exactly how much ſilver the quantity of ore contained, weigh it nicely in a fine balance, and take out the ſmall *reguline* lumps from the other coppel, and weighing that, deduct its weight from that of the other, becauſe ſo much ſilver that owes to the lead uſed in making it, and the remainder is the proportion of ſilver contained in the ore. *Cramer's* Art of Aſſaying, p. 211.

REGULUS *criſtatus*, the *creſted* or *golden crown wren*, the name of a very beautiful little bird, the ſmalleſt of all the European birds. Its whole weight is not more than a dram, and the crown of its head is adorned with a very beautiful ſaffron coloured, or orange red ſpot, which is called its creſt, and by ſome its crown, and from this golden crown the bird has obtained the name of the *regulus*, *tyrannus*, *baſileus*, and other appellations of royalty.

This crown the bird can at pleaſure draw together, by wrinkling its forehead, and by this means hide it from ſight. The edges of this crown are of a pale yellow, and its end circumſcribed by a black line. It is of an oblong figure, and is extended ſtrait from the origin of the beak to the back part of the head. The ſides of this little bird's neck are of an extremely gloſſy greeniſh yellow, and the ambit of its eyes white. Its neck and back are of an obſcure yellowiſh green, and its breaſt of a duſky white, ſometimes of a pale greeniſh caſt. Its wing feathers are brown, with their edges yellowiſh without, and whitiſh within; and the middle ones are ſo tinged in part with black, that when they are folded in the ſhutting of the wing, they make a black ſpot in its middle; and the tips of one ſeries of the feathers being white, they make alſo a white tranſverſe ſtreak on each wing. The tail is browniſh, the feet yellow, and the beak half an inch long, and very ſlender and black. They are common about the Peak in Derbyſhire, and in ſome other parts of England. They ſit uſually on the tops of oaks, and other high trees. They lay ſix or ſeven eggs, not larger than peas. *Ray's* Ornitholog. p. 163.

REGULUS *non criſtatus*, in zoology, the name of a bird more commonly known by the name *luteola*, and by ſome called *aſilus*. *Ray's* Ornitholog. p. 164. See LUTEOLA.

REJECTIO, a word uſed by medical authors for the caſting any thing up preternaturally by the mouth, whether it be by vomiting or by ſpitting.

REINS (*Cycl.*)—REINS, in the manege, a name given by the Duke of Newcaſtle to two ſtraps, or ropes of a caveſſon, which he ordered to be made faſt to the girths, or the pommel of the ſaddle, with intent that the rider ſhould pull them with his hand, in order to bend and ſupple the neck of the horſe.

Falſe REIN is a lath of leather paſſed ſometimes through the banquet, to bend the horſe's neck, which is diſapproved of by the Duke of Newcaſtle; by reaſon it ſlacks the curb, and makes the bit no more than a trench that has no curb.

REIS *effendi*, in the Turkiſh affairs, an officer of ſtate anſwering to our chancellor.

RELAIS, in fortification, a French term, the ſame with *berme*. See BERME, *Cycl.*

RELATION, *relatio*, in rhetoric, is ſometimes uſed to ſignify the ſame with recrimination. See RECRIMINATION, *Cycl.*

REMANCIPATION, *remancipatio*, among the Romans, a form of divorce obſerved in marriages that had been contracted by *coemption*. This was done by delivering the wife into the huſband's hands; ſo the marriage was diſſolved by the huſband's redelivering the wife into any perſon's hands, agreed upon between them. *Pitiſc.* in voc. See COEMPTION.

REMISSION (*Cycl.*)—REMISSION, *remiſſio*, ανεσις, in the antient muſic, was uſed to ſignify the paſſage of the voice from acute to grave; being oppoſite to intention. *Ariſtoxen.* p. 10—13. *Ariſtid.* Quint. p. 8, 9.

REMOLADE, or CHARGE, in the manege. See the article CHARGE, *Cycl.*

REMORA (*Cycl.*)—This is a ſmall oblong fiſh, whoſe body is of a cylindric figure, and tapers off to a thinneſs at the tail. Its mouth is triangular, and the upper part is ſhorter than its under. Its head is flat, and marked with ſtreaks, ſo as to look like the palates of ſome fiſhes: theſe run tranſverſely, and are carried on to the back, making a ſtriated ſubſtance of two fingers breadth, by which it faſtens itſelf to any other ſubſtance, as the body of a larger fiſh, the hulk of a ſhip, or the like. The eyes are ſmall and yellow, with a black pupil. It has no teeth, but in their places a multitude of ſmall prominences. It has two fins under the gills, and two more lower on the body. Beſide theſe it has two longitudinal fins, one on the back, the other on the belly, running the length of the body to the tail. The whole fiſh is of a greyiſh colour, and it is caught in the Eaſt and Weſt Indies, and in many other ſeas. See Tab. of Fiſhes, N° 14. and *Marcgrave's* Hiſt. Braſ. p. 117.

REMORA *mutiani*, in natural hiſtory, a name given by ſome to the genus of ſhells called *concha venerea*, and *porcellana*. See PORCELLANA.

REMOTION, *remotio*, in rhetoric, the ſame with what is otherwiſe called *metaſtaſis*. See METASTASIS.

REMOULIN, in the manege, is uſed to denote a ſtar upon a horſe's forehead.

REMPHAN, in antiquity, the Egyptian name for the planet Saturn. Some think that *remphan* was the moon. See the article CHIUN.

REMURIA, among the Romans, a feſtival inſtituted in honour of Remus by his brother Romulus. Mem. Acad. Inſcr. Vol. 1. p. 45.

RENALIS *lapis*, in natural hiſtory, the name given by many authors to a ſort of ſiderochitum, or cruſtated ferrugineous body of that kind, containing a nucleus of a different matter from that of the cruſts. It is found about Prague, and in ſome other places, lying near the ſurface in ſtrata of a yellow clay. Its uſual bigneſs is that of a ripe peach, and its cruſts are of a duſky ferrugineous brown colour; and its internal nucleus of a pale yellowiſh green, compoſed of a marley earth, and uſually of a kidney-like ſhape, whence its name.

RENDS, in a ſhip, are the ſame as the ſeams between her planks.

RENES (*Cycl.*)—RENES *ſuccenturiati*. Valſalva has endeavoured to prove the *renes ſuccenturiati*, or *glandulæ renales*, to be organs of generation, or aſſiſtant to them. Valſalva claimed this diſcovery. Mr. Ranby ſuſpected that the duct

which the Italian journals mentioned, as the principal part of this diſcovery, was no other than an artery ſent off from that of the capſula on each ſide, to the teſticles of men, and ovaria of women. Morgagni explained Valſalva's doctrine more fully. Valſalva gives the following reaſons for his opinion. He obſerves the ſeminary veſſels of ſeveral fowls to come out from theſe capſulæ, before they are ſent from the teſticles. In the viper and water tortoiſe, he remarks ſuch membranous connections between the *renes ſuccenturiati*, and teſticles, as make it probable that ſuch excretories are ſent through the capſulæ to the teſticles. He affirms, his having ſeen veſſels, which were neither nervous, ſanguiferous, or lymphatic, going from the human capſulæ to the teſticles. His obſervations are much the ſame as to females. To theſe he ſubjoins the conſent and ſympathy obſerved between the loins and genital parts. To confirm all, he cut away one teſticle, and extirpated the *kidney* of the oppoſite ſide, of a whelp. The wounds healed, but the creature was of a very lax habit, and ſo far from attempting coition, that he did not ſeem fond of bitches when they were proud. Acad. Bonon. Comment. p. 376. & ſeq. See alſo Phil. Tranſ. N° 387. Sect. 3. where we have an inquiry into this diſcovery, made by Valſalva, of an excretory duct from the glandula renalis to the epididymis by Mr. John Ranby. And in N° 395. Sect. 12. there are mentioned, by the ſame gentleman, two newly diſcovered arteries in women going to the ovaria; which he thinks to be probably the ſame with what Valſalva took for excretory ducts of the glandulæ renales. Valſalva's diſcovery was firſt mentioned in the *giornale di leterati* of Venice for 1719, and inſerted in the Phil. Tranſ. N° 385. Sect. 9.

RENETTE, in the manege, is an inſtrument of poliſhed ſteel, with which they ſound a prick in a horſe's foot.

RENIFORM *leaf*, among botaniſts. See LEAF.

RENTAL, a roll wherein the rents of a manor are written and ſet down, and by which the lord's bailiff collects the ſame: it diſtinguiſhes the lands and tenements, and the names of the tenants, the ſeveral *rents* ariſing, and for what time, uſually a year. Comp. Court Keep. 475.

REPART, in the manege, is to put a horſe on, or make him part a ſecond time.

REPAND *leaf*, *repandum folium*, among botaniſts. See the article LEAF.

REPHON. See the article REMPHAN.

REPOLON, in the manege, is a demivolte, the croupe in, cloſed at five times. The Italians are mighty fond of this ſort of manege. In making a demivolte, they ride their horſes ſhort, ſo as to embrace or take in leſs ground, and do not make way enough every time of the demivolte.

REPRISE, in the manege, is a leſſon repeated, or a manege recommenced. Thus we ſay to give breath to a horſe upon the four corners of the volte with only one *repriſe*, that is, all with one breath.

REPROOF, *objurgatio*, in rhetoric, is diſtinguiſhed from *invective*. See the article INVECTIVE.

REPRODUCTIVE *ſyſtem of preſervation*. See the article ANNIHILATION.

RERE *county*, a word uſed in the ſtatutes of Weſtm. 2. c. 39. And 2 Ed. 3. c. 5. And ſeems by thoſe ſtatutes to be ſome public place, which the ſheriffs appointed for the receiving of the king's money after his county court was done. *Terms of Law. Blount.*

REPUDIUM, among the Romans. See DIVORCE.

RESCUSSOR, in law, the party that commits a *reſcous*. 2 Cro. 419. *Blount.*

RESEDA, *baſe rocket*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the polypetalous anomalous kind, conſiſting of ſeveral diſſimilar petals; from the cup of which there ariſes a piſtil, which finally becomes a membranaceous capſule uſually of a trigonal form, or elſe ſquare, though ſometimes oblong and cylindric, and containing roundiſh ſeeds.

The ſpecies of *reſeda* enumerated by Mr. Tournefort are theſe. 1. The common *reſeda*. 2. The French *reſeda* with curled leaves. 3. The broad leaved *reſeda* with yellow flowers. 4. The white flowered *reſeda* with leaves like the calcitrapa. 5. The common ſmall *reſeda*, called by many authors the phyteuma. 6. The common leſſer *reſeda* with leaves not ſo deeply cut. 7. The common whole or uncut leaved ſmall *reſeda*. *Tourn.* Inſt. p. 423.

RESIANT *rolls*, are rolls wherein the *reſiants* of a tithing, &c. are ſet down. Comp. Court Keep.

RESIDUARY *legatee*, is he to whom the *reſiduum*, or what remains of an eſtate, after funeral charges, debts, and legacies are paid, is left by will.

RESIN (*Cycl.*)—According to Theophraſtus *reſin* was obtained by ſtripping off the bark from pines, and by inciſions made in the ſilver fir and the pitch pine. The inhabitants of mount Ida, he tells us, ſtripped the trunks of pines, on the ſunny ſide two or three cubits from the ground. He obſerves, that a good pine might be made to yield *reſin* every year, but the indifferent pines only every other year, and the weaker trees once in three years; and that three runnings were as much as a tree could bear. It is remarked by the ſame author, that a pine doth not at once produce fruit and *reſin*; but the former only in its youth and the latter in its old age.

RESISTANCE (*Cycl.*)—RESISTANCE *of fluids*. The greateſt part of authors have eſtabliſhed it as a certain rule, that, whilſt the ſame body moves in the ſame medium, it is always *reſiſted* in the duplicate proportion of its velocity; that is, if the *reſiſted* body move in one part of its track, with three times the velocity with which it moved in ſome other part, then its *reſiſtance* to the greater velocity will be nine times the *reſiſtance* to the leſſer. If the velocity in one place be four times the velocity in another, the *reſiſtance* to the greater velocity will be ſixteen times the *reſiſtance* to the leſſer, and ſo on. This rule, though exceſſively erroneous, when taken in a general ſenſe, is yet undoubtedly very near the truth, when confined within certain limits.

In order to conceive the *reſiſtance of fluids* to a body moving in them, it is neceſſary to diſtinguiſh between thoſe fluids which being compreſſed by ſome incumbent weight, perpetually cloſe up the ſpace deſerted by the body in motion, without permitting, for an inſtant, any vacuity to remain behind it; and thoſe fluids in which (they being not ſufficiently compreſſed) the ſpace left behind the moving body remains for ſome time empty. Theſe differences, in the reſiſting fluids, will occaſion very remarkable varieties in the laws of their *reſiſtance*, and are abſolutely neceſſary to be conſidered in the determination of the action of the air in ſhot and ſhells; for the air partakes of both theſe affections, according to the different velocities of the projected body.

If a fluid was ſo conſtituted, that all the particles compoſing it were at ſome diſtance from each other, and there was no action between them, then the *reſiſtance* of a body moving therein, would be eaſily computed, from the quantity of motion communicated to theſe particles: for inſtance, if a cylinder moved in ſuch a fluid in the direction of its axis, it would communicate to the particles it met with a velocity equal to its own, and in its own direction, ſuppoſing that neither the cylinder, nor the parts of the fluid were elaſtic; whence, if the velocity and diameter of the cylinder be known, and alſo the denſity of the fluid, there would thence be determined the quantity of motion communicated to the fluid, which (action and re-action being equal) is the ſame with the quantity loſt by the cylinder, conſequently the *reſiſtance* would be hereby aſcertained.

In this kind of diſcontinued fluid, the particles being detached from each other, every one of them can purſue its own motion in any direction, at leaſt for ſome time, independent of the neighbouring ones; wherefore, if, inſtead of a cylinder, moving in the direction of its axis, a body, with a ſurface oblique to its direction, be ſuppoſed to move in ſuch a fluid, the motion the parts of the fluid will hereby acquire, will not be in the direction of the *reſiſted* body, but perpendicular to its oblique ſurface; whence the *reſiſtance* to ſuch a body will not be eſtimated from the whole motion communicated to the particles of the fluid, but from that part of it only, which is in the direction of the *reſiſted* body. In fluids then, where the parts are thus diſcontinued from each other, the different obliquities of that ſurface, which goes foremoſt, will occaſion conſiderable changes in the *reſiſtance*; although the ſection of the ſolid, by a plain perpendicular to its direction, ſhould in all caſes be the ſame. And Sir Iſaac Newton has particularly determined, that in a fluid thus conſtituted, the *reſiſtance* of a globe is but half the *reſiſtance* of a cylinder of the ſame diameter, moving in the direction of its axis with the ſame velocity.

But though the hypotheſis of a *fluid*, thus conſtituted, be of great uſe in explaining the nature of *reſiſtances*; yet, in reality, no ſuch fluid does exiſt within our knowledge: all the *fluids* with which we are converſant are ſo formed, that their particles either lie contiguous to each other, or at leaſt act on each other in the ſame manner, as if they did; conſequently, in theſe fluids, no one particle, contiguous to the *reſiſted* body, can be moved, without moving at the ſame time a great number of others, ſome of which will be diſtant from it; and the motion thus communicated to a maſs of the *fluid* will not be in any one determined direction, but will in each particle be different, according to the different manners in which it lies in contact with thoſe, from which it receives its impulſe; whence, great numbers of the particles, being diverted into oblique directions, the *reſiſtance* of the moving body, which will depend on the quantity of motion communicated to the fluid in its own direction, will be hereby different in quantity, from what it would be in the preceding ſuppoſition, and its eſtimation becomes much more complicated and operoſe.

If the fluid be compreſſed by the incumbent weight of its upper parts (as all fluids are with us, except at their very ſurface) and if the velocity of the moving body be much leſs than that with which the parts of the fluid would ruſh into a void ſpace, in conſequence of their compreſſion; it is evident, that in this caſe the ſpace left by the moving body will be inſtantaneouſly filled up by the fluid; and the parts of the fluid, againſt which the foremoſt part of the body preſſes in its motion, will, inſtead of being impelled forwards in the

direction of the body; circulate, in ſome meaſure, towards the hinder part of the body, thereby to reſtore the equilibrium, which the conſtant influx of the *fluid* behind the body would otherwiſe deſtroy; whence the progreſſive motion of the fluid, and conſequently the *reſiſtance* of the body, which depends thereon, would be, in this inſtance, much leſs than in our firſt hypotheſis, where each particle was ſuppoſed to acquire, from the ſtroke of the *reſiſting* body, a velocity equal to that, with which the body moved, and in the ſame direction. Sir Iſaac Newton has determined, that the *reſiſtance* to a cylinder, moving in the direction of its axis, in ſuch a compreſſed fluid as we have here treated of, is but one fourth part of the *reſiſtance*, which the ſame cylinder would undergo, if it moved with the ſame velocity, in a fluid, conſtituted in the manner we have deſcribed in our firſt hypotheſis, each fluid being ſuppoſed to be of the ſame denſity.

But again, it is not only in the quantity of their *reſiſtance* that theſe fluids differ, but likewiſe in the different manner, in which they act on ſolids of different forms moving in them. We have ſhewn, that in the diſcontinued fluid, which we firſt deſcribed, the obliquity of the foremoſt ſurface of the moving body would diminiſh the *reſiſtance*; but in compreſſed fluids this holds not true, at leaſt not in any conſiderable degree; for the principal *reſiſtance* in compreſſed fluids ariſes from the greater or leſſer facility, with which the fluid, impelled by the forepart of the body, can circulate towards its hindermoſt part; and this being little, if at all, affected by the form of the moving body, whether it be cylindrical, conical, or ſpherical, it follows, that while the tranſverſe ſection of the body, and conſequently the quantity of impelled fluid is the ſame, the change of figure in the body will ſcarcely affect the quantity of its *reſiſtance*.

And this caſe, that is, the *reſiſtance* of a compreſſed fluid to a ſolid, moving in it with a velocity much leſs than what the parts of the fluid would acquire from their compreſſion; this caſe, I ſay, has been very fully conſidered by Sir Iſaac Newton, who has aſcertained the quantity of ſuch a *reſiſtance*, according to the different magnitudes of the moving body, and the denſity of the fluid. But he very expreſsly informs us, that the rules he has laid down are not generally true, but upon a ſuppoſition that the compreſſion of the fluid be increaſed in the greater velocities of the moving body: however, ſome unſkilful writers who have followed him, overlooking this caution, have applied his determinations to bodies moving with all kinds of velocities, without attending to the different compreſſions of the fluids they were *reſiſted* by; and by this means they have accounted the *reſiſtance* of the air to muſket and cannon-ſhot, to be but one third part of what it is found to be by experience.

Indeed, from all we have ſaid, it appears plain enough, that the *reſiſting* power of the medium muſt be increaſed, when the *reſiſting* body moves ſo faſt, that the fluid cannot inſtantaneouſly preſs in behind it, and fill the deſerted ſpace; for when this happens, the body will be deprived of the preſſure of the fluid behind it; which in ſome meaſure balanced its *reſiſtance*, and muſt ſupport on its forepart the whole weight of a column of the fluid, independent of the motion it gives to the parts of the fluid; and beſides, the motion in the particles driven before the body, is, in this caſe, leſs affected by the compreſſion of the fluid, and conſequently they are leſs deflected from the direction, in which they are impelled by the *reſiſted* ſurface; whence this ſpecies of *reſiſtance* approaches more and more to that deſcribed in our firſt hypotheſis, where each particle of the fluid being unconnected with the neighbouring ones, it purſued its own motion, in its own direction, without being interrupted or deflected by their contiguity; and therefore, as we before obſerved, that the *reſiſtance* of a diſcontinued fluid to a cylinder, moving in the direction of its axis, was four times greater than the *reſiſtance* of a fluid ſufficiently compreſſed of the ſame denſity, it follows, that the *reſiſtance* of a fluid, when a vacuity is left behind the moving body, may be near four times greater than that of the ſame fluid, when no ſuch vacuity is formed; for when a void ſpace is thus left, we have ſhewn the *reſiſtance* to approach, in its nature, to that of a diſcontinued fluid.

This then may probably be the caſe in a cylinder moving in the ſame compreſſed fluid, according to the different degrees of its velocity; ſo that if it ſet out with a great velocity, and moves in the fluid till that velocity be much diminiſhed, the reſiſting power of the medium may be near four times greater in the beginning of its motion than in the end. In a globe the difference will not be ſo great, becauſe, on account of its oblique ſurface, its *reſiſtance* in a diſcontinued medium, is but about twice as much as in one properly compreſſed; for its oblique ſurface diminiſhes its *reſiſtance* in one caſe, and not in the other: however, as the compreſſion of the medium, even when a vacuity is left behind the moving body, may yet confine the oblique motion of the parts of the fluid, which are driven before the body, and as in an elaſtic fluid (as is our air) there will be ſome degree of condenſation in thoſe parts; it is highly probable, that the *reſiſtance* of a globe, moving in a compreſſed fluid with a very great velocity, will be between that of a globe and of a cylinder, in a diſcontinued medium; that is, (in proportion to its velocity) we may ſuppoſe it be more than twice, and leſs than four times the *reſiſtance* of the ſame globe, moving ſlowly through the ſame medium; whence, perhaps, we ſhall not much err in ſuppoſing the globe in its ſwifteſt motions to be reſiſted near three times more, in proportion to its velocity, than when it is ſloweſt.

And as this increaſe of the *reſiſting* power of the medium will take place, when the velocity of the moving body is ſo great, that a perfect vacuity is left behind it, ſo ſome degree of augmentation will be ſenſible in velocities much ſhort of this; for even when, by the compreſſion of the fluid, the ſpace left behind the body is inſtantaneouſly filled up; yet, if the velocity, with which the parts of the fluid ruſh in behind, is not much greater than that, with which the body moves; the ſame reaſons we have urged above, in the caſe of an abſolute vacuity, will hold in a leſs degree in this inſtance; and therefore we are not to ſuppoſe, that, in the increaſed *reſiſtance*, which we have hitherto treated of, it immediately vaniſhes, when the compreſſion of the fluid is juſt ſufficient to prevent a vacuum behind the *reſiſted* body; but we muſt conſider it as diminiſhing only, according as the velocity, with which the parts of the fluid follow the body, exceeds that with which the body moves.

Hence then we conclude, that if a globe ſets out in a *reſiſting* medium, with a velocity much exceeding that with which the particles of the medium would ruſh into a void ſpace, in conſequence of their compreſſion, ſo that a vacuum is neceſſarily left behind the globe in its motion; the *reſiſtance* of this medium to the globe will be near three times greater, in proportion to its velocity, than what we are ſure, from Sir Iſaac Newton, would take place in a ſlower motion. We may further conclude, that the *reſiſting* power of the medium will gradually diminiſh, as the velocity of the globe decreaſes, till at laſt, when it moves with velocities which bear but a ſmall proportion to that, with which the particles of the medium follow it, the *reſiſtance* becomes the ſame with what is aſſigned by Sir Iſaac Newton in the caſe of a compreſſed fluid.

And from this determination we may learn how falſe that poſition is, which aſſerts the reſiſtance of any medium to be in the duplicate proportion of the velocity of the *reſiſted* body; for it plainly appears, by what we have ſaid, that this can only be conſidered as nearly true in ſmall variations of velocity, and can never be applied in the comparing together the *reſiſtances* to all velocities whatever, without the moſt enormous errors. See new Principles of Gunnery, by Mr. *Robins*, Part 2. Prop. 1.

As to the *reſiſtance* of the air, it has been thus determined from experiments. Mr. Robins, in his New Principle of Gunnery, pag. 74, 75, *&c.* having taken a muſket barrel, and charging it ſucceſſively with a leaden ball of three quarters of an inch diameter, and about half its weight of powder, and taking ſuch precaution in weighing of the powder, and placing it, as to be ſure, by many previous trials, that the velocity of the ball could not differ by 20 feet in 1′ from its medium quantity. It was fired againſt a pendulum (deſcribed under the head GUNNERY, *Append.*) placed at 25 feet, 75 feet, and at 125 feet diſtance from the mouth of the piece reſpectively. In the firſt caſe it impunged againſt the pendulum with a velocity of 1670 feet in 1′; in the ſecond caſe with a velocity of 1550 feet in 1″; and in the third caſe with a velocity of 1425 feet in 1′; ſo that in paſſing through 50 feet of air, the bullet loſt a velocity of about 120, or 125 feet in 1″; and the time of its paſſing through that ſpace being about $\frac{1}{32}$, or $\frac{1}{30}$ of 1″, the medium quantity of *reſiſtance* muſt, in theſe inſtances, have been about 120 times the weight of the ball; which, as the ball was nearly $\frac{1}{12}$ of a pound, amounts to about 10 lb. avoirdupoiſe.

Now if a computation be made, according to the method laid down for compreſſed fluids in the 38th Propoſ. of lib. 2. of Sir Iſaac Newton's Principia, ſuppoſing the weight of water to be to the weight of air, as 850 to 1, it will be found that the *reſiſtance* of a globe of three quarters of an inch diameter, moving with a velocity of about 1600 feet in 1″, will not, on thoſe principles, amount to any more than a force of $4\frac{1}{6}$ lb. avoirdupoiſe; whence we may conclude (as the rules in that propoſition for ſlow motions are very accurate) that the *reſiſting* power of the air in ſlow motions is leſs than in ſwift motions, in the ratio of $4\frac{1}{6}$ to 10, a proportion between that of 1 to 2, and 1 to 3.

Again, charging the ſame piece with equal quantities of powder, and balls of the ſame weight, and firing three times at the pendulum, placed at 25 feet diſtance from the mouth of the piece, the medium of the velocities with which the ball impinged was 1690 feet in 1″. Then removing the piece 175 feet from the pendulum, the velocity of the ball, at a medium of five ſhots, was 1300 feet in 1′. Whence the ball, in paſſing through 150 feet of air, loſt a velocity of about 390 feet in 1″; and the *reſiſtance*, computed

puted from theſe numbers, comes out ſomething more than in the preceding inſtance, amounting to between 11 and 12 pounds avoirdupoiſe: whence, according to theſe experiments, the *reſiſting* power of the air to ſwift motions is greater than in ſlow ones, in a ratio which approaches nearer to the ratio of 3 to 1, than in the preceding experiments.

Next, to examine this *reſiſtance* in ſmaller velocities, the pendulum being placed at 25 feet diſtance, was fired at five times, and the mean velocity with which the ball impinged was 1180 feet in 1″. Then removing the pendulum to the diſtance of 250 feet, the medium velocity of five ſhot at this diſtance, was 950 feet in 1″; whence the ball, in paſſing through 225 feet of air, loſt a velocity of 230 feet in 1″, and as it paſſed through that interval in about $\frac{3}{4}$ of 1″, the *reſiſtance* to the middle velocity will come out to be near $33\frac{1}{2}$ times the gravity of the ball, or 2 lb. 10 oz. avoirdupoiſe. Now the *reſiſtance* to the ſame velocity, according to the laws obſerved in ſlower motions, amounts to $\frac{7}{11}$ of the ſame quantity; whence in a velocity of 1065 feet in 1″, (the medium of 1180 and 950) the *reſiſting* power of the air is augmented in no greater proportion than of 11 to 7; whereas in greater degrees of velocity, as before, it amounted very near to the ratio of 3 to 1.

That this *reſiſting* power of the air to ſwift motions, is very ſenſibly increaſed beyond what Sir Iſaac's theory for ſlow motions makes it, ſeems hence to be evident. It being, as has been ſaid, in muſket, or cannon ſhot, with their full charge of powder, near three times the quantity aſſigned by that theory.

The *reſiſtance* of a bullet of three quarters of an inch diameter, moving in air with a velocity of 1670 feet in 1″, amounting, as we ſaid, to 10 lb. the *reſiſtance* of a cannon ball of 24 lb. fired with its full charge of powder, and thereby moving with a velocity of 1650 feet in 1″ (which ſcarce differs from the other. See GUNNERY, *Append.*) may hence be determined. For the velocity of the cannon ball being near the ſame as the muſket bullet, and its ſurface above 54 times greater, it follows, that the *reſiſtance* on the cannon ball will amount to more than 540 lb. which is near 23 times its own weight. And from hence it appears how raſh and erroneous the opinion of thoſe is, who neglect the conſideration of the *reſiſtance* of the air as of no importance in the doctrine of projectiles. See PROJECTILE.

RESPIRATION (*Cycl.*)—The alternate motion of the thorax and lungs in *reſpiration* is evident, but it is not eaſy to determine the mechaniſm by which theſe motions are performed. Dr. Martin thinks this has not been accounted for in a ſatisfactory manner, either by Swammerdam, Borelli, Ballivi, Pitcairn, or Boerhaave, and has given us an eſſay on this ſubject in the Medic. Eſſ. Edinb. Vol. 1. Art. 12.

Dr. Hoadley [a] endeavours to prove, that the external intercoſtal muſcles ſerve for *inſpiration*, while the internal intercoſtals are their antagoniſts, depreſſing their ribs in *expiration*. He thinks it proved by Dr. Hales's experiments [b], that there is air in the cavity of the thorax, between the lungs and the pleura, and endeavours to take off the force of Dr. Houſton's aſſerting that he ſaw the lungs and pleura contiguous. He grants, however, that ſometimes there may be little or no air. He accounts for *reſpiration* much in the ſame way with thoſe who aſſume the contiguity of the lungs and pleura. He joins with thoſe who think the impetus, which the internal ſurface of the lungs ſuſtains in common *reſpiration*, to be very little. The uſes of *reſpiration* are, to diſcharge from the venal blood and chyle, ſuch parts as are unfit to render them arterial blood, and to admit air into the blood. From this doctrine he accounts for the phænomena of the diſeaſes of the lungs. He ſubjoins the picture and deſcription of an ingenious inſtrument for illuſtrating the manner in which *reſpiration* is performed. —[a Lectures on Reſpiration. b Veget. Statics exp. 112, 113. and *Hæmaſtat.* p. 83.]

Organs of RESPIRATION, in fly worms. Theſe afford us not only great matter of admiration in their general ſtructure, but by their almoſt endleſs variety in the different ſpecies of theſe creatures, give ample room for the forming claſſes and genera from them.

The firſt claſs of theſe creatures is of thoſe with variable heads, whoſe organs of *reſpiration* are principally behind, the large ſenſible ſtigmata, or breathing holes, being placed there; and which have no ſcaly legs, nor any regularly formed membranaceous ones; and which have, under their belly, certain fleſhy protuberances, each ſeeming a portion of a ring, which is inflated at certain times.

Theſe are the characters common to a vaſt claſs of theſe creatures, which are transformed into two winged flies; but ſeem never to be the marks of thoſe which are produced from the eggs of the four winged claſs. *Reaumur*'s Hiſt. Inſect. Vol. 4. p. 164.

RESPONDEAS *ouſter*, in law, is to anſwer over in an action to the merits of the cauſe.

RESSELA, a term uſed by Paracelſus to ſignify, as himſelf explains it, any thing that expels heat, in oppoſition to *aſſa*, which with him ſignifies any thing that promotes it.

REST (*Cycl.*)—Monſieur de Maupertuis aſſerts, that when bodies are in equilibrio, they muſt be ſo ſituated, that if any ſmall motion be impreſſed on them, the quantity of action reſulting will be the leaſt poſſible. This he calls the law of *reſt*, and from this law he deduces the fundamental propoſition of ſtatics. See Mem. de l'Acad. de Berlin, Tom. 2. p. 294.

Monſieur de Maupertuis deduces the laws of percuſſion from the ſame principle. See *Quantity of* ACTION.

REST-*harrow*, *anonis*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the papilionaceous kind. The piſtil ariſes from the cup, and finally becomes a turgid ſeed veſſel, in ſome ſpecies longer, and in others ſhorter, and uſually containing kidney ſhaped ſeeds. The characters of the leaves are, that they uſually grow three on each ſtalk, though ſometimes they ſtand ſingly in other parts of the ſame plant.

The ſpecies of *anonis* enumerated by Mr. Tournefort are theſe. 1. The common prickly *anonis* with purple flowers. 2. The prickly *anonis* with white flowers. 3. The red flowered *anonis* without prickles. 4. The white flowered *anonis* without prickles. 5. The *anonis* with ſmooth procumbent ſtalks. 6. The leaſt red flowered *anonis* without prickles. 7. The hairy and viſcous purple flowered ſmall *anonis*. 8. The perennial red flowered *anonis* with broad, roundiſh, and deeply ſerrated leaves. 9. The early flowering purple mountain ſhrubby *anonis*. 10. The Spaniſh ſhrubby *anonis* with fleſhy tridentated leaves. 11. The low alpine *anonis* with a ſweet fleſhy root. 12. The ſmooth ſea *anonis* with flowers ſtanding in the alæ of the leaves. 13. The dwarf annual purple *anonis*. 14. The dwarf ſmooth purple flowered alpine *anonis* without prickles. 15. The Sicilian *anonis* with the appearance of the alopecuros. 16. The round leaved Spaniſh purple ſpiked *anonis* without prickles. 17. The hoary procumbent ſea *anonis*. 18. The purple flowered American ſhrubby *anonis*, called by many *crotolaria*. 19. The great yellow viſcous *anonis* without prickles. 20. The ſmooth *anonis* with yellow variegated flowers. 21. The broad leaved yellow annual viſcous *anonis* without prickles. 22. The annual broad leaved erect Portugal viſcous *anonis*. 23. The narrow leaved ſea *anonis* without prickles, with yellow variegated flowers. 24. The yellow flowered dwarf *anonis* with ſmooth narrow leaves. 25. The little yellow French *anonis* without prickles. 26. The *anonis* with ſmall yellow flowers. 27. The ſhrubby Aſiatic *anonis* with large yellow flowers. 28. The ſhrubby Spaniſh *anonis* with rounder leaves. 29. The roſe leaved ſhrubby Spaniſh *anonis*. 30. The broad and roundiſh leaved American *anonis*. 31. The creeping bituminoſe kidneybean-like *anonis*. *Tourn.* Inſt. p. 408.

RESTY, (*Cycl.*) in the manege. A malicious unruly horſe, that ſhrugs himſelf ſhort, and will only go where he pleaſes, is ſaid to be *reſty*. A *reſty* horſe is much the ſame with what the French call *ramingue*. See RAMINGUE.

RESUSCITATION (*Cycl.*)—RESUSCITATION *of plants*, in chemiſtry, the art of reproducing a plant from its aſhes. See PALINGENESIA.

Many have pretended to this art, and have ſhewn *reſuſcitated* plants in vials [c]; but all theſe ſeem only particular inſtances of artificial chemical vegetations, of which many others may be given. The external appearances of theſe reſemble plants, and the ignorant may eaſily take them for ſuch; but when cloſely conſidered, there is a great difference to be found.—[c *Boyle*'s Works Abr. Vol. 1. p. 69.] See *artificial* VEGETATION.

RETCH, or RETCHES, a name given by our farmers to an iron, or a pair of irons, which in the common plow ſerve to faſten the ſheat to the beam. The *retches* are faſtened to the ſheat with nails, and to the beam with pins.

RETENEGI, in the materia medica, a name uſed by Aviſenna, and others, to expreſs the common reſin of the pine, or fir tree, and ſometimes common black pitch. The lexicographers have given us ſtorax as the explanation of *retenegi*, but this is not warranted by any paſſage in the authors who uſe the word. It is certain, indeed, that the generality of authors have confounded the ſeveral ſorts of reſin and pitch making trees together, and among them the pine, fir, cedar, and turpentine trees, are called by the ſame name, but the ſtorax tree is never included among the number. Theſe were only confounded together, becauſe of the ſimilitude of the things they produced; but the ſtorax was too different from all theſe, and too precious a gem not be diſtinguiſhed. See ERZ.

RETENTA, a word uſed by the medical writers to expreſs things retained in the body, or which are not to be retained in a ſtate of good health.

RETENTION *of the firſt ſtools*, in infants. See INFANT.

RETIARIUS, among the Romans, a kind of gladiator, who entered the liſts armed only with a trident in his left hand, and a net in his right. He was to uſe his utmoſt addreſs to throw the net over, and thereby entangle his antagoniſt; and if he miſſed of his aim, he was to betake himſelf to flight, till he had the good luck to recover his net. *Pitiſc.* Lex. Antiq. in voc.

RETINACULUM, the name of a chirurgical inſtrument uſed in caſtration, and in the operation for a hernia, to prevent the inteſtines from falling into the ſcrotum.

RETORT (*Cycl.*)—The quantity of air riſing from ſome ſubſtances is apt to burſt glaſſes in diſtilling; Dr. Browne Langriſh has therefore given us a new contrivance of applying receivers to *retorts*, by which ſuch accidents may be prevented. To his firſt receiver he adapts a ſecond, inſerted into an opening at the top of the firſt, in order to give more room to the rarefied and new generated air. To an opening, at the bottom of each of theſe receivers, he fixes a bottle, tied on cloſe by means of a bladder, ſo that they may be removed at any time, and another inſtantly placed in their room; by which means very little of the ſteam will eſcape. He alſo ties on a bladder to an opening, or upper neck of the ſecond recipient; and this bladder being much thinner and weaker than any of the glaſſes, will always give way firſt, and prevent their burſting. And even when there is the greateſt danger of this accident, the ſmalleſt pin hole made through the top of the bladder, as ſoon as the fumes begin to riſe, will be ſufficient to let out the air as faſt as it is generated. See Philoſ. Tranſ. N° 475. Sect. 3. where we have a figure of the whole apparatus. See alſo Tab. of Chemiſtry, N° 22, and 34.

RETREAT, (*Cycl.*) or TATTOU, in the art of war, is a beat of the drum in the evening, at the firing of a piece called the *warning piece*, at which the drum-major, with all the drums of the battalion, except ſuch as are upon duty, beats round the regiment; the drums of the quarter guards, of the generals guards, and all other ſmall guards, do likewiſe beat; the trumpets at the ſame time ſounding at the head of their reſpective troops. This is to warn the ſoldiers to forbear firing, and the centries to challenge, till break of day, that the reveille is beat. The *retreat* is likewiſe called *ſetting the watch*.

RETTO *moto*, in the Italian muſic. See MOTO.

RETURNS (*Cycl.*)—RETURNS *of a mine*, in the military art, are the turnings and windings of the gallery.

RETURNUM *averiorum*, a judicial writ, the ſame with *retorno habendo*. Reg. Judic. 4.

RETUSE *leaf*, *retuſum folium*, among botaniſts. See the article LEAF.

REVE-*land*. The land which in Domeſday is ſaid to have been *thaneland*, and afterwards converted into *reveland*, ſeems to be ſuch lands as being reverted to the king after the death of his Thane, who had it for life, was not ſince granted out to any by the king, but reſted in charge upon the account of the *reve*, or bailiff of the manor. *Spelm.* Feuds, c. 24. *Blount*.

REVERSE, in the military art, ſignifies on the back, or behind. Thus we ſay, a *reverſe view*, a *reverſe commanding ground*, a *reverſe battery*, &c.

REVOLUTUM *folium*, among botaniſts. See LEAF.

REUTELE, in zoology, a name uſed by ſome for the *umbla minor*, or red charre, a fiſh common in the lakes of Germany, and of the northern parts of England and Wales. The name is originally German. *Willughby*'s Hiſt. Piſc. p. 196. See CHARRE.

REWARDS. Military *rewards*, among the Athenians, conſiſted ſometimes in crowns preſented to thoſe that had merited them; on which their names and noble actions were inſcribed. Some had leave granted them to erect pillars or ſtatues, in honour of ſome god, with inſcriptions ſetting forth their victories. This was a favour that was ſeldom granted; Cimon indeed was honoured with it, but Themiſtocles could never obtain the like. Another honour conferred at Athens on the valiant, was to have their arms placed in the citadel, and to be called *Cecropidæ*, or citizens of the true old blood. Others were preſented with a πανοπλια, or compleat ſuit of armour. Songs of triumph were honorary compliments paid to ſome. The children of thoſe who were killed in battle were maintained at the public expence, till they came to maturity; at which time they were preſented before the aſſembly of the Athenian people with a compleat ſuit of armour, one of the public miniſters proclaiming before them, "that hitherto, in remembrance of "their fathers merits, the commonwealth had educated "theſe young men, but now diſmiſſed them ſo armed, to "go forth and thank their country by imitating their fathers "examples."

Solon made a farther proviſion for the parents of thoſe that died in the wars, it being extremely reaſonable that they ſhould be maintained at the public expence, who had loſt their children, the comfort and ſupport of their declining age, in the ſervice of the public.

As for thoſe who were any wiſe diſabled, they had an allowance from the public towards their maintenance. *Potter*, Tom. 2. p. 118, ſeq.

REWEY, a term among clothiers, ſignifying cloth unevenly wrought, or full of *rewes*, 43 Eliz. c. 10. *Blount*, *Cowel*.

REX *mullorum*, in zoology, a name given by ſome authors to a ſpecies of *mullet* diſtinguiſhed from all the others by its having a prominent belly, and having no beards under the mouth. *Willughby*'s Hiſt. Piſc. p. 286. See the article MULLUS *imberbis*.

REY *graſs*. This is a hardy ſort of *graſs*, much eſteemed among the farmers for that quality. It will grow on any land, and therefore produces crops where nothing elſe will. It thrives beſt of all on ſower, clayey, and weeping grounds, and equally endures the ſevereſt droughts of ſummer, and froſts of winter, ſuffering no damage from either. It is the beſt of all winter foods for cattle, the ſhorter it is eaten the better, and it ſprings the earlieſt of any. There is no danger of overſtocking it, for if it be left to grow too much, the ſtalk becomes hard and ſticky. It is beſt for horſes and for ſheep, and very much prevents the rotting of the latter. The beſt way of ſowing it is with clover. The common quantity of ſeed is two buſhels to an acre, but three buſhels is much better; though in ſome lands, where the clover is likely to ſucceed very well, they ſow eight pounds of clover ſeed, and one buſhel of *rey* ſeed to an acre, and this makes a crop that will laſt ſeven or eight years.

Some mow it as hay, and thraſh it for the ſeed, which about London ſells from half a crown a buſhel to three ſhillings. Four or five quarters of this ſeed will be ſometimes produced from an acre of the *graſs*. If at any time a field of this *graſs* is found to grow thin, it is only neceſſary to ſtrew on a buſhel of the ſeed, and roll it with a wooden roller, and the plants riſing from this addition will make the whole crop ſufficiently thick. *Rey graſs* has this great advantage, that it kills weeds without any other ſown plant; even thiſtles cannot grow among it. When the *rey graſs* is cut for hay before perfectly ripe, the hay is the better, but the ſeed will not grow ſo well. When the ſeed is newly thraſhed, it muſt not be laid too thick, for it is very apt to heat and ferment, and the whole will be ſpoiled. *Mortimer*'s Huſbandry, p. 40.

RHABARBARUM, in botany, the name given to the plant of which *rhubarb* is the root, and which Mr. Tournefort makes to conſtitute of itſelf a peculiar genus, of which there is no other ſpecies. The characters he delivers of the genus are theſe. The flower conſiſts of one leaf, formed into the ſhape of a bell, and divided into ſeveral ſegments; from the bottom of this riſes a piſtil, which ripens into a thick fruit, containing one large triangular ſeed, which is ſo affixed to its triangular capſule as it ripens, that there is no ſeparating it from it. *Tourn.* Inſt. p. 89.

RHABDOMANTIA, ῥαβδομαντεια, among the antients, a ſpecies of divination performed with rods. *Potter*, Archæol. Græc. l. 2. c. 16. Tom. I. p. 334.

RHABDONALEPSIS, ῥαβδου ἀναλημψις, among the Greeks, the reception or elevation of the rod, a feſtival kept every year in the iſland of Cos, at which the prieſts carried a cypreſs tree. *Potter*, Archæol. Græc. l. 2. c. 20. Tom. I. p. 429.

RHABDOPHORI, ῥαβδοφοροι, among the Greeks, officers appointed to preſerve peace and good order, and to correct the unruly at their public games. *Potter*, Archæol. Græc. Tom. I. p. 448.

RHABDUS, ῥαβδος, among the antients, the iron rod with which the boy rolled the *trochus*. See TROCHUS.

RHAGADIOLUS, in botany, the name of a genus of plants, the characters of which are theſe. The flower is compoſed of a number of ſemifloſcules ſtanding on the embryo fruit, and each perforated in its bottom part by the capillament which ariſes from that embryo. Theſe are all contained in one common cup, the ſeveral leaves of which afterwards become ſo many pods, diſpoſed in the form of a ſtar, and containing long ſhaped and pointed ſeeds.

There is only one known ſpecies of this plant, which is the ſtarry headed *hawkweed* of authors, or the *hawkweed* with falcated ſeeds. *Tourn.* Inſt. p. 479.

RHAGE, a word uſed by medical writers for a fiſſure or chap in any part. The ſtones of grapes are alſo by ſome called *rhages*; and by others the ſame word is made to expreſs the extremities of the fingers or toes.

RHAMNOIDES, a name given by Tournefort, and others, to a genus of plants, called by Linnæus *hippophae*. See the article HIPPOPHAE.

RHAMNUS, *buckthorn*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is compoſed of only one leaf, and is of the ſhape of a funnel, and divided into four ſegments at the edge. From the bottom of this there ariſe a number of ſtamina ſurrounding a piſtil, which finally becomes a ſoft and juicy berry, uſually containing four callous ſeeds, gibboſe on one ſide, and flat on the other.

The ſpecies of *rhamnus*, enumerated by Mr. Tournefort, are theſe. 1. The common *buckthorn*. 2. The leſſer *buckthorn*. 3. The ſmaller *buckthorn* with oblong and narrow leaves. 4. The green flowered *buckthorn* with black berries. 5. The ſmall Spaniſh *buckthorn* with leaves like box. Theſe are called by ſome authors *lyciums*. 6. The Spaniſh *buckthorn* with larger box-like leaves. 7. The olive leaved Spaniſh *buckthorn*. 8. The Spaniſh *buckthorn* with hypericum leaves. 9. The Spaniſh *buckthorn* with the leaves and whole appearance of the *ceratia*, or *ſiliqua*. 10. The capillaceous leaved Spaniſh rock *buckthorn*. *Tourn.* Inſt. p. 593.

RHAPSODOMANTIA, Ῥαψωδομαντεια, among the antients, a ſpecies of divination performed with the works or rhapſodies of the poets, particularly Homer and Virgil, who were looked upon as divine and inſpired perſons; whence this kind of divination was called *ſortes Homericæ* and *Virgilianæ*. *Potter*, Archæol. Græc. l. 2. c. 16. Tom. I. p. 333. See SORTES, *Cycl.*

RHEEDIA, in botany, the name of a genus of plants, ſo called from Mr. Van Rheed. The characters of the genus are theſe: the flower has no cup. It conſiſts of four petals, which are of an oval figure, and are hollowed, and expanded wide open. The ſtamina are five filaments. The germen of the piſtil is globoſe. The fruit is ſmall, and of an oval figure. It is ſucculent, and conſiſts only of one cell, and contains three very large ſeeds, which are of an oval oblong figure, and marked with ſtrangely irregular lines, reſembling ſeveral characters. *Linnæi* Gener. Plant. p. 523. *Plumier*. 18.

RHEGMA, a word uſed by the antients to expreſs any breaking, or burſting of a ſoft part without a wound, but moſt frequently for abſceſſes breaking inwardly.

RHENONES, among the antient Germans, a kind of garment covering the ſhoulders and breaſt down to the middle. It was either entirely made of ſkins, or covered over with them; the long hair of which being outward, proved a good defence againſt rain. *Pitiſc.* in voc.

RHEO-STATICS, is uſed by ſome for the ſtatics, or the ſcience of the equilibrium of fluids. *Caſtel.* Math. Univ. p. 73.

RHEUMATISM (*Cycl.*)—In obſtinate *rheumatiſms* ſmall doſes of emetic wine are much recommended by Dr. Huxham.

RHEXIA, in natural hiſtory, the name of a genus of plants, the characters of which are theſe. The perianthium conſiſts of one leaf; it is of an oblong figure, tubular, inflated at the bottom, and divided into four ſegments at the mouth. It remains after the flower is fallen. The flower conſiſts of four petals; they are of a roundiſh figure; they ſtand expanded, and are affixed to the cup. The ſtamina are eight capillary filaments longer than the cup. Theſe are affixed to the cup, and are terminated by long drooping antheræ. The germen of the piſtil is roundiſh, the ſtyle is ſimple, and of the length of the ſtamina. The ſtigma is ſomewhat thick and obtuſe. The capſule is contained within the belly, or inflated part of the cup; it is roundiſh, compoſed of four valves, and containing four cells. This contains a number of roundiſh ſeeds. It is to be obſerved, that in ſome ſpecies of this genus the calyx is ſmooth, in others it has ſeveral hairs diſpoſed in a ſtellated manner. *Linnæi* Gen. Pl. p. 161. *Pluknet*, f. 173. f. 4. *Gronovius*.

RHINANTHUS, in botany, the name of a genus of plants, the characters of which are theſe. The perianthium is roundiſh, but compreſſed, ſomewhat inflated and compoſed of one leaf, divided into four ſegments at the end. This is permanent, and does not fall with the flower. The flower is of the labiated kind, and conſiſts of one petal. Its tube is of the length of the cup, its limb open but compreſſed at the baſe. The upper lip is hooded, compreſſed, marginated and narrow; the under lip is broad, flat, and obtuſe, and lightly divided into three ſegments; the middle one ſomewhat larger than the reſt. The ſtamina are four filaments, of the length of the upper lip of the flower, under which they are hid, two of them are ſomewhat ſhorter than the others. The antheræ are incumbent, and are bifid and hairy. The germen of the piſtil is oval and compreſſed. The ſtyle is capillary, and of the length of the ſtamina, or ſomewhat more than that. The ſtigma is obtuſe and bent. The fruit is an erect orbicular but compreſſed capſule, it is compoſed of two valves, and divided into two cells. The ſeeds are numerous, and of a flatted figure, and fall out by the opening of the capſule at its ſides. *Linnæi* Gen. Pl. p. 282.

RHINE (*Cycl.*)—RHINE, in ichthyology, a name given by Ariſtotle, Appian, and moſt of the Greek writers to that ſpecies of the *ſqualus*, which we uſually call the *ſquatina*; the *ſquatus* of Iſidore and Pliny. Artedi has diſtinguiſhed this from all the other ſpecies of the *ſqualus*, by the having no pinna ani, and the mouth in the extremity of the ſnout.

RHINECHITIS, a name of a chirurgical inſtrument, uſed for ſyringing the noſtrils.

RHINGAU, a name given by ſome authors to the *lavaretus*, a ſmall fiſh, caught in the German lakes, and ſent in pickle into many parts of the world. *Willughby*'s Hiſt. Piſc. p. 183. See the article LAVARETUS.

RHINOBATUS, in zoology, the name of a flat cartilaginous fiſh, of the *ſquatina*, or *monk fiſh* kind, but differing from it in this, that the body is proportionably longer, and the head is more pointed; and the mouth is a great way below the end of the ſnout, and placed under the head. It is from three to four feet long, and is common in the Mediterranean, and brought to market in ſome parts of Naples. *Fab. Column.* p. 119.

RHINOCEROS, in zoology, the name of a genus of quadrupeds, ſo called from an horn growing on their noſe.

Of this genus there are only two known ſpecies. 1. The *rhinoceros* with only one horn on its noſe; and, 2. The *rhinoceros* with two horns.

In the year 1739 we had a young *rhinoceros* ſhewn in England, of which Dr. Parſons has given a very accurate account in the Philoſophical Tranſactions.

The creature fed on rice, ſugar, and hay; his keeper uſed to mix the rice and ſugar in the following manner: ſeven pounds of rice and three pounds of ſugar made the proviſion for one day; he eat this at three meals; and beſides this he eat about a truſs of hay every week, and a large quantity of greens that were brought to him, at different times, and of which he ſeemed more fond than of dried food. He drank often, and always ſwallowed a large quantity of water at a time. See Tab. of Quadrupeds, N° 13 and 14.

He appeared very peaceable in his temper, and bore to be handled on any part of his body, with great patience, except when he was hungry; but he was then always outragious, as alſo when he was ſtruck. His moſt violent paſſions, even on the laſt occaſion, were however always immediately appeaſed by giving him victuals.

Notwithſtanding the lumpiſh aſpect, and heavy make of this creature, he would jump about very nimbly in his fits of paſſion, and often leap to a great height; and one common mark of his fury was the ſtriking his head againſt the walls, or any thing elſe that was in the way, and this he would do with terrible violence. He was very apt to fall into theſe paſſions in a morning before his rice and ſugar were given him, and from the whole he appeared quite untractable, and ſeemed able, in his paſſions, to have run ſo faſt, as that a man on foot could not have eſcaped him.

This creature was two years old, and did not exceed a young heifer in height, but was remarkably broad and thick. His head was very large; and the hinder part of it, near the ears, remarkably elevated above the reſt of the face, which was flat, and ſunk down, in a remarkable manner in the middle, riſing again toward the origin of the horn, but in a much ſmaller degree. The horn ſtands upon the noſe of the animal as upon a ſort of hill; and when the ſceleton of the head is ſeen, that part of the ſkull on which the horn is fixed, is found to riſe into a blunt cone, to anſwer to a cavity in the baſis of the horn, which is very hard and ſolid; in other reſpects, having no manner of hollow, or core, like thoſe of other quadrupeds. The horn in this young animal did not riſe above an inch high from its tough baſis, and was black and ſmooth at the top, but ragged downwards; and the determination of its growth is backward, not ſtrait up; this is very evidently ſeen in the horns of old *rhinoceroſes*, which are always curved in a conſiderable degree that way. If we conſider the proportion of this animal's ſize, to the length of its horn, and thence carry the proportion to that between the large horns we ſee in the muſeums of the curious, we muſt ſuppoſe the animal of a very ſtupendous ſize, when at its full growth. Phil. Tranſ. N° 470. p. 530.

The ſides of the under jaw, in this creature, ſtand very wide aſunder, ſlanting outward to the lower edge, and backward to the neck; the edges turn outwards from this ſtructure of the bones, and the head neceſſarily looks very large. That part of the head which reaches from the forepart of the horn to the upper lip may be called the noſe; this is very thick, and bulky, and has a kind of circular ſweep down towards the noſtrils; on all this part there are a great number of rugæ or wrinkles.

The noſtrils are ſituated very low, in the ſame direction with the opening of the mouth, and not more than an inch from it; and when viewed in a foreview, the whole noſe, from the top of the horn to the verge of the lower lip, is ſhaped like a bell. The under lip is like that of an ox, but the upper more like that of a horſe, and he uſes it as that creature does, to gather up hay from the rack, or graſs from the ground; but, with this ſuperior advantage, that this creature has a power of extending this lip to ſix or ſeven inches in length from the noſe, and there drawing it to a point; with this lip, thus extended, the creature is able to graſp a ſtick, or any ſmall ſubſtance, and hold it extremely faſt; and this power of prolonging the lips ſerves, in many purpoſes, to the ſame end as the trunk of that other unweildy animal the elephant.

The tongue of the *rhinoceros* is ſaid to be ſo rough as to be able to rub a man's fleſh off from the bones; but, in this young ſubject it was ſo ſoft, that it reſembled that of a calf. It may poſſibly grow harder with age; but the ſtory of its effects ſeems of a piece with the many other falſe marvels reported of this animal. The eyes are dull and ſleepy, much like thoſe of a hog in ſhape; he ſeldom opens them entirely; and it is to be obſerved, that they are ſituated nearer the noſe than thoſe of any other known quadruped. The ears are broad and thin toward the top, much like thoſe of a hog; but they ariſe each from a narrow round baſe, with ſome wrinkles on it, which iſſues out of a ſinus, as it were ſurrounded with a fleſhy fold. The neck is very ſhort, and has two folds, or wrinkles, wholly ſurrounding it, only that the anterior one is broken underneath; and has a flap

hanging

hanging from it ſo deep, that it would contain a man's hand; from the middle of the poſterior plica of the neck, there ariſes another, which paſſing backward, is loſt before it reaches the body. The ſhoulders are thick and heavy, and have each a fold paſſing downward. The body is very large and thick, and ſtands out at the ſides like that of a cow with calf. The legs are very thick and ſtrong, they are round, and ſomewhat ſmaller downwards than in the upper part; and when the creature ſtands upright they bend inward at the knee, ſo that they are nothing like ſtrait. In ſome quadrupeds the fetlock bends to the weight of the animal, but in this creature there is no appearance of any ſuch bending, ſo that he ſeems to ſtand upon four ſtumps, eſpecially when viewed behind. He has three hoofs upon each foot forward, but the back part is a great maſs of fleſh, rough like the reſt of the ſkin; and the ſole of the foot is very plump and callous in the ſurface, but eaſily yielding to the preſſure from the ſoftneſs of the ſubjacent fleſh. Its ſhape is like that of a heart, with a blunt apex before, and a broad baſe behind. The tail is very ſmall in proportion to the ſize of the animal, not exceeding ſeventeen or eighteen inches in length, and but thin or ſlender; it is very rough, and has a kind of twiſt or ſtricture towards the extremities, ending in a flat maſs; this gave occaſion to ſome authors to compare the whole tail to a ſpatula; on the ſides of this flat part there grew a few ſhort, but very thick and ſtrong black hairs, but theſe grow much longer in the more advanced ſtate of the creature; and are not round, like other hairs, but flat, like ſmall pieces of whalebone. The creature has no other hair about it, except a very ſmall quantity at the edge of the ears. See Tab. of Quadrupeds, N° 13 and 14.

The penis of the male *rhinoceros* is of a very remarkable ſtructure, being incloſed in two caſes. The female differs in nothing from the male except in the pudenda, which are ſhaped like thoſe of a cow.

The ſkin of the *rhinoceros* is thick, and ſeems almoſt impenetrable; it feels like a piece of board of half an inch thick. It is covered in all parts, more or leſs, with a ſort of incruſtations, reſembling ſcales. Theſe are ſmall on the neck, and largeſt of all in the ſhoulders and hips; between the folds of this thick ſkin, the cuticle, which is left bare, is ſoft, and eaſily penetrable. The ſcabby incruſtations of the ſkin have been called ſcales, by ſome writers; but this is a very wrong term, for they have nothing of the nature of ſcales, nor any thing of regularity in them.

The creature is of the retromingent, and therefore probably of the retrogenerative kind; the penis, when erect, is not more than nine, or at the utmoſt ten inches long, and is curved backward at the end. This was the deſcription of the *rhinoceros* ſhewn in England at this time, and of all the others that have been ſeen in this part of the world as to the general characters; but though theſe creatures, which we have ſeen, have but one horn, it is very certain, that there is a ſpecies of *rhinoceros* which has two. Martial has mentioned a *rhinoceros*, as ſhewn in the amphitheatre at Rome, which had two horns; but his commentators ſuppoſing the copies erroneous, have been at great pains to alter it, ſo as to make it expreſs what they had ſeen or heard of, that is a *rhinoceros* only with one horn: but it appears, from almoſt indiſputable teſtimony, that there not only is in nature ſuch a *rhinoceros* with two horns, but that ſuch were ſhewn in the public ſports at Rome, and therefore the text ſeems to have been very right, and the commentators in the wrong. The creatures we have ſeen have indeed only had one horn; and the accounts of travellers, and the great number of horns preſerved in the cabinets of the curious, which are all ſingle, ſeem to prove this; but though the *rhinoceroſes* of Aſia are all one horned, yet it is certain, that there is a kind found in Africa which has two horns, and not leſs certain, that the Romans had beaſts from this laſt part of the world as well as the other. Peter Kolbe, in his voyage to the Cape of Good Hope, deſcribes *rhinoceroſes*, which he ſaw, and which had a horn on the noſe, and another cloſe behind it. Sir Hans Sloan's muſeum affords two horns of a *rhinoceros*, ſtanding juſt as this author has deſcribed them, which are ſtill fixed to the ſame integument; and we are convinced of the Romans being acquainted with this ſpecies, from a braſs medal of Domitian, which has on it a *rhinoceros*, with two horns on the noſe placed in this manner.

Redi, who has been very ſagacious in diſcovering the falſity of many of the pretended medicines taken from animals, yet gives us, on the teſtimony of his own experience, an account of ſome very remarkable virtues in the parts of the *rhinoceros*. The blood he aſſures us is excellent in colics and in dyſenteries. The decoction of the ſkin, he aſſures us, is a grand ſtomachic antidote, and the horns are very valuable and alexipharmic. *Redi*'s Eſperience.

RHINOCEROS *avis*, the *rhinoceros bird*, a name given by authors to a ſpecies of Indian raven, called by others *corvus indicus cornutus*. The beak of which is frequently brought over into Europe.

It is a very ugly bird, and of a very rank ſmell. It much exceeds the European raven in bigneſs, and its head and neck are very thick. Its eyes are very large, and its beak of a very remarkable figure, having a large and thick horn like protuberance on its upper part. The whole beak is bent like a bow, not hooked at the end like the beaks of the hawk, *&c.* It is of a yellowiſh white below, and on the upper part toward the head is of a fine gay red, and the reſt of a yellowiſh white: the upper chap is ſerrated. The horn grows out from the head with this and runs along it, and bends up at its extremity; its upper and under part are red, its middle yellow. The bird feeds on carrion, and the guts of dead animals. *Aldrovand* de Avibus.

RHINOPTES, a word uſed by the antients to expreſs a perſon, who from an ulcer in the great canthus of the eye, laying open the paſſages to the noſe, can ſee through his noſtril.

RHIPTASMOS, a word uſed by the antients, to expreſs a reſtleſſneſs and frequent toſſing about, a very common ſymptom in fevers.

RHIZAGRA, the name of a chirurgical inſtrument uſed to extract the ſtumps of teeth.

RHIZOPHORA, in botany, the name given by Linnæus to a genus of plants, deſcribed under the name of *mangles* by Plumier, the characters of which are theſe: the perianthium is erect, and is compoſed of one leaf, divided into four oblong ſegments. The flower is erect, and is compoſed of one petal, divided into four ſegments, and is ſhorter than the cup. The ſtamina are twelve erect filaments, alternately ſhorter one than the other, and the antheræ are ſmall. The germen of the piſtil is ſubulated; there is ſcarce any ſtyle; the ſtigma is acute, and the receptacle is of an oval figure; this becomes fleſhy, and contains the baſe of the ſeed. The ſeed is ſingle, and extremely long; it is of a clavated figure, and pointed at the end. There is ſome variation in the number of the ſtamina in this plant; they are always, however, of ſome number between eight and twelve, theſe being the higheſt and loweſt extremes. *Linnæi* Gen. Pl. p. 207. *Plumier* Gen. 15. Hort. Mal. Vol. 6. p. 31, 32.

RHODIOLA, in botany, the name given by Linnæus to a genus of plants, commonly called *rhodia*. The characters of which are theſe: it produces two kinds of flowers, the one hermaphrodite, acting as male flowers; the other ſimply female. In the male flower, the cup is a concave erect perianthium, divided into four obtuſe ſegments, and not falling with the petals. The flower conſiſts of four petals, which are oblong, obtuſe, erecto-patent, and twice as long as the ſegments of the cup: theſe fall ſoon after they are open: they have four erect nectaria, ſurrounded with a thin rim, and ſomewhat ſhorter than the cup. The ſtamina are eight pointed filaments, longer than the petals of the flower. The antheræ are ſimple. The piſtil has four oblong and pointed germina. The ſtyles and ſtigmata are very imperfect. The fruit that ſhould ſucceed theſe is very abortive.

In the female flower the cup is of the ſame kind with that of the male. The flower is compoſed of four rude, erect, and obtuſe petals, of the ſame ſize with the ſegments of the cup, and remaining with it. The nectaria in this flower are the ſame with thoſe of the male. The piſtil has four oblong pointed germens, which go off into ſo many ſtrait ſimple ſtyles, crowned with obtuſe ſtigmata. The fruit conſiſts of four corniculated capſules, which are univalve, compreſſed inwards, and opening in that part. In theſe capſules are contained a number of ſeeds of a roundiſh ſhape. *Linnæi* Gen. Pl. p. 498.

RHODITES *lapis*, the *roſe ſtone*, in natural hiſtory, the name given by authors to a kind of *aſtroites*, or *ſtar-ſtone*, in which the figures more repreſent roſes than ſtars: they are in both owing to coralloide bodies immerſed in the ſtone; which, according to their various ſpecies, afford a different figure, when cut tranſverſely, in the cutting the ſtone into plates for uſe. See ASTROITES and STAR-*ſtone*.

RHODIUM *marmor*, a name given by the antients to a marble brought from Rhodes; it was of a good white, but inferior to the Parian, and was uſed by the Romans in their public buildings, and ſometimes in ſtatuary.

RHODOMELON, a name given by the antients to a confection made of roſes, quinces, and honey, uſed as a grateful aſtringent and detergent in many caſes.

RHODOPUS *gallinula*, in zoology, a name given by ſome authors to the bird more uſually known by the name *tringa*. *Geſner* de Avid. See the article TRINGA.

RHOITES, the name of a medicine among the antients, which is a ſort of rob of the juice of pomegranates. Dioſcorides deſcribes it as the ſimple juice of the fruit, evaporated over the fire to the conſiſtence of an extract; but Paulus Ægineta gives the receipt to be three parts juice of pomegranate, and one part honey, boiled to the evaporation of a third part. So that the *rhoites* of Dioſcorides was a true rob of pomegranates; the other, rather honey of pomegranates, like our honey of roſes.

RHOMB. See the article RHOMBUS, *Cycl.* and *Suppl.*

RHOMBO, the name of a peculiar fiſh of the *rhombus*, or turbot kind, called *rhombus aculeatus* by Aldrovand, Geſner, and other authors. It is a large fiſh, of an aſh coloured green on the back, and white on the belly. It has no ſcales;

but the ſkin of its back is divided by lines, ſomething in the manner of the ſkins of ſnakes. The mouth is very large, and is well furniſhed with teeth; and the palate has a number of tubercles, armed alſo with a ſort of teeth. It feeds on fiſh, and its fleſh is very delicate. It is very common in the markets at Venice, and is caught in the neighbouring ſeas, and in many other places. *Willughby*'s Hiſt. Piſc. p. 92. *Geſner*, p. 778. *Aldrov.* de Piſc. l. 2. c. 48.

RHOMBOIDÆUS *major* and *minor*, names given by Albinus to what he makes two muſcles; though Winſlow and others account it only one. What Winſlow calls the inferior portion of the rhomboidalis, Albinus calls *rhomboidæus major*, and what he calls the upper portion of that muſcle, Albinus calls *rhomboidæus minor*. See the article SCAPULA.

RHOMBOIDALIS. See the articles RHOMBOIDÆUS and SCAPULA.

RHOMBOIDES, in anatomy, a muſcle, which is a thin, broad, and oblique ſquare fleſhy plane, ſituated between the baſis of the ſcapula and the ſpina dorſi. It may be divided into two portions, one ſuperior, the other inferior, which ſometimes appear ſeparate. The ſuperior portion, which ſeems in ſome ſubjects to be made up of two, is fixed by an inſertion wholly fleſhy in the two or three loweſt ſpinal apophyſes of the neck, and partly in the poſterior cervical ligament. The inferior portion is fixed by a tendinous plane in the three or four uppermoſt ſpinal apophyſes of the back.

Theſe two portions, of which the inferior is much the broadeſt, being united, are inſerted in the edge of the baſis ſcapulæ, from the ſmall triangular ſpace to the inferior angle, the ſuperior portion covering a ſmall portion of the angularis at its inſertion. This whole muſcle is covered by the trapezius, and covers the ſerratus poſticus ſuperior, being joined to each of theſe muſcles by a filamentary or cellular ſubſtance. *Winſlow*'s Anatomy, p. 174.

RHOMBOIDIA, in natural hiſtory, the name of a genus of ſpars, given them from their being of a rhomboidal form. They owe this figure to an admixture of particles of iron, and conſiſts of ſix planes.

Of this genus there are only two known ſpecies. 1. A white thin one with very thin cruſts; and 2. A whitiſh brown thick one with thicker cruſts. Theſe are both found in the foreſt of Dean in Glouceſterſhire, and in other places where there are iron ores.

RHOMBUS (*Cycl.*)—*Solid* RHOMBUS, in geometry, two equal and right cones joined together at their baſes.

RHOMBUS, in zoology, a genus of fiſhes, which are oviparous, and have a flat, ſhort, and ſomewhat ſquared body, and ſwim on one ſide. The turbot and other fiſh of that make, are of this genus. The ſides of theſe fiſh are equal, but their angles unequal. *Willughby*'s Hiſt. Piſc. p. 93.

RHOMBUS, in conchyliology, the name given by the generality of authors to a genus of the ſhell fiſh, much more properly called by ſome *cylindrus*. See CYLINDRUS.

RHOPALOSIS, a diſtemper of the hair deſcribed by the antients, and ſeeming to be the ſame with what we call the *plica polonica*, being a ſort of matting together of the hair into long and thick treſſes.

RHOPE, a word uſed by the Greek writers, to expreſs a violent tendency of the humors to any particular part of the body.

RHOX, a word uſed by ſome authors to expreſs the tunica uvea of the eye.

RHUBARB (*Cycl.*)—The Indian *rhubarb* ſown in our gardens has this peculiar property, that it yields a fine and clear gum. This is perfectly white and pellucid, and in the months of June and July is ſo plentiful, that an ounce may ſometimes be gathered at a time from one plant of it. It exſudates of itſelf from all parts of the ſtalks and ribs of the leaves, and ſometimes from the under part of the leaves themſelves. It ſtands in ſome places in large drops, and in others the ſtalks, *&c.* ſeem only to be covered with a thin layer of it; and the under part of the leaves in ſome have it in form of twiſted wires or long icicles. The plant may always be ſeen wounded by a ſort of cauſtic in the places where the germen makes its way out, and theſe may be followed with any pointed inſtrument through the ſkin; in ſome parts of the plant this juice is found to be turned gummy within it, and looks like clear ice. As this is the only known herbaceous plant, that yields a true gum like that of trees, it would be worthy obſervation, whether or not ſome of our own plants have ſome tendency of nature, to form a juice of the ſame kind. It would be moſt proper to look for this in the plants of the ſame genus, and as nearly related to the *rhubarb* as we can. The docks ſo common about our fields are of the ſame genus; and the ſorrel ſhews, by its taſte, that it is particularly allied to the plant; for both are alike of the dock kind, and both alike ſour. It would be proper to look carefully about the leaves of ſorrel a little before it flowers, to ſee whether any thing like the ſame gum appears on it.

There is yet this farther analogy between this *rhubarb* and our common ſorrel; that the huſks of our ſorrel, boiled in water, with a little alum, turn it to a fine red colour; and the huſks of *rhubarb* do the ſame, and both the one and the other often turn red in decaying.

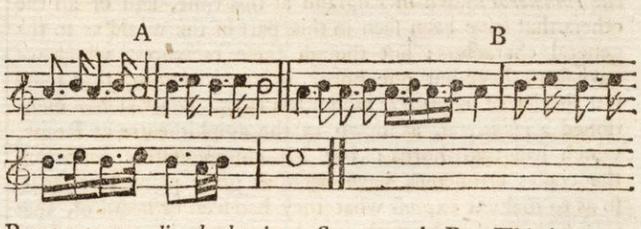
The juice of the roots of this *rhubarb*, extracted by bruiſing and ſteeping it in common water, when the liquor is ſtrained and evaporated, becomes only a clear uninflammable gum, and melts in the flame of a candle. This gum, as well as that of the ſtalks and leaves, is of an inſipid taſte; and it is obſervable, that though the plant naturally yields it in ſo large a quantity, yet it will not flow from wounds made by art in any part of the plant. Upon the conſideration of the inſipid taſte of this gum, and its ſolubility in water, we may find ſome probable conjecture, in regard to the different virtues of this plant in purging and binding. The woody fibres have a ſtrong taſte; and, in all probability, are alone endued with the aſtringent quality. An infuſion of *rhubarb* is known to purge, and a powder of it to bind: the reaſon is eaſily ſeen on this conſideration. The water in the infuſion takes up all this gummy juice, and its other juices, but leaves the fibroſe part behind, in conſequence of which it ought to purge without binding; but in caſe of giving the powder, the juices are in great part evaporated in the drying, and the woody part left almoſt alone; it therefore purges but little, and proves powerfully aſtringent. Phil. Tranſ. N° 224.

RHUS, *ſumach*, in botany, the name of a genus of trees, the characters of which are theſe. The flower is of the roſaceous kind, and is compoſed of ſeveral petals, diſpoſed in a circular form. The piſtil ariſes from the cup, and finally becomes a roundiſh fruit, with a depreſſion on one ſide, which gives it ſomewhat of a kidney like ſhape, and containing a ſeed of the ſame figure.

The ſpecies of *ſumach* enumerated by Mr. Tournefort are theſe. 1. The common or elm leaved *ſumach*. 2. The Virginian *ſumach*, and 3. The Canada *ſumach* with long leaves ſmooth on both ſides. *Tourn.* Inſt. p. 611.

RHUSELINUM, in botany, a name given by ſome authors to the *ranunculus*. *Ger.* Emac. Ind. 2.

RHYNE, in botany, a name uſed by ſome authors for the camphor tree. *Breyn.* Prod. VI. p. 4.



RHYTIDOSIS, the name of a diſtemper of the eye in which it waſtes and wrinkles up.

RHITHM. See the article RYTHM.

RIB. See RIBS, infra.

RIBATTUTA, in the Italian muſic, a ſtriking or ſounding the ſame note over again. Hence,

RIBATTUTA *di gola*, one of the graces in ſinging, is performed by repeated beating or ſtriking a note, from that which is immediately above it. See example A. It differs from a ſhake.

RIBATTUTA *di gola doppia*. See example B. This is pretty near what the French call *tour de goſier*, or *double cadence*. *Broſſard.* Dict. Muſ.

RIBESIA *nigra*, *black currants*, have been long famous in England for quinſies and ſore throats, ſo as to obtain the name of ſquinancy or quinſy berries. See GROSSULARIA.

RIBS (*Cycl.*)—The number of theſe varies in different ſubjects, ſometimes in one ſide only, and ſometimes in both.

Anatomiſts have divided each *rib* into the middle part or body, two extremities, the one anterior, the other poſterior; two ſides one external and convex, the other internal and concave; two edges, one ſuperior and the other inferior; and two labia in each edge, one external, the other internal. The poſterior extremity, which may be called the head of the *rib*, is articulated with the vertebræ of the back. At the anterior extremity freſh *ribs* are lengthened out by cartilaginous epiphyſes, ſtuck into their bony ends. Each of the true *ribs*, at the poſterior extremity, has two ſmall cartilaginous impreſſions, diſtinguiſhed by a kind of angle, by which they are articulated with the lateral cartilaginous impreſſions in the bodies of two vertebræ of the back; but the firſt *rib* has no more than one ſuch impreſſion, being articulated with one vertebra only. At a ſmall diſtance from the head of this extremity poſteriorly is another cartilaginous impreſſion on each ſide, a little convex, and cloſely joined to a ſmall tuberoſity. By theſe the *ribs* are articulated with the lateral cartilaginous impreſſions in the tranſverſe apophyſes of the dorſal vertebræ; and the tuberoſities ſerve for the inſertion of the ligaments; the portion which lies between the head and theſe impreſſions is contracted, and repreſents a neck. When the poſterior extremity of a *rib* is articulated with two vertebræ, the ſecond articulation is always with the tranſverſe proceſs of the loweſt two. Between the tuberoſity and middle part of the *ribs*, there is on their outſide a kind of oblique rough angle of different breadths. In the firſt *rib*, this angle is not diſtinct from the tube-

tuberoſity; in the ſecond, it reaches but to a ſmall diſtance from it; in the third *rib*, this diſtance is ſtill greater, and from thence it continues to increaſe gradually all the way to the third falſe *rib*; ſo that if we look directly at the back of a ſceleton, theſe angles repreſent the legs of a pair of compaſſes opened pretty wide. On the inſide of the *ribs*, toward the lower edge, we obſerve a groove reaching all the way from the angle to the extremity, and that chiefly in the five lower true *ribs*, and the three firſt falſe ones. The upper edge of the three firſt *ribs* is ſharp, the lower a little rounded. The upper edge of the third is more obtuſe, and the lower a little more flat. In the reſt, the upper edge is rounded, the lower, more or leſs ſharp.

In all the *ribs* the anterior extremity is lower than the poſterior; the *ribs* are much more crooked in the back than in the forepart; the appendices, epiphyſes, or cartilaginous portions of the true *ribs*, increaſe in length, as they deſcend in the ſame manner as the *ribs* themſelves; the cartilages of the firſt three or four *ribs* lie nearly in the ſame direction with the *ribs* themſelves. In the *ribs* below theſe, the cartilages make angles, at which they turn upward towards the ſternum, and this curvature increaſes in proportion as the *ribs* deſcend; and the loweſt cartilages, in changing their direction upwards, lie very cloſe to each other, and thoſe of the laſt two *ribs* have often, at their inferior edge, a ſort of apophyſis or production, by which they are connected with the cartilages immediately below them. The laſt two *ribs* extend conſiderably in breadth toward their lower ſharp edges, from the angle for a good diſtance anteriorly. Afterwards they contract in breadth and increaſe in thickneſs, forming a ſort of neck, a little longer than that at their poſterior extremity; then their breadth begins to increaſe again, by degrees, to the anterior extremity. In all the *ribs*, this extremity terminates in a cavity, in which the cartilages are graſted. The three uppermoſt falſe *ribs* increaſe in breadth from the angle forward, and the grooves are moſt conſiderable in theſe. They have alſo heads, necks, tuberoſities, and angles, almoſt the ſame as in the laſt true *ribs*. All the falſe *ribs* have cartilaginous appendages; the firſt of which is longeſt, and fixed to the cartilage of the laſt true *rib*; the two following are united together at their extremities, and the two laſt are connected only to muſcles and ligaments. They are both very ſhort, eſpecially the laſt, which is not above a quarter of an inch in length, and all theſe cartilages of the falſe *ribs* are pointed at their extremities.

The *ribs* are articulated anteriorly with the ſternum, and behind with the vertebræ of the back; the firſt *rib* is entirely united with the ſternum, by means of its cartilage, and in the ſix following the extremities of the cartilages join that bone. The three upper falſe *ribs* are joined to each other by the extremities of their cartilages; the connection of the *ribs*, with the vertebræ of the back, is for the moſt part by ginglymus. The ten upper *ribs* are confined to two motions only, upward and downward; whereas the two laſt are left more at liberty, and are therefore termed floating *ribs*. *Winſlow*'s Anatomy, p. 65.

Cartilages of the RIBS. All the *ribs* have cartilaginous portions, which differ from each other in length, breadth, incurvations, adheſions, and in their extremities. It is to be obſerved, that theſe cartilages are white, more poliſhed, broader and thicker in their natural ſtate, than in the dried ſceleton. The cartilages of the falſe *ribs* are naturally ſofter, and more pliable than thoſe of the true; the middle or inner ſubſtance of theſe acquires the conſiſtence of bones in old age, and their extremities ſometimes oſſify, and are immoveably fixed to the ſternum. Ibid. p. 149.

Ligaments of the RIBS. All the *ribs* are connected to the bodies of the vertebræ by ſtrong, ſhort, ligamentary faſciculi, fixed by one end round the foſſula in the vertebræ, and by the other round the head of each *rib*. They are alſo tied together by thin ligaments, which go from the cartilage of each *rib* obliquely to that of the next. The ten uppermoſt *ribs* on each ſide are connected to the tranſverſe apophyſes of the vertebræ of the back by ſtrong, ſhort, articular ligaments fixed to the tuberoſities of the *ribs*, and round the foſſula of the apophyſes; and this much in the ſame manner with thoſe which go between the heads of the *ribs* and bodies of the vertebræ: both theſe articulations are provided with capſular ligaments. The eleventh *rib* on each ſide having no articulation with the tranſverſe apophyſes, is connected to them by auxiliary ſtrong ſhort ligaments fixed in its neck. The laſt *rib* is only joined by its head to the body of the twelfth vertebra of the back; but it is connected, in a particular manner, to the tranſverſe apophyſis of the firſt vertebra of the loins by a broad ligament, fixed in the whole upper edge of the apophyſis, and in the lower edge of the *rib*, though about two thirds of its length. The firſt true *rib* has no ligamentary connection with the ſternum, the cartilaginous ſymphyſis being ſufficient; the reſt are cloſely joined to that bone by ſmall ligamentary portions, fixed by one end round the extremity of the cartilage, and by the other round the notches in the ſternum. The cartilage of the firſt falſe *rib* is joined to that of the laſt true *rib*, by ſeveral ſhort filaments, which go from the lower edge of the one to the upper edge of the other near its ſmall extremity. The other falſe *ribs* are connected together much in the ſame manner; except that the filaments, by which the fourth is connected to the third, are longer than thoſe above them, and thoſe between the fifth and fourth are much longer than any of the reſt; and for this reaſon theſe *ribs* are leſs ſteady than the others. The ligamentary expanſions of the vertebræ are in place of a perioſteum, but the *ribs* and ſternum have a perioſteum like other bones, only that the cartilaginous portions of the *ribs* generally give their covering the name of a pericardium.

Diſlocated RIBS. The *ribs* are ſometimes, though but ſeldom, diſlocated; for they are ſometimes diſplaced by ſome external violence, and thruſt either upwards or downwards, outwards or inwards. They cannot eaſily indeed be luxated outwards, becauſe prevented by the vertebral proceſſes, and reſiſted by very thick and ſtrong muſcles; but when they are driven into the cavity of the thorax, which oftener happens, they not only lacerate the pleura, or membrane, which lines the cavity of the thorax, but generally do great injury alſo to the contained parts: in conſequence of which ariſe moſt ſharp pains, inflammation, difficulty of breathing, coughs, ulcers, immobility, and many other dangerous ſymptoms.

When the *rib* is luxated either upwards or downwards, in order to replace it conveniently, the patient is to be laid on his belly upon a table, and the ſurgeon muſt endeavour to reduce the luxated bone to its right place with his hands; or the arm of the diſordered ſide may be ſuſpended over a gate or ladder; and while the *ribs* are thus ſtretched up from each other, the heads of ſuch as are luxated may be puſhed into their former ſeat.

Thoſe luxations, where the heads of the *ribs* are found to be thruſt inwards into the cavity of the thorax, are much the moſt difficult to be reduced, becauſe neither the hand, nor any other inſtrument can be applied internally, to aſſiſt and direct the bone in the operation. In this caſe it ſeems proper to lay the patient on his belly, over ſome gibbous or cylindric body, and move the forepart of the *rib* inwards toward the back, ſhaking it ſometimes; for thus it ſometimes happens, that the head of the luxated *rib* ſlips into its former place. But if this method of cure will not avail, we have no remedy left but inciſion, and endeavouring to replace the luxated head of the *rib* by the fingers, plyers, or little hooks. In the mean time, where the ſymptoms are not very urgent, and the heads of the *ribs* but little diſplaced, it is much more adviſeable to have recourſe to none of theſe means, becauſe there are ſeveral inſtances where the luxated *ribs* have ſafely retained their diſlocated ſtations; but above all, care muſt be taken to lay on a compreſs, dipped in warm ſpirit of wine upon the part, and retain it on by the napkin and ſcapulary bandage. *Heiſter*, Surg. p. 157.

Fractured RIBS. Sometimes the *ribs* are only fiſſured in ſuch a manner, that the external or internal part of them are only hurt, without their being removed out of their place. This is uſually attended by no bad accident, and the bone frequently grows together again of itſelf, without the accident's being diſcovered. But if the whole *rib* be fractured, and ſome part of it removed out of its place, it is a more dangerous caſe: for the coſtal muſcles, and the pleura, that lines the internal cavity of the thorax, will be much diſturbed by the fragments of the bone.

When a *rib* is fractured, it projects either externally or internally in the form of a broken arch; when it projects externally the ſymptoms are uſually much milder; but when it is drove inward the caſe is uſually much worſe, eſpecially if any vein or artery be divided by it, ſo as to let blood run into the cavity of the thorax: in conſequence of which there follow prickings, inflammation, difficult reſpiration, coughs, fevers, ſpitting of blood, ſuppuration, extravaſation of blood, and other bad ſymptoms, particularly if any of the viſcera are hurt at the ſame time.

In order to replace fractured *ribs*, it is neceſſary firſt to enquire whether they project internally or externally; when externally, the patient is to be placed upon a high table, and the ſeparated bones muſt be gently forced by the fingers into their places; the proper compreſſes, dipped in ſpirit of wine, muſt be laid on, and then covered with ſlips of paſtboard, or ſplints, and the circular bandage, or napkin and ſcapulary. But when the ſplinters are thruſt inward, while the patient retains a deep breath; both ſides of the bone muſt be compreſſed with the hands, and agitated till they are properly fixed. When they are replaced, the paſtboard muſt not be applied in this caſe, but only the bandage drawn a little leſs tight; by theſe means, fractures of this kind are uſually cured in three or four weeks. Ibid. p. 123.

RIBS *of fiſhes*. There is a very great variety in the ſhape, and other peculiarities of the *ribs of fiſhes*. They are in ſome ſmooth and flatted ſideways, as in the cyprini. In others they are rounded, as in the cotti and gadi. In the

cyprini

cyprini the ſeveral ſpecies have from thirteen to nineteen *ribs* on a ſide, and the vertebræ are from thirty-ſeven to forty nine in number, differing greatly in number in the ſeveral ſpecies of the ſame genus. The *ribs*, in many fiſh, adhere to the vertebræ, by means of cartilages, and ſeem only continued parts of them; but in others they are free, and looſe, and do not ſo much as touch the vertebræ. We find inſtances of the firſt ſort of ſtructure in the cyprini, ſalmons, *&c.* and of the other in the pearch, the gadi, and the pleuronectæ. In the ſpinoſe fiſhes, the laſt vertebra always is terminated by a pair of broad apophyſes placed perpendicularly, and touching one another, and by means of cartilages theſe are fixed to the bones of the tail. *Artedi*, ichthyolog.

RIBS, among jewellers, the lines, or ridges, which diſtinguiſh the ſeveral parts of the work, both of brilliants and roſes. *Jeffries* on Diamonds.

RICA, among the Romans, a veil with which the ladies covered their heads. *Danet*, in voc.

RICCIA, in botany, the name of a genus of plants of the lichen claſs, or, according to Linnæus, of the algæ: the characters of this genus are theſe. The male flower ſtands on the ſurface of the leaf, without a pedicle, and has neither cup nor petals, nor even ſtamina, but is a ſimple anthera or apex, of a tapering form, but truncated, and opening at the top when ripe. The female flower grows ſometimes on the ſame, ſometimes on different plants. It has ſcarce any cup, and no petals, but is loaded with a globoſe fruit, having only one cell, which contains a vaſt number of ſeeds. *Linnæi* Gen. Pl. p. 507. *Michel.* Nov. Gen. p. 57.

RICE (*Cycl.*)—The Chineſe water their *rice* fields by means of moveable mills, placed as occaſion requires, upon any part of the banks of a river. The water is raiſed in buckets to a proper height, and afterwards conveyed in channels to the deſtined places. *Boyle*'s Works abr. Vol. 1. p. 108.

RICERCATA, in the Italian muſic. See RESEARCH, *Cycl.*

RICHARDIA, in botany, the name of a genus of plants, the characters of which are theſe. The cup conſiſts of one leaf, divided into ſix parts, and is erect and pointed, and of about half the length of the flower. The flower is monopetalous, and of a cylindric funnel like ſhape, the edge is divided into ſix ſegments. The ſtamina are ſix filaments, ſo ſhort as to be ſcarce obſervable. The antheræ are roundiſh and ſmall, and ſtand in the notches of the flower. The germen of the piſtil ſtands beneath the cup. The ſtyle is capillary, of the length of the ſtamina, and divided into three parts at the top. The ſtigmata are obtuſe. The ſeeds ſtand naked, and are three in number; they are roundiſh, but angular, and are broad at the upper part and gibbous. *Linnæi* Gen. Pl. p. 150.

RICINOCARPODENDRON, in botany, the name of a genus of plants, eſtabliſhed by Dr. Ammann, the characters of which are theſe. The flower is of the roſaceous kind, conſiſting of three petals, diſpoſed in a circular order, in the center of which there ariſes a large and open tube, through which ſhoots up the piſtil, which grows at the bottom of the cup. This piſtil finally becomes a trigonal fruit, divided into three cells within, and containing each one ſeed in a rough coat.

The leaves of this tree ſomewhat reſemble thoſe of the aſh, being compoſed of three or four pairs of ſmaller leaves joined to a middle rib; theſe are not ſerrated, and terminate in a ſharp point. The flowers grow at the alæ of the leaves, they are white, and are diſpoſed in lax ſpikes. The fruit is green at firſt, afterwards it becomes of a yellowiſh red, and finally ſcarlet. It is of the bigneſs of a walnut, and in ſhape much reſembles the fruit of the ricinus. The covering of the ſeeds is black on the outſide and red within, and each ſeed is divided into two lobes. When ripe, the fruit burſts, and the ſeeds fall out. It is a native of the Eaſt Indies. Act. Petropol. Vol. 8. p. 214.

The word is compounded of *ricinus*, κάρπος, *fructus*, and δένδρον, *arbor*. See RICINUS.

RICINOIDES, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, being compoſed of ſeveral petals arranged in a circular form, and placed in a many leaved cup; theſe, however, are male, or barren flowers; for the embryo fruits appear on other parts of the plant; theſe are contained in a cup, and finally become each a fruit, which is fiſſile into three capſules, containing oblong ſeeds.

The ſpecies of *ricinoides* enumerated by Mr. Tournefort are theſe. 1. The common French *ricinoides*, from which the French turnſole is prepared, and which is called by many authors heliotropium, or turnſole. 2. The American arboreſcent *ricinoides* with divided leaves. 3. The cotton leaved American *ricinoides*. 4. The American *ricinoides* with ſtave's acre leaves. 5. The hairy poplar leaved American *ricinoides*. 6. The cheſnut leaved American *ricinoides*. 7. The ſhrubby marſh mallow leaved and American *ricinoides*. 8. The mullein leaved American *ricinoides*. 9. The æleagnus leaved American *ricinoides*, 10. The citron leaved American tree *ricinoides* with ſilvery duſt. *Tourn.* Inſt. p. 656. See HELIOTROPIUM.

RICINUS, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the apetalous kind, conſiſting only of a number of ſtamina which ariſe from a cup. Theſe flowers are barren, and the embryo-fruits grow on other parts of the plants; theſe become at length each a trigonal fruit, compoſed of three capſules, containing ſeeds covered with a hard rind.

The ſpecies of *ricinus* enumerated by Mr. Tournefort are theſe. 1. The common *ricinus* or palma chriſti. 2. The great American *ricinus* with green ſtalks. 3. The great American *ricinus* with red jointed ſtalks. 4. The ſmall American *ricinus*. 5. The *ricinus* of Ceylon with deeply divided leaves. See Tab. 1. of Botany, Claſs 15.

The ſeeds of almoſt all the ſpecies of this plant are very violent emetics and cathartics. Some have ventured to give them in ſmall doſes, in dropſies, but the practice is hardly juſtifiable.

RICKETS (*Cycl.*)—*Rickety* children have larger livers, and leſs hearts, and leſs blood, than children in health, from too full and too groſs a diet, and too little exerciſe; and they have larger livers than children in health, from the livers always increaſing in weight, when the weight of the heart and quantity of blood leſſen. See HEART and LIVER.

Dr. Hahn, in a letter on the cyrtonoſus, or *rickets*, which is commonly thought to be a modern diſeaſe; quotes Hippocrates, and ſeveral other antient writers, as treating of it. Med. Eſſ. Edin.

RIDE (*Cycl.*)—To RIDE *land-locked*, at ſea. See the article LAND-*locked*.

To RIDE *by the ſtoppers*, at ſea. See the article STOPPERS.

RIDGES (*Cycl.*)—The method of plowing land up into *ridges*, is a particular ſort of tillage. The chief uſe of it conſiſts in the alteration it makes in the degrees of heat and moiſture; theſe being two of the grand requiſites of vegetation, and very different degrees of them being requiſite to the different ſorts of plants. Thoſe plants commonly ſown in our fields require a moderate degree of both, not being able to live upon the ſides of perpendicular walls in hot countries, nor under the water in cold ones, neither are they amphibious; but they muſt have a ſurface of earth, not covered, nor much ſoaked with water, which deprives them of a proper degree of heat, and cauſes them to languiſh. In this caſe they look weak, and their leaves yellowiſh. They ceaſe growing; and, in fine, die in a weak and very bad ſtate.

The only way to cure the land of giving this diſeaſe to plants, is to lay it up in *ridges*, that the water may fall off, and run into the furrows below, from whence it may be conveyed by drains and ditches into ſome river, or otherways carried wholly off from the land.

The more any ſoil is filled with water the leſs heat it will have. The two ſorts of land moſt liable to be overglutted with water are hills, the upper ſtratum of mould in which lies on clay; and generally, all deep and ſtrong lands. Hills are made wet and ſpewy, by the wet that falls in rains, dews, and miſts; and this wet not being able to ſink through the clay, in theſe ſoils, runs down between it and the mould; but extending itſelf through the mould all the way, and making it continually waſhy. The plowing this ſort of land in *ridges*, made from the higher to the lower part of the field, is of no benefit; for the water will preſs from below upwards in theſe *ridges*, being forced by the addition of freſh ſupplies above.

There are two methods of draining a hill ground like this. The one is to dig ſeveral deep trenches croſs-wiſe, or horizontally on the ſides of the hill: let theſe be nearly filled up with ſhores, and the ſurface covered in the common method: the wet will be received into theſe in all parts, and diſcharged at the ends; and the plow will go over the ſtones, without ſtriking through the depth of earth that covers them. Thus the land will be dried for a time; but, as theſe channels fill up with earth, between the ſtones, they become of no uſe, and the expence of making new ones is very great.

The other way is to plow the land in *ridges* almoſt horizontally, and then the furrows between them are ſo many drains, carrying off the water at their lower ends; if the plow is made to ſtrike a few inches deep into the clay, and the ends of the furrows are no higher than the other parts: every furrow will be a drain to every *ridge*, and the land of the *ridges* will be kept dry. If there were no other manner of plowing the *ridges*, on the ſides of hills, than there is in the plain lands, this method of having open furrows, or drains, on declivities, would be impracticable; becauſe the plow could not turn up the furrows againſt the hill and againſt the *ridge* alſo, from the lower ſide of it. But the eaſy remedy againſt this inconvenience, is to plow ſuch *ridges* in pairs, without throwing any earth into the trenches, and then the *ridges* will be plain at top, and the rain water will run ſpeedily downward to the next trench, and thence to the head land, and ſo out of the field. Theſe trenches will be made, as well as kept always open by plowing in pairs; and this is abundantly more eaſy than the way of plowing *ridges* ſingly.

Every time of plowing the *ridges* muſt be changed as to the pairs;

pairs; ſo that the furrow, which had two *ridges*, or lands, turned towards it one time, muſt have two turned from it the next time; and this method keeps the ſurfaces of all the *ridges* or lands pretty nearly even. This, however, cannot be done on a hill, whoſe declivity is ſo great, that the plow is not able to turn a furrow againſt it; but, in this caſe, perhaps, it may be ſufficient to plow the *ridges* obliquely enough for the furrows to be turned both ways.

This plowing in an horizontal manner, on hills, is the beſt of all others; but our farmers are not to be eaſily brought into it, though they ſee thin lands of this kind ruined for want of it; their reaſons for not doing it, are, that it would prevent the ſuppoſed benefit of croſs plowing; and that they loſe more ground by having more furrows between the *ridges*, than when they lay their lands flat; where the lands are made much larger than the round *ridges* can conveniently be. But theſe are in reality very erroneous, as well as miſchievous opinions; for more miſchief than good is done by croſs-plowing in general; and inſtead of any real loſs of land by *ridges*, the true ſtate of the caſe is, that much ground is gained by it; that is, the ſurface of the earth is increaſed in quantity; for if a flat piece be plowed into *ridges*, and if in earth ſixteen feet breadth, there be an empty furrow of two feet; and yet, by the height and roundneſs of the *ridges*, they have eighteen feet of ſurface, capable of producing corn equally with eighteen feet, while the piece was flat; there is then, inſtead of any loſs, one eighth part of profitable ground, gained by the altering the piece from a level into a *ridge*.

RIDGES, in the manege, are the wrinkles, or riſings of fleſh in the roof of a horſe's mouth, which run acroſs from one ſide of the jaw to the other, like fleſhy *ridges*, with interjacent furrows, or ſinking cavities. It is upon the third or fourth *ridge* that we give the ſtroke with the horn, in order to bleed a horſe whoſe mouth is overheated. See HORN.

RIDING (*Cycl.*)—RIDING *caſt*, in huſbandry, a term uſed by the farmers for a particular method of ſowing their grounds, by making two *caſts* upon a ground at the ſame time. This is not much uſed, but it is a quicker way than the double *caſt*, which is the method now moſt uſed. *Plot*'s Oxfordſhire, p. 251.

RIDING *clerk*, one of the ſix clerks in chancery; who, in his turn, for one year, keeps the controlment books of all grants that paſs the great ſeal. *Blount*.

RIEMLING, in zoology, a name given by ſeveral to the ſmall freſh water fiſh, called by the Latins *phoxinus*, and vulgarly the *pink*. *Willughby*'s Hiſt. Piſc. p. 267.

RINÆUS *muſculus*, the name of a muſcle mentioned by Douglaſs, which he alſo calls *naſalis*: it ariſes fleſhy from the extremity of the os naſi, and adjacent parts of the os maxillare, and is inſerted into all the cartilages of the alæ. Its uſe is to open and dilate the noſtril, by pulling that part outwards.

RINAR, a word uſed by the chemiſts to expreſs filings of any thing.

RINEUS *marinus*, a name given by ſome botanical writers to the *crithmum*, or *ſamphire*, a ſea plant uſed as a pickle. *Ger. Emac.* Ind. 2.

RING, (*Cycl.*) in angling, an inſtrument intended to free the hook, when accidentally entangled among weeds. It is a circular piece of lead, of about ſix inches round, and is faſtened to a long packthread when it is to be uſed. It is ſlipped over the end of the angling rod, and let down into the water where the line conducts it to the hook; the rod and line have then no farther buſineſs; but the hook is endeavoured to be diſengaged by the pulling this ring backwards and forwards by the ſtring which is faſtened to it; the hook is generally freed from the weed by this means; but if not, and nothing but the breaking of the tackle will do, the breach is made in this manner near the hook; whereas if done without this ring, it might have happened in ſome other part of the line, or the rod itſelf might have been deſtroyed by it.

RINGS *of flies*, in natural hiſtory, the ſeveral rounds, or circular portions, of which the bodies of theſe and other inſects are compoſed.

In the *fly* kind theſe are cruſtaceous or cartilaginous, and conſequently of a matter little capable of extenſion; many actions of theſe inſects require, however, that their bodies, or a part at leaſt of their bodies, ſhould be able to inflate or diſtend, and contract their ſize occaſionally. Were every *ring* of the body one entire ſcale, or ſhelly ſubſtance, theſe changes could not be eaſily effected; nature has therefore ſo provided, that the tender bodies of theſe little creatures are ſufficiently defended, and yet all the neceſſary motions may be performed.

In many flies each *ring* is indeed one entire ſcale; but, in this caſe, it makes a circle round the body of the creature, whoſe ends do not join, but have a furrow between them, and running the whole length of the body; this furrow is placed under the belly, and is of different ſizes in the different ſpecies. It is very narrow in the great blue fly, and much broader in many ſmaller ſpecies. This furrow is filled with a matter merely membranaceous, or in other ſpecies, with a ſeries of ſmall moveable ſcales, ranged endwiſe one to another, and in number exactly equal to the *rings* of the body; and on each ſide, between theſe ſcales and the extremities of the ſeveral *rings*, there is a ſmall membranaceous ſubſtance, which is capable of extending and giving way, as the inflation or contraction of the body on different occaſions may require. *Reaumur*'s Hiſt. Inſ. Vol. 4. p. 256.

Other ſpecies of flies have to every *ring* two ſcaly arches, which differ a little in bigneſs; the one covering the back, and the other the belly of the creature; theſe arches are joined on each ſide by a muſcular membrane. When the body is in its ſtate of ſmalleſt extenſion, and is flatted, or contracted, this membrane is ſeen to make ſeveral foldings laid cloſely over one another, and making the whole take up but a very ſmall ſpace; and, in this caſe, the ſuperior ſcaly arch ſeems immediately to touch, and be joined to the inferior: but when the creature inflates, and extends its body, the membrane opens from its ſeveral foldings, and gives room for a vaſt increaſe in diameter; and the extremities of the two ranges of ſcales ſeparate to a very conſiderable diſtance from one another. The flies produced from the rat tailed water worms, give us an inſtance of this mechaniſm. In other flies there are none of theſe membranes, nor furrows, but the body is compoſed of *rings* made up each of two ſingle ſcales, one covering the back and the other the belly; but theſe, in the common ſtate of the body of the creature, are laid a great way over one another, and are not fixed to that poſition, but can ſlide aſunder as the creature diſtends itſelf; and in many ſpecies of inſects theſe ſcales continue to cover each other in part, even when the body is diſtended to a very great degree. Bees, waſps, *&c.* are thus formed; and it is extremely neceſſary that they ſhould be ſo, ſince they have frequent combats with one another: if they were not thus armed, the ſtrokes of their ſtings would eaſily find entrance through ſuch membranaceous commiſſures as are found in other flies, and would prove fatal. Ibid. p. 257.

RING *of ſaturn*, in aſtronomy, an opake, ſolid, circular arch or plane, like the horizon of a globe, which entirely encompaſſes, but no where touches the planet. See the article SATURN, *Cycl.*

RING *dove*, in zoology, the name of a bird of the pigeon kind, called by Aldrovand and other authors the *palumbus torquatus*, and by the Greeks *phaſſa*. Its beak is yellow, its feet naked and red, its legs feathered almoſt down to the feet. The upper part of its neck has a very regular and beautiful white circle, from which the bird has its name; and its whole neck, above and below this, is beautifully variegated with changes of colours, according as it is oppoſed to the light. Its head and back are of a duſky blue grey, and its throat and breaſt of a grey mixed with purple, its belly of a plain grey. The colours are all deeper, and more lively in the male than female. It ſeldom flies ſingle, but in large flocks, and builds on trees; its food is ivy berries and other vegetable matter. See Tab. of Birds, N° 27. *Ray*'s Orn. p. 185.

RING *head*, an engine uſed in ſtretching of cloth. 43 Eliz. c. 10. *Blount*, *Cowel*.

RING-*ſcalpel*. We have a deſcription and figure of a *ring-ſcalpel*, for aſſiſting the delivery of women in child-birth, by Dr. Thomas Simſon, in the Medical Eſſays of Edinburgh, Vol. 5. Art. 39.

RING-*tail*, in zoology, the Engliſh name for the female of the *ſubbuteo*; the male and female in this ſpecies, differing ſo much in colour, as to be called by two names; the male being called the *henharrier*. See the article HENHARRIER.

The *ring-tail*, or female *ſubbuteo*, is a moderately large bird. It has a ſort of *ring*, or chain of feathers, round the back part of its head, reaching to its chin on each ſide, which ſtand erect, and are brown in the middle, and of a reddiſh white at the edges, and make a ſort of crown which ſurrounds the head; and from this there hang down a naked ſkin, which covers the ears. It has a white ſpot on each ſide under the eyes; its breaſt and belly are of a tawny white, with long browniſh ſtreaks; and the middle of its throat is browniſh; its back and wings are of a duſky ferrugineous colour; its tail variegated with tranſverſe ſtreaks of black and tawny. The upper part of the beak is covered with a yellow ſkin. Its legs are yellow, and the inſide of its mouth is black. It feeds on ſmall birds, and its eggs are of a reddiſh hue, with very little clear white appearing in them *Ray*'s Ornitholog. p. 40.

RIONDO, in zoology, a name uſed by ſome for the fiſh more commonly called *aper*, a ſmall fiſh, of the ſhape of the faber or doree, caught in the Mediterranean. *Ray*'s Ichthyogr. p. 296. See the article APER.

RIPIENO, in the Italian muſic, is uſed in pieces of muſic in parts, to diſtinguiſh thoſe that play to fill up, from thoſe that play throughout the piece. There are, ſays Mr. Broſſard, two kinds of the *ripieno*: one plays the part of the little chorus exactly, and does not, therefore, increaſe the harmony or number of parts. What is to be played by all the muſicians is marked with the words *tutti* or *omnes*. This ſort of *ripieno* is found in almoſt all compoſitions. The other ſort is much better, a different part being played, whereby

whereby the number of parts is increaſed, and the harmony made fuller. Thus in pieces where in ſtrictneſs two trebles, and baſs, and thorough baſs are ſufficient, becauſe theſe parts are diſpoſed in ſuch a manner, as that their harmony is complete when played all together; yet, in order to render the piece more perfect, and to give it more grandeur, a counter tenor, tenor, and often two violins are added, whoſe parts are entirely different from the other; and the harmony then has ſeven parts inſtead of three, and is conſequently more complete and full. The parts thus added are properly called *ripieni*. *Broſſard*.

RIPIERS, *ripiarii*, in our old writers, thoſe that bring fiſh from the ſea coaſt to the inner parts of the lands. Camb. Brit. 234. *Blount*, *Cowel*.

They were thus called a *fiſcella*, *qua in devehendis piſcibus utuntur*, *anglice* a rip.

RIPOSTE, in the manege, is the vindictive motion of a horſe that anſwers the ſpur with a kick of his foot.

RIPPERS, in the wire works, are the people who attend in the mills, take the prepared ſmall rods of iron, and work at the barrels where they are drawn into wire. *Ray*'s Engliſh words, p. 133.

RISCUS, among the Romans, ſometimes ſignifies a cheſt or trunk covered with ſkins; ſometimes it is uſed for a hamper, made of twigs or ruſhes to hold lint; and ſometimes for a hollow place in the wall of a houſe, uſed likewiſe for holding lint, or the like. *Pitiſc.* in voc.

RISENTITO, in the Italian muſic, a briſk, lively, or expreſſive manner of playing.

RISIGALLUM, in the materia medica, a ſubſtance of a red colour, generally placed among the kinds of arſenic or orpiment of the antients. Some of the later writers underſtand by it the ſandarach, and others the factitious red arſenic; that it was looked upon to be poiſonous is plain from Aviſenna, who recommends it for killing rats, mice, and other vermin; and this ſeems to refer it to the factitious kind, or ſomething of that ſort, known in thoſe times; for the native ſandarach, does not ſtand in the rank of poiſons with them, nor indeed is ſuch.

Dioſcorides ſeems to diſtinguiſh the red orpiment from ſandarach, in that he ſays, it approaches to the ſandarach in colour; he would never ſay that a thing was of the like colour with itſelf; and therefore it appears, that he knew two kinds of red ſubſtances, under the names of red orpiment and ſandarach. Aviſenna mentions a red, a yellow, and a green zarnicle. We find theſe writers called the lapis armenus by the ſame name zarnicle with the orpiment; and it is probable, that this author confounding the two different ſubſtances together, means real orpiment by the red and yellow, and a poor greeniſh blue lapis armenus by the green.

RISING (*Cycl.*)—Rising *timbers*, in a ſhip, are the hooks placed on her keel; and are ſo called, becauſe as they riſe in proportion, ſo her rake and her run riſe on her flat floor by degrees.

RISORIUS *novus*, in anatomy, a name given by Santorini to a muſcle, formed of that part of the *quadratus genæ*, which ariſes from the cheek.

RISVIGLIATO, in the Italian muſic, is uſed to ſignify, that after having played or ſung a doleful and lamenting ſtrain, a gay and lively air is to follow.

RITHER, or RIDER, in mining, is a ſtone or thin clift that lies in the vein; the ore ſometimes runs on both ſides it. Sometimes the *rither* is ſo thick, it parts the vein, and makes one vein two. *Houghton*'s compl. Miner in the Explan. of the Terms.

RITUALES *libri*, among the antients. See Aruspici *libri*.

RIVERS (*Cycl.*)—It has been held by many, that all ſprings and *rivers* owe their origin to rains and dews; but there are ſome ſprings which cannot be accounted for on this principle, though others very well may. The intermitting ſprings, which flow violently in rainy ſeaſons, and are dry in ſummer, are probably owing to rains; but there are ſome ſprings, which diſcharge more water annually, than all that falls in rain and dews in the neighbouring country. The great perennial ſprings at Willowbrig in Staffordſhire is of this kind, and that of the Sorgne in France is much more eminently ſo; the *river* of that name, being, according to Gaſſendus, navigable up to the very ſprings which are its ſource.

But if ſuch ſprings, as theſe, diſcharge too great a quantity of water for the ſupply of rains and dews; how is it poſſible, that ſuch ſmall ſupplies of water as theſe, can afford the conſtant currents of the larger *rivers*? The Volga alone, according to Ricciolus, pours forth as much water in a year's time into the Caſpian Sea, as would ſuffice to drown the ſurface of the whole earth. The *river* of St. Lawrence, in the Weſt Indies, pours forth nearly as much as this. If either of theſe *rivers* alone do, as has been affirmed, from calculations, diſcharge annually as much water, as falls in the ſame time in rains and miſts upon the ſurface of the whole earth; from whence are all the reſt to be ſupplied, according to the ſyſtem of their all being made by brains; and particularly where is left the ſupply for the Rio de la Plata; which Ricciolus affirms to be larger than the Nile, the Ganges, and the Euphrates put together? its mouth being ninety miles wide, and running with that violence into the ſea, that it makes it freſh for two hundred miles together. Theſe, and the other *rivers* of the ſeveral parts of the globe, upon a very moderate calculation, diſcharge at leaſt five hundred times as much water into the ſea, as falls upon the whole ſurface of the earth, in rains, miſts, dews, ſnows, &c. in a like ſpace of time.

As it is evident, therefore, that theſe cannot be ſupplied by rains, ſo neither is it poſſible that the ſeveral hot ſprings, and the ſalt ſprings can be ſupplied that way: the origin of ſprings alſo in places where there falls little or no rain, and where the conſervatories muſt needs be too ſmall to contain a ſupply, are great proofs that rain and miſts are not the origin of ſprings, at leaſt not in all places. The iſles of Mago, Rotunda, and the Strophades, and the rock whereon the maiden tower ſtands in the Thracian Boſphorus, cannot be ſupplied with, or retain a ſufficiency of rain water to ſupply conſtant ſprings, yet ſuch are always found running there.

It cannot be otherwiſe but that there are ſubterranean communications between the ſea and the ſources of fountains, *rivers*, and the larger ſprings, by which theſe are ſupplied; and there are certainly charybdes which ſwallow the ſea for theſe purpoſes; and when theſe happen to be ſtopped, the largeſt *rivers* have been dried up, and wholly ceaſed to run for a conſiderable time: this we have accounts in hiſtory has happened to the Thames, the Trent, and Medway in England; the Elve, the Motala, and Gulſpang in Sweden, and other *rivers* in other countries. If, on the other hand, theſe charybdes happen to be too open, freſh water ſprings depending upon them will become ſalt. This we have inſtances of in hiſtory alſo; and even ſo old a writer as Pliny has ſaid, that this once happened in Caria near Neptune's Temple. *Plot.* de Origine Fontium. See Penuaria.

It is pretended, by ſome writers of voyages, that there are two *rivers* in China, the Chiemo and Jo, both in the province of Henſi, the water of both which is ſo light that the ſmalleſt ſtraw cannot ſwim in them, but ſinks to the bottom; but we have no authentic teſtimony of this wonderful thing. *Redi*'s Eſperience.

River *horſe*, in zoology. See Hippopotamus.

RIVET, in the manege, is the extremity of the nail that reſts or leans upon the horn when you ſhoe a horſe. See the articles Nail and Shoe.

RIVINIA, in the Linnæan ſyſtem of botany, a genus of plants, the characters of which are theſe. The cup is a perianthium, divided into four ſegments, of a different colour from the reſt of the plant, and remaining till the ſeed ripens. Its ſegments are oblong, oval, and obtuſe. It has no petals. The ſtamina are four filaments ſhorter than the calyx ſtanding in pairs, and remaining with the cup; the antheræ are very ſmall. The germen of the piſtillum is large and roundiſh, the ſtyle is very ſhort, and the ſtigma ſimple and obtuſe. The fruit is a round berry, ſtanding on the cup, the leaves of which are bent back; this berry contains only one cell, in which is contained one roundiſh, but flatted, rough ſeed. *Linnæus*'s Gen. Plant. p. 52.

RIVOLGIMENTO, in the Italian muſic, is the placing a treble or upper part in the place of the baſs, or any low part, or *vice verſa*. This often happens in double counterpoint, where the treble ſerves for the baſs, or the baſs for the treble; and that in ſuch a manner, that the harmony, though different, remains as correct after this change, as it was in the natural order of the parts.

RIZIUM, in botany, a name given by the antients to a peculiar kind of red root brought from Syria, and uſed by the Grecian women to paint their cheeks red.

The Latin writers, who have mentioned this, have called it *radicula*; and Pliny, who has more than once mentioned it, calls it *herba lanaria*, or *radix lanaria*. This, however, is a very great error, confounding it with the *ſtruthium* of the Greeks. It is probable, that the *rizium* was no other than the *ancuſa*, or *alkanet root*, which grows very plentifully in the countries from whence the Greeks had their *rizium*, and which will anſwer all the purpoſes for which they uſed it. See Ancusa.

ROACH, (*Cycl.*) in ichthyology, the Engliſh name of a fiſh, called by the generality of authors the *rutilus* and *rubiculus*, by ſome the *rubellio*. It is a ſpecies of the *cyprinus*, according to the new ſyſtem of Artedi. See the articles Rutilus and Cyprinus.

ROACHING *of alum*, one of the laſt proceſſes uſed in the *alum* making, and is what renders it fit for the market.

After the *alum* liquor has been left four days in the cooler, and is ſufficiently ſhot, they drain it out; and taking out the *alum*, they waſh it in a ciſtern of *alum* water ſo ſtrong, that it can ſcarce take up any more of that ſalt, but only cleanſes it of its accidental foulneſſes. After this waſhing the *alum* is put into large pans, and a quantity of water added to it. It is ſet over the fire to melt in this water and boil a little; then it is ſcooped into a great caſk, where it is ſuffered to ſtand about ten days; and it is then fit for the market under the name of *roach alum*, or *roached alum*; the

liquor let out of the cooler is boiled up again, and ſhoots more *alum*.

ROAD *gooſe*, in zoology, the name of a ſmall ſpecies of wild *gooſe*. See the article GOOSE.

ROAN, in the manege. A *roan* horſe is one of a bay, ſorrel, or black colour, with grey or white ſpots interſperſed very thick: when this party-coloured coat is accompanied with a black head and black extremities, he is called a *roan* with a black-a-moor's head. And if the ſame mixture is predominant upon a deep ſorrel, it is called claret *roan*.

ROASTING, in metallurgy, is the ſeparation of volatile bodies, from thoſe which are more fixed by the combined action of air, and fire; and is generally the firſt proceſs in the ſeparation of metals from their ores: it differs from ſublimation only in this, that in this operation the volatile parts are diſſipated, when reſolved into vapours; whereas in that they are preſerved.

Sulphur and arſenic are in this manner collected and preſerved in the *roaſting* of many ores; and ſublimation made, as it were, occaſionally in the proceſs.

The ſeparation of the volatile parts of bodies, from the more fixed is, however, in many caſes very difficult, and much nicety is required in the conducting this operation; this is the caſe, for inſtance, when the whole compound body melts in almoſt the ſame degree of fire that is neceſſary to raiſe, and diſſipate the volatile parts in the air; in ſuch caſes, care muſt be taken, firſt previouſly to pound a little the body to be *roaſted*, that its ſurface contiguous to the air may be increaſed in extent. A gentle fire is alſo neceſſary on ſuch occaſions, and a very free acceſs of the air, which is the vehicle of theſe vapours. When the body in the *roaſting* grows on theſe occaſions into large lumps or clots, the ſurface of it muſt be reſtored to the neceſſary extent, by repeated poundings, for it is neceſſary above all things, that the matter be kept extended and recent, and never collected into a heap.

Bodies the moſt refractory in the fire, are always the moſt eaſily *roaſted*; for a great fire may be conſequently kept up to ſuch, nor need the operation be repeated ſo often. Care muſt always be taken, however, that while the volatile bodies are diſſipating in the fire, they do not carry up with them ſomething from the fixed ones alſo; for this is a diſadvantageous accident, and too often happens, eſpecially when a fire too violent is uſed in the beginning of the operation; to prevent this, it is ſometimes neceſſary to add ſome fixing body to the maſs. *Cramer*'s Art of Foſſ. p. 189.

The buſineſs of *roaſting* of ores of metals, as now uſually practiſed, is ſubject to many inconveniences, which may be moſt of them eaſily remedied, and the whole buſineſs reduced to a few eaſy rules. 1. The *roaſting* of ores ſhould be always performed, without addition, when the ores are rich, or of itſelf merely of a metallic nature. But the additions of quicklime, potaſhes, iron filings, and the like, are neceſſary, when arſenical, antimonial and ſulphureous matters are found to be mixed with the ores. 2. The fire is to be ſo regulated from the firſt, that only the lighter or more volatile ſulphureous or arſenic fumes may fly off, otherwiſe the more metallic part would likewiſe go, and without ſome contrivance to catch it would be loſt. The ore muſt, however, always feel the force of an open flame, otherwiſe the ſulphur, arſenic, *&c.* will never be thoroughly diſlodged. 3. The more theſe immature ſubſtances abound in ore, the gentler the fire ſhould be at firſt; and when the greater part of the ſulphureous matter is thus exhaled, the fire is then to be quickened. 4. Where ſuch additions are uſed, as are not metalline, as lime, mud, pot-aſh, *&c.* they ought always to be ſeparated afterwards from the matter before the fuſion, by waſhing. *Shaw*'s Lectures, p. 251.

ROB, (*Cycl.*) in pharmacy, the inſpiſſated juice of any ſubſtance, uſually boiled up to the conſiſtence of honey.

It is poſſible, that great improvements might be made, by introducing the uſe of this form among the malt diſtillers. The great inconvenience attending that art being, that the malt being of a large bulk, in proportion to its ſaccharine part, and requiring a large proportion of water to extract that ſaccharine part, many large veſſels, ſuch as maſh tubs, coolers, fermenting backs, *&c.* are neceſſary; and the neceſſary labour on the ſubject is increaſed, and the commodity rendered dearer. The remedy of this ſhould ſeem the introducing a new art ſubſervient to that of the malt diſtiller, and confining itſelf to the boiling down of malt wort to a *rob*, ſo as to ſupply the malt ſtiller with his ſubject, in the ſame manner as the fine ſtillers are ſupplied with treacle by the ſugar baker. By this means the buſineſs of the malt ſtiller would be reduced to a great degree of ſimplicity, and the ſpirit produced would be alſo much finer than at preſent, becauſe the ſubject would come tolerably refined to his hands, and purged of its groſs, mealy and huſky matter, which yields a diſagreeable oil in diſtillation, and is alſo apt to burn to the ſtill, and ſpoil the ſpirit. It is poſſible that a ſpirit purer and finer than that from treacle might this way be procured from malt prudently managed. Ib. p. 219.

ROBALO, in zoology, a name by which ſome have called the *camuri* an American ſea fiſh of the *lupus marinus*, or baſſe kind. *Willughby*'s Hiſt. Piſc. p. 272. See BASSE.

ROBBINS, in a ſhip, ſmall lines which make the ſail faſt to the yards, being reeved into eylet holes in the ſail under the head-rope for that purpoſe. The word is *make faſt the Robbins:* for at ſea they don't ſay *tie*, but make faſt.

ROBERSMEN, or ROBERDSMEN, in our old writers, a ſort of great thieves, mentioned in the ſtatutes, 5 Ed. 3. c. 14. And in Rich. 2. c. 5. Sir Edward Coke ſays, that *Robin Hood* lived in the reign of Rich. 1. on the borders of England and Scotland by robbery, burning of houſes, rapine and ſpoil, &c. And that theſe *roberdſmen* took their names from him. 3. Inſt. 197. *Blount*, *Cowel*.

ROBIA HERBA, in Botany, a name given by Paulus Ægineta, and many others to a plant uſed in dying.

The near reſemblance of the name to the word *rubia*, has made many conclude that it was the *rubia*, or madder which they meant by it, but they have taken care in their writings to diſtinguiſh it from that plant, and it is plainly the *geniſtella tinctoria*, or dyers weed, that they meant by the *robia herba*. They ſay it was uſed to dye yellow, and that it was alſo a cuſtom to ſtain the hair with it.

Theſe are the properties recorded of the *cymene* and *æcomenium* of the Greeks, and *lutum* or *lutea herba* of the Latins, which were names of the *geniſtella tinctoria*. Pliny ſays, that the *lutum* had leaves like flax and flowers like broom, which is exactly the caſe with the *geniſtella tinctoria*, but by no means agrees with the glaſtum or woad.

ROBINIA, in botany, the name of a genus of plants, called *pſeudo-acacia* by Tournefort, and the generality of authors. The characters are theſe; the perianthium is ſmall and one leaved, it is divided into four ſegments at the end, the three under ſegments are very narrow, but the upper one four times as broad, tho' of the ſame length with the reſt, and is ſlightly emarginated; the flower is of the papilionaceous kind. The vexillum is large, round and obtuſe. The alæ are of an oblong oval figure, and ſtand free, having a very ſhort obtuſe appendage: the carina is nearly of a ſemiorbicular figure, it it compreſſed, obtuſe and of the ſame length with the alæ. The ſtamina are diadelphous filaments pointing upwards. The antheræ are roundiſh. The germen of the piſtill is oblong and of a cylindric figure; the ſtyle is capillary and turns upwards, and the ſtigma is hairy and placed forward at the apex of the ſtyle. The fruit is a large and long pod of a compreſſed figure and ſomewhat gibbous; it contains a few kidney ſhaped ſeeds. *Linnæi* Gen. Pl. p. 349. *Tourn.* Inſt. p. 417. *Rivin.* 4. 74.

ROCELLA, a kind of fucus or ſea wrack found in the Mediterranean and other ſeas, and in ſome places uſed by the dyers for a purple colour, and called by the botanical writers, in general, *alga tinctoria*. *Caſp. Bauhin.* Pin. p. 365.

ROCHET, the name given to a fiſh, otherwiſe called *cuculus* and *red gurnard*. See CUCULUS and GURNARD.

ROCHETTA, in the glaſs trade, another name for polverine. See the article POLVERINE.

ROCKS (*Cycl.*)—Theſe are generally ſuppoſed great enemies to vegetation, and the people of Scotland have been deterred from cultivating many of their beſt lands, from an obſervation that they had a *rocky* bottom. This is however but a vulgar error among them, for *rocks* of a proper kind and properly diſpoſed, as very many of theirs are, fertilize and are beneficial to the land, not hurtful.

In many parts of England we ſee gardens the moſt beautiful that can be imagined, both in regard to flowers and excellent plants, on a ſoil where the bottom is a hard *rock*, and the earthy covering not more than a foot or thereabout in depth. In ſome of theſe, all the diſadvantages the Scotch complain of take place, and yet the gardens are fruitful, many of them having lofty hills on the ſouth ſide; the declivity due north, and the *rock* perfectly bare next the walls on the north ſide.

The north ſides of theſe hills in this very aſpect, only with the *rock* covered with two or three foot of earth make very good hop gardens, producing a vaſt quantity of a very valuable commodity at a ſmall expence; and it is remarkable that thoſe gardens, which ſtand in this expoſure, inſtead of being ſubject to particular evils, often eſcape thoſe blaſts and other miſchiefs which affect the plantations of the ſame kind on the ſouth ſide of the hills. It might be a very valuable article of trade, if the bleak hills of Scotland, or thoſe of ſome of our northern plantations in America, could be made thus fruitful in ſo uſeful a commodity, and there ſeems only the want of a proper trial.

Another extremely valuable plant that might be raiſed on theſe barren *rocky* places, as they are generally ſuppoſed to be, is flax, in places where the deſcent is too ſteep for ploughing in the common way. It has been proved that a hand plough with a ſtem of aſh of about ſeven feet long, and a plate on each ſide near the end to turn the turf, a coulter to be let out ſhorter or longer to four or five inches deep to cut the earth up as deep as it lies upon the *rock*, and an iron wheel, may be managed with eaſe and conveniency by two people, and will prepare ground for producing large crops of the fineſt flax. The beſt ſort of flax ſeed of Flanders ſown on this ſort of ground ſucceeds ſo well, that if brought

into

into general uſe it might give the only advantage that is at preſent wanting to the Scotch holland manufactory, and make it excell that of all the world beſide. The northern American colonies might alſo furniſh us with the ſame ſort of flax raiſed at a ſmaller expence than almoſt any other vegetable commodity, and coming to a ſure market and at a very conſiderable price.

Agriculture in Scotland is too much neglected to the great impoveriſhing of the country, and the diſtreſs of a numerous poor, for whom it would find conſtant employment. It is not yet known whether many of the moſt valuable plants for medicinal and mechanic uſes will not proſper as well there, as where there are immenſe ſums made by the raiſing them; and the owners of lands would do well in this ſcheme to try the effect of liquorice, madder, woad and the like plants on their grounds. Wherever the ground is deep enough, it is pretty certain that madder and liquorice would flouriſh, and the laſt of theſe needs ſo little culture, that if once planted it may almoſt be left to it ſelf. The *rocky* bottoms of lands, not too bleak, may alſo ſucceed very well with ſaffron, which is one of the moſt profitable plants that can be cultivated. Phil. Tranſ. N° 109.

ROCK-*cryſtal*, otherwiſe called *ſprig cryſtal*, in natural hiſtory, a name given to the third order of *cryſtals* from their being affixed to a *rock*, or other ſolid body.

This kind of *cryſtal* is the moſt common of all others, and is what the generality of authors deſcribe under the name of *cryſtal of the ſhops*, being that kept for medicinal purpoſes. See the article CRYSTAL.

The cleareſt, pureſt, and moſt tranſparent that can be had, ought to be choſen; and to prove its genuineneſs, it may be tried with aqua fortis, true *cryſtal* making no effervescence with that menſtruum. *Hill*, Hiſt. Mat. Med. p. 280.

ROCK-*fiſh*, a common engliſh name for the *gobius marinus* or ſea gudgeon. *Willughby*'s Hiſt. Piſc. p. 207. See GOGET.

ROCK-*oil*, See the article PETROLEUM.

ROCK-*ſalt*, See the article *rock* SALT.

ROD (*Cycl.*)—ROD, in the manege, called in french *gaule*, is a ſwitch held by the horſeman in his right hand, partly to repreſent a ſword, and partly to conduct the horſe, and ſecond the effects of the hand and heels.

Golden-ROD, in botany. See GOLDEN *rod*.

ROGATORES, among the Romans, thoſe who in the *comitia centuriata* brought the cheſt into which the people threw the ballots containing their votes. *Pitiſc* in voc.

ROHEL, a word uſed by ſome authors as the name for dragons blood.

ROLLER (*Cycl.*)—ROLLER, in zoology, the common name of a bird of the mag-pie kind, called *garrulus argentoratenſis* by authors, and ſuſpected to be the ſame with the bird deſcribed by Geſner under the name of the *blue crow*, *cornix cærulea*, and by Aldrovand under the name of *pica marina*. Its beak is black and long, ſomewhat crooked at the end, otherwiſe like that of the common mag-pie; its eyes are of a greyiſh hazel colour, and near them are two tubercles bare of feathers. Its rump and part of its wing feathers are of a fine blue, like the ultramarine colours uſed in painting; the middle of its back is of a reddiſh brown, and the head is of a bluiſh green, and its breaſt and belly are of a whitiſh blue or dove colour. It is brought to market in Italy and ſome other places. See Tab. of Birds, N°10. *Ray*'s Orn. p. 89.

ROLLER, in gunnery, a round piece of wood of about nine inches diameter, and four foot long, which ſerves in moving mortars from one place to another when near. This is done by raiſing the fore part of the bed ſo high that a *roller* may be laid under it; then puſhing the bed forwards, and laying another in its way, and another before that and ſo on, the mortar is eaſily moved.

ROLLUS *aquaticus*, in zoology, the name given by authors to the *water rail*, a bird of the gallinula kind, called by ſome *ortygometra*, and by others *gallinula chloropus altera*, or a different ſpecies of the common green legged moorhen. It is very like the common moorhen but ſmaller; its head is ſmall; its body flatted, and its feet neither webbed nor enlarged by membranes, tho' it ſwims on the water; its beak is like that of the ruff or avis pugnax, about two fingers breadth long and flatted ſideways. It has a ſmall bald ſpot on its forehead, which is roundiſh and black; its whole upper part is of a mixed colour of black and a browniſh yellow; the middle of all the feathers being black, and the ſides of a duſky yellow. Its throat is of a greyiſh red, its breaſt is of a dead blue with a longitudinal white line in the middle; its belly is reddiſh, and the lower part of its tail white; its legs are very robuſt and ſtrong, and it runs very nimbly; it is common about the ſides of waters, and is a very well taſted bird. *Ray*'s Ornitholog. p. 234.

ROMAIN, in huſbandry, the name of a plant cultivated in the fields in many parts of the world, particulary in France, and called by our farmers *french vetches* or *french tares*; it is an annual plant but a very quick grower, and is extremely good food for cattle, particularly for horſes: they let theſe creatures feed on it all the fore part of the ſummer, and then cut it for hay in Auguſt or September. Its ſhort continuance in the ground makes it leſs valuable than ſaint foin and clover, but it has this advantage over them, that it will grow on poor ground.

ROMAN (*Cycl.*)—ROMAN *Citizen*. See CITIZEN.

ROMPION, this kind of bell flower was formerly much eſteemed in England for the ſweet taſte of the roots, and univerſally cultivated in kitchen gardens; but we at preſent diſregard it, tho' the French continue to be very fond of it. The ſeeds are to be ſown in a bed of light dry earth in March, and in May the young plants will be of a ſize to remove, or they may be left when ſowed, only houghing them up to four inches diſtance; being kept clean from weeds for the remaining part of the ſummer, they will be fit for eating in the ſucceeding winter.

RONDINE, in zoology, a name by which ſome authors have called the *milvus*, or flying fiſh. *Willughby*'s Hiſt. Piſc. p. 283. See the article MILVUS.

RONDINE-*peſce*, in zoology, a name by which ſome have called the *hirundo piſcis* or *ſwallow fiſh*, called by others *mugil alatus*. *Willughby*'s Hiſt. Piſc. p. 233. See the article HIRUNDO *piſcis*.

ROOD (*Cycl.*)—In Scotland, the *rood* contains forty ſquare falls. Tr. Pract. Geom. p. 82. See FALL.

ROOK, in zoology, a well known bird of the crow kind. See the article CORNIX.

Rooks are very deſtructive of corn, eſpecially of wheat, they ſearch out the lands when it is ſown, and watching them more carefully than the owners, they perceive when the ſeed firſt begins to ſhoot up its little blade; this is the time of their feeding on it, they will not be at the pains of ſearching for it at random in the ſown land, for that is more trouble than ſo ſmall a grain will requite them for; but as ſoon as theſe blades appear they are directed without loſs of time or pains by them to the places where the grains lie, and in three or four days time they will root up ſuch vaſt quantities of them that a good crop is often thus deſtroyed in embryo. After a few days the wheat continuing to grow, its blades appear green above ground, and then the time of danger from theſe birds is over, for then the ſeeds are ſo far robbed of their mealy matter that they are of no value to that bird, and it will no longer give itſelf the trouble to deſtroy them.

Wheat that is ſown ſo early as to ſhoot up its green blades before the harveſt is all carried in, is in no danger from theſe birds, becauſe while it is in a ſtate worth their ſearching for, the ſcattered corn in the harveſt fields is eaſier come at, and they feed wholly on this, neglecting the ſown grain; but as this cannot always be done, the farmers to drive away theſe ravenous and miſchievous birds dig holes in the ground and ſtick up the feathers of *rooks* in them, and hang up dead *rooks* on ſticks in ſeveral parts of the fields; but all this is of very little uſe, for the living *rooks* will tear up the ground about the feathers, and under the dead ones, to ſteal the ſeeds. A much better way than either is to tear ſeveral *rooks* to pieces and ſcatter the pieces over the fields, but this laſts but a little while, for the kites and other birds of prey ſoon carry off the pieces and feed upon them. A gun is a good remedy while the perſon who has it is preſent; but as ſoon as he is gone they will return with redoubled vigour to the field and tear up every thing before them.

The beſt remedy the farmer has is to watch well the time of the corn's being in the condition in which they feed upon it, and as this laſts only a few days, he ſhould keep a boy in conſtant pay to watch the field from day break till the duſk of the evening. Every time they ſettle upon the ground or fly over it the boy is to hollow, and throw up a dead *rook* into the air; this will always make them riſe, and by degrees they will be ſo tired of this conſtant diſturbance, that they will ſeek out other places of preying, and will leave the ground even before the time of the corn's being unfit for them. The reaſon of their riſing at the toſſing up of their dead fellow creature is, that they are a bird extremely apprehenſive of danger, and they are always alarmed when one of their comerades riſes. They take this for the riſing of an out-bird, and all fly off at the ſignal. *Tull*'s Horſehoing Huſbandry.

ROOM (*Cycl.*)—*Rooms* in houſes might be warmed by the ſteam of boiling water conveyed in pipes along their walls. See Philoſ. Tranſ. N°. 476. p. 370. ſeq.

The contrivance is a copper with a ſtill head, and a lead or copper pipe fixed to this head, which conveys the hot ſteam of the boiling water thro' the different *rooms* intended to be warmed.

ROOM, in a ſhip, a place diſtinguiſhed by partitions, or bulk-heads, as the gun-*room*, bread-*room*, cook-*room*, powder-*room*, &c.

ROOT (*Cycl.*—The *roots* of plants, of all kinds, have great numbers of fibres, iſſuing horizontally from them on all ſides, and running a great way; but theſe ſeldom go deeper than about ten or twelve inches, the depth to which the earth is commonly ſtirred in agriculture by the plough ſpade. Some plants have all their *roots*, even the large ones, directed horizontally and ſpreading in this manner; but of the others, even thoſe which have top roots, or ſuch as run perpendicularly

pendicularly down into the earth, the greater part have viſible fibres running horizontally from them in great numbers, and even thoſe which ſeem to have none, are not truly without them, they being only more fine and therefore leſs diſtinguiſhable by the eye.

The horizontal *roots* iſſuing from the main body of the *root* ſeem to the eye to be ſhort, and reach only a little way, but they in reality extend many times farther than they ſeem to do, often ſpreading to the diſtance of many yards, after their extream fineneſs and earthy colour makes them imperceptible to the eye.

Mr. Tull has made experiments of this kind, and found that a turnep, which is a plant whoſe root ſeems to have as few, and thoſe as ſhort fibres growing from its main ſtem as any, yet has ſuch as when the ground about it is properly moved by digging, extend to the diſtance of ſix feet every way. The diſtance to which theſe fibres of the roots of plants extend may be diſcovered by trials with ſalt; the common garden plants will not live, if their *roots* reach to a place where there is ſalt; therefore if ſeveral plants of the ſame kind be planted in different parts of the ſame bed of earth, and a trench dug round each at different diſtances, and ſalt buried in this trench, it will be ſeen by the decaying of ſome of theſe plants, and the thriving of others, according to the diſtance at which the ſalt lies, which of them has reached it with their roots, and which have not; that is, which ſalt is placed at a diſtance, to which the plants cannot extend their *roots*, and which is the fartheſt place to which they do. If a furrow be cut in the ground of the depth of nine inches, and at the diſtance of a yard from a turnep *root*, that *root* will extend its horizontal fibres to this diſtance, at the depth of ſix inches or thereabout from the ſurface; but when they are come thus far they will deſcend perpendicularly below the level of the bottom of the furrow, and when they have paſſed it, they will riſe to the level of the others on the oppoſite ſide, and extend to the diſtance of a yard beyond it. This could ſcarce be conceived of a plant which ſeems to have ſo few horizontal fibres as the turnep, but experiment has ſhewn it to be a certain fact.

This is not peculiar to the turnep; for all other plants do it on occaſion. The open mould being the natural ſoil for them to draw nouriſhment from, if they deſcend perpendicularly out of this to avoid expoſing themſelves to the open air where there is a cut or ditch, as ſoon as they have paſſed this, they always mount upwards again to enjoy the vegetable mould again at their proper depth: this is the reaſon of what ſeems ſo ſtrange a thing in the turnep fibres as their riſing after they had paſſed the furrow.

The *roots* of a common thorn hedge may be obſerved to run horizontally in their natural direction, and if they come to a ditch they will deſcend perpendicularly till lower than its bottom, and then running acroſs it, they will immediately mount again toward the ſurface, and extend themſelves horizontally at the depth of eight or ten inches to a great diſtance: on opening the earth at five feet diſtance from the ditch, the *roots* will be found tolerably large, and none of them reaching deeper than the common mould, which ſeldom is above a ſpade deep.

Mr. Tull mentions a very extraordinary inſtance of the ſpreading of the *roots* of trees in that of a witch elm; a chalk pit contiguous to a barn, the area of which was about forty perch of ground, was made clean and ſwept, ſo that it could plainly be ſeen that there was no vegetable matter about it, any more than in the floor of the barn: ſtraw was thrown from thence into the pit for cattle to lie on, and about three years after the pit was cleanſed, the dung made in it being taken up; the bottom of the pit, and the top of the chalk were at this time covered with *roots*, and theſe were found to come from a witch elm, of not more than five or ſix yards in height, which was about five yards above the area of the pit, and eleven yards from it; ſo that in three years the *roots* of this tree had extended themſelves to eight times the length of the body of the tree, beyond the extremity of the old *roots*, at eleven yards diſtance from the bottom of the trench, whence the original *roots* proceed. The annual encreaſe of the length of the *roots* in this caſe was about three times as much as the whole length of the tree.

The vegetable mould which lies uſually from the ſurface, to about a foot deep, being a proper place for the *roots* of trees, they will riſe into it, tho' the unſkilful hand of man plant them deeper. Thus in an orchard where the trees are ſet too deep, their *roots* all aſcend till they come to a proper ſcene of nouriſhment; but if the ground be moiſt there is a diſadvantage in this, for the *roots* paſſing thro' a watery place are chilled, and the circulation retarded.

The generality of the world ſuppoſe, that the horizontal *roots* of plants are much ſhorter than they really are, becauſe they ſee that they are pretty taper near the *root*, and ſeem to come to a point very ſoon: by this obſervation they conclude that they diminiſh on in the ſame proportion that they do there, and conſequently that they very ſoon come to an end. But by this means they calculate their length at leſs than one twentieth part of what it really is; for the truth is, that after the length of a few inches from the main *root*, they are not diſcernibly taper, but paſs on in the ſame bigneſs to their very ends. This may be ſeen at any time in the *roots* of plants growing in water, and with care in the tracing them it may alſo be ſeen in thoſe which grow in the earth; but the reaſon why it is not commonly ſeen in theſe, is that they generally break off in the taking up about the part where they grow taper. Many plants which ſeem to have only large naked *roots* have theſe horizontal ones, which tho' ſmall are branched out into many leſſer fibres, and convey a great deal of nouriſhment to the plant, and that from a great diſtance. If a common carrot be taken up and examined, there will be found many fine fibres, like hairs growing from its ſides: each of theſe examined with a microſcope, will be found to be a *root* not going taper, but all the way of the ſame bigneſs broken off at the end, and ſending numerous fibres from its ſides; all theſe are extended to ſome length, and then appear broken off as the other; and it is very probable from what is known to be the caſe in the turneps, that this horizontal *root* is in its natural ſtate extended four, five, or ſix feet from the carrot, all the way of the ſame length, and all the way ſending out its lateral ſhoots or fibres which run upwards and downwards the whole ſpace of the ten or twelve inches of vegetable mould. If ſo, from what a diſtance every way, and by what an immenſe number of channels does this plant receive nouriſhment?

The uſe of digging the earth to a great diſtance every way from the *roots* of ſuch plants as are deſired to thrive well, is evident from this: for theſe tender *roots* which in an open mould will run to ſo many feet diſtance, are pinched up, and deſtroyed when they come into a hard and undug earth. The advantage of having clear ſpaces between plants cultivated for uſe, is alſo plain from this, ſince they all have *roots*, tho' imperceptible to us, which occupy thoſe ſpaces, and draw nouriſhment from them.

Many plants are of a ſort of amphibious nature, and grow as well in water as on land; the perſicaria ſalicis folio, or willow leaved arſmart, called when in the water, the long leaved pond-weed, is an inſtance of this kind. This in the water and on the land makes ſo different an appearance, that the old botaniſts have taken it for two different plants. The *roots* of this, and of all other ſuch plants, are much longer when they grow on land, than when in water.

The ſecrets of vegetation as carried on by *roots*, and the uſes one part of the *root* is of to the other parts, are yet far from being underſtood to perfection. We know indeed that all *roots* imbibe moiſture from the earth, but it alſo appears, that they part with that moiſture again in the form of water, as they received it without carrying it all up into the body of the plant on certain occaſions. If a piece of flouriſhing mint in a water glaſs be ſo contrived, that while the *roots* from one joint are all immerſed in water, thoſe of an upper joint he received into a box, and laid all at one corner of it, and the box filled with ſand dryed at the fire; after a nights ſtanding, the water in the glaſs will be found ſenſibly decreaſed, and the ſand at that corner of the box where the *roots* of the mint are, will be found very wet, while all the reſt remains dry. This water which has thus wetted the ſand, muſt have been received into the lower *roots*, and from thence conveyed to the upper ones, and they muſt have again delivered it out into the ſand, inſtead of carrying it up into the body of the plant. Let a trough of earth be prepared of two feet in length, and let a ſtrong ſhoot of mint be ſet in a glaſs of water at each end of the trough, and while half the *roots* of each are placed in the water, let the other half be laid in the trough and covered with dry earth in powder; this dry earth will ſoon become moiſt, and the *roots* will ſhoot out beyond its ſurface. Theſe are to be covered with ſoft earth as they appear, till the trough will hold no more; the whole trough will thus be ſoon filled with the *roots* of theſe two ſhoots of mint, and thoſe *roots* which riſe to the ſurface, and are not covered, will be ſeen to bend down their points and enter the earth again.

Theſe mints grow greatly faſter than thoſe which are planted either in water alone, or in water with earth in it; and the earth in the trough will always be found thoroughly moiſtened, tho' no water is put to it, except what ariſes from the lower *roots*, and is carried to theſe upper ones, which are placed in the earth. The quantity of water thus ſent up by the lower *roots*, and thrown into the earth above by the upper ones, is more than a thouſand times the whole weight of the plants, and ſeems to have never mixed itſelf with the juices of the plant at all, but to have been evacuated pure water as it was received without ever going any higher than the upper *roots*.

The glaſſes in theſe experiments need very frequent ſupplies, a day or two being ſufficient to drain them; but what is remarkable is, that if they are ſuffered to be without water in the glaſſes, they will not dry up or wither, but the *roots* below, as well as the plant above, will be

kept in a flouriſhing ſtate for ſome time by the wet earth in the box. Theſe experiments ſhew us a uſe in the ſeveral parts of the *roots* of plants, which providence has wiſely allotted for the ſervice of the whole, and which we can otherwiſe have no idea of. Every part of the *roots* of the ſame plant is thus found to be capable of ſupplying all the reſt; and it is evident, that the ſeveral portions of the *roots* in the mint communicate one with another by means of veſſels which ſerve only to carry water from the one to the other, without mixing it with the juices of the plant. Such veſſels of communication there muſt have been between the two ſets of *roots* of this mint, which muſt have paſſed thro' that part of the ſtalk of the plant, which was between the two joints, tho' ſeveral inches in length, and by theſe while one root was kept moiſt, the other was moiſtened by it, whether the upper one, or the lower one was in the moiſt place, and then the nouriſhment was carried up by both to the plant.

From this we ſee the great uſe of tap *roots* to plants, and underſtand the reaſon why the lucerne, ſaint-foin, and other plants which have long tap *roots* produce ſuch numerous branches and ſucceed ſo well in dry ſeaſons, when the ſhorter *rooted* plants are nearly deſtroyed. The earth at a great depth is always moiſt, and theſe tap *roots* penetrating to that depth imbibe that moiſture, and ſend it up to the upper *roots*, which diſcharge it into the earth near the ſurface, as the upper *roots* of the mint do into the earth in the trough; and thence all the fibrillæ of the whole ſet of horizontal *roots* are ſupplied with a proper degree of moiſture in the earth, where they run and grow almoſt as well as in moiſt weather. If this was not the caſe, the *roots* which are ſpread thro' the upper ſurface of the earth could be of no ſervice to the plant in dry weather.

The ſtirring of the earth about the *roots* of plants has been a practice long uſed by our gardiners, who were well acquainted with the effects of it, tho' ignorant of its cauſe. The *roots* of plants ſend out horizontal fibres every way, and theſe ſend out fibrillæ on every ſide from them, which run thro' the whole upper ſtratum of vegetable mould: every time this mould is ſtirred, a great number of theſe fibres and fibrillæ are broken off, and the conſequence of this is, that they encreaſe in number, ſeveral new *roots* always ſhooting out in the place of one that was broken off; and as the number of *roots* is the great means of the ſupply of a plant, every time the earth is ſtirred, that number, and conſequently that ſupply is encreaſed.

There ſeems no danger of the plant's being ſurfeited by an over ſupply of nouriſhment this way; for we ſee nature has provided for a diſcharge of the abundant moiſture by the other *roots*, as we find by the water diſcharged into the earth in the trough. It remains yet to try whether the fluid thus evacuated be pure water as received, or be altered into the nature of the plant. This cannot be eaſily determined by mint; but if a ſtronger flavoured plant, ſuch as garlick, be ſet in water, and part of its *roots* placed in a bed of flower inſtead of earth, it will be ſoon ſeen whether the flower in this caſe be moiſtened as the earth in the other, and the taſting it will ſhew whether it be moiſtened with pure water, or with water altered to the taſte and nature of the plant. *Tull*'s Horſehoeing Huſbandry.

Preparation of ROOTS, there are ſeveral ways of preparing *roots* for medicinal uſe in the eaſtern nations, which ſtrongly alter them from their original form and appearance. An inſtance we have of this in the drug called *ſalep*, which is no other than the *root* of an orchis thus prepared. See the article SALEP.

Other *roots* they alſo prepare in the ſame manner, or ſomething like it; an inſtance of which we have in ſome of the oriental ginſeng, which is clear and pellucid as a reſin, and friable like one, retaining very little of the ſtructure or appearance of the *root*. Kempfer gives the method by which the people in the eaſt do this, and it may be well worth trying on ſome of our own *roots*.

The Chineſe, this author informs us, give their ginſeng its colour and tranſparence in this manner. They macerate the freſh *root* for three days in cold rice water, then expoſe it in cloſe veſſels, to the vapour of the ſame water; after which they carefully and leiſurely dry it, and it becomes hard and brittle, of a browniſh red colour, and as tranſparent as a reſin.

All the ginſeng of China is not of this ſort, and it has been ſuppoſed by ſome, that ſuch as was ſo, had aſſumed that appearance by age, as many of the more ſucculent *roots*, which have very ſmall fibres, will become much leſs opake when perfectly dry, than they were at firſt; but experience ſhews that this is not the caſe, for many perſons have kept the oriental ginſeng a great many years, but it has never been known to aſſume that appearance. There is no doubt however, but that if the Weſt Indian ginſeng were treated in this manner, it would equal the prepared ginſeng of the eaſt: for the *roots* of ſome of our umbelliferous plants, particularly the ſkirret, may be made clear and tranſparent in this manner, by only boiling it in common water, and afterwards drying it in the open air. Mem. Acad. Scien. Par. 1740.

Flower-ROOTS. See the article FLOWER.

ROOT *of oſteocolla*, a word uſed to expreſs a ſort of ſoft and rotten matter, on which the *oſteocolla* of Germany is found in ſandy grounds.

The workmen ſeek after the *oſteocolla* by the direction of certain lumps, of a white marley matter, which they find lying on the ſands; under this they always find a parcel of rotten vegetable matter, branching out from a main ſtem or trunk, at ten or twelve feet deep up to the ſurface; this rotten ſubſtance they call the *root of the oſteocolla*; and they obſerve, that where the matter they ſeek after is not found round it at the time of their digging, they need only mark the place, and dig again a year afterwards, and they will find it formed in a perfect manner. The *oſteocolla* found near Frankfort is all of this kind; and we find the holes in the center of all the pieces, through which this *root* had paſſed. It is ſo tender that it uſually moulders away on the *oſteocolla*, being expoſed to the air; but ſometimes they waſh it out. Phil. Tranſ. N° 39. See OSTEOCOLLA.

It is not eaſy to conceive what this is, unleſs the remains of foſſile branches of trees; but even then it is as difficult to account for the formation of the *oſteocolla* about them, as there is none of it found concreted where they are not. We have a ſort of *oſteocolla* found with us in what we call petrifying ſprings; but as this is done in the water, it is eaſier to conceive how it becomes ſo pure, than how a ſoft and pappy ſubſtance found in the midſt of a bed of ſand, comes not to have ſome ſand embodied in it.

ROOT, in mathematics (*Cycl.*)—The extraction of the *roots* of algebraic quantities, may be performed in a manner analogous to that uſed in arithmetic, for extracting the *roots* of numbers; and if the *root* cannot be accurately found, the proceſs may be continued indefinitely, which will give a ſeries. Thus the quantity $aa + xx$ being propoſed, its ſquare *root* thus extracted will be found to be,

$$a + \frac{x^2}{2a} - \frac{x^4}{8a^3} + \frac{x^6}{16a^5} - \frac{5x^8}{128a^7} + \frac{7x^{10}}{256a^9} -, \&c.$$

See Newton's *Meth. of Fluxions & inf. ſeries*, p. 4. of Mr. Colſon's Edit.

But the extraction of *roots* may be abbreviated by that great author's *binomial theorem*, which he thus expreſſes in his letter to Oldenburgh.

$$\overline{P+PQ}^{\frac{m}{n}} = P^{\frac{m}{n}} + \frac{m}{n}AQ + \frac{m-n}{2n}BQ + \frac{m-2n}{3n}CQ + \frac{m-3n}{4n}DQ +, \&c.$$

Where $P + PQ$ ſignifies the quantity whoſe *root*, or dimenſion, or *root* of any dimenſion, is to be inveſtigated. P, is the firſt term of the quantity; Q, the reſt of the terms divided by the firſt. And $\frac{m}{n}$ is the index of the dimenſion or power of $P + PQ$, whether that denomination be a whole number, a fraction, affirmative or negative. Laſtly, A, B, C, D, &c. repreſent the terms of the *root* as they are found; that is, A ſtands for the firſt term $P^{\frac{m}{n}}$, B for the ſecond $\frac{m}{n}AQ$, &c. The uſe of the rule will appear by a few examples.

1. To find the ſquare root of $cc + xx$; that is, $\sqrt{cc+xx}$, or $\overline{cc+xx}^{\frac{1}{2}}$. Subſtituting cc for P, $\frac{xx}{cc}$ for Q, 1 for m, 2 for n, $cc^{\frac{1}{2}} = c = P^{\frac{m}{n}} = A$, &c. we ſhall have $\overline{cc+xx}^{\frac{1}{2}} = c + \frac{xx}{2c} - \frac{x^4}{8c^3} + \frac{x^6}{16c^5} -, \&c.$

2. In like manner $\frac{N}{\sqrt[3]{y^2 - a^2y}}$ or $N \times \overline{y^3 - a^2y}^{-\frac{1}{3}}$ will be found equal to $N \times \frac{1}{y} + \frac{a^2}{3y^3} + \frac{2a^4}{9y^5} + \frac{14a^6}{81y^7} +$ &c.

For $P = y^3$, $Q = \frac{-aa}{yy}$, $m = -1$, $n = 3$, $A = P^{\frac{m}{n}} = y^{3 \times -\frac{1}{3}} = y^{-1} = \frac{1}{y}$, $B = \frac{m}{n}AQ = -\frac{1}{3} \times \frac{1}{y} \times \frac{-aa}{yy} = \frac{aa}{3y^3}$, &c.

3. Simple powers may be found in the ſame way. Thus, if $\overline{d+e}^5$, or $\overline{d+e}^{\frac{5}{1}}$ were required. Then by the rule $P = d$, $Q = \frac{e}{d}$, $m = 5$, and $n = 1$. Hence, $A = P^{\frac{m}{n}} = d^5$, $B = \frac{m}{n}AQ = 5d^4e$, &c. $C = 10d^3e^2$, $D = 10d^2e^3$, $E = 5de^4$, $F = e^5$; and laſtly, $G = \frac{m-5n}{6n}FQ = 0$.

Here the ſeries terminates, and therefore $\overline{d+e}^5 = d^5 + 5d^4e + 10d^3e^2 + 10d^2e^3 + 5de^4 + e^5$.

4. Di-

4. Diviſion may be performed by the ſame rule. Thus, if it were required to divide 1 by $d+e$. Then $\frac{1}{d+e} = \overline{d+e}^{-1} = \overline{d+e}^{-\frac{1}{1}}$. Hence by the rule, $P=d$, $Q=\frac{e}{d}$, $m=-1$, $n=1$, $A=P^{\frac{m}{n}}=d^{-\frac{1}{1}}=d^{-1}=\frac{1}{d}$, $B=\frac{m}{n}AQ=-1\times\frac{1}{d}\times\frac{e}{d}=\frac{e}{d^2}$, and $C=\frac{ee}{d^3}$, $D=-\frac{e^3}{d^4}$, &c. That is, $\frac{1}{d+e}=\frac{1}{d}-\frac{e}{d^2}+\frac{e^2}{d^3}-\frac{e^3}{d^4}+$ &c.

See *Newt. Epiſt. ad Oldenburgh.* Tom. 3. Oper. Wallis. *Analyſ. per quant. Series*, &c. Lond. 1711. p. 23. ſeq.

The method of extracting the *roots* of numbers, mentioned in the Cyclopædia under the head EXTRACTION, is the ſame as that given long ago by Vieta, and is to be met with in almoſt all books of arithmetic and algebra. Monſ. de Lagni and Dr. Halley have given us much more expeditious methods. Dr. Halley's rules for the ſquare and cube are inſerted in the Cyclopædia, under APPROXIMATION; only one of the formulæ for the cube is erroneouſly printed. We ſhall here inſert the doctor's rules which extend to the ſeventh power, and may eaſily be continued at pleaſure, the law of the continuation being obvious.

$\sqrt{aa\pm b}=\sqrt{aa\pm b}$, or $a\pm\frac{ab}{2aa\pm\frac{1}{2}b}$.

$\sqrt[3]{a^3\pm b}=\frac{1}{2}a+\sqrt{\frac{1}{4}aa\pm\frac{b}{3a}}$, or, $a\pm\frac{ab}{3a^3\pm b}$

$\sqrt[4]{a^4\pm b}=\frac{2}{3}a+\sqrt{\frac{1}{9}aa\pm\frac{b}{6aa}}$, or, $a\pm\frac{ab}{4a^4\pm\frac{3}{2}b}$

$\sqrt[5]{a^5\pm b}=\frac{3}{4}a+\sqrt{\frac{1}{16}aa\pm\frac{b}{10a^3}}$, or, $\pm\frac{ab}{5a^5\pm 2b}$

$\sqrt[6]{a^6\pm b}=\frac{4}{5}a+\sqrt{\frac{1}{25}aa\pm\frac{b}{15a^4}}$, or, $a\pm\frac{ab}{6a^6\pm\frac{5}{2}b}$

$\sqrt[7]{a^7\pm b}=\frac{5}{6}a+\sqrt{\frac{1}{36}aa\pm\frac{b}{21a^5}}$, or $a\pm\frac{ab}{7a^7\pm 3b}$

For the application of theſe formulæ or rules, obſerve, that a denotes the neareſt *root* to that of the propoſed number, whether greater or leſs than the true; and that b is the difference between this *root*, involved to the proper power, and the propoſed number. Thus, if it were propoſed, to extract the cube *root* of 231, the neareſt cube to it is 216, the *root* of which is $6=a$, and the difference between 231 and 16 is $15=b$. The *root* required will therefore be $=\frac{1}{2}a+\sqrt{\frac{1}{4}aa+\frac{b}{3a}}=3+\sqrt{9+\frac{5}{6}}=3+\sqrt{9.8333}=6.1358$. But this is only a firſt approximation. For a ſecond ſuppoſe $6.1358=a$; then its cube will be $=231.000853894712$, which is greater than the truth, and the difference $0.000853894712=b$. Therefore the *root* $=\frac{1}{2}a+\sqrt{\frac{1}{4}aa-\frac{b}{3a}}=3.0679+\sqrt{9.41201041-\frac{0.000853894712}{18.4074}}=6.13579243$-966195897 true to the eighteenth figure, which Dr. Halley aſſures us he computed within an hour.

By this example the method of working may be ſufficiently clear, and the uſe of the double ſign $\pm$ is obvious. When a is leſs than the truth, then a^3+b repreſents the given number; but when a is greater than the truth, the propoſed number will be repreſented by a^3-b. In the firſt caſe, the *root* is $\frac{1}{2}a+\sqrt{\frac{1}{4}aa\pm\frac{b}{3a}}$ or $a+\frac{ab}{3a^3\pm b}$, and in the ſecond caſe it is $\frac{1}{2}a+\sqrt{\frac{1}{4}a^2-\frac{b}{3a}}$ or $a-\frac{ab}{3a^3-b}$.

Dr. Halley juſtly obſerves, that the irrational formulæ, $\frac{1}{2}a+\sqrt{\frac{1}{4}aa\pm\frac{b}{3a}}$ is preferable to the rational, $a\pm\frac{b}{3a^3\pm b}$; becauſe the extraction of the ſquare *root* is much eaſier than a diviſion by ſo great a diviſor, as $3a^3\pm b$.

Theſe rules are at leaſt triple the figures of the *root* at every new operation. Thus, in the foregoing example, by the firſt operation, we had five figures, *viz.* 6.1358 for the *root*; and at the ſecond, we had the *root* true to eighteen places.

Monſ. de Lagni publiſhed a rule for the ſurſolid *root*, or fifth power, which quintuplicates the figures of the *roots*, at leaſt. The rule is this,

$\sqrt[5]{a^5\pm b}\quad\sqrt{\frac{1}{2}a+\sqrt{\frac{1}{4}a^4\pm\frac{b}{5a}}-\frac{1}{4}aa}$

See Phil. Tranſ. N° 210, or Lowthorp's Abridgment, Vol. 1. c. 1. Sect. xx. p. 81. Mac Laurin's Algebra, p. 242. Simſon's Algebra, p. 155. Where various general theorems for approximation to the *roots* of pure powers are given. See alſo EQUATION.

For common uſe, theſe extractions may be moſt commodiouſly performed by logarithms: dividing the logarithm of the power by the index of the required *root*, that is two for the ſquare, three for the cube, &c. the quotient is the logarithm of the *root*; which may therefore be found by the tables.

In ſome books we have tables of ſquare and cube numbers, by which the neareſt ſquare or cube to any propoſed number within the limits of the table, may be found by inſpexion. *Preſtet* has given a table of this kind in his *Elemens des Mathematiques.*

For the *roots* of adfected equations. See EQUATION.

Seminal ROOT. See the article SEMINAL.

Cube ROOT, in geometry. Obſerve, that the *cube root* of any quantity A^3 may be A, or $\frac{-1+\sqrt{-3}}{2}\times A$, or $\frac{-1-\sqrt{-3}}{2}\times A$.

This follows from what was ſhewn under the head UNITY, that the *cube roots* of unity or 1 are 1, $\frac{-1+\sqrt{-3}}{2}$, $\frac{-1-\sqrt{-3}}{2}$. Hence the *cube roots* of A^3 or of $1\times A^3$ will be as above mentioned. *Mac Laurin's* Algebr. p. 226. where he ſhews the uſe of ſuch expreſſions.

In general, every power has as many *roots*, real and imaginary, as there are units in the exponent of the power. *Mac Laurin* Ibid. p. 128.

Impoſſible ROOT is not only the ſquare *root* of a negative quantity, but any other *root* denominated by any even number. Thus $\sqrt[4]{-1}$, $\sqrt[6]{-1}$, $\sqrt[8]{-1}$, or in general $\sqrt[2m]{-1}$ or $\sqrt[2m]{-x}$ are all impoſſible roots, or quantities.

Some call them *imaginary roots* or quantities.

ROPALON, in botany, a name given by ſome authors to the *nymphæa*, or *water lilly*, and alſo to the *faba ægyptia* of the river Nile.

ROPE (*Cycl.*)—*Standing* ROPES, in a ſhip, the ſhrowds and ſtays are ſo called, becauſe they are not removed, unleſs to be eaſed or ſet taught.

ROQUET, in zoology, the name of a ſpecies of American lizard, of ſmall ſize, and of a reddiſh brown colour, variegated with black and yellow ſpots. Its fore legs are remarkably long for a creature of this kind; its eyes are particularly vivid and ſparkling, and its head is carried continually erect; and the creature is almoſt eternally in motion, hopping about like a bird, and it uſually carries its tail bent into a ſemi-circle over the back. It is far from being ſhy or timorous, and is delighted at the ſight of men; when tired with play or with running, it will open its mouth and pant, and loll out its tongue as the dogs do. *Rochefort*, Hiſt. Antill.

ROS (*Cycl.*—ROS *mayalis*, *maydew*, the *dews* that fall in the beginning of ſummer, particularly in this month, have great virtues attributed to them by many authors, when newly gathered and clean filtered. It is not of a watery appearance, or colourleſs, but is yellowiſh, and much reſembles the urine of a healthful perſon. The common methods of putrifying water alſo have no effect on *dew*. Several quantities of it have been placed in digeſtion with different degrees of heat, from that of dung to that of a ſand ſurface, but no putrefaction brought on it, though continued two months together; the heat, in whatever degree, ſerving to purify it, not to hurt it. The ſummer ſun, for all the hot months together, has no more effect on it. It only ſends out a green vegetable matter of the conferva kind which floats on the ſurface, and adheres to the ſides of the veſſel, and the whole quantity of the liquor remains as pure as before. Phil. Tranſ. N° 3.

Though theſe common methods of putrefaction do not take place in this fluid, a much more ſimple proceſs will. If a quantity of it be put into an open wooden veſſel, and ſet in a cool ſhady place, with a canvas ſtretched over it to keep out duſt and inſects, it will in three or four weeks putrefy and ſtink, and depoſite a large quantity of a black and thick mud. The manner of the formation of this ſediment is this: a ſmall quantity of a foul matter firſt ſeparates itſelf from the liquor, and floats at the top in form of a ſkin or film; this ſoon after precipitates itſelf to the bottom, and another ſucceeds in its place at the top, which is ſoon after precipitated in the ſame manner. Thus the mud is a congeries of theſe films one on another. If a quantity of *dew* be put into a long and narrow glaſs veſſel, theſe films, inſtead of ſinking, as ſoon as formed, will combine one with another at the top, and form a thick ſcum, which may be taken off with a ſpoon, and is very different from the black mud, ſeparated to the bottom in the former experiment, being

being a white and thick ſlime: if a quantity of this be put into a drinking glaſs, or other ſuch veſſel, and the water drained from it, it will ſomewhat ſhrink in twelve hours ſtanding, and will become ſo ſolid as to take the form of the glaſs, and may be ſhook out; it then reſembles a lump of boiled white ſtarch, but is ſomewhat more tranſparent.

We have, in the Philoſophical Tranſactions, a very remarkable account of a vegetable production from this jelly. A perſon having put a quantity of it into a double veſſel, in order to putrify it, obſerved, that after ſome days, the moiſture was in great part evaporated, through a fault in the luting of the junctures, and that a large muſhroom was growing up out of the almoſt dry reſiduum. It was, he ſays, of a ſpungy and watery nature, and of the ſame nature with ſome which he had ſeen growing out of rotten wood. The warmth employed in this digeſtion was that of a *balneum mariæ*. The probable account of this is, that the ſeeds of this muſhroom, which are very light, and eaſily wafted about every where by the winds, had fallen into the jelly, in the time of its being expoſed; and finding it a proper nidus, had, by means of the additional warmth, which is alſo greatly beneficial to all the muſhroom claſs, been ſet a growing, and arrived at their perfection in the form of the parent plant they fell from. There are in the ſame paper other odd accounts of productions of the animal kingdom, in the ſame *dew*, which might puzzle any one not verſed in experiments of this kind with other fluids. In one of the veſſels of this *dew* he found millepides, differing from the common kind in ſome particulars. Theſe were the common water millepides; and in another he found a quantity of green matter, probably a conferva, with numerous eulæ of inſects inhabiting it; for in a few days there were produced from this a vaſt number of flies. Another parcel of the *dew*, ſet in an open glaſs, was found after ſome days filled with the eulæ of the common gnat, and the flies were hatched from theſe. Phil. Tranſ. N° 3.

It is eaſy for a bad philoſopher to infer from theſe accounts the equivocal generation of theſe creatures in the water; but the inſight we have had into the wonders of nature in the inſect world are ſuch, that at preſent we know their generation to be in many ſpecies, particularly in the gnat and fly kinds, from the eggs of their parents depoſited in water, or any watery fluids, and that common ditch water will at any time do what the *dew* does in this experiment.

Ros *ſolis*, *ſundew*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, compoſed of ſeveral leaves, arranged in a circular form. The cup is tubular, and the piſtil which ariſes from it is at length converted into an oval pointed fruit, which opening at the extremity, diſcovers a number of oblong, or roundiſh ſeeds. To theſe marks, it is to be added, that the leaves are covered with long hairs, from which there ſeem to be ſeparated large drops of water.

The ſpecies of *ſundew* enumerated by Mr. Tournefort are theſe. 1. The common round leaved *ſundew*. 2. The common long leaved *ſundew*. 3. The perennial round leaved *ſundew*. 4. The perennial long leaved *ſundew*. 5. The largeſt, long leaved *ſundew*; and 6. The Portugal *ſundew*, with leaves like thoſe of the ſmaller aſphodel. *Tourn.* Inſt. p. 244.

ROSA, the roſe. See the article ROSE.

ROSA *crucis*, in church hiſtory. See ROSYCRUCIANS, *Cycl.*

ROSA *fatuina*, in botany, a name given by ſome authors to the piony.

ROSA *junonis*, in botany, a name given by ſome authors to the lilly.

ROSACEOUS *flower*, *roſaceus flos*, in botany, a term uſed to expreſs ſuch flowers, as are compoſed of ſeveral petals or leaves, diſpoſed in a ſort of circular form, like thoſe of the roſe: ſuch are the flowers of the piony, crowfoot, cinquefoil, *&c.* In this ſort of flowers the diſpoſition only of the leaves is regarded, their number being of no conſequence. It is very ſeldom that the number is two or four, except in the circæa and onagra. The moſt frequent number of leaves in theſe flowers is five, and ſuch as have four differ from the cruciform flowers, not only in their diſpoſition, but in this, that the number is in the ſame ſpecies indeterminately four, five, or ſix, as is the caſe in the clematitis, the capers, and the ſpecies of rue, whereas in the cruciform ones it is ever conſtant. See Tab. 1. of Botany, Claſs 1. *Tourn.* Inſt. p. 234.

ROSACLORUM, or according to ſome authors *roſi-chiero*, a fine red uſed to enamel on gold with. It is prepared in this manner: take ten pound of cryſtal glaſs, put it into a pot, and when it is well melted, add to it, at twice, a pound of the beſt red lead, ſtir the maſs well together, and afterwards caſt it into water. Repeat this proceſs three times, then when the matter is again in fuſion, mix with it five ounces of calcined braſs, and the ſame quantity of the deepeſt cinnabar; ſtir the whole well together, and let it ſettle three hours; then add of glaſs of tin three ounces, mix the whole, and it will be of a fine roſe colour. *Merret*'s Notes on Neri, p. 350.

ROSALIA, a name uſed by authors for the meaſles, or a diſeaſe very like the meaſles, conſiſting in a number of aſperities and protuberances of the ſkin, which ſoon die away.

ROSARBA, in botany, the name of an imaginary plant, which has given great trouble to the commentators on the works of the antients.

The Arabian writers, Aviſenna, Serapion, and others, have mentioned two kinds of carob or ceration; the one eſculent, and endued with the virtue of a gentle purgative, the other an aſtringent.

This laſt they have diſtinguiſhed from the other by the name of the nabathæan pod or aljembut. They ſay, in their deſcriptions, that the aljembut is like the *roſarba*, ſo run the old tranſlations, but the true meaning of the original is *roſa vineæ*. This was a name given to the common wild acacia tree, and the tree which produced the nabathæan pod, might be very well likened to this; it being, in reality, only a ſpecies of the acacia, and the ſuccus acaciæ, or inſpiſſated acacia juice of the ſhops; being, according to Iſidore, made oftentimes from the unripe fruit of this very ſpecies.

ROSARIA, among the Romans, a kind of perfumes, ſo called, either from their being chiefly made of roſes, or becauſe they had a moſt exquiſite odour.

ROSARY (*Cycl.*) is a word frequently met with in the antient hiſtories of Ireland, and uſed to expreſs a peculiar ſort of baſe money coined abroad, in the form of the penny, current in that kingdom; but of ſo much baſer an alloy, that it was not worth quite half the real value of the penny. This and many other ſuch coins were decried, and it was made death to import any of them by Edward the firſt in 1300.

ROSBOTH, a word uſed by ſome authors to expreſs a ſoft excreſcence from any part.

ROSCOLÆ, a name given by ſome medical writers to the meaſles.

ROSE, ROSA, in botany, the name of a genus of trees, the characters of which are theſe. The flower is compoſed of ſeveral petals arranged in a circular form. The cup is compoſed of ſeveral leaves, and finally becomes a roundiſh or oblong fleſhy fruit, which is unicapſular, and contains a number of angular hairy ſeeds.

The ſpecies of *roſe* enumerated by Mr. Tournefort are theſe. 1. The ſingle red *roſe*. 2. The double red *roſe*. 3. The double reddiſh black *roſe*. 4. The red *roſe* which does not open. 5. The ſingle pale red *roſe*. 6. The double pale red *roſe*. 7. The deep or blackiſh red *roſe*. 8. The purple *roſe*. 9. The ſingle purple *roſe*. 10. The changeable coloured *roſe*. 11. The Engliſh changeable *roſe*. 12. The red and white variegated *roſe*. 13. The Ciphian *roſe*, or ſmall pimpernel leaved Scotch *roſe*, with elegantly variegated flowers. 14. The greateſt double *roſe*. 15. The middle ſized double *roſe*. 16. The great ſingle white *roſe*. 17. The great double white *roſe*. 18. The ſmall white *roſe*. 19. The large muſk *roſe*. 20. The ſingle flowered muſk *roſe*. 21. The double flowered muſk *roſe*. 22. The evergreen muſk *roſe*. 23. The large flowered *roſe* without prickles. 24. The ſmall flowered *roſe* without prickles. 25. The curled leaved *roſe* with bright red flowers. 26. The common wild *roſe* with a pale ſweet ſcented flower. 27. The wild *roſe* with a large deep red flower. 28. The double flowered dog *roſe* or wild briar. 29. The *eglantine*, or *ſweet briar*, with double flowers. 30. The common ſingle flowered *ſweet briar*. 31. The wild *roſe* with red very ſweet ſcented flowers. 32. The wild *roſe*, with a white very ſweet flower. 33. The ſingle cinnamon *roſe*. 34. The double flowered cinnamon *roſe*. 35. The ſmall red *roſe*, commonly called the May *roſe*. 36. The ſingle yellow *roſe*. 37. The double yellow *roſe*. 38. The very thorny field *roſe* with a white ſweet ſcented flower. 39. The dwarf very thorny *roſe* with red flowers. 40. The dwarf alpine *roſe*, with ſmall roundiſh pimpernel leaves, and very little flowers, of a livid red. 41. The wild dwarf red *roſe*. 42. The great wild apple *roſe*. 43. The white field *roſe*. 44. The creeping white field *roſe*. 45. The ſmalleſt *roſe*. 46. The two flowered field *roſe* without prickles. 47. The pale red mouth *roſe*. 48. The white mouth *roſe*. 49. The double pale red mouth *roſe*. 50. The ſingle purple mouth *roſe*. 51. The crimſon *roſe*. 52. The Frankfort *roſe* with a thick cup, which does not open its flowers; and 53. The wild *roſe* or briar with large hairy fruit. *Tourn.* Inſt. p. 637.

We have a vaſt variety of theſe beautiful flowers preſerved in our gardens; ſome few of which are natives of our own country, but the far greater number are of foreign origin. They are all propagated either by ſuckers, by layers, or by binding them on the other ſorts of *roſes*; the laſt method is but ſeldom practiſed, but is neceſſary for the finer ſorts, which do not naturally ſhoot vigorouſly, and which produce few or no ſuckers. The beſt ſort of *roſe* for ſtocks is the Frankfort kind; the ſeaſon for doing it is in June, and there muſt be great care afterwards, that the ſtock produce no ſuckers at the bottom, for theſe would ſoon ſtarve the bud. *Miller*'s Gardner's Dict.

When *roſes* are to be propagated from ſuckers, they are to be taken off annually, and planted into nurſery beds, or into the places where they are to remain. They always take

take root well the firſt year, but if ſuffered to remain on the ſtock longer, they grow woody, and often fail.

But the beſt method of obtaining vigorous plants, is, by laying down the ſhoots; this is to be done in autumn, and by the autumn following they will have taken root ſo well, that they may be taken off from the old plant, and removed to the places where they are to remain. Theſe may be tranſplanted any time from October to April, but the earlier the better.

Roſes, in general, delight in a rich moiſt ſoil, and an open ſituation, in which they will produce great quantity of flowers, and thoſe much more beautiful than when they are on a dry ſoil and ſhady ſituation.

All the pruning they require is to have their dead wood cut, and their ſuckers taken away every autumn; and if there are any very luxuriant branches they may be ſhortened, and the doing this will ſupply the other parts of the tree with freſh wood. *Miller*'s Gardners Dict.

Eſſence of ROSES. There is ſcarce a more valuable perfume in the world than the eſſence of damaſk *roſes*, and ſcarce any thing is obtained from its ſubject with more difficulty and in leſs quantity. All eſſences or eſſential oils are, while in the plant, contained in certain veſicles, lodged in different parts, and of different ſtructure; theſe veſicles are in the *roſe* particularly ſmall and tender, and are placed very ſuperficially; the conſequence of this is, that there is originally but a very little of this eſſence in the flower, and this is the very ſubject that will be diſſipated and loſt when the flowers are gathered and thrown in a heap together, as they are ſucculent, and very quickly heat in lying together. To avoid all diſſipation and waſte of this choice eſſence, the *roſes* ſhould be thrown into the ſtill as ſoon as gathered, and diſtilled with very little water, and that in a balneum mariæ; then the fire is to be continued ſo long as the flowers float ſeparate about in the water; but as ſoon as ever they form themſelves into a cake, and ſtick to the bottom, the diſtillation ſhould be finiſhed, as they then yield no more eſſence. With all theſe precautions, however, it is with great difficultly we can procure any eſſence of *roſes*. What we obtain by this diſtillation being chiefly a very odoriferous and fragrant water. In the warmer countries the ſame caution affords a larger quantity of oil, which may be ſeparated and preſerved under the name of the eſſence. In Italy they make ſome quantity of it, but there it is very dear; a vaſt quantity of the flowers yielding only a very little eſſence, and that being thick and troubleſome in the procuring, as it every where ſticks to the veſſels.

It is to be obſerved, that the ſeaſon of the year, as to wet or dry, makes a very great difference in the eſſential oils of all plants; they are always much finer in dry and hot ſeaſons than in cold and moiſt: we find our *roſe* water in England much finer, and more fragrant, though diſtilled in the ſame proportion in hot and dry ſummers than in colder and rainy ones; and Mr. Geoffroy gives an account that he ſucceeded, one very hot and dry year, in the making eſſence of *roſes* in France, in the following manner.

As the *roſes* were brought to him freſh gathered, he turned them immediately into the ſtill; and drawing over the water into a glaſs matraſs, when it had ſtood by ſome time, and was perfectly cold, he diſcovered ſome of the eſſence fixed to the ſides of the matraſs, and the ſurface of the water covered with a thin reticular pellicle. All the contents of the matraſs were put to filter through a paper, ſupported by a fine linnen cloth; and the filtrated water was added to new *roſes* for many ſucceeding diſtillations, the produce of which was all filtered through the ſame paper. After a long courſe of diſtillations, with freſh flowers every time, but ſtill with the ſame veſſels and the ſame water, there was found in the paper of the filtre a quantity of thick eſſence; this being carefully waſhed out of the paper with a ſmall quantity of the moſt fragrant of the water, and afterwards ſeparated pure from its ſurface was very white, and extremely fragrant, and as thick as fine butter. This is not the only eſſential oil which naturally concretes into this firm ſtate; oil of anniſeed, though fluid, when diſtilled, always concretes in the ſame manner on the firſt approach of cold; and another oil of this kind is that of the laurel, which is uſed in ſome places, though very improperly, to give the ſcent and taſte of bitter almonds, or apricot kernels, to foods of different kinds.

Monſieur Homberg has taught us how to gain a larger quantity of the eſſential *oil of roſes* than is uſual in diſtillation, by the previous addition of mineral acids, as the ſpirit of ſalt, vitriol, &c. thereto; which increaſe the fermentation, and joining with the *oil* render it more liquid, and eaſier to be raiſed by heat. He adviſed a perfumer, who before ſcarce obtained an ounce of *oil* from an hundred weight of *roſes*, to ſteep his flowers for fifteen days in water made ſharp with ſpirit of vitriol, by which means the perfumer, upon diſtillation, found his quantity of *oil* increaſed almoſt a third.

The perfumers keep the ſtructure of the veſſel they employ in this diſtillation in great ſecret. Mr. Homberg tells us, it is a large convenient ſtill, that opens in a tube at the top to receive the water which muſt often be poured upon the *roſes* to bring over the *oil* with it; this it does but very ſlowly, and ſo requires that its quantity be large; the ſtill alſo opens below, that the flowers, when they will yield no more *oil*, may be eaſily taken out; but the principal contrivance is the figure of the veſſel which receives the *oil*; this is made like an ordinary matraſs, from the lower part of the belly whereof comes a tube, as from an old faſhioned cruet, and riſing to the bottom of the neck of the receiver, it bends outwards; ſo that though the veſſel uſually contains but two or three French pints, it conveniently receives and lets paſs many hundred pints of the *roſe* water, without any neceſſity of being changed; for a change would loſe the ſmall quantity of the *oil* obtained. The water diſtilled runs through a pipe into a ſecond receiver: the *oil* being lighter than the water, floats upon its ſurface, and adheres to the neck of the veſſel as high as the aperture of the little pipe, while the water runs from the bottom of the firſt receiver into the ſecond. See Mem. de l'Acad. des Sciences, 1700.

Mr. Homberg obſerves that this ſtill may be uſeful to draw off any kind of precious eſſential *oils*.

ROSE *fly*, in natural hiſtory, the name given by authors to a peculiar ſpecies of *fly* found very frequently on *roſe* buſhes, and produced out of a baſtard caterpillar, which feeds on the leaves of that tree.

The male of this *fly* has a long body, the female a ſhort and thick one; ſhe depoſits her eggs in ſmall holes, which ſhe makes in the bark of the young branches, and for this purpoſe is furniſhed with a very remarkable inſtrument placed at the hinder part of the body, which is a kind of ſaw. This is a four winged *fly*, and is ſo common on *roſe* buſhes, that it is ſcarce poſſible to miſs it in any of the ſummer months; and the parts of the branches where it has depoſited its eggs, are ſo vitiated by it, that they alſo are eaſily known. They are uſually ſwelled to a greater bigneſs, than either the part above or below them, and are uſually ſomewhat bent; they are often black on the underſide, and among this blackneſs the holes made for the eggs, and often the eggs in them may be ſeen. The head and breaſt of this *fly* are black. Its wings alſo are edged with black, its body is yellow, and its legs yellow, with a few black ſpots.

If theſe *flies* be obſerved in a ſummer morning, as they are crawling upon the branches of the *roſe* tree, they will ſoon be found at work for the depoſiting of their eggs. Theſe creatures give us a very good opportunity of obſerving the manner in which they perform this, as they are of a very ſluggiſh diſpoſition, and will ſtand ſtill even to be taken between the fingers; ſo that when one of them is in a proper ſituation, it may be examined, by bringing the eye near it, and by uſing the common magnifying glaſſes, without quitting its place or its work; and if there be leaves of the tree, or ſmall branches of it in the way, they may be removed without diſturbing the creature. *Reaumur*'s Hiſt. Inſ. Vol. 9. p. 145.

As ſoon as the *fly* has found a proper place for her eggs, ſhe directs the hinder part of her body downwards, and opening a pair of ſcaly ſubſtances placed near her tail, ſhe thruſts out from between them an inſtrument exactly repreſenting two common ſaws, with ſharp teeth and ſmooth backs; when ſhe has ſo placed theſe, that their points touch the bark, ſhe preſſes down her body in order to force the points to enter, and afterwards continues this preſſure till the whole length of both ſaws is immerſed in the wood. If the whole be nearly examined, however, it will be found that a ſimple preſſure is not all the means employed to force them in; but that as ſoon as ever the points are entered the bark, the two ſaws begin to work by means of tendons and muſcles made for that purpoſe, and are moved about exactly as the common ſaw in the hand of a carpenter; only that as there are two of them, they always move the contrary way, one being forced in while the other is drawn out; by this means they become a ſupport to one another.

As theſe inſtruments are extremely ſmall, they would not naturally cut an opening large enough for the receiving and covering the egg which is to be depoſited there. The creature therefore uſes great art and addreſs in the working with them. She opens the branch, not by making a bare puncture, but in the ſame manner in which a ſurgeon opens a vein, by plunging the point of his lancet perpendicularly in, and then raiſing it out obliquely; and, in order to enlarge the width of the wound, ſhe makes the teeth of each of the ſaws work forcibly againſt the ſides of it at every return. When the aperture is thus made of a proper ſize, the creature immediately draws out the ſaw, and preſſing her body down upon the bark, depoſits an egg in the hole; immediately after which, ſhe covers the orifice with a viſcous fluid, which bubbles up in the manner of ſoap ſuds, and ſerves at once to preſerve the egg, and to prevent the wounded fibres of the tree from decaying too ſoon. Ib. p. 150.

When the laying of one egg is thus finiſhed, the creature moves a little way forward or backward on the branch, and then begins the like operation for another egg, and goes on in this manner till ſhe has laid her whole ſtore. If the branch be all the way proper to receive them, ſhe lays them

them in a train, twenty or more, at ſmall diſtances, in a ſtrait line before one another; but if ſhe finds the branch become leſs proper for her purpoſe after ſhe has laid three or four, ſhe leaves it and ſeeks out another, where ſhe finiſhes what ſhe had there begun. There is not any apparent difference in the ſeveral young branches of the ſame *roſe* tree, that can ſhew us why one is, and another is not proper for this purpoſe; but the creature herſelf is very curious in her choice, and uſually examines a great number before ſhe fixes upon a proper one. The operation might ſeem very difficult to ſo ſmall an animal; but though the creature be of a very ſluggiſh diſpoſition, in all reſpects, it ſeems to find no trouble in this, and will uſually finiſh the laying ſix eggs in this manner in half an hour. The apertures are ſo ſmall, that there are uſually about fifteen of them in the ſpace of an inch, and yet there is always a ſmall ſpace between each, and thoſe above and below it. On ſtripping the bark from one of theſe branches, the wounds are ſeen to enter into the wood, and reſemble ſo many openings of a vein, by a ſurgeon in blood letting. In each of theſe there is depoſited one egg, which is conſiderably large, of a yellow colour, and pointed at one end. If the branch of a *roſe* tree, in which the eggs of this inſect are thus depoſited, be examined from time to time afterwards, the part where they are placed will be found to change colour, the bark will turn brown and then black, and the wounded parts will elevate themſelves above the reſt of the ſurface, and reſemble a ſtring of beads, or a long chain of olives. This elevation of the wounded parts is not to be attributed to the growth of them; but they are, on the contrary, ſo far deſtroyed, as to be rendered incapable of increaſe that way. This ſwelling is owing to another very ſingular cauſe, which perhaps nature does not give us another inſtance of in the whole animal world. The egg daily increaſes in ſize after it is laid, and this is very evidently ſeen on opening the ſeveral lodgments, formed at different times; thoſe which have been made two or three days, always containing eggs more than twice as large as thoſe made within a few hours. It is to be obſerved, in favour of this ſtrange occurrence, that the egg of this creature is not covered with a hard ſhell in the manner of a bird's egg; but only with a thin, and eaſily diſtenſible membrane; but then all other eggs of inſects are in the ſame manner covered with a diſtenſible membrane, not a hard ſhell, and yet none of them are ever known to increaſe in ſize after their being laid. The egg, in thus increaſing in ſize, raiſes up the wood and the bark which cover it; and in conſequence of this, the train of eggs make a ſtring of regular elevations of the part, as the egg increaſes, and the tumor grows larger; the aperture at the ſurface grows alſo wider in proportion, ſo that the worm, when hatched out of it, finds no difficulty in getting out, but immediately crawls to the leaves and begins eating.

There is, beſide this ſpecies, another *fly* of the ſame genus, produced from a baſtard caterpillar of the *roſe* tree, and of the ſame ſhape and ſtructure of parts with this, but differing in colour: the head and breaſt of this *fly* are of a deep violet colour, the body is yellow, and the legs and wings are of a ſomewhat paler violet tinge. This creature alſo depoſites its eggs in holes, made in the branches of the *roſe* tree, by means of a double ſaw placed at the hinder part of the body; but, as the former ſpecies lays them in a ſingle ſtrait line, this diſpoſes them in a very beautiful and very regular manner in two rows. Two eggs are firſt laid by the creature, at ſome ſmall diſtance, ſideways, one from another, but at the ſame height of the branch. The bottoms of theſe meet almoſt one with the other; but their tops are expanded a little, ſo that they make an acute angle, or expreſs the ſhape of the letter V; behind theſe there are placed two others, making a ſomewhat wider angle, and ſo behind theſe two others. Thus the creature frequently depoſits ten, twelve, or fourteen pair of eggs, which are all placed at ſome ſmall diſtance from one another, and are ſeparated into two diſtinct rows by an intermediate line. Theſe are not ſo well defended from injuries as the eggs of the former ſpecies, and are entirely buried in the wood; and lodged in ſuch large holes, that they appear naked even when firſt laid. Mr. Valliſnieri, who has elegantly deſcribed this inſect, obſerves, that as the ſaws of the former ſpecies are toothed only on one ſide, having a flat back in the manner of our common ſaws, thoſe of this ſpecies are toothed both ways: he obſerves alſo, that the two pieces which make a caſe for theſe ſaws, and which are opened to give them paſſage when they are to be uſed, are each of them hollow, and are of the greateſt uſe to the creature; the one ſerving as the paſſage for the eggs, the other for that of the glutinous liquor with which the creature covers the wound in the wood, after depoſiting her egg in it. But Mr. Reaumur, in comparing the ſize of the egg, when new laid, with the aperture, which this author ſuppoſes it to be depoſited through, is of opinion that it is much too large to have gone through ſuch a paſſage; he alſo obſerves, that the eggs may always be forced out of the body by preſſing it between the fingers; but that, in this caſe, they are always ſeen iſſuing out at the anus.

The *roſe* tree ſeems the peculiar favourite of theſe ſorts o flies, for beſide the two ſpecies already deſcribed, there is another very ſmall one which is found on this tree in great abundance in the months of April and May. This is every way ſhaped like the large kinds, but it is all over black except ſome white ſpots on the legs; the ſaw of this ſmall inſect is not of a ſufficient ſtrength to penetrate the branches of this ſhrub, it therefore always is ſeen upon the leaves, and depoſits its little eggs in a row of holes made in the middle rib of a leaf. It is to be obſerved that all the falſe or baſtard caterpillars produce theſe ſerrated flies; yet it is very ſingular that they do not all make the ſame apparent uſe of their ſaws that theſe do. The fly produced by the falſe caterpillar of the gooſeberry, always depoſits its eggs in ſingle rows along the middle ribs of the leaves; but the eggs are not let into them by holes made for that purpoſe, but are merely laid along upon the ſurface. It may be however, that the creature makes a wound where every egg is to be depoſited, which though not large enough to receive it, may yet ſuffice to afford a neceſſary moiſture to it. Mr. Reaumur was at the pains to keep ſome of the falſe caterpillars produced from the eggs of this fly the whole ſeaſon, and obſerve them through all their changes. When they had eaten ſufficiently in the caterpillar ſtate, they crept into the earth which he had put into the bottom of his boxes, and then changed into chryſaliſes in a double covering of a ſilky matter of their own ſpinning; they remained all the winter in this ſtate, and in the ſucceeding ſpring came forth out of the earth in form of flies. This author obſerves, that on putting a male and female together into another box, in which there were ſome branches of gooſeberry buſhes, the female immediately ſearched out the proper places for depoſiting her eggs, and laid ſeveral before his face in ſingle rows on the moſt prominent part of the ribs of the leaves: the creature ſeemed to give herſelf all the motions that the other ſpecies do in piercing the branches of the *roſe* tree, before the depoſiting of every egg; but that on examining the places afterwards, he never could find any mark of a wound in them, the eggs all lay upon the ſurface, but they were ſo firmly fixed on the place, that there was no removing them without breaking them, and a piece of the ſkin was always left behind, which ſtuck faſt on the place and covered the hole if there was any. There are alſo ſome other ſpecies of theſe *flies*, which make no apparent uſe of the curious ſaws they have behind: yet they all are poſſeſſed of them. *Reaumur*'s Hiſt. Inſ. Vol. 9. p. 160. See the article SERRATE *Flies*.

ROSE *galls*, in natural hiſtory, a name given by authors to certain unnatural productions of the *roſa ſylveſtris*, or dog *roſe*, occaſioned by the bites of inſects: there are two kinds of theſe, the one very common, the other more rare.

The ſcarcer kind is uſually found on the young ſhoots, and on the heps or fruit, and is of a woody ſubſtance; the other is hairy and ſpungy and is found on the old branches. The woody kind uſually appears in the months of June and July, and is always found in cluſters. Theſe are compoſed of ten, twelve, or more *galls* of different ſizes and figures, ſome round, others oblong, ſome of the ſize of an olive, and others not larger than a pea. They are of the common ſubſtance of the white wood or blea of trees, and when ſituated on the fruit they prevent its ripening and make a very ſingular figure. They are of a reddiſh colour and are uſually ſmooth and gloſſy, but ſometimes they are beſet with ſhort and fine prickles.

The hairy *roſe gall* is too common, and too ſingular a figure to have eſcaped the obſervation of perſons in all ages; it has been introduced into medicine in many parts of the world, and is at this time preſcribed in Germany, when reduced to powder, in diarrhœas, dyſenteries and other diſorders of the bowels, and to promote urine and break the ſtone. Theſe *roſe galls*, though they appear at firſt ſight compoſed of tufts of hair, are however in reality made up of ſeveral ſmall *galls* growing from a bud on the branch and forming a cluſter on the part. They are of an oblong figure and reſemble the ſhape of a plum-ſtone. Each of them is the habitation of a ſingle worm, each having one cell in the center. This is perfectly ſmooth and even on the inſide, but from the outer ſurface of each of theſe ſeparate *galls* there go off a vaſt number of filaments which uniting and intermingling with one another form one complex maſs, and give the whole cluſter the figure of one *gall* of the bigneſs of an Indian or horſe cheſnut. Theſe filaments are of a reddiſh or greeniſh colour, and are often nearly an inch in length. They are called by ſome hairs, but very improperly, having no true character of a hair, but being of a rough ſurface, flatted, and branched with ſeveral ſhorter filaments growing from their ſides. The tubercles within, from which theſe grow, are of a hardneſs greater than that of moſt ſpecies of wood. Though theſe *galls* are uſually found on the branches of the ſhrub, and ariſing from the buds or eyes of young ſhoots, and are therefore ſuppoſed by authors to be the vitiated matter of a whole branch.

branch with its leaves divided into theſe filaments, yet they are ſometimes found growing to the middle rib of a ſingle leaf, where yet they do not want all their filaments, though there have been no vitiated leaves to form them. *Reaumur*'s Hiſt. Inſ. Vol. 6. p. 251.

Though theſe *galls* and the ſmooth ones before deſcribed are extreamly different in external appearance, yet on a cloſe examination they appear to be more nearly allied than might be ſuſpected. They are doubtleſs both the work of the ſame inſect, and their principal difference is, that the one is ſmooth, and the other covered with theſe filaments. It is to be obſerved however, that the ſmooth ones have ſometimes a ſort of ſhort and ſoft ſpines upon them, and theſe ſeem the rudiments of theſe hairs; and there ſeem to be *galls* found ſometimes more, ſometimes leſs hairy, and indeed of all the middle degrees between the two ſorts.

The naked *galls* are uſually larger and of a more ſpungy texture than the hairy ones; which is owing to all the matter, which ſhould have formed the filaments, being united and wrought up into the body of the *galls*. There is alſo another variety of the ſmooth kind, which might appear an abſolutely diſtinct ſpecies. This is a ſingle and large *gall* of a ſmooth ſurface and ſpungy but woody texture. When cut open, it is found to contain ſeveral cells, each inhabited by one worm; and when nearly examined is found to be a congeries of as many ſmaller *galls* as there are cells, which have grown firmly together.

All theſe *galls* of the *roſe* tree afford the ſame ſpecies of worms, and the ſame ſpecies of flies. The proper inhabitants, however, are hardly to be diſtinguiſhed by the moſt curious obſerver from the great variety of ſpecies which are found in them, all produced of the eggs of other flies, whoſe worms are of the carnivorous kind, and are lodged in the *gall*, not to feed on the juices of the tree, but on the fleſh of the proper inhabitant. When the parent fly who gives origin to the *galls* has depoſited her eggs, and the tumor in conſequence begins to be formed, an enemy of this kind pierces the covering, and ſends in her offſpring to feed on the inhabitant. Theſe are flies of the ichneumon kind, and ſeveral ſpecies of them are of great beauty. All the flies deſcribed by authors as iſſuing out of this *gall* ſeem to have been of this kind: the proper inhabitant being a ſmall black fly of no great beauty is diſregarded, while the others have been particularly deſcribed. Mentzelius has given an elegant account of a ſpecies whoſe back is of a fine blue and its belly purple, and others have figured and deſcribed greeniſh and gold coloured ones, but theſe are all ichneumons, all bred of devouring enemies which have fed on the proper inhabitants of the *galls*, and lived and transformed themſelves in their cells. *Reaumur*'s Hiſt. Inſ. Vol. 6. p. 254.

Oil of ROSES. See *eſſence of* ROSES, *ſupra*.

ROSEA, a name given by ſome authors to the eriſipelas or St. Anthony's fire.

ROSLAND, in our old writers, heathy land, or ground full of ling; alſo watry and mooriſh land. 1. Inſt. 5. *Blount*.

ROSMADIAN, a name uſed by the alchemiſts for what they call mercury of the philoſophers.

ROSEMARY, *roſmarinus*, in the linnæan ſyſtem of botany, a diſtinct genus of plants, the characters of which are, that the cup is a perianthium compoſed of one leaf, tubulated, and flatted in its upper part; its rim is erect and labiated, the upper lip whole, and the lower indented in three places. The flower is a ſingle petal in form of a tube, and longer than the cup. It is labiated at the extremity; the upper lip is ſhort, erect, divided into two ſegments, acute, and has bent edges; the lower lip is bent back, and is trifid, the middle ſegment large and hollow with a narrow baſe, the lateral ones are narrow, the ſtamina are two pointed filaments bent toward the upper lip and longer than it, the antheræ are ſingle. The piſtil has a quadrifid germen, the ſtyle is of the length, figure, and ſituation of the ſtamina, and the ſtigma ſingle and acute. The cup holds in its bottom four oval ſeeds. *Linnæi* Gen. Pl. p. 6.

The characters of *roſemary*, according to Tournefort, are theſe. The flower conſiſts of one leaf, and is of the labiated kind; the upper lip is bifid, and turned backwards and upwards, and adorned with crooked ſtamina; the under one is divided into three ſegments, the middle one being larger than the reſt, and hollowed in the manner of a ſpoon. The cup is divided into two or three ſegments, and is furniſhed with a piſtil, which is fixed in manner of a nail to the hinder part of the flower; this is ſurrounded with four embryos which afterwards become four roundiſh ſeeds ripening in the cup of the flower.

The ſpecies of *roſemary* enumerated by Mr. Tournefort are theſe. 1. The common narrow leaved garden *roſemary*. 2. The ſilver leaved garden *roſemary*. 3. The broad leaved wild *roſemary*. 4. The variegated leaved *roſemary*. 5. The large ſpiked purple flowered *roſemary*. The ſeveral ſpecies of *roſemary* when neither in flower or ſeed may be known by their having hard woody ſtalks, narrow leaves, and a ſmell much approaching to that of camphor. *Tourn.* Inſt. p. 198.

We have five or ſix different ſpecies or varieties of this ſhrub in our gardens; they grow wild in the ſouth of France, and in Spain and Italy, on rocks near the ſea where they multiply prodigiouſly. With us they grow the moſt vigorouſly on a moiſt rich ſoil, but they are much ſweeter ſcented when on a poor ſoil, and on ſuch they bear the ſeverity of our ſeaſons much better, than where they grow more freely.

They are all propagated by planting ſlips or cuttings of them, in the ſpring of the year, on a bed of light freſh earth, and when they are rooted, they are to be removed into the places where they are to remain. The beſt ſeaſon for doing this is in Auguſt, if they are planted later than this, they ſeldom live through the winter; therefore ſuch as are not tranſplanted at this time ſhould be left till the following ſpring, when March is a very good time for removing them; and if this be done in ſhowery weather they take root almoſt immediately. The plants are ſometimes killed in cold winters in our gardens, but when by accident they have rooted themſelves in an old wall, as is often the caſe, they ſtand all weathers unhurt, which is owing to their being ſtunted and their roots dry.

The flowers of *roſemary* are uſed on many occaſions in medicine; they are cephalic, good in all nervous and hyſteric caſes, and are ingredients in many compoſitions of the ſhops; they are eſteemed of great ſervice in apoplexies, palſies, vertigoes and epilepſies. They ſtrengthen the ſight, are good againſt a ſtinking breath; they are alſo preſcribed in obſtructions of the liver and ſpleen: the conſerve of the flowers is an excellent thing to bring other medicines in theſe intentions into form, when they are intended to be given in boluſes and electuaries.

The hungary water ſo long famous in England and elſewhere, is made of the flowers of *roſemary* diſtilled with rectified ſpirit of wine.

ROSMARUS, in zoology, the name of an animal called alſo by ſome the ſea horſe, and more uſually known by the name *morſe*. See MORSE.

ROSOMACHA, in zoology, a name given to a ſpecies of hiæna. They are, ſays Olaus, taken by hunters chiefly on account of their ſkins, which are much eſteemed by people of fortune for robes, as being variegated with very bright colours reſembling flowers. *Hoffm.* lex univ. in voc. See the article HIÆNA.

ROSPUS, a name uſed by ſome authors for the ſtrange fiſh called the *rana piſcatrix*, or frog fiſh. *Willughby*'s Hiſt. Piſc. p. 86. See RANA.

ROSSE, in ichthyology, the name given by Bellonius to that kind of the cyprinus of Artedi which we call the roach. See the article CYPRINUS.

ROST, in metallurgy, a term uſed by the miners at Chemnitz to expreſs the ore of gold after it has been waſhed and powdered, and melted firſt with lime ſtone, and afterwards burnt with charcoal alone. See LECH.

ROSTEN, in the materia medica of earlier ages, a name given to crab eyes.

ROSTRUM (*Cycl.*)—The *roſtrum* or ſnout in fiſhes varies very much in figure, and ſerves as a conſiderable article of diſtinction. It is 1. in ſome plagioplateous or depreſſed, as in the pike, *&c.* 2. In ſome it is conic in ſhape as in the oxyrynchus, *&c.* 3. In ſome it is extended into a long and ſharp point, as in the common ones; and 4. In others it is triangular, or nearly ſo, as in the rays.

ROSTRUM is alſo uſed to ſignify an inſtrument wherewith paper is ruled for muſical compoſitions.

ROT, in ſheep (*Cycl.*)—This is the greateſt of all the inconveniencies that attend the keeping theſe uſeful animals.

It is a very hard thing to prevent the *rot* if the year prove very wet, eſpecially in May or June. Salt marſhes and lands, where broom grows, are the beſt places of preſervation for them. Sheep are ſometimes all cleared of the *rot* when not too far gone with it, only by removing them into broom fields. Scurvy-graſs, muſtard, parſley, and thyme, are alſo good for the prevention of it.

Some propoſe the giving ſheep half a handful of bay ſalt every month or oftener; and there is great probability that this may be of ſervice; but the rational way of attacking all diſorders in cattle, is by conſidering what are the cauſes of them. It will appear, upon enquiry, that wet ſeaſons are the general occaſions of the *rot* in ſheep, and therefore it would be adviſeable for the owners, when ſuch ſeaſons come on, to remove the animals into the drieſt paſtures they can, and then to feed them principally with dry ſweet hay, oats, bran, and the like, this would prevent the occaſion; and if they were already a little infected, ſome ſalt given with their dry food, would be a happy means of curing them. *Mortimer*'s Huſbandry, p. 244.

ROTATED, *rotatus*, in botany, the name of a ſort of flowers, ſo called from their ſhape, ſomewhat reſembling a wheel. Theſe are of the monopetalous kind, and are only a ſub-diſtinction of the infundibuliform flowers. *Tourn.* Inſt. p. 116. Tab. 1. of Botany, Claſs 1. See the article INFUNDIBULIFORMIS.

ROTA-

ROTATION (*Cycl.*)—Mr. Winſlow has given an account of this, as well as of pronation, and other circulatory animal motions. See Mem. de l'Acad. des Sciences, 1729.

ROTCHET, an Engliſh name for the fiſh, called by authors *cuculus*, and more frequently by us the *red gurnard*. *Willughby*'s Hiſt. Piſc. p. 282. See the article CUCULUS.

ROTELE, in zoology, a name by which ſome call the *rutilus latior*, or *rubellio fluviatilis*, more frequently known by the name of the *rud* or *finſcale*, a river fiſh with red belly-fins and tail. *Ray*'s Ichthyogr. p. 252. See RUBELLIO.

ROTHALS, in zoology, a name given by Geſner, and ſome others to the *pochard*, or *red headed wigeon*; a bird diſtinguiſhed from all others of the duck kind, by having no variegation in its wings. See POCHARD.

ROTKNUSSEL, in zoology, a name by which the Germans call the *gallinula melampus* of Geſner. It is a bird ſomewhat approaching to the ſnipe kind; its back is brown, with a ſlight admixture of reddiſh, and ſome ſpots of a duſky colour; its wings are variegated with black and white, and its beak and legs are black. It is common in many parts of Germany.

ROTOLO, an Egyptian weight of twelve ounces, each ounce conſiſting of twelve drachms, and each drachm of ſixteen carrats. *Pocock*'s Egypt. p. 175.

ROTSCHWENTZEL, in zoology, the name of a bird, deſcribed by Geſner and ſome other authors, and ſeeming to be the ſame with our *ruticilla*, or *red-ſtart*. See the article RUTICILLA.

ROTSIMPA, in ichthyology, a name given by the Swedes to a ſpecies of *cottus*, called by Jonſton and Schonveldt *ſcorpius marinus*. It is different from the *ſcorpæna* of the generality of writers, and is of the *cottus* kind. It is diſtinguiſhed by Artedi by the name of the ſmooth *cottus*, with many thorns upon the head, and with the upper jaw ſomewhat longer than the under one. See the article COTTUS.

ROTULA (*Cycl.*)—ROTULA, in natural hiſtory, the name of a genus of the *echini marini*, of the general claſs of the placentæ. The characters of the *rotulæ* are, that they are flat ſhells in form of a cake, compoſed of various flat pieces, and formed into a round, ſomething like that of a wheel; but wanting one or more parts of its outer ring, and radiated or dentated. Their mouth is ſituated in the middle of the baſe, and the aperture of the anus in the third region of the axis, and marked with a cinquefoil flower at the ſummit. The great and obvious character is however the dentated edge. Of this genus there are two known ſpecies. 1. A kind with three very deep ſinuſes, and four pervious foramina at the top, or ſometimes only with two, and with a finely crenated pentagonal vertex; and 2. The ſolar echinus, which has uſually nine rays free from the outer ring. The vertex, in this ſpecies, is round and denticulated, and variegated with very elegant lines. See Tab. of Teſtaceous Animals, N° 10. *Klein*'s Echin. p. 32.

ROTULA, in ichthyology, is alſo a name given by ſome to the *faber* or *doree*. See the article FABER.

ROTUNDUS *major*, (*Cycl.*) in anatomy, a name given by Riolan, and ſome others, to a muſcle, called by Veſalius and others the *tertius humeri*, and *tertius brachium moventium*. Albinus, Cowper, and others, call it *teres major*.

ROUGET, in ichthyology, a name given by the French to the fiſh called the *lyra* and *capo* by authors. It is a ſpecies of the *trigla*, and is diſtinguiſhed by Artedi by the name of the *trigla* with the long bifid ſnout and tubulous noſtrils.

ROUGH (*Cycl.*)—ROUGH-*ſea*, in the ſea language. See the article OVER-GROWN-*ſea*.

ROUND (*Cycl.*)—ROUND *in*, or ROUND-*aft*, at ſea, a term belonging to the main and fore ſail. When the wind largeth, they ſay, *Let riſe the main tacks*, or *the fore-tacks! Hale aft the fore-ſheet to the cat head*; *and the main ſheet to the cubbridge-head!* And when theſe ſheets are thus haled down they keep them from flying up with the *paſſarado rope*. This work is called *rounding in* or *rounding aft* the ſail.

ROUND-*ſeam*, in the ſea language. See SEAM.

ROUND-*ſplice*, in the ſea language. See SPLICE.

ROUND-*top*, in the ſea language. See TOP.

ROUSSIN, in the manege, is a ſtrong well knit, well ſtowed horſe, ſuch as are commonly brought into France from Germany and Holland.

ROWELS *of a ſpur*, in the manege. See SPUR, *Cycl.*

ROWLE, in a ſhip, is a round piece of wood or iron, wherein the whip goes, being made to turn about, that it may carry over the whip the eaſier from ſide to ſide.

ROYENA, in botany, the name of a genus of plants, the characters of which are theſe. The perianthium conſiſts of one leaf, which is inflated and permanent, and is lightly divided into five obtuſe ſegments at the edge. The flower is monopetalous, and conſiſts of a tube of the length of the cup, and an expanded mouth, which is divided into five oval and reflex ſegments. The ſtamina are ten very ſhort filaments growing to the flower. The antheræ are oblong, acute, and double, and they ſtand erect, and are of the length of the tube of the flower. The germen of the piſtil is of an oval figure and hairy, and is divided into two ſtyles, which are a little longer than the ſtamina. The ſtigmata are ſimple; the fruit is an oval capſule, compoſed of four valves, and furrowed with four deep lines, and contains only one cell, in which are four oblong and triangular nuts covered with a calyptra. This has been deſcribed in Paradiſus Batavus, and ſome other books, under the name of a ſpecies of the bladder nut, *ſtaphylodendri ſpecies*. *Linnæi* Gen. Pl. p. 193. *Hort. Amſtel.* Vol. 1. p. 187. *Herm.* P. B. p. 232.

RUBECULA, in zoology, the name of a bird, commonly known in England, under the name of the *red breaſt*, and called by ſome *erithacus*. This is a ſolitary bird, and naturally ſhy, but in winter will even come into peoples houſes in ſearch of food. It is very careful in building its neſt. It builds in the thickeſt buſhes and hedges, where there are multitudes of fallen oak leaves, or the like large light matter. It covers its neſt very artfully with large quantities of theſe leaves, and makes only one way to get into it, which is by a narrow paſſage, and which it always covers with leaves when it goes abroad for food. *Ray*'s Ornitholog. p. 160.

RUBELLIO, in ichthyology, a name given by ſome authors to a ſmall ſea fiſh of a red colour caught in the Mediterranean, and more uſually called by writers on theſe ſubjects the *erythrynus*. *Aldrovand.* de Piſc. p. 154. See the article ERYTHRYNUS.

RUBELLIO *fluviatilis*, the name of a freſh water fiſh of the leather mouthed kind, called in Engliſh a *rudd* or *roud*, and in ſome places a *finſcale*. It is a common fiſh in many of the rivers of England and Germany, and eſteemed a well taſted fiſh. They are in ſeaſon all the year, except in the month of April, which is their ſpawning time, and the males at that time are ſubject to a great number of white ſpots upon their heads, and are more rough than at any other ſeaſon. It is a fiſh broader than the carp, but thicker than the bream. It is of a browniſh yellow colour, and has very large ſcales; the tail and belly fins are red, and the gills are commonly marked with a red ſpot. *Willughby*'s Hiſt. Piſc. p. 252.

RUBELLUS, in zoology, a name given by ſome authors to the common roach, and by others to the rudd or finſcale. *Geſner*, de Aquat. p. 965. See the articles RUTILUS and RUBELLIO.

RUBEOLA, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of one leaf, faſhioned like a funnel, and either lightly dentated, or divided into four ſegments at the edge. Theſe have ſometimes a ſingle, ſometimes a double cup, and that of the two which was the lower, or the ſingle one, if there were no other, is finally converted into a fruit compoſed of two ſeeds.
