Dr. Shaw has very well recommended to the world the method of ſelling and buying ſpirits in their moſt highly-rectified ſtate, that is, when they are totally inflammable. By this means, as the burning a ſpoonful of the goods would always be a proof of their quality, there could be no room for thoſe cheats, which are now too common between the ſeller and buyer. As this, however, is not likely to be brought into practice, it may be of great uſe to thoſe, who traffic in ſpirits, to have ſome more certain way of judging of their *ſtrength* than that by the bubble proof, or crown of ſpume ariſing on ſhaking; which being wholly owing to a mixture of the eſſential oil of the ingredient from which the ſpirit is made, with the ſpirit, may be ſophiſticated by the addition of other oils, or ſaponaceous ſubſtances, or by any thing that can give a greater viſcoſity to the ſpirit than it had before.

The ſureſt method of judging of the *ſtrength of ſpirits* is by the hygrometer, water-poiſe, or balance; or 2. by diſtillation; or finally, by deflagration. The ſpecific gravity of totally inflammable ſpirit is ſo much leſs than that of phlegm, or common water, that it is eaſily ſenſible upon the balance; whence an exact hygrometer, well balanced and graduated, and furniſhed with a proper ſcale and weights, may be of great uſe to aſſign the proportions in which pure ſpirit and water are mixed in any given liquor. Though perhaps a readier way than this may be that of Mr. Homberg's, mentioned in the Memoirs of the Paris Academy 1718, for determining the different gravities of different fluids, by means of a bottle with a very long and ſlender neck; which being filled to a certain height with any mixture of ſpirit, is weighed againſt the ſame bottle filled with pure water.

The moſt exact, of all methods of determining the *ſtrength* of any ſpirit, is by diſtillation, rectifying it up to an alcohol, or totally inflammable ſpirit; but this, though liable to no error, is too tedious to come into common uſe. And, upon the whole, the beſt method, of all others, ſeems to be that of deflagration, which Mr. Geoffroy has been at much pains to adjuſt and improve. *Shaw*'s Eſſay on Diſtillery. See the article SPIRITS.

STRENGTHNERS *(Cycl.)*—An artificial method of procuring a powerful, ſafe, and innocent *ſtrengthner*, is the following. Put half a pound of fine Peruvian bark, reduced to a ſubtile powder, into a long or tall glaſs body, and pour upon it two quarts of ſpirit of wine; ſhake them well together, and ſet them in a ſand-heat two or three days, or till the ſpirit of wine is of a fine purple colour; pour off this tincture, and preſs the fæces very ſtrongly, to get it all away; then return the powder into the ſame veſſel, and pour upon it two quarts of ſtrong white wine; ſet this in ſand for two or three days, then pour off this tincture; mix it with the former, and putting the whole into a glaſs body, diſtill off a great part of the ſpirit of wine; then put the remainder into a glazed earthen pan, and evaporate it to the form of an extract, adding, toward the end, three ounces of ſyrup of orange peel.

This is the invention of Charas, and ſeems the beſt preparation of bark known. Beſide all the common caſes in which the bark is given, this preparation may be tried in other weakening diſtempers, as well as intermitting fevers, as the inconveniencies attending the taking the bark in ſubſtance are obviated by this preparation, which is equally powerful and innocent. It may be aromatized at pleaſure with any of the eſſential oils. *Shaw*'s Lectures, p. 232.

STREPITOSUS, the name of a diſtemper common to the inhabitants of ſome parts of the Alps, in which the face, neck and arms, are ſo diſtended with flatulencies, as to make a noiſe, when ſtruck, like a dry bladder half diſtended with wind.

STREPSICHEROS *ovis*, in natural hiſtory, the name of a ſpecies of ſheep deſcribed by Bellonius, and found in the iſland of Crete in great flocks. They are of the ſize of our common ſheep, but their horns are erect, and twirled into a ſpiral line, and beautifully furrowed on their outſide. *Bellon.* Obſerv. lib. 1. cap. 14.

STRETTO, in the Italian muſic, is ſometimes uſed to ſignify that the meaſure is to be ſhort and conciſe, and conſequently quick. In this ſenſe it ſtands oppoſed to *largo*. See the article LARGO.

STRETWARD, in our old writers, an officer whoſe buſineſs it was to take care of the ſtreets, like our ſurveyor of the high-ways, or rather ſcavenger. *Blount.*

STREVER, in zoology, a name given by many to the fiſh called by authors *aſper piſciculus*.

It in ſome degree reſembles in figure the *lucioperca*, or pike-pearch, but is more ſlender than that fiſh toward the tail. Its back has a hollow on its anterior part near the head, and its ſides are marked with ſeveral obliquely tranſverſe lines, like thoſe of the pearch. Its back is ſcaly, its breaſt braked. It has two back fins, a ſhort and prickly one before, and a longer behind; and the bony coverings of its gills terminate each in a ſharp ſpine. *Geſner*, de Aquat. p. 478.

Geſner, in particular, calls this fiſh *gobius aſper*. It is a genuine ſpecies of pearch, and is diſtinguiſhed by Artedi by the name of the *pearch* variegated with eight or nine tranſverſe black lines on a ſide.

STRIATA *corpora*, a term uſed by anatomiſts to expreſs two protuberances of the brain, upon the crura of the medulla oblonga. See CEREBRUM.

STRIATED *leaf*, among botaniſts. See LEAF.

STRIATED *ſtalk*. See the article STALK.

STRIATULA, in natural hiſtory, a name given by Mr. Lhuyd to a ſpecies of foſſile plants of the fern kind, remarkable for their *ſtriated* appearance. See the article *Foſſile* PLANTS

STRIBILIGO, a name given by ſome authors to any ſort of cutaneous efflorescence.

STRIGA, among the Romans, a ſpace or interval in a camp, 120 feet long, and 60 feet broad, uſed for currying and rubbing down the horſes. *Pitiſc.* in voc.

STRIGA is alſo uſed for a furrow drawn out at length, for a long row, or ſeries of any thing, and by ſurveyors for a long meaſure. *Pitiſc.* in voc.

STRIGIL, an inſtrument uſed among the antients in their baths, and at ſome of their gymnaſtic exerciſes.

It ſerved to abſterge the ſweat, or other ſordes from the body. Perſons who intended to bathe, or to uſe any of theſe exerciſes, when they entered the gymnaſium, put off their clothes in the apodyterium; after which, ſuch of them as intended to box, wreſtle, or uſe any of the more violent exerciſes, went into the alipterium, where they were anointed, and thence returning into the place where the duſt was, they were ſprinkled with this as they paſſed along, and then

entred upon their ſeveral exerciſes; after this they returned to the alipterium, where they had the ſweat and ſordes wiped off from their bodies by the alipta with an iron *ſtrigil*.

The ſordes taken off from the body, and conſiſting of oil, duſt, and ſweat, were preſerved for medicinal purpoſes, and we find them uſed among the old phyſicians.

The *ſtrigils* were of the ſhape of a gardner's knife; they were made of different materials, as ivory, horn, gold, ſilver, iron, braſs, and the like; but in ſome after times the word was only uſed to ſignify a linnen cloth, or a piece of ſpunge, which every one carried about him for his own uſe. The ſordes, ſaved for medicinal purpoſes, were called *ſtrigmenta*. See the next article.

STRIGMENTUM, the filth, dirt, or ſordes, abſterged from the ſkins of thoſe that bathed in the baths and places of public exerciſe among the antients, or from the walls of bathing places, or ſtatues ſet up in them.

Theſe were all reſerved for medicinal purpoſes, and were properly of three kinds. The firſt, or bath *ſtrigments*, conſiſted of the ſweat, oil and ſordes, collected in thoſe places. The ſecond kind was the *ſtrigments* of the palæſtra, conſiſting of the ſame things, with the addition of duſt, which was thrown upon the bodies of the perſons before they entred on thoſe exerciſes. The third kind was that collected from the walls of the gymnaſia, and from the ſtatues, of whatever materials they were made, which were placed there. Hence the nature of the firſt and ſecond kind might always be aſcertained, but that of the third was very different; for as it was often collected from braſs and copper ſtatues, it partook of the nature of the ruſt, or ærugo of thoſe metals which was collected from them with it.

Theſe *ſtrigments* were ſuppoſed to be of a heating, drying quality, and diſcutient; they were, therefore, uſed for diſcuſſing the parotides, and for condylomata of the anus. Thoſe of the palæſtræ were uſed to diſcuſs collections of matter about the joints; and applied in the manner of a cataplaſm, were ſaid to be of great uſe in the ſciatica: and thoſe collected from the walls and ſtatues were uſed to cleanſe old ulcers.

STRIGONIENSIS *terra*, earth of *Strigonium*, in the materia medica, a red earth of the bole kind, found about the gold mines at *Strigonium* in Hungary, and uſed in ſome places as an aſtringent and ſudorific.

The characters by which it is known from the other earths, are theſe. It is but of a coarſe and impure texture, and lighter than moſt of the boles; in colour it is of a ſtrong, but dull red, and is of a tolerably ſmooth ſurface. It is apt to crumble to pieces between the fingers, and ſtains the ſkin in handling. It melts freely in the mouth, and has a remarkable ſmoothneſs, but very little aſtringency in its taſte, and leaves a ſenſible grittyneſs between the teeth. It is ſometimes veined and ſpotted with ſmall moleculæ of an earth, like the whitiſh variegations of the red French bole. It makes a ſlight effervescence with aqua fortis, or any other acid menſtruum, and ſuffers no change of colour by burning. *Hill*'s Hiſt. of Foſſ. p. 11.

STRIGOSULA, in natural hiſtory, a name given by Mr. Lhuyd to a ſpecies of foſſile oiſter-ſhell. See the article *Foſſile* SHELLS.

STRIKE (*Cycl.*)—STRIKE *a nail*, in the manege, is to drive through the horſe's ſhoe, and the horn or hoof of his foot, and to rivet it for holding on the ſhoe.

STRIKE *a vein*, in the manege. See BAR, *Append.*

STRIKING (*Cycl.*)—STRIKING-*wheel*, in a clock, the ſame with that which by ſome is called the *pin-wheel*, becauſe of the pins which are placed on the round or rim (which in number are the quotient of the pinion divided by the pinion of the detent-wheel.) In ſixteen days clocks, the firſt, or great wheel, is uſually the pin-wheel; but in ſuch as go eight days, the ſecond wheel is the pin-wheel, or *ſtriking-wheel*. See PIN-*wheel*, *Cycl.*

STRILLOZZO, in zoology, a name by which ſome authors have called the emberiza alba, or bunting, or perhaps a bird ſomewhat different from our bunting, and common in Italy: for it is not yet aſcertained, whether the *ſtrillozzo* ſpecifically differs from the bunting, or only by ſome accidental variegations.

STRING (*Cycl.*)—STRINGS *of metal*, a term uſed by our miners to expreſs thoſe thin and ſmall veins of ore, into which the beds or veins degenerate toward their terminations. Theſe are from an inch to a tenth part of that in thickneſs, and run through the ſolid rocks to a great diſtance. The ore in them is uſually very pure and rich, and as they lie in the rocks, communicating with the larger veins of ore, they reſemble the ſeveral ſmall brooks and rivulets in a hilly country, which by degrees uniting all their ſtreams, form the rivers. See the articles LOAD and VEIN.

STRINSIA, in ichthyology, a name given by authors to that ſpecies of the gadus, which is called by ſome *lota*, and by others *muſtela fluviatilis*; by us in Engliſh the *eel-pout*. Olaus Magnus calls it the *borbocha*; and Artedi, who refers it to the genus of the gadi, diſtinguiſhes it by the name of the *gadus* with two fins on the back, with even jaws, and beards at the mouth. See the article GADUS.

STRIP, at ſea. A chaſe is ſaid to *ſtrip* himſelf into ſhort or fighting ſails, when he puts out his colours in the poop; his flag on the main-top; his ſtreamers or pendants at the end of his yard-arm; furls his ſprit-ſail; peeks his miſen; and ſlings his main-yard. In which caſe the chaſer muſt prepare himſelf for fight.

STRIVALE, in zoology, the name uſed by many for the fiſh more uſually known by the name of *aper*, the boar-fiſh. It is a ſmall fiſh, of the ſhape of the doree, caught in the Mediterranean. *Aldrovand.* de Piſc. p. 270. See Tab. of Fiſhes, N° 19. See the article APER.

STRIX, the *owl*. In the Linnæan ſyſtem of zoology, this makes a diſtinct genus of birds of the hawk kind, the diſtinguiſhing characters of which are, that the feet have three toes before, and only one behind, none of which are moveable backwards. *Linnæi* Syſt. Nat. p. 44.

STRIX is more particularly made the name of the common *brown owl*, or *ivy owl*. This is diſtinguiſhed from the other ſpecies of the *owl* kind by theſe characters.

Its beak is of a pale horn colour, and but ſhort, yet the opening of its mouth is very wide. Its eyes are remarkably large and protuberant, and the apertures of its ears very large, and covered with a membrane; and its eyes are nearer to its ears, than in any other animal. Its face is ſurrounded with a double circle of feathers, and its back is mottled with brown and black, and its belly of the ſame colour, but ſomething paler, as if it had a mixture of whitiſhneſs. The legs are feathered almoſt down to the toes, and the outer feather of its wing is much ſhorter than the reſt, by which it is diſtinguiſhed from the aluco without any farther mark. *Ray*'s Ornitholog. p. 66.

STROBILE, a word uſed by chirurgical writers to expreſs a pledget of a twiſted form.

STROBILUS, among botaniſts, a kind of pericarpium, formed of a number of vaginæ with contorted points applied cloſe to one another. See PERICARPIUM.

STROBULUS, among the antients, a kind of mitre, which roſe to a height by many windings and turnings, and uſed by the barbarians; inſtead of which the Romans wore the *apex*, which had a high, but ſtreight top. *Pitiſc.* in voc. See the article APEX.

STROCAL, in glaſs making, a long iron inſtrument like a fire-ſhovel, uſed to empty the metal out of a broken pot into a whole one. *Neri*'s Art of Glaſs Append.

STROMATEUS, in ichthyology, a genus of fiſhes of the malacopterygious, or ſoft-finned kind, the characters of which are theſe. The body is very much compreſſed, and very broad and thin; it has no belly fins, and has only one back fin, which is extended over the whole back. The only known ſpecies of this genus is the *callichthys* of authors, a fiſh called the *fiatola* at Rome. The tail is very forked; the mouth is very ſmall; the teeth are placed in the jaws and palate; and the tongue is ſmooth and broad. The body is ſtriped croſsways. *Artedi*, Gen. Piſc. p. 15.

The *ſtromateus* is a broad, flat, and ſhort ſea-fiſh, ſomething reſembling the turbot in figure, and thin both on the back and belly, but ſwimming erect, not flatwiſe.

Its common ſize is of about a pound and half weight; its colour on the back a pale bluiſh, and on the ſides and belly a ſilvery white; and on its back, and upper part of its ſides, it is very beautifully variegated with yellow lines and ſpots, and towards its belly with others of a paler tinge of the ſame colour. There are two longitudinal lines on the ſides, the one ſtrait, the other arched and bent. Its ſkin is extremely thin and tender, and is covered with ſcales. The tail is forked, the end of the ſnout obtuſe, and the mouth very ſmall. It has only one row of teeth in each jaw, but it has, beſide theſe, two bony ſubſtances in its mouth, all over covered with ſmall teeth. It has no belly fins, but has two ſmall ones at the gills, and one long one running down the back, and another ſingle long one anſwering it near the tail. It is caught in the Mediterranean, and brought to market at Rome under the name of the *lampuga*, and is a very delicate fiſh. *Ray*'s Ichthyography, p. 156.

STROMBUS, in conchyliology, the name of a genus of ſhells, nearly allied to the buccinums, and called by the generality of authors *turbo*. See the article TURBO.

STROMLINGUS, in ichthyology, a name given by ſome writers to the *aras* of the Greeks, which is no other than the common herring. See the article HALEC.

There is no other difference between the *ſtromling* and herring, but that the former is ſmaller.

STROPHIARIUS, among the Romans, a perſon who prepared and made the *ſtrophia*. See STROPHIUM.

STROPHIUM, among the Romans, a ſhort ſwath or band, wherewith the young women kept down the ſwelling of their breaſts. *Pitiſc.* Lex. Ant. in voc.

STROPHIUM was likewiſe a bandage for the head, made of two or three garlands of flowers tied together. *Pitiſc.* loc. cit.

STROPPUS, among the Romans, the thong with which the oars were tied to the *ſcalmus*. *Pitiſc.* Lex. Ant. in voc. See the article SCALMUS.

STRUFERTARII, among the Romans, perſons hired to perform ſome kind of ſacrifices near the trees that had been thunder-ſtruck. *Pitiſc.* in voc.

STRUMARIA, a name by which Galen has called the little burdock. *Ger.* Emac. Ind. 2.

STRUMUS, in botany, a name given by ſome of the old Roman authors to the *cucubalus*, or berry-bearing chickweed.

It had this name from its being found of ſervice in *ſtrumous* and ſcrophulous ſwellings, when externally applied. The name *cucubalus* ſeems to have been derived from the word *haliccacabum*, or the winter cherry, for the antients eſteemed both theſe plants ſpecies of nightſhade; and ſome of them have plainly deſcribed the *cucubalus* under the name of *ſolanum hortenſe*.

STRUPPI, among the Romans, garlands or wreaths of vervain, wherewith the ſtatues of the Gods were crowned. *Pitiſc.* in voc.

STRUT, a term uſed by ſome builders for that brace which is framed into the king-piece and the principal rafters. See BRACE, *Cycl.*

STRUTHIO, in zoology, the name of the oſtrich in the Linnæan ſyſtem. Others uſually call it the *ſtruthio camelus*. According to the ſyſtem of that author, this makes a diſtinct genus of birds, the characters of which are, that it has only two fore toes on each foot, and no hinder ones. See Tab. of Birds, N° 19. *Linnæi* Syſt. Nat. p. 47.

STRUTHIOMELA, a word uſed by Pliny and the antients to expreſs a ſort of quinces, which were ſmaller than the common kind, and of a ſweeter juice and leſs aſtringent.

STRUTHIOPTERI, in natural hiſtory, a name given to a ſeries of flies, of the claſs of thoſe which do not feed on fleſh: theſe have remarkable ſhort wings, and are always found on flowers and leaves of plants. There are ſeveral ſpecies of theſe. The moſt frequent among us are a white-bodied one with black wings, which cover but a very ſmall part of the back, and with feathered wings; and two others with long bodies, of a duſky grey, ſtreaked with white. Theſe are all early flies, being found in the ſpring in hedges and buſhes.

STRUTHIOPTERIS, in botany, a name by which Tragus, and ſome other authors, have called the *lonchitis*, or ſpleen-wort. *Ger.* Emac. Ind. 2.

STRUTHIUM, in natural hiſtory, a name given by the Greeks to a plant called by the Latins *lanaria herba*, from its uſe in the manufacture of their wool. Many have ſuppoſed the *chaſcuſa* of the antients to be the ſame with this plant, but that is an error, for the *chaſcuſa* of the Greeks is the *antirrhinum* of the Latins, as is plain from Pliny; and the ſame author tells us, that it has leaves like thoſe of flax, ſmall, narrow, and ſmooth. All the account we have of the *ſtruthium* is from Dioſcorides, who ſays, that it was a kind of thiſtle, ſomewhat reſembling the ſcolymus, and having a large root, long, and of the thickneſs of two or three fingers, and very ſharp prickles on the leaves. This ſhort account, though not enough perhaps certainly to inform us what the plant was, is yet abundantly ſufficient to prove, that it was not the chaſcuſa, or antirrhinum.

Many have ſuppoſed that the *candes*, or *candiſi* of the Arabian writers, is the ſame plant with the *ſtruthium* of the Greeks, and the old interpreters of the works of Avicenna and Serapion tell us that it is ſo; nay, Avicenna himſelf gives us the deſcription of the *ſtruthium*, as it ſtands in Dioſcorides, under his name *candiſi*, and Serapio under his title of *candes*: but all that we may learn from this, is, that the Arabians were as liable to errors about the Greek Phyſicians works as ourſelves, and that the *ſtruthium* of the antients was as much unknown in their days as in ours. Alphagus gives us a genuine deſcription of the candes, or candiſi, out of the writings of Ebenbita *de Simplicibus*, who ſays, that it was common in Syria; and expreſsly adds, that neither Dioſcorides, nor Galen, were at all acquainted with it, nor had any where mentioned it under any name.

It may ſeem ſtrange to ſome, that Serapio and Avicenna ſhould miſtake the plants of Dioſcorides, and their other Greek predeceſſors; but we find, by Avicenna's character of the artanita, which is not the *artanita*, but the *leontopetalon* of Dioſcorides, that the Greek phyſicians works were at that time tranſlated into the Arabic language; and theſe Arabians uſed that tranſlation in their own tongue, never troubling themſelves to refer to the original. Now though it is probable, that neither Serapio nor Avicenna would have erred about the plants of Dioſcorides, had they read the works of that author in the original, yet is very eaſy to ſuppoſe that a common tranſlator might make blunders about ſuch nice ſubjects as the ſynonyms of plants; and theſe muſt all be tranſplanted into the works of the Arabian writers, who, according to their own accounts, made uſe of theſe tranſlations, inſtead of the originals; and on this foundation we may ſafely affirm, that the *artanita* of the Arabians is the *leontopetalon*, not the *artanita* of the modern times, and that the *candes*, or *candiſi* of the Arabians, though we do not know what it is, yet evidently is not the *ſtruthium* of the Greeks.

We find the *ſtruthium* celebrated among the Romans for its virtues; but all the account we have of it from them, is, that it was a prickly plant, and was very common in the Grecian iſlands. This however is ſufficient to convince us of the great error of thoſe who make this plant, and the *oſtrucium* of the later writers, to be the ſame plant. The oſtrucium is the Smyrnium, or Alexanders, and can by no means be ſuppoſed the ſame with this prickly plant; yet Macer has made them the ſame, and has attributed to the Smyrnium, or Alexanders, the virtues which Theophraſtus gives to the ſtruthion.

STRUTHIUM, in the materia medica, is uſed by modern authors as the name of the *luteola*, or dyers weed, a common wild plant with narrow leaves and yellow flowers. *Dale's* Pharm. p. 248.

STRUTHIUM is alſo uſed by ſome for the *ſaponaria*, or ſoap-wort. *Ger.* Emac. Ind. 2.

STRYCHNUS, a name given by the antients to the plant we call *ſolanum*, or nightſhade. Some of the old authors have alſo called this *tithymal*; and in the times of Theophraſtus, we find that tithymal and nightſhade were ſynonymous terms.

The oldeſt authors [b] mention only three kinds of *ſtrychnus*, or nightſhade; the one they call the *ſleepy nightſhade*, the other the *mad nightſhade*; theſe two being poiſonous, and exerting their bad effects, by making people ſleepy or mad; and the third they called the *eſculent nightſhade*. This ſeems to have been the ſame with our *pomum amoris*, or love apples; which, though not much eſteemed in England, yet in Spain, and many other parts of the world, are univerſally eaten in ſoups, *&c.*—[b *Theophraſtus*, lib. 9. cap. 11.]

Pliny [c], in his account of the ſolanum, ſeems to intend the ſame thing as Theophraſtus; but having collected the accounts of different authors, and put them together in a confuſed manner, it is not eaſy to comprehend what he means; and to add to the perplexity, this is one of the parts of that author where the copies are very faulty.—[c Lib. 21. cap. 31.]

STUB, in the manege, is uſed for a ſplinter of freſh-cut under-wood, that goes into a horſe's foot as he runs; and piercing the ſole through to the quick, becomes more or leſs dangerous, according as it ſinks more or leſs into the foot.

STUD, in the manege. See BREED.

STUDDING-*ſail*, in a ſhip, the ſame with what is called a *gooſe-wing*. See the article GOOSE-*wing*.

Studding-ſails, are bolts of canvas, or any cloth that will hold wind, extended in a fair gale of wind along the ſide of the main-ſail, and boomed out with a boom. They are ſometimes alſo uſed to the clew of the main-ſail, fore-ſail, and ſprit-ſail, when the ſhip goes either before the wind, or quartering.

STUFFING, or CONGESTION, in medicine, the name of a diſtempered ſtate of the body, in which there is a ſpecial and peculiar direction of the blood, in larger quantities than ordinary, to ſome particular places, in order to its there making its way out by an hæmorrhage, and relieving nature from an over-abundant quantity of it, that the reſt may circulate the more freely and eaſily.

Congeſtions differ in regard to the places where they appear; ſome are made in the head, others in the breaſt; ſome in the hypocondria, and ſome in the kidneys; and others in the hæmorrhoidal veſſels. In this alſo there is ſome regularity in regard to the age and conſtitution of the patient; for in young perſons *congeſtions* are uſually made in the head, in middle-aged people in the breaſt, and in thoſe ſomewhat farther advanced in years toward the abdomen.

Medical writers diſtinguiſh *congeſtions* into two kinds, the *complete*, and the *incomplete*. The complete *congeſtions*, are thoſe in which the blood is directed to ſuch a part where it is natural and eaſy for it to be diſcharged by an hæmorrhage; ſuch are the head, the lungs, the uterus, and inteſtinum rectum; and in which it is carried in large quantities to the very parts.

The incomplete *congeſtions*, are thoſe in which the blood is indeed directed toward theſe, or the like parts, from whence it ought to be diſcharged, but never is carried to them, or indeed near them, but collecting itſelf at a diſtance from them, can never come to a diſcharge by a hæmorrhage. Something of this kind is obſerved in the rheumatiſm, gout, and what are called the *cold catarrhs*.

Congeſtions are alſo divided into two kinds, from the matter they are occaſioned by: the one are called *ſanguineous*; in theſe the blood is always ready to appear in its own form in an hæmorrhage. The other are ſtiled *bechic*; theſe extend themſelves farther than the ſanguineous, and theſe have their origin from the blood: but when a paſſage is by any means denied to the whole ſubſtance of the blood, its ſerous parts only form the *congeſtions*; and theſe, as they are become either mucidoſeroſe, or ſeroſoſaline, are the occaſion of coryzæ, gravedines, moiſt coughs and aſthmas, cold œdematous, ſcirrhous, and glandulous tumors.

Authors diſtinguiſh *congeſtions* from ſtaſes ſanguinis, by this, that in theſe the quality and progreſſive motion of the humors are greatly altered, in the others, as ſuch, they are not altered at all.

The ſigns of *congeſtions* are deduced from their effects, and are theſe. In the parts affected there is a diſtenſion of the veſſels, ſo that the very ſmall ones, which ſcarce appear at another time, are now found turgid, with heavy and tenſive pains, and often, as it were, with a ſenſation of pricking; if the *congeſtion* be carried farther, there ſucceeds to theſe redneſs, and preternatural heat in the part: when upon this there appears an hæmorrhage, all the ſymptoms vaniſh; but if this diſcharge does not happen, there are frequently formed tumors, and running ulcers, with violent pain and inflammation. Theſe are the ſymptoms in the affected parts; in the more remote ones, there is a conſtriction of the veſſels, ſo that they appear leſs than natural, and a ſenſation of coldneſs in the fleſh.

The perſons moſt ſubject to *congeſtions* are thoſe of a plethoric habit, and ſuch as live ſedentary lives, and eat and drink high; and to theſe are to be added, ſuch as have been uſed to ſome habitual diſcharge of blood, whether natural, or by regularly bleeding in the arm at ſtated times of the year, and afterwards live wholly without theſe; and ſuch as have had iſſues, bliſters, or old natural ulcers dried up, without uſing the neceſſary precautions on ſuch occaſions. *Junker*'s Conſp. Med. p. 90.

Cauſes of CONGESTIONS. Theſe are principally a plethoric habit of body, and an effort of nature to relieve herſelf from the load, by diſcharging part of it at ſome proper outlet. To theſe are to be added many external and occaſional ones; ſuch are a moiſt and cold air, and ſometimes a moiſt and hot one; a refrigeration of the remoter parts, or of thoſe oppoſite to ſuch as are proper for the *congeſtion*.

The effects of *congeſtions* are generally ſtagnations; and from theſe ſtaſes and corruptions of the blood and humors, too frequently ariſe. When *congeſtions* are become habitual to a perſon, they very rarely yield to the effects of medicines, even though the material cauſe is removed, but often after this renew their ſymptoms in ſome different way. When *congeſtions* are ill treated, eſpecially when narcotics are given, or hot medicines, or a warm diet are indulged, they always return the more frequently upon the patient, or bring on a ſeries of other diſorders; and *congeſtions* in themſelves are not without danger, when they affect perſons at a certain time of life. Finally, *congeſtions* in the breaſt are always of more unhappy conſequence than thoſe of the head and abdomen, becauſe the evacuation of the blood, which is what nature aims at in a *congeſtion*, is not to be effected any way happily in the breaſt.

Method of treating them. In the time of the paroxyſm, the bowels, which are uſually bound in this caſe, are to be looſened by a gentle emollient clyſter, or by ſome of the gentle purges; and the too great expanſion of the blood, and ſtricture of the fibres, is to be prevented by abſorbents, and nitrous medicines, with the addition of cinnabar, and of the common diaphoretics: to this purpoſe powders are to be given three or four times a day, compoſed of crabs eyes, nitre, antimonium diaphoreticum, and cinnabar, either native, or that of antimony; and if the pains are violent, a gentle opiate may be added to the powder to be taken at night. To theſe things are to be added the temperate alexipharmics, and the mild and diluent diaphoretics; ſuch as tea made of the flowers of lavender, of ſage, and the like: and when the blood begins to ſtagnate in the place of the *congeſtion*, topics may be uſed; ſuch as camphorated ſpirit of wine, or a cataplaſm of caraway ſeeds, juniper berries, ſalt, and crumb of bread: and in ſome caſes repellents may be ſafely uſed; ſuch as the vinegar of roſes, and mixtures with nitre, and with ſaccharum ſaturni. *Junker*'s Conſp. Med. p. 92.

STUFFINGS *of the breaſts*, in infants. See INFANT.

STUM, (*Cycl.*) in the wine trade, a term for the unfermented juice of the grape, when it has been ſeveral times racked off, and ſeparated from its ſediment. The caſks are for this purpoſe well matched, or fumigated with brimſtone every time, to prevent the liquor from fermenting, as it would otherwiſe readily do, and become wine.

It is this fume of the ſulphur from the match that prevents, in this caſe, all tendency to fermentation, and continues the natural juice of the grape in a ſweet ſtate, fit to be readily mixed with wines inſtead of ſugar; for which purpoſe it is very much uſed in Holland, and ſome other countries, as alſo for giving a new fret, or briſkneſs, to decayed wines. So that very large quantities of this *ſtum* are annually imported to all parts along with the foreign wines; and after the ſame manner a *ſtum* is prepared in England from the juice of apples, which ſerves the ordinary purpoſes of the wine-cooper. In the preſerving this liquor in this ſtate, we ſee the vaſt uſe of brimſtone, for it could never be done otherwiſe, than by the matching the caſks. *Shaw*'s Lectures, p. 192. See the article MATCHING.

Artificial STUM. An artificial muſt, or *ſtum*, as good as the natural, and as fit for the re-fermenting, fretting, improving, or making of wines, vinegars, and ſpirits, may be prepared in the following manner.

Take three pound of fine lump ſugar, or ſuch as has been well refined from its treacle, melt it in three quarts of water, and add in the boiling of Rheniſh tartar, finely powdered, half an ounce; this diſſolves with a remarkable ebullition, and gives a grateful acidity to the liquor; take the veſſel from the fire, and ſuffer it to cool, and you have an artificial muſt, which in all reſpects reſembles the natural taſte and ſweet juice of a white flavourleſs grape, when well purified, and racked off from its ſediment, in order to make *ſtum*. If this artifical muſt be ſtummed, that is, well fumigated with burning brimſtone, it becomes a perfect *ſtum*, and may be made of any flavour, at the diſcretion of the artiſt. *Shaw*'s Lectures, p. 202.

STUPHA, a name given by ſome writers to a balneum vaporis.

STUPIO, a name given by ſome of the writers in chemiſtry to tin. See TIN.

STURDY, in cattle, a kind of diſtemper, otherwiſe called the *turning-evil*. See TURNING-*evil*.

STURIO, the *ſturgeon*, a very well known, large, and fine-taſted fiſh, caught in many places, and ſometimes in the river Thames, being one of thoſe fiſhes called *anadromi* by authors, which ſpend a part of their time in the ſea, and a part in rivers.

It never goes into the ſea to any great diſtance, and never is caught there of any very great ſize. The ſea ſerves for its production, but it is only in large rivers that it grows to its uſual ſize. *Ray*'s Ichthyogr. p. 248.

STURNUS, the *ſtarling*, a bird very well known, and of the thruſh, or turdus kind.

There is, beſide the common ſpecies, a very beautiful one, deſcribed by Bontius under the name of the *Indian ſtarling*, or *ſturnus Indicus*. This is of the ſize and ſhape of our common *ſtarling*, but is variegated with a deep blue, a lead colour, and a pale grey, and has on its head a very beautiful yellow creſt. It learns to imitate the human voice, and talks much better than the parrot, but is troubleſome in being over noiſy. *Ray*'s Ornitholog. p. 145.

Linnæus makes the *ſturnus* a diſtinct genus of birds, of the order of the *paſſeres*; the diſtinguiſhing characters of which are, that the tongue is membranaceous, ſharp, and edged with a rim, or margin; the beak is of a ſomewhat cylindric form, and is pointed and crooked. *Linnæi* Syſtem. Naturæ, p. 49.

STYE, or STITHE, the Engliſh name for a diſorder on the eyelids, called by the phyſicians *hordeolum*, and by ſome *crithe*, *chalazium*, or *grando*.

It is a ſmall encyſted tumor, uſually of about the bigneſs of a barley-corn, which ſometimes degenerates into matter, and occaſions great pain and uneaſineſs.

The tenderneſs of the organ of ſight makes it neceſſary to be careful about theſe tumors, which, if ſituated in any other part of the body, would hardly deſerve much attention. Some authors commend cataplaſms, and the like applications, to theſe, but the eye is often hurt by thoſe applications; and it is obſerved beſides, that theſe tubercles ſeldom give way to topical applications of any kind.

When they are ſmall, it is beſt to let them take their own courſe; but if ſo large as to occaſion deformity, or danger of hurting the ſight, the way to extirpate them, is to make a longitudinal inciſion on the part, and carefully take them out whole; or if it cannot be thus got out clean, it muſt be cut out, as far as may be, with ſciſſors, and dreſſed with Ægyptian ointment, and a little red precipitate, or touched at times with the common cauſtic, till eaten thoroughly away, and then the wound dreſſed and healed in the common manner.

This is the method by which the flat and broad-bottomed tumors of this kind are to be extirpated; and in this great care muſt be taken that none of the ſharp applications touch the eye, as they might injure the ſight. It is common, however, with theſe tumors to hang by a ſort of ſmall root, and then they are much more eaſily managed, there being no more neceſſary than the cutting them cloſe off with a pair of ſciſſors, or the tying them firmly round with a piece of ſilk, or horſe-hair. They are ſometimes, if taken in time, diſperſed by rubbing them with faſting ſpittle, or with applying the pulp of a roaſted apple mixed with ſome ſaffron and camphor. *Heiſter*'s Surgery, p. 365.

STYGIA *aqua*, a term uſed ſometimes to expreſs aqua regia; ſometimes for the other ſtrong acid ſpirits.

STYLE, among botaniſts. See PISTIL.

STYLOBATON, or STYLOBATA, in architecture, the ſame with the pedeſtal of a column. It is ſometimes taken for the trunk of the pedeſtal, between the cornice and the baſe, and then called *truncus*. It is alſo called by the name of *abacus*.

STYLOCERATOIDES, in anatomy, a name given by Riolanus, and ſome others, to a muſcle, more generally known by the name of *ſtylohyoidæus*. See the next article.

STYLOHYOIDÆUS, a ſmall fleſhy muſcle, lying obliquely between the apophyſis ſtyloides, and os hyoides.

It is fixed laterally by one extremity to the root, or baſis of the apophyſis ſtyloides, and by the other to the os hyoides, at the place where the baſis and cornu unite, and likewiſe to the cornu itſelf, from whence it has been called *ſtylo-cerato-hyoidæus*. The fleſhy fibres of this extremity are often parted, and incloſe the middle tendon of the digaſtricus. *Winſlow*'s Anatomy, p. 255.

STYLOHYOIDÆUS *novus*, a name given by Santorini to a ſmall muſcle of the os hyoides, called by Albinus *ſtylohyoidæus alter*, and by Douglaſs *ſtylochondrohyoidæus*. See the articles MOUTH and Os *hyoides*.

STYMMATA, a word uſed by ſome authors to expreſs the ſtiff ointments. The antients uſed the word both for their more ſolid and ſtiff ointments, and for the ingredients which gave thoſe ointments that conſiſtence: they alſo called by the ſame name the ſeveral ſweet ingredients which they put into their ointments, to give them a fragrancy, and preſerve them from corruption; ſuch were the powders of ſpikenard, mint, amomum, and the ſeveral ſpices.

STYMPHALIA, Στυμφαλια, in antiquity, a feſtival at Stymphalus in Arcadia, in honour of Diana, called from that place *Stymphalia*. *Potter*, Archæol. Græc. Tom. I. p. 431.

STYMPHALIDES *aves*, in fabulous antiquity, birds of an extraordinary ſize, which in their flight are ſaid to obſcure the ſun. They fed only on human fleſh; but Hercules, by the help of Minerva, drove them out of Arcadia by the noiſe of cymbals. *Danet*. in voc.

STYPTIC (*Cycl.*)—STYPTIC *powder of Helvetius*, in pharmacy, a compoſition of alum and dragon's blood. In the Edinburgh diſpenſatory, two parts of alum are directed to be made into powder with one of the dragon's blood: others uſe equal parts of both. See Med. Eſſ. Edinb. Vol. 4. Art. 7.

This medicine is ſaid to be extremely ſerviceable in uterine hæmorrhages, either to correct the too frequent return of the menſes, or their too great abundance; alſo to ſtop the flooding, to which women with child are ſubject, and to moderate the flow of the lochia. It has alſo been found to have ſurpriſing good effects in the fluor albus.

In violent bleedings it may be given in the quantity of half a drachm every half hour, and it ſeldom fails of ſtopping the bleeding before three drachms, or half an ounce has been taken. See Medic. Eſſ. ibid.

Heiſter alſo, in his Compendium Medicinæ Practicæ, p. 143, recommends this powder, or alum alone, with a decoction of lin-ſeed, from Helvetius Traitè des pertes de ſang.

Eaton's STYPTIC, a medicine famous for curing freſh wounds in a very ſmall time, and immediately ſtopping their bleeding.

The method of curing freſh wounds in a few days without ſuppuration, where neither nerves, large veſſels, bones, nor any of the viſcera are concerned, has been a practice long ago uſed.

Purman, a famous ſurgeon of Breſlaw, in his Chirurgia Curioſa, tells us of a mountebank who gave himſelf thirteen wounds by inciſion in the upper part of his left arm, and applying his noſtrum with a common roller, the wounds were all well in two days: and both this author, and Blegny, mention what they call a *martial ſtyptic*, which cures wounds in two days, eſpecially if the patient take alſo a few drops of it inwardly.

The French were a long time very fond of a *ſtyptic* ball made of filings of iron and tartar, mixed to a conſiſtence with French brandy, which was afterwards publiſhed by Helvetius, and from him has been generally known by the name of *Helvetius*'s *ſtyptic*. This was extolled with us as one of the greateſt medicines in the world for the cure of wounds, bruiſes, and external injuries of all ſorts: but the author never ſaid ſo much about it; he only modeſtly introduced it into the world as an uſeful thing for a firſt dreſſing of freſh wounds with people who lived too far off for the immediate aſſiſtance of a ſurgeon: and he mentions ſeveral caſes, in which it ought not to be uſed. In fine, he publiſhed it as a good medicine under proper reſtrictions; but we made it an univerſal one. The only univerſal remedy of this kind, that we have had recommended by the author as ſuch, is the famous *ſtyptic* of Dr. Eaton, which the inventor ſays is good to ſtop all manner of bleeding both without and within, without any manner of exception.

Sir Richard Blackmore, ſoon after the publication of this great ſecret, wrote a treatiſe on conſumptions, in which he highly extols this *ſtyptic* of Dr. Eaton, declaring poſitively, that it will be of more ſervice to the world than all the diſcoveries that had been made before it. On this Dr. Sprengel, who had before examined *Eaton*'s *ſtyptic*, and judged it to be no other than that of Helvetius; which, after having been tried and diſcarded in France, Germany, and Holland, had been ſet on foot as an univerſal medicine here, thought it worthy a more ſtrict and public examination, and ordering an apothecary of credit to prepare him ſome of Helvetius's *ſtyptic* in the common way, he produced before a judicious audience a bottle of that, and another of *Eaton*'s *ſtyptic*; and giving them both the ſame trial, they both anſwered in the ſame manner, and proved, beyond all poſſibility of doubt, that they were in effect the ſame medicine.

The ſame trials were made by ſeveral other chemiſts, phyſicians, and apothecaries; and the event proving the ſame in all, it appeared wonderful that a man, who had a mind to ſell a known medicine under the notion of a ſecret, ſhould not have had the caution to alter or diſguiſe it either in taſte, ſmell, or colour; which he might very eaſily have done, without at all impairing its virtues as a medicine.

The uſual method of trying a *ſtyptic* is upon the crural artery of a dog cut open for that purpoſe. In this manner the *ſtyptic* of Helvetius and Eaton were both tried, and both anſwered very well; and plain French brandy being alſo tried, had the ſame ſucceſs; whence it appeared, that there was no very great virtue in either, more than the heat of the ſpirit, which forcibly conſtringed the fibres: and when we conſider the ſmallneſs of the crural artery in a dog, we ſhall not wonder that a trifle ſtops the bleeding of it, ſince, with a bit of dry lint, or even with no application at all, the bleeding will ſtop of itſelf, without any hurt to the animal. By this, and by the common experiments made upon this *ſtyptic* on other occaſions, its external virtues appear to be very trifling. Internally, however, it is a much worſe medicine. It is too often given in natural hæmorrhages; and in all theſe caſes, as there is a ſtimulation and feveriſh diſpoſition, which gives occaſion to the bleeding, it is certain that any thing, of the nature of brandy and a chalybeate, muſt add to it, inſtead of curing it. Upon the whole, the virtues of theſe *ſtyptics* externally are too trifling to be truſted to; and internally too precarious to meddle with, without the greateſt caution. Philoſ. Tranſ. N° 383. p. 110.

STYRAX (*Cycl.*)—STYRAX, the *ſtorax-tree*, in botany, the name of a genus of trees, the characters of which are theſe. The flower conſiſts of one leaf, and is of the funnel-faſhioned kind, and divided into many ſegments at the edges. The piſtil ariſes from the cup, and is fixed, in the manner of a nail, into the hinder part of the flower: this finally becomes a roundiſh, or fleſhy fruit, containing one or two kernels, in which are ſoft ſeeds.

There is only one known ſpecies of this tree, which is the common, or quince-leaved *ſtorax-tree*. *Tourn.* Inſt. p. 598. See the article STORAX.

SUBARMALE, among the Romans, a coarſe and thick kind of caſſock worn by the ſoldiers under their arms, in order to keep them from being hurt with their weight. *Pitiſc.* Lex. Ant. in voc.

SUBBUTEO, in zoology, the name of a bird of the hawk kind, called in Engliſh the *ringtail*; the male of which is called the *hen-harrier*. Some authors give it the name of *pygargus accipiter*. *Ray*'s Ornithol. p. 40. See the articles RINGTAIL and HEN-HARRIER.

SUBCLAVIUS, a ſmall oblong muſcle, lying between the clavicle and firſt rib. It is fixed by one end in all the middle lower portion of the clavicle, at the diſtance of about an inch from each extremity; and by the other in the cartilage, and a ſmall part of the bone of the firſt rib. It ſeems likewiſe to adhere to the extremity of the clavicle, next the ſternum, by a kind of broad thin ligament. *Winſlow*'s Anatomy, p. 177.

SUBCOSTALES. Theſe muſcles are fleſhy planes of different breadths, and very thin, ſituated more or leſs obliquely on the inſide of the ribs near their bony angles, and running in the ſame direction with the external intercoſtals. They are fixed by other extremities in the ribs, the inferior extremity being always at a greater diſtance from the vertebræ than the ſuperior, and ſeveral ribs lying between the two inſertions. Theſe muſcles are more ſenſible in the lower ribs than in the upper, and they adhere cloſely to the ribs that lie between their inſertions. *Winſlow*'s Anatomy, p. 233.

SUBDUPLICATE *ratio* of any two quantities, is the ratio of their ſquare roots. See RATIO.

SUBER, the *cork-tree*, in botany, the name of a genus of trees, the characters of which are theſe. The fruit and flowers are the ſame with thoſe of the ilex, but the bark of the tree is thick, fungous, and light.

There are two ſpecies of this tree. 1. The ever-green broad-leaved *cork-tree*. 2. The *cork-tree* with narrow, and not ſerrated leaves. *Tourn.* Inſt. p. 584.

SUBETH, the word uſed by the Arabian writers to expreſs a carus.

SUBETH *ſabala*, a term uſed by the Arabian writers to expreſs a coma vigil.

SUBFRONTALIS *futura*, a name given by ſome anatomical writers to the future, by which the os frontis is connected with the bones of the ſuperior jaw.

SUBJECT (*Cycl.*)—SUBJECT, in the manege. To keep a horſe *ſubject*, is an expreſſion relating to volts; ſignifying, to keep the croupe of the horſe in the round, ſo that it may not ſlip out; that he may not traverſe; and that he may work

work in the manege, croupe in, marking his equal times, without losing his ground.

SUBJECT, in music. See SOGGETTO.

SUBJECTION, *subjectio*, in rhetoric, is used for a brief answer to a preceding interrogation: thus Cicero, *Quid ergo? audaciſſimus ego ex omnibus? minimè. Voſſ.* Rhet. lib. 5. p. 416.

SUBINTRANTES *febres*, a term used by some medical writers to express those fevers in which one fit begins before the other is perfectly worn off.

SUBITO, in the Italian music, is used to signify that a thing is to be performed quickly and hastily: thus we meet with *volti ſubito*, turn over the leaf quickly.

SUBLIMABLE *bodies*, a term used by some of our chemical writers to express such substances as are capable of *ſublimation* in a dry form.

They say that only those things are *ſublimable*, which contain a dry exhalable matter in their original construction; and among these they find a great variety, which require various methods and means to execute that effect. Among the minerals, sulphur, antimony, and orpiment, are named as the principal among *ſublimable* bodies: these are of a very lax compage, or structure, and are easily raised by fire in small particles, which concrete again on being stopt from flying off by the cover of the vessel; while, on the contrary, iron, silver, and the other metals, being of a closer structure, remain fixed in the greatest heat, and never ascend, unless mixed with some volatile substance that is itself capable of rising, and of taking up some of them with it.

Thus copper and iron will be raised in *ſublimation* by means of sal armoniac mixed with them; and even gold itself is said to be subject to the same law, Mr. Boyle assuring us, that he had a secret method of preparing a certain saline substance, by means of a very small admixture of which, the gold would be made to rise in *ſublimation*, and form fine purple crystals.

Fire is the great agent in *ſublimation*; and according as these bodies are more or less dense and compact, this is to be made more or less strong, and continued a longer or a shorter time. Very often the internal heat alone, occasioned in vegetable or animal substances by fermentation, is sufficient to *ſublime* certain of their principles, as is evident in Wedelius's instance of a ball of woad, or glastum.

Many substances of a looser texture are to be *ſublimed* alone, and many others are to have other things mixed with them, as before observed, in order to make them subject to this operation of the fire. The admixtures, which are to make bodies *ſublimable* which are not so in themselves, are to be of various kinds, according to the nature of the body to be *ſublimed*; and the attempt of this process upon any particular body is never to be given over on the first essay, but the whole round of those things, which render *unſublimable* bodies *ſublimable*, are to be tried first, that what one does not effect, another may have its chance of doing.

Among these bodies, used as mixtures in *ſublimation*, some act by rendering the body more easily fusible, and disuniting those particles more readily which the fire is expected to carry up; others act only by preventing the cohesions of the particles of the substance to be *ſublimed*, which heat would otherwise occasion; and finally, others by entering the body of the fixed substance they are mixed with, and giving wings, as it were, to its subtle particles, so that they may ascend with its easily *ſublimable* matter, and join with it in the formation of one mixed substance in the top of the vessel, by partaking of the nature of both. Others act potentially in the same way, but by different means, themselves not being capable of *ſublimation*, but acting on the substance to be *ſublimed*, by enervating, weakening, or absorbing those substances, or parts of the mixed body, which would have otherwise prevented the ascent of the rest; and finally, some act as dissolvents only, and by that means render things easy of *ſublimation*, which would have been very difficultly so, while their parts were in a more strict continuity.

The use of this management of *ſublimable* bodies is to prepare the flowers, the sulphurs, or the volatile salts of those bodies, pure and separate from their terrestrial fæces, from phlegm, from impure oils, and from acids; and the mixing together the *ſublimable* bodies of two or more kinds into one substance, proper for the uses of medicine, painting, &c. as in the combination of mercury with sulphur into cinnabar; a noble medicine, and a very valuable paint; or with corrosive salts into the common drugs, called, by way of pre-eminence to all others, *ſublimate*. *Hoffman*'s Acta Laborat. Chem.

SUBLIMATE (*Cycl.*)—*Corroſive* SUBLIMATE. In making *ſublimate*, the quicksilver is extinguished by trituration in calcined vitriol. But Monsieur Lemery observes, that bole armeniac and potters clay are cheaper, and extinguish the mercury sooner.

It has been said, that to try whether *ſublimate* has been sophisticated with arsenic or not, it was to be rubbed with salt, or oil of tartar; and that if sophisticated, it would turn black. But Mr. Lemery agrees with Barchusen and Boulduc, that this is no trial; for the salt of tartar has the same effect on the good and the bad *ſublimate*. See Mem. de l'Acad. des Scien. 1734.

Dr. Kirsten affirms that *ſublimate*, rightly prepared, becomes first saffron coloured, and then red, when oil of tartar is dropped on it: whereas, if it is adulterated with arsenic, it becomes first near the colour of brimstone, then red, afterwards ash coloured, and lastly black. He is positive in this, notwithstanding what Barchusen and Boulduc have said to the contrary. Commerc. Norimb. 1738. Hebd. 12. §. 2.

An anonymous chemist affirms, that *ſublimate* prepared with arsenic becomes at last white, instead of black, when touched with oil of tartar. He says, that in the *ſublimation* of sweet mercury, where the *corroſive ſublimate* has been adulterated, the upper part is of an orange colour, and a white earth remains in the bottom, and the belly of the glass becomes dark coloured, or smoaky; whereas, when the corrosive mercury is genuine, the upper part is white, the powder in the bottom is red, and the middle is not smoaky coloured. But the sweet mercury, prepared with genuine or adulterated corrosive, appears on every trial the same. Dr. Kramer relates the history of a lad who swallowed half an ounce of *corroſive ſublimate*; soon after which his mouth and stomach were so eroded, that he voided large quantities of blood, both upwards and downwards, with violent gripes, coldness of the extremities, startings of the tendons, and racking pain. A vomit was soon given; notwithstanding which the symptoms continuing, Dr. Kramer ordered mild drink, with large quantities of oil of tartar *per deliquium* in it, by which the symptoms soon were mitigated, and the cure was compleated by giving theriaca andromachi, with terra sigillata, and putting him into a warm bath. Commerc. Norimb.

Blue SUBLIMATE, a preparation of mercury with some other ingredients, yielding a fine blue for painting. The method of making it is this: take quicksilver two parts, flower of brimstone three parts, sal ammoniac eight parts; grind these upon a porphyry, and with the quicksilver put them into a long-necked glass vessel luted at bottom; place it in a sand-heat, and when the moisture is ascended, you will have a fine *blue ſublimate* for painting. *Neri*'s Art of Glass, p. 164.

SUBLIMIS, in anatomy, a name given by Albinus, Hunaud, and others, to the muscle of the wrist, called by others the *perforatus*. See the article PERFORATUS.

These authors call the perforans the *profundus*. See the article PERFORANS, *Cycl.*

SUBLINGUALIA, a term used by some authors to express such medicines as were intended to be laid under the tongue, and gradually dissolving there.

These have been principally intended either to cure coughs, or give a sweet scent to the breath.

SUB-MARSHAL, an officer in the Marshalsea, who is deputy to the chief marshal of the king's house, commonly called the *knight marſhal*, and hath the custody of the prisoners there. He is otherwise termed *under marſhal*. Crompt. Jurisd. 104. *Blount*, *Cowel*.

SUBMARINE *navigation*. See the article *Submarine* NAVIGATION.

SUBMERSION, *ſubmerſio*. See DROWNING.

SUBMISSIO, a word used by medical writers to express a remission.

Sometimes it imports the same as *ſyſtole* with respect to the arteries, that is, their contraction.

SUBPRINCIPALIS, in some Latin writers of music, is used for the note or chord called by the Greeks παρυπατη, *parhypate*.

SUBPURGATION, *ſubpurgatio*, a word used by some writers to express a gentle purgation.

SUBROTUND *leaf*, among botanists. See LEAF.

SUBSCAPULARIS, (*Cycl.*) a muscle of the same breadth and length with the scapula, of which it occupies all the inner or concave side; and having its name from its situation.

It is thick, and made up of several penniform portions, nearly in the same manner with the deltoides. It is fixed in the internal labium of the whole basis, and in almost the whole internal surface of the scapula; its fleshy portions lying in the intervals between the bony lines, when these are formed. Near the neck they leave the bone, and form a very broad tendon, which is inserted in the surface of the small tuberosity of the head of the os humeri, close by the bony channel. The lower edge of this tendon probably sends off the ligamentary frænum, mentioned in the descriptions of the latissimus dorsi, teres major, and coracobrachialis. This muscle covers immediately the serratus major, being in a manner inclosed between it and the scapula: the upper edge of its tendon is joined to the lower edge of that of the supra spinatus, except at the upper part of the bony channel, where they give passage to one tendon of the biceps. It likewise adheres to the capsular ligament. The tendons of the supra spinatus, infra spinatus, teres minor, and *ſubſcapularis*, being all joined by their edges, form a sort of cap, which covers the upper part of the head of the os humeri. *Winslow*'s Anatomy, p. 184.

SUBSISTENCE, in the military art, is the money paid to the ſoldiers weekly, not amounting to their full pay, becauſe their clothes, accoutrements, tents, bread, &c. are to be paid; it is likewiſe the money paid the officers upon accompt, till their accompts be made up, which is generally once a year, and then they are paid their arrears.

SUBTERRANEAN (*Cycl.*)—SUBTERRANEAN *fires*. Among the many places where theſe *fires* are found, England is not wholly without them; though with us they appear only in the coal countries, and plainly feed on nothing but the upper ſtratum of the coal, called by the miners *day coal*, unleſs where they have by accidents been kindled by actual fires at great depths, or fired downward, by being pent in for room. See VOLCANO.

They have, in many places, been known to burſt out ſpontaneouſly from the ſurface, and make their courſe both ways from the place along the ſtratum. There is no actual native ſulphur found there, but there are plenty of the marcaſites, to which the *fire* is probably originally owing; as we know that theſe ſtones, piled up in a heap in the air, will often take fire of themſelves.

If at any time a ſmall quantity of melted ſulphur ſhould be found in the earth, it is not to be ſuppoſed to be native there; for the *fire* acting on the other marcaſites it meets with, may very well melt and ſeparate the ſulphur from them, as is done at Goſſelaer, and in ſome other places, where the ſulphur we commonly uſe is made in that manner by art.

It has been ſaid, that crude ſal armoniac is found in the earth in theſe places; but it is only met with at the mouths of the *fire*. Where the ſmoak aſcends in theſe places, there continually ariſe vaſt quanties of the vapours of ſulphur, as well as ſal armoniac; and cruſts of the flowers of ſulphur, and of ſublimed ſal armoniac, are found together around theſe openings. The brimſtone generally ariſes firſt, and forms a cruſt, under which there is a cruſt of ſal armoniac.

It is remarkable, that in the places where theſe *fires* have burnt, there are often found cavities in the rocks, containing a white milky liquor of a ſtyptic taſte: this is a ſort of liquid alum, and yields generally about one half of that ſalt.

The ſal armoniac is found in conſiderable quantities in ſome of theſe places, yet its origin is not eaſily accounted for on the common principles; for neither nitre, nor common ſalt, are found in the earth thereabouts. The ſprings alſo, which ariſe in the neighbourhood of the places where the *fire* is, have been diligently examined, and no ſuſpicion of the leaſt admixture of ſal armoniac appears in them. The water that runs through the ſtrata of coal in all theſe countries is vitriolic, and turns black with a decoction of galls. There needs no more than burning pit coal to produce ſal armoniac; for it has been found produced in brick-kilns, where nothing but coals and clay have been laid together: and here it muſt be aſcribed to the coal alone, no one ever having found it in clay. Phil. Tranſ. N° 130. See FIRE.

We have an account, in the Philoſophical Tranſactions, of a *ſubterranean* town found at Portici, near Naples, in which many antique ſtatues, paintings, and other curioſities, have been found.

This *ſubterranean* town is probably the antient city of Herculaneum, which was ſwallowed up by an earthquake. See Phil. Tranſ. N° 458. ſect. 4, 5, and 6.

It is remarkable, that ſome of the antique paintings found there are as freſh and perfect, as if lately painted. Ibid. ſect. 6.

SUBTRACTION. See the article SUBSTRACTION, *Cycl.*

SUBVERSIO *ſtomachi*, a term uſed by ſome authors to expreſs a violent vomiting, when what ſhould paſs through the inteſtines is voided conſtantly by the mouth.

SUBULARE *folium*, among botaniſts. See LEAF.

SUBULATED *leaf*, among botaniſts. See LEAF.

SUBULO, a term uſed by Pliny for deer two years old. See the article FERULÆ.

SUBULO, in natural hiſtory, a word uſed by the antients to expreſs a deer, or ſtag, at that time of its life when the horns firſt begin to appear.

Others have underſtood it as the name of the oryx, whoſe horn was narrow at the ſummit, and thence gradually larger toward the baſe, ſo that it reſembled the figure of the ſubula. This is the fabulous creature called the *unicorn*, and deſcribed as a nimble and terrible animal. But it is certain that no ſuch animal ever exiſted, as is called by this name, and thus deſcribed: the only one-horned animal in the world is the rhinoceros, and this is an unwieldy heavy animal, not at all reſembling the characters or figures we have of the *ſubulo*, or oryx.

It is to be obſerved, that the *ſubula* of the moſt antient writers was an inſtrument of iron, ſharp at the point, uſed in the ſtone-quarries to break way through large maſſes.

SUCCENTURIATI (*Cycl.*)—It is the opinion of Dr. Kerkring, and of many ſince his time, that theſe are caſes in which there is elaborated a bilious juice, which afterwards, either by the emulgent vein, or, as often is the caſe, immediately paſſes to the cava, and being thence conveyed to the heart, raiſes there that efferveſcence, which Sylvius contends to be excited in that part by the mixture of a ſaltiſh liquor with an acid: for although experience contradicts the conveyance of the juice out of the liver through the cava, yet that efferveſcence in the heart, upon which the whole ſyſtem of Sylvius is grounded, may ſtill hold, if this opinion about the uſe of the *ſuccenturiati* be true. As there needs but very little leaven to ferment a large maſs, which is in a proper ſtate and condition to be fermented, a very minute quantity of ſalt of tartar, mixed with a very large portion of oil of vitriol, will occaſion not only a very conſiderable, but a very laſting fermentation; though a very conſiderable quantity of the latter, poured on a quantity of the former, cauſes but a languid and ſhort efferveſcence. This account of an opinion, though not now received, may be worthy the conſideration of thoſe who remember how cautiouſly both ſides of a queſtion ought to be heard, before any thing is determined in regard to it. *Kerkring*, Spicileg. Anat.

SUCCIFERA *vaſa*, in natural hiſtory, a name given by thoſe who have written of the anatomy of plants, to thoſe veſſels which contain the juices, by way of diſtinction from thoſe which only give paſſage to the air, and are called *tracheæ*. Lewenhoek tells us, that the microſcope diſcovers the *ſucciferous* veſſels of plants to be, in all reſpects, analogous to thoſe of animals, and that they are of two kinds, veins and arteries: the latter receiving the juices from the root, and carrying them all over the plant; and the others receiving the juice from their extremities, and carrying it back again to the root, where it is again delivered to the arteries.

SUCCINUM, *amber* (*Cycl.*)—The origin of *amber* has been much diſputed among the naturaliſts, and many erroneous, and ſome even abſurd, conjectures made about it. There ſeems however, from experiment and a cloſer obſervation, to be no doubt but that it is wholly of mineral origin, and is a bitumen which was once liquid, and of the naphtha, or petroleum kind, hardened and brought into its preſent ſtate by a mineral acid, of the nature of ſpirit of ſulphur, or oil of vitriol; both theſe ſubſtances abounding in the earth, and an artificial mixture of them producing a body much reſembling *amber*, and affording all its principles on a chemical analyſis.

Flies, and other ſmall inſects, found bedded in *amber*, have by ſome been ſuppoſed mere *luſus naturæ*, and never to have been real animals; but this needs only the eye to diſcover its abſurdity: and with others, who allow them to be real, they are uſed as proofs that *amber* is of vegetable origin, and was once ſoft and fluid. That they do prove the laſt is certain, but by no means the firſt. To judge properly of this, we ſhould conſider the true ſtate of the caſe, which is this: that more than a thouſand pieces of *amber* are found without inſects, for one that has any; and that moſt of the pieces which have them, have not been dug out of the earth, but found on the ſea ſhores. The ſides of hills we well know are continually trickling down the liquid bitumens; and there is no abſurdity in ſuppoſing, that ſmall quantities of this might, in its paſſage, be detained in little cavities of rocks, &c. and there ſuffer leiſurely its change into *amber*, from the matter of its natural acid being near. And it can be no wonder that flies, &c. ſhould be drowned in ſuch a maſs of matter, which being afterwards hardened, might be found on the ſurface of the earth, or waſhed down to the ſea, in the form of common *amber*. Nor is there any thing impoſſible in the maſſes, thus formed on the ſurface, being afterwards buried in the earth, by the various changes we know the ſurface of the earth at times is ſubject to.

Beſide the places whence *amber* is uſually brought, which are Pruſſia, Pomerania, &c. we have it on our own ſhores, and even in our clay-pits; the pits dug for tile clay, between Tyburn and Kenſington Gravel-pits, have afforded many ſpecimens; and that behind St. George's Hoſpital, at Hyde-park Corner, has afforded fine ſpecimens, one of which has been wrought into a beautiful cane-head of three inches long. *Hill*'s Hiſt. of Foſſ. p. 409.

If the people, who collect *amber* on the ſhores of the Baltic, were more curious and particular in their obſervations of the maſſes they find, we ſhould doubtleſs have much more lights into its true hiſtory and nature. There is no queſtion, but that ſome pieces of it are toſſed up there ſo imperfectly formed, that the proceſs of nature may be ſeen in their different ſtages. Pieces have been ſometimes found ſo ſoft, as to receive the impreſſion of a ſeal: theſe are always not only perfect *amber* in other reſpects, but they are obſerved to have a ſmell ſtronger than the common *amber* has. Theſe pieces ſometimes harden immediately, on being expoſed to the air, but ſometimes they retain this ſoftneſs many months. We have an account of ſuch a piece in the Philoſophical Tranſactions, which had retained this ſoftneſs a whole year, in which time it had lain among other pieces of *amber*; and of another maſs very ſoft on one ſide, and hard on the other, and containing in the ſoft part a fly buried. Phil. Tranſ. N° 57.

This foſſil has been of great repute in the world from the very earlieſt times we have any knowledge of, many years

before Chriſt it was in eſteem as a medicine; and Plato, Ariſtotle, and Herodotus, and among the poets Æſchylus, and others, have commended its virtues. In the times of the Romans it became in high eſteem as a gem; and in the luxurious reign of Nero immenſe quantities of it were brought to Rome, and uſed for ornamenting works of various kinds. Long after this Theodoric, king of the Goths, ſhewed a high eſteem for it. However well known, and however highly eſteemed this ſubſtance was in theſe ages, its nature and origin yet remained unknown through a long ſeries of time, and various conjectures were made about it in the different places where people were poſſeſſed of it among their gems; ſome ſuppoſed it the product of Africa, others of Aſia, and others of America; and the gardens of the Heſperides, Ægypt, Æthiopia, and Numidia, were ſuppoſed, in the firſt mentioned part of the world, to give it birth. Thoſe who made it the produce of Aſia, gave Arabia, and ſome parts of the Eaſt-Indies, as the places of its production; and thoſe who ſuppoſed it brought from Europe, gave Italy, the river Eridanus, and the borders of the Adriatic, as the only parts whence it came: but the Romans, when they ſpread the terror of their arms through Germany, found it on the ſhores of the German ocean and the Baltic, and Spain, and afterwards Britain, were added to the liſt of places where it was found.

The antients, who had leſs traffic, and leſs knowledge of the world than we have, are the more pardonable in allotting ſo great a number of places, and many of them falſe ones, for the production of *amber*, and for not diſcovering the true place where it has been at all times found in the greateſt plenty, and whence moſt parts of the world have long been, and are to this day ſupplied; but the moderns are much more unpardonable, who in their accounts give us Aſia, Africa, and America, as the places where *amber* is found, as if it were to be had no where elſe; and ſome of them diſtinguiſh the finer pieces under the name of *Oriental amber*.

The generality of theſe falſe accounts of *amber*, have been owing to the ignorance of the perſons who have taken upon them to give the hiſtory of it: they have, in general, taken upon hearſay what they have related, or borrowed it from books they were not able to underſtand. Thus we find the many places in Aſia and Africa celebrated for producing large ſtores of *amber*, are taken upon credit from the old authors, who have mentioned ambra as being found there. Theſe copiers not diſtinguiſhing, that ambra in theſe places is not given as the name of *ſuccinum*, or *amber*, but as that of the rich perfume called *ambergris*, which is found there, though the real *amber* never was.

The name of *Oriental amber*, ſo common with ſome, ſeems to have been owing alſo to a miſtake, but of another kind; the gum copal, brought from the Eaſt-Indies, is very like *amber*, and ſome of the fantaſtic writers in chemiſtry have called this by the forced name of *Oriental amber*. Hence thoſe who read their works, without perfectly underſtanding them, have ſuppoſed that *amber* was common in the Eaſt-Indies; and as all the gums of that part of the world are ſuperior to thoſe of other places, they began to call all the fine pieces of this foſſil by the pompous name of *Oriental amber*.

We are not to limit the operations of nature ſo far, as to ſay that ſhe does not, or cannot produce *amber* in Aſia, Africa, or America; but it is certain, that we have no authentic account of its ever having been found in any of thoſe regions, and there is the greateſt reaſon in the world to believe that it is peculiar to Europe. This we are very well aſſured of, that the Chineſe, who are as cunning a people as any in the world, expend annually with us vaſt ſums of money in buying European *amber*, and have done ſo at all times ſince we have trafficked with them; and it is by no means to be ſuppoſed that they would purchaſe it of us, if they had it nearer home. All the intelligent perſons, who have reſided in the Eaſt-Indies, ſay, that they never ſaw or heard of *amber* being found there. And, upon the whole, it ſeems very rational to conclude, that *Oriental amber* never exiſted, otherwiſe than in the error before-mentioned, of calling copal by that name.

Europe ſeems the only region of the world where *amber* is produced: it ſeems alſo to be produced almoſt all over Europe, but not in equal plenty, nor perfection; the German dominions, and the country about the Baltic, claim the prerogative above all other places. Hartman, who has given the abovementioned account of the errors of the antients, *&c.* in regard to the places of its origin, has been too free in cenſuring the moderns for giving it to ſome parts even of Europe: he ſcruples to believe that Italy, Spain, and even England, produce *amber*; but in this he errs: he ſuppoſes that jet, which is called by ſome *black amber*, being found in theſe places, has impoſed upon the authors of theſe accounts, and made them ſay *amber* was found there; but nothing is more certain, than that *amber*, and that of the fineſt kind in the world, is found in England, at leaſt, if not in the other places where he doubts of its production. *Amber* is at this time thrown on the ſhores of Yorkſhire, and many other places, and found at great depths under the earth, in ſtrata of clay, as well about London, as in more inland places; and if we mention Dr. Woodward, and the other authors, who have themſelves taken it up, we ſhall have no room to doubt its being real *amber*, not jet, as Hartman ſuppoſes.

Poland, Sileſia, and Bohemia, are famous for the *amber* dug up there at this time. Germany affords great quantities of *amber*, as well dug up from the bowels of the earth, as toſſed about on the ſhores of the ſea and rivers there. Saxony, Miſnia, and Sweden, and many other places in this tract of Europe, abound with it. Denmark has afforded, at different times, ſeveral quantities of foſſile *amber*; and the ſhores of the Baltic abound with it. But the countries lying on the Baltic afford it in greateſt abundance of all; and of theſe the moſt plentiful country is Pruſſia, and the next is Pomerania. Pruſſia was, as early as the times of Theodoric the Goth, famous for *amber*; for this ſubſtance coming into great repute with this prince, ſome natives of Pruſſia, who were about his court, offered their ſervice to go to their own country, where that ſubſtance, they ſaid, was produced, and bring back great ſtores of it. The offer was accepted, the journey ſucceſsful, and from this time Pruſſia had the honour to be called *The Country of Amber*, inſtead of Italy, which had before undeſervedly that title.

The *amber* of Pruſſia is not only found on the ſea coaſts, but in digging; and though that of Pomerania is generally brought from the ſhores, yet people, who dig on different occaſions in the very heart of the country, at times find *amber*. Philoſ. Tranſ. N° 248. p. 5, ſeq.

In Pruſſia the cliffs are very high and abrupt, and are all of naked earth, except a few rocks; the ſhore is very even, and the ſea ſhallow for a long way; after this there is a conſiderable depth for ſome furlongs, and behind this the ſhallows riſe again, and continue a great way. The ſtormy ſeas, and high tides, waſhing againſt theſe cliffs, break down vaſt maſſes of them from time to time; in the matter of theſe maſſes of earth lie great quantities of *amber*; this mixture falling upon the flat ſhore, is daily waſhed by the waves, and the earth waſhed, and broken to pieces in a little time, and carried back by the waves into the ſea; while the lumps of *amber*, being too hard to break, and too large to be carried away ſo eaſily as the diſunited particles of earth are, remain naked on the ſhore, or in the ſhallower water. If they are any of them waſhed away, they are only carried into the firſt deep water, and by its riſe and fall in the tides they are thrown up, either on one ſide or the other, and lodged on the ſhallows, from whence the people, employed to gather them, eaſily obtain them.

The whole country about theſe cliffs abounds in *amber*, but it is impoſſible to get at it by digging, becauſe of the nature of the ſoil, which is boggy, and full of water, riſing in ſome places up into ſprings, and in others making the ground ſo ſoft, that there are a ſort of bogs and quickſands, which ſwallow up cattle, and ſometimes men and their horſes. A little higher up in the country, where digging is practicable, the earth is found of the ſame nature as in the face of the cliffs, and abounds with minerals of various kinds. The pyritæ, and vitriols of many ſorts, are found there, and ſtrata of a ſort of black earth, with white veins, in great abundance. Under theſe ſtrata there is found a great quantity of a cortical ſubſtance, reſembling the barks of trees, among, or under which the *amber* is uſually found. The whole face of the country is very barren; in this part tracks of ſand often cover vaſt ſpaces, and ſometimes a few weeds of the hardieſt kinds appear; ſometimes a buſh, but rarely, and ſcarce any ſuch thing as a tree is to be ſeen. The *amber* in theſe places, when dug up, is uſually foul, and covered with a rough opake coat, which muſt be taken off, or broke through, in order to the ſeeing its beauty; but that on the ſhores is uſually found clear and fine, this outer cruſt having been worn off by the waſhing of the waves. This *amber* on the ſhores is ſometimes found buried in the ſand, ſometimes naked on the ſurface of it, and ſometimes covered over with large bundles of the ſea-wrack, and other weeds. The vulgar have thought, from this laſt accident, that the *amber* was a gum flowing out of the leaves of thoſe plants, but that is a very abſurd opinion.

Sand, vitriol, and ochre, with a blue clay, are the ſubſtances which make up the principal part of the ſtrata in the cliffs; and the vitriol, in particular, ſeems to have ſome conſiderable ſhare in the formation of the *amber*, becauſe *amber* is ſcarce any where found foſſile, where there is not alſo vitriol: but neither of theſe ſubſtances can be properly called the matrix of the *amber*, ſince it is ſeldom found bedded in them; and when it is, only in ſmall quantities. The blue clay contains more *amber* than either of the other of theſe ſubſtances, but the true matrix of it is the wood, or cortical ſubſtance, which is found among theſe ſtrata, and of which alone there are immenſe hills in ſome places. Phil. Tranſ. N° 248. p. 12. See the article MATRIX *ſuccini*.

The bodies of inſects, found buried in *amber*, are viewed with admiration by all the world; but of the moſt remarkable of theſe, many are to be ſuſpected as counterfeit, the great price, beautiful ſpecimens of this kind ſell at, having

tempted ingenious cheats to introduce animal bodies in ſuch artful manners into ſeemingly whole pieces of *amber*, that it is not eaſy to detect the fraud. The antients have deſcribed globes of *amber* with bees immerſed in them, and the cabinets of the modern virtuoſi afford many ſuch pieces; but Sendelius, after accurately examining many of theſe ſpecimens, ſuſpects them all to be ſophiſticated. Many ſpecies of the fly kind, however, are obviouſly and indiſputably lodged by nature there: among this tribe of animals, the ſeveral ſpecies of the ichneumon fly are found the moſt numerous; the common houſe and fleſh flies are alſo frequently found thus preſerved; and it is remarkable, that of theſe ſome have preſerved, and others have wholly loſt their natural colours. Theſe are ſometimes found in cloudy pieces of *amber*, but much more frequently in the perfectly clear and fine ones; and in theſe many are ſeen plainly to be encruſted with a thin coat of the matter of the *amber*, ſeparate from the maſs. Beſide the animals already named, the cabinets of the curious afford us numerous inſtances of the ſmall ſpecies of butterflies, the cricket, the graſhopper, beetles of various kinds, but theſe only ſmall ones, the larger and ſtronger being able to force their way out of the once viſcid maſs, and therefore never remaining entangled in it. Some of theſe, which are incloſed in it, are plainly ſeen to have ſtruggled hard for their liberty, and even to have left their limbs behind them in the attempt; it being no unuſual thing to ſee, in a maſs of *amber* that contains a ſtout beetle, the animal wanting one, or perhaps two of its legs; and thoſe legs left in different places, nearer that part of the maſs from which it has travelled. This alſo may account for the common accident of finding legs, or wings of flies, without the reſt of their bodies, in pieces of *amber*; the inſects, to which theſe have belonged, having, when entangled in the yet ſoft and viſcid matter of the *amber*, eſcaped, at the expence of leaving theſe limbs behind them. Drops of clear water are ſometimes alſo preſerved in *amber*. Theſe have doubtleſs been received into it while ſoft, and preſerved by its hardening round them. They are uſually contained in cavities too large for them, though ſometimes the holes are filled up. In ſome ſpecimens, the holes alone remain without any moiſture. Naturaliſts, who have been ſo curious as to examine this liquor contained in the *amber*, have found it to be of an auſtere taſte, like that in which vitriol had been diſſolved: others mention the having met with it wholly inſipid, and ſome taſting of ſea ſalt. It is eaſy to account for a drop of water, of any of the three kinds, being found in *amber*, but the vitriolic water is the moſt natural there, as there is always great plenty of vitriol where the *amber* is found. Some people, who have been poſſeſſed of pieces of *amber* thus containing water, have thought that the quantity was continually increaſing and decreaſing, according to the increaſe and decreaſe of the moon; but this is not countenanced by any certain obſervation. *Hartman*, Hiſt. Succin.

Amber, though fuſible with a ſmall fire, and concreting again when cold, yet differs from the metals, and other fuſible bodies of that kind, in this, that as ſoon as cold they are the ſame as before melting; but *amber*, when it has once been melted, is no longer *amber*, it loſes its beauty and hardneſs: and the true reaſon of this is, that being compoſed of bitumen and ſalt, the ſalt flies off in the heating, and leaves the remainder little better than the ſimple reſiduum of an evaporated petroleum, or any other liquid bitumen. There have been people, at different times, who have pretended to have an art of melting ſmall pieces of *amber* into a maſs, and conſtituting large ones of them; but this ſeems ſuch another undertaking as the making of gold, all the trials, that have yet been made by the moſt curious experimenters, proving, that the heat which is neceſſary to melt *amber*, is ſufficient to deſtroy it. Phil. Tranſ. N° 248. p. 25.

Hartman indeed mentions an accident, which ſhews a poſſibility of many pieces of *amber* being combined into one by an operation of nature, though it never could be effected by art. A ſheep was once killed in Pruſſia, in whoſe ſtomach a large piece of *amber* was found, which was compoſed of ſeveral other ſmaller pieces, the joinings of all which might be ſeen, though as firm as the pieces themſelves. This is a proof that the creature had ſwallowed the whole in ſmall pieces with its food, and that nature, by the heat and juices of its ſtomach, had ſoftened thoſe pieces without melting them, ſo as to make them unite firmly, though not be thoroughly blended with each other. Could art arrive at this, which it is not probable it ever will, even this is far ſhort of what is pretended of melting *amber*, and caſting it into what form is deſired. The factitious curioſities in *amber*, which are pretended to be pieces of this foſſil, with inſects embedded in it, are uſually no other than a hardened varniſh, not having the hardneſs, or other qualities of *amber*. Some few of them are *amber* melted, into which the inſects have been put in that ſtate, but theſe are very coarſe and brittle. Theſe two kinds of cheat are eaſily diſcovered by their want of hardneſs, and the other by obſerving the ſides of the piece, to find the joining where it has been ſplit.

Among the numbers of inſects thus preſerved, as ſome are covered within the maſs with a thin coat, or cruſt of pure *amber*; ſo others are covered with a cruſt of a white matter of a like thickneſs, but ſeeming different from the nature of the *amber*. The true cantharides are ſometimes alſo included in *amber*, and preſerving all the beauty of their colours there, they make a very ſplendid appearance. The ant is moſt frequently met with in pieces of *amber*; and the earwig is ſometimes found very perfect and beautiful in it. The ſpider kind afford very numerous ſpecies. The millepedes are not unfrequently met with. The ſcolopendræ appear in great beauty, when their bodies are twiſted and contorted, as not unfrequently happens in the large globes of *amber* where they lie. Caterpillars are alſo ſometimes found, but the ſoftneſs of their bodies has made them ſubject to great injuries, and they are often ſqueezed, compreſſed, and injured, ſo as ſcarce to be known.

Theſe are the ſpecies of land animals moſt frequently found in *amber*; to theſe ſome add the louſe and flea: and though theſe have brought great diſcredit upon all the inſects incloſed in *amber*, in the judgment of many, as ſeeming certainly counterfeit, yet Sendelius, who had carefully examined ſeveral of the maſſes in which they were found, and could find no trace of fraud in any of them, attempts to account for ſuch animals being naturally included in the ſubſtance of the *amber*, while yet ſoft, in the manner of the other inſects.

To theſe animals thus impriſoned, many authors add accounts of ſmall fiſh, young water newts, and other aquatic animals, but theſe ſeem in general to have been ſophiſticated maſſes; and indeed it is obſerved, that even the moſt common water inſects are very rare in *amber*. The way in which all the inſects, that are truly found lodged by nature in *amber*, were placed there, is not hard to gueſs, when we are ſo far acquainted with the nature of *amber*, as to be aſſured from experience, that it is at firſt a fluid, and by degrees becomes viſcid and thick like turpentine, from which ſtate it gradually hardens into the ſolid form we find it in; and this is ſufficiently proved; ſince there have been at times found quantities of true *amber* yet in its fluid ſtate; and the ſtructure of ſome globes of *amber* abundantly ſhew, that they have hardened from a fluid ſtate, ſome being plainly compoſed of ſeveral plates, and ſome containing a maſs of *amber* in another larger maſs; the internal maſs having undoubtedly hardened firſt, and the external, while yet in a fluid ſtate, gathered and concreted round it.

This being the manner of the including of the inſect tribe in *amber*, it ſeems that inſects alone ſhould not be ſubject to that fate, but that other matters, which fall in the way of the *amber* while yet ſoft and viſcid, ſhould ſhare the ſame fate. The locomotive power of the animal kingdom gives its creatures opportunities of falling into theſe maſſes, while vegetables and minerals have not; yet as theſe cannot but ſometimes fall in the way of the hardening matter of *amber*, they are ſometimes found immerſed in it. Beautiful leaves of a pinnated ſtructure, reſembling ſome of the ferns, or maiden-hairs, have been found in ſome pieces; but theſe are rare, and the ſpecimens of great value. Other leſs beautiful vegetable ſubſtances are more frequently found than theſe, though all of this tribe are ſcarce in compariſon to the animals. Small pieces of heath, and fragments of the alga, and ſome other plants, common about the ſea ſhores, are ſometimes found; as alſo ſmall fragments of wood, the ſeeds of ſome plants, and pieces of the ſtalks of others. Theſe are ſometimes found alſo, but a little way, buried in the *amber*, and at other times are only faſtened to its ſurface; the ſmall ſpecific gravity of theſe bodies, too little to immerſe them into the fluid, and the different conſiſtence of that hardening fluid, may have been the occaſion of theſe bodies having made their way into the maſſes but to ſmall depths: and indeed, if we conſider the whole proceſs, many happy accidents muſt concur to the perfect and beautiful immerſion of a foreign body in this bitumen.

Mineral ſubſtances are alſo found at times lodged in maſſes of *amber*: ſome of the pompous collections of the German princes boaſt of ſpecimens of native gold and ſilver in maſſes of *amber*; but as there are many ſubſtances of the marcaſite, and other kinds, that have all the glittering appearance of gold and ſilver, it is not to be too haſtily concluded, that theſe metals are really lodged in theſe beds of *amber*. Iron is found in various ſhapes immerſed in *amber*, and as it is often ſeen eroded, and ſometimes in the ſtate of vitriol, it is not impoſſible but that copper, and the other metals, may be alſo ſometimes immerſed in it in the ſame ſtrata; and that the bluiſh and greeniſh colours, ſometimes found in the recent pieces of *amber*, may be owing, like the particles of the gem colours, to thoſe metals; but as the gems, by their denſe texture, always retain their colours, this lighter, and more lax bitumen uſually loſes what it gets of this kind, by keeping ſome time. Small pebbles, grains of ſand, and fragments of other ſtones, are not unfrequently alſo found immerſed in *amber*. Theſe, it is very plain, have fallen into the maſs while not yet quite hardened; though things of this ſpecific gravity, when found lodged deep in it, muſt have

fallen

fallen in when it was almoſt hard, otherwiſe they would have ſunk through. The pieces of *amber* including other pieces are alſo of this origin; and when it has happened that the included piece, and the ſurrounding maſs, have been of different degrees of colour, the inner piece is obvious, and the effect plain; but when theſe have been both of the ſame colour, which probably moſt frequently has been the caſe, we have no traces of the accident; and probably this, though by accident concealed, is a much more frequent caſe than is commonly imagined.

To all theſe accidental beauties in *amber* it is to be alſo added, that as in the Mocoa ſtones, and many other foſſils, ſo alſo in this there are ſometimes found beautiful delineations of trees, ſhrubs, and the like. The natural beauties of theſe pieces have tempted the cunning artificers ſometimes to counterfeit them; but in theſe, as well as in the ſophiſticated maſſes with inſects, the fraud may always be diſcovered by a curious and attentive inſpection. *Sendelius*'s Hiſt. of Amber.

On opening the ditches for the fortifications of Copenhagen, it is ſaid that ſeveral large maſſes of *amber* were found, all of them adhering to the ſides of large bodies of trees, which were black as ebony. The pieces are preſerved in the cabinet of the king of Denmark in that place, and ſome of them weigh forty or fifty ounces. This is an additional circumſtance to the common obſervation of ſomething, reſembling wood, being always found where *amber* is, and deſerves to be conſidered, as it tends to overthrow the preſent received ſyſtem, of *amber* being originally a mineral production.

Amber is the baſis of all varniſhes. For the method of diſſolving this ſubſtance into varniſh, ſee the article VARNISH. But if *amber* could be diſſolved without impairing its tranſparency, or one large maſs be made of it by uniting ſeveral ſmall ones, it is eaſy to ſee what would be the advantages of ſuch a proceſs. The art of embalming might poſſibly be alſo carried to a great height by this, if we could preſerve the human corps in a tranſparent caſe of *amber*, as the bodies of flies, ſpiders, graſhoppers, *&c.* are to a great perfection. Something of a ſubſtitute of this kind we have in fine roſin, boiled to a great hardneſs, and perfect tranſparence; this being diſſolved by heat, and the bodies of ſmall animals ſeveral times dipped in it, they are thus coated with colophony, that in ſome degree reſembles *amber*; but this muſt be kept from duſt. *Shaw*'s Lectures, p. 425.

Amber, in medicine, is given in its crude ſtate, only reduced to powder, as an aſtringent and balſamic. It is preſcribed in the fluor albus, in convulſions, and in all diſorders of the nerves. It is alſo given in coughs, and diſeaſes of the lungs; and is by ſome greatly recommended in inveterate head-achs. Its doſe is from one ſcruple to two.

Its preparations are, 1. *ſal ſuccini*, or ſalt of *amber*. 2. *Oleum ſuccini*, or oil of *amber*. 3. *Tinctura ſuccini*, or tincture of *amber*.

Oleum SUCCINI, or *oil of amber*. To purify the dark muddy *oil of amber* drawn *per ſe*, take two pounds of good brandy, one of ſea ſalt, half a pound of the oil; mix them, and diſtil them together, and a large proportion will come over very tranſparent, and finely coloured. *Boyle*'s Works, Vol. 1. p. 329.

Plants in SUCCINUM, or *amber*. See PLANTS.

SUCCURY, or SUCCORY, *cichorium*, in botany. See the article CICHORIUM.

The common blue-flowered *ſuccory*, or cichorium, is celebrated among ſome of the botanical writers for a property in its flowers, ſuppoſed to be peculiar to it, and eſteemed very ſingular; this is, that though naturally of a fine bright blue, they become red as blood on being a little time buried in an anthill. By what accident this property was diſcovered we do not know, but probably only by the falling of ſome of the flowers off from the plant into a neſt of theſe little animals. Langham, in his Garden of Health, has related this, but it is no diſcovery of his; for Tragus, long before his time, tells us, ſpeaking of this plant, that nature affords a miraculous phænomenon in its flowers, which is, that if put amongſt living ants in their hill, it changes from blue to red, as if bluſhing with ſhame and fear of ſuch numerous and ſmall enemies; and John Bauhine records the ſame thing from Otho Brunfelſius. It would have been well, if all who have related this wonderful change of colour, would have varied the experiment with the violet, and other blue flowers; they would then have found, that it was not the property of the plant, but of the animal, that was the true object of wonder. All blue flowers of plants will turn red on the rubbing them over with acids, and the wonder is, to find that the ants have a natural animal acid about them, capable of making ſuch a change; not that the flowers of the *ſuccory* are ſuſceptible of ſuch a change with acids. *Tragus* in Stirp. *John Bauhine*, Hiſt. Plant.

The method of making the experiment is this: lay bare the top of an anthill with a ſtick, and then throw ſome of the flowers of *ſuccory* on the place; the ants will immediately be ſeen to creep over them, and as they move along, they may be obſerved frequently to let fall a drop of clear water from the lower part of their bodies; wherever this falls upon the flower, it makes a large red ſtain; by degrees they let fall more of theſe drops, and every one making its own particular ſtain, the whole flower becomes at length coloured. Sometimes they make this change very quickly in the flower, and ſometimes they are a great while about it; but the body of the ant, bruiſed upon a leaf of the flower, will immediately ſtain the whole, ſo far as it reaches. It deſerves inquiry, whether the ants ſimply depoſit this liquor on the flower, or whether they make a wound or puncture on the ſurface of the flower firſt. The laſt is moſt probably true; becauſe this flower is covered with ſo thick an external membrane, that the acid ſpirits of vitriol, ſalt, or the like, being barely touched upon it, do not inſtantly change its colour; but if it be picked or bruiſed, ſo as to let in the liquor, the change of colour is then inſtantly produced. If the flowers of this plant be ſteeped in the ſtrongeſt vinegar for a long time together, they will not change colour while the menſtruum remains cold; but if it be heated a little, it is by that means put in motion, and rendered capable of entering the pores, and then the colour is inſtantly changed. It is not obſerved that the ant makes any puncture, and if it does not, it is evident, from the immediate change in the flower, where the ſtrong mineral has no ſuch effect, that the acid in this little animal is of a very peculiar nature.

It has been ſuppoſed by ſome, that the tingling felt in the ſkin, and the bumps raiſed on it by ants, are owing to the falling of this penetrating acid liquor, as the creature moves along. The venomous effect of the ſting of the bee and waſp, is ſaid by authors to be owing to the introducing into the wound a ſharp liquor, lodged by nature in this animal at the root of the ſting. It would deſerve a trial, whether the liquor of theſe creatures be of the ſame penetrating acid nature with that of the ant, which might be eaſily diſcovered, by forcing out the ſting of one of theſe animals by preſſure, and making it enter into the petal of the flower of a violet, bugloſs, *ſuccory*, or any other of the like plants. This liquor of the ants may eaſily be procured in ſome quantity from them. If their neſts be diſturbed with a ſtick, thruſt in among them, they will crawl about the ſtick, and leave a great number of the drops of their acid upon it, and theſe, if immediately ſmelt to, will twinge the noſe like newly diſtilled ſpirit of vitriol. The larger kind of ants, called by the country people *horſe-ants*, afford this liquor ſtronger, and in greater quantity, than the ſmaller, or common ants; and, on trials, it proves nearly allied to the mineral acids in its properties.

The ants, diſtilled either by themſelves, or with water, yield an acid ſpirit like that of vinegar, or of verdigreaſe, which is more pungent and penetrating. Lead put into this ſpirit affords a good ſaccharum ſaturni; and the ſame ſalt is produced from that metal, if only put into fair water with a large parcel of living ants in it, they ſoon parting with enough of their acid to make the water a menſtruum ſharp enough for diſſolving that metal. There is alſo ſomething very ſingular in this acid, which is, that it will preſerve itſelf, and be regained from the metalline admixture in its own nature. The common ſaccharum ſaturni being diſtilled, does not yield back the acid employed in making it, but only an inflammable oil and water; but the ſaccharum ſaturni, made by the animal acid of the ant when diſtilled, returns back that acid in the ſame quantity and ſtrength, and no way altered. The vinegar diſtilled from verdigreaſe, and called *ſpirit of verdigreaſe*, is an acid very like this, but ſtronger, and more penetrating. Phil. Tranſ. N° 68.

SUCK-*fiſh*, in ichthyology, an Engliſh name for the *remora*, or *echeneis* of Artedi. See REMORA.

SUCKING (*Cycl.*)—Though there are very few inſtances of children which are born with an inability of *ſucking*, yet the writings of phyſicians have recorded ſuch caſes; and one, which happened ſome years ago in France, gave occaſion to the members of the Academy to examine ſtrictly into the cauſe of it. Mr. Maloet, who examined the child, found that it wanted the whole palate of the mouth, and that in looking up to the top of the cavity of the mouth, the inner part of the noſe was ſeen; the child not only wanted the bony parts which form this arch, but alſo the inveſtient membrane they are naturally covered by. Mr. Maloet conceived that he had now found out the reaſon of the child's not having the power to *ſuck*, which he explained in this manner.

In the action of *ſucking*, while the infant has in its mouth the nipple of the nurſe, the air about it is diſperſed, and there is made a little void all about it in the cavity of the mouth. At this time the whole breaſt is preſſed upon as uſual by the external air, though the nipple is not, or at leaſt is much leſs ſo, and hence the mouth performing the office of a pump, the milk contained in the breaſt cannot but diſcharge itſelf by degrees through the apertures in the nipple. In order to this, however, it is evidently neceſſary that the communication between the mouth and the noſe ſhould be ſtopped by the proper organs; ſince, if this were open, the air, which continually paſſes through the noſe in reſpira-

reſpiration, getting into the child's mouth, would equally preſs the nipple with the other parts of the breaſt, and conſequently the cauſe of the iſſuing out of the milk would no longer ſubſiſt; the mouth being no longer capable of performing the office of a pump, than while it is empty. Hence, according to Mr. Maloet's account, the child born without a palate could not ſuck, becauſe the noſe and mouth had, by the abſence of this organ, a conſtant and uninterrupted communication.

This account however did not ſeem right to Mr. Petit, for theſe reaſons: a void in the mouth is not at all eſſential, or neceſſary to *ſucking*, as appears every day by women's milking their cows; when, without any ſuch void, and by the mere preſſure of their hands, they get out the milk. All the mechaniſm uſed here, is a continual ſucceſſion of ſtroaking down the teat, one hand ſupplying the place of another, and here is milk extracted without either a void, or a pump; and if the action of *ſucking* be nicely obſerved in an infant, it will be found to amount only to the ſame thing. It ſeizes the nipple, and makes with its lips a ſort of fleſhy canal, which receives, and continues gently to preſs it. The lips are found by anatomy to be compoſed of partly longitudinal, and partly tranſverſe fibres; in the action of ſeizing the nipple, the firſt of theſe are extended as far as they are capable, and afterwards their natural contraction ſqueezes the nipple, and does what the hands of the milker do on the cow's teat, preſſing out the milk in the very ſame manner. The ſhape of the nipple being larger at its origin, than at the end, makes it eaſily ſlide out of the child's mouth, and this gives the infant conſtant occaſion of laying hold of it higher up, and then if it ſlip a little, that is only a motion which, as the child's lips incloſe it round, will the more facilitate the flowing out of the milk, which is thus forced from above downwards. The lips of the infant, though they are thus aſſiſtant, are not however the only organs employed in *ſucking*, the jaws are of great uſe, by their force and power of compreſſion, and the tongue is a very ſerviceable aſſiſtant.

The tongue in infants is extremely thin, tender, and flexile: this is applied cloſely to the under part of the nipple, and when it afterwards is drawn down toward the bottom of the mouth, there is then indeed formed in that place a ſort of void, which determines the milk to flow readily in there, eſpecially as the tongue itſelf has before given the principle of ſuch a motion. Nor is this all the uſe that Mr. Petit allows the tongue in *ſucking*; he obſerves, that the root of it may be as ſerviceable to the child in the ſwallowing the milk, as the tip of it was in getting it out of the nipple; for when the milk has been conveyed along it to the lower part of the palate, in the manner of a gutter, the root at that time preſſing againſt the œſophagus, compels the milk to run down it, and then the tip is again employed to the *ſucking* out more milk; and the action of *ſucking* is thus alternately relieved by ſwallowing, and both greatly aſſiſted by the tongue. It is very poſſible, from the different ſtructure of the parts, that in the infant firſt mentioned, the root of the tongue might be incapable of its office of aſſiſting in ſwallowing, while the tip of it readily performed its office of *ſucking*; and this Mr. Petit takes to have been the occaſion of its death, for the child lived only five hours.

From this theory of *ſucking* it is plain, that a child born without a palate may yet be able to *ſuck* by means of its tongue. Mem. Acad. Scienc. Par. 1735.

We are told of a man's giving *ſuck* to a child, and thereby rearing it; but we do not find any other evidence of the truth of the ſtory, than the word of the man, or pretended man, who was a beggar. See Philoſ. Tranſact. N° 461. p. 813.

In the Philoſophical Tranſactions we have an account of a woman, of ſixty eight years of age, giving *ſuck* to her grandchildren. This woman had not borne a child for twenty years, or upwards. It would ſeem, as if the *ſucking* of the child had brought milk into the breaſts. See N° 453. ſect. 10.

SUCKING *fiſh*, in ichthyology. See the article REMORA.

SUCU, in botany, a ſpecies of apple-tree, ſaid to be frequent in the province of Canton in China. The fruit is dried like figs to be kept all the year, and is brought into Europe. It is ſomewhat larger than our apple, almoſt round, and of a reddiſh colour, or ſometimes green. When it is dry, it has a cruſt reſembling honey or ſugar. *Hoſm.* Lex. Univ. in voc.

SUDARIUM, in eccleſiaſtical writers, the ſame with *brandeum*. See the article BRANDEUM.

SUDIS, in zoology, a name uſed by moſt authors for the ſea pike, a fiſh called by others *lucius marinus*, and *ſphyræna*. See Tab. of Fiſhes, N° 44.

It in ſome degree reſembles the common river pike, but is thinner in proportion to its length, and in ſome degree approaches to the *acus*, or tobacco-pipe-fiſh, in that particular. Its ſcales are ſmall, and its noſe long, and of a conic form, the under jaw running out a good way beyond the upper, and ending in a ſharp point. Its mouth is very wide, and yellow within; its tongue large and narrow, and armed all along with ſharp and ſmall teeth. The jaws are furniſhed each with a ſingle row of large and ſharp teeth, ſet at ſome diſtance one from another; and in the middle of the lower jaw is one tooth longer than the reſt, which has a hollow in the upper jaw made to receive it. It has two fins on the back, which are both, but eſpecially the fore one, very prickly; and the tail is very deeply forked. It is caught in the Mediterranean, and uſually ſwims in ſhoals together. Its uſual length is ten or twelve inches; and it is eſteemed a very well taſted fiſh. *Ray*'s Ichthyogr. p. 273.

SUDORIFIC (*Cycl.*)—A ſafe, eaſy, and effectual *ſudorific* may be prepared in the following manner. Take an ounce of refined camphor, beat it in a marble mortar with two ounces of blanched almonds, till it be reduced to a ſmooth and even paſte. This may be formed into pills, or boluſes, and given, according to the ſtrength of the patient, and other conſiderations, from three grains to forty.

Sudorific, perſpirative, and alexipharmic medicines, make a large part of the common diſpenſatories. A few medicines, well choſen, might ſupply the place of all theſe; and of theſe one principal one would prove to be camphor, which trial will always ſhew to be greatly ſuperior to bezoar, Gaſcoign's powder, lapis contrayerva, and the like. *Shaw*'s Lectures, p. 227.

SVEGLIATO, in the Italian muſic, is uſed for a briſk, lively, gay manner of ſinging or playing. Thus they ſay *maniera ſvegliata*.

SUETA, in ichthyology, a name given by Bellonius, and ſome other writers, to the *naſus*, a ſpecies of cyprinus, according to the Artedian ſyſtem, and diſtinguiſhed by that author by the name of the *cyprinus* with the ſnout ſtanding prominent, in form of a noſe, and with forty rays in the pinna ani. See the articles CYPRINUS and NASUS.

SUFFIBULUM, among the Romans, a name given to the *prætexta* of the pontiffs, and *palla* of the Veſtal virgins. *Pitiſc.* Lex. Antiq. in voc.

SUFFIMENTA, *fumigations*, in pharmacy. The *fumigations* preſcribed by diſpenſatory writers are reduced to two kinds; the one conducive to health, the other only to pleaſure; and of each kind ſome are of moiſt, or liquid ingredients, others of dry ones.

The *fumigations* for pleaſure are compoſed of fragrant and ſweet-ſcented ſubſtances, and are uſed in form of powders, troches, or medicated candles. The firſt are uſually prepared of ſtorax, benjamin, lignum aloes, cinnamon, camphor, muſk, ambergris, and civet, mixed in due quantities, and all reduced together to a powder. The ſecond kind, or troches, are compoſed of the ſame kind of powdered ingredients, and are made into a paſte with a mucilage of gum tragacanth, and then cut into form. And the laſt kind, or candle *fumigations*, are prepared of the melted ſweet gums, with labdanum, made up into the form of large candles, with as much of the beforementioned ſweet ingredients as can be received into the maſs. Theſe, though only meant for luxury and pleaſure, yet have medicinal virtues; and as they abound in cordial ſubſtances, cannot but revive the ſpirits, and reſiſt contagion. The moiſt *fumigations* of this kind conſiſt of the powders before named, blended among a large quantity of roſe and orange-flower water, and of ſolutions of ſtorax, and other of the ſweet gums in ſpirit of wine.

The *fumigations* uſed to reſtore health are of ſeveral kinds. Some are meant only as corroboratives, and theſe are compoſed of much the ſame ingredients with thoſe uſed for pleaſure; others are uſed to dry up abundant humors, to purge the lungs, or to promote the menſes. In all diſorders of the uterus, there ſhould be added to theſe *fumigations*, galbanum, caſtor, and aſſa fœtida. A common *fumigation* is alſo uſed, by throwing tobacco on coals, and receiving the ſmoak through a funnel; and to this are ſometimes added colt's foot leaves, with other pectoral herbs, and a little ſulphur. Theſe are very uſeful for drying up ulcerations of the lungs, and other diſorders of the breaſt.

The moiſt *fumigations*, for the ſake of health, conſiſt either of ſome ſimple liquor, ſuch as vinegar, wine, aqua vitæ, or roſe water; and in ſome caſes, as for the diſcuſſing hard tumors, a red-hot brick, or ſtone, is thrown into vinegar, and the ſteam is received on the part. This is alſo a *fumigation* often uſed in times of peſtilential contagion, and that with great ſucceſs. Decoctions of uterine herbs are alſo frequently uſed for *fumigations* in ſeveral diſorders of the womb.

Olibanum, amber, ſtorax, and balſam of Tolu, make a fine dry *fumigation* for a catarrh: and in hyſteric caſes, great benefit is often found from holding the head, with the mouth open, over a hot ſolution of an ounce of aſſa fœtida in a pint of ſtrong wine vinegar.

SUFFITION, *ſuffitio*, among the Romans, a kind of luſtration, practiſed by perſons who had attended a funeral; it was performed by walking over fire, and being ſprinkled with water. *Pitiſc.* in voc.

SUFFOCATIVE *catarrh*, in medicine, the name of a diſeaſe, which conſiſts in a copious eruption of a ſerous and mucous humor into the veſicles of the lungs; which takes its origin from a ſudden congeſtion of humors about the breaſt, and a flaccid and weak ſtate of the breaſt and lungs.

This diſeaſe is not to be confounded with the ſpaſtic aſthma; nor with a moiſt cough, treated injudiciouſly with expectorants and opiates; nor with that ſudden oppreſſion of the breaſt, which is brought on by the ſtriking back of rheumatic humors, or cutaneous exanthemata; or the ſtopping the diſcharges of old ulcers: all theſe, though they have ſomething of the general appearance of the *ſuffocative catarrh*, and are therefore miſtaken for it by the leſs judicious, yet differ greatly and eſſentially from it in ſeveral points; of which hereafter.

Another diſtemper, with which it is alſo confounded, and from which it no leſs differs, is that aſthmatic anxiety which attends young and plethoric perſons, who are unhappily labouring under a latent ſcirrhus, or vomica of the lungs. The *ſuffocative catarrh* differs as widely from this, as from any of the others; but as the cauſe of this is ſeldom gueſſed at firſt, it is liable to miſconſtructions. Others have confounded this diſeaſe with a convulſive aſthma. Theſe diſtempers are in a great meaſure to be diſtinguiſhed by the habit of body of the perſons afflicted with them; plethoric perſons, who abound in rich blood, being very ſeldom ſubject to this diſeaſe, though frequently to the convulſive aſthma. They are alſo diſtinguiſhed from the abundant afflux of matter in the *ſuffocative catarrh*, and by there being none in a convulſive aſthma. In the catarrh of this kind there is a relaxation of the tone of the muſcles of the breaſt; but, on the contrary, in this kind of aſthma they are continually contracted into convulſions; and hence there is, in this caſe, rather an actual preſſure and cohibition of reſpiration, than an impotence of it, which is truly the caſe in a *ſuffocative catarrh*. In this caſe alſo there is a remarkable loſs of the ſtrength, whereas, in the convulſive aſthma, there are violent efforts, and ſtrong palpitations of the heart. Some have alſo buſied themſelves in determining the differences between a ſerous apoplexy, and a *ſuffocative catarrh*; but this is not neceſſary, ſince they very often concur, and make but one diſeaſe: but when the ſerous apoplexy comes alone, it is known by having been preſaged by diſorders of the head, redneſs and lippitude of the eyes, a dull and heavy cephalæa, and a foaming, or voiding of frothy matter by the mouth. *Junker*'s Conſp. Med. p. 507.

Signs of a ſuffocative catarrh. This diſeaſe always ſeizes the patient at once, without any previous notice; his breath becomes extremely difficult, and the fullneſs of the breaſt is eaſily diſtinguiſhed by a ſound of rattling of a frothy matter at the time of drawing in the breath. There is an immediate debility and loſs of ſtrength and ſpirits, as the patient calls it, but there is in reality a ſpaſmodic tenſion; there follows this a reſtleſsneſs, ſo that the patient cannot ſuffer his limbs to lie a minute in the ſame poſture or place; and there is always a deſpondency in the mind, and the patient thinks he is certainly going to die. There is uſually either no cough at all, or, at utmoſt, only a very ſlight and inſufficient one, and the very ſtrength to cough is wanting. The breaſt, and even the ribs, are ſenſibly affected by this diſeaſe, and the eyes always look red and tumid.

Perſons ſubject to it. Scarce any one is ever ſeized with this diſeaſe, except ſuch as are, according to the common acceptation of the word, troubled with habitual catarrhs, or have for many years been ſubject to defluxions from the head upon the fauces and lungs; and the perſons moſt of all ſubject to it, are old men of a phlegmatic and plethoric habit, and are of that kind of temperament which ſubjects people, at other times, to palſies and apoplexies. Lean perſons are ſcarce ever afflicted with this diſorder, unleſs they have long laboured under a violent cough, or have ulcerous diſorders of the lungs. Young people are alſo very little ſubject to this diſeaſe, excepting only ſuch as are very corpulent and phlegmatic, and already habituated to large defluxions of this kind. Infants alſo, which are very fat, and have had a ſudden ſuppreſſion of their natural ſweats, ſometimes fall into this diſeaſe, but with them it is not ſo violent.

Cauſes of it. The occaſional cauſes of this diſeaſe are ſeen in what has been already obſerved, but its true origin is to be ſought for in the head, not in the breaſt or lungs; yet, though it is eaſy to ſee what may occaſion a congeſtion of ſuch ſerous humors in the upper parts, it is difficult to ſay how the lungs become rendered fit to receive it all at once in this dangerous manner. It is accidentally brought on in children, as well by the repulſion of their cutaneous eruptions, as by the ſtopping their ſweats; and in grown people, from the omiſſion of habitual bleedings, from coldneſs and dampneſs in the air, from frequent drunkenneſs, and from an injudicious treatment of cutaneous humors, and particularly from drying up runnings of the eyes. *Junker*'s Conſp. Med. p. 509.

Prognoſtics in it. It is a very terrible diſeaſe, and very ſpeedily proves fatal, for the patient, if not relieved, uſually dies in twenty four hours. Sometimes it degenerates into a fever, and the patient ſeems cured by the change; but the remedy in this caſe proves as bad as the diſeaſe, for the fever proves incurable, and becomes a ſettled hectic, attended with terrible difficulty of breathing, and finally carries off the patient, after making him endure, for ſome time, a life of terrible pain. Sometimes it goes off into an aſthmatic laxity of the breaſt, attended with a cough, and a continual diſcharge of large quantities of mucous matter by ſpitting; and ſometimes into an abſolutely cachectic flaccidity of the body: and in general, if not carefully treated from the beginning, it either entails ſome of theſe diſorders upon the patient, or leaves him ſo poor and weak a conſtitution, that he becomes eaſily liable to all the diſeaſes of this kind from the ſlighteſt occaſions.

Grown perſons are ſooner taken off by this diſeaſe than young children, with whom it ſometimes continues above a week or a fortnight. In old people, the fatal event of the diſeaſe is ſo ſudden, that it is often dubious whether it were this diſorder, or an apoplexy; and in general it ſeems probable, that many of the perſons, ſaid to die of apoplexies, die, in reality, of the violent attacks of this terrible diſeaſe.

Method of cure. In the time of the fit a ſtimulating clyſter muſt be given, made of a decoction of marjoram, and other warm herbs, with colocynth, and a few grains of euphorbium, in order to abate the infarction of the breaſt, and give a new courſe to the matter that might add to it; and when there appears to be a plethora beſides, a vein muſt be immediately opened after the clyſter. After this, if the ſtomach be nauſeating and uneaſy, let a ſcruple of ſalt of vitriol be given as a vomit, with a large quantity of warm water; and if the patient is of a very phlegmatic habit, a few grains of gamboge may be added to this, to carry the humor off downward; or, if the caſe be very preſſing, a draught of a decoction of aſarum, or of tobacco, may be taken, the bad effects of which laſt are taken off by a draught of wine with the ſpices; and all this time there may be frictions and ſinapiſms applied to the lower extremities: and finally, to attenuate and diſcuſs the mucous ſtaſis, gentle alexipharmics and ſudorifics may be given, ſuch as the eſſence of amber, tincture of ſalt of tartar, and tartariſed tincture of antimony; and all nitrous medicines are alſo of the greateſt uſe, as they partly mitigate the cauſes, and partly prepare the humors for evacuation; and after all theſe, the cortex elutheriæ is of great uſe in diſcuſſing and mitigating the pain.

As ſoon as the fit is over, the corroborating medicines are to be given, and all things that can reſtore the parts to their due tone: of this number are the milder chalybeates, and the like; and with theſe analeptics are to be given, to recruit the fleſh and ſtrength, ſuch as emulſions, and a proper diet; and in ſuch as are uſed to wine, the richeſt wines, in moderate quantities, and the higheſt foods, will be of ſervice. If there be perceived a fever after the other ſymptoms are gone off, this muſt be cured by the gentle alexipharmics, and by powders of nitre, and the abſorbents; and if a chronic indiſpoſition ſeems left behind, then the gums, which act as diſcutients, are to be given for ſome time, ſuch as the ammoniacum and ſagapenum, and a warm regimen is to be recommended. And finally, to prevent a return of the diſeaſe, bleeding is very proper in the ſpring and autumn, and purging medicines taken in the intermediate time; the patient muſt alſo avoid all violent paſſions of the mind, and muſt never ſleep in a damp air. We are not to fear bleeding in the time of the fit, becauſe of the patient's complaining of want of ſtrength; for as the danger of *ſuffocation* is ſudden and imminent, it muſt be ſuddenly removed, and when that is done, the patient's ſtrength will return in good time: the ſame is alſo to be alledged in favour of the violent vomits. In people of a very phlegmatic habit, bleeding is not neceſſary nor proper; but in theſe caſes a vomit is ſafe and right, and uſually gives great relief, eſpecially if the patient have eaten heartily ſome little time before. *Junker*'s Conſp. Med. p. 513.

SUFFOLK *powder*, the name of a medicinal powder, good for the bite of a mad dog. It had its name from a Counteſs of *Suffolk*, who uſed to give it with great ſucceſs. It is ſtill kept as a ſecret in ſome private families, but ſeems to be only the ſtar of the earth, or the common buckſhorn plantain dried and powdered, or this powder with ſome very trifling addition. This plant has been famous for its virtues in this caſe a great while among us, and De Grey, in his Complete Farrier, gives the method by which he had cured dogs by it with great ſucceſs. See Phil. Tranſ. N°450. p. 455.

SUGAR (*Cycl.*)—The curious in the whole art of *ſugar*-making, or the reducing vegetable juices to what we call *ſugar*, by expreſſion, decoction, clarification, graining, claying, and cryſtallization, will find farther accounts and directions, in the ſeveral proceſſes of this art, in Piſo's Hiſt. Ind. in Angelus Sala's Saccharologia, in Dr. Slare's Treatiſe on *Sugars*, and in Sir Hans Sloane's Hiſtory of Jamaica. There are alſo ſeveral valuable papers on theſe ſubjects in the Philoſophical Tranſactions.

Sugar has been ſaid to be a ſpecific againſt the famous Indian poiſon mentioned by Mr. de la Condamine; but this ſeems a miſtake. See the article POISON.

Coarſe *ſugar*, in which there is more oil than in refined *ſugar*, is recommended as a good medicine in Collyria for diſcharging ulcers of the cornea, in which aſtringents are hurtful. *Demour*'s Diſſ. ſur les Malad. des yeux.

Labourers in *ſugar*-houſes are very ſubject to dyſenteries. The *vitrum antimonii ceratum* is an effectual remedy in theſe caſes. See VITRUM *antimonii ceratum*.

Maple SUGAR. See MAPLE.

SUGAR *of milk*. See MILK.

SUGAR *ſpirit*, a name given by our diſtillers to a ſpirit made in England, Holland, and other places, from the waſhings, ſcummings, droſs, and waſte of a *ſugar*-baker's refining-houſe. The manner of preparing it is the ſame with that uſed for the malt and melaſſes ſpirits. The refuſe of the *ſugar* is fermented with water in the uſual manner, then diſtilled into what is called *low wines*, and afterwards rectified, without any addition, into proof ſpirit.

When the operation is well performed, and no foul fœtid, or foreign matter, has got in among the waſh, this is a tolerably clean ſpirit. We uſually make it ſuch, but in Holland it is uſually made very nauſeous and diſagreeable; though capable, by an eaſy rectification familiar with us, though not much known abroad, of being brought to a fine and clean ſpirit. With us this *ſugar* ſpirit is uſed to mix with, and adulterate brandy, rum, and arrack, which will receive a large doſe of it without its being at all diſcoverable; but the Dutch, who have it very coarſe, can only adulterate rum with it, and even that will bear but a ſmall proportion, without being betrayed by its nauſeouſneſs.

This *ſugar ſpirit* reduced to alcohol makes one of the pureſt ſpirits we are acquainted with, much ſuperior to that of melaſſes, and much more to that of malt. *Shaw*'s Eſſay on Diſtillery.

We have, in the Philoſophical Tranſactions, an account of a volatile and pungent ſpirit of ſugar, which was made from what the *ſugar*-bakers call *ſugar-water*, which is no other than the water in which the aprons, moulds, and other utenſils, employed in the refining of *ſugar*, are waſhed. This was ſo extremely pungent, that a man could not ſmell to a large quantity of it without danger of ſuffocation; and ſo volatile, that no ſtopping it up could preſerve its ſpirit for any length of time. Phil. Tranſ. N° 130.

SUGGESTUS, among the Romans, a place in the *campus martius* raiſed higher than the reſt, where every magiſtrate, according to his rank, was allowed to harrangue the people; but private perſons could not, unleſs they firſt obtained leave from ſome magiſtrate to do it. *Pitiſc.* in voc.

SUGGRUNDARIUM, among the Romans, a place where infants, not exceeding forty days old, were buried; it being unlawful to burn them. *Pitiſc.* in voc. See the articles BURNING and BURIAL.

SUGITIVA, a term uſed by ſome authors to expreſs medicines, which ſuck up and abſorb the ſeroſities in dropſical perſons.

SUIT (*Cycl.*)—SUIT-*ſilver*, in our old writers, a ſmall rent, or ſum of money, paid in ſome manors to excuſe the appearance of freeholders at the courts of their lords. *Blount.*

SUKOTYRO, in natural hiſtory, the Chineſe name of a very large and remarkable horned animal, which ſeems to be the ſame with the carnivorous bull of Pliny and the antients.

It is of the ſize of a large ox; its head is ſhaped like that of a hog; its ears are long and hairy; and its tail is buſhy. On each ſide of the head, near the eyes, there ſtands a large horn, reſembling the ivory tuſk of the elephant, but not altogether ſo thick. Nieuhoff, who gives this account, adds, that it is very rarely caught, and that it feeds on graſs; but this laſt obſervation may poſſibly have been ſpoken of courſe, without any one's having certainly known it. All that we have ever ſeen of this animal, is a pair of horns of an enormous ſize, now in the poſſeſſion of Sir Hans Sloane, and of which he has given an account to the Academy of Sciences at Paris.

Theſe were found in ſome part of Wapping, by Mr. Doyly, the inventor of the Engliſh ſtuff of that name, in a cellar he had hired; they were much injured by time, and in many places rotten, and worm eaten. No one could remember any account of the place whence they came, or how they were brought to that place.

They are ſtrait for ſome diſtance from the baſe, but higher up they begin to bend, and go on crooked to a point. They have much more of the external appearance of the horns of the goat, than the ox kind, being not round, but flatted, and variouſly undulated with high tranſverſe ridges and furrows. They are not both exact in length, but the longeſt meaſures ſix feet, ſix inches and a half in length. The diameter at the baſe is ſeven inches, and the circumference there a foot and a half. The weight of the largeſt is nearly two and twenty pounds, and it will hold in its cavity a gallon and a pint of water; and would hold much more, were it not for the worm-holes near the baſe.

The captain of an Eaſt-Indian ſhip, on ſeeing theſe horns, aſſured Sir Hans that they belonged to a large ſpecies of bull in the Eaſt, which he had ſeen, and which, by his account, ſeemed to be the ſame with the creature before mentioned, as deſcribed by the antients; though none of the modern naturaliſts having ſeen it, it has been left out of their accounts. Agatharcides, who lived about a hundred and twenty four years before Chriſt, has well deſcribed this animal; and whatever has been occaſionally ſpoken of it by any others, is all tranſcribed from his writings. The creature ſeems to be a native only of Ethiopia, ſome few parts of the Eaſt-Indies, and ſome inland countries in Africa, never viſited by our travellers. From all the accounts we have, its ſize appears to be, at leaſt, twice that of our ordinary oxen, and with horns proportionably large. The pair here mentioned ſeem not to be the only ones preſerved in Europe, for Geſner tells us of one of an enormous ſize, which is ſtill hung up in the cathedral church of Straſburg. Mem. Acad. Par. 1727.

SULA, in zoology, a name given by Hoier, and ſome others, to a bird, deſcribed as a diſtinct ſpecies of the webfooted water-fowl, but ſeeming to be no other than the *anſer baſſanus*, or ſoland gooſe. *Ray*'s Ornitholog. p. 249.

SULCATED *leaf*, among botaniſts. See LEAF.

SULMO, in ichthyology, a name given by Bellonius, and ſome others, to the ſalmon.

SULPHUR, (*Cycl.*) in natural hiſtory. *Sulphurs* are defined to be dry, ſolid, but friable foſſile bodies, melting with a ſmall heat, when fired in the open air, burning almoſt wholly away with a blue flame and noxious vapour, indued with an electric power, and not diſſoluble in acids.

Some have uſed the word *ſulphur* as a name for the whole ſeries of inflammable bodies, but as we have alſo been uſed to diſtinguiſh thoſe of a particular kind by the ſame name, it ſeems much more eligible to reſtrain that name to thoſe bodies, and to give ſome other for the more general claſſes.

The word *ſulphur*, in this acceptation, becomes the name of a regular genus of foſſils, of which there are four known ſpecies. 1. The yellow native *ſulphur*, which in its pureſt ſtate is of a pale ſtraw colour, and as pellucid as the fineſt amber; but is more frequently found coarſer, and more opake. It is found in the gold mines of Peru, in Hungary, and in ſome other places. 2. The green native *ſulphur*. This is harder than the other, and is uſually found in ſmall maſſes compoſed of ſeveral cruſts. It is found, ſo far as is yet known, only about mount Veſuvius. 3. The grey native *ſulphur*, which is common in Iceland, and many other places, and is the coarſeſt and worſt of all the kinds. And 4. the moſt rare and beautiful of all the kinds, the red native *ſulphur*. This is of a fine glowing red, like cinnabar, and very bright and tranſparent, and is found, ſo far as is yet known, only in the gold mines of Peru. *Hill*'s Hiſt. of Foſſ. p. 402.

Mr. Homberg having given the original compoſition of *ſulphur*, in his accurate analyſis of that mineral, Mr. Geoffroy attempted to bring that analyſis to the niceſt teſt, by compoſing *ſulphur* out of ſuch ſubſtances as appeared to be its conſtituent principles.

It appeared from Mr. Homberg's analyſis, that what paſſed in the earth for the production of *ſulphur*, was, that the vitriolic acid, and the common mineral bitumen; both which are always found in great abundance in all places where native *ſulphur* is produced, being joined by a long digeſtion under ground, and mixt with ſome of the native alkalis of the earth, by an intimate union of all three together, formed one mineral *ſulphur*. The beſt way of trying the juſtneſs of this hypotheſis, was by attempting to make *ſulphur* with the ſame ſubſtances by a chemical digeſtion. With this view Mr. Geoffroy mixed the perfectly deflegmated ſpirit of *ſulphur* with an equal quantity of Mr. Homberg's balſam of *ſulphur*, carefully prepared; after digeſting theſe alone for ſome time, he added ſome oil of tartar by way of alkali, and then gave the whole a new digeſtion. After this the whole being diſtilled by the retort with a briſk fire, there came over into the receiver ſome phlegm, and a little oil; and when the veſſels were cooled, there was found in the retort a ſaline matter, yellow in ſome parts, and red in others, and every where ſmelling very ſtrongly of *ſulphur*. He made a lixivium of this ſubſtance, filtered the clear liquor, and adding diſtilled vinegar to it, the liquor became turbid, and ſmelt ſtrongly of *ſulphur*, and, in fine, precipitated a white powder, which was true *ſulphur*, and would burn wholly away.

This was the firſt experiment: the next was to try whether other ſubſtances, of the nature of thoſe ſeparated from *ſulphur*, would produce a true *ſulphur* in the ſame manner. For this purpoſe the ſubſtances fixed upon were oil of vitriol for the acid, and oil of turpentine for the bitumen; equal quantities of theſe being mixed together, the whole became very hot, and after ſtanding ſome time it became red, and had an agreeable ſmell, like the citron: this however, in longer ſtanding, became ſtronger, and leſs agreeable. The mixture having ſtood till it was conſiderably thick, there was added to it a quantity of oil of tartar; the whole then fermented together for a long time, but not with any great

violence, after which it became a thick ſoapy liquor. Part of this was diſtilled, and yielded by the retort a yellow tranſparent oil, of a ſtrong ſmell, and an acrid taſte, and a phlegm of a like acrid taſte: after theſe there came over a thick brown oil, ſweet to the taſte, and ſmelling like the oil of wax; and after this there followed a ſubſtance, wholly reſembling the butter of wax. At the bottom of the retort there remained a ſaline matter of a very ſtrong *ſulphureous* ſmell, reſembling alſo the ſtink of rotten eggs: this matter being diſſolved in water, and diſtilled vinegar poured on the ſolution, the whole became turbid, and, in fine, precipitated a grey powder, which proved true ſulphur.

Thus was the proceſs of nature fairly imitated, and a mineral ſubſtance produced by a mixture of bodies not drawn from that mineral. The author, after this, was deſirous to ſhorten the operation, dried the remainder of the firſt mixture over an open fire; then putting it into a red-hot crucible it flamed, and emitted a ſmell wholly reſembling that of olibanum when burnt; and after that a very penetrating ſmell of *ſulphur* iſſued from it. The whole being then taken from the fire, part of it was yellow, and part red, but all had the ſmell of *ſulphur* very ſtrong.

The vitriolic acid is not peculiarly neceſſary in the making of *ſulphur*, for the ſpirit of alum was found to finiſh the proceſs in the ſame manner.

As it appeared, that in the courſe of this proceſs there had been made a tartarum vitriolatum, by the mixture of the oil of tartar with the acid ſpirits, Mr. Geoffroy was induced to try whether the common tartar vitriolate would not anſwer the purpoſe, and the event proved, that this ſalt, mixt with any of the inflammable oils, would yield a burning and true *ſulphur*; and not only this ſalt, but many others of a like kind, anſwered the ſame purpoſe. The ſalt, produced by mixing oil of tartar and ſpirit of *ſulphur*; colcothar, or fixed ſalt of vitriol; Glauber's ſalt, which is a compoſition of the acid of vitriol, fixed by the alkali of ſea ſalt; and burnt alum, which is the vitriolic acid, mixed with a large portion of earth, all made genuine *ſulphur*, on being properly mixed with the inflammable oils. Another way of making this mineral is thus.

Mix together one ounce of the ſalt of colcothar with two drachms of ſalt of tartar; melt them together over a fierce fire, and as they begin to fuſe, throw in, at ſeveral times, an ounce of rectified ſpirit of wine. When the whole ceaſes to fume, it will yield a very penetrating ſmell of *ſulphur*; take it from the fire, and the flame will appear bluiſh. When it is cold, the matter will appear yellow in ſome places, and red in others, as in the former proceſſes, and will ſmell very ſtrongly of *ſulphur*, or of rotten eggs. Make a lixivium of this matter, and pour diſtilled vinegar into it, and a true inflammable *ſulphur* will be produced, in form of a precipitate, at the bottom of the veſſel.

The ſalt of tartar, in this mixture, ſerves only to aſſiſt the fuſion of the colcothar, and to render the mixture of the ſpirit with it more exact; but it appears very wonderful, that ſo volatile a *ſulphur*, as that of ſpirit of wine, ſhould be able at once to unite and fix itſelf in mixture with a fixed ſalt in fuſion. Nor is ſpirit of wine any more eſſential in this proceſs, than any peculiar acid in the former, ſince petroleum, oil of amber, oil of turpentine, or any of the fetid oils of animals, in the ſame manner produce *ſulphur* with theſe ſalts. Nay, any inflammable matter mixt with theſe ſalts, whether charcoal, common pit coal, or whatever elſe of the ſame kind, will produce *ſulphur* in the ſame manner, though in different proportions.

Decrepitated ſea ſalt and fixt nitre were tried in the manner of the former ſalts, but they would not yield any *ſulphur* on a like proceſs. Theſe ſeveral experiments all join in proving the truth of Mr. Homberg's obſervation, that *ſulphur* is compoſed in the earth by a mixture of an acid ſpirit, a bituminous oil, and an alkaline earth; and do great honour to that elaborate analyſis by which he diſcovered it.

Mr. Geoffroy, though he carried the art of making artificial *ſulphur* to theſe great lengths, is not however the firſt author who attempted it, Mr. Boyle and Glauber both did it before him, but on different plans; Mr. Boyle by a mixture of oil of vitriol and oil of turpentine, and Glauber by a mixture of his own ſalt and powder of charcoal; but though both ſucceeded in ſome degree, neither proceſs could be compared with theſe, nor the *ſulphur* be made near ſo pure. Mem. Acad. Par. 1704.

Stahl's method of producing *ſulphur* is very eaſy, and is thus performed. Mix with tartar vitriolate, in order to facilitate the melting of that refractory ſalt, an equal quantity of potaſh, and add to this an eighth part of ſoft powdered charcoal; put this mixture, at ſeveral times, into a red-hot crucible, and cover it with a tile, leſt a great quantity of the phlogiſton ſhould be diſſipated by the fire; the mixture will ſoon melt, and there will be produced a true *hepar ſulphuris*, or liver of *ſulphur*. When this is diſſolved in cold water, true *lac ſulphuris* may be precipitated from it; and this may be ſublimed into true and perfect flower of brimſtone. *Cramer*'s Art of Aſſaying, p. 390.

The pureſt gold, when melted with common *ſulphur*, remains perfectly the ſame as before; it lets the *ſulphur* burn freely away, remaining itſelf entire, and in a maſs. Silver, when it begins to grow red-hot in a crucible, melts immediately on adding common *ſulphur*; and when poured out, it proves a maſs that cuts very eaſily, is very malleable, and is of the colour and conſiſtence of lead: this maſs, however, being a ſecond time expoſed to a very ſtrong fire for a conſiderable time, is freed from its *ſulphur*, which becomes diſſipated, and the ſilver germinates into a kind of woolly ſubſtance, if the fire be ſlackened toward the end of the operation.

Tin, granulated and ſtratified with an equal, or double quantity of *ſulphur*, deflagrates in the fire as if nitre had been added, and leaves the fluid, which becomes ſolid and conſiſtent while it is yet red in the fire; whence it is plain, that the fuſion of tin is retarded by *ſulphur*. The remaining regulus is very brittle under the hammer, much like a ſemi-metal, and is of the colour of lead; but the part of the tin, thus turned into ſcoriæ, looks like aſhes and duſt upon the ſurface, but is darker coloured, and cleaner within. The whole quantity of the tin will be converted into theſe ſcoriæ, by repeating the burning with freſh quantities of brimſtone.

Lead melted with brimſtone, after the deflagration, is reduced to a maſs which is hardly fuſible by a great fire, but forms a friable maſs, conſiſting of very bright and glittering particles.

Copper ſtratified with *ſulphur* melts immediately in the fire, and turns to a black brittle maſs. The ſame thing alſo happens, if *ſulphur* be put upon copper when red-hot. Iron being taken red-hot out of the fire, and rubbed with *ſulphur*, melts into a ſpungy droſs; it afterwards quits this *ſulphur* with difficulty, but melts very eaſily with it. There is no metal, or ſemi-metal, that ſeems ſo nearly allied to iron, as *ſulphur*, or that melts ſo eaſily, and remains ſo intimately mixed with it. Regulus of antimony being well powdered, and mixed with *ſulphur*, and ſtirred with an iron while in fuſion, returns into crude antimony again. The fuſion of crude antimony is alſo greatly promoted and aſſiſted by common *ſulphur*; but it does not mix ſo readily with the *ſulphur* as the regulus.

Biſmuth melted with common *ſulphur* runs into a maſs reſembling antimony, of a faint grey colour, conſiſting of minute and very bright needles, each cutting the others acroſs: this maſs is extremely brittle.

Zink melted with *ſulphur* does not readily mix with it, but if it be kept a long time in a moderate fire, and *ſulphur* be many times poured over it, ſo as to cover the whole ſurface, and it be continually ſtirred together, it at laſt produces a very brittle dark-coloured ſhining ſubſtance.

From theſe experiments with *ſulphur* on the metals it appears, 1. that iron being very greedy of *ſulphur*, all the other metals, and ſemi-metals, may be freed from *ſulphur*, by adding iron to them. 2. That a very ſmall quantity of iron, a greater quantity of copper, and a much larger of lead, or tin, are neceſſary to abſorb the ſame proportion of *ſulphur*. *Cramer*'s Art of Aſſaying, p. 43.

Dr. Liſter has given it as his opinion, that there is no ſuch thing as pure mineral *ſulphur* found native, or in its original ſtate, in the earth. He ſuppoſes all the pyrites to contain a vaſt quantity of *ſulphur*, as indeed experience proves; and is of opinion, that as we by art can, by means of fire, melt and ſeparate pure *ſulphur* from the pyrites, ſo nature, acting by ſubterranean fires, can do, and frequently does the ſame; and that the *ſulphur*, found pure about the burning mountains, and in mines, is all of this kind. He ſuppoſes, alſo, that thunder, lightning, and earthquakes are all owing to this matter; and that it is owing to the exhalations of the pyrites, which are in effect the pyrites itſelf. Philoſ. Tranſ. N° 156.

It is evident, from numerous experiments, that vitriol and *ſulphur* are things very nearly allied to one another. The vitriolate ſalt, in common *ſulphur*, differs ſcarce at all from common vitriol, and the acid liquors obtained from both, under the different names of *ſpirit of ſulphur*, and *oil of vitriol*, are the ſame, except in degree of ſtrength.

The effects of theſe two acids in the body, and alſo on metals, *&c.* are exactly the ſame. It is obſerved, that the *ſulphur* yields but a very ſmall quantity of this acid, in compariſon of the vitriol; but the reaſon of this is, that in the operation the rapid motion of the flame ſublimes the far greater part of the ſubſtance, unſeparated in the form of flowers.

There are ways however of remedying this, and by ſome ſuch means it was that the famous Drebbel obtained, at the rate of eight, and ſometimes ten ounces of ſpirit, from a pound of *ſulphur*; whereas, in the common proceſs, one ounce is a conſiderable quantity to obtain. Poſſibly the grand ſecret, Mr. Ward poſſeſſes at preſent, of making oil of vitriol, as he calls it, cheaper than others, may depend on this ſort of contrivance. The veſſels he uſes are vaſt ſpheres of glaſs, of three feet in dameter, which muſt ſerve as well, at leaſt, if not much better, than bells; and oil of *ſulphur*, and oil of vitriol, are ſo much the ſame, that there is no deceit in ſelling the one for the other.

In

In all the operations for the making oil of *ſulphur*, the weather is a material thing to be regarded; for when the operation is performed in moiſt weather, there is always a greater quantity of ſpirit or oil prepared, than when in dry; and Drebbel acknowledged, that he could obtain one fourth more in theſe, than in other ſeaſons. This great chemiſt tells us, that he was convinced the contrivance he uſed was capable of very great improvements, and that he made no doubt of carrying it ſo far, at length, as to obtain an equal weight of acid ſpirit to that of the *ſulphur* uſed in the experiment; the humidity of the air, at leaſt, adding as much as the quantity of the *ſulphur* loſt in the operation. There are ſeveral common menſtrua, by means of which *ſulphur* may be reduced into the form of a highly-rectified acid, and corroſive liquor; and even ſpirit of nitre, or aqua fortis, well rectified, being digeſted upon the flowers of brimſtone, and then diſtilled in aſhes, and the proceſs repeated five or ſix times after the laſt operation, there will remain with the flowers nearly an equal weight of an acid ſpirit, in all things reſembling that made by the bell, the ſpirit of nitre being ſcarce at all changed from what it was before the operation: and it ſeems, from experiment, that if the proceſs were frequently reiterated, and the ſpirit of nitre changed, the whole may be thus tranſmuted into an acid ſpirit, abating only for ſome ſmall proportion of earthy, or metalline particles. Phil. Tranſ. N° 104.

There is a preparation of common *ſulphur*, ſtrongly recommended by Mortimer for preſerving timber from being worm eaten, as it is very ſubject to be when felled before the ſap is wholly at reſt. A quantity of common yellow brimſtone is to be put into a common retort of glaſs, and covered three fingers deep with aqua fortis; this is to be diſtilled off to a dryneſs, and the ſame repeated three times. The *ſulphur* then is to be taken out, and laid on a marble, or put into an open flat glaſs veſſel, where it will ſoon run into an oil by deliquium. This oil is to be rubbed on any curious piece of wood that is in danger of worms: it will deſtroy them if they have begun to breed in it, and wholly prevent them if not yet begun. It alſo gives the wood an agreeable tinge or colour, which no art can ever rob it of afterwards. It is alſo a great preſervative of wood that is to be ſet in the earth, or under water; and may be uſed with ſucceſs to rub over the cables in ſhipping, or any other ropes that are indangered by lying much in the water. *Mortimer*'s Huſbandry, Vol. 2. p. 104.

SULPHUR, in medicine, is given in its crude ſtate with great ſucceſs in diſeaſes of the lungs: it ſtrengthens and cleanſes them, by promoting expectoration. It has always been famous for its virtues in cutaneous diſeaſes, and in hæmorrhoidal complaints. It generally proves a little looſening to the bowels, and increaſes the diſcharges by perſpiration: it even communicates its ſmell to the perſpired matter for a conſiderable time after taking it, and will often blacken gold or ſilver that is worn by people who take any conſiderable quantity of it.

The preparations of *ſulphur* are, 1. *flores ſulphuris*, flowers of *ſulphur*. 2. *Sulphur precipitatum*, commonly called *lac ſulphuris*. 3. *Balſamum ſulphuris*. 4. *Aqua ſulphurata*. 5. *Spiritus ſulphuris*, the oil, or ſpirit of *ſulphur*.

SULPHUR *of antimony*. The method of Angelus Sala for preparing the *ſulphur of antimony* ſeems, according to Dr. Plummer, preferable to the common way. The curious may find the deſcription of Sala's in the Medic. Eſſ. Edinb. Vol. 1. Art. 6. The doctor thinks, that in the common preparation much of the true *ſulphur* is conſumed by the deflagration, and the precipitated powder conſiſts of many of the groſs earthy parts of the ſalts in antimony. However, the *ſulphur of antimony*, uſed by the doctor in the preparation of his *æthiops*, was made in the common way. See PLUMMER's *æthiops*.

SULPHUR *auratum*, a name given by ſome chemiſts to a preparation of *ſulphur* and arſenic, called by others *rubinus arſenicalis*. See RUBINUS.

Balſam of SULPHUR. See BALSAM, *Cycl.*

Embryonatum SULPHUR. See EMBRYONATUM.

Fixed SULPHUR. *Fixed ſulphur* is uſed by the enamellers, and is prepared in the following manner. Boil flower of brimſtone in common oil for an hour; take the matter off the fire, and pour on it a quantity of very ſtrong vinegar, the flower of brimſtone will on this ſink to the bottom; pour off the liquors, and repeat the operation to the third time, and the powder then ſeparated is the *fixed ſulphur*. *Neri*'s Art of Glaſs, p. 188.

Spirit of SULPHUR. The uſual methods of preparing the acid *ſpirit of ſulphur*, or oil of *ſulphur*, by the bell, are ſo tedious and expenſive, that few are at the pains to make it. Both the methods, deſcribed by Mr. Charras in the Pharmacop. Royale, p. 883, are liable to many uncertainties and inconveniencies, as well as that recommended by Mr. Homberg in the Memoirs de l'Acad. des Sciences, anno 1703. In the Medical Eſſays of Edinburgh, Vol. 5. Art 14. we have an eſſay on extracting the acid of *ſulphur* in an eaſy manner, by placing a crucible with about three ounces of flower of *ſulphur* in it under a retort. The *ſulphur* being fired by throwing a lighted coal into it, the crucible is then gradually raiſed till it be juſt received within an orifice cut in the bottom of the bole of the retort, to which a large receiver with a ſpout is adapted. When the *ſulphur* is conſumed, the ſame quantity of new lighted *ſulphur* is to be put into another crucible; and thus the proceſs may be continued, till as much acid is obtained as is required. See the book loc. cit. or the Abridgment, Vol. 1. p. 160, ſeq. for the details of practice.

This method is indeed an improvement on the common one; but there are two other more elegant and eaſy ways of extracting the acid from *ſulphur*. The firſt is by Stahl, who directs woollen cloths to be moiſtened in a ſolution of fixed alkaline ſalt, and then dried. Theſe are to be ſuſpended over the fume of burning *ſulphur*, which will be imbibed and locked up in the ſalt, from whence it may be eaſily ſeparated by the addition of oil of vitriol, and the aſſiſtance of common glaſs diſtilling veſſels.

The ſecond is by Mr. Seehl, who pours oil of vitriol on a *hepar ſulphuris* placed in a glaſs retort, to which he adapts a receiver, and by a ſmall heat draws off the acid liquor. See Improvement on making Volatile *Spirit of Sulphur*, by Ephr. Rinh. Seehl, Lond. 1744. and Medic. Eſſ. Abridg. Vol. 1. p. 164. Not.

A pound of flowers of *ſulphur* may be burnt in about ſeven or eight hours, and will yield about ſeven drachms, or an ounce of pure acid. But it is obſervable, that the quantity of acid liquor varies greatly with the weather, being, as before mentioned, conſiderably more when the air is moiſt, than when it is dry.

It is ſaid that *ſulphur* may be made by contriving a fat, oily, or bituminous ſubſtance, with any mineral acid ſalt; but, in reality, the difficulty of making *ſulphur* with every acid is very great, if not impoſſible. With the vitriolic acid, indeed, the inflammable part of bodies eaſily combines into a true *ſulphur*; but it does not appear that any way has yet been found, by which the marine or nitrous acid may directly be combined into ſuch a ſubſtance. Stahl is expreſsly of this opinion in his Opuſcul. Phyſ. Medic. 4to. See Medic. Eſſ. Abrig. p. 163. Not.

Oil of SULPHUR. Some think there is an eſſential difference between the acid of *ſulphur* and its ſuccedaneum, the oil of vitriol; but a late author aſſerts, notwithſtanding the experiments brought to ſupport this opinion, that if the two acid liquors be reduced to the ſame ſtrength, and perfectly freed from all heterogeneous ſubſtances, they will be perfectly ſimilar, and not to be diſtinguiſhed. See Eſſay for Reforming of the London Pharmacopœia, London, 1744. p. 64.

SULPHUR *præcipitatum*, a name given in the London Pharmacopœia to the medicine called by other authors *lac ſulphuris*, or milk of *ſulphur*. It is by ſome directed to be made with the addition of an alkaline ſalt, but according to the method now in uſe, is thus prepared. Boil flowers of *ſulphur* in water, with three times their weight of quick lime, till they are thoroughly diſſolved; filtre the ſolution through paper, and pour on it weak ſpirit of vitriol, till a precipitation is procured; ſeparate the precipitated matter, by pouring off the water, and waſh it with freſh water, till it is become quite inſipid. *Pemberton*'s Lond. Diſp. p. 210.

Purified SULPHUR, is uſed in the making of gunpowder, and other occaſions. The method of preparing it at the powder-mills is this: they diſſolve the *ſulphur* by a very gentle heat, and then ſkum it, and paſs it through a ſtrainer. If the brimſtone ſhould happen to take fire in the melting, they have an iron cover that fits on cloſe to the melting veſſel, and damps the flame. The brimſtone is judged to be ſufficiently refined, if it will melt without yielding any fetid odour between two hot iron plates, and be changed into a kind of red ſubſtance. *Shaw*'s Lectures, p. 389.

SULPHUR *rapax*, in chemiſtry, a name given to arſenic, from its carrying off a great quantity of many metals in the fire, which it carries up with it, and ſublimes in form of flowers, called by ſome *cadmia fornacum*.

Volatile acid of SULPHUR. The *volatile acid of ſulphur*, according to ſome, contains not only the oil of *ſulphur*, but, at the ſame time, the pure native *gas*, or highly volatile ſpirit of the *ſulphur*. Mr. Seehl has given us an eaſy method of procuring this *volatile acid of ſulphur*, which he thinks of ſuperior virtue, both as a menſtruum and as a medicine, to the oil of *ſulphur* by the bell. For this purpoſe he gives us two proceſſes; one with an alkaline ſalt *per ſe*, mentioned above; and the other, which he prefers, by means of the ſame ſalt, with the addition of quick lime. See Phil. Tranſ. N° 472. The ſpirit, obtained thus by quick lime, is ſtronger, more acid, and more volatile, although ſpecifically heavier than the former.

The caput mortuum, remaining after diſtillation, makes an excellent tartar of vitriol, by ſolution, filtration, and cryſtallization. Ibid.

SULPHUR-*water*. See AQUA *ſulphurata*.

SUMA, a name given by ſome of the chemical writers to tartar.

SUMAGE, SUMAGIUM, or SUMMAGIUM, in our old writers, toll for carriage on horſeback. *Pro uno equo portante* ſummagium *per dimidium ann. obolum. Chart. de Foreſt.* cap. 14. *Crompt.* Juriſ. 191. Terms of Law. *Blount, Cowel.*

SUMEN, a word uſed by ſome anatomical writers to expreſs the hypogaſtrium.

SUMMER (*Cycl.*)—It is ſaid, that a froſty winter produces a dry *ſummer*; and a mild winter a wet *ſummer*. It often happens ſo, in fact; but why it ſhould be ſo, is perhaps a queſtion difficult to determine. The curious may, on this ſubject, conſult the Philoſophical Tranſactions, N° 458. ſect. 10.

SUMMER *teale*, in zoology, the name of a bird, the ſmalleſt of all the duck kind, called by Geſner the *anas circias*. See the article CIRCIAS.

SUMP, in metallurgy, a round pit of ſtone lined with clay within, for the receiving the metal on its firſt fuſion from the ore. *Ray*'s Words, p. 114.

SUMP, in the Engliſh ſalt works, where ſea water is boiled into ſalt, is uſed as the name of a ſort of pond, which they make at ſome ſmall diſtance from the ſaltern on the ſea ſhore, between full ſea and low water mark. From this pond they lay a pipe, through which, when the ſea is in, the water runs into a well adjoining to the ſaltern; and from this well they pump it into troughs, through which it is carried to their ciſterns, in order to be ready to ſupply the pans. See the article SALT.

SUN (*Cycl.*)—SUN-*fiſh*, *mola*, in ichthyology. See Tab. of Fiſhes, N° 27. and the article MOLA.

One of theſe fiſhes, of five hundred weight, was taken ſome years ago near Plymouth, and on boiling a piece of the fleſh, to try how it would taſte, (as ſome authors have deſcribed it as a fine fiſh for the table) it was found, inſtead of a firm maſs, to be all converted, in a few minutes, into a perfect jelly, ſo that it could not be taken out otherwiſe than with a ſpoon. In colour and conſiſtence this jelly reſembled boiled ſtarch when cold, and had little or nothing of a fiſhy flavour, but a very agreeable taſte; it ſtuck firmly to the lips, however, and to the fingers, appearing very remarkably glutinous: and as the antients had no other glue than one made of fiſh, this jelly was tried, as to its ſticking quality, on leather, and on paper, and was found to anſwer as well as common paſte; but by ſome accident it was not tried upon wood.

It will be extremely worth while, on ſome other opportunity, to try whether a true ichthyocolla may not be prepared, by boiling down this jelly. Philoſ. Tranſ. N° 456. p. 220.

SUN-*flower*, *corona ſolis*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the radiated kind; its diſk is made up of floſcules, and its outer edge of ſemifloſcules; theſe ſtand upon the embryo ſeeds, and are ſeparated from one another by little leaves of an imbricated figure, and contained in a ſcaly huſk, or cup: the embryos finally ripen into ſeeds, furniſhed with two little leaves.

The ſpecies of *ſun-flower*, enumerated by Mr. Tournefort, are theſe. 1. The common great *ſun-flower*. 2. The great branched *ſun-flower*. 3. The great *ſun-flower* with greyiſh white ſtriated ſeeds. 4. The perennial *ſun-flower* with large flowers and large ſeeds. 5. The leſſer, or female *ſun-flower*. 6. The ſmall-flowered *ſun-flower* with tuberous roots. 7. The ſmall-flowered *ſun-flower* with long roots. 8. The talleſt broad-leaved *ſun-flower*. 9. The tall *ſun-flower* with alated ſtalks. 10. The rapunculus-rooted *corona ſolis*. 11. The ſmall-flowered large-leaved *corona ſolis*. 12. The throat-wort-leaved *ſun-flower* with creeping roots. 13. The golden-rod-leaved very tall *ſun-flower*. 14. The creeping narrow-leaved *ſun-flower* with pale yellow flowers. 15. The willow-leaved *ſun-flower* with alated ſtalks. 16. The ſhrubby American *ſun-flower* with lychnis leaves, and yellow flowers. 17. The ſhrubby American *ſun-flower* with ſpurge-laurel leaves, and yellow flowers. 18. The dwarf ſea American *ſun-flower* with fleſhy three-pointed leaves, and yellow flowers. 19. The ſmall *ſun-flower* with deeply jagged leaves. 20. The *ſun-flower* with large jagged leaves. 21. The narrow-leaved *ſun-flower* with jagged leaves. 22. The New England *ſun-flower* with very large trifid leaves. *Tourn.* Inſt. p. 489.

There are ſeveral different ſpecies of this flower, all which are very beautiful in large gardens. They are moſt of them annual plants, and are to be ſown every ſpring in a bed of good light earth. When the ſhoots are about three inches high, they muſt be tranſplanted into nurſery beds, and ſet at eight inches diſtance every way; they ſhould remain here till they are a foot high, and then be carefully taken up with a ball of earth at their roots, and planted in large borders, or intermixed in the boſquets of large growing plants; they muſt be frequently watered till they have taken root, and after that will require no farther care. In July the flowers appear, and ſtand a conſiderable time: the largeſt of theſe ſhould be left to ſtand for ſeed. The birds are very apt to devour this ſeed, but it ſhould be carefully guarded from them, and the head left on the plant till October, at which time it ſhould be cut off, and hung up to dry in an airy place, and in a month more the ſeeds will be perfectly hardened.

Several ſpecies of this plant alſo are perennial, and increaſe greatly by the root. Among theſe the common ſmaller-flowered one is a very valuable plant in gardens, as it requires no culture, will grow in all ſoils and ſituations, and is a very ornamental flower, continuing in bloom from June to October. *Miller*'s Gard. Dict.

Small SUN-*flower*. See HELIANTHEMUM.

SUN-*dew*. See ROS *ſolis*.

SUN-*ſcorched*, a term uſed by our gardners in ſome parts of England to expreſs a diſtemperature of fruit trees, owing to the *ſun*'s affecting them too forcibly and too ſuddenly; the conſequence of which is the loſs and withering of the fruit. Such trees only are ſubject to this, as are planted in places ſheltered from the ſpring *ſun*, and only open to the ſummer's; and it may be always cured by proper waterings.

Mr. Merret gives us an account of three cherry-trees, of that kind we call *May-dukes*, which he cured in this manner. Theſe trees were planted in a very rich mould, which lay to a ſouth wall, ſhaded four months of the winter from the *ſun* by a high building, ſo that the *ſun* never came upon them till the latter end of March; when being high, and ſhining ſomewhat fiercely upon them, from that time the fruit had been always uſed to wither. In a very hot ſummer, when theſe trees ſeemed going into a worſe way than ordinary, the roots of one of them was bared, and a hole being made about it, a gallon of water was poured into it every morning and evening for about a fortnight before the cherries came to a redneſs.

The effect of this was, that the fruit was full and good, while the two trees that ſtood next it had their fruit withered and ſcorched up. One of theſe was taken into conſideration more late, and being watered from time to time, thoſe fruits which were moſt withered on it fell off, and the reſt grew ripe of themſelves, and proved very good ones. The third tree, which was left to itſelf, produced not one ripe good cherry. Phil. Tranſ. N° 23.

SUNCOPULLY, in natural hiſtory, a name given by the people of the Eaſt-Indies to a kind of ſparry ſubſtance of a whitiſh colour, which they calcine, and afterwards give in agues, and other intermittent caſes.

It is erroneouſly by ſome ſuppoſed to be a ſpecies of arſenic; for it has none of its qualities.

SUONATA, in muſic. See SONATA, *Cycl.*

SUONATINA, or SONATINA, in the Italian muſic, a little, ſhort, eaſy *ſonata*. See SONATA, *Cycl.*

SUPERBUS *muſculus*, a name given by ſome to the elevator oculi, or the muſcle whoſe office is to raiſe and lift up the eye; that motion giving a haughty look.

The *ſuperbus muſculus* is one of the muſcles called by Albinus the *quatuor recti oculi*. See ATOLLENS.

SUPERFICIAL (*Cycl.*)—SUPERFICIAL *fourneau*, in fortification, the ſame with *caiſſon*, which is a wooden cheſt, or box, with three, four, five, or ſix bombs in it. Sometimes it is filled only with powder, and uſed in ſieges, by being buried under ground, with a train to it, to blow up any lodgment that the enemy may make.

SUPERFICIALIS *ſphincter*, in anatomy, a name given by Riolanus, and ſome others, to the muſcle of the anus, called by Winſlow and Albinus *ſphincter internus ani*. This author, and ſome others, call it alſo *ſphincter cutaneus*.

SUPERFICIES (*Cycl.*)—*Internal* SUPERFICIES *of the earth*, a term uſed by Tull, and others, to expreſs that part of the earth which affords the pabulum, or what is called the *paſture of plants*.

Plants themſelves are the paſture of animals; but it is from this *internal ſuperficies of the earth* that vegetables firſt receive the nouriſhment which they afterwards give to animals. This inner *ſuperficies of the earth* is the *ſuperficies* of the pores, cavities, and interſtices of the divided parts of the earth; and theſe are of two kinds, natural and artificial. Tull is the firſt who has uſed this term, and he juſtifies himſelf from the imputation of having uſed an abſurd phraſe, as it might at firſt ſeem, the adjective expreſſing ſomething within, and the ſubſtantive ſomething without, by obſerving, that though the vegetable paſture is within the earth, yet it is alſo on the outſides of the divided parts of the earth.

Of the natural and artificial paſture of plants, or the natural and artificial cavities, pores, and interſtices of the earth, the natural alone will ſuffice to furniſh a country with vegetables for the maintenance of a few inhabitants: but if the artificial, that is, if agriculture, the ſole buſineſs of which is the making this artificial paſture for plants, were aboliſhed out of the world, it is much to be feared, that the people of all populous countries, eſpecially of thoſe toward the borders of the frigid zones, (for there the trees often fail of producing fruit) would be reduced to the utmoſt neceſſities for want of this proper kind of food.

The artificial paſture of plants is that inner *ſuperficies* of the earth, which is made by dividing the ſoil by art. This, on all parts of the globe where it is uſed, maintains many more people

people than the natural one; in the colder countries it maintains ten times as many as the natural one, and when the art of agriculture is more advanced to perfection, it will maintain twice as many as it does at preſent; and this improvement is eaſy, and to be done by ſimple means.

The natural paſture is not only leſs than the artificial, in an equal quantity of ground; but the little there is of it conſiſting alſo of the *ſuperficies* of pores and cavities not having a free communication with one another, they are leſs pervious to the fine roots of all vegetables, which require a greater force to break through their partitions; and by that means roots, eſpecially of weak plants, are excluded from many of thoſe cavities; ſo that the benefit of a great part of the paſture that really is there, is loſt to the huſbandman.

The artificial paſture, on the other hand, conſiſts in *ſuperficies* of cavities that are pervious to all roots, and give them free paſſage throughout the whole extent of the cultivated place; and conſequently, the fine horizontal roots of plants, which run much farther than is generally ſuppoſed, (thoſe of a turnep, for inſtance, running ſix feet diſtant from the main root every way; ſee ROOT) will find an eaſy paſſage in every part to the utmoſt extent to which nature allows them to run.

The *internal ſuperficies of the earth*, which is the paſture of plants, is not like the external ſurface, which is the paſture of animals, in that it cannot be inlarged without the addition of more ſurface taken from land adjoining to it, by inlarging its bounds or limits: but the *internal ſuperficies*, or artificial paſture of land, may be inlarged without addition, or more land, only by diviſion of the ſame earth: and this artificial paſture may be increaſed in proportion to the diviſion of the parts of the earth, whereof it is the *ſuperficies*.

A cube of earth of one foot has but ſix ſquare feet of *ſuperficies*; but divide this cube into cubical inches, and then its *ſuperficies* will be increaſed twelve times, that is, it will be ſeventy two *ſuperficial* feet. Divide theſe cubes again into ſuch others, as bear the ſame proportion to an inch that an inch does to a foot, and then the ſame quantity of earth, which had at firſt only ſix feet *ſuperficies*, will have a *ſuperficies* of eight hundred and ſixty four feet of natural paſture: and in the ſame manner is the ſoil diviſible, and conſequently this paſture increaſable *ad infinitum*.

Poor land does not afford an *internal ſuperficies* ſo well ſtocked with theſe fruitful particles as rich land does, but this we may compenſate by dividing it more, and then what it wants in quality may be made up in quantity.

The common method of dividing the ſoil is by dung, or by tillage, or by both; and none of the natural paſture is ever loſt, or injured by the uſe of the artificial means, but, on the contrary, it is mended by ſuch means, a free communication being made by them between pore and pore. *Tull*'s Horſehoeing Huſbandry, p. 18.

SUPERFLUOUS *interval*, in muſic, is one that exceeds a true diatonic interval by a ſemitone minor. Thus the

SUPERFLUOUS *ſecond*, or *tone*, contains a ſemitone minor more than a tone, or greater ſecond; and will therefore be expreſſed by $\frac{125}{108}$, or by $\frac{75}{64}$. The firſt of theſe expreſſions is a tone minor, and a ſemitone minor; ſince $\frac{10}{9} \times \frac{25}{24} = \frac{125}{108}$: and the other is a tone major, and ſemitone minor; for $\frac{9}{8} \times \frac{25}{24} = \frac{75}{64}$. This laſt occurs in practice, and is one of the intervals of the chromaticum toniæum. See the article CHROMATIC.

In temperate ſcales theſe two *ſuperfluous* tones coincide. Thus from B♭ to C ſharp, or from F to G ſharp, are *ſuperfluous* tones.

SUPERFLUOUS *third* is greater than the third major by a ſemitone minor, and will therefore be expreſſed by $\frac{125}{96} = \frac{5}{4} \times \frac{25}{24}$. It is not in uſe. It ſeems a fourth on our harpſichords. Thus from B♭ to D ſharp is, properly ſpeaking, a *ſuperfluous third*; but D ſharp and E♭ being confounded, it paſſes for a fourth.

SUPERFLUOUS *fourth*. This interval is expreſſed by $\frac{25}{16} = \frac{4}{3} \times \frac{25}{24}$. It is by practitioners, and in temperate ſcales, confounded with the tritonus. See INTERVAL.

SUPERFLUOUS *fifth* is expreſſed by $\frac{25}{16} = \frac{3}{2} \times \frac{25}{24}$. This is equal to two thirds major, for $\frac{5}{4} \times \frac{5}{4} = \frac{25}{16}$. The *ſuperfluous fifth* occurs in practice, as from C to G ſharp.

SUPERFLUOUS *ſixth*. This interval is of two kinds; being the reſpective complements of the two diminiſhed thirds to the octave. One only, ſtrictly ſpeaking, anſwers to the general definition of a *ſuperfluous* interval, which is that interval which exceeds the ſixth major by a ſemitone minor, and is therefore expreſſed by $\frac{125}{72} = \frac{5}{3} \times \frac{25}{24}$. But the other interval, which is a comma more than the former, and is two ſemitones major leſs than the octave, is chiefly uſed in harmony, as between B♭ and *a* ſharp, where it has a fine effect. It is expreſſed by $\frac{225}{128} = \frac{2}{1} : \frac{16}{15} : \frac{16}{15} = \frac{2}{1} : \frac{256}{225}$. See the articles INTERVAL and DIMINISHED *third*.

SUPERFLUOUS *ſeventh* is expreſſed by $\frac{15}{8} \times \frac{25}{24} = \frac{125}{64}$. This is a dieſis leſs than the octave. See INTERVAL.

SUPERFLUOUS *octave* is a ſemitone minor more than the octave, as from C to *c* ſharp. It ſometimes occurs in the baſſes of inſtrumental pieces.

SUPERGEMINANS, a name given by ſome anatomical writers to the epididymis.

SUPERGENUALIS, a name given by ſome authors to the patella, or knee pan. See PATELLA.

SUPERIOR (*Cycl.*)—SUPERIOR *auriculæ muſculus*, in anatomy, a name given by Santorini, and by Winſlow, to one of the muſcles of the ear, called by Albinus and Cowper the *attollens auriculam*, and by many *auriculæ primus*.

SUPERIOR *courts of record*. See the article COURT.

SUPERNUMERARII, in the later times of the Roman empire, ſoldiers added to the legion after it was completed. They were the ſame with thoſe in former times, called *accenſi*. *Pitiſc.* in voc. See ACCENSI, *Cycl.* and *Suppl.*

SUPERNUMERARY (*Cycl.*)—SUPERNUMERARY *bones of the head*. Anatomiſts diſtinguiſh by this appellation ſeveral bony pieces found in ſome ſkulls, chiefly between the parietal and occipital bones. They form breaks in the lambdoidal ſuture, and are joined by true ſutures to the bones already mentioned.

Their figure, number, and ſize vary extremely; ſometimes they are triangular, or approaching to that form, but oftener they are of no determinate figure: in ſome ſubjects they incroach on the occipital bone, and in others on the parietal bones; and ſometimes they extend themſelves every way. They are commonly indented, and broader on the outſide of the ſkull than on the inſide, in which they have no viſible indentations; and ſometimes, when they are ſmall on the outſide, are hardly at all to be ſeen within. They have by ſome been termed keys, a name uſed by joiners for the pieces which ſerve to ſtrengthen the joints of boards; but this can agree to them only in reſpect to their ſituation, not in reſpect to their uſes with regard to the other bones of the head. Some ſuch bones have alſo been found in the joints, between the bones of the head and face; and between thoſe of the bones of the face with each other. *Winſlow*'s Anatomy, p. 53.

SUPERONERATIONE *paſturæ*, a judicial writ, that lies againſt him who is impleaded in the county court for the ſurcharging, or overburthening a common with his cattle, in a caſe where he was formerly impleaded for it in the ſame court, and the cauſe is removed into one of the courts at Weſtminſter. Reg. Judic. *Blount*, *Cowel.*

SUPERPARTICULAR (*Cycl.*)—SUPERPARTICULAR *ratio*. Ptolemy, in his Harmonics, ſeems to lay a great ſtreſs on *ſuperparticular ratios* [c], beyond the ſuperpartient in muſic. He does not call the intervals which may be expreſſed by the former ratios, excepting 2 : 3 and 3 : 4, diſſonants, as the Pythagoreans did, but concinnous, as if they were of a middle nature between conſonant and diſſonant. But all this doctrine of *ſuperparticular ratios* is a precarious hypotheſis. The two thirds, major and minor, expreſſed by 5 : 4 and 6 : 5, are *ſuperparticular*, and concords. Their octaves, 5 : 2 and 12 : 5, are *ſuperparticular*, and concords alſo. Ptolemy himſelf refutes the Pythagoreans for excluding the diapaſon diateſſaron, expreſſed by 8 : 3, from the number of concords, becauſe its proportions were ſuperpartient; yet his own doctrine is equally precarious [d].—[c See RATIO, *Cycl.* d Vid. *Euler*, Tentam. Nov. Theor. Muſic. p. 63, 64.]

SUPER-PRÆROGATIVA *regis*, a writ which formerly lay againſt the king's widow for marrying without the ſucceſſor's licence. F. N. B. 173. *Blount*, *Cowel.*

SUPER-STATUTO *de articulis cleri cap.* 6. a writ lying againſt the ſheriff, or other officer, that diſtrains in the king's highway, or in the lands antiently belonging to the church. F. N. B. 173. *Blount*, *Cowel.*

SUPER-STATUTO *facto pour ſeneſchal & marſhal de roy, &c.* a writ that lies againſt the ſteward or marſhal for holding plea in his court, or for treſpaſs or contracts not made, and ariſing within the king's houſhold. F. N. B. 141. *Blount*, *Cowel.*

SUPER-STATUTO *verſus ſervantes & laboratores*, a writ which lies againſt him who keeps any ſervants departed out of the ſervice of another contrary to law. F. N. B. 167. *Blount*, *Cowel.*

SUPINATOR (*Cycl.*)—SUPINATOR *brevis*, in anatomy. This is a ſmall thin fleſhy muſcle, ſurrounding a great portion of the upper part of the radius.

It is fixed by one end to the lower part of the external condyle of the os humeri, to the external lateral ligament of the joint, to the annular ligament of the radius, and to part of the lateral eminence in the head of the ulna; from thence it paſſes obliquely over the head of the radius, covering ſome part of it, and running down upon, and in ſome meaſure ſurrounding the neck, it turns in under the occipital tuberoſity, and is inſerted by the ſide of the interoſſeous ligament, in the inſide of the ſuperior quarter of the bone, and even a little lower. In ſome ſubjects we may obſerve the marks of the paſſage of this muſcle over the outſide of the bone. It makes an angle with the pronator teres, reſembling the Roman V. *Winſlow*'s Anatomy, p. 190.

SUPINATOR *longus*, a long flat muſcle, lying on the external condyle of the os humeri, and on the convex ſide of the radius, from one end to the other.

It is fixed by fleſhy fibres to the external intermuſcular ligament, and to the criſta of the external condyle of the os humeri, for five or ſix fingers breadth above the condyle, between the brachiæus, and anconæus externus; from thence it runs along the whole convex ſide of the radius, and is inſerted by a flat narrow tendon, a little above the ſtyloide apophyſis, in the angle between the concave and flat ſides of the extremity of this bone. *Winſlow*'s Anatomy, p. 189.

SUPPLE. To *ſupple* a horſe, in the manege, is to make him bend his neck, ſhoulders, and ſides, and to render all the parts of his body more pliable.

SUPPOPLITÆUS, in anatomy, a name given by Spigelius, and ſome others, to the muſcle more generally known by the name of the *poplitæus*. See POPLITÆUS.

SUPPRESSION (*Cycl.*)—SUPPRESSION *of urine*. There are commemorated, in the Philoſophical Tranſactions, three caſes of an actual and total *ſuppreſſion of urine*, ſuppoſed to proceed from a ſtone lodged in the neck of the bladder; but in all which, on introducing the catheter, it was found that there was no ſtone there, nor any urine in the bladder. In all theſe caſes the ſame remedy was uſed; that is, a great quantity of acids diluted largely with water, and in conſequence of this the urinary ſecretion was immediately reſtored, and the patient ſoon voided it in a proper manner, and was reſtored to health without any further uſe of medicines. Philoſ. Tranſ. N° 253.

A *ſuppreſſion of urine* ſometimes happens to women with child, by the womb falling down, and preſſing on the urethra. See Act. Acad. Nat. Curioſ. Not. 4. Obſ. 113.

SUPPRESSIONIS *ignis*, a *fire of ſuppreſſion*, a term uſed in chemiſtry to expreſs ſuch an application of fire to any ſubject, that it ſhall at once act upon it above and below in the ſame manner. The uſual way of giving this heat, is by covering the veſſel, in which the ingredients are put, with ſand, and then laying hot coals upon that, ſo that they may heat through the ſand downwards.

SUPPURATION (*Cycl.*)—When in tumors and phlegmons nature ſhews a tendency to *ſuppuration*, or ripening, all the reſolving, or diſperſing medicines muſt be laid aſide, and great care muſt be taken to forward the maturity of the inflammation, that is, to convert the ſtagnating blood into laudable matter; then to give a diſcharge, or vent, to this *ſuppurated* matter, afterwards to cleanſe the part, and finally to incarn, and heal it.

The firſt of theſe intentions, the ripening the ſwelling, is to be promoted by ſuch of the emollient medicines as obſtruct the pores of the ſkin, as fats, oils, and glutinous medicines; as alſo the ſharp, pungent, and, in ſome degree, cauſtic medicines, which may be uſed in form of cataplaſms, or plaſters. Of the firſt kind are mallows, marſhmallows, figs, linſeed, honey, crumb of bread, the various animal fats, and the oils of lillies, chamæmile, *&c.* and of the latter, or the ſharp and pungent ripeners, are garlic, onions, ſaffron, turpentine, and many of the gums, as galbanum and ammoniacum; and laſtly, ſour leven of bread.

Medicines compounded of theſe are to be applied hot to the part, and the application frequently repeated, till the matter within is found to be ſufficiently ripened, by the ſoftneſs and whiteneſs of the tumor. But when the abſceſs is ſmall, it is more convenient, and ſufficient, to apply ſome of the ripening plaſters, as diachylon, with the gums, or the like, till the *ſuppuration* is perfected.

Nor are internal remedies wholly to be neglected in caſes of this kind, eſpecially where the tumors are large, or of conſequence. In theſe caſes, when the blood moves too ſlowly, which may be known by the pulſe, the patient muſt be allowed to eat meat, and muſt take ſuch medicines as are warm and ſtimulating; by means of which, and by the increaſed motion of the blood, the inſpiſſated particles contained in the ſmaller veſſels will be the more eaſily converted into matter.

Strong broths are very proper for this purpoſe, as alſo the uſe of wine, or ale, in moderation; and Venice treacle, diaſcordium, and the confection of alkermes, are to be the medicines taken three or four times a day, and medicated teas, made of ſanders-wood, ſaſſafras, or cinnamon. But, on the contrary, when the motion of the blood is too violent, and the heat too great, cooling medicines are to be given, ſuch as the thin and watery drinks, the ſubacid medicines, and nitre: bleeding, in a ſmall quantity, is alſo often neceſſary in this caſe. But when the conſtitution is ſound, and the blood's motion regular, the uſe of internal medicines, to promote *ſuppuration*, is trifling, and may be altogether rejected. When by theſe means the matter is perfectly formed, the abſceſs is to be carefully opened by the ſurgeon, and the matter diſcharged, after which the wound is to be cleanſed and healed in the common way. *Heiſter*'s Surgery, p. 183.

SUPRACOSTALES, muſcles irregularly triangular, and ſituated on the back part of the ribs, near the vertebræ, commonly called *levatores coſtarum*.

Each of theſe is fixed by one tendinous extremity in the tranſverſe apophyſis, which lies above the articulation of each rib, and to the neighbouring ligament; the firſt being inſerted in the tranſverſe apophyſis of the laſt vertebra of the neck, and the laſt in that of the eleventh vertebra of the back. From thence the fleſhy fibres run down obliquely, increaſing in breadth as they deſcend, and are inſerted in the back part of the outſide of the following rib: ſome of the fibres often paſs beyond that rib, and are fixed in one or more of the ribs below it by ſeveral digitations, which lie at a greater diſtance from the vertebræ, in proportion as they run lower. In the inferior ribs theſe digitations are more conſiderable than in the ſuperior. *Winſlow*'s Anatomy, p. 232.

SUPRACOSTALES *longi*, in anatomy, a name given by Verheyen to thoſe muſcles of the loins, which Albinus has deſcribed under the names of the *levatores longi coſtarum*. See the article LEVATORES.

SUPRASPINATUS, in anatomy, is a thick narrow muſcle, in ſome meaſure penniform, filling all the *ſupra-ſpinal* cavity of the ſcapula.

It is fixed to all the poſterior half of the *ſupra-ſpinal* foſſa, and ſometimes its inſertion reaches near the neck of the bone. Then the fibres leave the ſurface of the bone, and being, as it were, ſupported by the fat, or cellulous ſubſtance, paſs between the acromium, and neck of the ſcapula, under the arch formed by the acromium and extremity of the clavicle, and under the ligament between the acromium and apophyſis coracoides; being afterwards inſerted in the ſuperior ſurface of the great tuberoſity of the head of the os humeri, very near the bony channel. This muſcle is covered by the trapezius. *Winſlow*'s Anatomy, p. 184.

SUPREME *pear*, a name given by the gardners to a ſmall pear, called alſo by ſome the *little muſk pear*. It is of a roundiſh ſhape, and is uſually produced in cluſters. The ſtalk is ſhort, and when it is ripe, the ſkin is yellow. The juice is ſomewhat muſky. If it be not ſuffered to hang till too ripe, it is an excellent pear. It ripens in the beginning of July, and continues good but a few days. The French call it *le petit muſcat*. *Miller*'s Gard. Dict.

SURA, (*Cycl.*) the name of a drink uſed in the Eaſt-Indies, and made of the juice that flows from the cocoa-tree. *Boyle*'s Works Abr. p. 51.

This juice being evaporated, and expoſed to the ſun, forms a ſugar, but it is little eſteemed. *Boyle*, ibid. p. 53.

SUR CUI *in vita*, in law, a writ that lies for the heir of a woman, whoſe huſband aliened her land in fee, and ſhe neglected to bring the writ *cui in vita* for recovery thereof, her heir may bring this writ againſt the tenant after her deceaſe. F. N. B. 193. Terms of Law. *Blount*, *Cowel*.

SURCULUS, in the anatomy of plants, a word uſed to expreſs that part of the branching of the ribs of a leaf which is of a middle kind, between the great middle rib and the ſmalleſt reticular ramifications. The middle rib is, by the writers on theſe ſubjects, called *petiolum*.

The firſt diviſions, that go off laterally from theſe, are called *rami*, or branches; the next diviſion of theſe, into more minute ones, are called *ſurculi*; and the final divarications of theſe into the reticular work, that ſpreads itſelf over the whole leaf, are called *capillamenta*.

Many, however, confound theſe two laſt diviſions, and call all beyond the ſecond diviſion, or lateral branches of the middle rib, by this name of *ſurculi*. Act. Erudit. 1722. See PETIOLUM and RAMUS.

SURD (*Cycl.*)—Simple *ſurds* are commenſurable in power, and by being multiplied into themſelves give, at length, rational quantities. But compound *ſurds*, multiplied into themſelves, commonly give irrational products. Yet in this caſe, when any compound *ſurd* is propoſed, there is another compound *ſurd*, which multiplied into it, gives a rational product. Thus if $\sqrt[3]{a} - \sqrt[3]{b}$ were propoſed, multiplying it by $\sqrt[3]{a^2} + \sqrt[3]{ab} + \sqrt[3]{b^2}$, the product will be $a - b$.

The inveſtigation of that *ſurd*, which multiplied into the propoſed *ſurd*, gives a rational product, is made eaſy by three theorems, delivered by Mr. Maclaurin, in his Algebra, p. 109, ſeq. to which we refer the curious.

This operation is of uſe in reducing *ſurd* expreſſions to more ſimple forms. Thus ſuppoſe a binomial *ſurd* divided by another, as $\sqrt{20} + \sqrt{12}$ by $\sqrt{5} - \sqrt{3}$, the quotient might be expreſſed by $\frac{\sqrt{20} + \sqrt{12}}{\sqrt{5} - \sqrt{3}}$. But this might be expreſſed in a more ſimple form, by multiplying both numerator and denominator by that *ſurd*, which multiplied into the denominator, gives a rational product: thus,

$$\frac{\sqrt{20} + \sqrt{12}}{\sqrt{5} - \sqrt{3}} = \frac{\sqrt{20} + \sqrt{12}}{\sqrt{5} - \sqrt{3}} \times \frac{\sqrt{5} + \sqrt{3}}{\sqrt{5} + \sqrt{3}} = \frac{\sqrt{100} + 2\sqrt{60} + 6}{5 - 3} = \frac{16 + 2\sqrt{60}}{2} = 8 + 2\sqrt{15}.$$

To do this generally, ſee Mac Laurin, lib. cit. p. 113.

When the square root of a *surd* is required, it may be found, nearly, by extracting the root of a rational quantity that approximates to its value. Thus, to find the square root of $\sqrt{3 + 2\sqrt{2}}$, first calculate $\sqrt{2} = 1{,}41421$. Hence, $3 + 2\sqrt{2} = 5{,}82842$, the root of which is found to be nearly 2,41421.

In like manner we may proceed with any other proposed root. And if the index of the root, proposed to be extracted, be great, a table of logarithms may be used. Thus $\sqrt[7]{5 + \sqrt[13]{17}}$ may be most conveniently found by logarithms.

Take the logarithm of 17, divide it by 13; find the number corresponding to the quotient; add this number to 5; find the logarithm of the sum, and divide it by 7, and the number corresponding to this quotient will be nearly equal to $\sqrt[7]{5 + \sqrt[13]{17}}$.

But it is sometimes requisite to express the roots of *surds* exactly by other *surds*. Thus, in the first example, the square root of $3 + 2\sqrt{2}$ is $1 + \sqrt{2}$: for $\sqrt{1 + \sqrt{2}} \times \sqrt{1 + \sqrt{2}} = 1 + 2\sqrt{2} + 2 = 3 + 2\sqrt{2}$.

For the method of performing this, the curious may consult Mr. Mac Laurin's Algebra, p. 115, seq. where also rules for trinomials, *&c.* may be found.

For extracting the higher roots of a binomial, whose two members being squared are commensurable numbers, we have a rule in Sir Isaac Newton's *Arithmetica Universalis*, p. 59, but without demonstration. This is supplied by Mr. Mac Laurin, in his Algebra, p. 120, seq. as also by 'sGravesande, in his *Matheseos Universalis Element.* p. 211, seq.

It sometimes happens, in the resolution of cubic equations, that binomials of this form $a \pm b\sqrt{-9}$ occur, the cube roots of which must be found. To these Sir Isaac's rule cannot always be applied, because of the imaginary, or impossible factor $\sqrt{-9}$; yet, if the root be expressible in rational numbers, the rule will often lead to it in a short way, not merely tentative, the trials being confined to known limits. See *Mac Laur.* loc. cit. p. 127, seq.

It may be farther observed, that such roots, whether expressible in rational numbers, or not, may be found by evolving the binomial $a + b\sqrt{-9}$ by the Newtonian theorem, and summing up the alternate terms. *Mac Laur.* loc. cit. p. 130.

Those who are desirous of a general and elegant solution of the problem, *to extract any root of an impossible binomial* $a + \sqrt{-b}$, *or of a possible binomial* $a + \sqrt{b}$, may have recourse to Mr. De Moivre's Letter to Dr. Saunderson, inserted by way of Appendix to his Algebra, p. 744, seq. and to the Philosophical Transactions, N° 451. or to Dr. Martyn's Abridgment, Vol. 8. p. 1, seq.

SURFACE *(Cycl.)*—A *surface* is not a body of the least sensible magnitude, as some have imagined, but it is the termination, or boundary of a body; neither is a line to be considered as a *surface* of the least sensible breadth, but as a termination, or limit of a *surface:* nor is a point to be considered as the least sensible line, but as the termination of a line; and in this sense it is plain that a point cannot be conceived to have parts, or magnitude. See MAGNITUDE. See also *Mac Laurin*'s Fluxions, Vol. 1. p. 245. and Mr. *John Bernoulli*'s Letter to Monsieur Crouzas, concerning his Comment on the Analyse des Infiniment petits. *Jo. Bernoul.* Oper. Vol. 4. p. 160, seq.

SURF *of the sea*, the great breakings, or rolling of the sea against some shores; making it dangerous to land in such places.

SURMULLET, in zoology, a name used, both by the French and English, for the *mullus major*, a fish of the cuculus kind, in many things resembling the mullus barbatus, but differing from it in that it is twice as big, being often caught of twelve or fourteen inches in length. Its fins also are yellowish, and have a slight blush of red mixed with that colour. Its scales are large and broad, and thick, and are more firmly joined to the flesh. It has also three or four strait yellow lines, running parallel with one another down its sides. It is caught in the Mediterranean, and in the British seas, especially on the coast of Cornwall, and is every where esteemed a very delicate fish. *Ray*'s Ichthyography, p. 285.

SURO, in zoology, a name given by some to a fish of the cuculus kind, much resembling the mackrel in taste and in shape, and more usually known by the name of the *trachurus*. *Willughby*'s Hist. Pisc. p. 290. See TRACHURUS.

SURRECTORIUM, the name of a chirurgical instrument, mentioned by Ambrose Parè, and intended to keep the arm in an erect situation when required.

SURVEYING *(Cycl.)*—A *surveyor* ought to be provided with an off-set staff, equal in length to ten links of the chain [b], and divided into ten equal parts. He ought likewise to have ten arrows, or small strait sticks, near two feet long, shod with iron ferrils. When the chain is first opened, it ought to be examined by the off-set staff. In measuring any line, the leader of the chain is to have ten arrows at first setting out. When the chain is stretched in the line, and the near end touches the place from which you measure, the leader sticks one of the ten arrows in the ground at the far end of the chain. Then the leader leaving the arrow, proceeds with the chain another length; and the chain being stretched in the line, so that the near end touches the first arrow, the leader sticks down another arrow at his end of the chain. The line is preserved strait, if the arrows be always set so, as to be in a right line with the place you measure from, and that to which you are going. In this manner they proceed till the leader have no more arrows. At the eleventh chain the arrows are to be carried to him again, and he is to stick one of them in the ground, at the end of the chain: and the same is to be done at the 21, 31, 41, *&c.* chains, if there are so many in the right line to be measured. In this manner an error can hardly be committed in numbring the chains, unless of ten chains at once [c].—[b See CHAIN. c Treat. Pract. Geom. p. 72, 73.]—See farther under FIELD-*book*, OFF-SETT, STAFF, and THEODOLITE.

If the lands to be plotted are hilly, and not in any one plane, the lines measured cannot be truly laid down on paper, without being reduced to one plane, which must be the horizontal, because angles are taken in that plane.

In viewing objects, if they have much altitude or depression, either write down the degree and decimal, shewn on the double sextant, or the links shewn on the back side, which last subtracted from every chain in the station line, leaves the length in the horizontal plane; but if the degree is taken, the following table will shew the quantity.

A TABLE *of the links to be subtracted out of every chain in hypothenusal lines of several degrees altitude, or depression, for reducing them to horizontal.*

degrees.	links.	degrees.	links.	degrees.	links.
4.05	$\frac{1}{4}$	14.07	3	23.074	8
5.73	$\frac{1}{2}$	16.26	4	24.495	9
7.02	$\frac{3}{4}$	18.195	5	25.84	10
8.11	1	19.95	6	27.13	11
11.48	2	21.565	7	28.36	12

Let the first station line really measure 1107 links, and the angle of altitude, or depression, be 19° 93′; looking in the table, I find 19° 95′ is 6 links; now 6 times 11 is 66, which subtracted from 1107 leaves 1041, the true length to be laid down.

It is useful in *surveying* to take the angles which the bounding lines form with the magnetic needle, in order to check the angles of the figure, and to plot them conveniently afterwards.

Large maps, representing considerable extents of ground, are subject to a good many inconveniencies, especially if carried into the fields, to be compared with them; such maps become very troublesome in the wind, and it is difficult to find out the part you want. To remedy this, a general and small map of the manor, or county, *&c.* should be first made on one sheet of paper, the several parts may be set off on other separate sheets, and the general map being divided into as many squares as there are of these particular sheets, the relation of the whole to the several parts is easily seen; and all these maps may then be bound up in a book. See Mr. *Baighton*'s Description and Use of his New Plotting Table, in Phil. Trans. N° 461. sect. 1.

SURVEYING-*scale*, the same with *reducing-scale*.

SURVEYOR *(Cycl.)*—*Surveyor* of the king's Exchange, an antient officer, mentioned in the Statute 9 Hen. V. Stat. 2. cap. 4. But what his office was is uncertain. *Cowel.*

SUS, the *hog*, in the Linnæan system of zoology, a distinct genus of animals, the characters of which are; that they have usually ten paps, situated along their belly; their dentes incisores are four each way; and in the males, the canine, or dog-teeth, are extremely long. Of this genus are the *hog* kind, the Mexican musk-boar, and the babyroussa. *Linnæi* System. Nat. p. 41.

SUS *piscis*, in ichthyology, a name given by Ovid, and some other of the antient writers, to the fish called also *us* and *mus*, and by the later writers *capriscus*. See the article CAPRISCUS.

SUS *agrestis*, the *wild boar*. This creature differs from the common domestic *hog*, in that the grown animal is not different in colour in the different individuals of the same species, but is always of a rusty iron grey. His snout is much longer also than that of the other; his ears shorter and rounder; and both these, and his tail and feet, are always black. It differs also, in that it is covered with two sorts of hairs, the one kind long, the other short: these last serve the creature to the same purposes, as the downy fur which the bever and otter have under their long hair. It is very common wild in Italy, and its flesh frequently brought to market. *Ray*'s Syn. Quad. p. 96.

SUSCEPTOR, among the Romans, a citizen chosen by the decuriones to collect the debts belonging to the public. *Pitisc.* in voc.

SUSCEPTOR is also a term used by ecclesiastical writers for *sponsor*. See SPONSOR, *Cycl.*

SUSCEPTOR *aurarius*, in middle age writers. See the article AURARIA.

SUSPENSORIUS, in anatomy, a muſcle of the eye. It is ſo called, from its uſe in ſuch animals as go much with their head hanging down. Veſalius has deſcribed it as belonging to man, in whom it is never found. Fiſhes and fowls are commonly without it, as well as man; but oxen, and, ſo far as has been obſerved, all quadrupeds, are provided therewith; though it is not of the ſame ſtructure in all. Dr. *Porterfield*, in Med. Eſſ. Edinb. Vol. 3. Art. 12.

The doctor thinks, that the uſe of this muſcle is not only to ſuſpend the eye, and preſerve the optic nerve from being too much ſtretched, but principally to aſſiſt the ſtreight muſcles in moving the eye, according as its different fibres act.

SUSSEX *marble*, a name given by many to a peculiar ſpecies of marble found in the county, the name of which it bears, and formerly much uſed in the pillars of churches, and other buildings, but now leſs regarded. The ground of this *marble* is grey, with a faint caſt of green, and it is very thick ſet in all parts with ſhells; theſe are chiefly of the turbinated kind, and they are generally filled with a white ſpar, which adds very greatly to the beauty of the ſtone.

It is plain, from conſidering the whole maſs of this *marble*, that this ſpar was received into the ſhells before they were depoſited in the *marble*. This is about the hardneſs of the common white Genoeſe marble, if any thing, ſomewhat more hard. The ſlender round ſcapi of the pillars in Weſtminſter-Abbey, and in many other of our old Gothic buildings, are made of this kind of *marble*. Some people have thought that the ſcapi of pillars of this kind, which occur in moſt of our Gothic buildings, are artificial, and that they are a kind of fuſile marble caſt in cylindric moulds. But any one who will compare the marble, of which thoſe pillars are made, with its ſhells, and the ſpar they are filled with, with the marble of the *Suſſex* quarries, will find both to be the ſame in every particular. *Woodward*'s Cat. of Foſſ. p. 20.

SUTORIUS, in anatomy, a name given by Riolanus to a muſcle of the leg, called by Cowper, Albinus, and others, the *ſartorius*. The French authors call it the *couturier*; Veſalius, and others of the more early anatomical writers, have called it the *primus tibiam moventium*.

SUTURE (*Cycl.*)—All wounds are not to be united by the needle, but thoſe only that are oblique, tranſverſe, or angular, and at the ſame time very large and deep; or in caſes where a part is very nearly cut off; or if a wound is ſo circumſtanced, that it cannot be kept in a proper ſituation by plaſters and bandages. Wounds that are to be ſtitched, ſhould be in their recent ſtate, and muſt be firſt well cleanſed from extravaſated blood, and all extraneous bodies; there ſhould alſo be no loſs of ſubſtance, except in thoſe fleſhy parts that are eaſily elongated; and no contuſion, nor any ſign of inflammation.

Dry SUTURE. This is to be uſed in ſlight wounds, and eſpecially when they happen in the face; and indeed, wherever it may appear of force enough to keep the lips of the wound together; and as it gives no freſh pain, and occaſions no ſcar, it is much fitter for wounds of the face than the needle. The plaſters, which are to form the *dry ſuture*, ſhould be of a ſufficient length, and ſhaped like the part to which they are to be applied, ſo as to ſurround the greateſt part of it, but not the whole, leſt they ſhould retard the circulation of the blood, and bring on tumors, and miſchiefs of that kind: they muſt alſo be ſuch as will ſtick very faſt, the diachylon, if good, or the common ſticking plaſter, are fitteſt for this purpoſe. The hæmorrhage being well ſtopt, and the wound well cleanſed, ſome vulnerary balſam of the gummy kind, as the balſam of Peru, or the like, is to be applied; and over all a ſticking plaſter is to be laid, adapted to the ſize of the part. Two or more of theſe may be applied, as occaſion ſhall require, leaving a ſpace between, and they are to be ſecured in their place by the application of proper bolſters and bandages.

Petit's method of making the *ſuture* of this kind, is by letting the plaſters have one, two, or more openings in the middle, through which the ſurgeon may diſcover, as by the ſpaces left between in the former method, whether the lips of the wound are properly united or not; and may alſo be able to apply proper remedies to the part, without removing the plaſters. Theſe plaſters are applied in the ſame manner as the former, and left on till the work is compleated.

But there is alſo yet another manner of performing the *dry ſuture*, to wit; ſpread two plaſters upon ſtrong cloth, anſwering in ſize to the wound; to the ſides or margins of theſe faſten three or four tape ſtrings, according to the length of the wound, and then, after warming the plaſters, apply them on each ſide of the wound, at about a finger's breadth from it; after this bring the lips of the wound together, dreſs it as in the former method, and while an aſſiſtant keeps the lips of the wound together in a proper ſituation, tie the ends of the tapes, firſt in a ſingle, and afterwards in a ſlip knot, to keep the part in contact; over each of theſe ſhould be laid an oblong compreſs, and over all a large ſquare one, and the whole kept on by a proper bandage. The day following the wound is to be again examined, and if the tapes are looſened, they muſt be drawn tighter again; but if they are not looſened, let them remain untouched, and only moiſten the parts with a few drops of balſam, and cover them up again with the compreſſes and bandages, as before. Some, inſtead of the tape, uſe claſps of braſs, or ſteel; but this method is much leſs convenient than the former, and therefore is little uſed. *Heiſter*'s Surgery, p. 37.

Bloody SUTURE. In large wounds, eſpecially tranſverſe ones, as their lips cannot be kept in their ſituation by means of the dry *ſuture*, which is frequently the caſe in wounds of the thigh, or in the abdomen, nates, or arms; or when pieces hang from the wounded part, as often happens in wounds of the forehead, cheeks, noſe, or ears; or when wounds are large, and made in an angular, or cruciform manner, the needle muſt be uſed to bring their lips together; and this is called the *bloody*, or the *true ſuture*. This operation is alſo diſtinguiſhed into two kinds, the ſimple, and compound.

The ſimple *ſuture* is that which is performed only by the aſſiſtance of the needle and thread: to this claſs belong the interrupted *ſuture*, the glover's *ſuture*, and the twiſted *ſuture*; the laſt of theſe is ſeldom uſed but in caſes of the hare-lip, and the ſecond only in wounds of the inteſtines; but the firſt is in common uſe for all wounds which require the true, or *bloody ſuture*.

The beſt method of making the common, or interrupted *ſuture*, is this. Take a double thread, well waxed, paſs it through a ſtrong crooked needle; when the lips of the wound are brought together, and held firmly in their proper ſituation by an aſſiſtant, with one ſtroke pierce through them both, paſſing the needle through the lower lip from without inwards almoſt to the bottom, and ſo on from within outwards, obſerving to make the punctures at a finger's breadth diſtance from the wound, which in this caſe we will ſuppoſe to be in length two fingers, varying this diſtance according to the ſize of the wound. After taking off the needle, tie the ends of the thread firſt in a ſingle knot, and then in a ſlip knot, covering all with the ſame dreſſings, as are uſed in the dry *ſuture*. But if the wound be ſo large, that one ſtitch will not be ſufficient, then two or more are to be made, according to the length of it, at about a finger's breadth diſtance one from the other. To prevent the knots from bringing on any miſchief, lay a ſmall linnen compreſs over the ſingle knot, and make the ſlip knot over that; which, if any pain or inflammation ſhould ſucceed, may be afterwards eaſily looſened at pleaſure.

This is the method to be obſerved in ſtrait, oblique, or tranſverſe wounds; but where there are angles, as in a triangular wound, you are to proceed in the ſame manner, but obſerve to let the *ſuture* begin at the angle, and the other ſtitches be taken about the middle, both ways; but if the wound be quadrangular, or have two angles, like the Greek letter Π, which ſometimes happens in the face, then the *ſutures* muſt be made in both the angles; and when the wound is ſo large, that theſe are not ſufficient, then as many more, as are neceſſary, muſt be made in the midway between them. When you meet with a cruciform wound, and the lips of it cannot be kept together by the uſe of plaſters, the *bloody ſuture* muſt be made, by paſſing the needle through the lips, near the end of each extremity of the wound; and when the ſtitches are all thus made, the threads muſt be tied as in the other caſes. *Heiſter*'s Surgery, p. 38.

Compound SUTURE. Some of the ſurgeons among the antients uſed a *compound ſuture* for large wounds, inſtead of the interrupted *ſuture*, now generally practiſed: they preferred this method, becauſe it prevented the lips of the wound from being lacerated, which ſometimes happened when the other method was uſed, and not only prevented the wound from uniting, but frequently brought on other grievous diſorders; and though this method has of late years been rejected, and particularly by Dionis, in his Surgery, yet many ſtill prefer it, in ſeveral caſes, to the common interrupted *ſuture*: but inſtead of the pieces of wood uſed by the antients, thoſe, who now practiſe it, uſe pieces of plaſter rolled up in a cylindrical form, of the length of the wound, and of about the ſize of a gooſe-quill, from whence it is called by ſome the *quilled ſuture*. This method prevents tumors, pain, and inflammations, which might be brought on by the hardneſs and preſſure of wood.

Palfynus performs this operation, in deep wounds of the muſcular parts, with a large and ſtrong crooked needle, furniſhed with a double thread well waxed, which has alſo a bow at one end. The needle thus fitted being paſſed thro' both lips of the wound, in the ſame manner as in the other operations of the true *ſuture*, and afterwards a ſecond, and a third, paſſed in the ſame manner, a roll of plaſter is to be introduced into the bow ends of the thread, which are left hanging out; then when the needle is taken out at the other ſide, another roll of plaſter is to be placed between the ends of the thread; and the lips of the wound being brough

brought together, these ends are to be gently tied over the roll, first in a single, and then in a slip knot. If there are three of these threads, you are to tie the middle one first, and afterwards the rest in the same manner. On the first days after the operation of the *future* is performed, in whatever method that be done, the bandage and compress are to be gently removed, and the state of the wound examined: if every thing now looks well, and there is little or no pain, or inflammation, the *futures* are to be left alone for six or seven days, or longer, and the wound dressed till there appears a strict union in the lips. If, in any of these examinations, the stitches of the *future* are seen to be too loose, they must be tightened, if too tight, loosened. When the lips of the wound appear to be inlarged, or bruised, they must be dressed with a digestive ointment, the continuance of which usually soon takes off those symptoms; but if the wound be attended with great inflammation and a fever, the stitches must be loosened, and the patient blooded, and kept on a thin diet: if this method remove the symptoms, the stitches must be tighted again, and the wound dressed and managed as before; but if this method proves fruitless, and the symptoms continue and increase, the stitches must then be cut, and the wound treated as if there were a loss of substance.

If the wound heals by the assistance of the *future*, the threads of it are to be cut with scissors, near the knots, and the lower lip of the wound to be suspended with one hand, while the threads are gently drawn out with the other. The punctures that are left from them will easily heal, by injecting the arquebusade water, or spirit of wine, or lime-water, and laying on compresses dipt in the same liquors. *Heister*'s Surgery, p. 39.

SUVERNA *guirecom*, in natural history, a name given by the people of the East-Indies to a kind of fossile, which they esteem greatly for certain imaginary virtues. It is a kind of fine and glossy foliaceous talc. Their manner of preparing it is this: they beat it to pieces in a mortar, and then boil, or rather fry it a long time in butter, and afterwards straining off the butter, they eat it to make them fat.

SWALLOW, in ornithology. See HIRUNDO.

SWALLOW-*fish*. See HIRUNDO *piscis*.

SWALLOW-*fly*, in natural history, the name of the chelidonius, a fly very remarkable for its swift and long flight. See CHELIDONIUS and the next article.

SWALLOW-*stone*, *chelidonius lapis*, in natural history, the name of a stone which Pliny, and many other authors affirm to be found in the stomachs of young *swallows*. It is always described to be small, roundish, convex on the outside, and concave on the other, and of a browniſh, yellowish, or blackish colour: this, and the figures given of it, plainly shew that it is either a small species of the lycodontes, or bufonitæ, or else a detached piece of one of the compound ichthyperia, or, as they are vulgarly called, *siliquastra*. These are the bony palates of certain species of fish, and are composed of several parts, the middle ones longish, and resembling the pods of a lupine, and those toward the edges roundish and small, convex on the outside, and concave within, but more hollowed, and consequently thinner than the lycodontes, to which otherwise they are very like in shape. The whole palates, or the long parts, when loose, are called *siliquastra* by authors; but the round pieces have been usually confounded with the bufonitæ, and mistaken for them, whenever they have been found loose. These, as they are thinner and hollower than the lycodontes, agree better than any species of those bodies with the figures and descriptions of the *chelidonii* in the more accurate writers, who make them small, thin, and tender; but the generality confound these fragments of palates, as well under the name of *chelidonii*, as of the bufonitæ, never guessing at their true origin. They are rarely larger than the eighth of an inch in diameter. The common report is, that when two of these *stones* are found in the stomach of one *swallow*, the one is more yellow, the other more red; but that when there is only one, it possesses the virtues of both. De Boot tells us, that he cut up several young *swallows*, but never found any such stones in them; and indeed it is no wonder, since they are not to be looked for there, but in the jaws of the wolf-fish, or in the palates of some of the less known kinds.

SWALLOW-*wort*. See the articles ASCLEPIUS and VINCETOXICUM.

Difficulty of SWALLOWING, in infants. See the article INFANT.

SWAN, *cygnus*, in zoology. See the article CYGNUS.

By the law of England, to take *swans* eggs is penal, in the same manner as taking hawk's eggs, that is, by fine and imprisonment. See HAWK.

SWAN-*shell*. See the article CIGNE.

SWARDY, in agriculture, a term used by the farmers for a soil well covered with grass. *Plot*'s Oxfordsh. p. 247.

SWARM. The signal of the going out of a *swarm* from a hive is sometimes only a humming noise made by one single bee, but that a very particularly acute, and clear sound: this seems to be the voice of the new queen, or female bee, calling together the *swarm* that is to follow her out, and animating them with a sort of martial music for the great adventure they are going to engage in.

Some who have pretended to be extremely well versed in the language of bees, as Butler, and others, say, that this is a voice of intreaty, by which the young queen begs permission of the old queen, or parent of the hive, to take out a *swarm* with her to some other place: they say this noise of intreaty usually lasts about two days, and that at the end of that time, if the parent grants the request, she is heard to answer with a louder and clearer voice of the same kind. These noises are not to be heard, unless the ear be applied close to the place; and they say, that when this last sound is made, the new *swarm* may be expected certainly to go out the next day, if the weather be proper.

But he seems to have taken great pains to distinguish these sounds; he gives all the modulations of the voice of the young female, and every note that she runs into; and observes, that all these are notes of supplication, and that the sounds issued by the parent, or reigning queen of the hive, have an air of majesty, and are greatly different; and adds, that if the young female attempts to make the sounds of the reigning bee, it is looked upon as a rebellion in the hive: and he pretends to be acquainted with the proceedings against her in these cases; he says she loses her head, and that several of the bees that followed her are treated in the same manner for having been seduced to a rebellion. *Reaumur*'s Hist. Insect. Vol. 10. p. 290.

All these different modulations of sounds, made by the bees, are the effect of the different vibrations of their wings in the air. It has been supposed by Swammerdam, that the air issuing from the stigmata of the body was very instrumental to the making of this sound; but this is proved to be an erroneous conjecture, by the easy experiment of cutting off a bee's wings, which always renders the creature perfectly mute; though this could not be the case, if the voice proceeded from other parts. It is evident, therefore, that all the sounds of the bee are made by the striking of its wings against the air; and it seems very easy to imagine, that when the motion of the wings can make a sound, the more quick or slow motion of them can modulate it in a different manner, and the moving them in several different directions, may also add greatly to the variety.

The hours of going out of *swarms* are always between eleven in the morning, and three in the afternoon: the air is at this time very hot, and the sun often shines brightly on the surface of the hive; the effect of this, in causing them to go out, is easily conceived. The few who are nearest the mouth of the hive, and are ready to follow their queen, soon find that this is a pleasant season for their expedition, and the numbers of others, which remained irresolute in the inner parts of the hive, now find the natural heat of the place increased to so great a degree by the action of the external warmth, that it is very natural for them to resolve at once to depart with those which are going off, in order to find a place where they may be more at ease, or less crowded and heated in their habitation. People, who have the care of bees, should attend to their *swarming*, or going out on these occasions; and if they are not at leisure to watch them in the hours before mentioned, should defend the hives, during that part of the day, from the heat of the sun, that they may not go off and be lost.

Immediately before the going out of a *swarm* there is heard a prodigious humming in the hive, much greater than what is heard at any other hive, and immediately after this, the openings of the hive are crowded with bees, in a violent hurry to get out; those which first come out immediately take flight, and if the female, or queen, be among these, vast numbers immediately follow, and the air is seen as full of them, as it is of flakes of snow in a winter storm; and, in fine, it is not a minute before all the bees, that are to make the new *swarm*, are out of the hive: when the body is thus joined, they rise and fall in the air, and seem very curious in choosing a place where to fix themselves. It does not appear that the female bee chooses the place for them, but they all seem to be assistant in it; and as soon as they have fixed upon a proper branch of a tree, or the like, they all fly towards it, and begin to form a cluster in one part of it. The female does not place herself at the head of this cluster, but sits on the branch near it, to see how she approves the management; as soon as the cluster is of a proper size, she adds herself to it, and from that instant it thickens in a surprising manner, all trying first to fix themselves to the rest, so that in a quarter of an hour they are all collected together into a vast mass, hanging to one another by the legs. In this condition they remain absolutely quiet, though exposed to the open air, and there are no more of them seen flying loose about, than there are about the hives in a summer's day. *Reaumur*'s Hist. Ins. Vol. 10. p. 293.

The hives of bees are commonly placed in gardens, that the bees may have some flowers at least in their own neighbourhood, and not be compelled to go far in search of food; and the *swarms* from these hives always succeed best, when there

there are ſome buſhes, as of filberts, barberries, or the like, in the garden, as well as high trees; for when the bees take a high flight, they often take a very long one before they ſettle, and ſometimes go ſo far, that the eye cannot trace them to the place of their ſettling; in which caſe, all attempts to ſearch for them are uſually vain, and they are loſt entirely. The low buſhes in view uſually determine them to low flights, and if they are ſeen to be aſcending too high, the cuſtom is to throw handfuls of duſt and ſand upon them; this uſually brings them down, as they probably miſtake the particles for drops of rain.

Another very antient cuſtom, and which is continued to this day, is the beating on inſtruments of braſs, and the like, to make a great noiſe, while they are gathered in the air: it is pretended, that this diſpoſes them to fix themſelves the ſooner. The origin of this cuſtom has been an obſervation, that thunder always ſends thoſe bees, which are abroad, from the flowers back to the hive, and it is ſuppoſed that this artificial noiſe may have the ſame effect; but in all probability, the bees are better acquainted with thunder than to be thus deceived: there is indeed much more probability of their miſtaking the particles of duſt, falling upon their backs, for drops of rain, than taking ſo unlike a ſound for thunder; for it is found by experience, that the making all the noiſe that can be conceived, this way, never was able to drive one bee from a flower where it was buſy, or to ſend one ſtraggler home.

When the time of a *ſwarm*'s going out of the hive is expected, the people, who have the care of them, ſhould always be prepared with a hive to receive them; and when the *ſwarm* ſettles upon ſome branch of a buſh, or low tree, the hiving of them is an eaſier matter than could be imagined. See HIVING.

The nature of the annual new *ſwarms* of bees, which we ſee depart from old hives, are not to be truly underſtood, otherwiſe than by knowing the hiſtory of the propagation of the ſpecies among theſe animals, for which ſee the articles BEE, and QUEEN *bee*.

The queen, or mother bee, which is the general parent of the hive of bees, continues laying eggs, in greater or leſſer number, during the whole ſummer months, but in the winter months ſhe deſiſts; and many bees periſh in the end of the autumn, and during the courſe of the winter, without the hive's having any ſupply from the female: by this means there are but a ſmall number of bees left, when there is but a ſmall proviſion in ſtore for them, as they are to live on their labours of the former ſummer. As ſoon as the ſpring comes on, and there appear flowers, out of which honey may be obtained, the parent bee begins to lay again; and by the vaſt number of eggs ſhe lays every day, ſoon provides a ſupply to repair the loſs. All theſe eggs are hatched, in two or three days after they are laid, into worms; and, in fine, they appear under the form of bees, and are fit for working, in about three weeks time.

All the eggs that the female lays, during the firſt week or two, are for the production of the common, or working bees, as they are the more neceſſary at that time: after this ſhe begins to lay eggs which are to produce drones, whoſe whole period of life is to be only of a few months, and who are never to work, but to feed on the labour of the others; they being the males of the hive, and all their buſineſs being to impregnate the eggs of the females for future ſupplies of young; and this office they are to perform, as well to this their parent, as to their ſiſter female, that is to be hatched from an egg laid afterwards in a peculiar cell. According to this rule we ſee, about the month of May, a great number of drones in a hive, where, before that time, there was not one, and ſoon after the appearance of theſe we find a new female, hatched out of an egg laid on purpoſe at a proper time; and ſometimes the ſame hive affords two or three of theſe females. *Reaumur*, Hiſt. Inſect. Vol. 10. p. 285.

All the time that this female, and theſe males, or drones, are hatching, the number of common, or working bees, is alſo increaſing very faſt, by a numerous progeny hatching every day from the eggs of the parent; and the conſequence of this is, that the number becomes too great to be contained in the hive. It is neceſſary then, that a certain number ſhould go off in form of a colony, and ſettle themſelves in ſome other place; this is ſoon reſolved, and the number thus detached from the reſt is what we call a *ſwarm*. This however they would never do, had they not a chief to lead them, and promiſe a future progeny for the object of their cares and labours; but as with them, when they become numerous, there is always hatched at leaſt one female, ſhe places herſelf at their head, and leads them out to ſeek a new abode. If by any accident ſhe is killed, they will never enter a hive at all, but fly ſeparate during the whole ſummer, and take no care but of the feeding themſelves. This alſo is carried ſo far among them, that if the hive be never ſo full, and there be no young female among them, none of the bees will ſtir, but they will hang in cluſters out at the mouth of the hive; and, on the contrary, if a hive be but half peopled at the time that a young female is produced, as ſoon as ſhe is able to go away, and to lay her eggs, the half, or at leaſt ſome conſiderable part of theſe few bees, will leave the hive, though they have plentiful room in it, and form a new *ſwarm*: ſo that though the overfulneſs of the hives be, in general caſes, one great reaſon of the departing of a colony, in form of a *ſwarm*, yet it is not the only reaſon.

The departure of the *ſwarm* uſually happens almoſt immediately upon the birth of the young female, or queen. This creature ſeems to be fœcundated, and ready to lay her eggs almoſt as ſoon as ſhe is out of the nymph ſtate, and very often actually places herſelf at the head of a company, and goes off within four or five days of her birth in the winged ſtate. It may happen, however, that the time of the departure of the *ſwarm* may be retarded by accidents, ſuch as very rainy, or ſtormy weather; for as ſuch a ſeaſon would render the *ſwarming* abroad very uncomfortable, they uſually ſtay in the hive till ſuch weather is over, though perfectly ready to go. It is very certain, that though the female is ready to go, ſo ſoon after her birth, to form a new *ſwarm*, that her eggs are at that time fœcundated, and ready to produce the young ones; for there often go no drones, or male bees, with the new *ſwarm*, and it ſeems accident, rather than the intent of nature, if any go out with them, as the female is plainly already impregnated, and needs no new impregnation, till ſome of her own offſpring are able to ſerve her. The time of the going out of the *ſwarm* is different in different countries, and even in the ſame country varies very much, on occaſion of the ſeaſon of the year, and the ſtate of the hive. *Reaumur*'s Hiſt. Inſect. Vol. 10. p. 288.

If a hive has been very well peopled during the winter, the young progeny go out early in the ſpring; and if it have been very thinly peopled, it is ſometimes as late as the middle of June before they go out, even without any accidental delay from the want of a queen.

The people who manage bees, are informed of the time when they are going to ſend out new *ſwarms* by ſeveral ſigns. One is, when the hive is ſo peopled, that many of the bees cannot find room within, but ſtand in cluſters on the outſide of the hive; another, is the appearance of a large number of drones, or male bees: theſe, however, are not certain ſigns, nor do they point out the very day of the *ſwarming*; but there is one which declares it very punctually, which is the obſerving, that though the hive be very full, and the day very fine, yet very few bees go out in ſearch of honey; in this caſe it is a certainty that they are aſſembling themſelves in the hive, and preparing to be gone in a very little time. If a perſon go near the hives, that are ready to ſend out *ſwarms*, in the evening, or even in the night, he will hear a ſort of humming noiſe in them, which is not to be heard at ſuch times on any other occaſion: in ſhort, the whole is in agitation on the occaſion, and the tumult never ceaſes till the new colony goes out.

SWARMS *of inſects*. We have an account[i] of an extraordinary *ſwarm of inſects* in New-England, that deſtroyed all the trees in the country for the ſpace of two hundred miles. It is ſaid there were found a great number of holes in the ground, out of which theſe creatures broke forth in the form of maggots, which became flies with a kind of tail or ſting, which they ſtuck into the tree, and thereby envenomed and killed it.—[i Philoſ. Tranſ. N° 8. p. 137.]

SWEAT (*Cycl.*)—Many diſtemperatures of the body have their riſe, as well as their cure, by means of the differences of this evacuation.

The faults of our *ſweats*, in regard to the general health of the body, are reducible principally to three kinds. 1. They are too exceſſive: theſe uſually happen early in the morning, as ſoon after three o'clock, and are in ſome degree periodical; but in others they are rather continual, or have very few intermiſſions. 2. The uſual and habitual ſecretions by *ſweat* are ſubject to be impeded, or retarded, and hence many diſtempers take their riſe. And 3. there is in ſome particular people a remarkable difficulty of being brought to *ſweat* at all.

The perſons principally ſubject to too profuſe *ſweats*, are men of a plethoric and ſanguineo-phlegmatic temperament; theſe, on the ſlighteſt motion of the body, are uſually thrown into profuſe *ſweats*; and the ſame perſons are uſually ſubject to violent nocturnal *ſweats* in the ſpring and autumn ſeaſons. Perſons in hectics alſo, when near the time of their death, uſually fall into profuſe nocturnal *ſweats*, which are always a fatal prognoſtic.

The perſons principally ſubject to a natural difficulty of *ſweating*, are thoſe who have a mucous and thick dyſcraſy of the humors; and ſometimes perſons of very tender and delicate conſtitutions, who are ſubject to emotions of the blood, and are continually thin in fleſh.

Prognoſtics in ſweats. A profuſe *ſweat*, though it conſiderably waſtes the fleſh and ſtrength, yet is leſs dangerous when left to itſelf, than when raſhly ſuppreſſed. The conſequences of habitual *ſweats* being ſuppreſſed, are uſually according to the habit and diſpoſition of the patient, either cutaneous eruptions, as the itch, and the like; or catarrhs, coryzas, and

and gravedos; and ſometimes they bring on congeſtions, inflammations, and convulſions.

Method of treatment. So long as *ſweats* bring on no bad ſymptoms in illneſſes, they are to be rather promoted than checked, even though they may ſeem profuſe in quantity; and in this caſe, the proper regimen is a moderate warmth, a quiet ſtate of the body, and frequent draughts of warm liquors; but when the ſtrength is found to be too much exhauſted by theſe *ſweats*, ſmall doſes of nitre are found of great ſervice.

When different diſorders ariſe from the ſuppreſſion of *ſweats*, nothing is of greater ſervice than the compound powder of antimonium diaphoreticum, crabs eyes, and nitre, given in ſmall doſes every three hours; and a quiet poſture of the body is to be ordered, which greatly tends to promote *ſweating*; and frequent draughts of warm and weak liquors are to be taken, and the bowels are to be relaxed with a clyſter, or a gentle purge, if there be no ſymptom neceſſarily forbidding it. In regard to thoſe perſons, who are naturally very difficult to be *ſweated*, a draught made of freſh arum-root and wine, or vinegar, uſually brings on profuſe *ſweating*, if they are put to bed, and warm liquors drank afterwards. It is a very good general caution, that profuſe *ſweats*, if they have continued ever ſo many months, are never to be repreſſed by aſtringents; for in that caſe they are uſually attended with ſymptoms much worſe than the original complaint. The common method of forcing out ſuppreſſed *ſweats* by the hot alexipharmics, and volatile ſalts, is by no means adviſeable in any caſe. Bleeding, judiciouſly timed, is often of very great ſervice in promoting *ſweats*. When the natural *ſweats* of children are repelled, they become ſuddenly feveriſh and ill, and nothing relieves them till the *ſweats* are recalled. This may be done ſimply, by keeping them warmer than before, in moſt caſes; but when that fails, the gentle abſorbents are to be preſcribed, and if they ſuck, the nurſe may take the common alexipharmic medicines: crabs eyes are as proper as any thing for the child in this caſe, and for the nurſe the lapis contrayerva. The convulſions of children very often ariſe from the ſuppreſſion of their *ſweats*, and are always then taken off by making them *ſweat* again. *Junker*'s Conſp. Med. p. 530.

SWEATING-*houſe*. The natives of North-America, when we firſt ſettled among them, had a great many houſes to *ſweat* in, it being their general remedy for diſeaſes of whatever kind; but at preſent they are leſs uſed among them.

The cave, or *ſweating-houſe*, was uſually eight feet in diameter, and four feet high, the roof being ſupported by ſticks, or boards. They uſually dug theſe caves in the ſide of a hill, and as near as could be to ſome river, or pond. The entrance into the cave was ſmall, and when any perſon was *ſweating* in it, the door was covered with a blanket, or ſkin. Near the cave they uſed to make a large fire, and heat in this a quantity of ſtones, perhaps five hundred weight; theſe they rolled into the cave, and piled up in a heap in the middle. When this is done the Indians go in naked, as many as pleaſe, and ſit around the heap of ſtones; and as ſoon as they begin to grow faint, which is uſually in a quarter of an hour, they come out, and plunge themſelves all over in the water, remaining in it a minute or two; and repeating this a ſecond time, they dreſs themſelves, and go about their buſineſs.

This has been for many ages uſed among them with ſucceſs, in caſes of colds, ſurfeits, ſciaticas, and pains fixed in their limbs, and the Engliſh have often uſed the ſame means, and found relief by it. It is practiſed equally at all times of the year, and the Indians do it not only in ſickneſſes, but by way of refreſhment after long journies, and other fatigues, and to ſtrengthen themſelves for any expeditions. Philoſ. Tranſ. N° 384. p. 131.

Turf SWEATING. See TURF-*ſweating*.

SWEATING-*iron*, in the manege, is a piece of a ſcythe about a foot long, and of the breadth of about three or four fingers, very thin, and ſuch as cuts only with one ſide. When a horſe is very hot, and the grooms have a mind to leſſen the *ſweat*, or make it glide off, they take this knife or iron in their two hands, and gently run the cutting edge along the horſe's ſkin, commonly with the grain, or as the hair lies, and but ſeldom againſt it; with intent to ſcrape off the *ſweat*, and dry the horſe.

SWEATING-*room*. See an account of the remains of a Roman *ſweating-room* in the Philoſophical Tranſactions, N° 461. ſect. 29.

SWEATING-*ſickneſs*. See SUDOR *Anglicanus*, *Cycl.* and *Suppl.*

SWEET (*Cycl.*)—By a *ſweet* is underſtood any vegetable juice, whether obtained by means of ſugar, raiſins, or other foreign or domeſtic fruit, which is added to wines, with a deſign to improve them. It is plain, from the making of artificial muſt, or ſtum, by means of fine ſugar, with a ſmall addition of tartar, that the art of *ſweet*-making might receive a high degree of improvement, by the uſing pure ſugar, as one general wholeſome *ſweet*, inſtead of thoſe infinite mixtures of honey, raiſins, ſyrups, treacle, ſtum, cyder, &c. wherewith the *ſweet*-makers ſupply the wine-coopers to lengthen out, or amend their wines: for pure ſugar being added to any poor wine, will ferment therewith, and improve it, and bring it to a proper degree of ſtrength and vinoſity. If the wine that is to be amended is tart of itſelf, no tartar ſhould be added to the ſugar, but if it be too *ſweet* or luſcious, then the addition of tartar is neceſſary. *Shaw*'s Lectures, p. 203. See the article *Artificial* STUM.

SWEET *ſublimate of mercury*. See MERCURIUS *dulcis*.

SWEET *corn*, a term uſed by the Indians to expreſs a ſort of corn they are very fond of, and generally keep in their houſes.

While the ear of the maiz, or Indian corn, is yet green, but full, they gather it, and firſt boil, and afterwards dry it, and lay it up for uſe in bags, or baſkets. When they eat it, they boil it again, either whole, or groſsly beaten in a mortar; they then mix it with fiſh, or with veniſon, or beaver fleſh, and account it a very fine diſh. The green ears, or freſh *ſweet corn*, they alſo ſometimes eat, as ſoon as it is gathered, roaſting it before the fire, and then picking out the grains. This is a new ſupply of food for them many times, when their winter, or laſt harveſt-ſtore is exhauſted. Their ſoldiers alſo commonly go out to war againſt their enemies about this time of the year, and find this ſupply in their enemies fields. See GUINEA *corn*.

SWEET-*Williams*, the Engliſh name of ſeveral ſpecies of *cariophyllus*, or pink. See the article PINK.

There is a great variety of ſpecies, and very elegant diverſities of colouring in theſe flowers; the principal difference, however, is between the ſingle and double kinds.

The ſingle kinds are to be propagated by ſowing their ſeeds in March on a bed of light earth; in May they will be ready to plant out, and muſt then be ſet at ſix inches diſtance in beds of the ſame kind of earth. In theſe beds they ſhould remain till Michaelmas, and then be tranſplanted to the places where they are to remain. They will flower the next year in May, and ripen their ſeeds in Auguſt, when that of the beſt flowers ſhould be ſaved.

The double kinds are propagated by layers in the ſame manner with the carnations, they love a middling ſoil, neither too light, nor too ſtiff; they continue flowering a long time, and are very beautiful, eſpecially the mule-kind, which produces yearly two full blooms of flowers, the one in May, the other in July. *Miller*'s Gardner's Dictionary.

SWELLING (*Cycl.*)—*Swellings* in the face and ſalivary glands, without any fever, or redneſs of the ſkin, ſometimes happen in ſummer months, and often give way to a gentle purge or two. See Medic. Eſſ. Edinb. Abridg. Vol. 1. p. 65.

Theſe *ſwellings* are ſometimes eriſipelatous, and fall chiefly on the forehead and eyelids, and yield to purges and bliſters. Ibid.

SWIFT, in zoology, a name given by many to the common newt, or eft. See the article EFT.

SWIFTERS, in a ſhip, ropes belonging to the main-maſts and fore-maſts, which help to ſuccour or ſtrengthen the ſhrowds, and to keep the maſts ſtiff: they have pendants faſtened under the ſhrowds, at the head of the maſts, with a double block, through which the *ſwifter* is reeved; which at the ſtanding part has a ſingle block with a hook, hitched into a ring at the chain-wale, and ſo the fall being haled up, helps to ſtrengthen the maſt; yet it is belayed about the timber heads of the lower rails aloft.

SWIFTING *of a boat*, is compaſſing her gun-wale round with a good rope, to ſtrengthen her in ſtreſs of weather, that ſhe be not ſhattered by the violence of the ſea.

SWIFTING *the capſtan-bars*, aboard a ſhip, is ſtraining a rope all round the outer ends of the capſtan-bars, in order to ſtrengthen them, and make them bear all alike, and together, when the men heave or work there.

SWIFTING *of a ſhip*, is either bringing her aground, or upon a careen; for then they uſe to *ſwift* the maſts, to eaſe and ſtrengthen them, that all the weight may not hang by the head; which is done by laying faſt all the pendants of the *ſwifters* and tackles with a rope cloſe to the maſt, and as near to the blocks as can be; and then to carry forward the tackles, and there to bowſe, or hale them down as hard and taught as poſſible. The word of command here, is, *Ho! bowſe men!* All this is done alſo to keep the maſt from riſing out of the ſtep.

SWIGGING, a particular way of caſtrating rams.

The operation is performed by throwing the creature on his back, in which poſture he is held; then a ſtring is drawn about his teſticles as tight as poſſible, and fixing it there, the part is anointed with freſh butter. The beaſt is then left to feed, and in two or three days the teſticles grow ſo rotten, as to fall off with the ſtring, or may be plucked away with a ſmall force. *Boyle*'s Works Abr. Vol. 1. p. 87.

SWIMMING *of fiſhes*. See NATATIO, and AIR-*bladder*.

SWINE, *ſus*. See the article SUS.

Swine are very profitable creatures to the owner, being kept at ſmall expence, feeding on things that would be otherwiſe thrown away, and producing a very large increaſe. They are apt to dig up the ground, and to break fences; but this may be prevented, by putting rings in their noſes, and yoaks about their necks. Leiceſterſhire, Northamptonſhire,

ſhire, and Hampſhire, are famous for theſe animals, which ſeems owing to their being clayey countries, and that more beans and peaſe are ſown there, than in other places. The wild kind never grow ſo large as the tame, but they are much better taſted. The keepers of hogs ſhould always chooſe ſuch boars to breed out of as are long bodied, and have deep bellies and ſides, ſhort noſes, thick thighs, ſhort legs, high claws, a thick neck, and a thick chine, well ſet with large briſtles.

It is not proper to keep too many breeding *ſows*; for they will produce ſo many young at a time, and this three times a year, that they will not find food enough. They uſually bring thirteen or fourteen young ones in a litter, ſometimes more, but they can bring up no more than they have teats to ſuckle; and they bring forth three times in a year. Young ſhoots, as they are called, that is, *ſwine* of three quarters of a year old, are beſt for pork, and thoſe of a year and half, for bacon. Moiſt and ſedgy grounds are good for *ſwine*, for they eat the roots of many of the plants that grow there; and the fruit of the beech, cheſnut, and hedge buſhes, fatten them well, and make their fleſh much better taſted, than when bred intirely in the ſtye. *Mortimer*'s Huſbandry, p. 253.

SWINE-*pipe*, in ornithology, a name uſed in many parts of England for the red-wing.

SWING-*wheel*, in a royal pendulum, that wheel which drives the pendulum. In a watch, or balance clock, it is called the *crown-wheel*.

SWINGING was preſcribed by antient phyſicians, as a good exerciſe in ſome caſes. See AGITATION.

SWINGLE, in the wire works in England, the wooden ſpoke which is fixed to the barrel that draws the wire, and which, by its being forced back by the cogs of the wheel, is the occaſion of the force with which the barrel is pulled. *Ray*'s Engliſh Words, p. 133.

SWINGLING. See the article BRAKE.

SWIT, in natural hiſtory, a name given by the people of the Philippine iſlands to a very ſmall bird of the humming bird kind, frequent in that part of the world. It is beautifully coloured, and lives on the honey of flowers.

SWORD (*Cycl.*)—SWORD-*hand*, in the manege, is the horſeman's right hand, as *bridle-hand* is uſed to denote his left hand.

Pleas of the SWORD. See PLEA, *Cycl.* and JUS *gladii*, *Suppl.*

SYCABIS, in zoology, a name by which ſome authors have called the *atricapilla*, or black-cap, a ſmall bird well known in England. See ATRICAPILLA.

SYCAMINOS, a word uſed by ſome for the mulberry fruit, and by ſome for the tree.

SYCAMORE-*tree*, a name improperly given by us to the *acer majus*. See the article MAPLE.

SYCAMORE-*moth*, in natural hiſtory, the name of a peculiarly large and beautiful moth, or night butterfly, ſo called, from its caterpillar feeding on the leaves of the *ſycamore*.

This caterpillar is remarkably large, very often growing to three inches and an half long, and three quarters of an inch in diameter. The head is ſmall, and the body conſiſts of twelve rings, each of which has five or ſix large and ſtiff hairs on it, each having at its extremity a ſmall, but hard globule of a blue colour, from which there often ariſe alſo ſeveral other hairs, ſmaller and ſhorter than the others, and having one in the middle a little longer than the reſt; on nine of the rings alſo there is above each foot a white oval mark, ſurrounded by a black line; theſe Malpighi diſcovered in the ſilkworm to be the organs of reſpiration.

This caterpillar has ſixteen feet, diſpoſed in three ſeries, or ranges; ſix are placed near the head, theſe ſtanding very cloſe together, eight more ſtand in the middle of the body, and the other two near the tail: the ſix that are placed near the head, are the only true feet, for the reſt ſerve as well to fix the creatures to any particular place, as to aſſiſt them in their motions. The ſkin is yellow and ſmooth, without a ſingle hair, except thoſe particularly before mentioned. Theſe caterpillars being put into a box, each ſpun itſelf a ſtrong and firm caſe, which it faſtened to the ſide of the box, and in it waited the time of its laſt transformation: in each of theſe ſhells there was left a ſmall aperture, by means of which the creature was to get out when in its butterfly ſtate, and the head of this animal was placed exactly againſt this aperture. In this ſtate they lie all the autumn, winter, and ſpring, and in the beginning of ſummer come out in the ſhape of a very elegant moth. The wings, when expanded, meaſure more than five inches, and each has an eye, like that on the peacock's tail, near the extremity. The horns are of the feathered kind, and are very large and elegant; and the body and origins of the wings are covered with very long hairs. Mem. Acad. Par. 1692.

SYCION, a word uſed by ſome authors to expreſs a decoction of dried figs.

SYCITES, the *fig-ſtone*, an idle name given by ſome authors to ſuch natural nodules of flint or pebbles, as happen to approach to a fig in ſhape.

SYCITES *vinum*, a term uſed by the antients to expreſs a wine impregnated with figs.

SYCOMANTIA, Συκομαντεια, in antiquity, a ſpecies of divination performed with fig-leaves; for which ſee *Potter*, Archæol. Græc. lib. 2. cap. 18. Tom. I. p. 353.

SYCOSIS, a term uſed by ſome authors to expreſs a tumor of the anus, differing only in bigneſs from the thymus. It had this name from the reſemblance of the fleſh about its edges to a ripe fig. The antients underſtood two ſorts of ulcerated tumors by this name, tho' both attending the ſame part; the one was hard and round, the other ſofter, and of an irregular figure: from the firſt there was diſcharged only a ſmall quantity of matter, from the latter a very large quantity, and that of a very ill ſmell. Some other of the antient phyſicians make the ſame word alſo expreſs two ſorts of ulcerated tumors of the head, or beard, which they diſtinguiſh by the ſame characters into a hard and a ſoft one.

SYCOTA, a word uſed by ſome of the antients to expreſs a ſort of food prepared of figs.

SYCOTON, a name given by the antients to the liver of a pig fed with figs. This was eſteemed a very elegant diſh among the old Greeks.

SYDEROPŒCILUS, in natural hiſtory, the name of a ſtone mentioned by the antients. It was found in Arabia, and ſeems to have obtained this name from its being ſpotted with a ferrugineous colour. The deſcriptions of the antients are, however, in this, as in many other inſtances, too ſhort to ſuffer us to gueſs what ſtone they meant. This might poſſibly be a granite with ſpots of this peculiar colour.

SYENITES, in the natural hiſtory of the antients, a name given by many to the granite, the ſame with the oriental granite of the moderns. It had this name from its country; but our artificers have of late learned to call a very different ſubſtance by a name that ſounds very like this, the beautiful purple and yellow marble, ſo frequent with us now in tables, *&c.* being called among them *Sienna marble*. *Hill*'s Hiſt. of Foſſ. p. 500.

SYLVA (*Cycl.*)—SYLVA, among the Romans, a ludicrous kind of hunting exhibited in the circus; ſo called, becauſe the circus was really planted with trees, which had been dug up with the roots by the ſoldiers and brought thither, and fixed to large beams, after which earth being thrown upon their roots, the circus actually reſembled a wood; then being filled with all ſorts of herbivorous animals, the people were let looſe upon them, and carried all clear off. *Pitiſc.* Lex. Ant. in voc.

SYLURUS, in ichthyology, a name given by Geſner to the *ſilurus* of Willughby, and others, which we call in Engliſh the *ſheat-fiſh*.

The names of fiſh are in general ſo arbitrary, that it is not eaſy to determine what is meant by them in the different authors who uſe them: but Artedi has very well diſtinguiſhed this by the name of the *ſilurus* with four cirri, or beards, at the mouth; by which it evidently is diſtinguiſhed from the fiſh called the *lake*, which, though a true *ſilurus*, has only one beard.

SYMBACCHI, Συμβακχοι, in antiquity, a deſignation given to the two men, who purified the city of Athens at the feſtival *Thargelia*. See THARGELIA.

SYMBOLISM, a word uſed by ſome of the chemical writers to expreſs a conſent of parts.

SYMBOLOGICE is uſed by ſome for that part of the ſcience of medicine, which treats of the ſymptoms of diſeaſes.

SYMPARATAXIS, a word uſed by Hippocrates to expreſs the conflict between nature and a diſeaſe, and the aliments or medicines given in it.

SYMPASMA, a word uſed by many authors to ſignify a cataplaſm.

SYMPATHETIC *inks*. See *Sympathetic* INKS.

SYMPATHETIC *powder*. The compoſition of the *famous ſympathetic powder*, uſed at Goſſelaer by the miners in all their wounds, is this. Take of green vitriol eight ounces, of gum tragacanth, reduced to an impalpable powder, one ounce; mix theſe together, and let a ſmall quantity of the powder be ſprinkled on the wound, and it immediately ſtops the bleeding. The vitriol is to be calcined to whiteneſs in the ſun, before it is mixed with the gum.

SYMPATHY, (*Cycl.*) in medicine. A part is ſaid to ſuffer by *ſympathy*, or conſent, when it is yet whole and ſound, and is only affected by the fault of ſome other part. Medic. Eſſ. Edinb. Abridg. Vol. 1. p. 449.

We have ſome practical remarks on the *ſympathy* of the parts of the body, in the Medical Eſſays of Edinburgh, Vol. 5. Art. 45.

SYMPESIS, a word uſed by the old Greek writers to ſignify concoction, or digeſtion.

SYMPHONIACA, in botany, a name given by ſome authors to the common *hyoſciamus*, or henbane. *Ger.* Emac. Ind. 2.

SYMPHONIALE, in the Italian muſic, is ſometimes prefixed to a canon, or fugue, to ſhew that it is at uniſon, *i. e.* that the ſecond part is to follow, or imitate the firſt in the ſame intervals, ſounds, notes, *&c.* the third to obſerve the ſame with regard to the ſecond, and ſo on.

SYMPHYTUM, *comfrey*, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe. The cup is an erect, acute, pentagonal perianthium,

divided into five ſegments at the rim, and remaining when the flower is fallen. The flower conſiſts of one petal, formed into a very ſhort tube, with a bellied tubular end, ſomewhat thicker than the tube, the extremity of which is divided into five ſegments. The opening of the flower has five tapering rays, ſhorter than the rim of the flower, and converging, ſo as to form a ſort of cone. The ſtamina are five tapering filaments, placed alternately with the rays of the mouth of the flower; the antheræ are acute, upright, and covered. The piſtillum has four germina. The ſtyle is ſlender, and of the ſame length with the flower. The ſtigma is ſimple. The cup becomes inlarged, and ſupplies the place of a fruit, containing four pointed gibbous ſeeds, with their tops converging one towards another. *Linnæi* Gen. Plant. p. 38.

The characters of *ſymphytum*, according to Tournefort, are theſe. The flower conſiſts of one leaf, and is funnel-faſhioned, but ſomewhat reſembling the bell-ſhaped ones. The cup is divided into ſegments, even to the baſe, and from this there ariſes a piſtil, which is fixed in the manner of a nail to the hinder part of the flower, and is ſurrounded with four embryos, which afterwards ripen into ſo many ſeeds: theſe are of the ſhape of a viper's head, and are contained in the cup, which becomes inlarged for their reception.

The ſpecies of *comfrey*, enumerated by Mr. Tournefort, are theſe. 1. The great purple-flowered *comfrey*. 2. The great bluiſh purple-flowered *comfrey*. 3. The white or yellowiſh-flowered great *comfrey*. 4. The deep yellow-flowered great *comfrey*. 5. The great *comfrey*, with variegated flowers. 6. The tuberoſe-rooted larger *comfrey*. 7. The ſmaller tuberoſe-rooted *comfrey*. 8. The large echium-leaved *comfrey*, with red roots, and yellow flowers. 9. The large echium-leaved *comfrey*, with red roots, and white flowers. 10. The narrow-leaved *comfrey*, with red roots, and yellow flowers.

Authors have been uſed to reckon another ſpecies of this plant, the little borage-like *comfrey*; but this is properly a ſpecies of omphaloides. *Tourn.* Inſt. p. 138.

The roots of the common *comfrey* are very powerful agglutinants. The common people uſe them with ſucceſs in freſh wounds, and a conſerve of them is found of excellent uſe in hæmorrhages of all kinds. They have been alſo recommended in the gout and ſciatica, as of great virtues in mitigating the pain, and ſhortening the paroxyſms.

Symphytum was a name given among the antients to ſeveral different plants, which had the common virtues of agglutinators. We have appropriated the word to *comfrey*; but Dioſcorides plainly uſes it ſometimes as the name of elecampane, and ſometimes as that of the common horſe-tail. He even ſeems to have led himſelf into an error in the uſe of theſe ſynonyms, in this very article, having preſcribed the horſe-tail, under the name of *ſymphytum*, for a ſhortneſs of breath. It is very evident, from the tenor of his other works, that he meant to preſcribe the helenium, or elecampane, that having the qualities neceſſary in ſuch a caſe; and neither this author, nor any other, ever having recommended the horſe-tail on any occaſion of this kind. Pliny has collected the virtues and characters of the *ſymphytum* from all the authors he had, in whom the word occurred, and therefore he has given a liſt of virtues that belong to no one plant.

SYMPLEXIUM, in natural hiſtory, the name of a genus of foſſils, of the claſs of the ſelenitæ, but not of the determinate and regular figure of moſt of the genera of thoſe bodies, but compoſed of various irregular connections of differently ſhaped, and uſually imperfect bodies.

The word is derived from the Greek, *σύμπλεκω*, to connect, or compound a mixt maſs of different things.

The bodies of this genus are of an irregular figure, and are variouſly notched, divided, and indented at their edges: they are compoſed of a number of other imperfect ſelenitæ, principally of the rhomboidal kind, though not unfrequently with the columnar, and uſually with parts of tabular maſſes among them. The different bodies that form this kind are ſeldom quite perfect, having uſually fallen together before they were wholly hardened; but generally, whether they form a larger or a ſmaller maſs, they together affect the external figure of a flat hexaedral column, though variouſly notched at the ſides, and truncated at the ends. *Hill*'s Hiſt. of Foſſ. p. 124.

SYMPLOCE, Συμπλοκή, in rhetoric, a figure, where the ſame word is repeated ſeveral times in the beginning or end of a ſentence: thus, *Quis legem tulit? Rullus. Quis majorem populi partem ſuffragiis privavit? Rullus. Quis comitiis præfuit? Idem Rullus. Voſſ.* Rhet. lib. 5. p. 289.

SYMPOSIARCH, Συμποσιαρχος, in antiquity, the director, or manager of an entertainment. This office was ſometimes performed by the perſon at whoſe charge the entertainment was provided; ſometimes by another named by him; and at other times, eſpecially in entertainments provided at the common expence, he was elected by lot, or by the ſuffrages of the gueſts. He was otherwiſe called *baſileus*, *rex*, and *modimperator*, &c. and determined the laws of good fellowſhip, obſerved whether every man drank his proportion, whence he was called *ophthalmus*, *oculus*, the *eye*. The gueſts were in all things obliged to obey his commands; on which account Cicero upbraids a certain perſon, that *qui nunquam populi Romani legibus paruiſſet, iis legibus, quæ in poculis ponebantur, obtemperabat:* he, who had never ſubmitted to the laws of the Roman people, yielded obedience to thoſe of drinking.

Arian reports, that the king being elected by lots commanded in this manner, *do you drink, do you fill the glaſs, do you go, do you come*, &c. The chief magiſtrates were not exempted from yielding obedience, if the lots gave another the preeminence. Plutarch relates, that Ageſilaus, king of Lacedæmon, being choſen *ſympoſiarch*, gave the following command to the cup-bearer, who aſked him how much wine every gueſt ſhould drink, *viz. If there is plenty of wine, let every man have what he calls for; if not, let every man have an equal ſhare.*

SYMPTOSIS, a word uſed by the antients to expreſs a contraction, or ſubſidence of the veſſels, ſuch as happens under evacuations. It alſo is ſometimes uſed to expreſs a remiſſion in a diſeaſe, and the falling away in fleſh of people in ſickneſs.

SYNAGELASTIC, an epithet uſed to expreſs the fiſhes of the gregarious kind, or which ſwim together in large ſhoals, in oppoſition to the ſolitary kinds.

SYNAGRIS, in zoology, a fiſh caught in the Archipelago, and ſome other ſeas, and much reſembling the *dentex*. Some have uſed it as a ſynonym for that fiſh, and others accounted it only a name applied to the *dentex* while young, but it is properly a diſtinct ſpecies. It is conſiderably ſhorter and thicker than the *dentex*, and much reſembles the carp in figure. Its head is yellow, and its ſides are variegated with bluiſh, and other coloured lines, laid in an oblique direction; but the longitudinal ſide lines are black. Its ſcales are remarkably round in figure, and its tail very forked. *Bellonius* de Piſc.

Ariſtotle, Athenæus, and others, apply the name *ſynagris* to the fiſh generally called the *dentex*, or *ſynodon*, the *dentale* of the Italians.

According to Artedi, it is a ſpecies of the ſparus, and is diſtinguiſhed by him by the name of the variegated *ſparus* with a ſharp back, and with four large teeth.

SYNARTHROSIS (*Cycl.*)—The articulation of bones, ſo joined together as to remain fixed in their ſituation, is of two kinds; one is made by ingrailing, and the other in the ſame manner, in which a nail, or pin, is fixed in wood. The firſt of theſe may be again ſubdivided into the deeper, and the more ſuperficial kind.

The deep kind is obſervable in the articulation of the broad bones; the antients term this a ſuture, from the reſemblance it bears to a coarſe ſeam, as is ſeen in the upper bones of the ſkull. It is made by jags, notches, and holes, in each of the articulated bones, by which they are mutually indented, much after the ſame manner as what is called *dove-tailing* among the joiners. By the antients this was called alſo *unguis*, probably becauſe the indented pieces are rounded like nails. Sutures have been divided alſo into the true and the falſe. See SKULL.

The other kind is that which is obſerved in bones joined together by more extended ſurfaces, in which no indentation appears outwardly. This kind of articulation the antients termed *harmony*; and the articulation of ſome of the bones of the upper jaw were given as examples of it. But though they deſcribe this as running in a ſingle line, they did not mean this in a ſtrict ſenſe, but only that the joint was like that of two rough boards without grooves; for they have expreſsly told us, that ſome ſmall inequalities might be obſerved in theſe joints, and ſome of them have uſed the terms *ſuture* and *harmony* indifferently. The other kind of *ſynarthroſis*, an example of which we have in the teeth, is called *gomphoſis*, a Greek term, ſtill retained. *Winſlow*'s Anatomy, p. 15.

SYNATHROISMUS, Συναθροισμος, in rhetoric, a figure which, in order to magnify a thing, whether good or bad, enumerates a great many different perſons, actions, &c. to which it relates: thus Cicero, *qui mihi fratrem optatiſſimum, me fratri amantiſſimo, liberis noſtris parentes, nobis liberos; qui dignitatem, qui ordinem, qui fortunas, qui ampliſſimam rempublicam, qui patriam, quâ nihil poteſt eſſe jucundius; qui denique noſmet ipſos nobis reddidiſtis.* See *Voſſ.* Rhet. lib. 5. p. 372.

SYNCAMPE, a word uſed by the old writers to expreſs the joint, or flexure, where the upper part of the arm is joined to the lower.

SYNCAUSIS, a word uſed by ſome medical writers to expreſs the drying, and, as it were, burning up of the excrements within the body, by a febrile heat.

SYNCHISIS, a word uſed by the old medical writers to expreſs a confuſion and perturbation of all the humors in concoction, from the imbecillity of the ſtomach. It is alſo uſed to expreſs a diſeaſe of the eye, which conſiſts in a confuſion of the humors: this generally proceeds from a violent blow; ſometimes from an inflammation of the uvea, occaſioning a rupture of the veſſels, and an effuſion of the humors.

SYNCHORESIS, Συνκωρησις, in rhethoric, the ſame with *permiſſion*. See PERMISSION.

SYNCHYSIS,

SYNCHYSIS, Συγχυσις, in rhetoric, a confuſed manner of expreſſion, where the natural order of the words is perverted. Horace affects it much: thus lib. 1. ſat. 5.

Pæne macros arſit dum turdos verſat in igne.

SYNCOMISTERIA, Συνκομιστηρια, in antiquity, the ſame with *thalyſia*. See THALYSIA.

SYNCOMISTON, a name given by Athenæus, and ſome other authors, to the coarſer ſort of bread eaten by the poor in many countries, and made of unſifted meal, the bran being mixed up among the reſt. This is a very nouriſhing food, and for laborious people, or thoſe who uſe much exerciſe, is highly preferable to all other ſorts of bread.

SYNCRISIS, a word uſed by the chemical writers to expreſs a concretion, or coagulation of any thing, effected by a ſpontaneous, or violent reduction of a liquid ſubſtance to a ſolid one, by a privation of the humid.

SYNCRISMATA, a ſort of ointment, of the nature of the acopa, in uſe among the antients.

SYNCRITICA, a name given by ſome writers to ſuch medicines as are of a coercive and aſtringent quality, whether uſed externally, or given internally.

SYNDESIS, a word uſed by the antient phyſicians to expreſs a binding, or ſtraitening.

SYNDESMOSIS, in anatomy, a connection of the bones, called alſo *ſynnexoſis*.

SYNDESMUS, in anatomy, a word uſed by ſome for a ligament. See LIGAMENT.

SYNECHES, in medicine, is the name of a fever of the next degree to the intermittent: it alſo ſeems to be ſomething of kin to thoſe, and is called the *continent*, or *remitting fever*. It is a continual fever in regard to duration, though not in degree, continuing many days together without intermiſſion: but then it has its diminutions and augmentations; ſometimes regular, ſometimes irregular, though no true intermiſſions. *Allen*'s Synopſis, p. 3.

SYNECTICON, a word uſed by the old writers to expreſs the proximate cauſe of a diſeaſe; called alſo the *cauſa continens*, and always remaining cloſely united with the diſeaſe.

SYNERGASMA, a word uſed by Libavius, and ſome other authors, to expreſs any operation in chemiſtry. The operations are by this author divided into two claſſes, the energetic, and preparatory: the firſt producing ſuch bodies as are of power to act on others as menſtruums, to cure diſeaſes, and the like; and the others producing no ſuch things, but being neceſſary preparatives to them.

SYNESTIC is ſometimes applied by phyſicians to expreſs the ſtools when firm, and of a conſiſtence; ſuch as to make them remain in their ſhape, in oppoſition to liquid ones.

SYNGENESIA, in botany, a claſs of plants with hermaphrodite flowers, whoſe ſtamina are naturally formed into a ſingle regular congeries.

The word is formed of the Greek σὺν, together, and γένεσις, formation. The plants comprehended under it are thoſe whoſe ſtamina, by the junction of their apices, are formed into a ſingle regular cylindric body; and among theſe are the lettuce, ſuccory, hawkweed, &c.

The *ſyngeneſia* expreſſes the ſame claſs of plants with the compound flowered plants of Ray, and others. The general characters of the claſs are theſe.

The cup is the crown of the ſeed, and ſtands on the ſummit of the germen. The flower conſiſts of one petal, and has a very narrow and long tube placed upon the germen: this is either tubular, ligulated, or naked.

The tubular flower of the *ſyngeneſia* has, at the ſummit of the tube, a wide campanulated mouth, divided into five ſegments, which are expanded, and ſomewhat bent backward. The ligulated flower is that which has a plain and ſtrait edge turning outwards, with a truncated apex undivided, but furniſhed with three or four teeth. The naked flowers are thoſe which have no mouth at all; and often in theſe, even the tube is alſo wanting. The ſtamina are five very ſhort and ſlender filaments, inſerted into the tube of the flower. The antheræ are of the ſame number with the ſtamina: they are ſlender, erect, and grow together at their ſides, ſo as to form a tubular cylindric body of the length of the mouth of the flower, and divided into five ſegments at the edge. The germen of the piſtil is oblong, and placed under the receptacle of the flower. The ſtyle is capillary, erect, and of the length of the ſtamina, and goes through the cylinder formed by the antheræ. The ſtigma is divided into two parts, which ſtand open, and bend backwards. Theſe plants have properly no pericarpium, though in ſome few ſpecies there is a coriaceous cruſt placed about the ſeed. The ſeed is ſingle and oblong, often of a quadrangular figure, and ſometimes narrower at the baſe than in any other part. *Linnæi* Gen. Plant. p. 370.

The ſeeds are, in the different genera of this claſs, of a very different appearance at the ends. Some are crowned with a downy matter, compoſed of a great number of ſingle ſhort filaments, placed circularly, or otherwiſe, on the head of the ſeed. In ſome the downy matter is radiated; in others it is ramoſe, or branched; and in ſome it is ſupported on a pedicle, while in others it ſtands immediately on the ſeed. In ſome genera the ſeeds have no down at all, but have a ſmall corona, formed of what was originally the cup of the flower: this is permanent, and divided uſually into five ſegments. In ſome genera the ſeed is wholly naked, having neither any down, nor this crown of a cup.

The ſexes of the plants of this claſs are very variouſly diſpoſed, and it is owing to this that there are among them ſeveral different kinds of flowers. The tubulated flower is called an hermaphrodite flower, when it contains both the ſtamina and piſtil. It is called a male flower, when it contains only ſtamina without any ſtigmata. It is called a female flower, when it contains a ſtigma and no ſtamina. And there is ſtill another ſort of flower, called neutral, among this claſs of plants; theſe have neither ſtamina, piſtil, nor ſtigma, nor indeed any other part of fructification. Theſe ſeveral kinds of flowers are, in the deſcriptions of the genera, called ligulated, campanulated, &c. from their ſhape.

A flower compoſed of a great number of theſe ſmall flowers is called floſcular, or floſculoſe flower; each of theſe, from their being ſmall, and only making up a part of a general flower, being called a floſcule. The common receptacle of the fructification in the floſculous flowers contains always ſeveral floſcules; and in the various genera the diſk, on which theſe are received, is either concave, convex, plain, globoſe, or, finally, pyramidal. This receptacle is called by ſome *thalamus*.

The ſuperficies of this receptacle is called by authors, in ſome genera, naked, in others paleaceous. In the naked kinds, it is either abſolutely bare, or elſe covered with a number of ſmall tubercles, or with ſhort and erect hairs. The paleaceous receptacles are covered on the ſurface with narrow, ſubulated, and painted paleæ, or chaffy ſubſtances. Theſe ſtand erect, and are placed between the floſcules.

The common cup, or perianthium, in theſe plants, contains, or incloſes both this receptacle, and all the floſcules: this is contracted together at the top when the plant is in flower, but it expands itſelf when the floſcules are fallen, and the ſeeds are to ripen. This general cup is, in its different appearances in the ſeveral genera, diſtinguiſhed by authors by the epithet *ſimplex*, *imbricatus*, and *auctus*. The perianthium ſimplex, or ſimple cup, is that which conſiſts of only one ſimple ſeries of leaves, which ſurround the flower. The imbricated cup is that which is compoſed of a vaſt number of ſhort ſquammæ, or ſcales, the exterior ones being gradually ſhorter than the inner ones, which they lie upon. The calyx auctus is that, in which while one ſeries of long and equal ſegments ſurrounds the floſcules, another ſmall ſeries ſurrounds only the baſe of the inner, ſimple, and larger cup. The compound flowers are very variouſly compoſed, in regard to the nature of the floſcules. *Linnæi* Gen. Plant. p. 371.

1. Some are compoſed of tubuloſe hermaphrodite flowers in the diſk, and of the ſame ſort of tubulous hermaphrodite flowers in the radius. 2. Others are compoſed of tubuloſe hermaphrodite flowers in the diſk, and of tubulous female flowers in the radius. 3. Some are compoſed of tubulous hermaphrodite flowers in the diſk, and of tubuloſe neutral flowers in the radius. 4. Some have tubuloſe hermaphrodite flowers in the diſk, and ligulated hermaphrodite flowers in the radius. 5. Some are compoſed of tubulous hermaphrodite flowers in the diſk, and of ligulated female flowers in the radius. 6. Some are compoſed of tubulous hermaphrodite flowers in the diſk, and ligulated neutral flowers in the radius. 7. Some are compoſed of tubulous hermaphrodite flowers in the diſk, and of naked and neutral flowers in the radius. 8. Some are compoſed of tubuloſe male flowers in the diſk, and of naked female flowers in the radius. And 9. ſome are compoſed of ligulated female flowers in the diſk, and ligulated hermaphrodite flowers in the radius.

The eſſential character of a floſculous flower conſiſts in its antheræ growing together into a cylindric body, and producing a ſingle ſeed, which ſtands under the receptacle of the ſeparate floſcule. Id. p. 372.

The common cup is uſual in moſt genera of this plant, but it is no univerſal character, for it is wanting in the echinopus. Nor is this the only variation they are ſubject to, for the common receptacle, which might ſeem a very eſſential part of the plant, is wanting in the milleria. It is evident from this, how very uncertain characters the common cup, and common receptacle of the ſeeds, are in this claſs of plants; for though they have been judged eſſential, and unerring marks, yet we find the two plants above named want them ſeverally; and we alſo find that ſome plants are poſſeſſed of them, which have not the other characters of the claſs. Thus ſcabious has a common cup, and dipſacus a common receptacle, yet neither ſcabious, nor dipſacus, are floſculous, or, as they may much more properly be called, *ſyngeneſious* plants.

It is very remarkable that Plumier has no genus of compound flowers. Tournefort, though he had not the aſſiſtances of the later obſervations on the ſtamina and antheræ to guide him, yet has fixed very natural genera in the claſs of the *ſyngeneſious*, or compound flowered plants.

Vaillant made more obſervations on the nature of the flowers of theſe plants, than any one who went before him, and the

only error he run into, was the making too many genera. Pontedera has rendered the method of this claſs very eaſy and clear, though he found it very confuſed. *Linnæi* Gen. Plant. p. 373.

SYNGNATHUS, in ichthyology, the name of a genus of fiſhes, the characters of which are theſe. The coverings of the gills are on each ſide compoſed of a thin and ſingle bony lamella; the head is oblong and compreſſed; the jaws are cloſed up at the ſides; and the mouth is only capable of opening at the extremity of the ſnout. The body is long and very ſlender; the ſhape is ſometimes roundiſh, but more uſually angular. The fins are in moſt ſpecies four in number, but in ſome only one.

The ſpecies of this genus, enumerated by Artedi, are four. 1. The ſquare-bodied *ſyngnathus*, having no fin at the tail. This is the creature called the *hippocampus* by authors. 2. The cylindric *ſyngnathus* without any breaſt, or tail fins. This is the *acus lumbriciformis* of Mr. Ray. 3. The *ſyngnathus* with the middle of the body heptagonal, and with a pinnated tail. This is the *acus Ariſtotelis ſpecies altera major* of Willughby. 4. The *ſyngnathus* with the middle of the body hexangular, and a pinnated tail. This is the common *acus Ariſtotelis*. In the diſtinguiſhing this genus, the number of the inciſures, in the body of the ſeveral ſpecies, is to be carefully attended to. *Artedi*, Gen. Piſc.

The name *ſyngnathus* is of Grecian origin, and is formed of the word συν, which in compoſition ſignifies the ſame as the Latin *con*, together, and γναθος, a jaw. It is given to this fiſh from that remarkable ſtructure of its mouth, by which the jaws are made to grow together, and the very end of the mouth only opens.

SYNGNOME, Συγνωμη, in rhetoric, the ſame with *conceſſion*. See CONCESSION, *Cycl.*

SYNNAS, or SYNNADIUM *marmor*, in the writings of the antients, the name of a ſpecies of marble uſed in the larger buildings of the Romans. It is by ſome confounded with the docimenum marmor, with which the temple of Jupiter, erected by Adrian, was built; but this is erroneous, ſince that elegant marble was always charactered as perfectly white, without blemiſh; and this was always ſpotted, and clouded with black, inſomuch that ſome writers have called it by an epithet, expreſſing thoſe variegations, *maculoſa ſynnas*.

SYNNEUROSIS, in anatomy, a kind of articulation of the bones, performed by the intervention of ligaments.

SYNOCHA, (*Cycl.*) in medicine, the name of a ſpecies of fever, of which authors diſtinguiſh two kinds, the ſimple, and the compound. The ſimple *ſynocha* is very rare in our parts of the world. The compound one is a mixed diſeaſe of the *ſynochal* and ordinary continued fever, and has been called by ſome the *putrid fever*, and *ſynocha putrida* by the antient medical writers.

Signs of it. The *ſynocha* always ſeizes people at once with a violent heat, without thoſe ſhiverings which frequently attend the firſt attacks of other fevers. It is attended with a violent thirſt, an univerſal languor, and laſſitude of the limbs; and often with anxieties, ſighings, and ſuffocative difficulties of breathing. Acute and violent pains are felt in the head, with a tumid redneſs of the face and eyes, noiſes in the ears, vertigos, and eternal reſtleſsneſs and toſſing about in the bed, with wildneſſes in the thoughts. The urine from the firſt is red and pellucid; it rarely admits of any breaking, or depoſits any ſediment before the fourth day, then it frequently precipitates a reddiſh matter. There is generally an obſtinate coſtiveneſs, and ſpaſmodic tenſions of the back and limbs are uſually very painfully felt during the whole time of the diſeaſe. The ſeventh day generally brings on a criſis in this diſeaſe, which in young people is uſually by an hæmorrhage of the noſe, in older by profuſe ſweats. The perſons moſt ſubject to this diſeaſe are thoſe of a plethoric habit, who eat high-ſeaſoned foods, and uſe little exerciſe; and eſpecially ſuch as have had any habitual evacuation of blood ſtopt upon them. It is more frequent in the ſpring and autumn, than at other ſeaſons. *Junker*'s Conſp. Med. p. 267.

Cauſes of it. Theſe are principally violent and unaccuſtomed exerciſe, drinking large quantities of ſpirituous liquors, long watchings, immoderate paſſions, violent ſweatings from hot medicines, and ſudden cooling the body when very hot, by drinking large draughts of cold water, or other weak liquors. All theſe occaſion the fever, by affecting the plethoric habit of the perſon; but this, which is the general and original baſis of the diſtemper, is uſually brought on by omiſſion of uſual bleedings at ſpring and autumn, and other ſeaſons, by ſuppreſſions of accuſtomed hæmorrhages by the noſe, and by ſtoppages of the menſtrual, or hæmorrhoidal evacuations.

Prognoſtics in it. The *ſynochal* fever, in itſelf, is ſeldom attended with any great danger; and when the criſis happens by profuſe ſweats, or by an hæmorrhage, on the ſeventh day, there is no fear of any ill accidents: but if this time paſs without a criſis, and the congeſtions remain, young perſons are uſually thrown into a violent phrenitis, and older ones into ſoporous affections; and even in ſome caſes, where the criſis comes regularly on by hæmorrhages, there is danger from its being too great in quantity, and too much impairing the ſtrength of the patient. There muſt be great caution, however, uſed in aſſwaging this hæmorrhage, if that be found neceſſary, ſince, when it is imprudently done, it often brings on terrible obſtructions in the viſcera, and hectics, dropſies, and cachectic complaints, that are very difficult to get rid of. The critical hæmorrhage is known to be coming on by a ſtricture and itching of the noſe, an intenſe pain in the head, a redneſs of the eyes and face, and a ringing in the ears. Very frequently, alſo, the criſis is predicted by a remarkable perturbation of mind, but this is not the peculiar ſymptom of the hæmorrhage, but happens as often, when it is by ſweat. Often there is a dripping of blood from the noſe on the fourth day; and in this caſe, if nature be not diſturbed, there will certainly be a farther bleeding on the ſeventh day. Complaints of an anxiety and uneaſineſs about the breaſt preſage an unhappy event. Other very bad ſymptoms, alſo, are involuntary tears, great reſtleſsneſs, no relief from ſleep, and the appearance of livid, or brown ſpots. The thick ſtate of the blood, in this fever, makes it very eaſily paſs into ſlow continued fevers and hectics; and ſometimes, when the criſis does not come on at the ſeventh day, and there appear clouds in the urine, it appears afterwards on the fourteenth day.

Method of cure. Bleeding is always neceſſary in the firſt ſtages of this fever, before the ſigns of coction appear in the urine; after this the violent emotions of the blood are to be quelled by nitrous and acid medicines, as the juice of lemons: to theſe muſt be added reſt, and a frequent drinking of warm and weak liquors. The bowels, if much bound, muſt be gently looſened by an emollient clyſter; and after the criſis, ſome gentle purgatives muſt be given to clear the primæ viæ. Bleeding is not to be ordered after the ſigns of coction appear in the urine, for it often prevents the critical hæmorrhage, and renders the patient ſoporous, or delirious; and in the compound, or putrid *ſynochal* fever, the patient is not to be blooded at all. Volatile ſalts are given by ſome in this caſe, but very improperly, for they always are attended with miſchief, and often occaſion cachectic tumors. Symptomatic quinſeys often attend this diſeaſe, and are to be relieved by gargariſms, rendered aſtringent by an admixture of terra Japonica, or the like medicines; and in this particular caſe, wine is to be more cautiouſly forbid than at other times. *Junker*'s Conſp. Med. p. 266.

SYNODON, in zoology, a name given by ſeveral authors to a fiſh caught in the Mediterranean, and more commonly known by the name of *dentex*. *Aldrovand.* de Piſc. lib. 1. cap. 12. See DENTEX.

SYNODONTIDES, in natural hiſtory, the name of a ſtone deſcribed by the antients, and ſaid to be taken out of the head of the fiſh, called by them *ſynodontes*, the *dentex* of the moderns. See DENTEX.

SYNONYMA. The perplexity in the writings of the antients, ariſing from the uſe of *ſynonymous*, as well as homonymous terms, is very great, when they uſe the ſame word as the name of two different things. The whole value of the accounts they have left us is loſt, by our not being able to diſtinguiſh which of the two they mean.

The great ſource of this confuſion has been in the love of ſecrets in medicine, which prevailed as ſtrongly among the antients, as it does among the moderns. In order to conceal the remedies they uſed, they often gave them new names, and often (which was worſe) uſed for them the names of other things.

Thus they called the pine-tree *itea*, the univerſally received name of the willow, and ſo in many other inſtances; from which we have, at this time, the ſame word in uſe in different authors, as the name of different things.

Galen gives a preſcription for baldneſs, in which almoſt all the ingredients are called by names wholly different from thoſe that the reſt of the world knew them by at that time, and by that means paſſed upon the vulgar for new-diſcovered medicines. The bay-tree is there called *ladonis*. The bear *amorphon brephos*, from the ſtory of its young cubs being ſhapeleſs till licked into form by the mother bear. The ladanum, or labdanum, is called *apotragopogon*, becauſe of its being gathered from the beards of goats. And the adarce is called *pericalamitis*, from its being found concreted about a reed.

The compoſition of Philo, called *cholice*, given in the ſame author, is thus given in the ænigmatical manner by the ſame means. The more learned and ingenuous people of theſe ages deteſted this idle practice, and gave all things their common names; but as the abſurdities of one man will generally find followers in others of the ſame ſtamp, though the phyſicians diſcarded the practice, the ſucceeding race of chemiſts, famous for their love of ſecrets, continued and improved it to ſo great a degree, that were there writings of any value, it would be wholly impoſſible, in many of them, ever to arrive at the author's meaning. See SYNONYMOUS, *Cycl.*

The Arabian writers have fallen more into the uſe of *ſynonyms*, and that in a more erroneous manner than any other authors. If two things have happened to be called by the

ſame

ſame name, be they ever ſo different, they always deſcribe them together, and attribute their virtues to one, as well as to the other; nay, they too often tranſcribe from other authors the virtues belonging to the one, and adding them to the account of the other, leave no room to trace out the truth, but by referring to the originals if they are in being. Thus theſe authors found the word *zarnich*, uſed by ſome as the name of orpiment, and by others as the name of the lapis armenus, a blue colour, uſed in painting. Aëtius, and ſome other authors, tell us, that the Syrians always uſed the word in this latter ſenſe, though all other people uſed it in the former. Aviſenna on this makes theſe two different ſubſtances, orpiment, and armenian zarnich, the ſame; and having ſeen no lapis armenus, but what was of a greeniſh blue, (as much of it was) he gives a chapter on zarnich, in which he tells us that it was of three kinds, yellow, red, and green: thus confounding the true ſpecies of orpiment, the red and yellow, with a blue green colour, wholly different from them in its nature and qualities. In the ſame manner the various ſubjects of the vegetable world, that happen to have been at ſome time called by the ſame name by others, are always confounded by theſe writers. The chamælea, and chamæleon, two very different plants, both in figure and qualities, and which are not indeed wholly *ſynonymous*, yet are confounded together, both by Serapio and Aviſenna; and the nature and qualities of both deſcribed ſo conjunctly in one chapter, that they muſt paſs for the ſame plant with all, but thoſe who have before made themſelves maſters of the hiſtory of the materia medica of the earlier times, and are able to diſtinguiſh which of the characters and virtues belong to the one, and which to the other. The two ephemerons are in the ſame manner confounded together by Aviſenna, and blended in one chapter: and what is ſtill more foreign than all theſe, the Ægyptian *lotus*, becauſe it happens to be called by the ſame name with the *lotus* of the Greeks, which is a trifoliate plant, is deſcribed together with it in the ſame chapter, though nature can ſcarce afford two plants more various, either in form, or qualities. And thus in numerous other inſtances.

SYNONYMISTS, among the botanical writers, ſuch as have employed their care in the collecting the different names, or *ſynonyma*, uſed by different authors, and reducing them to one another.

SYNTENOSIS, a word uſed by anatomiſts to expreſs an articulation of the bones when they are connected, as the oſſa ſeſamoidea of the toes, only by a tendon.

SYNTHENA, a term uſed by Paracelſus to expreſs an apoplectic, or epileptic diſorder, attended with violent griping pains in the bowels. This is generally mortal.

SYNTHETIC, or SYNTHETICAL, (*Cycl.*) a term given to that part of chemiſtry, which, after the analytical chemiſtry has taken bodies to pieces, or reduced them to their principles, can, from theſe ſeparated principles, either recompound the ſame body again, or, from the mixtures of the principles of one or more bodies in various manners, form a large ſet of new productions, which would have been unknown to the world but for this art: ſuch productions are brandy, ſoap, glaſs, and the like.

Synthetical chemiſtry, taken in the ſtrict ſenſe for the recompoſition of bodies from their own principles, is rather of philoſophical, than of ordinary uſe. This however is not eaſy, except in a few caſes, nor are we to imagine, becauſe it may be done in ſome, that nature has taken this way to compoſe them; her method of compoſition of bodies are a new ſubject, and worthy a diligent inquiry. *Shaw*'s Lectures, p. 169.

SYNTHETISMUS, a word uſed in chirurgical writings to expreſs the four operations neceſſary to the reſtitution of fractures, which are extenſion, coaptation, repoſition, and deligation, or the buſineſs of bandage.

SYNTONUM *diatonum*, in muſic. See GENUS.

SYNTROPHIC, an epithet uſed to certain diſeaſes, which grow up with the patient. Of this kind is the epilepſy, which often firſt ſeizes the perſon in infancy, and continues growing up with him, and increaſing in ſtrength as he does.

SYNULOTIC, a word uſed by ſome writers in the ſame ſenſe as epulotic.

SYNYMENSIS, a word uſed by ſome chirurgical writers to expreſs a conjunction of two bones by means of a membrane, as the bones of the ſinciput are connected to thoſe of the forehead in young children.

SYPHAR, a word uſed by ſome naturaliſts in the ſame ſenſe as exuviæ, to expreſs the ſkins which many reptiles caſt off at certain times. Thus the ſnake, the water newt, and all the caterpillar tribe, part with their ſkins during the time they remain in that ſtate.

SYRIACUS *lapis*, in natural hiſtory, a name given by Aëtius, and many other authors, to the petrified ſpines of the *echini ovarii*, called by us the *Jew ſtones*, and *petrified olives*, from their likeneſs to an olive in ſhape, and called by the antients *tecolithus*.

It has been a common opinion, that this *ſtone* was good againſt the gravel and ſtone; but Aëtius limits its efficacy to a particular caſe, which is that where the ſtony matter is lodged in the kidneys and ureters; but he frankly confeſſes, it is of no power to diſſolve or break the ſtone in the bladder.

This is contrary to the doctrine of Dioſcorides, and the other old Greeks; but more conſonant to reaſon and experience. Some have carried its virtue ſo far, as to pretend, that when rubbed to powder, and mixed in water, and that mixture rubbed on the groin and perinæum, it will break the ſtones concreted within, and bring them away in pieces by urine. This, though too groſs for belief, is yet given us by Pliny. In moſt of the common editions the words ſtand thus, *lingentium frangit calculos*; but all the beſt copies have it *ungentium*; and the word *lingentium* is only made by dividing the two perpendicular lines in the letter U.

SYRICON, a word uſed by ſome authors in the ſame ſenſe as ſandyx. Pliny makes it a compoſition of equal parts of ſinopis and ſandyx; and Aëtius gives it as the name of a collyrium, uſed in many diſorders of the eyes.

SYRINGA, the *pipe-tree*, in botany, the name of a genus of trees, the characters of which are theſe. The flower is of the roſaceous kind, being compoſed of ſeveral petals arranged in a circular form. The piſtil ariſes from the cup, and finally becomes a fruit adhering to the cup, of a turbinated form, and divided into four cells, which contain ſmall ſeeds.

There is no other known ſpecies of the *ſyringa* beſide the common one, and its variety, with double flowers. *Tourn.* Inſt. Bot. p. 617.

Many ſpecies of this flowering ſhrub, common in gardens, are called *lilacs*. See LILAC.

In the Linnæan ſyſtem of botany, *ſyringa* is the name of a ſeparate genus of plants, the characters of which are, that the flower cup is a perianthium formed of only one leaf, which is ſmall, tubulated, and erect, and has four notches at its extremity. The flower is a ſingle petal, formed into a very long and ſlender tube, divided at the extremity into four ſegments, which are ſpread open and bent; the ſeveral jags, or ſegments, being ſtrait, hollowed, and obtuſe. The ſtamina are two very ſhort filaments, terminated by ſmall antheræ, hid within the tube of the flower. The piſtillum is compoſed of an oblong germen, a thready ſtylus of the length of the ſtamina, and a thick and bifid ſtigma. The fruit is an oblong, compreſſed, and pointed capſule, containing two cells, and made up of two halves, containing each a ſingle, oblong, and compreſſed ſeed; pointed at each end, and ſurrounded with a membranaceous rim. *Linnæi* Gen. Plant. p. 3.

The ſeveral ſpecies of this beautiful and ſweet flowering ſhrub are eaſily propagated, by taking off their ſuckers in autumn, of which they always produce great plenty. Theſe ſhould be tranſplanted into the nurſery, where, after they have remained two years, they will be fit to be removed to the places where they are to remain. They are very hardy, and may be planted in almoſt any ſoil or ſituation; and require no farther culture, but to take away the ſuckers, and cut out the dead wood every year, and now and then to dig up the earth about their roots. They flower in May and June. *Miller*'s Gardner's Dictionary.

SYRINGITES, a ſtone mentioned by Pliny, and deſcribed as being always full of cavities. Some have ſuppoſed this author meant the oſteocolla by this name; but it is more probable, that he meant the ſtone we now call *ſyringoides*, or the pipe-ſtone.

SYRINGOIDES *lapis*, the *pipe-ſtone*, in natural hiſtory, the name of a very beautiful foſſile ſubſtance, of which there are ſeveral different kinds. The *tubuli marini*, or caſes of ſea worms, lodged in any ſolid ſubſtance of the foſſile kind, conſtitute what is called the *lapis ſyringoides*.

The moſt frequent kind is made of the common matter of the ludus helmontii, or ſeptaria, with tubuli of different kinds and dimenſions in it; but the moſt beautiful ſort is that made of the bottoms of ſhips, old boards, or piles of wood; which having been long in the ſea, have been pierced by the ſea worms, which have made their ſeveral burrows, and left their ſhells behind in them: the whole of theſe ſubſtances becoming afterwards petrified, is found in form of wood, with all the knots, veins, and other characters, but wholly of the hardneſs of ſtone. This is uſually of a blackiſh colour, and the pipes being of a pale yellow, the whole makes a very elegant appearance.

Our clay-pits about London afford alſo a *ſyringoides* of this kind, but the earth there abounding with the matter of the common vitriolic pyrites, that ſubſtance by degrees gets into the pores of the wood, and the whole ſeems a maſs of pyrites with theſe pipes lodged in it in different directions. This has been called by authors *pyrites ſyringoides*. *Hill*'s Hiſt. of Foſſ. p. 64.

SYRINGOTON, in ſurgery, an inſtrument to lay open fiſtulæ. We have a propoſal of a *ſyringoton*, of a new form, for laying open fiſtulæ in ano, by Mr. Freke. See Appendix to *Barroughby*'s Tranſlation of *Aſtruc* on the Fiſtula in ano.

SYRINGOTOMY, in ſurgery, a term uſed for the cutting for a fiſtula.

SYRITES, in natural hiſtory, a name uſed by ſome for the ſapphire, but by Pliny for a ſtone, which he ſays was generated in the bladder of a wolf.

SYRIUS, a word uſed by ſome authors for a very ſtrong purge, a preparation of ſcammony, being no other than a reſin, or magiſtery of that drug.

SYRMA, among the Romans, a long garment, common to both ſexes, that reached to the ground. It was uſed in tragedies, that the perſons of the heroes and heroines might appear the taller. *Pitiſc.* in voc.

SYRMÆA, a name given by the antients in general to a certain root, ſaid to be of the radiſh kind, and to be frequently uſed to provoke vomiting.

Some have made it alſo the name of a ſort of viand, prepared of honey, the fine fat of animals, and other ingredients, which was the prize beſtowed at one of the Spartan games: others have uſed it to expreſs a purging potion made only of ſalt and water, or plain brine. The Ægyptians frequently purged themſelves with this radiſh juice and ſalt, which operated gently both upwards and downwards, and theſe potions were called by the ſame name *ſyrmæa*.

SYRMÆA, Συρμαια, in antiquity, was uſed as a deſignation of the games at Sparta, the prize in which was συρμαια, or a mixture of fat and honey. *Potter*, Archæol. Græc. Tom. I. p. 431.

SYRMÆSMUS, a word uſed by the antient medical writers to expreſs a gentle purging of the ſtomach or bowels, either by ſtool or vomit. It had its name from *ſyrmæa*, a word expreſſing a medicine that acted in this gentle manner.

SYRTITES, in natural hiſtory, is uſed by ſome authors as the name of a gem of a very beautiful appearance, in the ſubſtance of which are interſperſed faint ſtars of a ſaffron colour. *Hofm.* Lex. Univ. in voc.

SYRUPS *(Cycl.)*—There ſeems to be no part of pharmacy, in which the writers of diſpenſatories have more erred, than in their directions about the making of *ſyrups*; which ſeems the more ſtrange, becauſe this part is particularly eaſy. The misfortune is, that great men cannot ſtoop to conſider common and ordinary things; whence, however, the credit of a phyſician may ſink in the eſteem of thoſe, who by their employments are led to a knowledge of theſe ordinary things.

The whole of the buſineſs of *ſyrup*-making may be, however, reduced to a few ſhort and eaſy rules. As firſt, it is matter of experience that aqueous infuſions, decoctions, or other aqueous liquors, require twice their own weight of dry ſugar-candy to make them into a *ſyrup* of a juſt conſiſtence, for keeping without candying or fermenting.

This rule, by directing the uſe of ſugar-candy, fixes the conſiſtence of *ſyrups* in an exacter manner than any way elſe, becauſe all ſalts require a determinate proportion of water in cryſtallizing; ſo that ſugar, in the form of candy, contains always one certain proportion of water, while different kinds of ſugar may hold more or leſs aqueous matter, according to their different manner of refining, the accidents of the weather, *&c.* Hence, therefore, all ſuch infuſions for *ſyrups* as are of a delicate, or deſtructible colour, which is impaired by boiling, ſuch as violets, clove July flowers, *&c.* and all ſuch infuſions as contain any volatile parts, which would evaporate by a boiling heat, as thoſe of cinnamon, orange peel, *&c.* ſhould have twice their own weight of ſugar added to them, and be kept cloſe covered in the gentle heat of a balneum mariæ, till the ſugar is diſſolved; which, to haſten the ſolution, ſhould be reduced to powder.

Secondly, the decoctions of all ſuch vegetable ſubſtances, as loſe no valuable parts by boiling, may be boiled down to the proper conſiſtence with their own weight of ſugar, the two being firſt clarified together with the whites of eggs in the uſual way: but if the ingredients here contain any unctuous, or balſamic parts, whereon their medicinal virtues depend, let the ſugar be added from the very firſt, and boiled along with the ingredients; afterwards ſtraining and clarifying it, before it be of near the conſiſtence of a *ſyrup*. This rule is founded on the property in ſugar of diſſolving reſins and oils, ſo as to make them intimately mix with water.

Thirdly, all vegetable juices are to be thoroughly purified, before they are boiled into *ſyrups*. Thus the juices of lemons, oranges, *&c.* are firſt to be filtered, and then made into *ſyrups* without boiling, according to the firſt rule: but the juices of mulberries, and the like, will not clarify without a beginning fermentation; wherefore they muſt firſt ſtand a day or two, and then they will paſs through a flannel; after which theſe are to be made into *ſyrup* with an eighth part leſs than twice the quantity of ſugar; that is, with one pound twelve ounces of ſugar to a pint of the juice, on account of their being ſomewhat ſaccharine themſelves. And wines, and vinegars, muſt be made into *ſyrups* with the ſame quantity. *Shaw*'s Lectures, p. 205.

Pectoral SYRUPS, *ſyrupus pectoralis*, a new form of medicine preſcribed in the late London Pharmacopœia, and intended to ſtand in the place of the *ſyrup* of maiden-hair, and ſome others of that kind. It is to be made thus: take leaves of Engliſh maiden-hair dried five ounces, liquorice four ounces, boiling water five pints; ſteep the ingredients for ſome hours, and afterwards ſtrain off the liquor; and when it is made clear by ſettling, add to it the neceſſary quantity of ſugar to make it a *ſyrup* in the common way. *Pemberton*'s Lond. Diſp. p. 299.

SYRUP *of ſaffron*. See SAFFRON.

SYRUS *lapis*, a name given by the writers of the middle ages to a foſſil, ſeeming to be the ſame with the *thyrreus* of Pliny; of which name this indeed ſeems only a corruption, according to the barbarous manners of thoſe times. There are many remarkable qualities recorded of this, one of which is, that it would ſwim on water. Hence it ſeems to have been a ſpecies of bitumen; but we want a fuller deſcription.

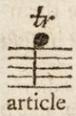
SYSSARCOSIS *(Cycl.)*—Beſides the uſe of this word to ſignify a kind of articulation of the bones, by means of fleſh, when the muſcles are extended from one bone to another; it is alſo uſed by ſome chirurgical writers to expreſs a method of curing wounds of the head when the cranium is laid bare, and the interſtice between the lips of the wound too wide for a contraction, by means of promoting the granulation, as it is called, or growth of new fleſh. Paulus Ægineta uſes it alſo to expreſs a preternatural generation of fleſh about the veſſels and coats of the teſtes, which is ſometimes the caſe in a ſarcocele.

SYSTASIS properly only denotes the conſiſtence of any thing, as of a ſyrup or ointment, but authors have uſed it alſo in a different ſenſe. Hippocrates underſtands by it a collection of humors about the palate; and ſometimes expreſſes by it a contraction of any part of the body from an uneaſineſs, or ſenſation of pain.

SYSTEMATICAL *qualities*, a term uſed by Mr. Boyle to expreſs ſuch qualities as are alſo called *coſmical*, and do not depend on the nature and conſtitution of the body itſelf, but on its being a member of this general ſyſtem of the univerſe, in which capacity it is acted upon by agents unperceived by us, which occaſions great changes in it.

SYSTEMATISTS, in botany, thoſe authors, whoſe works in this ſcience are principally employed about the arranging plants into certain orders, claſſes, or genera. *Linnæi* Fund. Bot. p. 2.

SYSIMBRIUM, *water-mint*, in botany, a name given by ſome to a ſpecies of mint. See MENTHA.



SYSTREMMA, a word uſed by Hippocrates to expreſs a collection of humors forming a hard tumor, or tubercle, in any part of the body; called alſo ſometimes *ſyſtrophe*.

SYSTYLE, in architecture, that manner of placing columns where the ſpace between the two fuſts conſiſts of two diameters, or four modules.

T.

T, In the Italian muſic, ſtands for *Tutti*, all or altogether. See the article TUTTI.

It is alſo uſed to mark the tenor, and has the words *primo*, *ſecundo*, or the figures 1°. 2°. added, to ſignify the firſt or ſecond tenor.

The letters T, *t*, or *tr*, are often uſed likewiſe to ſignify a ſhake or trillo, to be made on any ſound, and are placed over the note on which the ſhake is to be made; thus  or  being an abbreviation of the word *Trillo*. See the article TRILLO.

TABACUM, in botany, a name by which John Bauhine, and ſome others have called the tobacco-plant, more uſually known among authors by the name *nicotiana*. See the article NICOTIANA.

TABARZET, a word uſed by ſome writers to expreſs highly refined ſugar.

TABAXIR, and *Arundo* TABAXIFERA, names by which ſome authors call the Bamboo cane. *C. Bauhin.* Pin. p. 18.

TABERNA *Meritoria*, among the Romans, Mars's hoſpital, or a place where diſabled ſoldiers were maintained at the charge of the government. *Danet.* in voc.

TABES *Dorſalis* (*Cycl.*)—This diſtemper, according to a late author, is a particular ſpecies of conſumption, the proximate cauſe of which is a general debility of the nerves.

Of the ſeveral kinds of conſumptions incident to human bodies the *Tabes dorſalis* is the ſloweſt in its progreſs, but the moſt melancholy in its circumſtances; and, unleſs timely obviated, for the moſt part fatal.

This diſeaſe is incident only to young men of ſalacious diſpoſitions; and proceeds from too early venery, an immoderate uſe of it, or pollutions.

It ſeems therefore to derive its origin from too frequent venereal ſpaſms. And the immoderate loſs of the ſeminal fluid, has alſo a conſiderable ſhare in producing the effect.

The ſymptoms of the *Tabes dorſalis* are involuntary, nocturnal ſeminal emiſſions, a pain in the back, and often in the head; formication in the ſpine, an aching pain, rolling, and hanging down of the teſticles, a weakneſs of memory and ſight, and a mucous diſcharge from the urethra, eſpecially after ſtraining at the diſcharge of the excrements. The mucous diſcharge here mentioned, is called by Hippocrates *liquidum ſemen*; but it is no more than the mucus of the proſtate gland. This diſeaſe is farther attended with great melancholy and dejection of mind; and a gutta ſerena often follows. The eyes grow hollow, the viſage meagre and thin; the body emaciated and weak, a palpitation of the heart, and ſhortneſs of breath ſucceed; with a concourſe of hectical complaints, ending in death.

For the cure of this diſtemper, a regularity of the non-naturals is of the utmoſt importance. Good air, rather cool than hot, is of great uſe. As to diet, high-ſeaſon'd meats, ſpirituous and fermented liquors, ſhould be avoided. No food is ſo beneficial as milk: Chocolate alſo is eſteemed, in ſuch quantities as to ſit eaſy on the ſtomach. Animal food of eaſy digeſtion at dinner, does no harm. Suppers ſhould be avoided, at leaſt milk only ſhould be then taken, about two hours before going to bed. Sleep muſt be little, and in due ſeaſon; that is, the patient ſhould go to bed and riſe early. Indulgence in bed in a morning is hurtful. The general rule ſhould be, to riſe immediately upon waking; which, though irkſome at firſt, will by cuſtom be made familiar and agreeable. Moderate exerciſe, or ſo much as the patient's ſtrength will admit of without wearineſs, ought to be uſed. Some recommend riding, eſpecially a long journey, by ſuch daily portions as to avoid extraordinary fatigue. The ſecretions of the body, if out of order, ſhould be regulated: And the patient ſhould be entertained with chearful company. As to medicines, the claſſes of balſamics and aſtringents are chiefly uſeful. Among the latter, the Peruvian bark, either in ſubſtance, extract, or tincture, the acid elixir of vitriol, and the *tinctura ſaturnina* or *antiphthyſica*, are the moſt efficacious. Strengthening plaſters may alſo be laid on the loins; and, chief of all, the cold bath ſhould be uſed. See Pract. Eſſay on the *Tabes dorſalis*, Lond. 1748.

TABON, in natural hiſtory, a name given by the people of the Philippine iſlands to a bird called in other places *daie*, and remarkable for the largeneſs of its eggs; though ſome accounts of theſe are certainly fabulous. See the article DAIE.

TABULARIUM, among the Romans, the name of that part of the treaſury where the Elephantine books were kept. See the article ELEPHANTINE, *Cycl.*

TABUM, a word uſed by medical writers, to expreſs a thin ſanious and putrid humour, flowing from old ulcers, or from mortified parts, in caſes where the vital powers are not ſufficient for the generation of a perfect or concocted matter.

TACET, in the Italian muſic, is often uſed to denote a long reſt, or pauſe. It uſually ſignifies that a whole part is to lie ſtill: thus, *Chriſte Tacet*, *depoſuit Tacet*, intimates that while one or more parts are performing the *Chriſte*, or the verſe *depoſuit*, &c. the part marked *Tacet* ſhould be ſilent. *Broſſ.*

TAC-*Free*, in old charters, an exemption from payments. *Blount.* Law Dict. in voc.

TACHAS, in ichthyology, a name given by ſome authors to the manati, or ſea-cow. See the article MANATI.

TACIT *Decree*, in Roman antiquity, ſecret deliberations, to which none but old ſenators were ſummoned.

J. Capitolinus mentions a decree of this ſecret kind, which he calls *S. C. tacitum*, and ſays, that the uſe of them among the antients was derived from the neceſſities of the public, when upon ſome imminent danger from enemies, the ſenate was either driven to ſome low and mean expedients, or to ſuch meaſures, as were proper to be executed before they were publiſhed, or ſuch as they had a mind to keep ſecret even from friends; on which occaſions they commonly recurred to a *Tacit decree*, from which they excluded their clerks and ſervants, performing that part themſelves, leſt any thing ſhould get abroad. *Capitol.* de Gordian. c. 12.

In the early times of the republic there are ſeveral inſtances mentioned by hiſtorians, of ſuch private meetings of the ſenate, ſummoned by the conſuls to their own houſes; to which none but the old or proper ſenators were admitted, and of which the tribunes uſually complained. Vid. *Dion. Halic.* L. x. 40. L. xi. 55, 57. *Middlet.* of Rom. Sen. p. 90.

TACK, in a ſhip, a great rope having a wale-knot at one end, which is ſeized or faſtened into the clew of the ſail; ſo is reefed firſt through the cheſſe-trees, and then is brought through a hole in the ſhip's ſide. Its uſe is to carry forward the clew of the ſail, and to make it ſtand cloſe by a wind: And whenever the ſails are thus trimmed, the main-*Tack*, the fore-*Tack*, and miſen-*Tack*, are brought cloſe by the board, and haled as much forward on as they can be.

The bowlings alſo, are ſo on the weather-ſide; the lee-ſheets are haled cloſe aft, and the lee-braces of all the ſails are likewiſe braced aft. Hence they ſay, a ſhip ſails or ſtands cloſe upon a *Tack*, i. e. cloſe by the wind. The words of command are, *Hale aboard the Tacks*, i. e. bring the *Tack* down cloſe to the cheſs-trees. *Eaſe the Tack*, i. e. ſlacken it, or let it go, or run out. *Let riſe the Tack*. i. e. let all go out.

The *Tacks* of a ſhip are uſually belayed to the bitts, or elſe there is a chevil on purpoſe to faſten them.

TACKLE (*Cycl.*)—*Burton*-TACKLE, in a ſhip. See the article BURTON.

Gunners-TACKLE, in a ſhip, that which ſerves to hale the ordnance in or out.

Winding-TACKLE, in a ſhip, a *Tackle* that ſerves as a pennant, with a great double block and three ſhivers in each, ſeized faſt to the end of a ſmall cable about the head of the maſt; it has a guy brought to it from the fore-maſt. Into this block is reeved a hawſer, which is alſo reeved through another double block, having a ſtrap at its end; which being put through the eye of the ſlings, is locked into it with a fidd, in order to hoiſt in goods.

The fall of this *Tackle* is reeved into a ſnatch-block, and ſo is brought to the capſtan, whereby the goods are heaved.

TACOMAR-*Tree*, a name by which ſome authors call the ſugar-cane. *Marggrave*, p. 829.

TADPOLE. The animal called by this name is no other than the frog in its firſt ſtate from the ſpawn; and this creature furniſhes the curious in microſcopic obſervations with a beautiful view of the circulation of the blood, eſpecially when young. See Tab. of Microſcopical Objects, Claſs 1.

The method of procuring them for this purpoſe in the greateſt perfection, is this: Let a ſmall quantity of frog's ſpawn be kept for ſome days in water, and from this will be produced a vaſt number of young *Tadpoles*; theſe, while very young, are perfectly tranſparent, and when placed before the double microſcope, the heart may be eaſily ſeen, and its pulſation regularly obſerved; and the blood protruded thence may be beautifully ſeen circulating through the whole body; but particularly in the tail, where tho' ſo very minute, more than fifty veſſels may be ſeen at one view. The young brood grow more and more opake every hour, and in a day or two the circulation of the blood can only be ſeen in their tail, or in the fins near the head. *Baker*'s Microſcope, p. 126.

TADOMA, in zoology, a name given by many authors to a ſpecies of duck, called by others *vulpanſer*, and in Engliſh the *ſhell-drake*, or *burrow-duck*; and by ſome the *bergander*.

It is of a middle ſize between the duck and gooſe; its beak is broad, ſhort, and red; and at the origin of the upper chap there is a large red tubercle of fleſh. The head and upper part of the neck are of a mixed blackiſh and greeniſh colour, very gloſſy and ſhining; the reſt of the neck is white; the breaſt and ſhoulders are of an orange-colour, which makes a ſort of ring ſurrounding the whole anterior part of the body. The lower part of the breaſt and belly have a black broad line reaching to the anus; the reſt of the breaſt and belly are white; as are alſo the under ſides of the wings, but juſt below the tail there is a faint caſt of the orange colour. The middle of its back is white. The ſhoulder-feathers falling on each ſides of the back are black, and the wings are almoſt wholly white, only ſome of the longer feathers are black. The tips of moſt of the tail-feathers are alſo black. Its legs and feet are of a pale red, and their inveſtient ſkin ſo thin, that the veins may be ſeen under it. They are common on the coaſts of Lancaſhire, and build in deſerted rabbit-holes; but their fleſh is not well taſted. *Ray*'s Ornithol. p. 279.

TÆDA, in pharmacy, a term uſed by ſome authors to expreſs certain compoſitions made up in form of troches. Theſe are ſometimes meant as peſſaries to be introduced into the vagina, and therefore made into this form; ſometimes they are compoſitions of fragrant or other ingredients for fumigations.

TÆDA, in botany, a name given by ſome authors to the pinaſter or common wild pine or mountain pine. *J. Bauhin*, Vol. 1. p. 253.

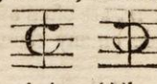
TAEL, an Eaſt-Indian weight, being the ſixteenth part of a *cati*. See the article BAHAR.

TÆNARIA, Ταιναρια, in antiquity, a feſtival in honour of Neptune, ſurnamed *Tænarius*, from *Tænarus* a promontory in Laconia, where he had a temple. *Potter*, Archæol. Græc. T. 1. p. 432.

TÆNARIUM *Marmor*, the name of a marble uſed by the antient architects and ſtatuaries. There were two kinds of it, very different in colour, but perfectly agreeing in hardneſs, and in the high poliſh they were capable of. The firſt or moſt frequent kind was black, and was dug from the promontory called *Tænarus*, in the Lacedæmonian ſtate; the other, which was more ſcarce, and much more beautiful, was of a green colour with a caſt of yellow; this was dug in the Tagetan quarries, and was called by ſome *marmor herboſum*, and *xanthon*. *Strabo*.

TÆNIA, (*Cycl.*) in ichthyography, the name of a fiſh of the anguilliform, or eel-ſhaped kind, common in the Mediterranean ſea, and brought to market in Italy, and elſewhere.

It is a very remarkable little fiſh, being of a pale fleſh colour with a ſlight admixture of blue, and is free from ſcales; and its fleſh ſo tranſparent, that the vertebræ of the back may be eaſily counted through it. Its body terminates in a long and very ſlender tail. The mouth is ſmall, and has one row of ſharp teeth in each jaw, and is very ſingular in that the belly-fin is twice as wide as the back one; and runs ſo far up to the head, that the anus which is ſituated at its termination, is very near the angle of the under jaw. The inteſtines are all covered with a ſilvery peritonæum, which is ſeen alſo plainly through the fleſh. It is commonly of a foot long, and not more than a finger's breadth. *Willughby*'s Hiſt. Piſc. p. 116.



There are two other ſpecies of this fiſh. See the articles FALX, and CAVIRAGO.

TÆNIA *Cornuta*, the *horned Tænia*, in ichthyology, a name given by many authors, to the ſpecies of cobitis, named by Artedi, the cobitis with a forked prickle placed under each eye. This fiſh is properly a ſpecies of the cobitis. *Schonfeldt* Hiſt. Piſc. See the article COBITIS.

TAGETES, *African Marygold*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the radiated kind: Its diſk is compoſed of floſcules divided into ſeveral ſegments, and its outer edge of ſemifloſcules; all ſtanding on embryo ſeeds, and contained in a one-leaved cup of a tabulated form. The embryos finally become ſeeds of an angular form, furniſhed with a foliaceous head, and affixed to the thalamus of the flower. There are alſo ſome ſpecies in which the flower is wholly compoſed of ſemifloſcules.

The ſpecies of *Tagetes*, enumerated by Mr. Tournefort, are theſe: 1. The great upright *Tagetes*, with ſingle pale yellow flowers. 2. The great upright *Tagetes*, with very large double flowers. 3. The ſmaller Indian *Tagetes*, with a ſingle flower, commonly called the ſingle African, or French marygold. 4. The ſmaller Indian *Tagetes*, with double flowers. 5. The ſmall Indian *Tagetes*, with a double reddiſh yellow flower. 6. The middle-ſized Indian *Tagetes*, with a double yellow flower. 7. The Indian *Tagetes*, with a ſingle fiſtulous flower. 8. The Indian *Tagetes*, with a double fiſtulous flower. 9. The leaſt Indian *Tagetes*, with a velvety flower. 10. The *Tagetes*, with extremely finely divided leaves. *Tourn.* Inſt. p. 488.

We have a great many ſpecies of this plant annually raiſed in our gardens, for the beauty of their flowers. They are propagated by ſowing the ſeeds in ſpring, on a moderately hot bed; when the young plants come up, they muſt have air allowed them; and when three inches high, they ſhould be removed to another hot bed, which ſhould be arched over with hoops that it may be ſheltered with mats. They are to be planted here at about eight inches diſtance, and when they are grown ſtronger, as about the beginning of May, they are to be taken up with a ball of earth about their roots, and placed where they are to remain; or elſe at eighteen inches diſtance in a nurſery, where when they flower the fineſt ſorts may be marked and removed, with a large ball of earth to their roots, either into pots, or into the borders of the flower-garden. They are very beautiful; but their ſmell is very offenſive. *Miller*'s Gardener's Dict.

TAGLIATO, in the Italian muſic, is uſed for a meaſure called by the French *Barré*; that is, when the character of common time is thus marked  with a pependicular line drawn down through its middle. It ſignifies a pretty quick motion, and contains a breve, or its quantity in ſmaller notes, in each bar. Hence it is called *Alla breve*.

TAJACU, in zoology, the name of an animal common in ſome parts of America, and called by many authors *aper moſchiferus*, or the muſk-boar.

It is of the ſhape of our hog, but much ſmaller, and has no tail, and its head is broader, and the ſnout much leſs pointed than in our hog; the neck is ſhort and thick, and the whole body of a griſly colour or mixture of black and grey. Its body is covered with hairs, much thicker and ſtronger than our hogs briſtles, ſomething like the briſtles of the hedgehog, and like them alſo variegated with circles of black and white; theſe are four or five fingers breadth long on the back, and gradually diminiſh to the ſides; on the middle of its head between the ears it has a ſort of creſt, made up of black briſtles; its ears are ſmall and erect. and its eyes ſmall; its ſnout, feet and hoofs, are juſt like thoſe of the European hog; but the two poſterior or exterior hoofs are longer than in any other of the cloven-footed beaſts.

What is moſt ſingular however, in this creature, is a certain gland which he has upon the back, and which has given occaſion to ſome to ſay its navel was placed there. This gland is ſituated on the very ridge of the back near the rump, and is ſo cloſely covered with long briſtles, that till they are removed by blowing, and keeping them back with the hand, the gland is not to be ſeen; when theſe are removed there is ſeen a ſpot almoſt naked, in the middle of which the top of the gland is ſeen; the lips of this gland uſually ſtand a little way above the fleſh, and its aperture eaſily admits a large ſtylus; and this gland, when lightly preſſed, ſpews out a liquid ſubſtance of a browniſh yellow colour, and very ſweet ſcent, ſomething like that of muſk or civet. The gland itſelf is placed between the ſkin and fleſh, and is not wholly covered by its conſtringing muſcle, but only ſurrounded by it at its bottom. *Ray*'s Syn. Quad. p. 120.

TAIIBI, in zoology, the name of an American animal, deſcribed by Marggrave and other authors, and ſuppoſed by ſome to be only the male of the Opoſſum. The Portugueſe in America call it the *Cachorro de mato*, and by the Dutch it is called *Boſchratte*.

Its body is long, its head ſhaped like that of a fox, its noſe ſharp, and it has whiſkers like thoſe of a cat; its eyes are black and prominent, and its ears roundiſh, ſoft, tender, and white. The tail near its inſertion has white hairs, and toward the extremity black ones, and near the end is naked of hair, having a ſkin like that of a ſnake over it. *Ray*'s Syn. Quad. p. 183.

TAIL (*Cycl.*)—TAILS *of Fiſhes*. This part in the fiſh kind is the ſubject of very great diſtinctions, among the characters of the ſeveral genera. It differs in the ſeveral kinds of fiſh in a very obvious manner, in number, ſituation, and figure.

In regard to the firſt difference, the *acus lumbriciformis*, and one of the kinds of the *ſerpens marinus*, have no *Tail* at all; in all other fiſhes there is a *Tail*, and it is never more than one on each fiſh.

In regard to ſituation, there is this great difference, that in ſome it is placed perpendicularly, in others horizontally. In almoſt all the known fiſhes it is placed perpendicularly, except in the dolphin, the phocæna, the orea, the manati, and all the whale kinds; for in all theſe it is placed horizontally, when the body is laid in its natural poſture.

In figure it has many very remarkable differences, which are of great uſe in ichthyological diſtinctions. 1. In ſome fiſh it is rounded at the end; as in the cottus, and ſome others. 2. In ſome it is cut off even as it were at the end, ſo that the whole *Tail* is a ſort of parallelogram; as in the tench, and ſome of the ſalmons. 3. In ſome fiſhes it is cuſpidated at the end, as is the caſe in the conger, the eel, and the petromyzon. 4. In others it has as it were a ſmall ſegment of a circle cut out at the end, and ſo is ſlightly hollowed out; this is the caſe in the caraſſius, and ſome of the ſalmons. 5. In many fiſh it is forked or opened into two points, making an acute angle; this is the figure of the *Tail* in the pearches, the cyprini of many kinds, &c. 6. Finally, the *Tail* is falcated in many fiſh, that is, it is of the ſhape of a creſcent; as in the ſword-fiſh, the tunny, mackrell, and the like. *Artedi*, Ichthyolog.

TAIL, in the manege. Many affirm that the dock of a horſe's *Tail* ſerves to point out his ſixth or ſeventh year; ſaying, that about the time that the black ſpeck, or eye of the bean begins to diſappear, and the cavity to be filled, the dock of the tail becomes longer, by reaſon that the vigour of the young years begins to abate; and nature has not ſtrength enough to nouriſh and keep up the joints or knots that form the dock; ſo that when the horſe is ſix years old, one of theſe joints ſlackens, and begins to fall down; and a year after, another deſcends in like manner. But this relaxation or downfalling happens ſooner in ſome than in others, according as they have been well or ill kept, with reference to feeding, houſing, and working. Accordingly we find the marks of a horſe's age, taken from his *Tail*, are ſo erroneous, that we ſee a great many jockies maintain, that the firſt joint deſcends when he is nine, and the ſecond when he is ten years old.

TAILS *of Comets*. We have an enquiry into the cauſe of the *Tails* of comets by Mr. Euler in the Mem. de l'Acad de Berlin, Tom. 2. p. 117. ſeq. He thinks there is a great Affinity between theſe *Tails*, the zodiacal light, and the aurora borealis; and that the common cauſe of them all is the action of the ſun's light, on the atmoſpheres of the comets, of the ſun, and of the earth. He ſuppoſes that the impulſe of the rays of light on the atmoſphere of comets, may drive ſome of the finer particles of that atmoſphere far beyond its limits; and that this force of impulſe combined with that of gravity towards the comet, would produce a *Tail*, which would always be in oppoſition to the ſun, if the comet did not move. But the motion of the comet in its orbit, and about an axis, muſt vary the poſition and figure of the *Tail*, giving it a curvature, and deviation from a line drawn from the center of the ſun to that of the comet; and that this deviation will be greater, as the orbit of the comet has the greater curvature, and that the motion of the comet is more rapid. It may even happen, that the velocity of the comet, in its perihelion, may be ſo great, that the force of the ſun's rays may produce a new *Tail*, before the old one can follow; in which caſe the comet might have two or more *Tails*. The poſſibility of this is confirmed by the comet of 1744, which was obſerved to have ſeveral *Tails* while it was in its perihelion. See the article ZODIACAL *Light*, and AURORA *Borealis*.

TAIPARA, in zoology, the name of a Braſilian ſpecies of peroquette. It is of the ſize of a lark, and of a pale green colour over its whole body; its tail is ſhort, not reaching beyond the tips of the wings when cloſed. Its beak is red, and its legs are grey. Near the origin of the beak it has a ſemilunar red ſpot on the head, and a yellow ſpot in the middle of each wing. It builds in the deſerted abodes of ants on trees. *Marggrave*'s Hiſt. Braſ.

TAINHA, in zoology, a name given by ſome to a ſpecies of mullet caught in the American ſeas, and more uſually called the *curema*. *Willughby*, Hiſt. Piſc. p. 277. See the article CUREMA.

TAL, a name uſed by ſome writers on the materia medica to expreſs the dung of peacocks; and by ſome of the chemical writers, for any alkali ſalt.

TALA, in botany, a name by which ſome authors call the plant whoſe ſeed is the ſeſamum or oily purging grain of the ſhops. *Herm.* Muſ. Zeyl. p. 58.

TALABONG, in natural hiſtory, a name given by the inhabitants of the Philippine Iſlands to a ſpecies of heron, common among them; which is much ſmaller than our heron, and perfectly white all over.

TALÆDITES, Ταλαιδιτης, in antiquity, gymnical exerciſes in honour of Jupiter ταλαιος. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 432.

TALARIUS *Ludus*, among the Romans, a game ſomewhat reſembling our dice-playing, and performed with a kind of gold or ivory dice, which they ſhook as we do in a box, before they threw them. There was this difference, however, between their game and ours, that our dice have ſix ſides, becauſe they are cubical; but theirs had but four, and were conically ſhaped. They made uſe of them for divination, as well as playing; and they concluded upon a good or evil augury, according to what came up. As they uſually threw four of them at a time, the beſt chance was when four different ſides came up. The ſides were called by the name of ſome animal, as the dog, vulture, baſiliſk, *&c.* Or of ſome deity, as Venus, Hercules, *&c.* Some authors have been of opinion, that they were marked with the forms of animals, or images of Gods, and not with numbers or dots, as our dice are. *Danet.* in voc.

TALASSIO, among the Romans, an acclamation uſed at marriages; for the origin of which ſee *Pitiſc.* and *Danet* in voc. and *Livy* 1. 9.

TALC, (*Cycl.*) in natural hiſtory, the name of a large claſs of foſſile bodies. See Tab. of Foſſils, Claſſ. 1.

The *Tales* in general are defined to be foſſils, compoſed of broad, flat, and ſmooth laminæ or plates, laid evenly and regularly on one another; eaſily fiſſile, according to the ſite of theſe plates, but not all ſo in any other direction; flexile and elaſtic; bright, ſhining, and tranſparent; not giving fire with ſteel, nor fermenting with acid menſtrua, and ſuſtaining the force of a violent fire without calcining.

By theſe characters, the *Talcs* may be diſtinguiſhed from all other bodies which reſemble them; and, according to their ſeveral natural and eſſential differences among one another, they are themſelves divided into two ſeparate orders, and under thoſe into four genera.

The *Talcs* of the firſt order are thoſe compoſed of plates of great extent, each making ſingly the whole horizontal ſurface of the maſs.

Thoſe of the ſecond order are thoſe compoſed of ſmall plates, in form of ſpangles, irregularly diſpoſed, and uſually many of them concurring in different directions, to the formation of one of the ſurfaces of the maſs. *Hill*'s Hiſt. of Foſſ. p. 71.

The genera of the firſt order are two: The firſt is of thoſe compoſed of viſibly ſeparate plates of extreme thinneſs, and each fiſſile again into a number of others yet finer. The *Talcs* of this genus are called *ſpeculares*.

The ſecond genus is of thoſe which are compoſed of ſeparate plates of conſiderable thickneſs, and thoſe not fiſſile into any thinner. The *Talcs* of this genus are called *hyalinæ*.

The genera of the ſecond order are alſo two. The firſt is of thoſe compoſed of ſmall plates, in form of ſpangles, each fiſſile into many yet finer and thinner ones. The *Talcs* of this genus are called *bractearia*.

The ſecond genus is of thoſe compoſed of ſmall plates in form of ſpangles, which are moderately thick, and are either not fiſſile at all, or are only ſo to a certain degree, or into a ſmall number of others yet thick ones, and thoſe no farther fiſſile. The *Talcs* of this laſt genus are called *elaſmides*.

Authors have hitherto been uſed to call alſo another ſet of bodies by the name of *Talcs*, with the addition of the adjective *fibroſe*; but as theſe are found not at all of the nature of the true *Talcs*, they are now diſtinguiſhed by the name *fibrariæ*. See the article FIBRARIÆ.

Authors are divided as to the origin of the word *Talc*. Lemery derives it from the High-Dutch *Talch*, tallow, becauſe it feels greaſy. But this is improbable; ſince Aviſenna, who had no commerce with the Germans, uſes the word, and tell us, that the aſter of Lemnos is *Tallz*, which cannot be calcined but with the moſt intenſe fire, and which is dangerous when taken inwardly. Its origin therefore, according to Mr. Pott, ſeems rather *Arabic*. Cæſalpinus tells us, that *Talc*, among the Moors, ſignifies *ſtar*, and that they underſtand thereby the *ſtella ſamia*. Johnſon alſo ſays the word is Arabic, ſignifying ſmall ſhining ſtars. This term does not occur among the antients, as Theophraſtus, Dioſcorides, or Pliny; tho' ſome critics pretend that Dioſcorides deſigned it by *ſtella terræ*. Cæſalpinus and Salmaſius endeavour to prove that *Talc* is the *aphroſelene* or *ſelenites* of Dioſcorides. Thoſe authors alſo pretend that Pliny meant the ſame thing by *ſchiſtus*. Cæſalpinus refers *Talc* to the *galeucos argyrodamanti ſimilis*; and Bœtius to the *argyrodamas* itſelf. Some think that a paſſage in Pliny, Lib. xxxvi. c. 22. may be underſtood of *Talc*. Aviſenna call it *lapis lunæ*; and Albertus Magnus, *aphroſelene*. The moſt common ſpecies in Germany is called *katzen-ſilver*, or *katzen-glimmer*. It is alſo named from a particular place where it is found, *Kiphauſer-glantz*. When it is of a yellow colour, they call it *katzen-gold*, and in Latin, *mica*, and *chærile nitidum*. In ſome places it is alſo called *ſper-glaſs*. *Pott.* in Mem. de l'Acad. de Berlin.

Talc is often confounded with ſimilar concretions, as with the *ſchiſtus* or *lapis foſſilis*, with the *ſpathum* or *ſpatum*, and *gypſum*, Muſcovy-glaſs, or *glacies-Mariæ*, and the *lapis ſpecularis*. Boyle takes it for an alkaline ſpathum, and others for other ſubſtances, from which nevertheleſs it differs. See *Pott.* in Mem. de l'Acad. de Berlin, 1746.

The repeated experiments of the chemiſts, who expect great things from an oil of *Talc*, have abundantly proved that this ſubſtance is indiſſoluble both in acids and alkalies in a liquid, form; and the moſt violent corroſive mineral acids, ſuch as ſpirit of nitre and aqua-fortis, and the like, make no change in it. Mr. Du Hammel, in his *topiarium hermeticum*, indeed ſpeaks very largely of a ſolution of *Talc* made by means of a long trituration in water alone: This, he ſays, in ſix hours will reduce *Talc* into an unctuous or oily fluid. And in the Commercium Literarium for the year 1732, there is a paper in which it is affirmed, that *Talc* may be in part diſſolved by the mineral acids, particularly by ſpirit of ſalt; and that the diſſolved *Talc* may be afterwards precipitated from the menſtruum; but, in reality, neither the fuming ſpirit of ſalt, nor the purer acid of ſalt, dried by a repeated ſolution and ſublimation, with ſublimate Mercury, exerts the leaſt effect upon this refractory ſubſtance. It has been alſo ſaid, in the Memoirs of the Paris Academy, that *Talc* and oil of vitriol produce alum; but neither is this found true on experiment; much leſs is any ſolution of *Talc* to be expected from the volatile ſpirit of vitriol, the ſpirit of naphtha, or oil of wine, ſo much recommended by ſome of the chemiſts for this purpoſe. The greater part of theſe pretences are abſolute frauds, intended only to impoſe on credulous perſons, who expect great matters from an oil of *Talc*; the others are probably owing to the error of taking other foliated bodies for *Talc*, ſuch as the plated ſpars, which eaſily ſplit into flakes like *Talc*, and are ſoluble in any acid.

The burning *Talc* and ſulphur together does not advance any thing

thing farther toward a ſolution of the *Talc*: Even after repeated trials of this, the *Talc* is only changed to a ſort of aſh-colour, which is owing to the impurity of the earth contained in the ſulphur. This is to be underſtood of the pure and genuine *Talc*, ſuch as that of Muſcovy, commonly called iſinglaſs; for the black and yellow kinds of *Talc*, after repeated calcinations, will be finally diſſolv'd in concentrated aqua-regalis, or in very ſtrong ſpirit of ſalt, into a yellow liquor reſembling the ſolutions of gold. This colour, in the ſolution, has given ſome perſons idle notions of its containing gold or ſolar ſulphurs, as they expreſs themſelves; but an accurate examination ſhews, that this colour is only owing to ſome attenuated particles of iron; and upon evaporation of the ſolution, there remains a mere crocus martis. If freſh aqua regalis be continued to be poured on this yellow *Talc*, it will draw ſtill more of a yellow tincture from it, till the remaining matter be perfectly white, retaining no remains of its golden appearance.

Common fire has very little efficacy upon *Talc*, it neither making it crepitate, nor melt, nor reducing it to the condition of gypſum or lime: All the change it can make in it, is the rendering it in fine ſomewhat more brittle, and in part deſtroying its foliated ſtructure. It ſuffers no diminution all this time in weight, and is as bright and lucid, and as unctuous to the touch afterwards as before. Angelus Sala had *Talc* kept forty days in a glaſs-houſe fire, and at the end of that time took it out unaltered: But according to the experiments of Neuman and Hoffman, the ſolar fire, concentrated by powerful burning-glaſſes, melts this ſtubborn ſubſtance into a greyiſh kind of glaſs. Thus we may eaſily conclude, that when Morhoff and the great Boyle talk of reducing *Talc* into a kind of gypſum in a common fire, in the ſpace of an hour, they deceived themſelves, and uſed ſome other ſubſtance which had the appearance of *Talc*, but was not ſo; ſuch is the plated ſelenites, which cannot be diſtinguiſhed from the pureſt iſinglaſs, till it is tried, by bending its ſeparated plates, theſe being not at all elaſtic, as thoſe of *Talc* are.

The action of ſalts rendered fluid by fire is much more powerful upon *Talc* than any of theſe before-mentioned ſubſtances; but to this purpoſe the fire muſt be very violent, the common fire of fuſion producing nothing; hence it is, that authors in general have not found the effect of this proceſs; for they affirm that *Talc*, in a ſtrong fire, mixed with three times its own quantity of a fuſile ſalt, ſuffers nothing, but renders the ſame appearances afterwards as before. Neuman alſo affirms, that he had uſed nitre, borax, and the corroſive ſalts in the ſame manner, without the leaſt ſucceſs: But Mr. Pott gives a different account of ſuch proceſſes, which he tried not with the common fire of fuſion, but with the higheſt degree he was able to give.

In his trials with this violent heat, *Talc*, fated with a ſolution of a cauſtic alkali, run into a lax and ſpungy maſs. Mixed with half its quantity of a purified alkaline ſalt, it run into an opake and blackiſh maſs. *Talc* calcined in a common furnace, and then mixed with half its weight of an alkali, melted and run into a hard and ſtony maſs of a browniſh black, which was capable of the fine poliſh of an agate; and on repeating the ſame experiment afterwards, the maſs produced by it was of the ſame hardneſs and denſity, but perfectly white as alabaſter; the colour was in many other trials found to be in great meaſure owing to the cleanneſs of the crucible, and to its containing no ferrugineous or other metalline or mineral matter. Kunkell has before obſerved, that *Talc* mixed with ſalt of tartar, and with fritt, and put into the fire, eaſily runs into glaſs with the fritt, without any greater degree of fire than what is always uſed on this occaſion: But Mr. Pott obſerves that *Talc*, with an equal quantity of hepar ſulphuris, does not run into a compact maſs, but riſes in foam and ſpume to the top of the crucible, and acquires a yellow colour, and the mixture afterwards ſuffers the greateſt fire that common *Talc* can bear, unhurt. *Talc* does not detonate with nitre, becauſe it contains no ſulphur, but they afterwards vitrify together in a violent fire; and this has been before obſerved in the German ephemerides. *Talc*, mixed with an equal portion of fixed arſenic, runs into a white hard maſs; and with double its quantity of Glauber's ſalt, it does not diſſolve, but only becomes a white friable maſs, yellowiſh on the ſurface. *Talc*, with equal parts of borax, runs in a violent fire into a tranſparent maſs, reſembling the gem called the *aqua marina*; and melted with different mixtures of borax, nitre, and arſenic, it runs into vitreous maſſes, of many different degrees of colour.

Talc is uſed with great ſucceſs in the diſtillation of acid ſpirits; that of ſalt is always naturally impure, and can ſcarce be rendered pure but by an admixture of a *talcy* earth in the retort.

The mixture of *Talc* with different kinds and quantities of glaſs, may be ſucceſsfully performed with a violent fire, but not with a ſmaller degree: Thus three parts of *Talc* with one part of cryſtalline glaſs, make only a ſpongy and friable maſs in a common fire; but in a more violent one they become a firm and ſolid maſs of a brown colour. Minium, or glaſs of lead, mixed in equal quantities with *Talc*, and ſet in a violent fire, run into a yellowiſh glaſs reſembling the opake pieces of amber; and two parts of minium to one of *Talc*, produce a clear and tranſparent yellow glaſs, which is of a hardneſs capable of giving fire with ſteel. The alkaline earths, mixed with *Talc*, produce a maſs ſcarce vitrifiable by any fire: Hence appears the reaſon why copels made of lime and *Talc* are ſo very hard to vitrify. Minium added to theſe mixtures makes them combine into a firm maſs, but without perfect fuſion; but borax added to them melts them readily into a true glaſs. The gypſous earths mixed with *Talc*, will not unite into a maſs in any degree of fire; but if borax be added, the *Talc* readily melts. Thus two parts of *Talc*, two parts of that ſpar or gypſous matter called *glacies mariæ*, or the common plated ſpar, with one part of borax, run into a yellow maſs reſembling a topaz.

The argillaceous earths do not vitrify with *Talc*, but they run into a maſs of great hardneſs, which will give fire with ſteel, and is very ſerviceable to make crucibles of, theſe veſſels not ſuffering the glaſs of lead to run thro' them. *Talc*, joined with the vitrifiable ſtones, forms no remarkable body, but the maſs remains friable; but from theſe maſſes, by the addition of proper matters to render them fluid, great variety of elegant compounds may be made. Thus *Talc* mixed in equal quantities with powder of flints, on adding to the whole a fourth part of cryſtal glaſs, the whole unites into an opake but ſolid white maſs. Alkali ſalt added in equal quantity to *Talc* and flint, gives a tranſparent yellow glaſs; and white ſand, *Talc*, and a fixed alkali, in equal quantities, afford a green glaſs; with other mixtures of this kind, in different quantities, the reſemblances of many beautiful ſtones are produced; and what is very remarkable, ſome grains of metalline matter are often found on the ſurface of the maſſes.

Cæſalpinus, Aldrovand, and ſome others affirm, that *Talc* melted with copper, or added to copper, while in fuſion, gave it a white colour; this being taken for granted, authors have hence agreed that *Talc* contains an arſenical earth. But experiment ſhews this to have been a falſe aſſertion, in regard to *Talc*; and probably it only owes its origin to the cant language of ſome of the alchemiſts, who have called the flowers of zink, *Talc*; tho' theſe alone muſt render copper yellow, not white. Antimony and *Talc*, firſt calcined with nitre, run in a violent fire into a ſort of flint, which will give fire with ſteel. With regulus of antimony and the black flux, it runs into a black maſs; and with biſmuth it calcines into a grey powder. So little is there in the propoſals of the chemiſts for the metallization of *Talc* by antimony and biſmuth. Mem. de l'Acad. de Berlin, Ann. 1746.

In what part of Mr. Boyle's works the learned author from whom the foregoing extract was taken, has found that *Talc* may be reduced by common fire to a gypſum in an hour, we know not; but we find that Mr. Boyle ſays, that the calcination of *Talc* is ſo very difficult, that eminent chemiſts have looked upon calxes of *Talc* as counterfeits. Works abr. vol. 1. p. 160.

Mr. Boyle mentions the extracting of gold from *Talc*, as having ſometimes ſucceeded. See Works abr. vol. 1. p. 160. but *vide ſupra*.

The mountains in Hungary and Germany many of them abound in the Muſcovy *Talc*, not inferior to the *Talc* of that country from whence it has its name. The mountain of Cliſſuro, which is a part of mount Hæmus, as alſo mount Pyrlipe, ſhine like ſilver in all parts both day and night, provided there be any moon.

The *Talc* in theſe hills is the only occaſion of this. There are alſo *Talc* rocks near Spittal in Upper Carinthia; and many other hills are ſaid alſo to contain great quantities of it; but there is a ſort of ſelenites ſo very like this *Talc*, that people are eaſily deceived by its appearance. This ſelenites ſplits into flakes like the *Talc*, but they are brittle. *Brown*'s Travels.

Mexico TALC. There is a famous cave ſome leagues from Mexico, on the north-weſt ſide of the city, beyond the lake, the top and ſides of which are ſaid to be lined with leaf gold; but that of ſuch a kind, that the common methods of fluxing the ores have no effect upon it. The Spaniards, after many trials, have given it over, but are ſtill perſuaded by the Indians that it is gold, and that the famous Montezuma obtained a great part of his treaſures from this cave. The leaves, as they are called, are no more than ſpangles of the ſize of a man's nail; and the account we have of it in the Philoſophical Tranſactions, and the various methods attempted in vain to reduce it to metal, abundantly prove that it is only a yellow *Talc*. Vid. Phil. Tranſ. N°. 39.

Muſcovy TALC, a kind of foliaceous body, well known by the Engliſh name of iſinglaſs. See the article SPECULARIS *Lapis*.

Philoſophic TALC, a name given by ſome of the chemical writers to the flowers of zink.

This ſubſtance, diſſolved in vinegar, affords what they have in their unintelligible language called, oil of *Talc*, and extolled as a thing of vaſt power in the fixing of Mercury, and many other imaginary operations; and beſide this, they call it a ſovereign remedy for all diſeaſes.

The chemiſts of after ages, ſeeing ſuch prodigious effects aſcribed to oil of *Talc*, and not conceiving that *Talc* was a mere

mere cant word in this place, have been at infinite pains, by means of a thouſand differently varied menſtruums, to obtain an oil from the common Venetian *Talc*, a dry ſtone which in a very remarkable manner reſiſts the force of all menſtrua, and of fire; and from which therefore no oil can be obtained. In the various operations uſed to this purpoſe, ſome have really hit upon liquors of a conſiderable power; but that power has been wholly owing to the menſtruums they employed, not to the ſtone; and even if it were, could have none of the effects of the oil of *Talc*, mentioned by theſe dark writers, who meant by it ſo very different a ſubſtance as a ſolution of theſe flowers, which are only, that till of late little underſtood metal, zink, in another form. See *Oil of* TALC, infra.

Venetian TALC, in the materia medica, the name of a foſſile ſubſtance famous among the chemiſts for the great things they have expected from the oil of it, if that could ever have been obtained; and among the ladies of Italy, and the neighbouring nations, as a coſmetic, when reduced to an impalpable powder after repeated calcinations, by levigating on a porphiry.

It is of an extremely irregular, though in ſome degree plated or foliaceous texture, and is remarkably ſmooth and ſoft to the touch, of a lax and ſomewhat crumbly texture; the ſeveral moleculæ it is compoſed of cohering but ſlightly, either in themſelves, or with one another. It is of ſeveral ſizes, from one inch to five or ſix in diameter; and in colour, of a pale ſilvery grey, with a large admixture of green. In many of the coarſer parts of this ſubſtance, it may be obſerved to have a great analogy with the common French chalk, or morochthus. It is dug in ſeveral parts of Italy, and is brought to us principally from Venice, whence it has its name. *Hill*'s Hiſt. of Foſſ. p. 76.

Oil of TALC, the name of a ſubſtance, which has given great trouble to the chemiſts of later ages.

It had been recorded by ſome old writers, that oil of *Talc* had the power of fixing ſilver, that is, giving it the weight and tenacity of gold, ſo that it ſhould no longer be diſtinguiſhable as ſilver, nor ſoluble in aqua fortis, but only in aqua regia, as gold. This was all idle and imaginary, no known ſubſtance having any ſuch power. Our chemiſts of later times, ſuppoſing this oil was to be obtained from Venetian *Talc*, a common flaky ſtone, have tortured it a thouſand ways to extract this divine liquor from it, but in vain; for unhappily this is a ſtone remarkable beyond almoſt all other bodies, for ſuffering almoſt nothing by any menſtruum, nor even by fire itſelf. Some have however compounded liquors with the pompous names of oil of *Talc*, from their preparations of this ſtone; but theſe have owed all their qualities to the menſtruums employed in making them, not at all to the ſtone; nor indeed had they owed them to that, would they have had any relation to the oil of *Talc* they were ſeeking after. The inventors of that barbarous term having never thought of Venetian *Talc*, or any other ſtone under the name of *Talc*; but given that name to the fibroſe and cottony flowers of Zink, which in ſome degree reſemble the diſunited filaments of the fribrariæ, or, as they are called by the vulgar, fibroſe *Talc*.

When zink is diſſolved in diſtilled vinegar, and the ſolution diſtilled again in a cucurbit, there is firſt drawn over an inſipid phlegm; after this there ariſe ſome fibroſe white flowers; and finally theſe melt down into a ſulphureous liquor, which is inflammable like ſpirit of wine. This being poured into a phial of water mixes with it, only leaving a few drops of a fragrant and aromatic oil ſwimming on the ſurface; this floating liquid is the ſo famed oil of *Talc*; but this is properly no preparation of zink, or its flowers, but merely the eſſential oil of the vinegar employed in the ſolution; and it is eaſy to conclude from this, that this ſo famed liquor can poſſibly have no title to any of the wondrous qualities aſcribed to it. Mem. Acad. Scienc. Par.

TALED, in the Jewiſh antiquities, a ſort of habit that the Jews wore, chiefly when they repeated their prayers in the ſynagogue. *Numbers* xv. 38. *Deuteronomy* xxii. 12.

It ſerved inſtead of that ſquare garment they wore heretofore, to which Moſes had appointed that they ſhould faſten borders of blue to the four quarters, and fringes or ribbands all along the borders. But at preſent, that they may not be expoſed to the laughter of the people for the too great ſingularity of their dreſs, they content themſelves with wearing a ſquare piece of cloth underneath, with four tufts at the four corners, and when they meet in the ſynagogue to ſay their prayers, they cover their heads with a ſquare woollen veil, which has four tufts at its four corners. It is this they call *Thaled*, or *Taled*. *Calmet* Dict. & *Leo of Modena*, Ceremonies of the Jews, P. I. ch. 5, 11.

TALLY (*Cycl.*)—TALLY *the Sheets*, at ſea, a word of command, when the ſheets of a main-ſail, or fore-ſail are to be haled aft. See the article SHEETS.

TALPA, (*Cycl.*) the *Mole*, in the Linnæan ſyſtem of zoology, makes a diſtinct genus of animals; the characters of which are, that they have feet with five claws on each, as well on thoſe behind as on thoſe before; and have their fore-feet made like hands, and fitted for digging. *Linnæi* Syſt. Nat. p. 37.

This, though a very common animal, is very little obſerved by the generality of the world. Its fur is very ſhort, ſoft and thick. Its noſe is like that of a hog; and its teeth like thoſe of the *mus araneus*, being ſingle and eminent on the ſides of the upper jaw, and thoſe farther within the mouth armed with many points. It has ſcarce any neck, its head ſeeming ſet between its ſhoulders. Its legs are very ſhort, its claws very ſharp, and its toes five in number on each foot; the inner part or ſole of the fore-feet is very broad, and much reſembles the palm of the human hand. Its claws on theſe are more robuſt and ſtrong, than in any other animal of its ſize: The whole feet and toes are not placed downward but ſideways, for the ſake of the creature's continual employment in digging, it being properly a ſubterranean animal. Its tail is ſhort, and hairy.

It has been ſuppoſed by many, that the *Mole* had no eyes; and others have affirmed, that it had eyes, but that they were covered with a membrane; but neither of theſe aſſertions are true. The eyes are ſmall, and have apertures in the ſkin, through which they may eaſily be diſcerned by a curious obſerver; and are very black, about the ſize of a millet-ſeed, and faſtened to a nerve.

The reaſon they have not been obſerved by the common people, is, that they are hid by the fur; but, on blowing that away, they always ſhew themſelves. It has no ears.

Its ſkin is extremely firm and tough, ſo that it requires a ſharp knife to pierce it.

This ſeems the care of nature to defend the creature from the cold; and the fineneſs of the fur, that is, the ſmallneſs of every hair, ſeems proportioned to the ſmall pores they had to grow out of. *Ray*'s Syn. Quad. p. 234.

TALPA, in ſurgery, a name given by ſome authors to an encyſted tumor, ſituated under the ſcalp. *Heiſter*'s Surgery, p. 324.

TALWOOD, *Taliatura*, in our old writers, fire-wood cut and cleft into billets of a certain length: It is otherwiſe written *Talghwood*, and *Talſhide*. Stat. 34 & 35 Hen. VIII. c. 3. 7 Edw. VI. c. 7. 43 Eliz. c. 14. *Cowel*.

TAMALAPATRA, in the materia medica, a name by which ſome authors have called the *folium Indum*, or Indian leaf, uſed in medicine. *C. Bauhin*, Pinax. p. 409.

The tree which produces this leaf is one of the *Enneandria monogynia* of Linnæus; and of the *arbores fructu calyculato*, of Mr. Ray. It is a large and lofty tree, the flowers and fruit of which reſemble the cinnamon-tree. Its leaves, when full grown, are ten inches or more in length; and ſix or eight, in breadth. The flowers ſtand in cluſters, in the manner of umbels on the tops of the branches, and are of a greeniſh white colour. The fruit is of the bigneſs of our currant.

The antients recommended *Indian-leaf*, as ſtomachic, ſudorific, and cephalic. At preſent, it is utterly diſregarded, being only kept in the ſhops as an ingredient in ſeveral compoſitions. Vid. *Hill*, Hiſt. Mat. Med. p. 419. ſeq.

TAMANDUA, in natural hiſtory, a creature called in Engliſh the ant-bear; and by the Braſilians *Tamandua-guacu*.

This animal has its Engliſh name from its feeding on ants, and having its hinder feet like a bear's. It has a very long and ſharp ſnout, and its tongue is ſlender, and extenſible to a very great length; and it has a long and bruſhy tail. *De Laët*. Ind. Occ. L. 16. c. 15.

The principal food of the *Tamandua* is ants, which he catches by ſcratching open their ſubterranean hives, and thruſting his long tongue into them; when the ants are gathered in great numbers upon this, he draws it back and eats them; and this he repeats till he is ſatisfied.

His tail ſerves him for a ſort of cover; and he can, upon occaſion, ſpread it almoſt over his whole body. *Barlæus* de Reb. Braſ. p. 223.

TAMARIND, *Tamarindus*, in botany, the name of a genus of trees; the characters of which are theſe: The flower is of the roſaceous kind, and is compoſed of ſeveral petals, arranged in a circular form. The cup conſiſts of one leaf, divided into many ſegments at the edge; and from this ariſes a piſtil, which finally becomes a flat pod, containing in it another in which are ſeveral flatted and angular-ſhaped ſeeds. The interſtice between the two pods is filled up with a ſoft pulpy ſubſtance.

The only known ſpecies of this tree is that which produces the common *Tamarind*, the pulp of which is uſed in medicine. *Tourn.* Inſt. p. 660.

The characters of this genus of plants, according to Linnæus, are, that the calyx is a plain four-leaved perianthium, the leaves of an oval figure, and equal in ſize. The flower is compoſed of three petals, which are of an oval figure, ſomewhat plane and flat, but folded and gaping open; theſe are ſmaller than the leaves of the cup, and are inſerted in them, leaving a vacant ſpace at the bottom of the cup. The ſtamina are three filaments, which have their origin together in the cavity in the cup, and are pointed, and bent toward the petala of the flower. The antheræ are ſingle: The piſtil has an oval germen. The ſtyle is pointed, and bent toward the ſtamina; and its ſtigma is ſingle. The fruit is a long pod, of a compreſſed ſhape, and covered with a double ſkin

between which is the pulp; it conſiſts of only one cell. The ſeeds are angular, and of a flatted figure; and are three in each pod. *Linnæi* Gen. Plant. p. 9.

We owe the knowledge of the uſe of *Tamarinds*, in medicine, to the Arabians. The antient Greeks knew nothing of them; and Serapion, Meſue, and Avicenna, are the firſt authors who preſcribe them.

The fruit of the *Tamarind* which is what we uſe, is only the piſtil of the flower ſwelled into a pod; this is greeniſh at firſt, but grows browniſh or reddiſh, as it ripens; its common ſize is four inches in length, and one in breadth; and it is undulated on the back, and deeply notched in three or four places at the front, which is terminated by a large rib, which runs from the pedicle on which it grows, to the end of the pod, and there frequently terminates in a ſort of hook.

This fruit is, properly ſpeaking, compoſed of two pods, the one incloſed within the other; the outer pod is fleſhy, and of the twelfth of an inch in thickneſs when freſh, and the inner one is thin as a fine piece of parchment; between theſe two there is an intermediate ſpace of about a quarter of an inch all the way; and this ſpace is filled up with a very ſoft and pulpy ſubſtance, of a tart but very agreeable taſte, which is what we uſe in medicine. This is blackiſh and of a viſcous texture, and is traverſed by three large veſſels, or rather bundles of veſſels, one of which runs all along the back of the pod, and the two others are placed on the oppoſite ſide, and often there are ſeveral ramifications of veſſels, which run off different ways from theſe. Theſe veſſels carry the vinous juice, which afterwards hardens into the viſcous matter of the pulp; but this is not all their office, for they alſo convey nouriſhment to the ſeeds in the inner pod.

We uſe the *Tamarinds* only in medicine; but the Africans, and the People of many of the Oriental nations, where they are common, make them into a ſort of confect with ſugar, which they eat as a delicacy, and which cools them in the violent heats of their climates; and at the ſame time keeps their bowels in a proper ſtate of laxity. The ſour taſte of this fruit proves, that acid particles abound greatly in it, and a chemical analyſis of it gives farther proof of this. There is indeed no alkali to be obtained fom *Tamarinds*, otherwiſe than by diſtilling them in a retort with quick-lime. A ſimple analyſis of them yields no other principles but acid and ſulphur. Six pounds of *Tamarinds* mixed with ſix pints of water, will yield ſix drams of eſſential ſalt; this however requires a long time to cryſtallize, not fixing itſelf to the ſides of the veſſels under two months ſtanding; in all this time however the liquor never grows mouldy, as ſuch liquors uſually do; and it in this ſomewhat reſembles tartar, or the eſſential ſalt of grapes, which never ſeparates itſelf from their juice under a very long time. Indeed, to be aſſured of gaining all the eſſential ſalt of any plant, the liquor ought to be covered half an inch deep with oil, to prevent its ſpoiling, and ſuffered to ſtand a whole year unmoved in the ſame veſſel. The ſalt of *Tamarinds* in all things reſembles cream of tartar; it is ſharp to the taſte, and will not diſſolve in cold water. It does not detonate on the fire, nor yield any vinous ſmell, when moiſtened with oil of tartar. *Tamarinds* diſſolved alſo in common water, and ſet in digeſtion for ſeveral months, yield on diſtillation only an acid ſpirit, like that from vinegar.

It is not uncommon in thoſe places where *Tamarinds* are frequent, to find an eſſential ſalt cryſtallized on the branches of the tree, this greatly reſembles cream of tartar in all reſpects, and is no other than the genuine ſalt of the plant formed by the ſun's drying up the accidentally extravaſated juices; nor is this peculiar to this tree alone, but many others are at times found with their juices thus extravaſated, and their ſalts thus cryſtallized by the heat. The leaves of that large ſpecies of maple, which we vulgarly but improperly called the ſycamore, are often in hot ſeaſons found thus covered with cryſtals of their eſſential ſalt which is ſweet, and very much of the nature of ſugar; and the lime-trees have their leaves often covered with a like ſaccharine matter, which being waſhed off from them and the liquor given any perſon to drink, is found to have the taſte and the purgative virtue of manna. Mem. Acad. Par. 1699. See the article TAMARINDS, *Cycl.*

TAMARISCUS, the *Tamariſk-tree*, in botany, the name of a genus of trees; the characters of which are theſe. The flower is of the roſaceous kind, being compoſed of a number of petals, arranged in a circular form; the piſtil ariſes from the cup, and finally becomes a capſule, reſembling that of the willow of a long figure and membranaceous ſtructure, and containing ſeeds winged with down. *Tourn.* Inſt. p. 661.

The ſpecies of *Tamariſk*, enumerated by Mr. Tournefort, are theſe: 1. The ſhrubby thick-leaved *Tamariſk*, called the German *Tamariſk*. And, 2. The tall arboreſcent fine-leaved *Tamariſk*, called the French *Tamariſk*.

It is a very remarkable property of this tree, that its ſalt made in the way of other lixivial ſalts is no alkali, but a mere ſal ſalſus. The ſalt of guaiacum alſo approaches to the nature of this.

TAMATIA, in zoology, the name of a very ſtrange bird of the Braſils. It is of the *Gallinula*, or moor-hen kind, but very different from the European birds of that genus.

Its head is very large, its eyes large and black, its beak is two fingers breadth long, and one broad, ſhaped ſomewhat like a duck's, but pointed at the end; its upper chap is black, its under one yellow; its legs are long, and the thighs in great part naked; its toes are long; its tail is very ſhort. Its head is black, and its back and wings of a plain duſky brown. Its belly is of the ſame brown, variegated with white. See Tab. of Birds, N°. 44. *Marggrave*'s Hiſt. Braſil.

TAMBOS, in Peruvian antiquity, buildings placed at certain diſtances for the lodging of the princes of that country, in their travels through their dominions. See Mr. de la Condamine, in Mem. de l'Acad. de Berlin, Tom. 2. p. 435. who tells us (p. 438.) that he ſaw ſeveral remains of theſe *Tambos*, in his journey from Quito to Lima.

TAMNUS, in botany, the name of a genus of plants, called by the old writers *Bryonia nigra*, and from them in Engliſh black bryony.

The characters of this genus are theſe: The flower conſiſts of one leaf faſhioned like a bell, open at the mouth, and divided into ſeveral ſegments. Some of theſe are ſteril, or male flowers, having no embryo; and others fruitful or female flowers, having in their center an embryo, which afterwards becomes a berry, uſually of an oval figure, and covered with a ſort of hood of a membranaceous ſtructure; this berry is full of roundiſh ſeeds. This is a climbing plant, as well as the white bryony, but it has none of the tendrills which that has.

The ſpecies of this genus, enumerated by Mr. Tournefort, are theſe: 1. The cluſtery *black bryony*, with ſmall yellowiſh green flowers. 2. The *black bryony*, with a larger white flower. 3. The American *black bryony*, with leaves like thoſe of the citrul. *Tournefort*, Inſt. Bot. p. 102.

TAMOATA, in zoology, the name of an American freſh-water fiſh, called by the Portugueſe *Soldido*.

It is a ſmall oblong fiſh, with a flat head, ſomewhat like that of a frog. Its mouth is ſmall, and from each angle of it there hangs a long ſingle filament, by way of a beard. It has no teeth, and its eyes are extremely ſmall. It has eight fins; two at the gills of one finger in length, and hard and firm like horns; two on the belly, of a ſofter ſubſtance; and one on the middle of the back, another near the tail, and another ſmall one oppoſite to it on the belly: Its tail is the eighth. Its whole head is covered above with a hard coat like a ſhell; and its body with a ſort of coat of mail made up of oblong hard ſquammoſe bodies, dented at their edges. Its colour is a ſort of ruſty iron colour. It is accounted a very well-taſted fiſh. It lives only in freſh-water rivers; and it is ſaid, when the water where it is dries up, it will crawl out upon the land, and go in ſearch of more. See Tab. of Fiſhes, N°. 34. *Marggrave*'s Hiſt. Braſil.

TAMPOE, in natural hiſtory, the name of an Eaſt-Indian fruit, approaching to the figure of the Mangouſtan, but not near ſo agreeable to the taſte. This fruit is very much of the ſize, ſhape, and colour of ſome of our common ſummer apples; but its ſkin is very thick and tough, and it has no crown. The Indians eat it in places where better fruits are ſcarce, and in ſome places call it the Mangouſtan.

TAN (*Cycl.*)—*Flowers of* TAN. Flower of *Tan* is a name given by the people employed in the tanning-trade, to a yellow ſubſtance, often found upon old *Tan*, or oak bark broken to pieces, which has been uſed as *Tan*, and is of no farther ſervice.

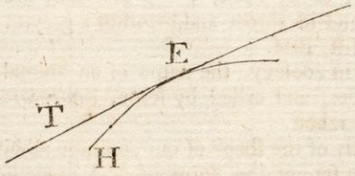
The name, however, is very improper; and though every body converſant in *Tan*-yards muſt have ſeen the thing, yet it has always paſſed as an efflorescence of the bark, till the curious Mr. Marchand enquired more accurately into its nature, and found it to be a plant of itſelf, wholly different from the matter of the *Tan*; and to which the bark which had been often wetted and dried again, ſerved as a proper matrix. He found it to be more nearly allied to the ſpunge, than to any other genus of plants, and therefore named it *ſpongia fugax mollis flava & amæna in pulvere coriario naſcens*, ſoft, beautiful, yellow fading ſpunge, growing on *Tanners* bark.

It makes its appearance moſt frequently in the ſummer months, and is then ſeen in ſmall tufts of a beautiful yellow colour, on different parts of the old heaps of bark. It appears at firſt in form of a thin yellow ſcum, and is of a ſort of jelly-like ſtructure; but it every day grows larger and thicker, till it ſtands above half an inch out from the ſurface of the bark. As it grows, its ſurface becomes more and more cavernous and ſpungy, the pores or holes being of different diameters, and the interſticial matter forming a ſort of net-work more or leſs regular, and often interrupted by irregular prominences in ſeveral parts; and, in fine, when the growth is compleat, the whole more reſembles a ſpunge, than any other vegetable ſubſtance, and is of a deep yellow colour, and conſiderably thick and tough conſiſtence; there are no roots to be diſcovered iſſuing from it; its ſmell is like that of rotten wood, and its taſte is ſomewhat ſtyptic. It always appears in the warm months, and always upon ſuch old *Tan* as has begun to ferment, and is in the ſtate in which our gardeners uſe it for hot-beds. If it happens to ſtand expoſed to the ſouth ſun, it is but of ſhort duration; but if it be in a ſheltered place, it will laſt a conſiderable time, and often ſpread itſelf to a great

extent, and make a very beautiful figure for many weeks. Mem. Acad. Par. 1727.

TANACETUM, *Tanzy*, in botany, the name of a genus of plants, the characters of which are these: The flower is of the floſculous kind, conſiſting of numerous ſmall floſcules, which are divided into many ſegments at the ends, are placed on the embryo ſeeds, and are contained in a ſort of ſcaly cup, of a ſemi-orbicular figure. The embryos ripen into ſeeds, which have no down adhering to them. To this it is to be added, that the flowers are collected into large cluſters.

The ſpecies of *Tanzy*, enumerated by Mr. Tournefort, are these: 1. The common yellow-flowered garden *Tanzy*. 2. The garden *Tanzy* with curled leaves. 3. The garden *Tanzy*, with the leaves and the ſmell of mint, called by authors, *corymbiferous mint*, and *coſtmary*. *Tourn.* Inſt. p. 461.



The leaves of the common *Tanzy*, either dried and given in decoction, or the expreſſed juice of them taken, are excellent in nephritic and hyſteric caſes. The good women in the country give the juice with great ſucceſs againſt worms, and in the colic. The infuſion of the dried plant is a remedy againſt flatulencies and colics, and is given in dropſies, and in ſuppreſſions of the menſes, and of the urine. It is pretended by ſome, that the diſtilled water deſtroys worms; but this is leſs probable.

TANGARA, in zoology, the name of a Braſilian Bird, of which there are two ſpecies: The firſt is of the ſize of the green-finch, and is of a fine ſhining ſea-green on its head and neck; and has a black ſpot on the front of the head, juſt above the inſertion of the beak; its ſhoulders are black, and the reſt of the back yellow. Its belly is of a very beautiful blue, and the wings variegated with blue and black. The tail is broad, and is variegated with blue and black. It feeds on vegetables, and is kept in cages for its beauty; where its only note is *zip*, *zip*.

The ſecond kind is of the ſize of the common ſparrow; its head is of a fine gay red, and its back, wings, and belly of a fine deep black; its thighs are covered with white feathers, and have each a large red ſpot, looking like a blotch of blood; the tail is ſhort, and the legs grey. *Marggrave*'s Hiſt. Braſil.

TANGARAC, a poiſonous Braſilian plant; but the root, ſays Piſo, is an antidote to the leaves, flowers, and fruit. *Boyle*, Works abr. vol. 1. p. 14.

TANGENT (*Cycl.*)—The definition of a *Tangent*, commonly given, is mentioned by Mr. Chambers; but it does not extend beyond the conic ſections; for in curves of higher orders a line may both touch and cut. A general definition is therefore neceſſary. As a right line is the *Tangent* of a circle, when it touches the circle ſo cloſely, that no right line can be

drawn through the point of contact between it and the arch, or within the angle of contact that is formed by them; ſo, in general, when a right line ET touches any arch of a curve, as EH in E, in ſuch a manner that no right line can be drawn through E, betwixt the right line ET and the arch EH, or within the angle of contact HET, that is formed by them, then is ET the tangent of the curve at E. *Maclaurin*'s Fluxions, Art. 181.

The *Tangent* of an arch is the right line that limits the poſition of all the ſecants that can paſs through the point of contact, though, ſtrictly ſpeaking, it is no ſecant. Ibid. Art. 505.

As to the methods of inveſtigating *Tangents* by Fluxions, ſee the ſaid treatiſe, book I. c. 7. where it is demonſtrated independently of infiniteſimals.

To determine the *Tangents* of curves, ſuppoſed to be deſcribed by the interſections of right lines revolving abour given poles. See Mr. *Maclaurin*'s Fluxions, Art. 210. ſeq.

In finding the tangents of curves by the method of infiniteſimal differences, it has been objected, that the concluſion is found by a double error. 1°. By taking the curve for a polygon of an infinite number of ſides. 2°. By the falſe rule for taking the differential of a power. But there is no need of ſuch ſuppoſitions in the method of fluxions, for it may be geometrically demonſtrated, that the fluxions of the baſe, ordinate, and curve, are in the ſame proportion to each other, as the ſides of a triangle reſpectively parallel to the baſe, ordinate, and *Tangent*. When the baſe is ſuppoſed to flow uniformly, if the curve be convex towards the baſe, the ordinate and curve increaſe with accelerated motions; but their fluxions at any term are the ſame as if the point which deſcribes the curve had proceeded uniformly from that term in the *Tangent*. Any farther increment which the ordinate or curve acquires, is to be imputed to the acceleration of the motions with which they flow. See *Maclaurin*'s Fluxions, Book. 1. chap. 7 and 8.

Any two arches of curve lines touch together, when the ſame right line is the *Tangent* of both at the ſame point. But when they are applied to each other in this manner, they never perfectly coincide, unleſs they be ſimilar arches of ſimilar and equal figures.

TANNERS *Bark*. This is a ſubſtance of prodigious uſe in gardening, and is the bark of the oak-tree chopped and ground into a ſort of coarſe powder, for the dreſſing of ſkins, after which uſe it becomes of ſervice to the gardener. Its fermentation is very laſting and very equal; hence it is the moſt valuable of all things for the making of hot-beds; and when it has ſerved to this uſe, and is thoroughly rotted, it makes a very valuable manure for land, one load of it doing as much ſervice as four loads of dung.

It has not been of very long uſe in England, and was brought to us from Holland in the reign of King William, and then uſed for the raiſing of orange-trees; but after this period it became diſuſed; and it is of a much later date that it has been brought into uſe again for the raiſing the pine-apple, ſince which time it is become generally uſed, wherever it is to be had, for all the purpoſes of the hot-bed, in raiſing tender plants.

There are ſeveral ſizes of this *tan*, and they heat in a different manner in proportion to their ſize, the ſmalleſt heating much quicker, and cooling again in a ſmaller time; and the largeſt acquiring its heat more gradually, but keeping it much longer. The ſkilful gardener therefore muſt uſe one or the other of theſe, or a mixture of both, according to the ſeveral occaſions he wants them for.

It ſhould always be taken within a fortnight after it comes out of the pit, and laid up in a round heap for a week, to drain out the moiſture; after which it ſhould be formed into a bed, and ſhould be laid at leaſt three feet thick. A hot-bed, properly prepared, of this ſubſtance, will retain a moderate heat ſix months. *Miller*'s Gardener's Dict.

TANNING (*Cycl.*)—The operation of *Tanning* is performed, on leather, better in the Weſt Indies than in England. They uſe three ſorts of bark, the mangrave bark, the olive bark, and another; and the whole buſineſs is ſo ſoon done, that a hide delivered to them is in ſix weeks ready to be worked into ſhoes, though they beſtow leſs labour than we do. Phil. Tranſ. N°. 36.

Every part of the oak-tree, of what age or growth ſoever, is fit for the tanners uſe, and all oaken coppice-wood, of any age or ſize, being cut and procured in barking-time, will tan all ſorts of leather, at leaſt as well as the bark alone. When this material is got at the proper ſeaſon, it muſt be very well dried in the ſun, more than the bark alone; thence it is to be cut up, and preſerved in a covered place for uſe.

When it is to be uſed, the greater wood muſt be firſt cleft ſmall, to fit it for the beating and cutting engine; and the ſmaller muſt be put into the engine as it is. Which done, it muſt be again dried upon a kiln, and after that ground in the ſame manner that the tanners grind their bark. Such wood as is to be uſed preſently after 'tis gotten, will require the better and the more drying upon the kiln; and if this is omitted, it will blacken and ſpoil all the leather it is uſed about. Where oak is ſcarce, black-thorn will tolerably well ſupply its place; and where that is not to be had in ſufficient plenty, the white thorn will do. Phil. Tranſ. N°. 108.

Birch alſo, being ordered in the ſame manner with oak, is fit for ſome uſes in *tanning*, particularly it does very well for *tanning* of ſhoe-ſoal leather. All theſe ingredients will *tan* much better than bark alone, and that with much leſs charge; ſo that this diſcovery may very well ſave the felling of trees when the bark is wanted, at a ſeaſon when the ſap is up, which, when 'tis done, cauſes the outſides of the trees to rot and grow worm-eaten; whereas if the trees had been felled in winter, when the ſap is down, they would have been almoſt all heart, as the people expreſs it, and not ſubject to worms. This manner of uſing the wood with the bark, in *tanning*, will alſo increaſe the value of underwoods very conſiderably. Phil. Tranſ. N°. 105.

The engine neceſſary for cutting the wood conſiſts of a long ſquare wooden block, and ſome pieces of iron to be faſtened on, and uſed about it, *viz.* a hammer, an anvil, an iron holding the wood to be bruiſed and cut, and a knife to cut it. The whole is a very ſimple and cheap machine, and is deſcribed at large, and figured in the above-mentioned number of the Philoſophical Tranſactions.

By Mr. de Buffon's experiments upon different ſkins, it was found that a decoction of young oak wood ſucceeded perfectly well in *tanning* ſheep and calves ſkins, but did not do equally well for ox, and the other harder ſkins. This, however, he imagines might be only for want of knowing the beſt method of uſing the wood. And certainly theſe trials deſerve to be farther proſecuted; ſince the ſmall branches of the oak, which are of little value, might be thus made to ſupply the place of a much dearer commodity, the bark; and as in many trees the bark of the young branches is found to be of greatly more virtue than that of the larger branches, or the trunk, the uſe of theſe ſmall boughs, bark and all, might very probably be found to anſwer to all the effects of the bark, of the larger kind alone. Memoirs Acad. Scien. Par. 1736. See the Phil. Tranſ. above cited.

TANT, in natural hiſtory, an Engliſh name for a ſmall ſpider of the opilio kind, having only two eyes, and eight very long legs, and commonly ſuppoſed to be very poiſonous.

It is all over of an elegant ſcarlet colour, reſembling that of the flowers of the red poppy when full blown, except that the belly has a whitiſh caſt. Four of its legs are inſerted in the upper part of the breaſt, and the other four near the belly; and near the origin of each leg there is a ſmall black ſpot. Its body is round and full, and it is all over covered with a fine ſhort velvety down. It is not unfrequent in dry paſtures in the ſpring ſeaſon. It is terribly dreaded by our farmers, who ſuppoſe that an ox will die who chances to ſwallow it. *Ray*'s Hiſt. Inſect. p. 44.

TANTALUS, one of the many names given by the chemiſts to mercury.

TANZY, *Tanacetum*, in botany, *&c.* See the article TANACETUM.

TAOS *Lapis*, the *Peacock Stone*, a name given by ſome of the antient writers to a very beautifully variegated agate, reſembling, in ſome degree, the great variety of colours in the peacock's tail.

TAP *Root*, in trees, that part of the root that deſcends ſtrait down.

In removing or tranſplanting young oaks, great care ſhould be taken not to wound this root, much leſs to cut it off; but it muſt be dug up to the bottom, and the hole prepared deep enough to ſet it; otherwiſe the tree either dies, or if not, yet it is always greatly ſtinted and impeded in its growth. *Ray*'s Engliſh Words, p. 129.

TAPAYAXIN, in zoology, the name of a very remarkable ſpecies of lizard, called by Hernandez the *lacertus orbicularis*. It is not of the long and ſlender ſhape of the common lizards, but as broad as it is long, and much reſembling the wray-fiſh in ſhape, though ſeldom exceeding four inches in length or breadth. It is a cartilaginous lizard, of a very beautiful variety of colours, always very cold to the touch, and ſo ſluggiſh a creature, that it often will not move out of its place even on touching it. Its head is extremely hard and elate, and has a ſort of crown of prickles for its defence; yet it is a perfectly harmleſs animal, and ſo far from having the fear of man, and ſhyneſs that other beaſts have, that it loves to be taken up and played with, and will ſtand perfectly ſtill, and ſeem very happy while handled. There is alſo another thing very ſingular in it, that if hurt about the head or eyes, or handled too roughly, it will throw out drops of blood from its eyes to three or four foot diſtance. *Ray's* Syn. Quad. p. 263. *Hernandez*, l. 9. c. 16.

TAPE-*Worm*, a ſpecies of worm breeding in the human bowels, and called by authors, *tænia*, and *lumbricus latus*, or the broad worm.

The Greek and Roman phyſicians, as well as thoſe of our own time, have deſcribed three ſorts of worms to which the human bowels are ſubject. The common long worms, which reſemble earth-worms; the aſcarides, or ſmall worms; and this *Tape-worm*, which they have alſo called *vermis cucurbitinus*, or the gourd worm, from its ſeveral joints reſembling, in ſome degree, the ſeeds of that fruit.

The interpreters of ſome of the Greek phyſicians have however been guilty of a great error, in confounding the gourd worms and the aſcarides together, tho' nothing can be more unlike. The antients ſeem to have had a very juſt opinion of this animal, in calling it *vermis cucurbitinus*, ſince it is plain by this, that they underſtood every joint, as we call them, of this creature, to be a diſtinct worm; and what we call the ſingle worm, to be a long ſeries of theſe worms joined together end to end.

Petrus de Abano was one of the firſt whom we find deſcribing the ſeries of theſe creatures forming a chain of this kind, and repreſenting a ſingle and very long animal. Arnoldus de Villa Nova mentions two kinds of theſe worms; but he gives no farther deſcriptions of them than ſaying, that one kind is broad and long, the other broad and ſhort. After theſe, he mentions the long and round worm, which is the common kind; and fourthly, the ſmall worm, or aſcarides. To theſe he adds a fifth, which he calls ſolium, from its being found ſingle in the bowels. This he alſo calls *cingulum*; and obſerves, that it is very long and large, and that only one can live in the bowels at the ſame time.

It has been ſuppoſed by ſome, that what this author deſcribes as a ſeparate ſpecies of worm, under the name of *ſolium*, was no other than a kind of ſacculus or bag incloſing a long ſeries of theſe *Tape-worms*.

The writers that ſucceeded ran into great errors about theſe worms: Some declared them a mere figment of the Arabian phyſicians, affirming that no ſuch animals ever exiſted in nature. Others who believed in general that there was ſuch a ſpecies of worm, yet diſcountenanced all the ſtories related concerning it; and many who wrote on theſe ſubjects, mentioned two kinds of the lumbricus latus, or broad worm, but knew nothing of what was the difference between them.

Another ſet of writers, of whom Platerus is the head, diſtinguiſh, by certain characters, two ſpecies of broad worms; the one, they ſay, is long and broad, and not jointed; the other jointed, or formed like a chain; this is the common *Tape-worm*, which they ſuppoſe to conſiſt ſingly of a number of joints, contrary to the opinion of Petrus de Abano; and they ſay, that the vermis cucurbitinus of the Arabian writers, is only one of the joints, or a fragment of the jointed tænia, ſometimes voided in this manner in ſeparate pieces. Finally, others confounding the cucurbitini with the aſcarides, if ever they chanced to ſee a real *Tape-worm*, looked on it as ſome monſtrous production; nothing that had any name. *Clerici* Hiſt. Nat. Lumbr. Lat.

In later times this animal has been better known, and Tyſon, Lewenhoek, Andry, and others, have treated very carefully of it, and all have referred it to the ſecond kind of tæniæ, mentioned by Platerus, which was of the ſhape of a chain, or compoſed of ſeveral joints, like ſo many links faſtened end by end to one another. Yet theſe have fallen into errors; and whent hey have found ſeveral of theſe tæniæ conjoined and encloſed in a ſacculus, they have taken the whole for one worm, whoſe head and tail they have deſcribed, but that in an inaccurate manner.

The true hiſtory of this animal is, that it is ſhort and broad. What is called a link of the long worm is really a diſtinct worm; and when one of theſe mutiplies in the bowels, its young adhere to it, and to each other endwiſe, ſo as to form a ſort of chain, which lengthens as they continue to increaſe, and in fine becomes immoderately long. Hence it is that the breaking, as it is called, of this worm, does not deſtroy it, and that the voiding large pieces of it is no cure, ſince it ſtill recovers that length again by new young ones. Every ſeparate link of ſuch a chain, if examined, is found to be entire, lively and briſk, and not at all injured by the ſeparation.

Authors who have treated of theſe worms as a diſeaſe, have given a canine appetite, or unnatural appetite to food, as one of the ſymptoms; but this is wrong, for it has never been found, in reality, that theſe worms, even where moſt numerous, have at all increaſed the natural appetite; and indeed it is very difficult to judge of their being in the body by ſymptoms, ſince they occaſion none which are not alſo common in many other diſeaſes. Many people have had them a long courſe of time, without being ſenſibly hurt by them; and there has never been a known inſtance of their occaſioning any one's death; or indeed any conſiderable diſorder. See the article WORMS.

TAPECON, in ichthyology, a name given by ſome to the fiſh generally called the *uranoſcopus*, or ſtar-gazer. It is properly a ſpecies of the trachinus, and is diſtinguiſhed by Artedi by the name of the *trachinus* with ſeveral beards at the lower jaw. *Aldrovand.* de Piſc. p. 258.

TAPERA, in zoology, the name of a Braſilian ſwallow, called by the Portugueſe there, *andorintra*. It is of the ſize and ſhape of our ſwallow, and it flies about in the ſame manner. The head, back, neck, wings and tail, are all of a greyiſh brown; and its throat and breaſt of a greyiſh white. *Margrave*'s Hiſt. Braſ.

TAPETI, in zoology, the name of an animal common in the Weſt Indies, and called by ſome, *cuniculus Americanus*, the American rabbit.

It is exactly of the ſhape of our common rabbit, and is of about double the ſize of the dormouſe. Its hair in length and colour is like that of the hare, and its ears long and erect, in the manner of our rabbits. It has a little reddiſhneſs on the forehead, and is ſomewhat whitiſh under the throat. It has uſually alſo a ſort of white circle or collar round the neck; but ſome of this ſpecies want that, and have their whiteneſs only under the throat, breaſt, and belly. It has no tail; its eyes are black, and its mouth bearded in the manner of our rabbits. The Indians eat the fleſh of it. *Ray*'s Syn. Quad. p. 205.

TAPHICESIUS *Lapis*, a name given by Pliny and the antients to a ſpecies of ætites, or eagle-ſtone, found in a place of that name near Leucadia.

TAPHNEUS, a word uſed by ſome writers to expreſs any thing when depurated or purified to the greateſt degree, as the ſalts by repeated ſolutions and cryſtallizations, and the like. Paracelſus uſes it for a ſpecies of earth, the things produced from which, he ſays, never alter their nature by calcination or reverberation, or the like operations.

TAPIA, in botany, a name given by Plumier to a genus of plants called afterwards by Linnæus, *crateva*. *Plum.* Gen. 21. See the article CRATEVA.

TAPIJERETE, in natural hiſtory, the name of an animal found in ſome parts of America, and called by the Portugueſe, *anta*. It is of the ſize of a young calf, and in ſhape ſomewhat approaching to the figure of the hog. Its head is thicker than a hog's, and ends in a ſharp ridge at top; and has a ſnout hanging over the opening of the mouth, in which he has a very ſtrong muſcle, ſerving to retract it at pleaſure. The dentes inciſores are ten in each jaw; from the end of theſe the jaw ſeems toothleſs for a little ſpace. The grinders are large, and are placed five on each ſide; ſo that, on the whole, the creature has twenty of each ſort of teeth. Its eyes are ſmall, and very like thoſe of the hog; its ears roundiſh; and theſe he can draw forward at pleaſure. Its legs are thick, and not longer than thoſe of our hogs. Its hoofs are divided into four portions. It has no tail; the ſkin is hard and ſolid; and the hair ſhort, and of a pale brown, variegated with white ſpots. It lives in the thick woods, and ſleeps all day; but at night, or early in the morning, goes out for its prey. It feeds on

vegetables, and is particularly fond of the ſtalks of the ſugar-cane; it often takes the water, and ſwims excellently. The natives, in places where it is common, eat its fleſh; which is but very coarſe and ill taſted. *Ray*'s Syn. Quad. p. 140.

TAPINOSIS, Ταπείνωσις, in rhetoric, the ſame with *diminution*. See the article DIMINUTION, *Cycl.*

TAPLINGS, in the Engliſh ſalt-works, the name given to certain bars of iron which ſupport the bottom of the pan in which the brine is boiled.

Theſe pans are very large, and cover a wide furnace; but as their width would make them apt to bend in the middle, which would ſpoil the working the ſalt, there is a ſort of wall of brick carried along the middle of the furnace; and on the top of this are placed theſe *Taplings*: They are about eight inches high, and from four to ſix in thickneſs, being ſmalleſt at the top. Theſe are placed at about three foot diſtance one from another, and the wall which ſupports them, and which is called the *midfeather*, is broad at the baſe, and ſo narrow at the top, as barely to give room for the baſes of the *Taplings*.

TAPPING (*Cycl.*)—In *tapping* for the dropſy, ſurgeons were formerly very careful to draw off only a ſmall quantity of water at one time, and therefore repeated it often, till the whole was evacuated. The reaſon of this was to avoid the ſyncope, which uſually attended the operation when all the water was evacuated at once. But Dr. Mead having diſcovered the true cauſe of this ſyncope to be owing to the removal of the preſſure from the deſcending aorta, it was ſoon found, that the bad conſequences might be prevented by emptying the belly at one operation, and preſerving a proper preſſure at the ſame time, which ſhould be done equally and gradually, as the water runs out. Bandages have been contrived for this purpoſe in England and in France; but, according to Mr. Monro, they are not ſufficient; and he therefore invented a belt made of fine flannel, and ſtrong linnen, which will better anſwer the purpoſe. For the draught and deſcription of this belt, we refer to the Medic. Eſſ. Edinb. vol. 1. art. 18. or its abridgment, vol. 2. p. 102. where the curious may find ſeveral practical obſervations about this operation.

Tapping has ſeldom proved more than a palliative remedy in dropſies. The chief improvements in the operation are owing to Mr. Monro, Monſieur Garengeot, and Mr. Warwick.

Mr. Monro has ſubſtituted a belt inſtead of the ordinary long bandage for compreſſing the abdomen; and has alſo aſcertained the proper place of puncture. Garengeot makes the evacuation at once, cleans the emptied cavity, to remove the feculent part of the waters which ſubſides therein, and is apt, by its acrimony, to occaſion mortifications.

Mr. Warwick tells us, however, that notwithſtanding theſe improvements, an aſcites ſhews, that the uſe of *Tapping* is but precarious, by returning as conſtantly as ever this method alone is put in practice to remove it. He has therefore endeavoured at a farther improvement, whereby the *Tapping*, inſtead of being a bare temporary relief of ſymptoms, becomes an abſolute cure. This method is, after evacuating the waters, to make an injection of equal parts of cahors, wine, or claret, and Briſtol water, blood-warm, into the emptied cavity. He mentions a cure he performed in this manner. See Phil. Tranſ. N°. 472. Sect. 3.

Dr. Hales has given us, in the ſame tranſaction, ſect. 4. a method of conveying liquors into the abdomen during the operation of *tapping*, by means of two trocars fixed at the ſame time one on each ſide of the belly, one of them having a communication with a veſſel full of the medicinal liquor, by means of a ſmall leather pipe. This veſſel might be raiſed high enough above the abdomen to force the liquor in by the laws of hydroſtatics. The advantage propoſed by this method, is to prevent a ſyncope from inanition. See a farther account of the ſucceſs of injecting medicated liquors into the abdomen, in the caſe of an aſcites, in Phil. Tranſ. N°. 473. Sect. 4.

TAR (*Cycl.*)—The antients eſteemed *Tar* good againſt poiſons, ulcers, the bites of venomous creatures; alſo for pthiſical, ſcrophulous, paralytic and aſthmatic perſons. But the method of rendering it an inoffenſive medicine, and agreeable to the ſtomach, by extracting its virtues in cold water, was unknown to them. Siris, Sect. 9. See the article TAR-*Water*, infra.

According to Pliny, liquid pitch, as he calls it, or *Tar*, was obtained by ſetting fire to billets of old fat pines or firs. The firſt running was *Tar*, the latter, or thicker running, was pitch. Theophraſtus is more particular; he tells us, that the Macedonians made huge heaps of the cloven trunks of thoſe trees, wherein the billets were placed erect beſide each other. That ſuch heaps or piles of wood were ſometimes an hundred and eighty cubits round, and ſixty, or even an hundred high; and that, having covered them with ſods of earth, to prevent the flame from burſting forth (in which caſe the *Tar* was loſt) they ſet on fire thoſe huge heaps of pine or fir, letting the *Tar* and pitch run out in a channel made for that purpoſe. Siris, Sect. 13.

Some modern writers inform us, that *Tar* flows from the trunks of pines and firs, when they are very old, through inciſions made in the bark near the root; that pitch is only *Tar* inſpiſſated, and both are the oil of the tree grown thick and black with age and the ſun. The trees, like old men, being unable to perſpire, and their ſecretory ducts obſtructed, they are, as one may ſay, choaked and ſtuffed with their own juice [a]. But the method uſed by our colonies in America for making *Tar* and pitch, is, in effect, the ſame with that of the antient Macedonians; as appears from the account given in the Philoſophical Tranſactions. And the relation of Leo Africanus, who deſcribes, as an eye-witneſs, the making of *Tar* on mount Atlas, agrees in ſubſtance with the methods uſed by the Macedonians of old, and the people of New England of this day [b].—[a Siris, Sect. 16. b Id. Sect. 17.]

According to Theophraſtus, not only the turpentine-trees, the pines, and the firs, yield reſin or *Tar*, but alſo the cedars and palm-trees; and the words *pix* and *reſin* are taken by Pliny in ſo large a ſenſe, as to include the weepings of the lentiſcus and cypreſs, and the balms of Arabia and Judæa; all which perhaps are near of kin, and in their moſt uſeful qualities concur with common tar, eſpecially the Norwegian, which is the moſt liquid and beſt for medicinal uſes. Thoſe trees that grow on mountains, expoſed to the ſun or north wind, are reckoned to produce the beſt and pureſt *Tar*; and the Idæan pines were diſtinguiſhed from thoſe growing on the plane, as yielding a thinner, ſweeter, and better ſcented *Tar*. Id. Sect. 28.

Tar in ſubſtance, mixed with honey, has been found an excellent medicine for coughs. Id. Sect. 21.

TAR-*Water*. As the cold infuſion of *Tar* has been lately much in vogue, and has been recommended by one of the moſt learned and ingenious writers of the age, it may not be improper to give ſome account of its virtues from the biſhop of Cloyne's *Siris*, or Chain of Reflections concerning the Virtues of *Tar-water*.

In ſome parts of America, *Tar-water* is made by putting a quart of cold water to a quart of *Tar*, and ſtirring them well together in a veſſel, which is left ſtanding till the *Tar* ſinks to the bottom. A glaſs of clear water being poured off for a draught, is replaced by the ſame quantity of freſh water, the veſſel being ſhaken, and left to ſtand as before. And this is repeated for every glaſs, ſo long as the *Tar* continues to impregnate the water ſufficiently, which will appear by the ſmell and taſte.

But as this method produces *Tar-water* of different degrees of ſtrength, the author ſays, he chuſes to make it in the following manner: Pour a gallon of cold water on a quart of *Tar*, and ſtir and mix them thoroughly with a ladle or flat ſtick, for the ſpace of three or four minutes; after which the veſſel muſt ſtand eight and forty hours, that the *Tar* may have time to ſubſide; when the clear water is to be poured off, and kept for uſe, no more being made from the ſame *Tar*, which may ſtill ſerve for common purpoſes.

This cold infuſion of *Tar* hath been uſed in ſome of our colonies as a preſervative or preparative againſt the ſmall pox, which foreign practice induced the biſhop to try it in his own neighbourhood, when the ſmall pox raged with great violence. He ſays, the trial fully anſwered his expectation; all thoſe within his knowledge, who took the *Tar-water*, having either eſcaped that diſtemper, or had it very favourably. Several were preſerved from taking the ſmall-pox, by the uſe of this liquor; others had it in the mildeſt manner; and others, that they might be able to take the infection, were obliged to intermit drinking *Tar-water*. He ſays, he has found it may be drank with great ſafety and ſucceſs for any length of time, and this not only before, but alſo during the aforeſaid diſtemper.

The general rule for taking it, is about half a pint night and morning, on an empty ſtomach, which quantity may be varied according to the caſe and age of the patient, provided it be always taken on an empty ſtomach, and about two hours before or after a meal.

It has been found, that ſeveral perſons infected with cutaneous eruptions and ulcers, were immediately relieved, and ſoon after cured, by the uſe of this medicine. It is ſaid, that even in the fouleſt diſtempers, it proved much more ſucceſsful than ſalivations and wood-drinks had done. It alſo ſucceeded beyond expectation, in a tedious and painful ulceration of the bowels, in a conſumptive cough, and (as appeared by expectorated pus) an ulcer in the lungs, in a pleuriſy and peripneumony. And when a perſon who had been for ſome years ſubject to eryſipelatous fevers, perceived the uſual forerunning ſymptoms to come on, the drinking of *Tar-water* prevented the eryſipelas.

Tar-water cures indigeſtion, and gives a good appetite. It is an excellent medicine in an aſthma; it imparts a kindly warmth, and quick circulation to the juices, without heating, and is therefore uſeful, not only as a pectoral and balſamic, but alſo as a powerful and ſafe deobſtruent in cachectic and hyſteric caſes. As it is both healing and diuretic, it is very good for the gravel. The biſhop ſays, he believes it to be of great uſe in a dropſy, having known it cure a very bad anaſarca in a perſon whoſe thirſt, though very extraordinary, was in a ſhort time removed by the drinking of *Tar-water*. It may likewiſe be ſafely uſed in inflammatory caſes; and, in fact, hath been found an admirable febrifuge, at once the ſafeſt cooler and cordial.

The ſalts, and more active ſpirits of *Tar* are got by infuſion in cold water; but the reſinous part is not to be diſſolved thereby,

thereby. Hence the prejudice which ſome, perhaps, may entertain againſt *Tar-water*, the uſe whereof might inflame the blood, by its ſulphur and reſin, as a medicine, appears to be not well grounded. It is obſerved by chemiſts, that all ſorts of balſamic wood afford an acid ſpirit, which is the volatile oily ſalt of the vegetable. Herein is chiefly contained their medicinal virtues; and this author affirms, that by the trials he has made, it appears, that the acid ſpirit in *Tar-water* poſſeſſes the virtues, in an eminent degree, of that of guaiacum, and other medicinal woods.

It is certain *Tar-water* warms, and therefore ſome may perhaps ſtill think it cannot cool. The more effectually to remove this prejudice, let it be farther conſidered, that, as on one hand, oppoſite cauſes do ſometimes produce the ſame effect; for inſtance, heat by rarefaction, and cold by condenſation, do both increaſe the air's elaſticity; ſo, on the other hand, the ſame cauſe ſhall ſometimes produce oppoſite effects. Heat, for inſtance, in one degree thins, in another coagulates the blood. It is not therefore ſtrange, that *Tar-water* ſhould warm one habit, and cool another; have one good effect on a cold conſtitution, and another good effect on an inflamed one; nor, if this be ſo, that it ſhould cure oppoſite diſorders. All which juſtifies to reaſon, what has often been found true in fact. The ſalts, the ſpirits, the heat of *Tar-water*, are of a temperature congenial to the conſtitution of a man, which receives from it a kindly warmth, but no inflaming heat. It is of admirable uſe in fevers, being at the ſame time the ſureſt, ſafeſt, and moſt effectual both paregoric and cordial; for the truth of which the biſhop appeals to any man's experience, who ſhall take a large draught of it milk warm, in the paroxiſm of a fever, even when plain water and herb teas ſhall be found to have little or no effect. To him it ſeems, that its ſingular and ſurprizing uſe in fevers of all kinds, were there nothing elſe, would be alone ſufficient to recommend it to the public. As *Tar-water* poſſeſſes the virtues of fortifying the ſtomach, as well as purifying and invigorating the blood, it may be preſumed of great and general efficacy in all thoſe numerous illneſſes, which take their riſe from foul or vapid blood, or from a bad digeſtion. The animal ſpirits are elaborated from the blood; ſuch therefore as the blood is, ſuch will be the animal ſpirits, more or leſs, weaker or ſtronger. This ſhews the uſefulneſs of *Tar-water* in all hyſteric and hypochondriac caſes; which, together with the maladies from indigeſtion, comprize almoſt the whole tribe of chronical diſeaſes. In very dangerous and acute caſes, much may be taken, and often, as far as the ſtomach can bear. But in chronical caſes, about half a pint, night and morning, may ſuffice. A medicine of ſo great virtue in ſo many different diſorders, and eſpecially in that grand enemy the fever, muſt needs be a benefit to mankind in general. There are nevertheleſs three ſorts of people to whom the biſhop ſays he would peculiarly recommend it; ſea-faring perſons, ladies, and men of ſtudious and ſedentary lives.

To ſailors, and all ſea-faring perſons, who are ſubject to ſcorbutic diſorders, and putrid fevers, eſpecially in long ſouthern voyages, he is perſuaded this *Tar-water* would be very beneficial. And this may deſerve particular notice, when ſo many of our countrymen have periſhed by ſuch diſtempers, contracted at ſea, and in foreign climates, which, it is probable, might have been prevented by the copious uſe of *Tar-water*.

This ſame water will alſo give charitable relief to the ladies, who often want it more than the pariſh poor; being many of them never able to make a good meal, and ſitting pale, puny, and forbidden like ghoſts, at their own table, victims of vapours and indigeſtion. Studious perſons alſo pent up in narrow holes, breathing bad air, and ſtooping over their books, are much to be pitied; as they are debarred the free uſe of air and exerciſe; this, he ſays, he will venture to recommend as the beſt ſuccedaneum to both. Though it were to be wiſhed, that modern ſcholars would, like the antients, meditate and converſe more in walks and gardens, and open air; which, upon the whole, would perhaps be no hindrance to their ſtudies.

It has been inſinuated, that *Tar-water*, made in the common way, as here deſcribed, contains noxious oils or particles of *Tar*, which renders it dangerous to thoſe who drink it. But the biſhop ſays, this is contrary to all his experience, and that *Tar-water* is ſo far from doing hurt by any cauſtic or fiery quality, that it is, on the contrary, a moſt potent medicine for the allaying of heat, and curing of all inflammatory diſtempers.

It has alſo been publickly aſſerted, that the acid juice of *Tar*, freed from the volatile oil, is much more ſafe and efficacious than *Tar-water*. But the above-mentioned author is of opinion, that if *Tar-water* be robbed of its fine volatile oil (which neither ſinks to the bottom, nor floats at the top, but is intimately united with it, and appears to the eye only in the colour of *Tar-water*) it can be no cordial, he having obſerved, that the moſt acid water is the leaſt cordial; ſo far is he from imputing the whole virtue to the acid, as ſome have thought. See *Two Letters from the Biſhop of Cloyne*, &c. publiſhed 1747.

The ſame author obſerves, that the uſe of *Tar-water*, made a ſecond time from the ſame *Tar*, is not at all noxious, or of a fiery cauſtic nature, only it is not ſo ſtrong as that firſt made.

If it be aſked, what preciſe quantity or degree of ſtrength is requir'd in *Tar-water*? it is anſwered, that the palate, the ſtomach, the particular caſe and conſtitution of the patient, the very ſeaſon of the year will diſpoſe and require him to drink more or leſs in quantity, ſtronger or weaker in degree. Preciſely to meaſure its ſtrength by a ſcrupulous exactneſs, is by no means neceſſary.

It is to be obſerved, that *Tar-water* ſhould not be made in unglazed earthen veſſels, theſe being apt to communicate a nauſeous ſweetneſs to the water.

The ſame ingenious author recommends *Tar-water* in the plague, and for the diſtemper among the horned cattle now raging; with what ſucceſs muſt be left to experience.

TARABE, in zoology, the name of a Braſilian parrot, larger than the common green parrot. Its general colour is green; but its head, breaſt, and the origin of its wings, are red. Its beak and legs are of a duſky grey. *Marggrave*'s Hiſt. Braſ.

TARAE *Lapis*, the name given by the writers of the middle ages to a ſtone which they ſay had the power of ſtopping all ſorts of fluxes. They have left us no deſcription of it, and it ſeems to have been loſt even in their times; for they obſerve that the phyſicians uſed the ſanguis draconis, or dragon's-blood, in its place.

TARAGUICO *Aycuraba*, in zoology, the Braſilian name for a ſpecies of lizard, much approaching to the nature of the taraguira; but its tail is covered from its beginning with ſmall triangular ſcales, and very regularly marked with four brown ſpots. The back alſo, particularly that part which is next the head, is variegated with undulated brown lines. *Ray*'s Syn. Quad.. p. 266.

TARAGUIRA, in zoology, the name of an American lizard. It grows to about a foot long; its body is rounded, and every where covered with ſmall triangular duſky grey ſcales. Its back is ſmooth, and it has not that falſe gullet under the throat which the iguana has.

This is the ſpecies of lizard of which it is reported, that it will wake a ſleeping perſon, if it ſee him in danger of being bitten by a ſerpent. It is very common about houſes and gardens in South America, and runs very ſwiftly, but with a waddling motion; and when it ſees any thing at a diſtance, has an odd way of nodding its head very ſwiftly. *Ray*'s Syn. Quad. p. 266.

TARANDUS, in zoology, a name given by Agricola, and ſome other authors, to the rein deer. See the article RANGIFER.

TARANIOLO, in zoology, a name by which the whimbrel, or ſmall curlew, called the *arquata minor* by authors, is known in the markets of Italy. *Ray*'s Ornithology. p. 217.

TARANTULA, (*Cycl.*) in zoology, a name given by the Italians to a peculiar ſpecies of lizard, called by Aldrovand and ſome others, *lacertus facetanus*. See Tab. of Quadrupeds and Serpents, N°. 36.

It is of a grey colour; its ſkin is extremely rough; and it is thicker and rounder bodied than the other lizards. It is found like our common eft, under old walls, and among the ruins of buildings, particularly in the neighbourhood of Rome, in great plenty; its colour looks dead and ghaſtly, and it is as odious to the ſight among the Italians, as the toad is with us, being never ſeen without a ſort of natural horror. It is eſteemed alſo a poiſonous creature, as the toad is with us, tho' it is not eaſy to find well-atteſted ſtories of any bodies ever having been hurt either by the one or the other of theſe creatures. *Ray*'s Syn. Quad. p. 264.

TARBASON, a word uſed by ſome chemical writers as a name for antimony.

TARCONANTHUS, in botany, the name of a plant deſcribed by Vaillant, the characters of which are the ſame with thoſe of the parthenium. *Vaillant*, A. G. 1719. See the article PARTHENIUM.

TARDA *Avis*, in zoology, a name given by many to the buſtard, more commonly known among authors by the name *otis*. *Ray*'s Ornithology, p. 129. See the article OTIS.

TARDO, in the Italian muſic, is uſed to denote a ſlow movement, being much the ſame as *largo*. See the article LARGO.

TAREIBOIA, in zoology, the name of a ſpecies of ſerpent found in America, and called alſo *cacaboia*; though, according to ſome authors, the *Tareiboia* and *cacaboia* are two different ſpecies.

They are both of the amphibious kind, and live in lakes and waters, as well as on land; but they are not very poiſonous. They are ſmall ſnakes, and all over black; when offended, they will bite; but the wound is eaſily curable. Authors have written differently of theſe ſerpents, ſome making the latter very different from the former, and of a yellow colour. *Ray*'s Syn. Anim. p. 329.

TAREIRA, in ichthyology, the name of a fiſh caught in the American ſeas, and eaten; but of no fine flavour.

It is of an oblong and thick body, gradually tapering toward the tail. Its head reſembles that of a ſnake, and is raiſed into two tubercles over the eyes: Its eyes are yellow, with a black pupil; its noſe pointed, and its mouth large and yellow within. It has extremely ſharp teeth in both its jaws, and on its tongue. It has eight fins, the tail being accounted one, and this is forked; but this, as well as the reſt, is of the conſiſtence of a poppy leaf, tender, thin, and ſoft, and ſuſtained by ſoft rays. Its ſcales are ſo nicely laid on one another, that it ſeems ſmooth to the touch. Its belly is white, and its back and ſides are variegated with longitudinal green and yellow lines. *Marggrave*'s Hiſt. Braſ.

TARGAR, a name given by ſome of the chemical writers to oil of juniper.

TARIERA, in ichthyology, the name of a river-fiſh caught in many parts of America.

It is an oblong fiſh, with a ſtrait back, and a belly ſomewhat hanging down. Its under jaw is longer than its upper, and its teeth are extremely ſharp. Among theſe there are two longer than the reſt in the middle of the under jaw, and four ſuch in the upper. Its ſcales are large, and its back brown, and its belly and ſides whitiſh. It is a well taſted fiſh, but full of bones. *Marggrave*'s Hiſt. Braſ.

TARIFILON, in botany, a name by which Avicenna, and ſome other authors, have called the *trifolium bituminoſum*, or ſtinking trefoil. *Ger. Emac.* Ind. 2.

TARIN, in ornithology, a name given by the French, and from them by many others to the *Citrinella*; a bird common in Italy, and kept in cages for its beauty and fine notes. *Ray*'s Ornithol. p. 93. See the article CITRINELLA.

TARINGTING, in natural hiſtory, a name given by the people of the Philippine iſlands to a ſpecies of lapwing which is common on the ſea-ſhores, and runs remarkably ſwift.

TARITH, one of the many names given by the chemiſts to mercury. See the article MERCURY.

TARRAGON, in botany. See the article DRACUNCULUS.

TARROCK, in zoology, the name of a ſea-fowl of the larus or gull-kind, and diſtinguiſhed by authors by the name of the *larus cinereus Bellonii*.

It is of the ſize of the common pigeon, and is not much unlike it in ſhape, except that the head is larger and thicker. Its tail is not forked; and its throat, breaſt and belly, are ſnow-white. Its head and the outer part of its neck are alſo white; but there is on each ſide of the head a black ſpot. The lower part of the neck is black; and the middle of the back and the ſhoulders are grey. Its long wing feathers are black and white. Its great diſtinction, however, from all the other birds of the gull kind, is, that it has no hinder toe. It is very common on the coaſts of Cornwal, and ſome other of the Engliſh ſhores. *Ray*'s Ornithol. p. 264.

TARSI, in the materia medica, a name by which ſome authors have called the root of the *cyperus eſculentus*, or ſweet cyperus of the ſhops; and by which it is in ſome places uſually called by the druggiſts. *Dale*'s Pharm. p. 257.

TARSO, in the glaſs-trade, a ſort of white ſtone found in many rivers of Italy, and other places; and uſed inſtead of ſand for the fineſt cryſtal glaſs, being firſt burnt, and calcined with the ſalt of the polverine into frit. *Neri*'s Art of Glaſs, p. 7.

Neri calls this ſtone a kind of white marble; and adds a general rule, that all ſtones that will ſtrike fire with ſteel, are fit to vitrify; and thoſe that will not ſtrike fire with ſteel, will never vitrify.

The criteria or determinate characters of foſſils were not at all fixed in this author's time, otherwiſe he had not called this ſtone a kind of marble; ſince his own general rule of trying ſtones by ſteel, is, though liable to a few exceptions, a very good one; and, according to that, this *Tarſo* could be of no affinity to marble; for marble will not ſtrike fire with ſteel, nor ever be converted into glaſs.

The great difference of ſtones is this; ſome are compoſed of cryſtal, variouſly debaſed by adventitious matter; others of ſpar, debaſed in the ſame manner. All cryſtal will give fire with ſteel; all ſpar will refuſe this. Flints, ſand, and the harder ſtones, are compoſed of cryſtal; and will therefore give fire with ſteel, and vitrify or make glaſs with the addition of ſalts. Marble, and other ſoft ſtones, are compoſed of ſpar; and can neither give fire with ſteel, nor make glaſs, but readily calcine in the fire.

The *Tarſo* therefore, of this and other authors, could be nothing of the marble kind; but is truly a cryſtalline matter debaſed by an admixture of white earth, and found in form of ſmall pebbles of a whitiſh, yellowiſh, or pale reddiſh colour; and this is common in all the gravel-pits of England, and in the beds of ſome of our rivers; and might be uſed with great advantage by our glaſs-makers, if they knew it was ſo eaſily to be had.

On comparing theſe ſtones of ours, with the cuogolo or *Tarſo* of the foreign glaſs-makers, there is no difference diſtinguiſhable to the eye, nor will the niceſt experiments by the fire, acid menſtrua, &c. ſhew the leaſt diſtinction between them. We are not to wonder however, that the glaſs-makers did not hitherto diſtinguiſh this to be the true cuogolo or *Tarſo*, ſince the characters of foſſils have been hitherto ſo little aſcertained, that the beſt and lateſt author on theſe ſubjects, Dr. Woodward, ſo far miſtook the ſtructure of this ſtone, as to call it a ſparry pebble. It is certain that ſpar could never have any thing to do with glaſs-making; but this ſtone has no ſpar in its compoſition.

TARSUS (*Cycl.*)—*Bones of the* TARSUS *luxated.* If any of the ſmall bones in the foot, the *tarſus* or *metatarſus* happen to be luxated by ſome external violence, the ligaments with the adjacent nerves and tendons, are generally ſo affected as to excite not only the moſt acute pains, but alſo violent inflammations and convulſions; and even death itſelf has been known to be the conſequence of accidents of this kind, unleſs the bones be ſpeedily replaced. The foot is for this purpoſe to be extended on an even table, and the ſurgeon is to replace the diſlocated bones with the preſſure of the palms of his hands, adjuſting them alſo with his fingers, where need requires. Compreſſes dipped in warm ſpirit of wine are then to be laid on the part, and both theſe and the reduced bones ſecured in their places, by means of the proper bandages; the patient is then to be enjoined to remain in bed till the new ſet bones have acquired a ſufficient ſtrength. *Heiſter*'s Surg. pag. 174.

TARTAR (*Cycl.*)—The ſweet wines afford always leſs *Tartar* than the ſharp ones, and it is alſo leſs valuable. The *Tartar* of Rheniſh wine, is better than that of any other; and in general, thoſe wines which have the moſt acid in them, afford the greateſt quantity of *Tartar*, and that in the largeſt cryſtals. It is objected by ſome to this ſyſtem, that vinegar affords no *Tartar*; but this is eaſily anſwered, by obſerving, that the wine from which vinegar is made, has before depoſited its *Tartar*. This ſalt of wine may be by chemiſtry reduced to elementary water, in this manner: let it be burnt to a fixed ſalt, and let this fixed ſalt of *Tartar* be diſſolved by ſtanding in a damp place into an oil *per deliquium*; let this oil be diſtilled in an alembic, and a phlegm only comes over: by repeating this proceſs, the whole will be reduced into perfect ſimple and inſipid phlegm, excepting a ſmall remainder of equally inſipid earth. *Portzius* de Vin. Rhen.

Beſide the uſual way in which *Tartar* is produced, there is a very remarkable account in the Memoirs of the Academy of Sciences at Paris, of its having been found in a more than ordinary beautiful ſtate on a human ſkull; the diſcovery was owing to accident, and was in this manner:

Mr. Morand wanting a human ſkull cleanſed from its ſoft parts, put into a dunghill of horſe-dung a whole human head; after it had lain there eight days, the fleſhy parts eaſily ſeparated, being as it were boiled to pieces; after this the ſkull was carefully waſhed, and then laid to ſoak for ten days in a large veſſel of water; after this it was drenched three or four times in freſh water, and finally, without wiping, was ſet out in the air to dry. As it dried it became covered with little cryſtals, compoſed of ſeveral planes or traces, but moſtly of a cubic form, very bright and glittering; and when expoſed to the light, of an extremely brilliant water. There were none of them on the baſis of the cranium, which was full of irregularities; but they all arranged themſelves on the upper part above the orbitary hollows; to the jaw-bones there were alſo many faſtened, as alſo to the teeth; theſe laſt were yellow, but they were not leſs bright and brilliant than the reſt.

On examining theſe cryſtals they were found to be *Tartar*, but in a purer ſtate than *Tartar* is ever uſed to appear in; and as it was ſoon judged that though theſe cryſtals owed their preſent form and extreme beauty to the ſkull, yet they could not be wholly produced from it, the whole matter was carefully examined, and it was found that there had been lees of wine in the veſſel in which the ſkull had been laid ten days in ſoak. Mem. Acad. Par. Ann. 1737.

The formation of the cryſtals of this *Tartar* on the ſkull, while the ſides of the veſſel had none concreted on them, ſhews that the ſkull had a diſpoſition for receiving the cryſtals more than any other body; and their peculiar brightneſs proves, that it had ſome ſhare in their formation.

The uſual method of refining *Tartar* is this: Take two pounds of common white *Tartar* reduced to powder, and put it into five gallons of fair water; put it over the fire to boil, and in the mean time beat up the whites of two or three eggs, mix theſe among the liquor, and ſkim it as it heats; finally ſtrain it and ſet it in a cool place for two days, at the end of which time a quantity of whitiſh cryſtals will be found ſticking to the ſides of the veſſel.

This is a very troubleſome and inconvenient proceſs, the *Tartar* requiring ſo very large a quantity of water to diſſolve it; and the operation muſt alſo be repeated more than once, to make the cryſtals fine. Veſſels of metal cannot be employed, becauſe the *Tartar* would corrode them; and earthen ones of ſize to make large quantities, are not eaſily procured. In many arts the crude *Tartar* does as well as the refined; but in many other occaſions none but the refined can be uſed. It were therefore much to be wiſhed, that we could get into a method of refining it here, as they do in France. *Shaw*'s Lectures, p. 158.

A great aſſiſtance in the diſſolving of *Tartar* is had from adding lime-water, pot-aſhes, or ſalt of *Tartar*; and if the alkali be here too great, it may be taken off by a proper quantity of oil of vitriol. But where a very pure *Tartar* is required, the beſt method of obtaining it is to diſſolve the common cryſtals or cream of *Tartar* in water, made highly acid with oil of vitriol. For this ſolution, after a proper evaporation, will afford perfectly fine cryſtals of *Tartar*, no way participating of the oil of vitriol.

The glaſs-men are very fond of a preparation, which they call burnt *Tartar*. This is no more than the larger lumps of red *Tartar*, burnt or calcined in earthen pans in an open fire till they have done ſmoaking, and is of a blackiſh purple colour. *Neri*'s Art of Glaſs, p. 69.

Soluble

Soluble TARTAR. The proceſs for making *ſoluble Tartar*, is this: Take of an alkaline fixed ſalt a pound, of water a gallon; and having diſſolved the ſalt in this water boiling, throw in cryſtals of *Tartar* in powder as long as any fermentation is raiſed, which uſually ceaſes before thrice the weight of the alkali is thrown in. Then ſtrain the liquor through paper; and after due evaporation ſet it by for the ſalt to cryſtallize, or elſe evaporate the liquor wholly away, that the ſalt may be left dry.

This ſalt by the action of the alkali on the acid of *Tartar*, being freed from thoſe groſs terreſtrious parts, with which the cryſtals of *Tartar*, how pure ſoever, remain ſtill charged; it diſſolves readily, and keeps ſuſpended in cold water. *Pemberton*'s London Diſpenſatory, p. 181. ſeq.

The ſeveral alkaline ſalts, that of *Tartar* itſelf, the common pot-aſhes, borax, *&c.* all make a very good *ſoluble Tartar*; and not only theſe but the common terreſtrial alkali's, whether of the mineral kingdom as chalk or lime, or of the vegetable, as the aſhes of plants after elixiviation; or of the animal, as oyſter-ſhells calcined or not calcined, and hartſhorn; all theſe give a better or worſe *ſoluble Tartar*; but of theſe none ſucceeds ſo well as the oyſter-ſhell, after it has been calcined; the *ſoluble Tartar* prepared with this, coſts alſo greatly leſs, than when prepared with ſalt of *Tartar*.

In wood-aſhes there is always a part, which when mixed with water ſwims, and is ſuſpended in it a long time, and at length ſubſides into a kind of ſoft and impalpable matter; and another part, which ſubſides readily to the bottom, and feels rough and harſh. It is the firſt of theſe ſubſtances alone, which being mixed with cream of *Tartar*, renders it ſoluble: The other part will not mix with the cream of *Tartar*, or produce any ſuch effect, unleſs reduced to the nature of the firſt, by repeated and violent calcinations, and then only a part becomes ſo altered, the whole never is ſo. It appears that the firſt portion has been wholly diveſted of its acid by the fire, and thence is become ſuſceptible of the impreſſion of the weakeſt acid, ſuch as is that of the cream of *Tartar*; but in the ſecond, or coarſer part, the acid it naturally contained remains fixed and concentrated, ſo that it is not ſuſceptible of any impreſſion from the weak acid of the cream of *Tartar*. Mem. Acad. Par. 1733.

The different kinds of *ſoluble Tartar* have alſo their different degrees of ſolubility, or different readineſs to run into a liquor *per deliquium*. The moſt eaſily ſoluble of all others are thoſe made with chalk, with lime, and with wood-aſhes; and that which is moſt differently ſo, is the kind made with borax; it will at length run however, and is truly *ſoluble Tartar*.

Regenerated TARTAR. When cream of *Tartar* has been made ſoluble by any alkaline ſubſtance whatever, it may be revived or regenerated into cream of *Tartar* again; its acid in this ſtate has diſſolved the alkaline matter preſented to it, and that has been itſelf attenuated in ſuch a manner as to render it capable of inſinuating itſelf between the molecules or integrant parts of the conſtituent matter of the cream of *Tartar*; on this only depends the ſolubility of this preparation: and to render the whole of its primitive nature again, there requires no more than the addition of a new acid, which ſhall free the *Tartar* from this alkali; but this muſt neceſſarily be ſtronger than that naturally in the *Tartar*. Thus ſpirit of nitre, or oil of vitriol, regenerate the *ſoluble Tartar* in a moment, as being more powerful acids than that in the cream of *Tartar* and therefore taking from it all its alkali's.

It might be ſuppoſed alſo, that theſe being mineral acids, and that of the *Tartar* a vegetable one, they might therefore be the more proper to take up its alkali's; but this is found not to be the caſe, for the acid of diſtilled vinegar, which is not only a vegetable acid, but is alſo the very ſame acid with that of *Tartar*, is alſo able to regenerate the ſoluble *Tartars*. It might ſeem wonderful that this ſhould be able to effect this change without any ſuperiority of force; but it is to be obſerved, that in the cream of *Tartar* the acid has a terreſtrial and alkaline baſis, which is natural to it in that form; but in the ſtate of *ſoluble Tartar* it takes a new alkaline baſis, which is not natural to it, but is ſuch as the artiſt gives it; and when we view the proceſs in this light, it does not appear wonderful that an acid of its own kind ſhould be able to take away from it this artificial alkaline baſis, though it was not able to take from it the natural one. Mem. Acad. Par. 1733.

This ſecond or artificial baſis is different, according to the different alkali's which have been employed to render the *Tartar* ſoluble, and conſequently the ſame acid may attach itſelf more to one than to another of thoſe alkali's, and quit them the more or leſs eaſily. There is one kind of *ſoluble Tartar* however, which is not to be regenerated at all; this is that, which is made with borax.

Dr. Huxham ſays, he as often experienced the good effects of *regenerated Tartar* in the cure of obſtructions of the bowels, and for ſluggiſh humours. See the article OBSTRUCTIONS *of the Bowels*.

TARTARI *Lixivium*. See the article LIXIVIUM *Tartari*.

TARTARON, a ſort of fine cloth or ſilk, mentioned in the ſtat. 4 Hen. VIII. c. 6. *Blount*, *Cowel*.

TARTARUM *Tartariſatum*, *Tartaris'd Tartar*, in chemiſtry, the name of a preparation of *Tartar*; the manner of doing which is given by Boerhaave, and is as follows: Reduce ſome of the pureſt white *Tartar* to powder, and boil this powder in ten times its weight of water in a large copper veſſel, till it appears perfectly diſſolved; let it after this continue boiling till the liquor become tolerably tranſparent, and of an acid taſte; then drop into it from on high oil of *Tartar per deliquium*, the liquor being ſtill kept boiling; upon the falling in of each drop there ariſes a great ebullition, occaſioned by the meeting of the acid and alkali. Large bubbles appear on this, and in theſe the chemiſts have imagined they found the figures of cluſters of grapes.

The operation is to be patiently continued till there is no more effervеſcence made by the falling in of the drops of the oil. The acidity of the *Tartar* will be then ſo perfectly ſaturated with its own alkali, that it will appear neither acid nor alkaline, but a third ſalt; great caution however muſt be uſed in obſerving the true point of ſaturation, otherwiſe the ſalt will be when finiſhed either a little acid, or a little alkaline, as the one or the other exceeds.

The liquor is then to be ſtrained ſeveral times through a flannel, till perfectly clear; it is of a deep browniſh colour, and brackiſh ſaline taſte, but has no ſcent. If this be evaporated to a pellicle, and ſet to cryſtallize, it forms a ſalt which is a *Tartar*, eaſily ſoluble in water, even when cold; and is very properly to be called ſoluble *Tartar*. *Boerhaav.* Chem. Part 2. p. 161.

Vitriolated TARTAR, *Tartarum Vitriolatum*. The chemiſts have ſometimes boaſted of great virtues, in what they call the magiſtery of this ſalt; this is the earth precipitated in the making of it. It is the opinion of ſome ingenious authors, that all fixed ſalts are produced by a blending together of the acid and alkaline ſalts, which the plants they are obtained from originally contained, with ſome earth. The making of this preparation of *Tartar* and vitriol, gives great ſtrength to his opinion by means of this magiſtery; which ſhews, that an earth neceſſary to the cementing a mixture of an acid and an alkali into a neutral ſalt, may exiſt even in one of the principles themſelves, though unſeen by us; and that, as in the preſent inſtance, in ſo large a quantity, as not only to be ſufficient for the combining the two volatile ſubſtances into a fixed one, but even to leave a remainder of it that was not neceſſary.

While the acid of vitriol is poured upon the diſſolved ſalt of *Tartar*, or its oil *per deliquium*, for the making of this ſalt, during the great effervеſcence between the acid and the alkali, there is a precipitation made of an earth, for the ſeparation of all which great care is to be had to the degree of ſaturation of the alkali with the acid. This earth afterwards may be ſevered by filtration. This earth is precipitated not out of the ſpirit of vitriol, but out of the ſalt of *Tartar*; and this experiment ſhews, that this fixed ſalt did originally contain that earth, which, according to the ſyſtem of the formation of fixed ſalts out of volatile ones originally reſiding in plants, muſt neceſſarily be mixed with them, and which not being able to mix with the acid, is ſeparated and thrown off in the conflict, in which the acid mixes itſelf with the reſt.

This earth is what is pompouſly called the magiſtery of vitriolated *Tartar*; but it is very wrong to give that name to an earth, which has none of the properties of that or any other ſalt; and they greatly deceive themſelves and their patients, who preſcribe it inſtead of the ſalt itſelf. Its ſaline taſte probably has induced them to think, that it poſſeſſed great virtues; but this is not innate, but adventitious, and the effect only of the fluid in which it was precipitated: It cannot but have ſome of the ſalts of that fluid hanging about it, when firſt made; but theſe may, by repeated waſhings, be carried wholly off, and the magiſtery will then remain a pure ſimple earth, and ſhew itſelf to be no other than that earth which may be properly called the earth of all fixed ſalts; and which, though neceſſary to give the ſalt of *Tartar* its form as a lixivial ſalt, yet being not neceſſary to it in its new form of a neutral ſalt, is depoſited in the making it into that form. It yet remains to be proved by more numerous experiments, that the fixed ſalts of plants owe that form only to a fixing earth, combining their two original volatile principles into a fixed maſs; for if this be truly the caſe, there then needs no more to the volatilizing them again, but the diveſting them of this earth. Phil. Tranſ. N°. 92.

TARTARHAN, a word uſed by ſome authors to expreſs ſpirit of tartar.

TARTARUGA, in zoology, a name by which the Portugueſe in America call a ſpecies of tortoiſe, known among authors by its Braſilian name *jurucua*. See the articles JURUCUA and TESTUDO.

TARTI *Lapis*, a ſtone mentioned by Ludovicus Dulcis, and ſome other authors, and ſaid to be very beautiful, having all the colours of the tail of a peacock, and to have many medicinal virtues. It was probably ſome ſpecies of agate; but the ſhort account given of it will not enable us to gueſs what particular kind.

TARTON *Raire*, in botany, a name uſed by ſome authors for the heath ſpurge, or that ſpecies of the thymelæa which is called *ſannamunda* in the catalogues of the materia medica. *Park.* Theat. p. 199.

TARUM, in botany, a name given by Pliny to the *agallochum ſylveſtre*, a ſpecies of aromatic plants. *Hofm.* Lex. in voc. See the article AGALLOCHUM.

TASIS, Τασις, in rhetoric, is uſed for the continuation of a period longer than the breath can bear. *Voſſ.* Ret. l. 4. p. 66.

TASCHENMUL, in zoology, a name given by authors to the *anas clypeata*, a ſpecies of duck, remarkable for the breadth of the end of its beak, and called in Engliſh, the *ſhoveler*. *Aldrovand.* de Avib. T. 3. p. 224. See the article SHOVELER.

TASTATURA, in the Italian muſic, the whole range of keys of organs, harpſichords, &c. See the articles ORGAN and HARPSICHORD, *Cycl.*

TASTE (*Cycl.*)—This is one of the moſt obvious characters of bodies, and much is to be judged from it of the nature of many things. Dr. Abercromby, in a treatiſe partly written on this ſubject, has carried his obſervations ſo far, as to lay down a ſet of rules for the judging of any plant, or other body, without knowing what it is, merely from its *Taſte*, in regard to its virtues in medicine.

In order to judge of what he expreſsly means by the names of the ſeveral *Taſtes*, it is proper to add the liſt of them, with ſome of the things to which they are applied.

Plants, fruits, &c. are either ſour as the common ſorrel, harſh as the medlar, auſtere or rough as the quince, ſweet as the freſh juice of ripe grapes, fat and oily as the ſeſamum, bitter as gentian, or the wild cucumber, ſalt as common ſea-ſalt, tart as garlick, or laſtly, inſipid as the gourd, or of ſome mixed *Taſtes*, made of two or more of theſe.

The harſh or acerb things are cold, repelling and binding, hardly concocted, and they may all be known upon the tongue by their contracting or drying it. The auſtere or rough things differ from theſe only in degree, as being ſomewhat milder in *Taſte*, and weaker in virtues.

The ſour or acid things are always cooling; but this never to exceſs, by reaſon of their penetrating parts; this *Taſte* is known by a biting on the tongue, but without any heat.

Sweet things are all nutritive; and, taking the word in its proper ſenſe, it is they only that are ſo. Their ſweetneſs ariſes from their neither being too hot nor too cold upon the tongue.

Fat things are moderately hot, and, on this account they all, in ſome degree, moiſten and relax; but they alſo obſtruct: they are known from the ſweet things by filling and, as it were, anointing the tongue, without giving that ſenſe of pleaſure that the others do.

Salt things are aſtringent and deterſive; the one quality they have from their earthy part, the other from their watery.

Bitter things may be very beneficial to the ſtomach; but, in improper caſes, they may alſo do hurt. The pungent bitters, ſuch as the elaterium, or wild cucumber, are all hurtful, unleſs rendered ſafe by other means.

Tart things are hot, and often bad for the head; but good in heavy and phlegmatic conſtitutions; they are known by their heat in the mouth.

Laſtly; inſipid things in general have no peculiar quality, but are cold and watery; they are generally hurtful to the ſtomach, unleſs mixed with hotter and ſpicy things. *Abercromb.* Nov. Medic. Clavis.

It is obſerved by Sir John Floyer, that the *Taſte* is ſo good a judge for us, that all the chemical principles in plants may be diſcovered by it, before their diſtillation. All watery plants ſhew their phlegm, as well to the *Taſte*, as by diſtilling; and in all dry woods, the *Taſte* diſcovers the earth they contain, as well as a chemical analyſis; by the mucilaginous and gummy *Taſte*, and by the manifeſt oilyneſs in ſome plants, we diſtinguiſh their abounding in oil, as well as by the retort. The ſmell alſo helps us greatly in an extemporary judging of plants, and we are able to declare upon the ſpot, that all the aromatic plants, and all the fœtid ones, contain a large quantity of a volatile oil and ſalt. By the acrimony and pungency, we are well aſſured, that there is a volatile ſalt in plants; and, by the burning taſte of others, we find that there is a corroſive ſalt in them. By a crude rough acidity, we diſtinguiſh the tartar or eſſential ſalt of plants to be in large quantity; but if the acidity be of a vinous ſmell, we obſerve that it is of a middle ſtate of digeſtion, and may be called a vinous tartar, and diſtinguiſhed from the firſt; but if the tartar have a pungent ſmell, then it is evidently a volatile tartar, or an acid acrid tartar.

The ſweet *Taſtes* are more numerous in plants, and more varied among themſelves than any other kind. Theſe, in general, ſhew their oil by thin ſlimy ſmoothneſs, and their tartar is evident in their extracts, as is very plain in the common liquorice juice.

The graſs ſweets, as the common dogs graſs, and the like, have much eſſential ſalt, and a moderate portion of oil; and the ruſh, reed, horſe-tail, and cats-tail, are all ſweet and rough; ſome of theſe have more oil, and others more acid; and the moſt crude among them have more oil than tartar.

The corn ſweets, as barley, rye, wheat, oats, millet, and rice, have much oil and eſſential ſalt, and a little volatile; ſo bread, prepared of any of theſe, yields on analyſis oil, and eſſential and volatile ſalt.

It is to be obſerved here, that fermentation and fire ſeverally produce a volatile ſalt, where it was not before, by ſubtilizing and volatilizing the eſſential ſalt; and the ſlimy mealineſs in corn ſupplies the oil. The goats beard and ſcorzonera kind, have the ſame principles as the graſſes, much oil and eſſential ſalt. The ſub-acrid ſweets, as rampions, campanulas, trachelia, and the like, contain much oil and eſſential ſalt; but the acrimony in theſe plants ſhews that they have alſo a volatile ſalt, and that in no ſmall quantity; though Lemery and the other chemical writers have not obſerved this.

The ferns, polypodys, and all that claſs of plants, contain much oil and eſſential ſalt; but the chemiſts in general have omitted to mention an acrid principle in all theſe, which beſpeaks a volatile ſalt; and fragrancy is obſerved in ſome of the harts-tongues, which beſpeaks a volatile ſalt alſo, and volatile oil, though hitherto unobſerved.

All the leguminous ſlimy ſweets have more oil than tartar; but all of them have a large quantity of both. Beans, Peas, and lentils, have alſo a volatile ſalt, as has alſo that ſtrange fruit, eaten in Ruſſia, and ſome other places, and called *lenticula aquatica* by ſome; but by the botanical writers, *tribulus aquaticus*; the other name belonging to the common duck-weed. The aromatic legumens, ſuch as melilot, have an exalted oil, and volatile ſalt. The honeyſuckle is ſaid by Lemery, and the other chemiſts, only to have an eſſential ſalt and oil; but as there is a highly aromatic flavour, and great acrimony, there muſt be alſo a volatile ſalt.

Theſe are ſome few inſtances, out of a vaſt number recited by the author, for the reſt of which we refer to the paper itſelf in N°. 280 of the Tranſactions. Philoſ. Tranſ. N°. 299. p. 1160.

TASTO, in the Italian muſic, the touch or part of any inſtrument, whereon, or by means of which its notes are made to ſound, be it on the neck, as lutes, viols, &c. which are called fixed and immoveable; or the front of organs, ſpinnets, or harpſichords, where the keys are diſpoſed to raiſe the jacks, called moveable touches; and is properly no more than the finger-board of each.

Taſto Solo is often found in thorough baſſes, where it ſhews that the inſtruments accompanying, as the lute, organ, &c. are only to ſtrike a ſingle ſound, from that place, till they find cyphers, or the words *accordo* or *accompanimento* placed in their part. Theſe intimate, that the accords are to begin again in this place.

TATA-*Youba*, in botany, a name uſed by ſome for the tree which yields what the dyers call the fuſtic, or yellow wood uſed in dying. *De Laët.* Ind. Occident. p. 603.

TATU, in zoology, the Brazilian name for the armadillo, or ſhell hedge-hog. *Grew's* Muſ. Reg. Societ. p. 17. See the article ARMADILLO.

We have ſeveral ſpecies of this creature deſcribed to us; but the moſt uſual, is of the figure of a hog, and of the ſize of a large pig, and has a bony covering, which extends over the whole body, the head and the tail. This is compoſed of a number of very elegant ſcales, which have two junctures near the hinder part of the head, by means of which the creature is able to move its neck. On the back there are ſeven diviſions, with a thick membrane between; and in all other parts of the body the ſhell is whole. The legs, ſo far as they come in ſight, are in the ſame manner defended by a bony covering, in form of a ſhell, but thinner than that of the back; the belly has nothing of this covering, but is beſet with a few whitiſh hairs, which grow out of very obſervable and eminent pores. The junctures of the head and back have alſo the ſame ſort of hairs; the head is like that of a hog, the noſe ſharp, the eyes ſmall, and ſet deep; the ears ſhort, naked, and brown; the teeth are but ſmall, and are in number eighteen in each jaw. The feet are made like hands; each has five toes, and the nails are round. Its colour is a ſort of reddiſh tawny. It digs up the ground with its noſe, in the manner of a hog, but much more nimbly; the tail is thick at the inſertion, and tapers to the extremity. The creature feeds on roots and fruits, as potatoes, melons, and the like; but will eat meat alſo if it comes in its way. It is uſually found in dry places; but ſometimes in watery ones. *Ray's* Syn. Quad. p. 233.

TATU-*Apara*, in zoology, the name of a creature of the armadillo kind; but differing from the others in many particulars: Its head is oblong, and of a pyramidal figure; its ears are ſmall, ſhort, and roundiſh; and its feet, as well the fore ones as the hinder ones, have each five toes. The fore legs are about three fingers long, the hinder ones five; the tail of a pyramidal figure, and little more than two fingers breadth long. It is covered with a ſhelly coat of a foot long, and eight fingers wide; it is ſmaller at both ends than in the middle; and is convex on the outſide, and concave within. In the middle, or a little toward the fore end, it has four junctures, which are placed tranſverſely, and by means of which it can, at pleaſure, either expand its ſhell, or contract it together into a round figure. The whole cruſt is compoſed of pentangular pieces, very nicely fitted to one another, and the ſeries of theſe between the commiſſures are parallellograms. The whole is compoſed of yelloviſh ſcales joined by an extremely tough ſkin.

When the creature would ſleep, or when it is afraid of being taken up, it contracts its cruſt into a round figure; and hiding its

whole body within, it might ſooner be taken for a ſea-ſhell than a land animal. Its fleſh is eatable, like the reſt of this kind; and its food is the ſame as theirs. *Ray*'s Syn. Quad. p. 234. See Tab. of Quadrupeds, N°. 21.

TATU-*Muſtelinus*, the *weaſel-headed armadillo*, in zoology, the name of a ſmall animal of the armadillo kind; its head is about three inches and an half long; his forehead two inches and a half broad, and very flat; the end of his noſe half an inch; his eyes ſmall; his ears very diſtant from one another; his body eleven inches long, and about ſix broad; and his tail five inches long, and not tapering to ſo extreme a thinneſs at the point as that of the common armadillo, but a fifth of an inch over. His fore leg two inches and a half long, and three quarters of an inch broad, with five toes; his hinder foot ſomething larger, and with the ſame number of toes. His head, back, ſides, and tail, all covered with a ſhelly armour. His breaſt, belly, and ears, all naked. *Grew*'s Muſæum Reg. Societ. p. 19.

TATU-*Porcinus*, in zoology, the name of the pig-headed armadillo, a creature of about twelve or fourteen inches long.

Its noſe is ſhaped like that of a pig, with four toes on its fore feet, and the hinder foot thicker, and having five toes; his tail eleven inches long, and extremely ſmall at the extremity. Its head, legs, back, and tail, are all covered with a ſhelly armour. The fore part of his tail covered with eleven ſhelly rings; his thighs, breaſt, belly, and ears, all naked; his eyes black, round, and very ſmall. His teeth are twelve in each chap, and no thicker than large needles. *Grew*'s Muſæum Reg. Societ. p. 18.

TATUETE, in zoology, the name of a ſpecies of *Tatu*, or armadillo, ſmaller than the common one, and differing alſo in many other reſpects.

Its head is ſmall and ſharp; its ears long and erect; its tail about three fingers long; and its legs much longer than in the common larger kind; but its moſt ſignal difference is, that it has only four toes on the fore feet, and five on the hinder ones; the two middle ones are the longeſt on the fore feet, and the three middle ones on the hinder; its whole length is about ſeven fingers breadth; its forehead and whole body are covered with a coat of armour, which ſtands out at the ſides ſo far, that the creature can, at pleaſure, draw in its head and legs under it; the armour of the back conſiſts of nine pieces nicely joined to one another; the tail is coated in the ſame manner, and has likewiſe nine junctures, and ends in a point. It is of an iron colour on the back, and whitiſh at the ſides; its belly alſo is whitiſh and naked, except for a few hairs.

The fleſh of this is accounted more delicious than that of any other creature of this kind, though they may all be eaten. *Ray*'s Syn. Quad. p. 234.

TATULA, in botany, a name uſed by Cluſius, and ſome other authors, for the ſtramonium, or thorn-apple. *Ger.* Emac. Ind. 2.

TAVACCARÆ, in the materia medica, the name by which many authors call the *coccus maldiviæ*, or maldive nut. *Piſo*, p. 203.

TAULACUM, in natural hiſtory, a name given by the people of the Eaſt Indies to a ſpecies of orpiment which is very common with them.

It is of a dirty yellow colour, and is compoſed partly of an irregular maſs, partly of fine flakes, like ſcales of fiſhes. Theſe are of the beſt colour. The whole maſs, on being expoſed to the fire, burns, and emits copious fumes; but it does not melt readily. After it has been ſeveral times calcined, the Indians give it internally in intermittent fevers, with ſafety and ſucceſs. *Woodw.* Catal. Foſſ. vol. 1. p. 24.

TAUREA, among the Romans, a puniſhment inflicted by whipping with ſcourges made of bulls hides. *Pitiſc.* in voc.

TAURIA, Ταυρια, in antiquity, a feſtival in honour of Neptune. *Pott.* Archæol. T. 1. p. 432.

TAURILIA, among the Romans, games in honour of the infernal gods. They were otherwiſe called *ludi taurii*. See *Pitiſc.* in voc. *Ludi*.

TAUROBOLIUM, or TAUROBOLION, among the antients, ſacrifices of bulls, which were offered to Cybele, the mother of the gods, to render thanks to the goddeſs of the earth, for her teaching men the art to tame thoſe animals, and fit them for labour. See *Pitiſc.* in voc.

TAUROCOLLA, *Bull-glue*, a ſort of glue much uſed among the antients in works that required ſtrength, being accounted far ſtronger than any other kind. It was made by boiling down the ears and genital parts of a bull in water.

TAURUS, (*Cycl.*) *Bull*, in zoology, the male of the ox-kind. See the articles BULL and BOS.

TAURUS, in ornithology, a name given by the antients to the bittern, or butterbump, from its imitating the roaring of a bull in its noiſe.

TAURUS *Æthiopicus*, the *Æthiopian Bull*, an animal deſcribed in a very remarkable manner by Pliny.

He indeed calls it the Indian *Bull*, and has led Solinus into the ſame error; but all the authors whom he quotes, and from whom he has tranſcribed his account, calling it the *Æthiopian Bull*, we may be aſſured that was its proper country. Agatharcides is the oldeſt author who has deſcribed theſe animals; he ſays, they lived only in Æthiopia, and that they were greatly larger than our oxen, and of a yellowiſh or tawny colour, and were ſwifter of foot than almoſt any other animal. Strabo, and all the other authors of credit, alſo mention this animal; but the deſcriptions they give of it are, in ſome particulars, carried too far into the marvellous.

They tell us, that all its hair ſtands the wrong way, and makes it the rougheſt animal, to appearance, in the world; and that its head is, as it were, all mouth, the opening of the mouth reaching from ear to ear. The horns, they ſay alſo, were very ſtrong and ſharp, and were moveable, ſo that the creature could turn them in any direction, at pleaſure, to take aim at the proper part of the creature he would gore; but that as ſoon as he had placed them in this direction, they became firm and unalterable in it by any force, till he choſe to alter the poſition himſelf. They, add, that its back, or hide in general, was of the hardneſs of flint, and turned away all ſorts of darts. This creature hunted and fed upon all other animals, according to the accounts of the ſame authors, and could itſelf never be taken but by pitfalls; and that when it was thus trapped, and let down into a hole or pit, out of which it was impoſſible to get out, its fury generally killed it in a few minutes, without any wound. Theſe are the wonderful things related by the antients of this animal; but they are ſo contrary to the courſe of nature in the ox kind, that we may very juſtly rank them among the other miraculous animals, ſuch as the mantichora; and the vermis cæruleus, of ſixty or ſeventy foot long. See the articles MANTICHORA.

TAXUS, the *Yew*, in botany, the name of a genus of trees, the characters of which are theſe: The flower is of the amentaceous kind, and is compoſed of a number of apices, uſually ſhaped like muſhrooms; theſe are the male flowers; the embryo fruit appears in different parts of the tree, and finally becomes a red berry, of a hollowed or cup-like ſhape, juicy, and containing a ſeed. There are alſo ſometimes, on the ſame trees with theſe, dry fruits, in ſhape of acorns; the ſeed being encloſed at its bottom, not by a juicy berry, but by a dry cup.

There is no other known ſpecies of the *Yew*, beſide the common kind; but that is ſometimes found with variegated leaves. *Tourn.* Inſt. p. 589.

TAXUS, in zoology, the name of the *Badger*, called in ſome parts of England, the *brock*, the *gray*, and the *pate*. The Greeks had no name for this animal, unleſs their *hyæna* was the ſame creature. See the article HYÆNA.

Authors who have deſcribed this animal, have all made two kinds; the *Taxus-Caninus* and *Taxus-Porcinus*, the dog and the hog-*Badger*. The laſt of theſe is our common kind; and 'tis indeed doubted whether there be any ſuch animal as the authors deſcribe under the other name.

The body of the *Badger* is ſhort and thick; its neck very ſhort, and its hairs long, and very rigid, and ſtiff like hog's briſtles. Thoſe on the back are of a pale yellow near the root; brown or black in the middle, and at the extremities yellowiſh again; ſo that the creature appears, upon the whole, of a mixt colour, or what we call grey, on the back. The ſides and belly are covered with hairs, which are all over of a pale yellowiſh hue; and the legs and ſhoulders, as alſo the belly, are wholly black. It has a broad white line from the top of the head to the noſe; and on each ſide of this a very regular pyramidal black mark reaching up to the ears; and below theſe the jaws are whitiſh, that the creature's face looks very oddly variegated. Its eyes are ſmall; and its ſnout wholly like a dog's. The teeth are like thoſe of a dog alſo; and the legs ſhort; its fore feet have ſharp claws, with which it digs itſelf burrows in the earth. Its face is very like that of the fox, being broad at the top of the forehead, and ſharpening to a point at the noſe, ſo as to appear triangular in ſhape; and its cheeks are tumid, and furniſhed with ſtrong muſcles, whence it bites very hard. It feeds on inſects and ſmall animals, and on the roots of vegetables. We have them in many parts of England, particularly in the counties of Eſſex, Suſſex, and Warwickſhire. *Ray*'s Syn. Quad. p. 185.

The *Badger*'s ſkin is of ſome uſe in commerce. Their fat is ſold by the druggiſts, as a remedy againſt diſorders of the kidneys, and the ſciatica; and their hair for the making pencils for painters and gilders. *Savar.* Dict. de Comm. p. 354.

TEA (*Cycl.*)—*Tea* is extolled by the orientals as the greateſt of all medicines; moderately and properly taken, it acts as a gentle aſtringent and corroborative; it ſtrengthens the ſtomach and bowels, and is good againſt nauſeas, indigeſtions, and diarrhœas. It acts alſo as a diuretic and diaphoretic. The immoderate uſe of it, however, has been very prejudicial to many, who have been thereby thrown into the diabetes.

TEALE. *Summer* TEALE, in zoology. See the article CIRCIAS.

TEARS (*Cycl.*)—Dr. Vaterus is of opinion, that the *Tears* come from the white lines ſeen on the inſide of the palpebræ, deſcribed by Meibomius. He obſerved two ſmall ducts, beſides the common naſal duct, from the lacrymal ſac into the noſe; one of them opened into the upper part of the noſe; the other opened into the *antrum maxillare*. Miſcel. Berol. Tom. 4. par. 3. §. 5.

TEASEL, *Dipſacus*, in botany. See the article DIPSACUS. Beſide the common wild ſpecies of this plant, there is a large kind of it, the heads of which are of ſingular uſe in raiſing the nap upon woollen cloth, for which it is propagated in great quantities in many parts in the Weſt of England. It is to be ſown in March, on a dry ſoil; a peck of the ſeeds are ſufficient to ſow an acre: The plants being come up, muſt be houghed up firſt to ſix inches, and ſome time after to a foot aſunder every way; and for the firſt ſummer the ground muſt be kept carefully cleared from weeds. The ſecond year after ſowing, the plants ſhoot up to heads, which are fit to cut in Auguſt, and tied up in bundles, and dried. The common produce of an acre of land is about a hundred and ſixty bundles, which are ſold at about a ſhilling a bundle. Some people ſow carraway among their *Teaſels*, but it only damages both. *Miller*'s Gardener's Dict.

TEBET, or THEVET, the fourth month of the civil year of the Hebrews, and the tenth of their eccleſiaſtical year. It anſwered to our moon of December, and has but 29 days. The ſecond day of this Month is the laſt of the octave of the dedication of the temple, after it was purified by Judas Maccabeus. V. 1 Macc. iv. 59. John x. 22. *Calmet*, Diction. Bibl. in voc.

TECHNICAL *Chemiſtry*. See CHEMISTRY.

TECOLITTROS, in natural hiſtory, the name of a gem, otherwiſe called *Syriacus lapis*, and *Judaicus lapis*, good for diſſolving the human *calculus*. See the articles SYRIACUS and JUDAICUS.

It has this name from τηκω, I diſſolve, and λιθος, a ſtone; becauſe it diſſolves ſtones. *Hofm.* Lex. univ. in voc.

TEE, in the manege. See the article BREAST-*Plate*.

TEETH (*Cycl.*)—When the *Teeth* are ſubject to be overſpread with a black or yellow cruſt, it is a very good method to rub them well every day with a mixture of tincture of gum lac, honey of roſes, and ſpirit of vitriol, which will not only whiten the *Teeth*, but render the gums more firm.

The world is fond of tooth powders, and a moderate uſe of them may do ſervice; but the daily rubbing with them does more harm to the *Teeth* than wholly neglecting them. Powders of this kind may be prudently uſed once in ſix or ſeven days, and will render the *Teeth* white and ſplendid. The common powders, prepared for this purpoſe, are too hard, and wear away the gums; ſofter ſubſtances ſhould be employed, and when the gums are f d, a few drops of ſome acid ſpirit be added to the powder. The following is a very efficacious and ſafe powder: Take chalk in powder, myrrh, burnt hartſhorn levigated, and Florentine rice root, of each two drams. Spirit of ſalt, ſix drops; mix all into a powder. *Heiſter*'s Surgery, p. 457.

The common trick of mountebanks, and other ſuch practiſers, is to uſe various waſhes for the *Teeth*, the ſudden effects of which, in cleaning and whitening the *Teeth*, ſurprize and pleaſe people; but the effects are very pernicious. All the ſtrong acid ſpirits will do this. As good a mixture as any thing can be, on this occaſion, is the following: Take plantane water an ounce, honey of roſes two drams, ſpirit of ſalt ten drops; mix the whole together, and rub the *Teeth* with a piece of linnen rag dipped in this, every day, till they are whitened. The mouth ought to be well waſhed with cold water, after the uſe of this or any other acid liquor; and indeed the beſt of all *Teeth*-waſhes is cold water, with or without a little ſalt; the conſtant uſe of this will keep them clean and white, and prevent them from aching. *Heiſter*'s Surg. p. 457.

Animalcules in the TEETH. No animalcules are to be found in any of the juices of the body, except the ſemen of male animals; and conſequently the ſaliva affords none: yet great numbers, and thoſe of different kinds, may be diſcovered in the white matter ſticking between the *Teeth*, if it be picked out with a pin or needle, and mixed with a little rain water, or ſpittle, without bubbles, and applied before the microſcope; and ſometimes they are ſo incredibly numerous, and full of motion, that the whole maſs ſeems alive. The largeſt ſort are of an oblong oval figure, and pointed at one end; theſe move along very ſwiftly; but of theſe there are but few. There is another ſort like theſe, in figure, but much ſhorter and ſmaller; theſe have a peculiar motion, being always running in an undulated or ſpiral line. A third ſort are roundiſh, and ſo minute, that a grain of coarſe ſand is equal to a million of them in bigneſs: Theſe move ſo very nimbly, that their ſhape is not eaſily diſtinguiſhed; yet they appear like large ſwarms of gnats.

Some, or all of theſe three kinds, may be found between the *Teeth* of perſons of all ages and ſexes, eſpecially between the grinders, and that though the mouth be waſhed ever ſo conſtantly. But from the *Teeth* of people who are more careleſs, there may uſually be taken another ſort of animal, in the ſhape of an eel or worm; theſe move backwards and forwards with great agility, and force their way through the cluſters of ſmaller animalcules with great impetuoſity; they move their bodies alſo into ſeveral bendings in their progreſſions. Beſide theſe, there are alſo ſeveral other ſpecies of animalcules, whoſe motion is ſo ſlow and languid, that it requires great attention to be ſure that they have life. They all die if a little vinegar be put to them; whence it ſeems a very proper method, to waſh the mouth with vinegar, in order to deſtroy them. *Baker*'s Microſcope, p. 167.

Clenched TEETH. The *Teeth* are in ſome caſes found ſo cloſely and firmly ſhut, that they cannot be opened ſufficiently to give the perſon liberty to eat or ſpeak. This generally ariſes from a ſpaſm or cramp of the elevating muſcles of the lower jaw. The cauſe of this ſpaſm is various; ſometimes it ariſes from a wound or blow, even from injuries of the nerves and tendons in different parts of the body; as after an amputation of an arm or a leg. Sometimes alſo, it is owing to an inflammation of the fauces themſelves.

When this diſorder ariſes from a wound, the firſt thing to be done is to ſearch whether there be not ſome extraneous body left in it, which excites theſe ſpaſms; if this be found to be the caſe, they always ceaſe immediately, upon the pulling out ſuch offending matters. If there be no ſuch bodies in the wound, and medicines give no relief to the convulſions, you may be ſure that ſome nerve is wounded; and the method then is to cut the nerve in two, if that may be done, and immediately the ſpaſms will ceaſe. Sometimes however, the nerve lies inacceſſible, or cannot be divided without danger of the patient's life; which is a very deplorable caſe, and generally brings on a neceſſity of amputating the limb. Theſe ſpaſms when from amputations are leſs to be dreaded, ſince they generally go off on untying the ligatures about the veſſels, and taking away the vitriol or other cauſtic applied to reſtrain the hæmorrhage.

When an inflammation of the tonſils or jaw excites this ſpaſm, theſe are to be treated in the common method; and the cauſe being removed, as in the other caſes, the effect will ceaſe. But if this diſorder be of ſo long continuance as to threaten the patient with ſtarving, he is to be ſupplied with broths and other liquid food, which may be ſucked through the *Teeth*.

The ſurgeons have an inſtrument, which they call *ſpeculum oris*, made to force open the mouth on theſe occaſions, and ſome adviſe the breaking out a *Tooth*, to give room for food and medicines; but both theſe practices are wholly to be rejected, as making the ſpaſms more violent and obſtinate. *Heiſter*'s Surg. p. 455.

Hollow TEETH. The *Teeth* which are hollow and decayed are uſually carious, and admit ſome parts of the food into their cavities, which by degrees putrifies, becomes acrimonious, and not only farther deſtroys the *Teeth* themſelves, but irritates the internal perioſteum and nerves of the *Teeth*, ſo as often to cauſe intolerable pain. Many methods have been contrived for relief in theſe caſes: One is to clean the cavity, and then fill it up with maſtick as often as there is occaſion; and another is the filling up the cavity with a piece of lead or gold. The cavity may alſo be filled at times with oil of cloves, and the like, or cauterized with a red hot iron; this generally proves a laſting remedy, and is attended with very little additional pain, if carefully performed, and no part of the mouth burnt. If all theſe methods fail, the laſt relief is the taking out the *Tooth*, and afterwards replacing it again. *Heiſter*'s Surg. p. 458. See the article TOOTH-*Drawing*.

Supernumerary TEETH. Theſe are ſometimes the cauſe of great diſorders, and may, without careful examination, be miſtaken for exoſtoſes or ſchirruſes of the palate. See Med. Eſſ. *Edinb.* Vol. 5. art. 16.

Mark of TEETH, in the manege. See the articles MARK and EYE *of a Bean*.

TEETH *of Fiſh*, *Dentes Piſcium*. The *Teeth* in the fiſh kind are ſo very various in their ſhape, and alſo ſo variouſly diſpoſed, that they make a very notable mark of diſtinction among the ſeveral genera.

As to ſituation, they are, 1. ſometimes placed only in the fauces and orifice of the ſtomach, the reſt of the mouth being entirely ſmooth: We have examples of this in the cyprini, and the ammodytæ or ſand-eels, and many other fiſh. 2. In ſome the *Teeth* are placed only in the jaws; the tongue, the palate, and the inner part of the mouth being ſmooth. 3. In ſome they are placed in the jaws, and on the tongue, the reſt of the mouth being ſmooth. 4. In ſome the tongue, the palate, and the jaws have *Teeth*, but the back part of the mouth is ſmooth; the herring has them diſpoſed in this manner. 5. Some have the fauces, tongue, palate, and jaws all beſet with *Teeth*, as the ſalmons, &c. 6. Some have them in the fauces and jaws only, the tongue and the palate being ſmooth: This we have inſtances of in the pleuronecti. And finally, 7. Some fiſhes have *Teeth* in the jaws, fauces and palate, and the tongue only remains ſmooth: This we ſee in the mackrel, &c. And all theſe are very eſſential marks and diſtinctions never varying in the ſame fiſh, and may ſerve as characters much better than the colours and other ſuch more obvious, but leſs eſſential things, remarked by the old authors.

The differences in the ſhape of the *Teeth*, are as many as thoſe in their ſituation, and may ſerve to as much purpoſe in their diſtinctions. 1. They are in ſome acute and ſharp at the ends; this is the caſe in moſt fiſh. 2. In ſome they are obtuſe, and as it were flatted at the end, as in the cyprini. 3. In ſome fiſh they are of a conic ſhape, as thoſe in

the upper jaw of the thymallus. 4. They are in ſome compreſſed or flatted at the ſides, as in the gadi and eſoces. 5. They are ſmooth and even at the ſides, as in the greater part of fiſhes: Or, 6. They are ſerrated or notched at the ſides, as in the ſhark kind, and ſome others. 7. They are in ſome ſtrait, as in the common acus or needle-fiſh, of Oppian. And, 8. They are ſometimes crooked inwards, as in the oſmeri, &c. Finally, they are ſometimes convex on one ſide, and flat on the other, as in the capriſcus.

The *Teeth* of fiſh differ in proportion alſo. 1. In ſome they are all of the ſame ſize in the ſame fiſh, as in the cottus, &c. 2. In ſome they are of very different ſizes in the ſame mouth; we have inſtances of this in the pike, the lucioperca, and many of the gadi. 3. They differ alſo in number and arrangement, for in ſome fiſh they are placed only in ſingle rows in the jaws, and other places allotted for them; but in others they are aggregated into ſeveral rows; the firſt is the caſe in the ſalmons, &c. the other in the cotti, and other fiſh. *Artedi* Ichthyolog.

Mammoth's TEETH. See the article MAMMOTH's *Teeth*.

TEFTERDAR, the name of an office of dignity in the Eaſtern nations. In Ægypt he is the lord high-treaſurer of the tribute paid out of the lands to the Grand Seignior. He is named for a year by the Porte; but is generally continued in his office many years. This office is ſometimes given to one of the poorer Beys, to help him to ſupport his dignity; and frequently to a quiet one, who is not likely to enter into intrigues. For one party never cares that a ſtirring man of the oppoſite party ſhould be inveſted with an office of this dignity. *Pocock's* Egypt. p. 165.

TEGS, a term uſed in ſome part of the kingdom by the farmers, to expreſs lambs of a year old.

When a flock of ewes and lambs are turned into a turnep-field, the young lambs of three weeks old will immediately fall to eating the turneps, and ſcoop them very prettily; but theſe *Tegs* will not touch them for ſeveral days. They uſually ſtay till almoſt ſtarved to death before they begin, but when they have begun they ſoon grow fat.

TEGULA *Hybernica*, Iriſh *Slate*; a ſtone of the ſlate kind, ſo ſtrongly impregnated with alum, as to deſerve the name of an alum ore. It is often likewiſe found to contain a large portion of vitriol.

It is found in great abundance in many parts of Ireland, as alſo in ſeveral of our own counties. Many preſcribe it in powder as a ſtyptic, in hæmorrhages of all kinds, with ſucceſs; but, perhaps, it would be full as prudent for the perſon who knows to what ſalt or ſalts it owes this virtue, to give thoſe ſalts alone, in a doſe that he can depend upon, and without the load of earthy matter, which is always to be found in this powder. Vid. *Hill*, Hiſt. Mat. Med. p. 257. ſeq.

This ſubſtance beaten to powder and infuſed twelve hours in water, will impart ſo much of the vitriolic ſalt it contains to the water, that being mixed with an infuſion of galls the liquor will become reddiſh, in the ſame manner that the medicinal waters of many parts of this kingdom do, which not containing vitriol enough to make ink with, the infuſion of galls yet turn reddiſh with it. It is hence not improbable, that many of theſe waters owe their virtues to this very ſubſtance. This kind of ſlate being very frequent in many parts of the kingdom, at different depths under the ſurface; and it being not hard to conceive, that a bed of water paſſing through a large ſtratum of it, may acquire thoſe virtues in its paſſage that we find common water, in our own experiments, becomes poſſeſſed of by a few hours cold infuſion.

This on being calcined, in order to try whether it be an iron ore, does not after burning, anſwer to the magnet; ſo that it ſeems to contain no iron at all in the ſtate of metal. But this is obſervable, that it calcines to a ſort of ochre, becoming of a yellow colour, and marking as ochres will do. The yellow of this ſlate being burnt too far becomes of an orange-colour, exactly like the ſediment of yellow matter, which we find about the ferrugineous waters; and this ſediment is hence eſteemed by ſome to be the remains of this ſlate diſſolved by the water, rather than iron ore. It is even doubted by ſome, whether the yellow ochres are indeed iron ores, or not; for many of them will not anſwer to the magnet, even after ſeveral days and nights continued calcination. It is indeed very certain, that all the naturally red ochres do contain iron, all of them having particles that anſwer to the magnet after a much ſlighter calcination than this given in vain to the yellow kinds. Phil. Tranſ. N°. 243. p. 272.

TEICHOPŒUS, τειχοποιος, among the Athenians, an officer who had the care of the city walls; their number was the ſame with that of the tribes, every tribe having the choice of one. *Potter*, Archæol. Græc. T. 1. p. 84.

TEITEI, in zoology, the name of a Braſilian bird called alſo *guiranheemegeta*, and *guroundi*.

It is of the ſize of our red-breaſt. Its beak is black, thick, and ſhort; its head, the upper part of its neck, its wings, its back, and its tail, are of a bluiſh black, ſhining like the fineſt high-poliſhed ſteel. Its throat, the lower part of its neck, its breaſt, and its belly, are yellowiſh. Its legs and feet are brown. The female is of the ſame ſize with the male, but differs in colour, being variegated with green, yellow, and grey. It ſings very ſweetly, and is kept in cages, five or ſix together in the ſame cage. *Marggrave's* Hiſt. Braſil.

TEJUGUACU, in zoology, the name of a ſpecies of lizard, common in the Brazils, and called alſo *Temapara*.

It much reſembles the iguana, in its general figure, but differs from it in that its whole body is black, only variegated with ſome white ſpots; its tail is thicker at its origin, it has not the ſeries of ſerrated ſpines, which the iguana has running all down its back. In the hinder feet the outer toe is alſo more remote from the reſt, and ſhorter; and it has a long red bifid tongue; and the animal can vibrate it an inch or more out of its mouth, in the manner of ſnakes; but it makes no hiſſing. It lives principally on the ſucking of eggs, but it is capable of bearing hunger a long time; Marggrave having kept one alive ſeven months without eating. This ſpecies afforded alſo a certain teſtimony to that author, of the reproduction of the tail when cut off. *Ray's* Syn. Quad. p. 265.

TEIUNHANA, in zoology, the name of a ſmall American lizard. It is about the thickneſs of one's little finger, and has a ſharp noſe. Its tail is very ſlender, ſix fingers breadth long, and terminates in a point almoſt as ſharp as a needle. Its head is covered with ſcales; its back, ſides, and legs, with a tender ſkin as ſoft as ſattin to the touch; and its tail is covered with extremely minute ſcales, of a ſquare figure. The throat and belly are covered alſo with ſcales of the ſame ſhape, but larger. Its head is wholly brown; its back and ſides are variegated with ſtreaks of brown and green, and with ſeveral beautiful longitudinal ſeries of green and black ſpots. The throat and belly are white; but they are beautifully variegated with ſpots of a fine deep blood-red. The tail is of a duſky yellow or wax colour on the upper part, and of a pale and beautiful fleſh colour underneath. *Ray's* Syn. Quad. p. 267.

TELAMONES, among the Romans, figures of men ſupporting the out-jetting of corniſhes in architecture. The word, according to ſome, is derived from the Greek τελαμων, from τειλαω, or τλαω, I bear.

Among the Greeks they were called *Atlantes*, Ατλαντες, which comes from the ſame word ταλαω, or τλαω, by the figure metatheſis. *Pitiſc.* in voc.

TELAMONES, is alſo uſed by the chirurgical writers ſometimes for lint, and ſometimes for the fillets or bandages, which they apply over their dreſſings.

TELE, Τελη, among the Athenians, thoſe revenues that were brought in by lands, mines, woods, and other public poſſeſſions, ſet apart for the uſe of the common-wealth; as alſo tributes paid by ſojourners and freed-ſervants, and the cuſtoms laid upon certain trades and goods. See *Potter* Archæol. Græc. T. 1. p. 80.

TELEOLOGY, the ſcience of the final cauſes of things. This is an ample and curious field of enquiry, though pretty much neglected by philoſophers. *Wolf.* Diſc. Prælim. Logic. §. 85.

TELEPHIUM *Orpine*, in botany, the name of a genus of plants; the characters of which are theſe: The flower is of the roſaceous kind, conſiſting of ſeveral petals, arranged in a circular form, and contained in a cup, conſiſting alſo of many leaves. The piſtil ariſes from the cup, and is finally converted into a triangular ſhaped unicapſular fruit, containing a number of ſmall and roundiſh ſeeds. To theſe marks it may be added, that the leaves ſtand alternately on the ſtalks.

The ſpecies of *Telephium*, enumerated by Mr. Tournefort, are theſe: 1. The common wild *Orpine*. 2. The American *Orpine*, with purſelain leaves. 3. The red-flowered houſe-leek-leaved ſea *Orpine*. And, 4. The white-flowered houſe-leek-leaved ſea *Orpine*. *Tourn.* Inſt. p. 248.

TELESCOPE (*Cycl.*)—Mr. Caleb Smith thinks that catadioptical *Teleſcopes* might be formed with ſpeculums of glaſs, inſtead of metal; and makes ſeveral obſervations as to remedying the diſorders cauſed by the different refrangibility of the rays of light. See Phil. Tranſ. N°. 456. ſect. 8.

TELETÆ, among the antients, were ſolemn rites performed in honour of Iſis. *Pitiſc.* in voc.

TELICARDIOS, in natural hiſtory, the name given by ſome authors to a ſtone found in the ſhape of a heart. It owes this figure to its having been found in the ſhell of ſome large bivalve of the cockle kind; and is more uſually known among authors under the name of *Bucardites*. See the article BUCARDITES.

TELIPHANO, in botany, a name uſed by ſome authors for the doronicum, or leopard's bane. *Ger. Emac.* Ind. 2.

TELLA *Sagrum*, in natural hiſtory, a name given by the natives of the Eaſt-Indies, to a kind of earth which they uſe externally to dry up ulcers, and internally in caſes of coughs and colds. It is of the nature of the finer clays, and is found at the bottoms of ſome of their rivers.

TELLA *Paſhnum*, in natural hiſtory, a name given by the people of the Eaſt-Indies to a kind of white arſenic, or rats-bane, found native among them.

It is well known to be a fatal poiſon, and uſed to deſtroy vermine. It lies in the cliffs of rivers among ſtrata of ſtone

in large white irregular lumps, when held to the fire it emits copious fumes ſmelling ſtrongly of garlick and ſulphur, but it does not readily melt or run.

TELLINA, in natural hiſtory, a ſea-ſhell, by the lateſt writers on theſe ſubjects, referred to the genus of muſcles. See the article MYTULUS.

Theſe ſhell-fiſh do not naturally live on the ſurface of the bottom of the ſea, but bury themſelves in the mud or ſand, in the manner of the chamæ, keeping a communication with the water above by means of the ſame ſort of tubes or pipes as thoſe fiſh are poſſeſſed of; but as the tubes of the *Tellinæ* are very ſhort, the fiſh can only bear to be buried to a ſmall depth.

When the water covers the bottom where they lie, they remain always buried in the ſand; but when the ſea in its ebb leaves the place dry, they very often come out of their holes, and are ſeen lying flat upon their ſides on the ſand; whether this be to take in freſh air, or, which ſeems more probable, to ſeek after the water which has abandoned them. They ſeem alſo to go far in ſearch of it, for it is common to ſee them at a foot diſtance from their hole, with the furrow marked by their progreſſion all the way behind them, from the aperture of their cell to the place where they are found. They perform this motion by means of a ſort of foot, ſuch as the chamæ, the ſourdon, and many other bivalve ſhells have; but the leg to which this foot is faſtened, is in this ſpecies very ſhort, and not capable of any great extenſion. Mem. Acad. Par. 1710.

TELON, a name given by the chemiſts to fire.

TELONÆ, τελωναι, among the Athenians, farmers of the public revenues; for the ſeverity with which they were handled, in caſe they failed, ſee *Potter* Archæol. Græc. l. 1. c. 14. T. 1. p. 81.

TELINO, a name given to the *Urogallus*, or great cock of the mountain. See Tab. of Birds, N°. 25. and the article UROGALLUS.

TELONIUM, among the Romans, is uſed to denote a cuſtom-houſe, or place where the toll was collected. See *Pitiſc.* in voc. and THELONIUM, *Cyc.*

TEM, or *brown* TEM, in zoology, the name of a water-fowl of the larus or gull-kind, called by Aldrovand *Larus cinereus minor*.

It is but a ſmall ſpecies. Its back and wings are of a pale grey, with ſome faint admixture of bluiſh; and the longer feathers of the wings are black within. The beak is very ſmall, ſomewhat crooked, and black. The back part of its head alſo is black. All other parts of the body are of a fine white. The feet are webbed, and the legs are yellow. *Ray*'s Ornithol. p. 268.

TEMACHIS, in natural hiſtory, the name of a genus of foſſils, of the claſs of the gypſums; the characters of which are theſe. It is of a ſofter ſubſtance than many of the other genera, and of a very bright and glittering hue.

The name is derived from the Greek τμαχος, *fruſtulum*, a ſmall irregular fragment; the bodies of this genus being compoſed of an aſſemblage of multitudes of irregular flaky fragments, as are all the gypſums; but no genus of them ſo viſibly ſo as theſe.

There are but three known ſpecies of this genus: 1. A ſoft ſhining green one. 2. A ſoft white one, of a marbly appearance. And, 3. A pale brown gloſſy one. The firſt is found in great plenty on the ſhores of rivers in the Eaſt-Indies; and though not known as a ſubſtance that would make a plaſter by burning, is given internally in nephritic caſes, being powdered without calcination. The ſecond is found in many parts of Derbyſhire, and is uſed for burning into plaſter for ſtuccoing of rooms, and caſting ſtatues, &c. And the third is found in Germany; and, beſide its common uſes in ſtuccoing and caſting, is in great eſteem among the metallurgiſts and aſſayers, for the making either ſingly or in mixture with bone-aſhes, their teſts. See the article TEST.

We have not this ſpecies in England ſo far as is yet known. *Hill*'s Hiſt. of Foſſ. p. 113, 114, 115, 116.

TEMAPARA, in zoology, the name of a peculiar ſpecies of lizard, called alſo *Tejuguacu*.

It approaches much to the nature of the *Iguana*, but is black ſpotted with white. See the articles IGUANA, and TEJUGUACU.

TEMBUL, in botany, a name uſed by ſome authors, for the plant called *betle*, an herb the people of the Eaſt-Indies are fond of chewing. *C. Bauhin.* pin. p. 410. See the article BETLE.

TEMELO, in zoology, a name uſed by ſome for the fiſh called in Engliſh the *greyling*, and in ſome places the *umber*.

It is a truttaceous ſpecies, known among the writers in ichthyography under the name of *Thymallus*. *Willughby*'s Hiſt. Piſc. p. 187. See the article THYMALLUS.

TEMPATLAHOAC, in zoology, the name of a broad-billed bird, of the Weſt-Indies, deſcribed by Nieremberg; and by him eſteemed a ſpecies of duck.

It is of the ſize of the common duck. Its head and neck are green, black and purple, and very bright and ſhining like the neck of the peacock. The body is of a browniſh yellow, and it has two large ſpots of white on each ſide near the tail. The tail is white all round the edges, and is of the ſame marks and colours with the peacock's, but black underneath. It is common on the lakes of Mexico, and is a good eatable bird. *Ray*'s Ornithol. p. 299.

TEMPERAMENT, or TEMPERATURE, (*Cycl.*) in muſic. Mr. Chambers, under this head, informs us, that the *Temperament*, or *Temperature*, denotes a rectifying or mending falſe and imperfect concords, by transferring to them part of the beauty of the perfect ones. This he took from Mr. de Fontenelles, in the Hiſt. de l'Acad. des ſciences, 1701.

But this requires a fuller explanation; for though it be true, conſidered in one light, that a *Temperature* corrects ſome falſe concords; yet it is no leſs true, that, in other reſpects, it ſpoils and falſifies both perfect and imperfect concords, and renders diſcords more harſh than they would otherwiſe be, if the intervals were juſtly taken. To explain this, we muſt conſider that all the intervals are founded on the primary proportions ariſing from the numbers 2, 3 and 5, that is, if we do not exceed the compaſs of an octave, $\frac{5}{4}$, $\frac{3}{2}$ and $\frac{2}{1}$. See the article INTERVAL.

The nearer we come in practice to the true intervals, the more perfect the melody and harmony will be; and it is certain, that the human voice, and ſome inſtruments, as violins, &c. which have no ſtops nor frets, will execute muſic to a great degree of exactneſs; but the caſe is not the ſame with fixed or fretted inſtruments, as harpſichords, organs, lutes, viols, &c. Accuracy is here impoſſible, unleſs we would content ourſelves with always playing in the ſame key, without any tranſition or tranſpoſition whatſoever. In this caſe, indeed, the harpſichord or organ might vie with the accuracy of the voice or violin. For inſtance; if we were to compoſe or play in the key of C, then we might make the ſeveral intervals of that key, to be in the following true proportions, $1 \cdot \frac{9}{8} \cdot \frac{10}{9} \cdot \frac{16}{15} \cdot \frac{9}{8} \cdot \frac{10}{9} \cdot \frac{9}{8} \cdot \frac{16}{15}$. that is in whole numbers $\frac{\text{C. D.}}{24 \cdot 27}$ E. F. G. A. B C. $\cdot 30 \cdot 32 \cdot 36 \cdot 40 \cdot 45 \cdot 48$. and the inſtrument, tuned in this manner, would perform any piece of muſic in C, juſtly compoſed, with great beauty and exactneſs, I here take for granted, that every key, fundamental note, or ſound, ought to have its true fifth and fourth, and that theſe ought alſo to have their true fifths and thirds.

Now this being premiſed, it will preſently appear, that in making any tranſpoſition or tranſition from C, we ſhall find ſome falſe concord. Thus, for inſtance, if we proceed to G, and conſider it as a key, or fundamental ſound, we ſhall have the following ſeries of numbers for the octave of G, *viz.* G . A . B . C . D . E . F . g $36 \cdot 40 \cdot 45 \cdot 48 \cdot 54 \cdot 60 \cdot 64 \cdot 72$. But here the interval between 40 and 54 is falſe, being a comma too much, for the ſecond of a key muſt make a true fifth with the fifth of the ſame key. In like manner, if we were to proceed from C to A, as a new key, we ſhould find the following ſeries for the octave of A, $\frac{\text{A . B . C . D . E . F . G . a}}{40 \cdot 45 \cdot 48 \cdot 54 \cdot 60 \cdot 64 \cdot 72 \cdot 80}$, where the interval between A 40 and its fourth D 54 is falſe, being too great by a comma. If any other tranſition were examined, we ſhall always find ſome note falſe; as in F, the ſixth would be redundant by a comma. And in D the fifth would be deficient by a comma. All which ſhews the impoſſibility of truth and exactneſs of muſic on fixed inſtruments. Yet as theſe inſtruments have their uſe and convenience in ſome reſpects, it was proper to endeavour to find out a method of making them tolerable.

It has been obſerved under the head INTERVAL, that the tone major exceeds the tone minor by a comma. Their difference is neceſſary for the truth and perfection of muſic; but yet if theſe tones were rendered equal, the ear would not be offended. And this has ſuggeſted the means of tempering fixed inſtruments. If we were to make all tones equal to the tone major, as ſome imagine the antients did, then we ſhould find the ditonus or third, exceeding a true third major by one comma, which would be intolerable. In like manner, if all tones were to be minor, we ſhould have thirds major defective by a comma, which would alſo be intolerable, not to mention other falſe intervals that muſt neceſſarily ariſe from ſuch a ſuppoſition.

Suppoſing then one tone increaſed, and the others diminiſhed by half a comma, we ſhould have our thirds major remain perfect. But ſtill it would be neceſſary to examine what fifths this ſuppoſition would give. Now it is evident that a tone major added to an octave, makes juſt too fifths, thus $\frac{2}{1} \times \frac{9}{8} = \frac{9}{4} = \frac{3}{2} \times \frac{3}{2}$. But the tone here added is a tone major, and the tone we have aſſumed is a temperate tone, deficient from the tone major by half a comma; hence the ſum of the two fifths, on this ſuppoſition, will fall ſhort of the truth by $\frac{1}{2}$ of a comma, and conſequently one fifth will be deficient by $\frac{1}{4}$ of a comma. Which difference, although it be ſenſible, yet experience ſhews, that fifths ſo diminiſhed are tolerable.

This *Temperature* is what is called the common or vulgar *Temperature*, and conſiſts, as has been ſaid, in diminiſhing the fifth by $\frac{1}{4}$ of a comma, in preſerving the third major perfect, and dividing it into two equal tones. Which being ſuppoſed, it follows that the fourth muſt exceed the truth by $\frac{1}{4}$ of a comma;

ma; that the third minor will be deficient by the ſame quantity; that the ſixth minor will be perfect, and the ſixth major redundant by $\frac{1}{4}$ of a comma; and laſtly, that the ſemitone major will exceed the truth by $\frac{1}{4}$ of a comma. If we introduce chromatic notes, or flats and ſharps, the ſemitone minor will alſo exceed the truth by $\frac{1}{4}$ of a comma, and conſequently the difference between the two ſemitones, or the dieſis enharmonica, will be preſerved.

If then we had a harpſichord or organ, with each feint or half note divided, we ſhould have the following notes or ſounds, *viz.* C . C♯ . D♭ . D . D♯ . E♭ . E . F . F♯ . G♭ . G . G♯ . A♭ . A . A♯ . B♭ . B . c. in the compaſs of an octave. Yet this ſyſtem of notes, numerous as they ſeem, would not be ſufficient for all tranſitions and tranſpoſitions. For tho' a piece of muſic, tranſpoſed to any of the natural keys C . D . E . F . G . A . B. and to the flats, as E♭ and B♭, and ſome others, would do well; yet in tranſpoſing to ſharps, as to C♯. we ſhould not find a true third major, unleſs we introduced E♯. and even in flats, as A♭ and E♭ we ſhould not find a true third major in deſcending, or a ſixth minor in aſcending, unleſs we introduced F♭ and C♭. and in like manner tranſpoſitions to G♯ and E♭ would oblige us to introduce B♯ and C♭. Nor would even this ſuffice; for if neceſſity required a tranſpoſition from the key of C to that of D♯, we ſhould not find a true third major without introducing F♯♯ and *c.* So that at laſt we ſhould come to a temperate ſyſtem, where, in aſcending, the notes C, D, F, G, A would each have its ſharp and double ſharp, and the notes B and E each a ſingle ſharp. In deſcending, the notes E, D, B, A, G would each have their flat and double flat, and the notes F and C each a ſingle flat. And thus the octave would be divided into 31 intervals, whoſe deſignations are C . D♭♭ . C♯ . D♭ .

1 . 2 . 3 . 4

C♯♯ . D . E♭♭ . D♯ . E♭ . D♯♯ . E . F♭ . E♯ . F . G♭♭ . F♯ .

5 . 6 . 7 . 8 . 9 . 10 . 11 . 12 . 13 . 14 . 15 . 16

G♭ . F♯♯ . G . A♭♭ . G♯ . A♭ . G♯♯ . A . B♭♭ . A♯ . B♭

17 . 18 . 19 . 20 . 21 . 22 . 23 . 24 . 25 . 26 .

. A♯♯ . B . C♭ . B♯ . C. Where the letters C . D . E .

27 . 28 . 29 . 30 . 31.

F . G . A . B. ſignify the common diatonic notes; thoſe marked with a ſingle ♯ or b are the chromatic, and thoſe marked with a double ♯♯ or bb are enharmonic notes; ſo called, becauſe the interval between them and the next diatonic note is an enharmonic dieſis; for which reaſon the notes E♯ . F♭. and B♯ . C♭. are alſo enharmonic.

But even in this diviſion of the octave, all the notes would not have a third major in aſcending and deſcending; thus, for inſtance, D♯♯ has no third major; for this would be F♯♯♯, which is not in the ſcale, nor can any number of additional notes ſuffice in all caſes. But this inconvenience is eaſily remedied, and the ſyſtem conſiderably improved by making all the 31 intervals equal. We have already obſerved, that in the common temperature the ſemitones major and minor exceed the truth by $\frac{1}{4}$ of a comma, and that the enharmonic dieſis is preſerved true. Hence it follows, that the hyperoche, or difference between the chromatic and enharmonic dieſis; for example, the interval between F♭ and E♯ or D♭♭ and C♯, *&c.* will alſo exceed the truth by $\frac{1}{4}$ comma. Now the hyperoche, by our table, under INTERVAL, is equal to 1 . 37695, to which adding $\frac{1}{4}$ comma = 0 . 25000, we have 1 . 62695, which differs from the enharmonic dieſis 1 . 90917 only by 0 . 28222, or about $\frac{7}{25}$ of a comma. Neglecting this ſmall difference, let us ſuppoſe all the 31 intervals of the octave equal, it will follow that tranſpoſitions to all the notes of the ſyſtem, whether diatonic, chromatic or enharmonic, will be equally good, and differ only in pitch or tone, as they ought, but not in accuracy, which muſt next be examined.

The diviſion of the octave into 31 parts may be conveniently done by logarithms. Under the head INTERVAL I find the logarithm of the octave = 55 . 79763 commas, conſequently each dieſis, or diviſion of the octave = 1 . 79992 commas; hence the fifth, being 18 dieſis, will be 32 . 399 commas. Now the true fifth is 32 . 640, the fifth conſequently in this *Temperature* is deficient by 0 . 241 parts of a comma, which is leſs than $\frac{1}{4}$ of a comma by $\frac{1}{110}$ part; and therefore this fifth will, ſtrictly ſpeaking, be better than that of the vulgar *Temperature* by $\frac{1}{110}$ of a comma; but this is inſenſible. Next, proceeding to examine the third, we ſhall find it equal to 10 dieſis or diviſions, that is 17 . 999 commas, and the true third major being 17 . 963 commas, the difference is 0 . 036, that is about $\frac{1}{28}$ of a comma. Now as the ear can bear a fifth, altered by $\frac{1}{4}$ of a comma, it will much more eaſily bear the alteration of $\frac{1}{28}$ of a comma in a third major. Again, in this *Temperature*, the third minor is indeed, ſtrictly ſpeaking, worſe than in the vulgar, which differs from the truth but by $\frac{1}{4}$ comma, whereas here it differs by about $\frac{1}{37}$ of a comma more; but then this difference is inſenſible.

Thus we have been led from the conſideration of the vulgar *Temperature*, to the invention of the *Temperature* which divides the octave into 31 equal intervals, commonly called, *Huygens's Temperature*. This great mathematician was indeed the firſt who gave a diſtinct account of it, and ſhewed its uſe and accuracy. But here, as in many other inventions, we find the hint of the thing much older than the true knowledge of it. See *Hugenii* Opera Omnia, vol. 1. p. 748, 749. Edit. 1. Lugd. Batav. 1724.

The diviſion of the octave into 31 parts, was invented in Italy about 200 years ago, by Don Nicola Vincentino. The title of his book is *L'Antica Muſica ridotta alla moderna prattica*, &c. Roma, 1555. Fol. and an inſtrument called *archicembalo* was made upon this ſcheme, as Salinas informs us, who at the ſame time condemns it as very diſagreeable in practice. But this could be owing to nothing but its not being tuned according to the intention of the inventor. For if all the thirds major of this inſtrument were made perfect, and the fifths diminiſhed by $\frac{1}{4}$ of a comma, it is evident that the inſtrument would be equally exact with any tuned according to the vulgar *Temperature*, and would ſuffice for tranſpoſitions to any diatonic or chromatic notes, though not to all the enharmonic, as D♯♯, *&c.* becauſe we ſhould not find its third major. And if the inſtrument were tuned according to Mr. Huygens's ſcheme, of making all the diviſions equal, it would then have all the 31 keys equally good, and very near the truth. See *Salinas*, lib. 3. The title of his work is *Franciſci Salinæ Burgenſis de Muſica Libri Septem, Salmanticæ*, 1577. Folio. *Merſennus*'s Work is entitled *Harmonicorum*, Libri XII. *authore* F. M. Merſenno *Minimo*, *Lutetiæ Pariſiorum*, 1648. Fol. He publiſhed another book before this, the title of which is, *Harmonie Univerſelle, contenant la Theorie & la Pratique de la Muſique. Paris*, 1636. Fol. 2 vol.

Hence it is plain, Salinas and Merſennus had not ſufficiently examined this matter.

The uſe of this *Temperature* of Mr. Huygens deſerves to be introduced into the practice of muſic, as it will facilitate the execution of all the genera of muſic, whether diatonic, chromatic, or enharmonic; nor does the multiplicity of its parts render it impracticable, the author aſſuring us, that he had harpſichord made at Paris with ſuch diviſions, which was approved of, and imitated by ſome able muſicians. Merſennus alſo gives a ſcheme for this purpoſe; and Salinas ſays, he ſaw and played upon ſuch an inſtrument. See alſo Don *Vincentino* before cited, lib. 5. p. 99, *&c.*

Mr. Huygens, to facilitate the tuning of inſtruments with ſuch diviſions, has given us a table of the parts of an octave, according to his ſyſtem, together with their logarithms. The table is as follows:

The diviſion of the octave into 31 equal parts.					The diviſion of the octave according to the common *Temperament.*

The ſecond column of this table contains the numbers expreſſing the lengths of chords making 31 equal diviſions, the longeſt anſwering to C, being ſuppoſed to be divided into 100,000 parts.

In the third column are the ſyllables by which the notes are uſually named in France; and the aſteriſc * ſhews ſome enharmonic notes, of which that near *Sol* is moſt neceſſary.

In the fourth column are the letters commonly uſed to denote the ſounds of the octave.

The numbers of the ſecond column were found by means of thoſe in the firſt, which are their reſpective logarithms; and theſe were found by dividing 0.30102999566 the logarithm

of 2 by 31. The quotient 97106450 is marked N. and being continually added to the logarithm of 50000 that is to 4.6989700043 gives all the logarithms of the first column to the greatest 4.9999999993, which being extremely near to 5.0000000000 the logarithm of 100000, shews the operation to have been rightly performed.

The fifth column shews the lengths of the chords in the common *Temperament*: And the sixth column contains their respective logarithms. V. *Huygenii* Opera, vol. 1. p. 752, 753. The learned author of this *Temperature* has not given the notes answering to all the divisions of the octave; but that may easily be supplied from what has been said above, when we derived this *Temperature*, from the consideration of the common.

We have already mentioned the advantages of Mr. Huygens's system; but its excellency will better appear by comparing it with the schemes of others. We may distinguish and name the different *Temperatures* by the number of equal parts, into which the octave is supposed to be divided. The *Temperatures* that occur in books, are *Temperatures* of 12, 19, 31, 43, 50, 53 and 55 parts, of which in order.

The *Temperature* of 12 parts is founded on the supposition that the semitones major and minor may be made equal. Hence the octave will be divided into 12 equal semitones, 7 of which will make the fifth, 4 the third, and 3 the third minor.

The *Temperature* of 19 parts goes upon the supposition that the semitone major is the double of the semitone minor. Hence the tone will be 3, and the third major 6. The diesis enharmonica will be 1, and consequently the octave being 3 thirds, and a diesis, will be 19. The fifth contains 11 parts. The harpsichord in this scheme will have every feint cut in two, one for the sharp of the lower note, and the other for the flat of the higher. Between B and C, and between E and F, will be interposed keys, which must serve for the sharps of B and E, and the flats of C and F respectively.

The *Temperature* of 31 parts is Mr. Huygens's already described; here the semitones are as 3 to 2. The third major is 10, and the fifth 18.

The *Temperature* of 43 is Mr. Sauveur's, and by him very fully described in the memoirs of the Royal Academy of Sciences, An. 1701, 1702. He supposes the proportion of the semitones to be as 4 to 3. Hence his tone is 7. The third major 14, the fifth is 25, and the octave 43. What musical foundation this learned gentleman went upon in the investigation of this *Temperature*, I know not: But it seems liable to insuperable difficulties; for here the diesis enharmonica is but the half of the difference between it and the chromatic diesis; whereas, in truth, this difference, instead of being double of, is really less than the enharmonic diesis, as was long ago objected to him by Mr. Henfling, and appears from the table under the head INTERVAL. Miscel. Berolin. Tom. 1. p. 285, 286.

Besides, his enharmonic diesis falls greatly short of the truth, being but 1.27 of a comma, which is an error of 0.64 or near $\frac{2}{3}$ of a comma. Whereas in Mr. Huygens's *Temperature*, the error of the diesis is almost insensible, being but $\frac{1}{16}$ of a comma. Nor are the practical advantages of Mr. Sauveur's system any way comparable to Huygen's. His fifth is indeed, strictly speaking, better; but so little, that the difference is not sensible, not being $\frac{1}{20}$ of a comma. On the other hand, his thirds are sensibly worse, the major being $\frac{1}{5}$ and the minor $\frac{2}{5}$ of a comma false. Whereas Huygens's third major does not differ sensibly from the truth, and the minor has no sensible difference from the third minor deficient by $\frac{1}{4}$ comma of the common *Temperature*, which ought to be deemed the limit of the diminution of concords. If we add to this, that the much greater number of parts in Mr. Sauveur's octave, makes it vastly more intricate than Mr. Huygens's, and that these parts would be false or useless, even supposing the enharmonic genus restored, I believe no musician will long hesitate which he ought to prefer.

The *Temperature* of 50 parts is proposed by Mr. Henfling in the Miscellan. Berolin. above cited; he takes the proportion of the semitones as 5 to 3; hence his tone is 8, the third major 16, the fifth 29, and the octave 50. The third major and fifth in this system will be worse than Huygens's, though the third minor be a little better. The third major is here less than the true, and the fifth deficient by more than $\frac{1}{4}$ comma, which is a fault, not to mention the inconveniency arising from dividing the octave into 50 parts; besides 5 : 3 the proportion of the semitones here assumed, although expressed in greater numbers, is not so near the truth as Mr. Huygens's of 3 : 2. We have given the proof of this under the head RATIO.

The *Temperature* of 53 parts is mentioned by Mersennus. Here the tones will be unequal, 9 being the tone major, and 8 the minor. Hence the third major will be 17, and the fifth 31, which last does not differ from the truth by above $\frac{1}{313}$ part of a comma. The third minor is also more perfect than in Mr. Huygen's system: But the multiplicity of parts in the octave of this system, render it too intricate; and the distinction of tones major and minor upon fixed instruments, is, I doubt, impracticable.

The last *Temperature* we have mentioned is that of 55 parts, which Mr. Sauveur calls the *Temperature* of practical musicians. Its foundation lies in assuming the proportion of the semi-tones, as 5 to 4, so the tone will be 9, the third 18, and the fifth 32. The fifth in this system, as in that which makes the semitones equal, is nearer the truth than Mr. Huygens's, but this advantage is not $\frac{1}{15}$ of a comma; and on the other hand, the thirds both major and minor are here greatly mis-tuned, as will appear by the annexed Table, exhibiting the thirds and fifths of these several *Temperatures*, as also the thirds and fifths of the common *Temperature*, and two mentioned by Salinas, marked 1st. Salin. 2d. Salin. The letter V. stands for the fifth; III. for the third major, and 3. for the third minor. The fifths are all deficient, but the thirds are sometimes greater and sometimes less than the true; the first are marked +, the others —.

Temperatures formed by the division of the octave into equal parts, may be called geometrical *Temperatures*. The common and the two mentioned by Salinas, do not proceed upon this foundation. The intention of the first inventors not having been to make transpositions to every note of the system equally good; but only to make the most usual transitions in the course of a piece of music tolerable. Hence the parts of the octave, in their suppositions, were not all equal.

The common *Temperature*, as we have said, preserves the third major perfect. The first of Salinas, preserves the third minor perfect. In the second of Salinas, the semitone minor is perfect. The foundation of his first *Temperature* is making the temperate tone equal to the tone-minor and $\frac{1}{3}$ of a comma, or to the tone-major less $\frac{2}{3}$ of a comma. Hence his fifth and third major will be deficient by $\frac{1}{3}$ of a comma; and the third minor consequently, will be true. The ground of his second scheme is, to add $\frac{2}{7}$ of a comma to the tone-minor, or take $\frac{2}{7}$ from the tone-major, for his temperate tone. Hence the fifth will be deficient by $\frac{2}{7}$ of a comma, and the thirds major and minor each deficient by $\frac{1}{7}$ of a comma. Consequently the semi-tone, being their difference, will be preserved.

As to Mr. Salmon's scale, in the Philosophical Transactions, there is nothing true in it, but the diatonic scale of C. His scale for A is false, the fourth being erroneous by a comma; most of his semi-tones are likewise false. In short, it can neither be considered as a true scale, nor as a *Temperature*.

Before we close this article, it may be proper to add a few words about the method of invention of the foregoing geometrical *Temperatures*. Mr. Huygens having had the hint of a division of the octave into 31 parts, had nothing farther to do but to examine it by logarithms. But, supposing no such hint had been given, he might have investigated it directly by the method laid down by himself, and also by Dr. Wallis, and Mr. Cotes, for approximating to the value of given ratio's, in smaller numbers. We have given Mr. Cotes's method, under the head RATIO. The application of that method to the present purpose, is thus: The ratio of the octave to the third major is 55.79763 to 17.96282, and the approximating ratios will be

1°. greater than the true 28 : 9, 87 : 28, &c.

2°. less than the true 3 : 1, 31 : 10, 59 : 19, 205 : 66, &c.

The ratios greater than the true, must all be rejected; because they give the third major less than true, and consequently the tone, (its half) deficient by above $\frac{1}{2}$ comma; which gives the fifth deficient above $\frac{1}{4}$ of a comma; but this ought not to be. The first of the ratios less than true, is 3 : 1, or 12 : 4, which is the *Temperature* of 12 parts before described, and too inaccurate. The next is 31 : 10, or Mr. Huygens's. The rest divide the octave into too many parts.

The

The ſame may be alſo found thus; the ratio of the octave to the common temperate fifth, deficient by $\frac{1}{4}$ of a comma, is 55·79763 to 32.38952. The approximating ratios to which are,

1°. greater than the true 2 : 1, 7 : 4, 19 : 11, 50 : 29, &c.

2°. leſs than the true 1 : 1, 3 : 2, 5 : 3, 12 : 7, 31 : 18, 205 : 119. Where we have the *Temperatures* of, 12, 19, 31, and 50 parts, before examined.

And here all ratios greater than the true, ought to be rejected; becauſe they give the fifth leſs than true, that is, in this caſe deficient by more than $\frac{1}{4}$ of a comma.

If we inveſtigate the approximating ratios to the ratio of the ſemi-tones major and minor, or 5.19529 to 3.28612, we ſhall have the ratios 1 : 1, 2 : 1, 3 : 2, 5 : 3, which reſpectively give the *Temperatures* of 12, 19, 31 and 50 parts, before deſcribed.

Again, inveſtigating the approximating ratios of the fifth to the third major, we ſhall find 7 : 4, 9 : 5, 11 : 6, 29 : 16, which will alſo give the *Temperatures* 12, 19, 31, 50, as before.

Laſtly, the approximated ratios of the octave to the true fifth, are 12 : 7 and 53 : 31 greater than the true. The others being of no uſe, ſince the fifth muſt neceſſarily be diminiſhed. Here we find the *Temperature* of 53 parts. As to the *Temperatures* of 43 and 55, being deſtitute of any muſical foundation, it is no wonder they do not appear by this method of inveſtigation.

Mr. Huygens, in his Coſmotheoros, ſays, that the tone or pitch of the voice cannot be preſerved, unleſs the conſonants be tempered, ſo as to deviate a little from the higheſt perfection. For the proof of this aſſertion, he brings a melody conſiſting of the following ſounds, C, F, D, G, C; where, if the intervals were to be ſung perfect, by taking the interval from C to F a true fourth aſcending, from F to D a third minor deſcending, from D to G a true fourth aſcending, and laſtly, from G to C a true fifth deſcending; we ſhould fall a comma below the C from whence we began. Therefore, if we were to repeat this ſeries of notes nine times, we ſhould at laſt fall near a tone major below our firſt ſound.

Mr. Huygens's ſolution of this difficulty is, that we remember the note from whence we ſet out, and return to it by a ſecret *Temperature*, thereby ſinging the intervals a little imperfect; which, he ſays, will be found neceſſary in almoſt all ſongs or melodies.

A like difficulty is mentioned in the Memoirs of the Royal Academy of Sciences; and is there urged for the neceſſity of a *Temperature*, even for ſinging in the ſame key. And Mr. Huygens's ſolution of the difficulty is there approved of. An. 1707. p. 264.

But the ſolution of theſe learned gentlemen is, as yet, far from being deciſive. No experiment has yet been brought to ſhew that the human voice ſings tempered notes; not even when accompanied by tempered inſtruments. It ſeems to us, on the contrary, that an exerciſed voice guided by a good ear, ſings true, even though accompanied by a miſ-tuned inſtrument, as harpſichords moſt frequently are, eſpecially in tranſpoſed keys. And were theſe inſtruments always as well tuned as art could make them, yet their tones would be equal; and it ſeems evident to the ear, that the human voice ſinging naturally two tones in ſucceſſion, as C, D, E, never makes them equal; and cannot, without great difficulty, and by means of a variation of harmony, be brought to make them equal.

Another ſolution, therefore, of Mr. Huygens's difficulty, muſt be ſought for. The truth ſeems to be, that the ſecond of the key muſt be the true tone-major above the key, and therefore the third between the ſecond and fourth of the key muſt be ſung deficient by a comma. Thus in the key of C, from C to D will be a tone-major $= \frac{9}{8}$, and from D to F will be a deficient third $= \frac{32}{27}$. See the article INTERVAL.

Mr. Huygens's melody therefore, will ſtand thus:

C, F, D, G, C.

$\frac{4}{3} \times \frac{32}{27} \times \frac{4}{3} \times \frac{2}{3} = 1$. And the voice would ſing the interval F, D, juſt as if the note E had been interpoſed; in which caſe the notes would be C, F, E, D, G, C.

$\frac{4}{3} \times \frac{15}{16} \times \frac{9}{10} \times \frac{4}{3} \times \frac{2}{3} = 1$.

Theſe notes all come within the diatonic ſcale of C; and the voice naturally falls upon the note from whence it ſet out. The ſame anſwer will hold in the example, mentioned in the Memoirs of the Academy of Sciences; where the intervals $^{\flat}$B, G, E, C, occur. And here the interval from $^{\flat}$B to G ſhould be taken $= \frac{32}{27} = \frac{15}{16} \times \frac{9}{10}$, as in the former example; and for the ſame reaſon, the key being F.

There ſeems therefore no repugnancy between the practice and theory of muſic, while the melody is confined to one key; but it muſt be owned, that in tranſitions from key to key, eſpecially where ſeveral parts are to make harmony with each other, there ſtill remain difficulties, not mentioned by Mr. Huygens, or any other writer we know of, which might deſerve a father examination.

We muſt not omit mentioning, that the learned Dr. Smith, in his Harmonics, has not only carried the theory of *Temperaments*, or *Temperatures*, far beyond all the authors that preceded him; but has ſhewn how to tune an inſtrument, according to any propoſed *Temperament*, by the ear only, which is certainly a moſt ingenious diſcovery.

This learned author [a] prefers what he calls the *Temperament* of equal harmony, which differs inſenſibly from the diviſion of the octave into 50 parts, to all others; and inſiſts, that it labours under the leweſt defects, and is of all others the moſt agreeable in practice. In the ſyſtem of equal harmony the *Temperaments* of the fifth, third major and third minor, are reſpectively, $\frac{5}{100}$ and $\frac{7}{100}$ and $\frac{3}{100}$ of a comma leſs than the truth [b]. It would be impoſſible here to do juſtice to the learned author's reaſonings on this ſubject; we ſhall only add, that he eſtabliſhes, contrary to the common opinion, that the leſs ſimple conſonances, generally ſpeaking, will not bear ſo great *Temperaments* as the ſimpler conſonances [c].—[a *Smith*'s Harmonics, p. 172, 188. b Ibid. p. 172. c Ibid. p. 146.]

Dr. Smith mentions a *Temperament* communicated to him by the ingenious Mr. Harriſon, which conſiſts in making the proportion between the octave and third major equal to that of the circumference of a circle to its diameter. In this *Temperament* the third major is diminiſhed by $\frac{1}{5}$ of a comma, but the third minor is very near the truth, and extremely beautiful. *Smith*. pref. p. xi.

A late author [a] ſeems to think the diviſion of the octave into 31 parts, not to be of modern invention, but neceſſarily implied in the doctrine of the antients. At firſt ſight it would ſeem, as if the antients made but 24 dieſis or diviſions in the octave, *viz.* ten to each fourth, and four to the tone; which (the octave being equal to two fourths and a tone) gives twenty-four dieſes to the octave. But the author juſt quoted contends, that this diviſion is to be underſtood only in one tenſion, that is either aſcending or deſcending; but that accurately ſpeaking, if we conſider all the dieſes or diviſions of the fourth, both aſcending and deſcending, we ſhall find thirteen; five to each tone, and three to the ſemi-tone major; and conſequently thirty-one diviſions in the octave. Theſe indeed are not all naturally equal; but if we make them ſo, we ſhall have a *Temperature* known by the moderns under the name of Huygens's *Temperature* [b].— [a Dr. *Pepuſch*, in Phil. Tranſ. N°. 481. p. 273. b Phil. Tranſ. ibid.] See the article DIESIS.

TEMPERATURE, or CLIMATE for plants. The difference of *Climate*, or *Temperature* of the air has a very great effect on plants. The different degree of heat is the great cauſe of theſe changes, and the different degree of moiſture ſomewhat aſſiſts in it. The American and Aſian plants, famous in medicine when of the growth of their native ſoils, yet when removed into our *Climate*, though they grow and even produce their flowers and ripen their ſeeds, which ſeems the laſt perfection of a plant, when put to the trial, have been always found to want their proper medicinal virtues.

Many of thoſe plants and trees, which though natives of another *Climate*, will endure the open air with us, and grow in our gardens; yet loſe much of their ſtrength, and become dwarfs, in proportion to what they were when in their proper *Climate*. But much leſs violent changes than theſe are able to produce the like effects, at leaſt in ſome degree. The ſeveral parts of Europe are able to alter the quality of the ſame plant, even while it grows naturally in them. Thus the blue aconite or napellus, the root of which is a terrible poiſon in the ſouth of France; yet in Britany, a northern province of the ſame kingdom, the root of the ſame plant, though it ſeems to grow with equal vigour there, and is equally large and ſucculent, has no bad effects; but has been eaten by old people and by children, without any injury.

In general, the farther north we go the leſs and leſs hurtful this plant becomes. It is common to almoſt all Europe, and we find the inhabitants of ſome places dreading it, and that with great juſtice, as a fatal poiſon; while thoſe of others eat the leaves in their ſallads, and even eſteem them good to reſtore the appetite.

The common woad which ſucceeds well in many parts of England, is not ſo certain in France; but the different *Climates* in different parts of that great kingdom, make ſtrange alterations in its juices. In Upper Languedoc they raiſe great quantities of it, and it makes an extremely fine blue dye for ſtuffs of all kinds; but in Britany, though the plant grows as high, and ſeems to flouriſh as well, yet the leaves never are ſo ſucculent, and the colour obtained from them is not of ſo fine a blue, but is duſky and browniſh.

This effect of the different *Climates*, in changing the nature of things produced in them, is not confined to plants; but the animal kingdom ſhares in it. The whole ſerpent kind are in general larger and more venomous, as we approach the hotter *Climates*. The tarantula, ſo poiſonous in the hot countries, is found greatly leſs ſo as it is found in more cold regions; and the ſcorpion, whoſe ſting is fatal in ſome parts of Africa, is little more miſchievous than the waſp or hornet in ſome of the coldeſt places where it lives. Nay, the Philoſophical Tranſactions inform us, that the bite of the tarantula, even in thoſe very places where moſt miſchievous, does not exert its power in cold weather; but that a perſon bitten at ſuch a time feels not the effect of the bite till the next ſultry hot day, though that may not happen till after two or three weeks.

The differences made by variety of *Climates* upon plants, are not limited to diſtance of place, but even in the ſame province the *Climate* differs greatly in different years, by means of accidents, and more or leſs heat; and more or leſs moiſture will do as much violence to plants ſometimes, as change of place, which only operates by means of the ſame agents. Our farmers complain of great miſchiefs, from long droughts; and the French huſbandmen, in many of the provinces, always find, that when there has fallen very much rain, or thick fogs have been very frequent, all the bread-corn of every kind degenerates; the wheat and barley are poor and thin in the ear, and the grain ſmall; but the rye becomes ſo altered, that it is pernicious to uſe it in making of bread; and the poor, who are obliged to eat the bread made with it, are ſubjected to many diſeaſes by it. They call the rye thus vitiated *Ergot*, and *blé cornu*. *Deſland*'s Trait. Phyſ.

TEMPERING *of Bricks*. See the article BRICK-*making*.

TEMPLE (*Cycl.*)—*Temples* were originally all open, and hence received their name. See Phil. Tranſ. N°. 471. ſect. 5. where we have an account of an antient *Temple* in Ireland of the ſame ſort as our famous Stonehenge.

The word *Templum*, in its primary ſenſe among the old Romans, ſignified nothing more than a place ſet apart, and conſecrated by the Augurs; whether incloſed, or open; in the city, or in the fields. *Middlet.* of Rom. Sen. p. 135.

TEMPLUM *Soſtrati*, the name of a kind of chirurgical bandage, deſcribed by Galen. He alſo deſcribes another under the name of *Templum parvum Apollonii Tyrii*.

TEMPO *di Gavotta*, in muſic. See the article *Tempo di* GAVOTTA.

TEMPORALIS, (*Cycl.*) a broad flat muſcle, reſembling the quadrant of a circle, and occupying all the ſemi-circular or ſemi-oval plane of the lateral region of the cranium, the *Temporal* foſſæ, and part of the zygomatic. Through all the circumference of this ſemi-circular plane, the pericranium is divided into two laminæ. The internal lamina, which is ſometimes taken for a particular perioſteum, covers immediately all the bony parts of this region; the external lamina ſeparated from the other, is ſpread out like an aponeurotic, or ligamentary tent, by means of its adheſions to the external angular apophyſis of the *os frontis*, to the poſterior edge of the ſuperior apophyſis of the *os malæ*, and to the upper edge of all the zygomatic arch all the way to the root of the maſtoide apophyſis.

This muſcle is compoſed of two planes of fleſhy fibres fixed to the two ſides of a tendinous plane, nearly of the ſame breadth with them by which they are ſeparated; it being ſpread quite through the muſcle, like a concealed middle tendon; and the body of the muſcle thus formed, is incloſed between the two aponeuretic or ligamentary laminæ in the following manner:

The internal fleſhy plane is fixed by a broad radiated inſertion to all the ſemicircular plane of the cranium by the intervention of the internal lamina of the perioſteum. Thus it is fixed to the lateral and external part of the *os frontis*, and to its external angular apophyſis, to the lower part of the *os parietale* to the ſquammous portion of the *os temporis*, to the great ala or temporal apophyſis of the ſphenoidal bone by which the temporal foſſa is formed, and a little to the backſide of the internal orbitary apophyſis of the *os malæ*, which forms part of the zygomatic foſſa.

The external fleſhy plane is fixed in the ſame radiated manner to the inſide of the external lamina of the pericranium, from the great ſemi-circular circumference, all the way to a ſmall portion of this lamina, more or leſs ſemi-circular above its inſertion in the zygomatic arch; here the fleſhy fibres leave the external lamina, aud the void ſpace is commonly filled with fat. The middle tendinous plane continues to contract by degrees, and ends at length in a very conſiderable tendon, the extremity of which, which is in a manner double, encloſes the coronoide apophyſis of the lower jaw. There is another ſmall plane, reckoned by ſome to be a portion of this muſcle, but in reality is no other than the third portion of the maſſeter. *Winſlow*'s Anat. p. 251.

When the *Temporal* muſcles are wounded, at the ſame time that there is a contuſion of the cranium, which is frequently the caſe, the patient will be attended with great diſorders; not only as theſe muſcles are neceſſary for the offices of dividing the food, and for forming of ſpeech, but becauſe they are furniſhed with nerves, tendons and arteries, all very conſiderable, which will partake of the injury. Where there is no violent ſymptom attending wounds on the external parts of the head, they are eaſily cured by the common method uſed to freſh wounds, and there will be no occaſion for ſutures, for ſticking plaſters will always anſwer the purpoſe; but the dreſſings muſt always be finiſhed with all poſſible expedition; the medicines muſt be always applied warm, and the air kept in a moderate heat with hot coals.

If there be any great degree of hæmorrhage from the wounded veſſels, dry lint, or the ſtyptic powders are to be uſed, and the whole kept on by compreſſes and a proper bandage; and after the hæmorrhage is ſtopped, the wound muſt be dreſſed with *mel roſarum*, or ſome digeſtive medicines, till ſufficiently deterged, and then with a vulnerary balſam, or dry lint till it is healed. *Heiſter*'s Surg. p. 83.

TEMPOREGIATO, in the Italian muſic, ſometimes ſignifies, that the muſicians who accompany the voice, or the perſon who beats time, ſhould prolong ſome particular part thereof, to give the actor or ſinger room to expreſs the paſſion he is to repreſent, or to introduce ſome graces by way of ornament to the piece.

TEMPOREGIATO is alſo uſed in a different ſenſe, for *à Tempo*, or *à tempo giuſto*.

TEMPORUM *Oſſa*. Theſe are two in number, ſituated in the lower and lateral part of the ſkull; the figure of each is partly ſemi-circular, reſembling the ſcale of a fiſh, partly like a ſhapeleſs rock ending in ſeveral points.

Each of them is divided into two portions, one ſuperior termed ſquammous, from its figure; the other inferior, called *apophyſis petroſa*, or the rocky apophyſis; but that more from its hardneſs, than from the irregularity of its figure. This portion is eaſily ſeparable from the former in children; and ſome marks of this diviſion are uſually found ſtill remaining in adults.

They are alſo divided into two ſides, one external and convex, the other internal and concave. Their external eminences are, the maſtoide apophyſis in the lower and poſterior part of the bone; the zygomatic apophyſis in the anterior part; the ſtyloide apophyſis under the bone, which ſeems originally to have been an epiphyſis; the capſular apophyſis, in which the bony ſtilet ſeems as it were to be ſet; the articular eminence of the zygomatic apophyſis, the lambdoidal angle, and the lower ſide of the apophyſis petroſa.

Its external cavities are, the articular one immediately behind the eminence, called by the ſame name; and which, with that, ſerves for the articulation of the lower jaw. The crack in the articular cavities; the maſtoide notch, in which the digaſtric muſcle is inſerted; the opening of the external *meatus auditorius*; the anterior indented border of that opening; the ſtylomaſtoide, or anterior maſtoide hole, which is the orifice of the paſſage of the *portio dura* of the auditory nerve, called from its form the aqueduct; the orifice or inferior hole of the carotide canal in the apophyſis petroſa, which alters its direction upward and forward, and ends at the point of the rock near the *ſella ſphenoidalis*; a portion of the jugular foſſa, and a portion of the *foramen lacerum*.

Among the external cavities we are likewiſe to reckon a portion of the *ductus palatinus* of the ear, commonly called the Euſtachian tube, and by ſome the aqueduct; but by no means to be confounded with the other aqueduct, or ſtylomaſtoide; the zygomatic notch; the parietal notch; the ſpheroidal notch; one or more little tubes, which receive the ramifications of the temporal artery; the groove in the apophyſis petroſa; by which it is connected to the great apophyſis of the *os occipitis*; the poſterior maſtoide hole; but this hole is ſometimes formed between this bone and the *os occipitis*, and is ſometimes entirely wanting in one of the bones, and ſometimes in both; and there is beſide theſe, in ſome ſubjects, a ſmall maſtoide hole, which loſes itſelf in the ſubſtance of the bone.

In examining the internal eminences and cavities, we muſt diſtinguiſh the ſquammous portion from the apophyſis petroſa. In the former we ſee the radiated indentations of the ſemicircular edge, which with the parietal bone forms the ſquammous ſuture; a portion of the middle foſſa of the baſis cranii on the ſame ſide, and ſeveral inequalities on the ſame ſide.

The apophyſis petroſa, or rock, is a ſort of pyramidal body, with three ſides ſituated obliquely, ſo that its baſis is turned backward and outward, and its apex forward and inward toward the *ſella turcica*: Of the three ſides, one is ſuperior and inclined a little forwards, the ſecond poſterior, and the third inferior: This laſt belongs to the outſide of the whole bone. The upper ſide aſſiſts in forming the middle foſſa of the baſis cranii; and we obſerve here a ſmall irregular hole appearing to be double, and partly covered by a ſmall bony plate; this is a kind of break or interruption in the duct, through which the *portio dura* of the auditory nerve paſſes.

In the back ſide of the rock we ſee the internal auditory hole, and a portion of the foſſa for the cerebellum: ſmall, indeterminate, and pretty deep depreſſions are ſometimes ſeen in it in children; but theſe are gradually obliterated as they grow up. At the baſis of this apophyſis we ſee a portion of a groove in the lateral ſinus, formed partly in this baſis, partly in the lambdoidal angle; as alſo a portion of the *foramen lacerum*, and a ſmall point which as it were divides this hole in two, and diſtinguiſhes the paſſage of the jugular vein, from that of the eighth pair of nerves.

As this apophyſis has three ſides, three angles are to be obſerved in it; the firſt ſuperior between the upper and back ſides, the ſecond poſterior between the back and lower ſides, and the third anterior between the lower and fore ſide. The ſuperior angle, which is the moſt apparent, has a groove for the ſmall ſinus of the *dura mater*. The poſterior angle is in a manner interrupted near the middle by the *foramen lacerum*, and from it proceeds the little bony point, which divides this hole; at the end of it is a grove by which it is connected with

the great apophyſis of the *os occipitis*. Between the apex of the apophyſis petroſa, and the ſuperior opening of the carotid canal, we ſometimes meet with a ſmall bone alſo of the ſeſamoide kind, mentioned long ſince by Riolan. Almoſt the whole ſubſtance of the *oſſa temporum* is compact; the ſquammous portion is thin and tranſparent; the maſtoide apophyſis is hollowed by conſiderable cells; the apophyſis petroſa is very hard and ſolid, with ſeveral internal cavities for the organ of hearing contained in it. *Winſlow*'s Anatomy, p. 30. See the article TEMPORIS *Os*, *Cycl.*

TENACIOUS *Bodies*. See the article TENACITY.

TENACITY, in natural philoſophy, that quality of bodies by which they ſuſtain a conſiderable preſſure or force without breaking. Mem. Acad. Berlin. 1745. p. 47.

Tenacity is the oppoſite quality to fragility or brittleneſs. See the article BRITTLENESS.

Tenacious bodies ſupport the effort of percuſſion, or preſſure, without receiving any damage: But here, and in many other caſes, as when we uſe the words *hard*, *ſoft*, *flexible*, &c. we muſt be underſtood in a ſenſe relative to the ordinary degrees of human ſtrength; otherwiſe it would be difficult to ſay, what is *tenacious*, brittle, hard, ſoft, *&c.* Ibid.

TENCH, the Engliſh name of the *tinca* of the modern authors, the *fullo* and *gnapheus* of the antients.

It is, according to the Artedian ſyſtem, a ſpecies of the cyprinus, and is diſtinguiſhed by that author by the name of the blackiſh, mucous, or ſlimy cyprinus, with the end of the tail even. See the articles TINCA and CYPRINUS.

This is a delicately taſted fiſh, though it lives in foul water, and ſeems to feed very coarſely. It is always found in the muddieſt parts of ponds, and where there are moſt weeds.

The ſlime of the ſkin of this fiſh is ſaid to be of a healing nature, and to cure all freſh wounds; and it is pretended that the other fiſh know this property in it, and always apply to the *Tench* when wounded. Whether their opinion be true or falſe, the *Tench* has obtained by it the name of the *fiſhes phyſician*. The pike is ſaid to pay ſuch reſpect to this fiſh, on this account, that he never ſeizes him. But theſe are things eaſier to be fancied and ſaid than proved; and if it ſhould prove that the pike does not eat the *Tench*, it may be reſolved into a much more natural cauſe, by ſuppoſing the ſlime of the *Tench* too diſagreeable in his ſtomach to ſuffer it.

The ſeaſon for angling for *Tench* is in June, July, and Auguſt. The time of their biting is early in the morning, or late in the evening, and in hot weather, all night long. The favourite bait for the *Tench* is a large red worm, and they will take this much more greedily if it be dipped in tar, after it is put on the hook. There are ſeveral ſorts of paſte alſo that he bites very well at, particularly one made of brown bread and honey, with an admixture of tar. All paſtes that have any of the ſtrong-ſcented oils in them, are alſo good baits. Other baits are the cad-worm, lob-worm, flag-worm, green gentle, marſh-worm, or ſoft boiled bread corn. All theſe will do very well at a proper ſeaſon.

When a number of *Tench* are to be taken out of a muddy pond, where they will not bite freely at the hook, the method is to take a very good and large caſting-net, well leaded, and with the meſhes from the crown to a full yard and half, not too ſmall, for then, if the pond be deep, the fiſh will ſtrike away before the net gets to the bottom. The place where the net is intended to be thrown, muſt be made clean from buſhes and large weeds, with a rake. When the place is thus cleared of any obſtacles to the even deſcent of the net, a bait is to be prepared to draw the fiſh together, where the net is to be thrown. This bait is to be thus made: Put a quarter of a peck of wheat into three quarts of water, ſend it to an oven, and let it be well ſoaked, then add to it five pints of blood, and as much bran as is neceſſary to give it the conſiſtence of a paſte. Mix ſome clay with it, that it may the better hold together; and finally add a quart of lobworms chopped to pieces. Let the whole be wrought up into a ſtiff paſte, and rolled into balls of the ſize of a hen's egg; and let theſe be thrown into the pond, in the place where the net is to be thrown. At times theſe, and at times ſome grains are to be thrown in; and the place in this manner thoroughly baited for ſeveral days. When the fiſh may be ſuppoſed to be very well acquainted with the ſpot, let a very good baiting be given in the morning, and in the cloſe of the evening let the caſting-net be carefully thrown in. When the net is ſunk, the mud all about is to be ſtirred up with a long pole, with a fork at the end; the net is to lie half an hour, and the mud to be thus ſtirred all the time; by this means the *Tench* will be raiſed, and will be taken in the pulling out the net; but if the net were to be thrown in and taken out in the common way, there would hardly be one fiſh taken; for the cuſtom of both *Tench* and carp, when they are frighted, is to plunge their heads up to the eyes in the mud, and thus placed, with their tails erect, any net in the world muſt draw over them, without a poſſibility of its entangling them.

TEND, in our old writers, ſeems to ſignify as much as *Tender* or offer; as to *tend* a traverſe, an averment, *&c.* Briton, c. 76. Staundf. Prærog. 16. *Blount*, *Cowel.*

TENDO *Achillis*, in anatomy, is ſometimes more peculiarly denominated *Chorda Achillis*, and *Chorda Magna*, or the great *Tendon*.

'Tis on the diſtance of the *Chorda Achillis* from the point of ſupport, that the ſtrength of the foot depends. The further this tendon is from the articulation, the ſtronger the part is found. Hence it is obſerved, that animals which run, or leap with the greateſt eaſe, are thoſe in which this *Tendon* is fartheſt removed. And men with long heels are better able to walk than others; and ſtill the longer the foot, the more neceſſary is the length of heel. Petit. in Mem. de l'Acad. R. des Scienc. 1722. p. 75.

Anatomiſts are divided about the rupture of the *Tendon* of Achillis. Some hold this *Tendon* impoſſible to be broken by any effort whatever, and in proof hereof alledge its ſituation, which ſeems to ſecure it from ſuch an accident. Others inſiſt, that conſidering the great force which draws this *Tendon* downward, when in a leap or fall, the whole weight of the body bears on the top of the foot, or on the heel; 'tis eaſy to conceive, that a ſingle effort may break it. Accordingly Pareus affirms, he has known it broken, on a ſlight occaſion; as by a falſe ſtep, a ſlip in mounting on horſeback; and this without any viſible injury, or ſolution of continuity of the part.

M. Petit, the ſurgeon, produces two other inſtances of his own knowledge: The firſt, of a poſture-maſter named Clochoix, who, at the fair of S. Germains, endeavouring to jump, with his feet cloſe together, upon a table 3 foot high, broke both the *Tendons of Achillis*, yet without any external wound [a]: The ſecond, of a woman who broke the *Tendon of Achillis* of the right foot, by a fall in a boat, from a bench 6 foot high [b].—[[a] Mem. de l'Acad. R. des Scienc. 1722. p. 68. ſeq. [b] Traite des Malad. des Os. Jour des Scav. T. 74. p. 328.]

The phænomena enſuing on the rupture of the *Chorda Achillis*, in the firſt inſtance, were, that the patient could ſtill contract or ſtretch his feet; that he could not ſtand upright; and that he felt no pain, either at the time of the rupture, or during the cure.

Notwithſtanding this, ſeveral perſons perſiſt in the belief of the thing's being impoſſible; and conteſt both theſe inſtances, as not real ruptures of the *Tendon of Achillis*. A warm diſpute has enſued between the author and Mr. Andry, and others, the particulars whereof are related by the Paris journaliſts. V. Jour. des Scav. T. 74. p. 328. ſeq. Id. T. 75. p. 483. ſeq. Id. T. 78, p. 230.—

Mr. *Petit* obſerves, that the *Tendons* are a ſort of cords, which at one end part from a muſcle, and at the other are joined to a bone, ſo that when the muſcle contracts itſelf in its action, the *Tendon* draws toward it the bone to which it is infixed, and makes it perform ſuch motions as it is capable of. The *Tendons* are ſubſtances not capable of extenſion; ſo that when a muſcle acts, if the bone which it ſhould, by that action, draw to a certain place, does not follow, either the bone muſt break, or the *Tendon* muſt be torn aſunder; provided that the action of the muſcle be of a proper ſtrength.

We are next to conſider, that in certain motions, ſuch as that of the dancer, who is going to riſe up from the ground, all the weight of his body is ſuſtained by, and even overpowered by a certain number of muſcles, which, having been thrown into a ſtrong contraction, violently expand themſelves again in a moment, and by that means cauſe the leap. If at the inſtant, when theſe muſcles have ſtretched their *Tendons* to the utmoſt violence, there happens ſome accident by which theſe *Tendons* are again pulled downward by the whole weight of the body, it cannot be wondered at, that, ſtrong as they are, they cannot reſiſt ſo violent a force; and it was in this very manner that the dancer, cured by Mr. Petit, broke the *Tendons*. He was about to leap upon a table placed three foot above him; the *Tendon* could not but be extended to its full power in the attempt; and in trying, he ſunk directly down again; by which means the weight of his whole body was added to the former force; and that force was yet increaſed by the acceleration of a fall from the height of three foot.

The *Tendo Achillis* is formed by an intimate union of the *Tendons* of two muſcles; now if theſe two *Tendons* are both broken, the rupture of the *Tendon* is judged compleat; if one only is torn, and the ether remains whole, the caſe is then called an imperfect or incompleat rupture of that *Tendon*.

There is a great difference between the compleat and the incompleat ruptures of this *Tendon*. The pain in the incompleat rupture is exceſſively great; whereas in the perfect one there is ſcarce any pain at all. When a *Tendon* is wholly divided, the two ends draw back different ways, like the ſtring of a bow when cut, and this produces no pain, or any farther bad ſymptom, than the loſs of the *Tendon*; which is ſo true, that, in order to take off the pain and other bad ſymptoms which attend the wounding, or imperfectly dividing a *Tendon*, the beſt means is to cut it wholly aſunder.

The *Tendo Achillis* is placed in a ſort of ſocket, where it plays freely every way, and has no connection or adherence with the adjacent parts; and hence a compleat rupture of it is without pain. This, however, is not the caſe, when only one of the two *Tendons* which compoſe it is divided, for then the ſeparated ends of this retiring back as far as poſſible, cannot but violently affect the remaining entire *Tendon*, which with

them

them formed the *Tendo Achillis*; and as the union of these two is very strict, the pain succeeding the separation of one, and the retraction of its ends, cannot but be proportionably violent and great.

The pain felt in the division of one of these *Tendons*, or the imperfect rupture of the *Tendo Achillis*, is only perceived upwards or above the wound, not below it; the reason of which is, that the upper part of the divided *Tendon* is forcibly drawn up by the muscle by which it is contracted, while it is also drawn downward at the same time by the *Tendon* to which it is intimately and firmly united, and which yet remains whole; and this contrary force must produce the most exquisite pain in the fibres which resist; while the inferior portion, having no force applied to it but what tends to draw it downwards, easily yields to that, and is in no condition to suffer a like pain. This difference between the sensation of the two extremities is, however, only to be felt at first; since, after some time, the inflammation spreading, affects the neighbouring parts, and the lower extremity must feel its share; though even then the pain is much less acute in that portion than in the upper.

In case of a compleat rupture of this *Tendon*, the foot may be bent without causing any pain to the patient; the only effect is the encreasing the space which is between the divided ends of the *Tendon*: But the case is far otherwise in an imperfect rupture of this *Tendon*; the foot then cannot be bent without the utmost pain and agony, because the space between the divided ends of the *Tendon*, which must be enlarged by this bending, cannot be enlarged without a tearing, and violently forcing the imperfectly divided parts.

In the imperfect rupture of this *Tendon*, the patient may walk, though it is with very violent pain; but in the perfect rupture, the person cannot walk, though he suffers no pain at all. In walking, at every step that we take, the whole weight of the body is sustained by the hinder foot; now the *Tendo Achillis* is the only support, by means of which the foot can sustain that weight, or regulate its pressure; and therefore when that *Tendon* can no more perform its office, we can no more walk. These are the several symptoms by which the imperfect ruptures of this *Tendon* may be known from the compleat ones; a knowledge highly necessary to all who are to undertake their cure. Memoirs Acad. Par. 1728.

There have been instances of the *Tendo Achillis* having been cut through, and cured without stitching. See Commerc. Norimb. 1740. hebd. 46.

When a *Tendon* is wounded or divided, the part to which it belongs loses its motion; but if it is divided only in part, the symptoms it produces are much the same with those arising from a nerve wounded in the same manner. *Heister*'s Surg. p. 28.

TENDON, in the manege, a sort of gristle that surrounds one part of a horse's foot, and is seated between the hoof and the coffin-bone, near the cronet. When a horse has a quitter-bone, the matter that gathers between the coffin-bone and the hoof, spoils the *Tendon*, and makes it black; and the cure of such a quitter-bone consists in cutting and extirpating the *Tendon*.

TENESMUS, (*Cycl.*) a name given by medical writers to a complaint, which is a continual desire of going to stool, but usually without any stool being ready to be voided. This is usually attended with some tumour, sometimes with a very considerable one in the part. This is properly no primary disease, but merely a symptomatic one, and differs in degree according to the disease on which it is an attendant.

Signs of it. These are a titillation and itching about the anus, attended with a violent burning pain, and a desire of compressing and voiding something, and this attended usually either with no excrement, or only a pulpous and mucous matter, and very often a procidentia ani, or falling down of the rectum.

Persons subject to it. This disease very often happens to people labouring under hæmorrhoidal disorders, especially when the discharges attending them do not succeed regularly, though nature gives all the necessary motions for their excretion. It happens also to people who are subject to void an acrid and bilious matter by stool, and not unfrequently to those who have a stone in the bladder. Women in the latter part of their time, in going with child, have also very often terrible fits of it, attended with considerable swelling; this happens to them from the pressure of the uterus, with its burden, upon the rectum and hæmorrhoidal veins. The procidentia ani happens also to all these subjects, and, beside these, is very familiar to infants, from their voiding an acrid matter by stool, and to all persons who are subject to great costiveness, and void their stools with great difficulty and pain; and finally, people who have paralytic weaknesses of the sphincter of the anus, incur this troublesome disorder after a time.

Causes of it. The causes of a *Tenesmus*, beside those already mentioned, of suppressions of the hæmorrhoidal discharges, and voiding acrid matter by stool, are the ascarides, a small sort of worms which usually infest the rectum, and occasion a continual iching and tickling there; the abuse of resinous purging medicines; and, among these, the resinous parts of aloes, and black hellebore, are, above all, most subject to remain in the rectum, and bring on this complaint: Much riding will also sometimes occasion it; and many people have been thrown into it by wiping their backside with paper in which pepper, ginger, or other hot and acrid things have been kept. The procidentia ani is owing usually to the same general causes, as also to the relaxation of the nervous and glandulous coat of the rectum, occasioned by long continued diarrhœas.

Prognostics in a TENESMUS. When a hiccough comes on upon a person in a *Tenesmus*, it is usually a bad omen; a violent *Tenesmus* coming upon women with child, sometimes occasions them to miscarry. In the mildest symptoms of the falling down of the anus, which is a frequent attendant on a *Tenesmus*, it is a very troublesome and painful disorder, especially when it continues some time, as it often does: And when there happens a tumour, and coldness in the part that is fallen, it very often becomes dangerous, threatening inflammation and mortification. In common cases, and where the distemperature has not before been frequent, the reducing the intestine to its place is usually an easy thing; but when there is any thing paralytic in the origin, it is more difficult both to restore it, and to prevent relapses.

Method of Cure. As the *Tenesmus* is merely a symptomatic disease, the primary disorder is to be examined, and treated, in order to a cure. Thus, when it is occasioned by ascarides, worm-medicines are to be given, and clysters of a proper kind injected, such as decoctions of tanzy, wormwood, and myrrh: When the worms are by this means destroyed, the *Tenesmus*, which was no more than a symptom, naturally ceases. In cases where it is caused by a flux of bilious matter by stool, or by a retention of the hæmorrhoidal discharges, it will be proper to give medicines to obtund the acrimony of the humours, and take off the spastic motions occasioned by them. To this purpose powders of nitre, crabs-eyes, and cinnabar, are to be given, and jellies of hartshorn, and the like, with gum-arabic, tragacanth, and such other agglutinants. The vapours of turpentine, and of the carminative seeds, received on the part, are also of great benefit; and hot fomentations of decoctions of the herbs of marshmallows and pellitory, and chamomile flowers. These ingredients may also be applied as a cataplasm; for beyond all things, external heat is of the most immediate service. The sitting over the steam of hot water is a very good thing, and the rubbing the part with an ointment made of mucilage of quince seeds, with oil of mullin, and the yolk of an egg. In cases where there is a procidentia ani, the gut is to be replaced as soon as possible; the person is, to this end, to be laid upon his belly, and a moderate force to be used in putting it back, the fingers being first rubbed over with oil of sweet almonds, before they touch the gut. If this is not to be done at the first attempts, the patient must be suffered to lie down again in a natural posture, and spunges, wetted with astringent dedoctions, are to be applied to the part; powders of mastic, with a very small quantity of alum among it, also is useful to be sprinkled on the gut on this occasion. The sitting upon a bag of oatmeal, boiled to the consistence of pap, and sprinkled over with a small quantity of alum, is also a very good method. And so long as the intestine remains out of its place, it must be carefully kept warm, for fear of a mortification. If there is an inflammation attending it, this must be first carefully discussed by epithems of scordium, sage, chamomile, and rose and elder flowers; and, after this, the usual methods of attempting a reduction are to be employed. And finally, when the sphincter has a paralytic weakness, the ordinary methods are to be assisted by bandages, to prevent its return; but in a case of this kind, all that is to be done, is simply palliative, since the cure is not to be hoped. In cases where the *Tenesmus* is owing to bilious stools, or to the suppressions of the hæmorrhoidal discharges, the patients are carefully to abstain from all medicines in which aloes is an ingredient, as the elixir proprietatis, and the like.

In cases of the *Tenesmus* from the pressure of the womb in women with child, there is no cure but delivery; but the methods before proposed will palliate and give ease. When milk is given in clysters, in these cases there must be great care taken that it is perfectly fresh, not the least turned sour. If there be a colic attendant on the *Tenesmus*, provided that it be not a bilious one, it is always proper to inject clysters with a small quantity of common salt, to absterge the mucous humours; and when powders of the astringent kind are used, they must always be extremely fine, lest their particles, sticking to the inner coats of the intestine, should increase, instead of mitigating the disease. Alum must be added, but in very small quantities, to these powders, lest it astringe too violently, and by that means prevent instead of forwarding the reducing the part. Hartman commends the beetles found in horse-dung, dried and powdered, as a very powerful remedy in all cases of this kind. *Junk.* Consp. Med. p. 583. seq.

TENGA, in botany, a name by which some authors have called the coco-nut-tree, or *Palma Indica nucifera* of other writers. Hort. Malab. vol. 1. p. 1.

TENSION, (*Cycl.*) *Tensio*, Τασις, in the antient music, was used to signify any pitch of sound, whether produced by intention or remission. Vid. *Aristoxen.* p. 10——13. Edit. Meibom.

Ariſtoxenus obſerves, there are five things to be conſidered about ſounds, τασις, tention; ἐπιλασις, intention; ἀνεσις, remiſſion; ὀξυτης, acumen; and βαρυτης, gravitas. Ibid. See theſe Terms in their proper Places.

TENSOR (*Cycl.*) — TENSOR *Tympani*, in anatomy, a name given by Albinus to one of the muſcles of the ear, called by Cowper, *internus auris*, and by others, *internus mallei*.

TENT, (*Cycl.*) a ſmall bundle of ſcraped lint, uſed in dreſſing ſome wounds, worked into the ſhape of a nail, with a broad flat head. They differ in thickneſs and length, according to the ſize of the wound for which they are intended.

They are chiefly uſed in deep wounds and ulcers, and are of ſervice to convey medicines to the moſt inner receſſes and ſinuſes of the wound. 2. To prevent the lips of the wound from uniting before it is healed at the bottom. And 3. By their aſſiſtance grumous blood, ſordes, and other foulneſſes, are readily evacuated.

They are to be made extremely ſoft, that the cure of the wound may not be retarded, by the pain they would otherwiſe bring on; but, that the wound may not be kept open too long, it is adviſable, as ſoon as the part is ſufficiently cleanſed, and the ſinuſes are found to heal up, to leſſen the ſizes of the *Tents* by degrees, and as ſoon as ſafely and conveniently may be, to leave them entirely off.

Many ſurgeons, of great note, have entirely forbid the uſe of *Tents*, from the frequent obſervation of the ill effects ariſing from the ſurgeon's neglecting, or not knowing theſe neceſſary cautions.

There are, however, beſide theſe *Tents* of ſcraped lint, another kind, made of linnen rags not ſcraped, worked up into a conical form, to the baſis of which is faſtened a ſtrong thread; the apex of it muſt be a little unravelled, to make it ſofter, that it may not become painful. The thread is faſtened to the baſis, that it may be recovered with the greater eaſe, if by any accident it ſhould be forced into the cavity of the thorax or abdomen, for theſe ſort of *Tents* are chiefly uſed to keep open wounds that penetrate into the thorax or abdomen; in order to make way for the proper diſcharge of blood, matter, &c. by the mouth of the wounds.

A third ſort of *Tents* there remains yet to be deſcribed, whoſe office is not only to keep open, but to enlarge, by degrees, the mouth of any wound, or ulcer, which ſhall be thought too ſtrait, by which means a freer paſſage may be procured for the blood or matter that was confined; and that the proper medicines may find a more ready admittance.

Theſe *Tents* are uſually called *ſponge Tents*, and are made either of ſponge, or of the roots of gentian, calamus aromaticus, &c. for theſe kind of things imbibe the matter that flows to them, and being enlarged, by that means dilate the lips of the wound. *Heiſter*'s Surg. p. 17.

TENTHREDO, in natural hiſtory, the name of a fly of the ſtinging kind. It is of the ſize and ſhape of the bee, but of the colour of the waſp. It loves to be among meat, as in kitchens and larders; it is a very gregarious animal, but makes no honey, though whole ſwarms live together.

TENTORES, among the Romans, were perſons appointed to hold the cloaths of the charioteers that contended in the circus. *Pitiſc.* Lex. Antiq. in voc.

TENUIROSTRÆ, in zoology, the name of a genus of ſmall birds, which feed on inſects, and have ſlender and ſharp beaks; of this genus are the lark, ſwallow, red breaſt, and a number of others. *Ray*'s Ornithology, p. 148.

TEPETOTOTL, in zoology, the name of a Braſilian bird, of the gallinaceous kind, more uſually called *mituporanga*. See the article MITUPORANGA.

TEPHRIA, in the natural hiſtory of the antients, a name given to the grey ophites. See the article OPHITES.

TEPHROMANTIA, τεφρομαντεια, in antiquity, a ſpecies of divination, performed with aſhes; for which ſee *Potter*, Archæol. Græc. T. 1. p. 353.

TEPID, in natural hiſtory, a term uſed by writers on mineral waters, to expreſs ſuch of them as have a leſs ſenſible cold than common water.

They diſtinguiſh all the medicinal ſprings into three kinds; the hot, the *tepid*, and the cold; but the middle term might eaſily be miſunderſtood to mean a great deal more than they expreſs by it; all that have what can be called the leaſt ſenſible warmth, are called hot; and the *tepid* are diſtinguiſhed from the abſolutely cold, only by their being leſs cold.

Some of this claſs of mineral waters, and ſome few alſo of the cold ones, have a ſharpiſh vinous taſte, which is never obſerved in any of the hot ones. This taſte is loſt on the giving the waters the ſlighteſt heat, and is therefore very difficult to be gueſſed at as to its origin. It is not only found in the aluminous and vitriolate waters, but alſo in thoſe which are manifeſtly nitrous, and which abound in ſulphureous ſalts, quite different in their nature from acids. 'Tis therefore an additional ſomewhat, quite diſtinct from the ſaline properties of the fluid, and as eaſily connected with one kind of that as with the others.

The cauſes of heat in the mineral waters remains yet wholly unknown, notwithſtanding all that has been written concerning it. It is hard to believe, that there are continual ſubterranean fires near enough the ſurface, to give a heat that preſerves itſelf in ſo great a degree to the very place of their eruptions; and it is equally hard to conceive, that there can be beds of fermenting mineral matters, ſufficient in quantity and force to have given the ſame degree of heat to waters for ſo many ages, as ſome of our hot ſprings are known to have ſubſiſted. *Duclos*'s Exam. des Eaux. Miner.

TEPIDARIUM, among the Romans, a *Tepid*, or blood-warm bath, which was joined to the cold and hot baths, and was a medium between the two; ſo that if any perſon wanted to go from the hot to the cold bath, or *vice verſa*, he always took the *Tepid* bath in his way. *Pitiſc.* in voc.

TERBEDH, in the materia medica, a name given by Aviſenna to the *Turbith*, a purging-drug, mentioned by all the authors of his time; but in general, in a very confuſed manner.

The *Turbith* of Serapion is the *Tripolium* of the Greeks. The *Turbith* of other authors is the *pityuſa* or the *alypum*-root; all theſe are things greatly differing from one another, and from the true *Turbith* of our ſhops deſcribed by Garcias.

The greateſt critics have been perplexed what to determine as to the *Turbith* of Aviſenna; it ſeems plainly different from all theſe; and though Scaliger, and others, make it alſo different from the *Turbith* of our times, and of Garcias; yet there is ſome reaſon to ſuſpect that they err in this, and that the drug is the ſame.

This author ſays, that the *Turbith* of his time was a woody ſubſtance, brought from the Eaſt-Indies. This cannot belong to any of the other plants, as they are natives of Greece, not brought from the Indies, and as they were not woody, but herbaceous plants; but the *Turbith*, which we at this time receive from the Indies, is a woody ſtalk, and the virtues of it agree well with thoſe aſcribed by Aviſenna to his *Turbith*.

Garcias tells us, that the Indians uſe it to purge phlegm, and that they add ginger to it by way of corrective; and Aviſenna ſays the ſame thing, of its uſe in his time.

TERDINA, in the materia medica, a name by which Paracelſus, and ſome other authors, have called the great garden Valerian. *Ger. Emac.* Ind. 2.

TEREBINTHUS, the *Turpentine-tree*, in botany, the name of a genus of plants; the characters of which are theſe. The flower is of the apetalous kind, being compoſed of ſeveral ſtamina, furniſhed with their apices; theſe are however barren, and the embryo-fruits are produced on other plants of the ſame ſpecies, which produce no flowers. Theſe finally become a capſule, compoſed of one or two cells, and containing oblong ſeeds. See Tab. 1. of Botany, Claſs 18.

To this it is to be added, that the leaves are pinnated, growing ſeveral over-againſt one another on a middle rib, which is terminated by an odd leaf.

The ſpecies of *Turpentine*, enumerated by Mr. Tournefort, are theſe: 1. The common *Turpentine*-tree. 2. The *Turpentine*-tree, with a larger eatable fruit, like the piſtachia nut. 3. The *Turpentine*-tree, with ſmall blue eatable fruit. 4. The Indian *Turpentine*-tree of Theophraſtus, the piſtachia of Dioſcorides. 5. The trifoliate piſtachia, or *Turpentine*-tree. 6. The *Turpentine*-tree of Cappadocia. 7. The American *Turpentine*-tree, with fruit like the piſtachia, but not eatable. *Tourn.* Inſt. p. 579.

TEREBOTIN, a word uſed by Paracelſus, for the common turpentine.

TEREBRA, (*Cycl.*) the name of a chirurgical inſtrument, uſed for the perforation of bones, or for the extracting of bullets, or other the like extraneous bodies, out of wounds.

TEREBRATULA, in natural hiſtory, a name given by Mr. Lhuyd to ſome ſpecies of the ſmooth conchæ anomiæ, which have near the head of the ſhell a ſmall hole, which looks as if bored by art. See the article CONCHÆ *Anomiæ*.

TEREDO, a name given by naturaliſts, to a ſpecies of ſea-worm, which eats its way into the bottoms of ſhips, lining the hole it makes with a kind of ſhelly matter.

The head of this creature is well prepared by nature for the hard offices it is to undergo. being coated with a ſtrong armour, and furniſhed with a mouth like that of the leech; by which it pierces wood, as that animal does the ſkin. A little above this it has two horns which ſeem a kind of continuation of the ſhell. The neck is as ſtrongly provided for the ſervice of the creature as the head, being furniſhed with ſeveral ſtrong muſcles. The reſt of the body is only covered by a very thin and tranſparent ſkin, through which the motion of the inteſtines is plainly ſeen by the naked eye; and by means of the microſcope, ſeveral other very remarkable particulars become viſible there.

At that part where the inteſtines end, the tail begins; this is longer than all the reſt of the body; it is depreſſed in the middle, and puffed out on each ſide, and is joined to the callous part of the lower end of the body, in an irregular manner, ſo that there is an indeterminate void ſpace left between; this occupies the middle part between what the natural hiſtorians call two ſoleæ-form fins. This creature is wonderfully minute, when newly excluded from the egg, and at its utmoſt bigneſs is a foot long; three or four inches is however its more frequent length.

The ſkin of this little animal being ſtripped off, the heart, ſtomach, and inteſtines come plainly in view, as alſo the callous muſcles of the neck, and two white ovaries; the heart is compoſed of two pyramidal veſſels.

The increaſe of this pernicious inſect is by eggs, and is ſo very great, that Sellius, who has written a whole folio of its hiſtory, computes there are in one parent more young at a time, than there are men in the eight largeſt cities of Europe; ſo that it is no wonder that ſo many of theſe creatures are found in the bottom of a ſhip, when they have once ſeized upon it; the only wonder is, that there are not many more.

When the bottom of a veſſel, or any other piece of wood conſtantly under water, is inhabited and injured by ever ſo great a number of theſe worms, there is no ſign of the damage to be perceived on the ſurface, nor are the creatures viſible till the outer part of the wood is cut or broken away, then their ſhelly habitations come in ſight; theſe lie ſo near the ſurface, however, as to have an eaſy communication with the water, and there are a multitude of little perforations in the very ſurface through which the inhabitant inſects throw out the extremities of their little ſhelly horns. Theſe are of a reddiſh colour, and may be diſtinguiſhed by an accurate obſerver in form of ſo many red prominent points; they all are retracted on the leaſt touch, and are thrown out again as ſoon as all is quiet. From theſe points, or the ſmall apertures which give them a way out, are the cells of the *Teredines* to be traced. They are compoſed of a pearly or ſhelly matter, which forms a long tube with various windings and turnings, which marks the abode of the creature; but which uſually neither adheres to the body of the animal, nor to the wood. Theſe caſes or tubes are always more or leſs looſe in the wood, and there is ever a large ſpace within them, for the body of the animal to be ſurrounded every way with water. They are very ſmooth on the inner ſurface, and ſomewhat rougher without; and are much harder and firmer in the cells of the older and larger animals, than in thoſe of the young ones.

Theſe ſhelly tubes are compoſed of ſeveral rings, or annular parts; but theſe differ greatly in their length.

There is an evident care in theſe creatures, as they are a republic, never to hurt or injure one another's habitations; and by this means each tubule or caſe is preſerved entire, and in ſuch pieces of wood as have been found eaten by them into a ſort of honeycomb, there never is ſeen a paſſage or communication between any two of the tubules, though the woody matter between them often is not thicker than a piece of writing-paper.

The creature depoſits its eggs on the outſide of the bottom of a ſhip, or any other piece of wood; the young worm hatched from this egg immediately eats its way into the wood, entering thus by a very minute hole, which is the reaſon why the ſurface of wood ever ſo much infeſted with them ſhews no ſign of them; when they have made their way into the ſubſtance, they work forward in different directions, and when they find they approach one another, they turn ſhort off, and direct their future courſe another way; and to this ſeems owing the twiſted ſhape of the tubules; neither are theſe every where of the ſame dimenſions, but are always wider where the head and the ſoleæ-form fins are placed, than elſewhere; a free motion of both theſe parts being extremely neceſſary to the well being of the animal.

The kind of wood in which theſe worms are lodged, makes a great difference in the appearance of their cells, as they work much more ſpeedily and ſucceſsfully in ſome kinds, than in others. The fir and alder are the two kinds they ſeem to eat with the greateſt eaſe, and in which they grow to the greateſt ſize. In the oak they ſeem to make but a very ſlow progreſs, and uſually appear very ſmall and poorly nouriſhed. The colour of their ſhelly tubules is often brown in this wood; which ſeems plainly owing to the effect of its juices.

Although the head of this creature ſeems extremely well formed for the eating into any ſubſtance, yet the hardneſs of oak, and of ſome other ſpecies of wood in which theſe animals are found, is ſo great, that it ſeems ſcarce credible that they could fairly have eat their way into it. Reaumur has proved that ſome kinds of ſhell-fiſh have in part of their bodies a corroſive liquor; and many have ſuppoſed the *Teredo* to have ſuch a liquor, and by that means to deſtroy the wood. But there are many reaſons againſt this, as the exact and regular figure of the hole, the difficulty of corroding wood, *&c.* Sellius reſolves the whole into the mere repeated action of water. He ſuppoſes the whole body of the *Teredo* to be an hydraulic engine, which, as it is always ſurrounded with ſea-water in its cells, takes in and throws out part of this as it pleaſes; and by continually diſcharging water with ſome violence againſt that part of the wood into which it would make its way, it is ſuppoſed by degrees either wholly to wear it away, or at leaſt to ſoften it in ſuch a manner, as that it may be eaſily gnawed away.

By this means alſo the tracheæ of the wood and other veſſels, which in its growing ſtate had ſerved for its nutrition, are opened and enlarged, and make the way for wider holes much eaſier than it would appear to any one who conſidered the wood as one ſolid maſs.

When there comes an iron ſpike, or other extraneous hard body in the way of one of theſe creatures in its courſe, it firſt trys if it can eaſily go round it, but if there appears any difficulty in that, it continues its battery of water againſt it, and either by continued induſtry makes its way through it, or periſhes in the attempt. The young ones when even but juſt hatched from the egg, have this art of darting forth water, and by that means make their way, as well as by eroſion into the wood.

One thing very remarkable is, that the body of the *Teredo* when grown to a moderate ſize becomes the habitation at pleaſure of a vaſt multitude of ſmall ſea-water inſects, which enter with the water into the cavity of the tubules, and are with it received into the body of the animal, and again thrown out againſt the wood. In this, doubtleſs, many of them periſh; but millions at a time are alſo to be ſeen, living perfectly at eaſe in the belly of the creature.

The vaſt increaſe of theſe animals, and their ſhelly tubules, naturally leads to a conſideration of the manner of their generation; and when we conſider that each of theſe creatures is, from the time when it is produced from the egg, immediately lodged in a cell, in which it lives without the leaſt poſſibility of getting into that of another animal of its own kind, or receiving one of them into its own; it is not eaſy to account for the propagation of the ſpecies in the common way. This, however, is ſolved by an accurate anatomical obſervation of the animals themſelves, ſince in every individual the parts of generation of both ſexes, and both the ſemen and ovula are found. Each individual therefore evidently ſerves by itſelf for the propagation of the ſpecies; and this is probably very often the caſe in earthworms, and other of the hermaphrodite animals. All the yet known kinds of theſe being ſoft-bodied; and probably, though they often meet one another, and copulate in pairs, yet when they have not that opportunity, the parts copulate in the individual.

The eggs are found in great plenty in the bodies of theſe animals in June, and are after this diſcharged with the water into the ſea, where the far greater part of them, doubtleſs, become food for other ſmall animals; and the few that come to good affix themſelves to any piece of wood they are waſhed againſt, and there hatch and get into its ſubſtance in the manner of their parents.

Many other animals are great deſtroyers of the eggs of the *Teredo* while they are fixed to the ſurface of the wood. The ſcolopendræ marinæ eat them in great abundance; the ſhrimps alſo, and the pulmo marinus devour them.

Poiſonous ointments are alſo found to be of ſome uſe in deſtroying them, on rubbing over the wood; ſome have thought that burning the ſurface was an effectual way of preſerving them, but this has been found to be otherwiſe. The ſureſt method of avoiding them in particular works, is the uſing bitter or very ſolid woods; the firſt kind they are found never to touch, and in the other they make but ſlow progreſs. Mixtures of lime, ſulphur, and collocynth, with pitch, for covering over the ſurfaces of boards, *&c.* have been found of ſome uſe.

It ſeems very evident, that boards and other pieces of wood have been ſubject to be eaten by theſe animals, from all times that we have any knowledge of; for the ſtone called *lapis ſyringoides* is evidently no other than wood thus eaten, petrified by long lying in the earth, together with the tubules of the worms. The maſſes of this with the grain of wood yet plain in them, are common in many places among ſea-ſhells, and other marine remains at great depths, and have evidently been brought thither in very diſtant times, and before changes were made in the ſurface of the earth of which we have no accounts in our earlieſt hiſtories. *Sellii* Hiſt. Natur. Teredinis.

TERENJABIN, in the materia medica of the antient Arabians, a word uſed to expreſs a kind of manna called by ſome *manna maſtichina*, from its round globules reſembling the drops of maſtic, and by the phyſicians of many parts of the world at preſent *manna perſicum*. See the article MANNA *Perſicum*.

Geoffroy indeed makes the *Terniabin*, or *Terenjabin* to be a kind of liquid manna; but this is an error into which he has been led by Bellonius, who, though a very cautious obſerver in moſt particulars, was evidently deceived in this, by the accounts of the monks of mount Sinai. Bellonius ſays, that theſe monks collect a kind of liquid manna, which is called *Tereniabin*, and ſold in the ſhops at Cairo under that name; and adds, that this is the *mel roſcidum* of Galen, and *mel cedrinum* of Hippocrates; but it is very evident from the general conſent of authors that this was not the ſubſtance called *Tereniabin* by the Arabians, and now *manna perſicum*.

It ſeems indeed very probable, that this liquid manna collected by theſe monks, is the ſame ſubſtance called *droſomeli*, and *aëromeli* by Galen, and *mel cedrinum* by Hippocrates (if there be no error in the text) though not the *Tereniabin*.

The deſcription which Galen has left us of the *mel roſcidum*, and of the manner of collecting it on mount Sinai in his time, agrees very well with what Bellonius ſays of it; and theſe circumſtances ſeem to be agreed upon by all authors in regard to it, but it does not appear that its uſe as a medicine was known any thing near ſo early as in the days of Hippocrates and Galen; the Arabian phyſicians ſeeming to have been the firſt who brought it into general uſe as a purge. Galen takes notice of the *mel roſcidum*, or liquid manna, more

as a curioſity than as a medicine, no where mentioning its qualities as ſuch, or ſaying any thing about its uſe. He ſays, that it was rarely met with in his country, but that it was gathered annually in conſiderable quantities on mount Sinai. And indeed from the manner in which it is ſpoken of by the old Greek writer cited by Athenæus, as mentioned by Salmaſius, it ſhould ſeem that it was only uſed for pleaſure, as an agreeable ſweet. What he ſays of it, being that it was ſweeter and more agreeable to the taſte than honey itſelf. Meſue tells us, that Galen mixed manna with ſcammony.

In the ſpurious piece *de dynamiis*, aſcribed to Galen, ſcammony is indeed ordered to be mixed with honey, but he never once mentions manna in any of his writings on any ſuch occaſion. As Galen is known to be very minute and particular in his account of the materia medica at that time in uſe, his ſilence is a ſtrong argument that even the mel roſcidum was not in uſe as a medicine, much leſs any other ſpecies of manna. Phil. Tranſ. N°. 472. p. 90.

TERES (*Cycl.*)—Teres *Folium*, among botaniſts. See the article Leaf.

TERETRON, the name of a chirurgical inſtrument, more uſually called *Terebra*.

TERFEZ, in natural hiſtory, the name given by the Africans to the truffles found in the deſarts of Numidia, and other places in that part of the world in great abundance.

Theſe are much more delicately taſted than the European truffles, and are white on the outſide. They are called by ſome of the Africans *kema*, and by the Arabian writers *cantha*, and *camahe*.

TERM (*Cycl.*)—The uſe of *Terms* is neceſſary in order to render our abſtractions clear and diſtinct, as alſo to retain them.

TERMOR, *Tenens ex termino*, in law, he that holds lands or tenements for a term of years, or life. *Litt.* 100. *Blount.*

TERNA, a word uſed by ſome authors, to expreſs an impetigo. See the article Impetigo.

Terna *Folia*, among botaniſts. See the article Leaf.

TERNARY *Number*, in antiquity, was eſteemed a ſymbol of perfection, and held in great veneration among the antient mythologiſts. Whence Virgil,

——— *Numero Deus impare gaudet.* Ecl. 8. v. 75.

Servius on this place remarks, that the Pythagoræans aſcribed the *Ternary* number to the ſupreme God, as being the beginning, middle, and end of all things. All the heathen gods had a threefold power attributed to them, as the *tria virginis ora Dianæ*, the three-forked thunderbolt of Jupiter, the trident of Neptune, the three-headed dog of Pluto. Again, the parcæ were three, the furies three, Hercules was three nights in begetting, the muſes were antiently three, the graces three, &c. *Hofm.* Lex. univ. in voc.

This number was likewiſe uſed in moſt religious ceremonies, but eſpecially in luſtrations; whence Virgil, Æn. l. 11. v. 188.

Ter circum accenſos, cincti fulgentibus armis
Decurrêre rogos.———————

TERPENTARIA, in botany, a name uſed by ſome authors for the *betonica aquatica*, or great water figwort, called waterbetony. *Ger. Emac.* Ind. 2.

TERRA, *Earth*, (*Cycl.*) in natural hiſtory, &c. ſee the article Earth.

Terra *de Baira*, in natural hiſtory, the name given by ſome to an earth of a white colour, found about Baira, not far from Palermo.

It is eſteemed a very great medicine in the cure of malignant fevers, and in the ſtopping hæmorrhages of all kinds. The powder of it is commonly ſold in Italy under the name of Claremont powder; a name it obtained from a perſon who firſt found out its virtues, and communicated them to the world in a treatiſe expreſly written on the ſubject. *Boccone* Muſ. de Fiſic. See the article Claremont *Powder*.

Chia Terra, in the materia medica of the antients, an earth of the marle kind, found in the iſland of Chio, and given internally as an aſtringent; but its chief uſe among them was as a coſmetic, the ladies eſteeming it the fineſt of all things for cleanſing the ſkin, and defacing wrinkles.

What title it has to theſe qualities, the world has not of late ages inquired into; but the ſubſtance is ſtill in being, and to be had in any quantities from the ſame place. And the deſcriptions Dioſcorides and Galen have left us of it are ſo accurate, that there is not the leaſt room to doubt but that the earth now found there was the very kind they uſed. It is a denſe compacted earth, yet very ſoft and of a texture eaſily diſunited and broken by water.

While in the ſtratum it is of a duſky greyiſh or bluiſh white, very dry, and of a ſhattery ſtructure; when thrown upon the ſurface of the earth and left to the weather, it ſoon breaks into an impalpable powder, or melts into a ſubſtance like butter, and ſinks into the earth again; but if taken up and dried, it becomes of a pale greyiſh white, and is ſeen to be laminated in its ſtructure, or compoſed of a great number of plates or thin cruſts. It is remarkably fine and ſoft to the touch; it adheres firmly to the tongue, is very eaſily broken and crumbled to pieces between the fingers, and a little ſtains the hands. Thrown into water it makes a ſlight bubbling and hiſſing noiſe, and afterwards ſwells and gradually melts into a ſubſtance like a thick cream. It ferments violently with acids, and ſuffers no change in a moderate fire, except that it becomes a little whiter; and by theſe characters may be diſtinguiſhed from all the other white earths. *Hill*'s Hiſt. of Foſſ. p. 46.

Terra *cimolia purpuraſcens*. See the article Steatites.

Terra *Foliata Tartari*. This ſaponaceous ſalt, which is a fixed alkali, ſaturated with diſtilled vinegar, is an excellent alterative and diuretic, when taken in the quantity of half a dram to two drams. If taken in the doſe of three to ſix drams, it is a mild cathartic which never ſinks the ſpirits, or occaſions any violent diſorder. It has been found of ſervice in dropſies. Med. Eſſ. Edinb. abr. Vol. 1. p. 166.

Terra *Goltbergenſis*. See the article Goltbergensis *Terra*.

Terra *Hydata*, in our old writers, land ſubject to the payment of *Hydage*. *Selden. Blount.*

Terra *Lignicenſis*. See the article Lignicensis *Terra*.

Terra *Livonica*. See the article Livonica *Terra*.

Terra *Melia*. See the article Melia *Terra*.

Terra *Melitenſis*. See the article Melitensis *Terra*.

Terra *Merita*, in the materia medica, a name given by ſome authors to the curcuma or turmeric root.

It is from a falſe pronunciation of this name *Terr merit*, that the Engliſh turmeric has its origin. *J. Bauhin.* V. 2. p. 146.

Perſica Terra. See the article Persica *Terra*.

Terra *Sigillata Magni Ducis*. See the article Etrusca *Terra*.

Terra *Sigillata fuſca*, a bole of a beautiful brown colour, found in Germany, England and America.

It is of a denſe texture, makes no fermentation with the ſtrongeſt acids, and if thrown into water, it ſoon ſeparates into a number of thin flakes.

The Germans give it in fluxes and malignant fevers, being an excellent aſtringent, and worthy to be introduced into our ſhops.

Sileſiaca Terra, *Sileſian Earth*, in the materia medica, a fine aſtringent bole, called by ſome authors *axungia ſolis*.

It is very heavy, of a firm compact texture, and in colour of a browniſh yellow. It breaks eaſily between the fingers, and does not ſtain the hands, is naturally of a ſmooth ſurface, and is readily diffuſible in water, and melts freely into a butter-like ſubſtance in the mouth. It leaves no grittineſs between the teeth, and does not ferment with acid menſtrua. Theſe are the characters by which it is known from all other earths of a like colour. It is found in the perpendicular fiſſures of rocks near the gold mines at Strigonium in Hungary, and is ſuppoſed to be impregnated with the ſulphur of that metal. It is, however that be, a good aſtringent, and better than moſt of the boles in uſe. *Hill*'s Hiſt. of Foſſ. p. 9.

The *Terra Sileſiaca* is alſo called *Terra ſigillata ſtrigonienſis*. *Boyle*'s Works, Vol. 1. p. 500, 501.

Montanus gives us a high character of its virtues, and ſays, it is gold tranſmuted by nature into an admirable medicine. Sennertus commends it as excellent againſt malignant fevers, diarrhœas, &c. *Boyle*, ibid.

Agricola tells us, that the ſpirit of this earth diſſolves gold, as well as aqua regia, though more ſlowly, into a red ſolution; which, in a few days precipitates the gold in fine powder. He alſo mentions another earth found at Weſterwald, preferable to this Sileſian earth. *Boyle*, ibid. See the article Westerwald *Earth*.

Sinopica Terra. See the article Sinopica *Terra*.

Terra *Solis*, in natural hiſtory, a name given by the German naturaliſts to a kind of black ſpungy earth, ſomewhat approaching to the nature of that Engliſh black earth, which we call *kellow*, but containing gold. It is not properly an ore of gold, but is an earth into which ſome ſmall particles of gold have been waſhed from ſome other place, and there detained. A good microſcope will diſcover theſe particles in the richer pieces of the earth, and they are bright and pure, though very ſmall. The earth is found in fiſſures of the other ſtrata, not in any beds or ſtrata of itſelf. It is not to be had in any great quantity, nor does it contain any large portion of gold.

Terra *Strigonenſis*. See the article Strigonensis *Terra*.

Turcica Terra. See the article Turcica *Terra*.

Terra *Virgine aurea*, in natural hiſtory, the name of a medicinal earth, mentioned by Boccone.

It is found at a place called Sancto Paolo, in the ſtate of Modena; and is thence ſent to Venice, and many other places, where it is eſteemed a very famous medicine.

Its great uſe is in hæmorrhages of all kinds; but it is alſo given with ſucceſs in malignant fevers. *Boccone*, Muſ. de Fiſic.

TERRÆJENBIN, in the materia medica of the antient Arabians, a word uſed as the name of a kind of manna; it is evidently only a corruption of the word *Tereniabin*, which is plainly that kind of manna now known under the name of *manna perſicum*. See the articles Manna *Perſicum*, and Terenjabin.

TERRAIGNOL, in the manege, a horſe that cleaves to the ground, that cannot be made light upon the hand, that cannot be put upon his haunches, that raiſes his fore-quarters with difficulty, that is charged with ſhoulders, and, in general, one whoſe motions are all ſhort, and too near the ground.

TERRAIN, in the manege, is the manege ground, upon which the horſe makes his piſte, or tread.

TERRE *Tenant*, *Terræ Tenens*, in law, he who hath the actual poſſeſſion of the land. For example: A lord of a manor has a freeholder, who letteth out his freehold to another, to be poſſeſſed and occupied by him, this third perſon is called the *tertenant*. *Weſt*. Symb. par. 2. *Blount*, *Cowel*.

TERRE *Verte*, in the colour trade, the name of a green earth much uſed by painters, both ſingly for a good ſtanding green, and in mixture with other colours.

The name is French, and ſignifies green earth.

It is an indurated clay, of a deep bluiſh green colour, and is found in the earth not in continued ſtrata or beds, as moſt of the other earths are; but in large flat maſſes of four or five feet in diameter; theſe break irregularly in the cutting, and the earth is generally brought out of the pit in lumps of different ſizes. It is of a fine regular and even ſtructure, and very hard. It is of an even and gloſſy ſurface, very ſmooth to the touch, and in ſome degree reſembling the morochthus, or French chalk, but adhering firmly to the tongue. It does not ſtain the hands in touching it; but, being drawn along a rough ſurface, it leaves an even white line, with a greeniſh caſt. It does not ferment with acids, and it burns to a duſky brown colour.

It is dug in the iſland of Cyprus, and in many parts of France and Italy. That from the neighbourhood of Verona has been uſed to be eſteemed the beſt in the world; but of late there has been ſome dug in France that equals it. There is alſo an earth dug on Mendip Hills, in the ſinking for coal, which, tho' wholly unobſerved, is nearly, if not wholly, of equal value. *Hill*'s Hiſt. of Foſſils, p. 31, 32.

TERRIFICATIO, a word uſed by ſome chemical writers to expreſs the coalition of the earthy particles of ſome bodies after fermentation, or during the time of it.

TERROR. The effect of *Terror*, or of ſudden frights, in diſeaſes, often are very great.

It is generally obſerved, that people who are moſt afraid of the plague in times of contagion, catch the infection ſooneſt, and that thoſe who are moſt terrified and diſheartened at firſt in the diſeaſe, generally die of it. It is indeed uncertain, whether this be to be attributed to the *Terror*, or whether the *Terror* itſelf, as a conſequence of dejection of ſpirits, be not merely a ſymptom of the diſeaſe. *Kerkring*, Spicileg. Anat.

Sudden frights, in acute diſeaſes, have evidently killed many, by the agitation into which they have thrown the ſpirits, already too much diſordered. We have alſo accounts of perſons abſolutely killed by *Terrors*, when in perfect health at the time of receiving the ſhock from them: People ordered to be executed, but with private orders for a reprieve, have expired at the block, without a wound. And Kerkring gives an inſtance of a perſon, who, walking along the ſtreets, was foretold by a beggar that ſhe ſhould die on a certain day, then nearly approaching, and who really expired on that day. The world gave the beggar the credit of predicting future events; but the phyſicians rather ſuppoſed that the effects of the *Terror* killed the patient. Id. ibid.

TERSIO, the name given by Pliny, and the antients, to the *porpeſs*. It is ranked among the cetaceous kind, and is the ſmalleſt fiſh of that tribe.

The *porpeſs*, properly ſo called, ſeldom exceeding five feet in length, in which it differs from the dolphin; a fiſh very often confounded with it; but which is frequently ſeen of ten or twelve feet in length. The ſnout of the dolphin is alſo much larger than that of the *porpeſs*; which is another thing that may ſerve to determine their difference.

In the diſſection of the head of this fiſh, the *meatus auditorius* was found to be two inches diſtant from the exterior canthus of the eye, forming a very ſmall hole, which ſeems the provident care of nature, leſt the water, getting in, ſhould prove an inconvenience to it. Ariſtotle and Mr. Ray, indeed, agree in ſaying, that there are no ear-holes found in the head of this fiſh; but a careful inſpection ſhews, that they were both miſtaken.

The *porpeſs* has no gall-bladder, and thence authors have concluded that it has no gall; but this is too haſty a concluſion; for there is a duct which ariſes in the liver, and has a great many branches, and which, tending downwards, joins itſelf to the pancreatic duct; and theſe two, ſo united together, form a canal, or common duct, about four or five lines long, before they diſcharge their contents into the duodenum; from whence it appears that the *porpeſs* has always a diſcharge of bile into the duodenum, though it is thin and diluted, and ſuch as, in other animals, is uſually called *hepatic bile*. *Klein*'s Hiſt. Piſc.

TERTHRON, a word properly ſignifying the extreme part of the ſail-yard in ſhipping. Hippocrates uſes it in a metaphorical ſenſe, to expreſs the extremity of a diſeaſe.

TERTIAN (*Cycl*)—The medical writers diſtinguiſh this diſeaſe into two kinds, the ſingle and the double; and beſide theſe, into the legitimate and the ſpurious and ſub-continual. In the ſpurious *Tertian* the cold fits are ſhorter, and the chilneſs leſs intenſe, and the heat ſcarce ever goes off at all; beſide this, it is uſually attended with a cough, and with violent laſſitudes and pains in the limbs after the fits; a vertiginous diſorder in the head, reſtleſsneſs in bed, and a want of appetite.

The ſimple *Tertian* is alſo carefully to be diſtinguiſhed from thoſe acute fevers, principally of the epidemic kind, which frequently affect the appearance of it, when they happen in the ſpring ſeaſon, and the patient is ſubject to crudities in the primæ viæ. Theſe laſt, beſide the appearance of the ſimple *Tertian*, always carry with them the certain marks of malignity, and often are attended with petechial ſpots on the fourth day or later. The juſt diſtinguiſhing all theſe appearances, in diſeaſes that reſemble the ſimple *Tertian*, is extremely neceſſary, as the treatment of them, in the way of the ſimple *Tertian*, muſt be attended with very bad conſequences.

The ſigns of the ſimple Tertian are theſe: It uſually ſeizes people in the morning, frequently about 11 o'clock, and often earlier, and begins with a very remarkable horror and coldneſs, with which the patient trembles violently: This is firſt felt in the region of the loins, and thence propagates itſelf up the back, and ſo to every part of the body; this is ſucceeded by a nauſea, and a ſtraitneſs of the præcordia; and when the *Tertian* is legitimate and genuine, this nauſea proceeds to abſolute vomiting, by which there is uſually voided a thick viſcous and mucous matter; but ſometimes a bilious ſaburra; and in the firſt fits, uſually ſome of the food of the day before, indigeſted. Sometimes there are only violent reachings to vomit, without any thing coming up; and in ſome a diarrhœa comes on in the place of the vomiting. When theſe ſymptoms have continued an hour or two, the coldneſs goes off, and there ſucceeds an univerſal languor and ſoreneſs in the joints; and this is the more violent, as the nauſea has been the leſs ſo. This languor is followed by a violent heat, which ſometimes comes on at once, and ſometimes ſlowly and gradually, and is attended with pains in the head, and a violent thirſt, and bitter taſte in the mouth. *Junker*'s Conſp. Med. p. 364.

As ſoon as the violence of the heat abates a little, a ſweat comes on; but this is not great, and often does not appear at all in the firſt paroxyſms. The more ſtill and quiet the perſon is, the more quickly the heat goes off, and the ſweating comes on. The whole fit rarely continues leſs time than ſix hours; uſually it holds eight, and ſometimes eleven hours; but when it continues longer than this, it is to be ſuſpected for being of the ſpurious kind, and degenerating into a continual one. The fit returns in the ſame manner as at firſt every other day, or, as the medical writers term it, every third, including the days of both paroxyſms; and uſually, while undiſturbed, returns on the patient at the very ſame hour.

The double Tertian. The ſigns of this are, that the fits return every day; but then the ſucceeding paroxyſms do not anſwer to one another, but the alternate ones; thus the third fit anſwers to the firſt, the fourth to the ſecond, and ſo on. It is by this, that this diſeaſe is diſtinguiſhed from the quotidian, which has its fits every day coming on at the ſame hour; while in the double *Tertian*, if the firſt fit comes on in the morning, the ſecond comes in the afternoon; then the third comes on in the morning as the firſt, the fourth in the afternoon as the ſecond, and ſo on.

The anomalous *Tertian* obſerves no regular time of coming on at all, but will begin one day in the morning, another in the evening, a third at noon, and a fourth in the afternoon, and ſo on.

Perſons ſubject to TERTIANS. Young people are much more frequently ſubject to this diſeaſe than older, and men oftener than women. People of an active life are more ſubject to it than thoſe of a ſedentary one: But no people ſo eaſily fall into it as thoſe men who are apt to be ſick after dinner, and make a cuſtom of ſuppreſſing their inclination to vomit.

Cauſes of it. Theſe are the eating immoderately of foods difficult of digeſtion, and eſpecially when this is done againſt the ſtomach, or while that is afflicted with nauſeas, violent commotions of anger, or the other paſſions, immediately after a full meal; and to theſe is to be added, a coldneſs of the abdomen after meals, by which digeſtion is impeded, and the driving back any cutaneous humour.

Prognoſtics and Method of Cure. It is commonly obſerved, that *Tertians*, when not improperly treated, are rather conducive to health, than injurious to it; and that people are uſually much better after they are cured of them, than before they were attacked by them. If thoſe who have a *tertian* uſe a moderate diet and good regimen, it often goes off of itſelf, without the aſſiſtance of medicines; but when ill treated, as by giving violent ſweating medicines in the time of the hot fit, the patients are greatly weakened, and ſometimes very dangerous inflammations of the viſcera, and acute fevers are brought on; and this the more certainly, as the patient is younger, of a more plethoric habit, and uſed to a high diet, and the uſe of wine, or other ſtrong liquors.

The more the gentle ſweat, which ſucceeds the hot fit, is encouraged, the weaker the fits grow at every period, and the

diſeaſe finally goes off much more ſafely by this means, than when violently thrown off at once by aſtringents.

The *double Tertian* requires the ſame method of cure with the ſimple one; for which ſee the articles PERUVIAN *Bark*, and AGUE. *Junker*'s Conſp. Med. p. 366.

Continual TERTIAN, in medical writers, a term uſed to expreſs a kind of compound fever, which has paroxyſms ſomething like thoſe of the *Tertian*, but in which the heat never goes wholly off; but is often ſo extream, as to continue in great violence from one fit to the time of another.

There are three ſpecies of theſe compound fevers; they are all compoſed of the intermittents of the ſeveral periods, and of an acute fever: The firſt is the *continual quotidian*, the ſecond this *continual Tertian*, and the third the *continual quartan*.

The firſt of theſe is the ſame with the catarrhal fever of the benign kind. The ſecond here treated of, is what was called by the antients, the *extended Tertian*. For the *continual quartan*, ſee the article QUARTAN.

Signs of it. The paroxyſms are begun in the ſame manner as in the ſimple *Tertian*, that is, by a ſhaking coldneſs; and this is ſucceeded by a heat which is at firſt very violent, but afterwards grows more and more languid, yet never goes wholly off, but continues, in ſome degree, to the acceſs of the next paroxyſm. In this diſeaſe the appetite is loſt, and the ſtrength fails very ſenſibly, the ſleep is troubled and unſound, and there is a continual head-ach; there is a quick pulſe at all the times of the fever, and a dryneſs of the mouth and tongue, with great thirſt. *Junker*'s Conſp. Med. p. 396.

Perſons ſubject to it. This fever is very often the conſequence of a common ſimple *Tertian*, when injudiciouſly treated, eſpecially when it has been ſuppreſſed by giving hot medicines juſt before the coming on of the fit, or when the patient has been cooled in the time of the ſweat, or has been blooded during the time of the diſeaſe; it ſometimes alſo attacks perſons who have had violent cutaneous humours, as the itch, *&c.* ſtruck in; and ſometimes the air alone gives it, from be-being full of fermentative particles.

Prognoſtics in it. When the diſeaſe is of this epidemic kind, and ariſes from faults in the air, it is always attended with greater danger, and has worſe ſymptoms than when proceeding from other cauſes; in this caſe it is ſometimes attended with purple ſpots on the breaſt and other parts. When treated cautiouſly, and with a gentle regimen, it very often changes to a common intermitting *Tertian*, and is then eaſily cured; but even from this leſs dangerous ſtate, it ſometimes changes into a hectic, when it has been treated with large doſes of abſorbents under that form; and finally, when it is treated with the common hot medicines and regimen, it too often degenerates into a violent and dangerous acute, and uſually inflammatory fever.

Method of Cure. Before the coming on of every fit, the patient ſhould take a ſcruple of a powder, prepared of diaphoretic antimony, oiſter-ſhells ſated with juice of lemons, nitre, and tartarum vitriolatum, each in equal quantities; and while the heat continues violent, he muſt drink plentifully of warm and weak liquors; and when this violent heat is gone off, he muſt be kept in a gentle ſweat, by the milder alexipharmics, till the return of the paroxyſm again.

In caſes where the heat is very violent, and the temperament of the body is hot and plethoric, the acids, ſuch as lemon-juice, and the like, are of very ſingular ſervice. During the whole courſe of the diſeaſe, the bowels muſt be kept open by all means; but they muſt not be ſtimulated; and as the force of the diſtemper wears off, more powerfully laxative medicines are to be given, and that at ſuch times that their effect may not be over at the time of the acceſs of the paroxyſm.

The bark can properly have no place in the cure of this diſeaſe; and after the cure of it by the means above preſcribed, the patient muſt continue the uſe of ſome of the medicines, and muſt harden himſelf to the air by degrees, for fear of a relapſe. *Junker*'s Conſp. Med. p. 399.

TERTIANARIA, in botany, a name given by ſome authors to the *ſcutellaria*, or hooded willow herb. *J. Bauhin.* vol. 3. p. 435.

TERTIAS, a word uſed very frequently in the writings of phyſicians, with the addition of *ad*; but it is capable of a double ſignification. *Ad Tertias* is often uſed to expreſs how far the liquor is to be boiled away in medicinal decoctions; yet it may in this caſe ſignify either the boiling to two thirds, or to one third part, of the whole. The more uſual ſenſe, however, is to boil away one third part of the original liquor, and in the ſame manner to fill a veſſel *ad Tertias*, does not ſignify to fill a veſſel one third part full, but two thirds, leaving only one empty.

TERTIUM *Sal*, a *third ſalt*, a term uſed in chemiſtry to expreſs a ſalt reſulting from the mixture of an acid and an alkali, which partakes ſo of the nature of both, as to be itſelf neither acid nor alkali, but neutral.

TERTIUS *Adducens*, in anatomy, a name given by Spigelius to one of the four muſcles called the *quatuor recti oculi* by authors.

This is the muſcle called the *adductor* by Molinett; and by ſome others, the *bibitorius*.

TERTIUS *Hyoidis Muſculus*, in anatomy, a name given by Fabricius and others, to the muſcle generally known by the name of *ſtylohyoidæus*.

TERTIUS *Oculum Movens*, in anatomy, a name given by Veſalius to one of the muſcles called by Albinus, the *quatuor recti* of the eye; this is the ſame with the firſt of that author, the *atollens oculi*, the *ſuperbus* of others.

TERTIUS *Palpebrarum*, in anatomy, a name given by ſome authors to the muſcle called by Albinus and others, *obliquus ſuperior oculi*.

TERTIUS *Thoracis*, in anatomy, a name given by many of the earlier writers to a muſcle now called *ſerratus poſterior ſuperior*. See the article SERRATUS.

TERZETTO, in the Italian muſic, a little tune or air in three parts. See the article TRIO.

TERZO, in the Italian muſic, ſometimes ſignifies a compoſition conſiſting of three parts, or deſigned for three voices or inſtruments.

It is alſo uſed for a third part of any thing, as *un Terzo di battuta*, a third part of the bar. See the article TRIO.

TERZOLA, in botany, a name by which ſome authors have called the *eupatorium cannabinum*, or water hemp agrimony. *Ger.* Emac. Ind. 2.

TESSARACONTA, Τεσσαρακοντα, among the Athenians, were forty men who went their circuits round the ſeveral boroughs, and had cognizance of all controverſies about money, if not above ten drachms; as alſo of actions of aſſault and battery. *Potter*, Archæol. Græc. T. 1. p. 122.

TESSARACONTERIS, in the naval architecture of the antients, a word uſed to expreſs a ſort of galley, in which there were no leſs than forty tires of rowers one above another.

Many have doubted whether ſuch monſtrous veſſels as theſe were ever built; but we have abſolute accounts of one ſuch of Philopater's, which muſt have required above four thouſand men to manage the oars.

Ptolemy Philadelphus is ſaid to have had one with thirty tires of rowers, requiring three thouſand men; and we have accounts of another at the ſame time of twenty tires, requiring two thouſand: But tho' ſuch veſſels as theſe were really built, we are not to ſuppoſe they were common. The triremes, or thoſe gallies which had three tires of rowers were found the moſt ſerviceable of all others; and from theſe they built pretty frequently up to the enneeres, which contained nine rows or tires; and theſe were the largeſt ever brought into common uſe, as is fully proved by Meibom againſt Salmaſius, on the authority of Pliny, Plutarch, and Polybius. *Meibom.* de Trirem.

This author has alſo taken off much of the imaginary height neceſſary, according to common computation, for theſe veſſels, having found a more convenient way of placing the rowers.

TESSARACOSTON, Τεσσαρακοστον, in antiquity, a ſolemnity kept by women on the fortieth day after child-birth, when they went to the temple, and paid ſome grateful acknowledgments for their ſafe delivery. *Pott.* Archæol. Græc. T. 1. p. 432. and T. 2. p. 335.

TESSELÆ, a word uſed in pharmacy to expreſs lozenges cut into regular figures.

TESSELARII, among the Romans, artificers of chequered or moſaic work. See the article MOSAIC, *Cycl.*

TEST, (*Cycl*) in metallurgy, is a veſſel of the nature of the coppel, uſed for large quantities of metals at once. The coppels or ſmall veſſels made of aſhes, ſerve for operations of this kind, when ſmall quantities only are concerned; but when larger are worked on, veſſels of a larger ſize and coarſer texture are employed, which are diſtinguiſhed by the name of *Teſts*.

Theſe are uſually a foot and half broad, and are made of wood-aſhes, not prepared with ſo much care as for coppel-making, and mixed with finely powdered brick-duſt; theſe are made into the proper ſhape either by means of an earthen veſſel of proper dimenſions, or only an iron ring.

To make them in the firſt manner, an earthen veſſel is to be procured, not glazed within, and by its depth and breadth proportioned to the quantity of metal to be worked; the inſide of this veſſel is to be well moiſtened with fair water, that the aſhes to be put into it may adhere the better. Put into this veſſel, thus prepared, the aſhes and brickduſt before-mentioned, and firſt moiſtened either with water alone, or with water with a little white of an egg mixed in it; let the quantity of this be ſo much as will half fill the veſſel, then preſs the maſs with a wooden indented peſtle, or, if not for a very large *Teſt*, with a wooden cylinder, only of an inch thick: When thus preſſed down, add freſh aſhes, and preſs them in a ſecond time, as in the making of coppels, and repeat this addition of freſh aſhes till the earthen veſſel be nearly full; then remove the ſuperfluous aſhes with an iron ruler, and let the inequalities remaining at the border be ſmoothed with a wooden ball rolled round about. This done, you are to cut the cavity with a bowed iron, that you may have a broad ſpherical ſegment, not very deep: And laſtly, by means of a ſieve, ſtrew this cavity carefully and regularly over with dry aſhes of bones of animals, ground extremely fine, and ſqueeze theſe hard

hard in, by the rotation of the wooden ball. Thus you have a *Teſt* finiſhed, which, together with its earthen pot, muſt be ſet in a dry warm place.

To make the *Teſts* in the other manner, or by means of an iron ring, let a ring of that metal be filled with aſhes mixed with brickduſt, and moiſtened as before-mentioned, in ſuch manner that they may riſe conſiderably above the ring; then preſs them ſtrongly either with your hands, or with an indented peſtle, and afterwards, with gentle blows of a rammer, preſs the aſhes from the circumference toward the center, in a ſpiral line, and that in ſuch manner, that, after having been ſufficiently preſſed, they may be a ſmall matter higher than the brink of the ring. If there are now any vacancies in the maſs, empty the ring, and fill it again with more aſhes; for if you ſhould attempt to fill up theſe by adding, were it but ever ſo little aſhes, the ſecond, or additional quantities, will never cohere ſo firmly with the firſt, but that they may probably ſeparate in the operation.

This done, turn the ring upſide down, and on the other ſide, or bottom, take out the aſhes to the quantity of one third part of the depth of the ring, and again fill the vacuity with the ſame aſhes, in ſuch a manner that there may remain no ſenſible cavity.

When the maſs is thus prepared, cut out a cavity in the larger ſurface of the ring, with a bowed iron, as in the former method.

The Germans have, beſide theſe, another kind of *Teſts*, which they call *treibſcherben*. Theſe are a ſort of veſſels which reſiſt the moſt violent fire, and are ſo extremely compact, that they ſometimes will retain not only melted metals, but even the glaſs of lead itſelf.

The figure and ſize of theſe veſſels may be the ſame with that of the coppel, but they are uſually made larger; and the great difference of theſe *Teſts* from coppels, and from the ordinary *Teſts*, which are indeed only a kind of large and coarſe coppels, is, that the matter of theſe is more compact and coherent.

The matter for the making theſe *Teſts* is thus prepared: Take of the pureſt and fineſt clay a ſufficient quantity, make it into balls, and dry them either in the air, or in the fire; when dried, beat them to powder in a mortar, and pour on the powder a great quantity of warm water: Let this mixture reſt a while, and when the clay has ſubſided, pour off the water which ſwims at top; and let this waſhing be ſo often repeated, that all the moſt minute lumps of the clay be broken, and whatever ſalt it contains perfectly waſhed out: Then add to this fine clay, of the pureſt ſand, of powder of calcined flints, ground, and well waſhed, of faulty, but clean Heſſian crucibles, or of any incombuſtible ſtones ground very fine, ſuch a quantity as will render the maſs thick, and hardly adhering to the hands in kneading it, or pliant when rolled into a thin lamina.

This is the matter for making this ſort of *Teſts*; but before any quantity of the veſſels be made of this earth, it will be prudent firſt to finiſh a ſingle one, and try it, by putting on it a quantity of glaſs of lead, and expoſing it for an hour or more to the ſtrongeſt fire; by this trial you will be certain whether or not the maſs is capable of making veſſels that will reſiſt both the fire and the glaſs of lead; and by no other means but this trial is it poſſible to determine the due proportion of the mixture of the ingredients for this uſe, on account of the variety of the clays. Nature in ſome places affords a clay ſo well tempered, that it is extremely proper for the making of *Teſts* without any preparation, or without the admixture of any other matter. Sometimes this only requires a ſimple waſhing, but commonly it is neceſſary to make it into balls, and powder and waſh them as before directed.

On the trial of a *Teſt* made of this, or the former mixed clay, if it runs into glaſs, you muſt add to it of the powder of ſtones, eſpecially ſuch as beſt reſiſt the fire. Great care is to be taken not to add too much powdered chalk to theſe compoſitions, ſince if the matter is tempered with that alone, the *Teſts* will indeed reſiſt the fire very well, but being too porous, they will yield a paſſage to litharge, which will ſoften them to ſuch a degree, that they will either fall aſunder of themſelves, or be totally cruſhed when taken hold of with the tongs.

Theſe veſſels are to be made in the following manner: Rub over the ſides and bottom of a ſmall mortar, and alſo its peſtle, with oil, or with the fat of bacon; fill it two thirds full of prepared clay, then make a ſlight impreſſion with your fingers in the middle of the clay; then place the bottom of the peſtle there, and force it down with blows of a hammer, the ſtronger the better. When thus properly hollowed, take it out of the mortar, and pare its edges, and dry it as the coppels are dried, in the air, in a dry warm place. *Cramer*'s Art of Aſſ. p. 60, 62.

Teſts, thus prepared, may be uſed as ſoon as dry, unleſs for ſalts, or litharge; but theſe bodies, when melted in veſſels not firſt baked or hardened in the fire, always make their way thro' them.

TEST *Liquor*, a term uſed by our dealers in brandies, *&c.* for a liquor which they uſe as the *Teſt* of brandy, *&c.* to prove whether they be genuine, or mixed with home ſpirit.

The people who uſe this, place great confidence in it, but it is really a very vague and uncertain thing. They pretend, that this liquor will ſhew by the colour which it makes, on being poured into brandy, whether it be genuine and unadulterated; or if not, in what proportion the adulterating ſpirit is mixed with it.

The whole fact is this: If a little common green or white vitriol be diſſolved in ſome fair water, it makes a *Teſt* liquor; a few drops of which being let fall into a glaſs of old French brandy, will turn the whole to a purple, or fine violet-colour; and by the ſtrength or paleneſs of this colour, the dealers judge the brandy to be genuine or mixed, in different proportions, with home ſpirits.

Old French brandy, having long lain in the caſk, takes a dilute tincture of the wood of the caſk, that is, of oak; and this being of the ſame nature with a ſolution or tincture of galls, naturally turns bluiſh or blackiſh with vitriol. A new diſtilled brandy, tho' wholly foreign, would not give this *Teſt*; and a common malt ſpirit, with oak chips infuſed in it, will turn as dark as the fineſt brandy. While our diſtillers indeed had nothing in uſe for the colouring their ſpirits but burnt ſugar, it was poſſible to make ſome gueſs at an adulteration with them, becauſe the brandy, in this caſe, would not become blackiſh in proportion to its former colour, the ſugar-colour not turning to ink with the vitriol like the other: But our diſtillers have of late found a way of uſing an extract of oak for the colouring of their ſpirits, and, ſince that, this *Teſt-liquor* is of very little uſe, our common ſpirits, of any kind, turning as deep with it as the foreign brandies.

The very beſt way of making this *Teſt-liquor*, is with a calcined vitriol of iron, diſſolved in a dilute or aqueous mineral acid. The liquor, when well made in this manner, is of a fine yellow colour, and will give, for a time, the fineſt blue to any ſpirituous tincture of oak.

The Engliſh were, at one time, very fond of high-coloured brandies, and it was then that the uſe of this *Teſt-liquor* was moſt eſteemed; afterwards we, as well as other nations, finding that this colour was only owing to the caſk, began to diſlike it, and to favour the pale brandies: At length we fell into the uſe of ſuch as were wholly limpid and colourleſs, and the re-diſtilling of all the old brandies people were poſſeſſed of took place; on this, the *Teſt-liquor* was found to be of no uſe at all, and accordingly rejected; but as we are of late again come into the eſteem of coloured brandies, and that with great juſtice, as the colour, when genuine, is a certain mark of the age of the liquor, this *Teſt-liquor* is again got into more credit than it deſerves.

The famous Helvetian ſtyptic depended wholly on this accident for its colour; and it was no ſmall mortification to our chemiſts, when, ſome years ago, it was introduced into uſe among us, that they could not make it with our own ſpirits, but muſt be at the expence of true French brandy for it; our own ſpirits, though equally coloured, would never make that violet tincture, becauſe their colour was owing to burnt ſugar, not a tincture of oak. At length this myſtery was explained, and a little ſcrapings of galls made all thoſe quantities of this ſtyptic, which had been ſet by as good for nothing, perfectly fine and well coloured. *Shaw*'s Eſſay on Diſtillery.

TESTA, in antiquity, the ſame with *oſtracon*. See the article OSTRACON.

TESTES (*Cycl.*) Theſe are wanting in moſt of the fiſh kind. The ſpinoſe fiſhes in general have neither *Teſtes* nor paraſtatæ; but all the cetaceous fiſhes have them, and not a few of the cartilaginous kinds. Thoſe fiſh that have them, have always two, as in land animals; but they differ much in figure and ſituation in the ſeveral kinds, particularly in the whale and flat fiſh. *Artedi* Ichthyol.

TESTICLE (*Cycl.*) *Tumours in the* TESTICLES. Tumours and inflammations of one or both the *Teſticles* are not unfrequently the conſequence of falls, blows, and contuſions, and very often are alſo brought on by venereal diſorders.

The beſt external applications to diſperſe theſe are vinegar of litharge, lime-water, ſpirit of wine camphorated, and ceruſs, tutty, or lapis calaminaris mixed in it. But in the night-time, when the applications of fomentations are not ſo convenient, a plaſter of the mercurial kind, doubly ſated with mercury, or, in ſlight caſes, one of ſimple diachylon, may very properly be kept on. Internal medicines, ſuch as nitre, and the thin decoctions of diſcutient remedies, are to be uſed; and, if occaſion call for it, bleeding in the arm is very proper.

This may be the method with tumours of theſe parts, from external injuries; but when they are from venereal cauſes, it is always neceſſary to give briſk purges, with the addition of a proper doſe of calomel to each, and warm and weak drinks ſhould be taken frequently, and by this means theſe tumours are often diſperſed. But if either remedies are applied too late, or the inflammation is very violent, the tumour generally ends either in a ſuppuration or gangrene. In this caſe the maturating remedies are to be applied, ſuch as warm cataplaſms, and the like; and if the tumour does not break of itſelf at a proper time, from the application of theſe, it muſt be carefully opened with the knife, and the matter being diſcharged, the wound is to be cleanſed by injecting vulnerary decoctions with

a ſyringe, and afterwards healed by the balſams, as that of Peru, or the like.

The taint that occaſioned the tumour is ſometimes wholly eradicated, and the patient freed from it by a proper management of theſe abſceſſes. It not unfrequently happens indeed in them, that the ſcrotum is in part conſumed, ſo as to leave the part bare, but this loſs of ſubſtance may generally be reſtored by proper treatment, with digeſtive and balſamic remedies. *Heiſter*'s Surgery, p. 191.

TESTICULATED *Roots*, are thoſe compoſed of two tuberoſe knobs, reſembling a pair of teſticles. Of this kind are the orchiſes, *&c.*

TESTICULI *Muſculus*, in anatomy, the name given by Fallopius, and ſome others, to the muſcle now generally known by the name of the *cremaſter*.

TESTO, in the Italian muſic, is applied to thoſe words of a ſong, to which ſome air or tune is to be compoſed.

It is a matter of great importance in muſic, to underſtand well how to appropriate or adapt the muſic to the words of a ſong, to expreſs the ſenſe, and make a juſt application of the long and ſhort ſyllables to the notes and times with which they are to be connected.

But this branch of the ſcience, which depends greatly on the knowledge of poetry, has lain a long time almoſt unregarded, and even at preſent very little care is taken with reſpect to this in the modern muſic.

TESTUDO (*Cycl.*)—TESTUDO, the *Tortoiſe*, in the Linnæan ſyſtem of zoology, makes a diſtinct genus of animals; the characters of which are, that the body is defended by a thick cruſt, and is furniſhed with a tail. *Linnæi* Syſt. Nat. p. 50. See Tab. of Quadrupeds, N°. 28.

The *Tortoiſe* is a well known animal, of which there are ſeveral ſpecies. The ſhell, which covers this creature's body, is compoſed of a number of variouſly ſhaped pieces, often pentangular; theſe are affixed to a bony ſubſtance, like the ſkull of ſome animals, which ſurrounds the animal, and has two apertures; one before, which gives way to the going out of the head and the fore-legs; and the other behind, through which the hinder legs and thighs are protruded.

This bony ſubſtance is, in different parts of very different thickneſſes; in ſome places an inch and half, in others not an eighth part of an inch. It is compoſed of two pieces, the one covering the creature's back, the other its belly; theſe are joined at the ſides by very ſtrong ligaments, but not ſo rigidly cloſed but that they eaſily give way to the creature's motions. *Ray*'s Syn. Quad. p. 253.

This is the general order of nature in the ſtructure of the ſhell of this creature; of which we have ſeveral ſpecies in different parts of the world, the ſhells of which are of different value.

1. The common *Tortoiſe*. This is variegated with black and yellow ſpots and lines on the back. The upper ſhell is extremely convex, and the under one flat. Its head is ſmall, and like that of a ſnake, and it can thruſt out this, or draw it into the ſhell at pleaſure. It has no eye-lids, nor any external ears; this is a very long-liv'd creature, and paſſes the winter without food under ground.

2. The *Jaboti* of the Braſilians, called by the Portugueſe *Cagado de Terra*. This has a black ſhell with ſeveral hexagonal figures engraved on it; the head is like that of the other kinds, and is brown, as are alſo the legs, but variegated with ſpots of a duſky greeniſh hue. The liver of this ſpecies is eſteemed a very delicate diſh.

3. The *freſh-water Tortoiſe*, or the *mud-Tortoiſe*. This lives in muddy places, frequently in the ditches that ſurround the walls of towns. The ſhell of this kind is ſcarce at all convex on the back, and the creature very diſagreeable and ugly; it is alſo remarkable for the length of its tail, which is ſlender and tapering like a rat's. The ſhell is black, and is compoſed of ſeveral ſmall pieces nicely joined together: it can at pleaſure thruſt out its head, or draw it back into the ſhell; it feeds on ſnails, inſects, *&c.* and will live a long time without any food; and even when the head is cut off will retain motion and an appearance of life in the limbs and body for a long time.

4. The *common Turtle*, or *Sea-tortoiſe*. This much reſembles the common land *Tortoiſe*, but that it is larger, and its ſhell much leſs beautiful and ſofter. Its feet are made like the fins of fiſhes, and well adapted for ſwimming. They have on each jaw a continued ſeries of bone, which is received in a ſinus in the oppoſite jaw, and ſerves to chew with.

They come out of the ſea to lay their eggs, which they depoſit on the earth in prodigious numbers; one female ſometimes laying an hundred, and theſe are left to be hatched by the heat of the ſun.

5. The *Jurucua* of the Braſilians, or *Tartaruga* of the Portugueſe, called alſo the *Frank Tortoiſe*. This has a ſort of fins in the place of feet, the fore-ones ſix inches long each, the hinder ones conſiderably ſhorter; and their ſhells are very elegantly variegated with different figures. *Ray*'s Syn. Quad. p. 258. See the article JURUCUA.

6. The *Cauoanne Tortoiſe*. This is a ſea-kind, much reſembling the former in ſhape; but the ſhell is thicker, and the fleſh but ill taſted.

7. The *Carette Tortoiſe*. This is a ſmall kind, and does not depoſit its eggs in the ſand, as the others; but lays them among gravel and heaps of ſmall pebbles. The fleſh of this ſpecies is but ill taſted, but its ſhell is extremely valuable for ornamental works.

8. The *Jurura* of the Braſilians, or *Cagado d'Agoa* of the Portugueſe. This is ſmaller than the other kinds, and its ſhell is of an elliptic figure. The ſhell of this ſpecies is conſiderably convex on the back; its head is long, and its tail ſhort. Marggrave kept one of this ſpecies in his houſe one-and-twenty months without food.

9. The *ſmall Eaſt-Indian Land-Tortoiſe*. This is not above three inches long, when at its full growth; its ſhell or cruſt is compoſed of three orders of ſcales, and a general rim ſurrounding them all. Its colours are white, purple, yellow, and black, and it is a very beautiful kind; when the ſcales of this ſhell are taken off, the veſtiges of them are plain in a mottled black and white colour, with ſome yellowneſs. The lower ſhell is white, and marked with a great number of beautiful lines. The head and beak in this ſpecies, are like thoſe of the parrot; and the upper part of the head is variegated with red and yellow; the neck is ſlender, and the fore-legs are covered with ſmall ſcales. The feet are flat, and are divided into four toes. The hinder legs are much longer and ſlenderer than the fore ones, and are only covered with a tough ſkin; the feet however of theſe are ſcaly, and have four toes, as the others. The tail is ſlender and tapering, and about three inches long. *Ray*'s Syn. Quad. p. 259.

10. The *leſſer checquered Tortoiſe*, marked with ſtars. The ſhell of this is about ſeven fingers breadth long, and five wide; it is black, and marked out into rhomboidal figures; and is compoſed of three orders of prominences, beſide the general ſurrounding rim; from the middle of theſe eminences there ariſe five, and from the ſides four tubercles, from which there are a number of ſtellar figures radiated. The lower ſhell conſiſts of eight pieees, two of which are much larger than the reſt, and this is of a blackiſh and yellowiſh mottled colour.

11. The *great checquered Tortoiſe*. This ſpecies is found in the iſland of Madagaſcar, and is the moſt convex of all the *Tortoiſes*. It is a foot long, eight fingers broad, and ſix high. This is the ſize of one kept in the Muſeum of the Royal Society.

12. The *teſſelated Surinam Tortoiſe*. 13. The *teſſelated Virginian Tortoiſe*. And, 14. The *ſcaly Tortoiſe*. This is of the mud or freſh-water *Tortoiſe* kind. It is uſually about a foot long, ten inches broad, and three and a half high; and the middle of the back riſes into a very remarkable longitudinal ridge. This is ſomewhat allied alſo to the *carette Tortoiſe*. *Ray*'s Syn. Quad. p. 260.

TETARTEMORION, among the antients, denotes the fourth part of the zodiac. *Pitiſc.* in voc.

TETHALASSOMENOS, a term uſed by the old medical writers, to expreſs wine mixed with ſea-water.

TETIMIXIRA, in zoology, the name of an American fiſh, more uſually known by the name of the *Pudiano*. It is a ſmall fiſh reſembling a pearch, with a purple back, and yellow ſides and belly. *Marggrave*'s Hiſt. Braſil. See the article PUDIANO.

TETRACERA, in botany, the name of a genus of plants; the characters of which are theſe: The cup is a ſix-leaved perianthium. The leaves are roundiſh, and ſtand expanded. There are no petals ſo far as can be ſeen in the dried ſpecimens, and the growing plant has not been examined ſince the time that Houſton was deceived by its external reſemblance with the petræa, and deſcribed its fruit and the flowers of the petræa under the character of one genus, which he called petrea. The ſtamina are numerous ſimple filaments, of the length of the cup; they are permanent alſo, and the antheræ are ſimple. The germina of the piſtil are four in number; they are of an oval figure, and gape open one from another. The ſtyles are ſubulated, and very ſhort; and the ſtigmata are obtuſe. The fruit is compoſed of four capſules, which are oval and crooked; and are compoſed of one valve containing only one cell, and opening at a future near the top when ripe. The ſeeds are ſingle and roundiſh. *Linnæi* Gen. Plant. p. 249.

TETRACHORD (*Cycl.*)—The names of the ſounds of a *Tetrachord*, conſidered by itſelf, were hypate, parypate, paranete, and nete. Ariſtoxenus calls them hypate, parypate, lychanos, and nete. *Wallis*'s Append. at *Ptolem.* Harm. p. 159, 160.

When *Tetrachords* came to be joined, the parypate was ſometimes called *trite*, as being the third from the *nete*; and the paranete was ſometimes called lychanos, as in the fore-mentioned place of Ariſtoxenus. *Wallis*, ibid. See the article LYCHANOS.

The *Tetrachord of Mercury*, contained four ſtrings or chords, in the proportions of 12, 9, 8, and 6; ſo as to give the fourth, fifth, and octave of the loweſt chord. This is the opinion of Boëthius, and after him of Zarlino. Vid. *Wallis*'s Append. Ptolem. Harm. p. 178.

TETRACTIS, in natural hiſtory, a name given by Linkius, and other authors, to a kind of ſtar-fiſh, compoſed only of four rays, the more common kinds having five.

TETRA-

TETRADECARHOMBIS, in natural hiſtory, the name of a genus of foſſils, of the claſs of the ſelenitæ.

The word is derived from the Greek τετρὰς, four, δεκὰς, ten, and ῥόμβος, a rhomboidal figure, and expreſſes a rhomboidal body conſiſting of fourteen planes.

The characters of this genus are, that the bodies of it are exactly of the ſame form with the common ſelenitæ; but that in theſe each of the end planes is divided into two; and there are by this means eight of theſe planes, inſtead of four. *Hill*'s Hiſt. of Foſſ. p. 120. See the article SELENITES.

Of this genus there are only three known ſpecies. 1. A thin pellucid one, with tranſverſe filaments; which is frequent in the clay-pits of Northamptonſhire, and ſome other counties. 2. A dull thicker kind, with very ſlender tranſverſe filaments; this is a very rare ſpecies, and found as far as is yet known only in Leiceſterſhire in the yellow brick clay, and at ſmall depths. And, 3. A large ſcaly kind, conſiderably long, and of a very rough ſurface; this is found in Yorkſhire, and that ſometimes looſe on the ſides of the hills, but more frequently buried in the ſtrata of clay. *Hill*'s Hiſt. of Foſſ. p. 133, 134, 135. See Tab. of Foſſils, Claſs 2.

TETRADYNAMIA, in botany, a claſs of plants, whoſe flowers have four of their ſtamina of more efficacy than the reſt: Theſe are always known by having the four efficacious ſtamina longer than the reſt.

The word is formed of the Greek τετρὰς, four, and δυναμὶς, power. Of this claſs of plants are ſcurvy-graſs, muſtard, radiſh, &c. See Tab. 1. of Botany, Claſs 1.

The *Tetradynamia* of Linnæus include thoſe called by Tournefort *cruciformes*, and by Ray *ſiliquoſæ*, and *ſiliculoſæ*. The general characters of the claſs are theſe:

The perianthium is of an oblong figure, and is compoſed of four leaves, which are oval, oblong, hollow, obtuſe, and converging toward one another, and are gibbous at the baſe; theſe all fall off with the flower, and ſtand in pairs; the oppoſite ones being always equal in length, this cup is properly the nectarium of the plant, and it is on this occaſion that it is gibbous at the baſe. The flower is of that kind, called by Tournefort, *cruciform*; it conſiſts of four equal petals, which have ungues of the length of the cup, erect, and flat; the petals are broad at the top, and obtuſe, and ſcarce touch one another at the ſides; and the inſertion of the petals and of the ſtamina is in the ſame place.

The ſtamina are ſix ſubulated erect filaments, the two oppoſite ones are of the length of the cup, the other four are ſomething longer, and are of a leſs length however than the petals. The antheræ are oblong and pointed, thick at the baſe and erect, with apices bending ſideways. The nectariferous gland in the different genera of this claſs is differently ſituated. It uſually however is found near the ſtamina, and moſt frequently of all is affixed to ſome ſhort filaments, and ſtands near their baſe. Two of the ſtamina are often curved, that they may not preſs upon this gland; and it is often owing to this, that two are ſhorter than the reſt. The germen of the piſtil is placed above the receptacle, and is every day in its growth raiſed higher and higher. The ſtyle is ſometimes wanting, but in ſuch plants as have it, it is of the length of the longer ſtamina. The ſtigma is always obtuſe.

The fruit or capſule is always a bivalve pod, which often contains two cells; this, when ripe, opens by ſplitting from the apex to the baſe, and it has always a little membranous ſubſtance ſerving within as a ſeptem, when the pod is bilocular; this ſtands out beyond the apex, and is the rudiments of what was before the ſtyle. The ſeeds are roundiſh, and the pod uſually narrow and oblong.

This is a very natural claſs of plants, and has been received as ſuch under whatever name by all the ſyſtematical writers in botany.

The plants of this claſs are generally ſuppoſed to be all antiſcorbutics. This claſs of plants is naturally ſubdivided into two ſeries: The one containing the ſiliculoſe plants, and the other the ſiliquoſe. The firſt have a ſhort pod, the others a long and ſlender one. The firſt pods uſually have more of the remains of the ſtyle than the others. *Linnæi* Gen. Plant. p. 309.

TETRAETERIS, τετραετηρὶς, in the Athenian chronology, a cycle of four years; for which ſee *Potter*, Archæol. Græc. l. 2. c. 26. T. 1. p. 459, ſeq.

TETRAGONIA, in botany, the name given by Linnæus to a genus of plants called by others *Tetragonocarpos*. The characters are theſe: The cup is compoſed of four oval coloured leaves, curled at their edges, and remaining after the flower is fallen. There are no petals. The ſtamina are twenty capillary filaments, ſhorter than the cup. The antheræ are ſhort, and incumbent. The germen of the piſtil is roundiſh, quadrangular, and placed under the receptacle. The ſtyles are four, ſubulated, crooked, and of the length of the ſtamina. The ſtigmata are longitudinal and hoary. The fruit is a coriaceous cruſt, formed into a kind of ſquare figure, by four longitudinal alæ. The ſeed is ſingle, oſſeous, and contains four cells, with oblong nuclei. *Linnæi* Gen. Plant. p. 249.

TETRANDRIA, in botany, a claſs of plants which have hermaphrodite flowers, with four ſtamina or male parts in each. See Tab. 1. of Botany, Claſs 1.

The word is formed of the Greek τετρὰς, four times, and ἀνὴρ, male. Of this claſs of plants are the teaſel, madder, plantane, &c.

TETRANGURIA, in botany, a name uſed by ſome authors for the citrul, a plant of the gourd kind, whoſe ſeeds are uſed in medicine. *Chabræus*, 133.

TETRAO, in the Linnæan ſyſtem of zoology, the name of a genus of birds of the order of the gallinæ; the diſtinguiſhing characters of which are, that the feet have each four toes, and the eyelids are naked and full of fleſhy tubercles. Of this genus are the pheaſant, partridge, quail, &c. *Linnæi* Syſt. Nat. p. 48.

TETRAO, is alſo uſed for a large bird of the gallinaceous kind, whereof there are two ſpecies, the one larger, and the other leſſer; they are called alſo by authors, the *urogallus major*, and *minor*.

The larger is common in Italy, and on the Alps; ſee the article UROGALLUS. The leſſer is common in ſome parts of England, and is called the *black game*, or the *grouſe*. *Ray*'s Ornithol. p. 123. See the article GROUSE.

TETRAPHOE, in botany, a name given by the people of Guiney to a plant, which they give in decoction as a cure for fluxes. This plant grows alſo in Malabar, where they uſe the roots boiled in whey in the piles; and in the colic they give the root in powder, about a ſcruple for a doſe. It is called in this latter place *wellia cadavalli*, and by Petiver *xanthium malabaricum capitulis lanuginoſis*. The ſtalks of it are woody and hoary, eſpecially about the tops. Its leaves ſtand by pairs on ſhort foot-ſtalks, and while young they are hoary underneath, with a very ſoft and velvety down; the others are rough like the ſpotted lungwort, but ſeldom are ſo large. The flowers grow in ſpikes, and conſiſt each of fine green leaves filled with ſcarlet filaments: After theſe the fruit ripens, and is a ſort of woolly bur covered with ſoft and hooked prickles, very like the common Engliſh burdock, but not of a third part of the bigneſs. Phil. Tranſ. N°. 232.

TETRAPYRAMIDIA, in natural hiſtory, the name of a genus of ſpars. The word is derived from the Greek τετρὰς, four, and πυρὰμὶς, a pyramid.

The bodies of this genus are ſpars influenced in their ſhape by an admixture of particles of tin; and are found in form of broad-bottomed pyramids of four ſides.

Of this genus there is only one known ſpecies, which is uſually of a browniſh colour, and is found in Saxony; as alſo in Devonſhire, Cornwal, and other counties of England, where there is tin. *Hill*'s Hiſt. of Foſſ. p. 378.

TETRASTŒCHON, in botany, a term often uſed by the the Greek writers, and generally miſunderſtood by thoſe who copy their accounts. Pliny has made an error in the deſcription of the euonymus, which has confounded two different ſhrubs together ever ſince, by miſtaking the ſenſe of this word, uſed by Theophraſtus in his account of it. He ſays, that the fruit is divided within into four orders or ſeries of ſeeds; this he expreſſes by the word *Tetraſtœchon*, which Pliny ſuppoſing to be the ſame with the word *Tetragonon*, has tranſlated into *granum quadrangula figura*.

But this is by no means the ſenſe of the word which was uſed by the Greeks, to expreſs, that a thing had τέτραρας τάξεις, four rows, orders, or ſeries of ſeeds in it: Nor does it at all expreſs the ſeed's being ſquare, much leſs its being ſingle; for the original derivation of the word was from the term κατα στοιχον, uſed in dances. Theſe were compoſed of ſeveral ſeries of perſons, called στοιχοι, *ſtœchi*; and every ſtœchon conſiſted of ſeveral perſons, who all moved together.

It is plain from this, that *Tetraſtœchon* could not ſignify a fruit's having ſingle ſquare ſeeds, but muſt mean that it had four ſtœchi or orders of ſeeds in it; ſuch was the euonymus of the Greeks, which had a pod like that of ſeſamum to contain them; and had flowers of an offenſive ſmell, like that of corrupted blood. Theſe are all characters ſo very different from that of our euonymus or fuſanus, that it never would have been ſuppoſed by any perſon that they meant the ſame plant that we do by that name, had not Pliny led the world on to that opinion by his falſe and ſcarce intelligible tranſlation of the words of Theophraſtus.

TETRATONON, in muſic, the ſuperfluous fifth is ſometimes thus called, as containing four tones. *Broſſard.*

TETRAX, in zoology, the name of a bird of the gallinaceous kind, called by ſome authors *anas campeſtris*, or the field-duck; and by others the *canna*.

It is a very common bird in France, where it is called *canne patriere*, and ſeems indeed peculiar to that country; it is not called anas from any reſemblance it has to the duck, or any other water-fowl, in its make or ſtructure; but from its ſitting on the ground, juſt as the duck does on the water. It is of the ſize of a pheaſant, and has a beak like that of the common hen. It is taken with nets, as the partridge: It runs very ſwiftly, and, like the buſtard, has no hinder toes; and it ſeems properly a bird of that kind. Its belly is white, and its back is variegated with grey, red, and black. It feeds on vegetables, and on ſmall inſects. *Bellonius* de Avibus.

TETRASARIUS, a word uſed by ſome of the medical writers, to expreſs half an ounce.

TETREUMA, in botany, a name given by the people of Guinea to a ſpecies of ſhrub, very common among them, and uſed to cure whitlows. They dry the leaves, and reduce them to powder; and, moiſtening them with any liquor, apply them to the place. Petiver has called this *arbor guineenſis lauruſtini facie*, from its great likeneſs to the common ſhrub, which we call the lauruſtine. The leaves are opake and ſtiff, and are an inch and a quarter broad, and two inches and a half long. Theſe ſtand alternately on all ſides the ſtalk, and are fixed on ſhort pedicles. The flowers grow out of the boſoms of the leaves, and ſtand in cluſters in the manner of thoſe of the common lauruſtine. Phil. Tranſ. N°. 232.

TETTAR, in the manege, is an ulcer almoſt as broad as one's hand, that appears commonly upon a horſe's croupe, ſometimes on his head, and ſometimes on his neck. It proceeds from bilious blood, that conſumes and eats through the hide or ſkin, and cauſes ſuch a violent itching, that it is a hard matter to keep the horſe from ſcratching, and ſo enlarging and ſpreading the ulcer.

TETTIGES, τεττιγες, graſhoppers, in antiquity, a title the Athenians aſſumed to themſelves. *Pott.* Archæol. Græc. l. 1. c. 1. T. 1. p. 2. See the article GEGENES.

TETTIGOMETRA, in natural hiſtory, a name by which the antients called the nymph of the Cicada, or *Tettyx*; and they named this nymph from which they frequently ſaw that fly hatched *Tettigometra*, which ſignifies the *mother of the cicada*.

It has been a great error in our dictionary writers, to call the *cicada* a graſhopper. It is a large four-winged fly, common in Italy, and other hot countries, and its noiſe is very troubleſome there. This noiſe is made by means of certain organs placed in the belly. See HARVEST-*Fly* and CICADA.

This creature lays its eggs with a wonderful art in the dead branches of trees, and from theſe eggs are produced ſmall animals like fleas, with ſix legs and a long trunk; theſe ſoon fall off from the tree. and, burying themſelves in the earth, feed and enlarge themſelves into a ſort of hexapode worms; after this they paſs into a ſtate like that of the nymphs of our flies, or the chryſalis of butterflies; but they move and eat in this ſtate.

They live in the form of the nymph more than a whole year, after which they crawl out of the earth, and climbing up the bodies of trees, there faſten themſelves by their claws, till they are transformed into flies. In the time when they are in this nymph ſtate they are found in great abundance buried about the roots of trees, often at two or three foot deep.

The antient Greeks uſed to dig them up from theſe places, and eat them; they were accounted a very good diſh among them; and, according to Ariſtotle, were moſt valued, and eſteemed the greateſt delicacy, juſt before the time of their ſkin breaking to let out the fly. The antients alſo eat the cicada in its winged ſtate, preferring the female when full of eggs, and the male at all other times. At preſent, though this creature is very common in moſt of the hot countries, and very troubleſome by its continual noiſe; there is no account of their being eaten any where.

TETTIGONIA, in natural hiſtory, a word uſed by the antients to expreſs the ſmaller ſpecies of *cicada*, with which they were acquainted. They called the larger *acheta*.

It is generally ſuppoſed that the *Tettigonia* was the ſame with our ſmalleſt kind, called by the French *cigalon*; but Mr. Reaumur obſerves, that as the antients knew two kinds of the *cicada*, we know three; and that our middle one ſeems to have been their *Tettigonia* or ſmall *cicada*, and that they were not acquainted with our ſmalleſt kind, or cigalon, which is not larger than a hornet. See the articles HARVEST-*Fly*, and CIGALON.

TEUCHITES, in botany, a name uſed by ſome for the ſcænanth or ſchænanth, camel's hay.

It was originally uſed only as an epithet added to the name *Schænanth*, to ſignify the place from whence a peculiar kind of it was brought; but after-writers appropriated it as a name of the plant itſelf.

Dioſcorides diſtinguiſhes the Arabian *Schænanth* from the Nabatæan; but this ſeems an unaccountable error, ſince Dioſcorides one would think could not but know, that Nabatæa was only a region in Arabia. He afterwards makes the Babylonian the ſame with the Arabian, and ſays that it was called *Teuchites*. Pliny, on the other hand, gives the name *Teuchites* to the Nabatæan *Schænanth*.

Authors do not ſeem well to have explained the word. It is evidently an epithet given to the *Scænanth*, from the name of the place where it was brought, and probably it ought to be written *Teuochitis*. There is a city *Teuochis* in Ægypt near the borders of Arabia, and the geographers all mention a lake in the neighbourhood of this city; in this lake it is probable the *Scænanth* might grow; and being gathered there, and ſold in the adjoining city of *Teuochis*, the purchaſers might diſtinguiſh it with an epithet formed of the name of the place where they bought it. See the article SCHÆNANTH.

TEUCHTLACOT-*Zanhqui*, in zoology, a name by which the natives of ſome of the American nations call the rattleſnake. *Ray*'s Syn. An. p. 291. See the article RATTLE-*Snake*.

TEUCRION, according to Pliny, a name given by ſome of the antient botaniſts to the *Chamædrys*, or germander.

This author ſuppoſes that plant and the *ſerrata* or *ſerratula*, to be the ſame in the accounts of ſome of the more early authors; but it does not appear, upon a ſtrict enquiry, that they ever called any other plant than the common ſawwort by the name *ſerrata*, though they called this plant by a great many other names beſide that, as *betonica*, *ceſtrum*, &c.

TEUCRIUM, *Tree-germander*, in botany, the name of a genus of plants; the characters of which are theſe. The flower conſiſts of one leaf, and is of the labiated kind; the ſtamina ſupplying the place of the upper lip; the lower lip is divided into five ſegments, the middle one being largeſt and hollowed like a ſpoon; the others ſtanding over-againſt one another in the neck of the flower. The cup is bell-faſhioned, and from it ariſes a piſtil which is fixed in the manner of a nail to the hinder part of the flower, and is ſurrounded by four embryos, which afterwards become four roundiſh ſeeds, and ripen in the bell-ſhaped cup of the flower.

The ſpecies of *Teucrium*, enumerated by Mr. Tournefort, are theſe: 1. The ſhrubby *Teucrium*, with ſinuated leaves, the Bœtic *Teucrium* of authors. 2. The broader-leaved Spaniſh *Teucrium*. 3. The American fox tail *Teucrium*. 4. The procumbent perennial *Teucrium*, with ſpear-pointed leaves. 5. The jagged-leaved annual procumbent *Teucrium* of Portugal. *Tourn.* Inſt. p. 208.

TEUGA, in botany, the name given in the Hortus Malabaricus, to a genus of plants called by Linnæus and others, *coccus*. Hort. Mal. L. 1. 4. See the article COCCUS.

TEUTHOPHACE, a word uſed by the antients, to expreſs a ſort of food made of beet-roots and lentils, often preſcribed as a good diet for the ſick.

TEXT, TEXTURE, in chemiſtry, is uſed for any thing having a texture in a proper ſenſe, or for an aggregate formed by admotion, compoſition, co-ordination, conſtruction, whether fortuitous, or deſigned for ſome end, ſo that without ſuch a texture the end could not be obtained; of which therefore, this texture muſt be conſidered as the true inſtrument.

In this ſenſe living bodies have a texture, and may be ſtrictly named *Texts*; and the more ſo, if they be ſentient and have local motion; all which bodies, whether ſmall or great, are formed of innumerable mixt and compound individual corpuſcles. Vid. Obſervat. Halens. Tom. 4. Obſ. 14. §. 8.

TEXT differs from *Aggregate*. See the article AGGREGATE.

TFUOI, in the Chineſe manufactory of porcelaine, a word uſed to expreſs a particular ſort of varniſh for that ware with violet colour and gold. The uſual method of doing this at firſt, was by mixing gold with the common varniſh, breaking the leaves very ſmall, and then adding the common blue and the powder of calcined agate of a coarſe kind, found in great plenty on the ſhores of their rivers. But they have ſince found, that the brown varniſh called *Tſekin* ſucceeds greatly better, for when the blue is mixed with this, its brown colour is loſt, and the gold lies on much better than it would any other way.

They had once a method of a varied varniſh, which was very beautiful, but is much neglected now; this was the giving a veſſel the brown varniſh on the outſide with a large portion of gold, and the common white varniſh within. They alſo varied the degree of colour on the outſide, by laying on more or leſs of the varniſh; and gave this way a variety, even in the ſame colour. Obſerv. ſur les Coutumes de l'Aſie, p. 308.

THACAS, Θᾶκας, in antiquity, a general name given to the place or ſeat where the augurs made their obſervations. *Pott.* Archæol. Græc. T. 1. p. 322. See the article AUGUR.

THAIS, a name given by Ægineta, to a coſmetic cerate, intended to give a beautiful red to the face. Galen uſes the ſame word to expreſs a ſort of bandage.

THALAMEGUS, among the antients, a ſhip of pleaſure, or yacht uſed by princes. It was always provided with a good cabin, or bed-chamber. *Pitiſc.* in voc.

Philopater king of Egypt had a very remarkable ſhip of this kind, for ſailing in parade with his wife and children on the Nile. It is ſaid to have been half a ſtadium, or 312 feet long; its breadth more than 30 cubits, and its height, with the pavilion erected on it, about 40 cubits. Its ſtructure was likewiſe very ſingular, being broad-bottomed, and very wide above, eſpecially towards the fore-part; and accommodated both with a double prow, and a double ſtern. On its decks were two long galleries of ivory, for walking in. *Hofm.* Lex Univ. in voc.

THALAMII, among the antients, thoſe rowers who ſat in the loweſt part of the ſhip. *Pitiſc.* in voc. See THALAMITÆ.

THALAMIUM, among the antients, a port-hole, through which the oars of the rowers in the bottom of the ſhip went. *Pitiſc.* in voc.

THALAMITÆ, in the naval architecture of the antients, a term uſed to expreſs thoſe rowers in the Polyerete galleys, or thoſe which contained ſeveral ſeries of rowers, who ſat on the *Thalamus* of the veſſel, and made the loweſt row. Theſe moved their oars and hands under the ſeats of the row that ſat

ſat next above them. The word occurs chiefly in the deſcription of the *Triremes*, or three-rowed galleys, in which the ſecond row of the men were called *Zygitæ*, and the uppermoſt *Thranitæ*. *Meibom.* de Trirem.

THALAMUS, in botany, a term uſed to expreſs that part of the flower in the capitated or floſculous flowered plants, where the embryo fruits of every ſeparate floſcule are lodged, and where afterwards the ſeeds are contained. This is the bottom of the cup, in the central part of which it adheres to the ſtalk. *Tourn.* Inſt. p. 438. See Tab. 1. of Botany, Claſs 1.

THALASSOMELI, the name of a medicine uſed as a purge among the antients. It was compoſed of equal parts of honey, ſea-water, and rain-water, expoſed to the ſun in the dog days, in a veſſel pitched on the inſide. It purged in the ſame manner that ſea-water alone would do, but only in a milder way.

THALIA, in botany, the name of a genus of plants, called by Plumier *cortuſa*. The characters of which are theſe: The cup is a ſpatha of an oval figure, terminating in a point, and compoſed of only one valve. The flower is compoſed of five petals, which are of an oblong ovated figure, and are hollowed and undulated at the margin; two of theſe, which are neareſt the cup, are ſmall and convoluted; the others are nearly equal in ſize, and are ſtrait and hollowed. The germen of the piſtil is of an ovated figure, and the fruit is a berry of an oval figure, having only one cell, and within that a ſingle bony ſeed which has two cells, in each of which is a thin kernel. *Plumier* 8. *Linnæi* Gen. Plant. p. 522.

THALICTRUM, *Meadow-rue*, in botany, the name of a genus of plants. The characters of which are theſe: The flower is of the roſaceous kind, being compoſed of ſeveral petals arranged in a circular form. The piſtil ariſes from the center of the flower, and is ſurrounded by a vaſt congeries of ſtamina. This finally becomes a fruit compoſed of ſeveral capſules gathered into a ſort of head; theſe are ſometimes alated, and ſometimes plain, and each of them contains one oblong ſeed.

The ſpecies of *Thalictrum*, enumerated by Mr. Tournefort, are theſe: 1. The larger *Thalictrum*, with angular or ſtriated ſeed-veſſels. 2. The larger *Thalictrum*, with ſmooth ſeed-veſſels. 3. The great yellow-flowered *Thalictrum*, with yellow ſtamina, and bluiſh-green leaves. 4. The columbine-leaved alpine *Thalictrum*, with purple ſtamina. 5. The great columbine-leaved alpine *Thalictrum*, with white ſtamina and green ſtalks. 6. The leſſer alpine columbine-leaved *Thalictrum*, with white ſtamina and green ſtalks. 7. The purple-ſtalked columbine-leaved Canada-*Thalictrum*, with white ſtamina. 8. The ſmaller American *Thalictrum*. 9. The great yellow-flowered ſweet-ſcented *Thalictrum*. 10. The large-flowered aſphodel-rooted ſmall *Thalictrum*. 11. The early-flowering mountain-*Thalictrum*. 12. The leſſer *Thalictrum*. 13. The narrow-leaved meadow-*Thalictrum*. 14. The little French *Thalictrum*, with thick ſhining leaves. 15. The narroweſt-leaved meadow-*Thalictrum*. 16. The ſmall ſtinking *Thalictrum*. 17. The little broad-leaved mountain-*Thalictrum*. 18. The little mountain-*Thalictrum*, with deep red ſhining leaves. *Tourn.* Inſt. p. 270.

THALLOPHORI, Θαλλοφόροι, in antiquity, the old men and women, who, in the proceſſion of the feſtival *Panathenæa*, carried olive boughs in their hands. *Potter*, Archæol. Græc. T. 1. p. 421.

THALYSIA, Θαλυσια, in antiquity, a ſacrifice offered by the huſbandmen after harveſt. For the origin and ceremonies of which, ſee *Potter*, Archæol. Græc. T. 1. p. 400.

THAMAR, a word uſed by the Arabian phyſicians, to expreſs a date. Hence a pectoral decoction made with dates and other ingredients, was called *diathamyron*; and the word was afterwards corruptly written *dicameron*.

THAOCINUS *Color*, a term uſed in the Latin tranſlations of the Arabian writers to expreſs what we call a blue purple, and the Latins *pavonaceus color*, peacock colour; which is alſo the literal ſignification of the Arabian term.

The antient writers all tell us, that their *Indicum* when diluted, made the moſt beautiful colour imaginable of that kind. This is one of many reaſons for ſuppoſing the *Indicum* of the antients, and our *Indigo* to be the ſame ſubſtance, becauſe this blue purple is the very colour of that drug when diluted.

THAPSIA, in botany, the name of a genus of plants; the characters of which are theſe. The flowers are diſpoſed in umbels, and are of the roſaceous kind, being compoſed of ſeveral petals, diſpoſed in a circular order on a cup, which afterwards becomes a fruit compoſed of two long ſtriated ſeeds, ſurrounded with a foliaceous edge, and from both ſides emarginated inwards. See Tab. 1. of Botany, Claſs 7.

The ſpecies of *Thapſia*, enumerated by Mr. Tournefort, are theſe: 1. The largeſt broad-leaved *Thapſia*. 2. The large hairy broad-leaved *Thapſia*. 3. The ſtinking *Thapſia*, with libanotis-leaves. 4. The ſtinking Portugal white-flowered *Thapſia*, with parſley leaves. 5. The narrower leaved Italian *Thapſia*, called *panax aſclepium*, and Eſculapius's all-heal. 6. The broadeſt-ſeeded *Thapſia*, or giant-turbith. 7. The ſhining alpine *Thapſia*, with thalictrum-leaves and white flowers. 8. The hairy thalictrum-leaved Portugal *Thapſia*. *Tourn.* Inſt. p. 311.

The root of the *Thapſia* is uſed in medicine: There are two kinds of it, the white, and the black.

The white *Thapſia*, called alſo by ſome grey turbith, is the root of a plant ſomewhat reſembling fennel. This is full of a milk-like juice, ſo very ſharp that it will bring off the ſkin, if ſuffered to touch the face. This root is ſeldom uſed under its own name, but is ſometimes ſold for the turbith root. They may be diſtinguiſhed however, by the turbith's being of a reddiſh grey without, and of a whitiſh grey within, and heavy and hard to break; on the contrary, white *Thapſia* is light, wrinkled, and of a ſilvery grey on the outſide, and ſo hot and acrid to the taſte, that if new it will bliſter the mouth.

The black *Thapſia* is of too duſky a colour to be uſed as an adulteration of turbith, and too hot and acrid to be preſcribed internally. *Lemery*'s Dict. des Drog.

Some of our druggiſts receive the roots of this plant inſtead of turbith, and ſell it as ſuch. It is happy for us, that it is not much in uſe. It purges very violently both upwards and downwards, and ought to be baniſhed from among the number of medicinal ſimples.

Beſide the poiſonous root known by the name *Thapſia*, the antients have deſcribed three other vegetable ſubſtances under it. The Lycium-wood uſed at this time, as alſo of old in Crete, as a yellow dye: The *Scythica radix*, or liquorice; and the *luteola*, or dyers weed. The Greek *Thapſos* ſignifies a pale dead yellow colour, and is applicable either to the ſubſtance or the juice or tincture of all theſe.

Paulus Ægineta and Alexander Trallian, in their catalogues of the things uſed to dye the hair yellow, mention the plant which they call *robia*, or *herba robia*, which they ſay dyed every thing of a gold colour.

Democritus calls the ſame plant *œcomenia*, and places it alſo among the herbs, uſed in tinging the hair. And ſome of the more modern Greeks have called it *cymene*. It is ſtill frequent in many parts of Greece, and is uſed there as well as here, to dye things yellow. Some have called it *carniola*; and Macer makes it the ſame with the *iſatis* or woad; but very erroneouſly. Some have called it *rubia*; but theſe have carefully diſtinguiſhed it from the *rubiæ radix*, or madder, which dyes red. The old ſcholiaſt on Ægineta has alſo called this plant by the ſame name with woad, and plainly ſhews he thought the two names ſynonymous, by rendering the *iſatis* of his author by the word *cymene*, which is plainly the ſame plant with the carniola, that is the *luteola* of the Romans. See the article CYMENE.

THAPSOS, in the materia medica of the antients, a name given to a kind of wood of a pale yellow colour, uſed of old in dying linnen and woollen cloths.

It has by ſome been ſuppoſed, that *Thapſos* and *Thapſia* were the ſame plant; but there is no one circumſtance in any of the accounts of authors, to favour ſuch a conjecture. The *Thapſia* was always deſcribed as a plant whoſe root was poiſonous; but the *Thapſos*, as a tree, whoſe wood was not eſteemed dangerous, and was uſed by the dyers; not the root, but the wood of the trunk and large branches. The natural colour of the wood being of a livid and dull yellow, it became an emblem of death; and the word *Thapſos* is uſed by ſome of the Greek writers, as a name for the colour of dead corpſes.

The people of Crete at this time uſe the lycium-wood in dying a yellow colour, and it is probable that the *Thapſos* was this very tree. Dioſcorides tells us, that the wood of this tree was alſo uſed at his time to tinge the hair yellow, which was a favourite colour with the Greeks. The lycium is of a colour ſomewhat deeper than our box-wood, and parts with its ſtain ſo eaſily that it ſeems very proper for ſuch a purpoſe. See the article THAPSIA, *ſupra*.

THAPSUM, among the old Roman writers, a common name for the *verbaſcum*, or mullein; but as there were many other plants, very different in their nature, yet whoſe names reſembled this; ſuch as the *Thapſia*, or deadly carrot, and the *Thapſum*, or *geniſtella tinctoria*; it was ſoon found neceſſary to add ſome other name, and it was then called *Thapſum barbatum*, or *barbaſſum*.

The Greeks uſed the word *Thapſon* for a yellow colour, and called in general all yellow things by that name. Hence the great confuſion that has ariſen by calling the *Thapſia* root the liquorice root, the lycium wood, and the geniſtella flowers, all by the common name *Thapſum*. The reaſon of the geniſtella being called *Thapſum*, was, that its flowers were yellow, and were uſed to colour the ladies hair; that being the favourite colour of thoſe days. The flowers of mullein are yellow, and ſeem more fit for the colouring the hair, than thoſe of the geniſtella; their colour being more eaſily ſeparated, and continuing on ſo well that the glovers of many parts of England uſe them in the ſeaſon for colouring their yellow gloves.

It is probable, that the ladies of old uſed this, as well as the geniſtella, for this purpoſe; and it might hence obtain the common name *Thapſum*. The other part of its diſtinction,

barbatum, ſeems owing to the leaves being ſo covered with a woolly down that they look bearded. And when this word is written *barbaſſum*, it may probably be given as the name of ſome of thoſe ſpecies of mullein, which are not hairy, as our black or ſage-leaved mullein, and be a corruption of the word *verbaſcum*. This black mullein has no leſs title than the white or bearded kind, to the name *Thapſum*. Its flowers being of a yet finer yellow than thoſe of that kind, and being as fit for the uſe of ſtaining. The glovers of Hertfordſhire uſing this ſpecies for their leather gloves.

THARGELIA, Θαργηλια, in antiquity, an Athenian feſtival, in honour of the ſun, and his attendants the hours; or, as others think, of the Delian Apollo and Diana. For an account of the ceremonies of this ſolemnity, ſee *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 400. ſeq.

THARGELION, Θαργηλιων, in chronology, the eleventh month of the Athenian year. It contained thirty days, and anſwered to the latter part of our April, and the beginning of May. See the article MONTH.

It took its name from the feſtival *Thargelia*, kept in it. See the article THARGELIA, *ſupra*.

THASIUM *Marmor*, in the writings of the antients, a name given to a ſpecies of marble, uſed in building. It had its name from the iſland Thaſus, one of the Cyclades, where it was dug; it was of a duſky greyiſh white, and ſeemed to be compoſed of the ſame matter with the common white marbles with greyiſh veins; only that the matter of the veins here did not run into thoſe determinate parcels, but were blended among the whole maſs.

THAUGHTS, or THOUGHTS, in a boat, are the benches on which the rowers ſit to row.

THEATRIC *Bandages*, a term uſed by Hippocrates, to expreſs the parade of ſurgery in applying bandages for ſhew, when there was no real uſe in them. All ſuch bandages he called *Theatric*, proper only to be looked at.

THEBANUS *Ophites*, in natural hiſtory, a name given by ſome of the antients, to that ſpecies of the *Ophites*, or ſerpentine marble, more commonly called *Ophites niger*, the black ſerpentine. See the article OPHITES.

THEDO, in ichthyology, a name given by Figulus and others, to the trout. See the article TRUTTA.

THEIOCRUS, in the materia medica of the antients, a name given by ſome to the *Melanteria*, a mineral ſubſtance of a vitriolic nature, and of a yellow colour, but turning black on touching common water.

This name *Theiocrus* ſignifies only ſulphur-coloured, and was at firſt uſed with the name of vitriol, as expreſſive of the difference of this kind from others; but in time it became common to uſe it alone.

THELE, a word uſed by ſome to expreſs the nipple, and by others for the whole breaſt.

THELIGONIUM, in botany, the name of a genus of plants, called by the common authors of botany, *cynocrambe*. The characters are theſe: The male and female flowers are produced in the ſame plant. In the male flower the cup is compoſed of one leaf, of a turbinated form, lightly divided into two ſegments with the jaggs turning downward. There are no petals. The ſtamina are numerous, being uſually twelve at leaſt; they ſtand erect, and are of the length of the cup; and the antheræ are ſingle. The female flower has an extremely ſmall one-leaved cup, which is bifid, and its ſegments gape open. There are no petals. The piſtil has a globoſe germen; the ſtyle is ſhort, and the ſtigma obtuſe. The fruit is a globoſe capſule, of a coriaceous texture, having only one cell, and containing only one globoſe ſeed. *Linnæi* Gen. Plant. p. 406. *Tourn.* Inſt. p. 485.

THEMIS, in aſtronomy, a name given by ſome to the third ſatellite of Jupiter. *Lowth.* Abr. Philoſ. Tranſ. Vol. 1. p. 408.

THENAR, (*Cycl.*) a very thick and fleſhy muſcle, in ſome meaſure pyriform, lying on the firſt phalanx of the thumb toward the palm of the hand, the large eminence in which is chiefly formed by it. It is fixed to the bone which ſupports the thumb, and to the neighbouring part of the great internal annular or tranſverſe ligament of the carpus. It is in ſome meaſure bicipital; two diſtinct portions anſwering to the two inſertions. As it runs along the firſt phalanx, theſe two portions unite, and diminiſhing in thickneſs, are both inſerted by one tendon in the lateral internal part of the head of the firſt phalanx, in the lateral part of the baſis of the ſecond, and in the lateral ligament of that joint. The void ſpace between the two portions of this muſcle gives paſſage to the tendon of the *flexor pollicis longus*. That portion which lies neareſt the hollow of the hand is largeſt; and its tendinous extremity is inſerted in the firſt ſeſamoide bone, ſituated at the baſis of the ſecond phalanx. *Winſlow's* Anat. p. 196.

THENAR *Pedis*, a muſcle made up of ſeveral portions, and lying on the inner edge of the ſole of the foot. It is fixed by three or four fleſhy faſciculi to the lower and inner part of the os calcis, ſcaphoides, and cruciforme majus, and a little in the annular ligament under the inner ankle, which belongs to the tendon of the flexor longus. From all theſe inſertions the faſciculi approach each other, as they advance under the firſt bone of the metatarſus, and are fixed in the internal ſeſamoide bone, and inſide of the firſt phalanx near its baſis; and there is another faſciculus fixed by one end of the os ſcaphoides, and cuneiforme majus; and by the other to the external ſeſamoide bone, and outſide of the firſt phalanx of the great toe. *Winſlow's* Anat. p. 222.

THENSA, among the Romans, a veil or canopy, uſed in the chariots at games; and likewiſe to cover a ſeat of ſtate. *Pitiſc.* in voc.

Thenſæ could not be granted to any but by the expreſs allowance of the ſenate. Hiſt. Acad. Inſcript. Vol. 1. p. 359.

THEOBROMA, in botany, the name of a genus of vegetables, including the cacao and the guazuma of Plumier. The characters are theſe: The cup is a three-leaved perianthium reflex and open, and is compoſed of oval, concave, and deciduous leaves. The corolla is compoſed of five petals, erect, open, concavely galeated, and terminated by a bifid briſtle. The nectarium is campanulated, and conſiſts of five petals; it is ſmaller than the flower, and conſiſts of five connected parts. The ſtamina are five-pointed filaments of the length of the nectarium; each has its top divided into five ſegments, and carrying five apices or antheræ. The germen of the piſtil is oval, the ſtyle is pointed, and is of the length of the nectarium, and the ſtigma is ſimple. The fruit is a woody ſubſtance, ribbed in five places on the ſurface, and divided into five lodgments of ſeeds within. The ſeeds are numerous, fleſhy, and of an oval figure. There is ſome difference in the fruit of the ſeveral ſpecies of theſe trees; the cacao having a long fruit, tapering at each end, and the guazuma a globular one, full of tubercles, and perforated in the manner of a ſieve, but divided into five lodgments within. *Linnæi* Gen. Plant. p. 367. *Plumier*, Gen. 18. *Tourn.* Inſt. p. 444.

THEODOLITE (*Cycl.*)—This inſtrument is now commonly made uſe of by ſurveyors. One of the beſt of the kind ſeems to be Mr. Siſſon's lateſt improved *Theodolite*; a deſcription of which may be found in Mr. *Gardner's Practical Surveying improved*; from whence it has been inſerted in a late treatiſe of practical geometry, publiſhed at Edinburgh 1745, in 8°. under the care, as it is commonly thought, of the late celebrated Mr. M'Laurin.

In this inſtrument the three ſtaves, by braſs ferrils at top, ſcrew into bell metal joints, moveable between braſs pillars, fixed in a ſtrong braſs plate; in which, round the center is fixed a ſocket with a ball moveable in it, and upon which the four ſcrews preſs that ſet the limb horizontal. Next above is ſuch another plate, through which the ſaid ſcrews paſs, and on which round the center is fixed a fruſtum of a cone of bell-metal, whoſe axis, being connected with the center of the ball, is always perpendicular to the limb, by means of a conical braſs ferril fitted to it, whereon is fixed the compaſs-box, and on it the limb, which is a ſtrong bell-metal ring, whereon are moveable three braſs indexes, in whoſe plate are fixed four braſs pillars, that joining at top, hold the center-pin of the bell-metal double ſextant, whoſe double index is fixed in the center of the ſame plate. Within the double ſextant is fixed the ſpirit level, and over it the teleſcope.

The compaſs-box is graved with two diamonds for north and ſouth, and with 20 degrees on both ſides of each, that the needle may be ſet to the variation, and its error alſo known.

The limb has two flower-de-luces againſt the diamonds in the box, and is curiouſly divided into whole degrees, and numbered to the left hand at every 10° to twice 180°, having three indexes (with Nonius's diviſions on each for the decimals of a degree) that are moved by a pinion fixed below one of them without moving the limb, and in another is a ſcrew and ſpring under, to fix it to any part of the limb: It has alſo diviſions numbered for taking the quarter girt in round timber; to which a ſhorter index is uſed, having Nonius's diviſions for the decimals of an inch; but an abatement muſt be made for the bark, if not taken off.

The double ſextant is divided on one ſide from under its center (when the ſpirit-tube and teleſcope are level) to above 60 degrees each way, and numbered at 10, 20, &c. And the double index (through which it is moveable) ſhews on the ſame ſide the degree and decimal of any altitude or depreſſion to that extent, by Nonius's diviſions; on the other ſide are diviſions numbered for taking the upright height of timber, &c. in feet, when diſtant ten feet, which at 20 muſt be doubled, and at 30 trebled; and alſo the quantities for reducing hypothenuſal lines to horizontal: It is moveable by a pinion fixed in the double index. See the article SURVEYING.

The teleſcope is a little ſhorter than the diameter of the limb, that a fall may not hurt it; yet it will magnify as much, and ſhew a diſtinct object as perfect, as moſt of treble its length; in its focus are very fine croſs wires, whoſe interſection is in the plane of the double ſextant, and this was a whole circle, and turned in a lathe to a true plane, and is fixed at right angles to the limb; ſo that whenever the limb is ſet horizontal (which is readily done by making the ſpirit-tube level over two ſcrews, and the like over the other two) the double ſextant and teleſcope are moveable in a vertical plane, and then every angle taken on the limb (though the teleſcope be never ſo much elevated or depreſſed) will be an angle in the plane of the horizon, and this is abſolutely neceſſary in plot-

ting an horizontal plane. Treat. Pract. Geom. p. 75. seq.

THEOGAMIA, Θεογαμια, in antiquity, a Sicilian festival in honour of Proserpine, which seems to have been instituted in memory of her marriage with Pluto. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 402.

THEOMANTIA, Θεομαντεια, in antiquity, divination by the supposed inspiration of some deity. For a particular account of which, see *Potter*, Archæol. Græc. l. 2. c. 12. T. 1. p. 298. seq.

THEOPHANIA, Θεοφανεια, in antiquity, a festival observed by the Delphians upon the day whereon Apollo first manifested himself to them. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 402.

THEOPHRASTA, in the Linnæan system of botany, the name of a genus of plants, the characters of which are these: The cup is a small perianthium, lightly divided into five obtuse segments, and remaining when the flower is fallen. The flower consists of a single petal, in form of a bell, slightly divided into five obtuse segments. The stamina are five tapering filaments, shorter than the flower. The antheræ are simple. The germen of the pistillum is of an oval figure. The style is tapering, and shorter than the flower. The stigma is acute. The fruit is a very large globose capsule, containing only one cell. The seeds are numerous and roundish, and are affixed to every part of their receptacle, which is loose. *Linnæi* Gen. Plant. p. 66.

THEOPHRASTICS, a name given to the followers of Paracelsus, from his name Theophrastus.

THEOPNEUSTÆ, Θεοπνευστοι, an epithet given to enthusiastical diviners. *Pott.* T. 1. p. 302.

THEOPROPIA, Θεοπροπια, a delignation given to oracles. See the article ORACLE, *Cycl.*

THEORI, Θεωροι, in antiquity, an appellation given to those Athenians who performed the solemnity called *Theoria*. See the next article.

THEORIA, Θεωρια, in antiquity, a solemn annual voyage to Apollo's temple in the island Delos, performed by the Athenians always in the same ship in which Theseus went. For the particularities of this naval procession, see *Potter*, Archæol. Græc. l. 2. c. 9. T. 1 p. 284. seq.

THEORY (*Cycl.*)—THEORY *of Chemistry*. Under the *Theory* of this art are to be laid down all the general truths which the particular experiments of chemists have hitherto demonstrated. These are, on this occasion, to be taken for granted, and the whole body of such truths makes the universal *Theory* of chemistry, for chemistry is no science formed *a priori*; 'tis no production of the human mind, or raised by reasoning, but collected *a posteriori* from experiments; it took its rise from various operations casually made, and observing those that had one and the same uniform tendency, without any expectation of what followed; and was only reduced into an art, by collecting and comparing the effects of such uncertain experiments, and noting the tendency thereof: So far then as a number of experiments agree to establish any unquestionable truth; so far they may be considered as constituting the *Theory* of chemistry. Such a *Theory* is necessary to be premised to every art; and something equivalent to this is practised by every artisan, in teaching his disciple how to proceed orderly in the exercise of his art; and accordingly it would be impossible to teach the practice of chemistry to advantage, without having first given some such *Theory*. Thus it would be to little purpose, to give a novice a parcel of rosemary, for instance, and bid him, without any addition, distil a water from it, which should contain the natural taste and odour of the plant; unless he knew before-hand this general truth, that plants, exposed to a gentle heat, like that of the summer's sun, do exhale their most subtle and volatile parts, which, being collected and condensed by means of proper vessels, appear in form of water, and are the thing required. *Shaw*'s new Meth. of Chem. p. 3.

In the forming such a *Theory* of chemistry, a direct use may indeed be made of the demonstrations in physics, as particularly in mechanics, hydrostatics, and hydraulics; since the properties common to all bodies, and what farther affections certainly flow therefrom, have their place in chemistry. One cannot, however, be too reserved in this use, since those singular properties found in some bodies, will, if applied to others, falsify the mechanical demonstrations, which might hold true every where else. Thus Galilæo has fully demonstrated the law, by which an heavy body, let fall from on high, descends in a spiral or elliptic line, with a certain degree of acceleration to a point of the earth, perpendicular to the horizon of the point from whence it was first let fall; but if a loadstone be thus let fall, and in the course of its descent enter the sphere of activity of another load-stone, the demonstration will not hold. So what Archimedes has shewn, concerning bodies equiponderant in water, holds infallibly true, if considered only in common cases, but proves false in the instance of gold; which, tho' it sink in other fluids, is suspended and dissolved in light aqua regia. *Boerhaave*, Chem. p. 3.

Due regard being had to this rule, the discoveries of naturalists and mathematicians will always be advantageous, never injurious to the art of chemistry.

Chemistry, as now conceived, is an assemblage of very different parts, which antiently subsisted separate, or at least had a subsistence prior to each other, as the preparing of metals for human uses, the attempts of transmuting the baser metals into gold, the preparing of medicines, &c. If we are to trace the antiquity of chemistry, as an art that teaches to convert other metals into gold, or to procure an universal remedy for all diseases, the research will not carry us far back; but as it relates to the discovery of metals in the mine, and the digging, separating and purifying them, it challenges even the highest antiquity.

The art of metals is, no doubt, of very early standing. To find, procure, fuse, refine, and render malleable, and apply metal to use, is even of antedeluvian origin, and was attributed by the antients to their gods. Moses, the oldest author extant, in his genealogy of the patriarchs, relates that Tubal Cain, the eighth from Adam, was the instructor of every artificer in brass and iron, to prepare the instruments and utensils of life; and 'tis apparent nothing of this could be effected without the knowledge of metallurgy. This account given us by Moses, is surprisingly seconded by prophane history and fables; for Diodorus Siculus, who lived in the time of Cæsar, when Ægypt was become a Roman province, had a fair opportunity of searching into the antiquities of the Ægyptians; and he relates, as the result of his enquiry, a very antient tradition of one Hephaistos, whom that people hold the first inventor of all arts and operations about metals, and every thing else that undergoes the fire; together with their uses; which art he delivered down to posterity, so far as it might be of service to mankind. This Hephaistos of the Ægyptians and Greeks, is the same with the Mulciber and Vulcan of the Latins, to whom the same art or invention is ascribed; and the Vulcan of the Latins we generally suppose to have been the Tubal Cain of the Hebrews, here mentioned by Moses as the inventor of the said art.

It appears from Homer, Hesiod, Orpheus, and all the most antient writers, that Vulcan had the art of working brass and iron; and that, living under mount Ætna, he was employed in forging arms for the gods and heroes. As Diodorus Siculus relates the story, he was the son of Jupiter and Juno, and the first king of Ægypt, and that he was afterwards preferred to be a god, for having invented fire, and taught men the use of it. The Ægyptians, as the same Diodorus observes, adored their god Vulcan as the inventor of the whole art and application of metals; so that the account of Moses and Diodorus perfectly agree, and prove the chemistry of metals almost coæval with mankind. *Shaw*'s Chem. p. 10.

THEOXENIA, Θεοξενια, in antiquity, a festival in honour of all the gods, and celebrated in many cities of Greece, but especially at Athens. *Potter*, T. 1. p. 402.

THEOXINI *Malagma*, the name of a sort of cataplasm, good against pains of the feet.

THERAPIDION, in botany, a name given by some authors to the common oister-green, or sea-laver, a plant of the tremella kind. See the article TREMELLA.

THERMASMA, a word used by some of the antients to express any thing that warms the body, and by others particularly for a warm fomentation, prescribed by Hippocrates for removing pains in the side, and giving ease in pleurisies.

THERMOMETER (*Cycl.*)—Dr. Martin has made useful remarks on the construction and graduation of *Thermometers*, and has reduced the most remarkable of these instruments, which have been employed in different parts of Europe, for observing the changes in our atmosphere, to one general standard, so as to enable us to compare the several observations together. See his Physical and Medical Essays.

THERMOPOLIUM, a name for a sort of public houses among the antients, in which hot liquors were sold, in the manner of our coffee-houses.

THESEIA, Θησεια, in antiquity, an Athenian festival, in honour of Theseus, and celebrated on the eighth day of every month. For the ceremonies of this solemnity see *Potter*, Archæol. Græc. T. 1. p. 404.

THESIS, (*Cycl.*) in music, denotes the fall of the hand in beating time. The Latin writers call it *depressio*. *Brossard.*

THESMOPHORIA, Θεσμοφορια, in antiquity, a festival in honour of Ceres, which was celebrated by many cities of Greece; but especially the Athenians observed it with great devotion and pomp. For the ceremonies of this solemnity, see *Potter*, Archæol. Græc. T. 1. p. 403. seq.

THESMOTHETÆ, Θεσμοθεται, in antiquity, an appellation given to six of the nine Athenian *archons*; the first and chief of the nine was called, by way of eminence, *archon*; the second in dignity was called *basileus*, the third *polemarchus*, and the other six *Thesmothetæ*; for an account of whose power and jurisdiction, see *Potter*, Archæol. Græc. T. 1. p. 77.

THESPHATA, Θεσφατα, in antiquity, an appellation given to oracles. See ORACLE, *Cycl.*

THESPIANA, the name of an antidote, intended for internal abscesses.

THETA, Θ, among the antients, one of the Greek letters. It was used as a mark on the ballots of judges, by which they condemned the person to death, it being the first letter of the word Θανατος, death. Whence it had the epithet of *niger* and *infelix*, thus:

O multum ante alias infelix litera Theta.

THETES, Θῆτες, in antiquity, the loweſt claſs of people at Athens. Ariſtides repealed Solon's law, by which the *Thetes* were made incapable of bearing any office in the government. *Potter*, Archæol. l. 1. c. 4. p. 16.

THEVET, a name of one of the Hebrew months, anſwering to our December moon. See the article TEBET.

THEXIS, a word uſed by the old medical writers, ſometimes for wounds made by puncture with ſmall inſtruments, and ſometimes for the operation of the ſuture, or the ſowing together the lips of a wound, to make it heal with a leſs ſcar.

THIGH (*Cycl.*)—THIGH-*Bone*. We have an account in the Philoſophical Tranſactions of a large piece of a young man's *Thigh-bone* being taken out, and the place ſo well ſupplied by a callus, that he walked ſtrait. See N°. 461. Sect. 2.

Fractured THIGH-*Bone*. The *Thigh-bone*, though the largeſt and ſtouteſt in the whole body, is yet frequently broken, both near its middle, and towards its ends or articulations; but more particularly near that part uſually called its neck, near its articulation with the hip-bone; and when this is the caſe, it is very difficult to ſet it, and retain it in its place. When the bone is broke in two places at once, which ſometimes happens, the danger is yet much greater; and if the patient, in this caſe, eſcapes death, which he ſeldom does, he is commonly lame, ever afterwards.

Sometimes this bone is broken tranſverſely, ſometimes obliquely, and at other times the ends ſlip a great way over one another, which makes it a very bad caſe; for the muſcles of this part being very robuſt, and ſtrongly contracted, draw the lower end of the bone with a conſiderable force upwards, ſo as to make it require great ſtrength to extend and replace it.

The oblique fracture of this bone more frequently ſlips out of its place again than the tranſverſe, and generally leaves the *Thigh* ſomewhat ſhorter than the other, notwithſtanding all the caution the ſurgeon can uſe in the ſetting it. It is therefore neceſſary, in theſe caſes, beſide the means that are common to all the fractures, to uſe a more ſtrict and tight bandage in this than in the tranſverſe fracture, to prevent the bones from being eaſily removed. When a fracture of the *Thigh-bone* happens near its middle, or towards it lower head, it is to be extended and replaced with the hands like other fractures, except that the extending force required is very great; and where the hands of a ſtrong aſſiſtant are not enough, ſlings, napkins, or linnen bandages, are to be bound round each head of the *Thigh*, whereby the fractured bone may be extended both ways, by the ſtrength of three or four perſons at once, while the ſurgeon cautiouſly reduces the fracture with his hands, and ſecures it with a proper bandage and dreſſing; there are ſometimes caſes where the joint ſtrength of three or four men, applid in this manner, are not ſufficient to make the neceſſary extenſion; in which caſe the ſurgeon is obliged to have recourſe to ropes and pullies, by means of which one man will pull more forcibly and equally than ſeveral can without them. But caſes that require this treatment are not common.

When the neck of the *Thigh-bone* is fractured, to which, from its oblique or tranſverſe direction, and ſpongy or brittle ſubſtance, it is very ſubject; it makes a fracture not only very difficult to reduce, but ſuch a one alſo as can ſeldom be cured without leaving the limb ſhorter than it was before. The reaſons of which are, that the fragments cannot but with great difficulty be preſſed into their right places, by reaſon of the great thickneſs and ſtrength of the muſcles which cover them; and that it ſeldom happens that the bones can be retained in their natural poſition, after they have been ever ſo well reduced; becauſe the muſcles which paſs over and are inſerted below the neck of this bone, draw its lower part upwards; and both theſe accidents happen the more naturally and eaſily, becauſe of the oblique poſition of the neck of this bone, which is inſerted into its head in a direction not perpendicular, nor parallel, but as it were ſloping on one ſide; ſo that it is no wonder that lameneſs, and other bad accidents, are the conſequences of this ſort of fracture.

To all theſe reaſons we may alſo add, that it is very difficult to diſcover when the neck of the *Thigh-bone* is fractured, this caſe being uſually taken for the head of the bone being ſlipped out of its ſocket or acetabulum; and this indeed, till of late, has been almoſt a general error. When we can think the external force to have been ſtrong enough to have produced a fracture, when the patient cannot bear any ſtreſs upon the limb, by ſetting his foot on the ground, when very acute pains are felt about the articulation itſelf; and when we find the affected limb ſhorter than the ſound one, it being an eaſy matter to turn the foot almoſt round from one ſide to the other, and any cracking or grating of the bones be perceived in that motion, me may reaſonably ſuppoſe the neck of the *Thigh-bone* is fractured; the limb muſt then be extended very gently and gradually, till it be brought to the ſame length with the ſound one; this may be eaſily done, either by means of a napkin, or the hands of an aſſiſtant in moſt caſes, in ſuch a manner, that the ſurgeon may be able to rejoin, in ſome meaſure, if not perfectly, the neck of the *Thigh-bone* with its head, ſtill firmly remaining in its ſocket: And though a ſhortneſs of the limb, or lameneſs, is generally left behind after this fracture; yet becauſe there are ſome cured without thoſe misfortunes, it is always beſt to uſe, for that end, ſo ſtrict or tight a bandage, that it may retain the neck and head of the bone together, ſo that they may be in a way of uniting evenly. The bandage called *ſpica inguinalis* is the moſt convenient for this purpoſe, and a large and broad napkin, or other linnen cloth, is, with this, placed between the *Thighs*, to keep the body of it from ſubſiding; and laſtly, ligatures are put about the knee and ancle, by which the foot is faſtened to the lower part of the bed, to prevent the limb from being contracted upwards.

If the fracture of the *Thigh-bone* be accompanied with a wound, it makes the caſe very difficult and dangerous. And if theſe accidents happen to be inflicted on the neighbouring joint, death is generally the conſequence, more eſpecially when any of the large blood-veſſels are alſo wounded, which will be readily enough known by the hæmorrhage. In theſe fractures, with a wound, the eighteen-headed bandage is to be uſed for the dreſſing; and if the wound be much contuſed, ſo that extravaſated blood be lodged under the ſkin, and about its interſtices, it is to be carefully opened by ſeveral inciſions, of a ſufficient depth, that the extravaſated blood, which would in a ſhort time putrify, may be diſcharged. The injured parts are to be afterwards waſhed with lime-water, mixed with a fourth part of ſpirit of wine camphorated, till the contuſed parts are digeſted.

When this kind of fracture is accompanied with no very violent loſs of blood, nor the bone near, the proper dreſſing is dry lint folded up, with which the wound is to be filled. If the flux be greater, rectified ſpirit of wine, or other aſtringent liquors are to be uſed; but if the hæmorrhage be very violent, from an artery, the tournequet is to be uſed, and the veſſel ſecured by a ligature. After the blood is ſtopped, and the wound cleanſed, the fragments of the bone are to be replaced, and the limb carefully bound up with compreſſes, ſplints, and the eighteen-headed bandage, and defended by a caſe of ſtraw. But if the fracture is attended with a violent hæmorrhage, and great ſplintering of the bone, from gun-ſhot wounds, ſo as to indicate the great crural artery to be wounded, the beſt method is to amputate the *Thigh*, and tie up the artery in time; for the crural artery is ſo large, that it ſeldom grows together; and if it does, the lower parts are ſoon ſeized with a gangrene. *Heiſter*, 129.

We have the deſcription and draught of a machine for reducing fractures of the *Thigh-bone*, by Mr. Ettrick, in the Phil. Tranſ. N°. 459. Sect 4.

Luxated THIGH. It has been formerly imagined, that the head of the *Thigh-bone* being diſplaced out of its acetabulum, was a very common caſe; but more knowledge in anatomy and ſurgery have convinced us now, that this accident is very rare. The reaſon it was before ſuppoſed common, was, that a fracture of the neck of the *Thigh-bone* was generally miſtaken for this luxation.

It will eaſily be conceived, that this is the true ſtate of the caſe, and that a real diſlocation of the *Thigh-bone* is very rare, if we conſider how very deep the ſinus or acetabulum is, into which the head of this bone is received, with what a broad concave cartilage the head of this bone is covered, how extremely ſtrong the ligaments are with which it is faſtened, how greatly it is defended with thick and ſtrong muſcles, and at the ſame time reflect how very weak and brittle the neck of the *Thigh-bone* is, in compariſon of any other part thereof; and from all theſe conſiderations, how vaſtly more eaſy it muſt be for the ſame force to break the bone off juſt under its head, than to diſplace it out of its ſocket. And, indeed, when luxations of the *Thigh-bone* do happen, it is much more frequently from internal than from external cauſes. For phyſicians have obſerved, that the ligaments of the *Thigh-bone*, though naturally of extreme ſtrength, may be, by various cauſes, and particularly by a flux of humours, ſo relaxed and weakened as to let the head of that bone ſlip ſpontaneouſly out of its acetabulum or ſocket; ſo that the *Thigh*, though not eaſily luxated by external violence, may eaſily happen to be ſo without any external violence, and while the patient lies in his bed. This is an accident, however, that happens much more rarely to adults than to infants.

Whenever the head of the *Thigh-bone* is thruſt out, it is almoſt always wholly diſplaced; ſo as to make a perfect luxation; the exact roundneſs of this head, with the great ſtrength of the circumjacent muſcles, and the narrowneſs of the ſides of the acetabulum, will not admit the bone to be partially diſlocated or thruſt out of its place a little way only; for as ſoon as the head of the bone is thruſt up to the edge of the acetabulum, it muſt unavoidably either turn quite out, or fall back again into its right place.

The thigh is found to be capable of luxation four ways, upward and downward, and backward and forward; but it is moſt frequently diſlocated downward and inward, toward the large foramen in the os pubis. For beſide, that the cartilaginous defence, on the lower part of the acetabulum, is not ſo high as in the reſt, the ligamentum rotundum is ever found to give way more readily in that part than in any other; and laſtly, the adjacent muſcles are found to be weakeſt in their reſiſtance on this part. And there is, beſide all theſe, a certain eminence in this edge of the acetabulum, which prevents the head of the bone from falling back again eaſily into its right place, when

when once it is got this way out of it. But if the head of this bone be diſplaced outwards, it generally ſlips upwards at the ſame time, it being ſcarce poſſible but that the very ſtrong muſcles of the *Thigh* muſt then draw the bone upwards; and there is no eminence in this edge of the acetabulum to reſiſt the head of the bone in that paſſage.

When the *Thigh* is diſlocated forwards and downwards, which is what moſt uſually is the caſe, the leg hangs ſtradling outward, and is longer than the other; the knee and foot alſo both turn outwards, and the head of the bone itſelf will be felt near the lower part of the inguen and os pubis. Sometimes there is a ſuppreſſion of urine in this caſe, which is occaſioned by ſome nerve which communicates with the bladder being violently compreſſed; in the buttock there alſo may be perceived a cavity from the trochanter major, and the reſt of the bones being diſplaced; and if the *Thigh-bone* be not timely reduced into its acetabulum, the whole limb withers ſoon afterwards. The patient, for this reaſon, can bear little or no ſtreſs upon that limb, but muſt always incline and throw the weight of his body upon the other; when he moves forward, he muſt move that limb in form of a ſemicircle, and ſupport his body by crutches under the arms; though there are not wanting particular caſes, where the head of the luxated *Thigh-bone* has grown ſo firmly to the adjacent parts, without the acetabulum, as to become, in proceſs of time, ſo ſtrong as to ſupport the body without ſticks, though the perſon could not, in any of the caſes that have been known of this kind, walk without halting.

If the *Thigh-bone* be diſplaced backward, it is uſually drawn upward alſo, as before obſerved, at the ſame time; hence there will be perceived, in this caſe, a cavity behind the inguen, and a tumour upon the buttock, becauſe the head, and trochanter of this bone, will be placed there. The tumour on the buttock being thruſt upward, the limb will become ſhorter than before, and the foot will be inclined to turn inwards. The heel will not touch the ground, but the perſon ſeem to ſtand upon his toes; and laſtly, the luxated limb will be much more eaſily bent than extended.

It is extremely rare that the *Thigh* is luxated forward or backward, without being alſo drawn upward or downward; but if it ſhould ſo happen, it will yet evidently be diſcovered by the rules before given, and by conſidering the nature of the arti culation of the bone: As it is, however, at beſt very difficult to diſcover when the *Thigh-bone* is diſlocated, and when it is fractured, either by feeling or inſpecting, becauſe of the great thickneſs of the muſcles and integuments, it is therefore a matter of ſome conſequence to propoſe the ſigns by which one of theſe caſes may be known from the other. There is reaſon to judge the *Thigh-bone* to be luxated, when we find the ligaments of the bone have been relaxed by ſome preceding congeſtion of humours, when no external violence has been exerted upon it, when neither violent pain, tumours, nor inflammation follow; and laſtly, when the whole limb may be bent, and turned about at the acetabulum, without the ſurgeon's diſcovering any grating or cruſhing of the bones; and the contrary of theſe ſigns, which are what uſually take place, in what have been uſed to be called luxations of this bone, are very ſtrong indications of a fracture.

When the bone is found to be really diſlocated, it is to be reduced in a method agreeable to the nature and direction of the diſlocation. When it is diſplaced forward and downward, the patient is to be laid flat upon his back on a table; then a linnen napkin, or ſtrong ſling, is to be made faſt about the groin, over the part affected, ſo that one end of the ſling may come over the belly, and the other over the nates and back, to be both tied together in a knot upon the ſpine of the os ileum, and afterwards either faſtened to a hook fixed in ſome poſt, or held firm by ſome aſſiſtance: In like manner at the bottom of the *Thigh*, a little above the knee, there muſt be faſtened another napkin or ſling, or elſe the girt of Hildanus, with a compreſs between it and the *Thigh*; both theſe ſlings being drawn tight, the *Thigh* is to be extended, but that not vehemently; but only ſo much as is ſufficient to draw the bone out of its ſinus, that it may be replaced into its proper acetabulum by the ſurgeon's hands; to this purpoſe the ſurgeon is, with one hand, to preſs the head of the *Thigh-bone* outward, while the other conducts the knee inward. Or the reduction may be made by napkins faſtened about the *Thigh* near its extremities, in the manner of ſlings, and the limb extended that way, the knee being at the ſame time preſſed inward by the hands.

If theſe methods are not ſufficient, it will be neceſſary to have recourſe to the polyſpaſton or pulley, well known to the ſurgeons on theſe occaſions. This is to be the method of reduction of the *Thigh-bone* when it is diſlocated forward; but when it is found to be luxated backward, the patient is to be placed flat on a table, with his face downward; the *Thigh* is then to be extended more ſtrongly than in the former caſe, and the reduction is then to be performed by the ſurgeon's hand, an aſſiſtant all the while turning the limb ſomewhat inwards, and by this method the head of the *Thigh-bone* generally ſlips very readily from this ſort of diſlocation into its proper place. The limb is then to be ſecured with proper bandages, and the patient to be kept to his bed for three or four weeks. *Heiſter*, Surg. p. 167.

Saltzmannus relates an inſtance of a luxation of the *Thigh-bone*, without any fracture of its neck, and confirms what Ruyſch had obſerved of the epiphyſis of the os femoris, being as it were annihilated, or at leaſt changed ſo, as it could not be obſerved, when ſought after in one who had it broken.

THIGH, in the manege. The effect of the horſeman's *Thigh* is one of the aids that ſerves to make a horſe work vigorouſly. See the article AID.

Fore-thigh, or *arm* of a horſe, is that part of the fore-leg that runs between the ſhoulder and the knee: Though the *fore-Thigh* does not bend or bow, yet we commonly ſay, a horſe goes fine, that bends well the *fore-Thigh*, importing thereby, that he bends well his leg.

THILYPTERIS, in botany, a term uſed by Dillenius to expreſs the common female fern or brakes. *Dill.* Cat. 174.

THIMHIO, in the materia medica, a name uſed by ſome authors for a peculiar ſort of lignum aloes, which is blackiſh and very heavy, and extremely ſweet. *Camell.* Syll. p. 87.

THIN, in the materia medica, a name given by the Arabian writers to earth of any kind.

Thus the bole armenic of Galen is called by Aviſenna *thin armeni*; and hence the word *muthin*, an adjective ſignifying earthy, or approaching to the nature of earth; a term applied to many medicines of this kind.

THINA, in botany, a name by which ſome authors have called the larix or larch tree. *Ger.* Emac. Ind. 2.

THIRD (*Cycl.*)—THIRD *Major*. The logarithm, or meaſure [a] of the octave $\frac{2}{1}$ being 1.000000, the meaſure of the greater *Third* $\frac{5}{4}$ will be, 0.321928. [b]—[[a] See INTERVAL. [b] *Euler*. Tentam. Nov. Theor. Muſ. p. 109.]

The *third major* is by practitioners often taken for the *third* part of an octave; but this is a great error, ſince three greater *Thirds* fall ſhort of the octave by a dieſis: For $\frac{5}{4} \times \frac{5}{4} \times \frac{5}{4} \times \frac{128}{125} = \frac{2}{1}$; or by logarithms $3 \times 0.321928 +$ log. dieſis $= 0.965784 + 0.034215 = 0.999999$ or 1.000000 the logarithm of the octave. See the article DIESIS.

THIRD *Minor*. The logarithm or meaſure of the octave $\frac{2}{1}$ being 1.000000, the meaſure of the *third minor* $\frac{6}{5}$ will be 0.263034. Hence it appears that four leſſer *Thirds* exceed the octave. But practical muſicians are apt to ſuppoſe them equal to the octave, as they are apt to confound three greater *Thirds* with that interval. Three leſſer *Thirds* exceed the octave by a dieſis and a comma; as is eaſily proved by logarithms. *Euler*. Tent. Nov. Theor. Muſ. p. 109. See the article INTERVAL.

Diminiſhed THIRD, in muſic. We meet with ſeveral kinds of *Thirds* in the writings of muſicians, as greater and leſs, commonly called ſharp and flat; diminiſhed, ſuperfluous, deficient, and redundant. See the articles INTERVAL, DEFICIENT, REDUNDANT, *&c.*

THIRST (*Cycl.*)—It is ſaid, that thoſe who travel through the ſcorching deſarts of Arabia, Perſia, *&c.* find that brandy, and the ſtrongeſt wines, quench their *Thirſt* beſt. *Boyle*, Works abr. vol. 1. p. 52.

THISMA, a name uſed by ſome for any ſubterranean vein, or bed of a mineral.

THISTLE, *Carduus*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the floſculous kind, being compoſed of ſeveral floſcules, which, at the upper end, are divided into ſegments, and ſtand upon the embryo ſeed. The general cup which contains theſe floſcules is of a prickly ſtructure; and the embryos finally become ſeeds winged with down. See Tab. 1. of BOTANY, Claſs 12.

The ſpecies of *Thiſtle*, enumerated by Mr. Tournefort, are theſe: 1. The calcitrapa, or ſtarry-headed *Thiſtle*. 2. The ſtarry-headed *Thiſtle*, with deep purple flowers. 3. The ſtarry-headed *Thiſtle*, with bright red flowers. 4. The ſtarry-headed *Thiſtle* with white flowers. 5. The ſtarry-headed *Thiſtle*, with broad jagged leaves, and large flowers. 6. The ſtarry-headed *Thiſtle*, with whole leaves ſerrated at the edges. 7. The yellow-flowered ſtarry-headed *Thiſtle*, with leaves like the blue-bottle or cyanus. 8. The yellow-flowered ſtarry-headed *Thiſtle*, with leſs ſcaly or prickly heads. 9. The ſtarry-headed *Thiſtle* with undivided leaves, and purple flowers. 10. The aſſes *Thiſtle*, with ſmall heads, or the common wild *Thiſtle*. 11. The broad-leaved ſpear-*Thiſtle*. 12. The white-flowered broad-leaved ſpear-*Thiſtle*. 13. The very large and tall exotic ſpear-*Thiſtle*. 14. The very prickly *Thiſtle*, with alated and prickly ſtalks. 15. The purple-flowered *Thiſtle* with a bending head. 16. The white-flowered *Thiſtle* with a bending head. 17. The bear's-breech *Thiſtle*. 18. The common ladies *Thiſtle*, or milk *Thiſtle*. 19. The ladies *Thiſtle* with no white variegations. 20. The eryngo-like *Thiſtle* with prickly heads. 21. The great exotic milk *Thiſtle*, with brown ſeeds. 22. The galactite *Thiſtle* of John Bauhine. 23. The galactite *Thiſtle* with white flowers. 24. The common woolly *Thiſtle*, with acanthus-leaves. 25. The white-flowered woolly *Thiſtle* with acanthus-leaves. 26. The woolly acanthus-*Thiſtle* with narrower leaves. 27. The white-flowered woolly narrower-leaved acanthus-*Thiſtle*. 28. The very tall acanthus-leaved Portugal woolly *Thiſtle*. 29. The Portugal acanthus-leaved woolly *Thiſtle*. 30. The great-flowered Aleppo woolly *Thiſtle*, with acanthus-leaves. 31. The purple *Thiſtle* with round woolly heads,

32. The white-flowered *Thiſtle* with round woolly heads. 33. The Pyrenean woolly *Thiſtle*, with glomerated purple flowers. 34. The common *Carduus* or polycantha. 35. The Spaniſh polycanthus, with very ſhort leaves, armed with very long prickles. 36. The yellow centaury-like corn *Thiſtle*. This has been called by many, the yellow *knapweed* with prickly heads. 37. The hoary ſea-*Thiſtle*, with very tall ſtalks. 38. The hoary cretic *Thiſtle*, with a yellowiſh purple flower. 39. The hoary Portugal-*Thiſtle*, with alated ſtalks, and woolly heads. 40. The prickly round-headed *Thiſtle*, called by ſome the globular-headed jacea. 41. The ſuccory leaved purple Spaniſh *Thiſtle*. 42. The hairy jagged-leaved *Thiſtle*, with white flowers. 43. The powdered or duſty *Thiſtle*. 44. The knapweed-leaved *Thiſtle*, with ſmall heads and three-pointed ſcales. 45. The rockett-leaved Malteſe *Thiſtle*, with yellow flowers. 46. The Malteſe *Thiſtle*, with conglobated heads. 47. The Portugal-*Thiſtle*, with large hairy coronopus leaves, and yellow flowers. 48. The Portugal-*Thiſtle*, with hairy, rigid, coronopus-leaves, and ſaffron-coloured flowers. 49. The yellow Portugal-*Thiſtle*, with ſmooth and rigid coronopus-leaves. 50. The rape-leaved cretic *Thiſtle*, called by ſome the prickly *cyanus*, and prickly *knapweed* of Crete. *Tourn.* Inſt. p. 440. ſeq.

Gentle THISTLE, *Cirſium*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the floſculous kind, being compoſed of a number of oblong floſcules, divided into many ſegments at their edges, and placed on the embryo ſeeds. Theſe are all contained in a ſcaly but not prickly cup; and the embryos finally become ſeeds winged with down; to this it is to be added, that the leaves are ſurrounded with ſoft prickles. The diſtinguiſhing characters of the *Cirſium* and jacea are therefore theſe: The *Cirſium* has prickly leaves, and not prickly cups, and the jacea has no thorns either on the leaves or cups.

The ſpecies of *Cirſium*, enumerated by Mr. Tournefort, are theſe: 1. The great *Cirſium* with aſphodel-roots. 2. The great *Cirſium*, with a large ſingle head, and purple ſtamina. 3. The great *Cirſium*, with a large ſingle head, and white ſtamina. 4. The great *Cirſium*, with a ſingle large head, and hoary divided leaves. 5. The great *Cirſium*, with a ſingle large head, and with green ſmooth leaves much divided. 6. The hoary large *Cirſium*, with ſingle heads, with large ſcales. 7. The *Cirſium* with ſmall ſingle heads. 8. The *Cirſium* with ſmooth leaves and compact flowers. 9. The *Cirſium* with narrow and undivided leaves. 10. The common narrow-leaved *Cirſium*. 11. The broad-leaved meadow *Cirſium*, with aſphodel-roots. 12. The aſphodel-rooted meadow *Cirſium*, with finely divided leaves. 13. The purple-flowered *Cirſium*, without a ſtalk. 14. The ſilver-ſpotted *Cirſium*. 15. The purple-flowered field-*Cirſium*, with creeping roots, and ſow-thiſtle leaves. 16. The white-flowered field-*Cirſium*, with creeping roots, and ſow-thiſtle leaves. 17. The creeping-rooted ſow-thiſtle-leaved field-*Cirſium*, with tuberous ſtalks. 18. The common many-headed meadow *Cirſium*. 19. The broad-leaved *Cirſium*, with burdock heads. 20. The low narrow-leaved *Cirſium*. 21. The mercury-leaved alpine *Cirſium*. 22. The *Cirſium* with very large leaves, of the ſhape of thoſe of the ſerratula. 23. The many-headed *Cirſium*, with a winged ſtalk, and ſinuous leaves. 24. The alpine *Cirſium*, with leſs divided leaves, armed with very frequent and long prickles. 25. The three-headed alpine *Cirſium*. 26. The purple-flowered acanthoide alpine *Cirſium*. 27. The acanthoide mountain *Cirſium*, with yellow flowers. 28. The many-headed meadow alpine *Cirſium*, with aſphodel-roots. 29. The many-headed alpine *Cirſium*, with ſmall purple flowers, and prickly ſtalks. 30. The tall Pyrenean *Cirſium*. 31. The oriental *Cirſium*, with jagged leaves. *Tourn.* Inſt. p. 447.

Torch-THISTLE. See the article TORCH.

Globe-THISTLE. See the article ECHINOPUS.

THISTLE *Fly*, in natural hiſtory, a ſmall fly produced from a fly-worm, hatching in the protuberances of the carduus hæmorrhoidalis. In the protuberances of this *Thiſtle*, while they are cloſed in all parts, the worm of this fly, from whoſe injuring it, at the time of depoſiting the egg from which it was hatched, the protuberances aroſe, undergoes its laſt transformation. It here makes of its own ſkin a ſhell, in form of an egg, within which it puts on the nymph ſtate. When this nymph becomes a living fly, the leaſt part of its difficulty is the finding its way out of this ſhell; it has a much ſtronger priſon than that, and before it can obtain its liberty, muſt force its way through the much more cloſely compacted fibres of the protuberance of the vegetable. It has, however, no other means of doing this difficult work, but that of inflating its head, and throwing out the bladder or muzzle with which all theſe creatures are provided in this ſtate. See the articles NYMPH, MUSEAU, and THISTLE-*Galls*, infra.

This is a difficult operation, and many of the creatures periſh in the attempt; but what much forwards the ſucceſs of it, in many caſes, is, that the ſtalk of the *Thiſtle* often becomes naturally half rotten before the time of the fly's egreſs. *Reaumur*, Hiſt. Inſ. vol. 4. p. 338.

THISTLE-*Galls*, a name given by the more accurate authors to the protuberances on the ſtalks of a ſpecies of *Thiſtle*, called by authors, *carduus hæmorrhoidalis*, from theſe tubercles, which are ſuppoſed to reſemble thoſe of the hæmorrhoidal veins, in perſons ſubject to the piles. Theſe have been ſuppoſed a natural production of the plant; but they are far otherwiſe. The whole hiſtory of them is, that the juices of this plant, being peculiarly agreeable to the worms of a certain ſpecies of fly, that creature always depoſits its eggs on the ſtalks; and the young ones, when hatched, gnaw their way into the ſubſtance of the ſtalk, and the copious derivation of the juice, occaſioned by their ſucking, produces the turbercles which are found on it. See Tab. of Inſects, N°. 28.

Theſe tubercles are of a roundiſh or oblong figure, and are of various ſizes, from that of a pea to the bigneſs of a nutmeg; they are much harder than the reſt of the ſtalk, approaching to a woody ſtructure; when cut open, they are found to contain each ſeveral oblong and narrow cells; theſe have no communication with one another, and are each inhabited by a ſmall white worm, which has two hooks at the head; with theſe it breaks the fibres of the plant, in order to get at its juices. When it has arrived at the time of its change into the nymph ſtate, it ceaſes to eat, and drawing up its body much ſhorter than uſual, its ſkin hardens, and forms a ſhell, under which it changes into a very beautiful two-winged fly.

The wings of this animal are of a very ſingular appearance; they are whitiſh and tranſparent in the middle, but ſurrounded at the edges with a border of black in the form of a chain of figures like the letter Z. When the fly is ſeen in ſome lights, the white parts of the wing is loſt, and the whole appears a circle of theſe notched figures.

The body and breaſt of this fly are of a beautiful black, with ſome ſlight variegations of yellow; and the ſhoulders are elegantly ſtreaked with the laſt colour. The anterior part of the head is white, which gives the creature a very ſingular appearance, and its back part is edged with a fine yellow down or hairyneſs. The antennæ are reddiſh; and the legs are in part black, and in part of a fine clear brown. In obſerving the changes of the worms of theſe galls, there are often obſerved ſome which go through them in a different manner from the reſt, and finally produce a very different ſpecies of fly. Theſe are the progeny of the eggs of ſome other ſpecies of fly, whoſe worm being carnivorous, is lodged by the art of its parent, while it is yet in the egg ſtate in the ſubſtance of this gall, there to prey upon the defenceleſs inhabitants.

There are many other ſpecies of galls, the inhabitants of which are expoſed to the ſame ſort of enemies. In thoſe it is common to find the proper inhabitant and the devourer in the ſame cell; the one feeding on the juices of the plant, the other on its juices; but this is not the caſe here, theſe worms immediately deſtroying the proper inhabitants, and being found always alone in their cells. *Reaumur*, Hiſt. Inſ. vol. 6. p. 221.

THLASIAS, a term uſed by the antients to expreſs an eunuch made by a compreſſion or contuſion of the teſticles, not by the cutting them out.

THLASIS, a word uſed by the antients to expreſs either a contuſion without a wound, or a wound made by ſome blunt inſtrument, which contuſed the parts.

THLASMA, a word ſometimes uſed like *thlaſis*, to expreſs a contuſion either with or without a wound; ſometimes applied particularly to a receſs of the cranium inward without a fracture, an accident principally affecting children.

THLASPEOS *Semen*, in the materia medica, the name of a ſeed produced by the common *thlaſpi arvenſe ſiliquis latis*, or common treacle muſtard. See the article THLASPI, infr.

It is a plant of about eight inches high; the leaves are broad and oblong, and the flowers are white, and each compoſed of four leaves. The ſeed-veſſels are broad and flat, and the ſeeds ſmall and dark coloured. It grows wild in England, but is not very common.

The ſeed ſhould be choſen clean and freſh, of a reddiſh caſt, and very ſharp, and biting on the tongue. Great care ſhould be taken in the buying this ſeed, becauſe it is often adulterated, and the ſeeds of common garden creſſes are too frequently ſold in its place. It is an ingredient in ſeveral of our ſhop compoſitions, and is eſteemed attenuating, deterſive and aperient, and is ſaid to promote urine, and the menſes, and to expel the after-birth. *Lemery*, Dict. of Drugs.

THLASPI, *Treacle Muſtard*, in botany, the name of a genus of plants, the characters of which are theſe: The flower conſiſts of four leaves, and is of the cruciform kind. The piſtil ariſes from the cup, and finally becomes a roundiſh fruit, of a flatted ſhape, and uſually terminated all round with a foliaceous edge ſplit at the extremity, and divided by an intermediate membrane into two cells, which uſually contain a number of flat ſeeds. To theſe marks it is to be added, that all the *Thlaſpis* have whole, not divided leaves, in which they evidently differ from the *naſturtium*, or creſs kind.

The ſpecies of *Thlaſpi*, enumerated by Mr. Tournefort, are theſe: 1. The common *Thlaſpi*. 2. The ſmaller hoary-leaved *Thlaſpi*. 3. The field-*Thlaſpi* with broad pods. 4. The hairy podded *Thlaſpi*. 5. The *Thlaſpi* with heart-faſhioned pods. 6. The *ſecrodo-Thlaſpi*, or *Thlaſpi* ſmelling ſtrongly of garlick. 7. The larger perfoliated field-*Thlaſpi*. 8. The ſmaller perfoliated field-*Thlaſpi*. 9. The little red-flowered rock-*Thlaſpi*. 10. The purple-flowered

alpine *Thlaſpi*, with round fleſhy leaves. 11. The little Portugal ſcurvygraſs-leaved *Thlaſpi*. 12. The little alpine *Thlaſpi*, with thick narrow leaves. 13. The *Thlaſpi* called the roſe of Jericho. 14. The Virginian *Thlaſpi*, with leaves like the Iberis, but broader and ſerrated at the edges. 15. The ever-green mountain-*Thlaſpi*. 16. The candy-*Thlaſpi*, with red and white flowers. 17. The bitter umbellated field-*Thlaſpi*. 18. The leſſer umbellated candy-*Thlaſpi*, with white umbellated flowers of a ſweet ſcent. 19. The graſſy-leaved purple-flowered umbellated Portugal-*Thlaſpi*. 20. The graſſy-leaved umbellated Portugal-*Thlaſpi*, with white flowers. 21. The rock-*Thlaſpi*, with vermiculated leaves. *Tourn.* Inſt. p. 212. See the article THLASPEOS *Semen*, *ſupra*.

THLASPIDIUM, in botany, the name of a genus of plants; the characters of which are theſe. The flower conſiſts of four leaves, and is of the cruciform kind. The piſtil ariſes from the cup, and finally becomes a ſort of double fruit, flat, and compoſed of two parts ſeparated one from the other by an intermediate membrane, and each containing uſually one long-ſhaped flatted ſeed.

The ſpecies of *Thlaſpidium*, enumerated by Mr. Tournefort, are theſe: 1. The French *Thlaſpidium*, with hairy leaves like thoſe of hawkweed. 2. The hairy *Thlaſpidium*, with auriculated flower-cups. 3. The pale yellow-flowered annual *Thlaſpidium*. 4. The reddiſh-leaved *Thlaſpidium*. 5. The ever-flowering ſhrubby *Thlaſpidium*, with leucoium leaves. 6. The ever-flowering ſhrubby *Thlaſpidium*, with variegated leaves. 7. The alkanet-leaved *Thlaſpidium*. 8. The ſpiked Italian *Thlaſpidium*. 9. The narrow-leaved ſmooth mountain-*Thlaſpidium*. 10. The dwarf alpine rough *Thlaſpidium*. *Tourn.* Inſt. p. 214.

THLIBIÆ, in antiquity, a kind of eunuchs. See the article CASTRATION.

THOCOS, Θῶκος, in antiquity, the ſame with *Thacas*. See the article THACAS.

THOKES, in our old writers, fiſh with broken bellies, forbid by ſtatute to be mixed or packed with *Tale-fiſh*. 22 Ed. IV. c. 2. *Blount*, *Cowel*.

THORACIS *Primus*, in anatomy, a name given by many of the anatomical writers to the muſcle called by the French the *Souclavier*. See the article SUBCLAVIUS.

THORACIS *Quartus*, in anatomy, a name given by many of the earlier writers to a muſcle called by the modern writers *ſerratus porticus inferior*. The ſame authors gave the name of *tertius Thoracis* to the *ſerratus poſticus ſuperior*.

THORÆ *Radix*, in the materia medica, the name of a root which keeps its place in the catalogues of officinal ſimples, but is ſeldom uſed.

The plant which produces it is the *Thora valdenſis* of Gerard. It is kept in the gardens of the curious, but grows wild in the mountainous parts of Germany. The root is compoſed of a number of granules or ſmall lumps, like that of the common ranunculus; the leaves are roundiſh and ſtand on ſmall pedicles, and the ſtalks are about ſix inches high, and the flowers yellow, and like thoſe of our common wild ranunculus's.

The root is acrid and corroſive, and the juice of the leaves is ſaid to poiſon animals, and to have been uſed by the antients for that purpoſe. *Pomet*'s Hiſt. of Drugs, p. 41.

THORAX (*Cycl.*) —Dr. Hoadley thinks it proved from Mr. Hales's experiments, in his vegetable ſtatics and hæmaſtatics, that there is air in the cavity of the *Thorax*, between the lungs and the pleura. See his Lectures on Reſpiration.

Abſceſſes in the THORAX, or breaſt. One of the moſt remarkable accounts we have ever had of the effects of an abſceſs in the *breaſt*, is from Mr. Chicoyneau, of the academy of Montpelier, given in the Memoirs of the Academy of Sciences of Paris, in 1731.

The caſe was this: A young lady of about nine years old, of a thin habit, a ſprightly temper, and dry conſtitution, ſeemed to be growing crooked, both her ſhoulders but particularly the left were more raiſed than they naturally ſhould be, and her whole body became ſomewhat more bent than uſual toward the right ſide. Mr. Chicoyneau was ſent for at this time, to know whether any ſtop could be put to the progreſs of this bad arrangement of the parts. On examining the lady it was found, that though ſhe was naturally lean, yet there was a fullneſs all about her ſhoulders, and that the edges of the ſhoulder blades toward the ſpine were ſo elevated as to have between them and the ribs a ſpace of two fingers breadth wide; and the ſpine of the back, inſtead of running down in a perpendicular line was crooked, and from the fourth vertebra downwards was puſhed out of its natural ſituation; this bending continued down to the loins, and formed a ſort of arch, the convexity of which was toward the left-ſide, and was ſo ſenſible a little below the ſhoulder-blade, that it ſeemed two fingers breadth out of its place. It ſeemed from this that the conſequences muſt be very bad, and that the young lady would inevitably fall into a terrible deformity, which neither art nor nature could prevent, and that the organs of reſpiration would be greatly injured, as is commonly the caſe in theſe bad arrangements of the parts.

Mr. Chicoyneau took his leave with giving her parents ſome flattering hopes that nature might reſtore the parts in their farther growth, as children whoſe bones are diſordered by rickets often have them right again in more advanced years, and was intending to preſcribe a ſlight regimen; when, about five days afterwards he was again called in on account of a fever which attacked the young lady with great violence, and was always worſt during the night, going off by gentle ſweating toward the morning; on thoroughly enquiring into the ſymptoms this appeared to be a putrid fever, and, beſide all the other ſymptoms of that diſeaſe, the patient had a conſtant and terrible pain in her ſhoulders, and with this a very troubleſome dry cough, and a difficulty of reſpiration, whence it appeared too plainly, that either the lungs or the pleura were threatened with an inflammatory fluxion: After twenty days the fever began to abate, but ſtill did not quite leave her; and it was not long after when all the ſigns of an internal ſuppuration appeared, and Mr. Chicoyneau dreaded an incurable phthiſis. The pulſe after this grew much worſe, and was very irregular; and two other phyſicians being called in, all agreed that the child had but few days to live, ordered only ſome gentle cordials, and acquainted the parents with the danger. When all hopes were over, the nurſes acquainted the doctors on one of their viſits, that ſince their laſt the patient had diſcharged by ſtool at ſeveral times a very large quantity of a white viſcid matter, reſembling pus; and that before every one of theſe evacuations the young patient had great irritations, and violent pains in the belly.

Nature had not given the patient over, though her doctors had, and ſoon ſhewed that ſhe could do what baffled the efforts of art. The matter voided was found, on examination, to be true pus, with a very ſmall mixture of blood, the voiding it by ſtool continued many days with the ſame frequency and violence, and the fever and other ſymptoms all going off at this time by regular degrees, the diſcharge was ſoon found to be critical, and there were ſome hopes of nature's performing a cure by it.

The diſcharge continued about twelve days, and at the end of a little longer time the patient was perfectly recovered. There is no doubt, from the cough and all the ſymptoms, that this matter was contained in the breaſt, and though it has appeared incredible to many, that matter thus formed ſhould be taken up into the blood-veſſels and carried in the courſe of circulation to the inteſtines, and there diſcharged, yet this caſe ſeems an inconteſtible proof of the poſſibility of it.

There remained now no danger to the patient, but that of the increaſe of her deformity by the progreſs of the diſplacing of the ſpine, and other bones, as there was all the reaſon in the world to believe, that during the time of this long and terrible illneſs theſe parts had grown much worſe; but, on inſpection, nature was found here to have been as good a phyſician as in the other caſe; and, to the amazement of all that were preſent, the bones were all found in their natural places.

It was eaſy to ſee from this, that the diſplacing of the bones had been wholly owing to this tumor within the breaſt, the inflammation and ſuppuration of which had occaſioned all the illneſs the patient had endured. The tumor was doubtleſs formed in the poſterior region of the *Thorax*, whence it enlarged itſelf afterwards, extending to the neighbouring parts, and as to this alone was owing the cauſe of the diſplacing the bones, it is no wonder that when this cauſe no longer ſubſiſted, they again reaſſumed their places. Mem. Acad. Scienc. 1731.

Mr. le Dran remarks, that whenever any conſiderable quantity of pus is contained in either cavity of the *Thorax*, that ſide will appear larger than the other. Med. Eſſ. Edinb.

Wounds of the THORAX. The wounds of the *Thorax* or breaſt, are of three kinds; either the wound is inflicted on the external parts only, or it penetrates into the cavity of the breaſt; or thirdly, the contents of the *Thorax* partake alſo of the wound.

It may be diſcovered whether wounds do or do not penetrate into the cavity of the *Thorax*, either by the ſight or by the hearing, obſerving whether any ſound proceeds from the wound at the time of inſpiration, by feeling with the probe or a finger, and obſerving whether they paſs into the cavity, or meet with any reſiſtance, by injecting warm water, which if the wound does not penetrate will return ſtrongly upon you; and laſtly, you will be convinced that it does not by the abſence of bad ſymptoms, ſuch as difficulty of breathing, fainting and ſick fits, which always attend a wound that penetrates into this cavity. If the wound is found not to penetrate, it is to be treated as a common ſlight wound. But ſometimes an external wound of this kind runs very deep, and obliquely between the muſcles and the ribs, and is thereby rendered very difficult to be cleanſed from grumous blood and matter; and the matter in this caſe frequently deſtroys the neighbouring parts, and produces ulcers, and very dangerous or incurable fiſtulæ; nay, ſometimes it makes its way through the pleura, into the cavity of the *Thorax*, and forms an empyema, or brings on a phthiſis, and death itſelf.

The great buſineſs in this caſe is to clear the ſinuſes from the blood and matter confined in them; and this is to be done either by preſſure, or by ordering the wound to be ſucked by

a healthy perſon, or by drawing it out with a ſyphon, or making farther openings with a knife. A proper ſyringe with its mouth applied to the wound, and a ſtrong ſuction made, often will fill itſelf with the confined blood and matter, and by repeating the operation prove of very ſignal ſervice.

In wounds that penetrate into the cavity, when a large quantity of blood is ſpilt into the cavity of the *Thorax*, the expanſion of the lungs, the office of reſpiration, and the courſe of the blood through the lungs are impeded, and the blood in the lungs being inſpiſſated by frequently being retarded there, life cannot be ſupported; but where the quantity of extravaſated blood is not ſo large as to occaſion theſe accidents, there ſtill is danger that it ſhould putrify by degrees, and corrupt either the diaphragm, pleura, or lungs, which muſt occaſion very bad ſymptoms, and finally death itſelf, and that in a ſhort time. When blood is extravaſated in the *Thorax*, we muſt therefore uſe all diligence to get it away. If the wound is inflicted on the middle or lower part of the *Thorax*, and has not a very narrow opening, it will be convenient to lay the patient upon the wounded ſide, and adviſe him to fetch his breath deep, or cough; and if the diſcharge is hindered by lumps of grumous blood ſtopping up the orifice, they muſt be removed with a probe, or with the fingers, or drawn out with a ſyringe. If the blood is become too thick to flow out of the wound, an injection of barley-water with the addition of a little honey of roſes and a ſmall quantity of ſoap muſt be uſed; this is to be injected, and the patient made afterwards to lie on the wounded ſide, and to let it run out again; and this muſt be repeated, till it appears that all the grumous blood is waſhed away. But if the wound is ſo narrow and oblique that this method cannot be uſed, it muſt be enlarged with the inciſion-knife. Great caution is to be obſerved not to fatigue the patient too much, by attempting to diſcharge all the extravaſated blood at one time. It will be more ſafe to do it by intervals, at different times, eſpecially if he be ſubject to ſwoonings; but the wound muſt be kept open in the mean time, by introducing a ſilver or leaden pipe into it, or at leaſt a large tent with a ſtring faſtened to it. This method of cleanſing the cavity of the *Thorax* is to be repeated, till the diſcharge ſhall entirely ceaſe, and the external wound can be conveniently healed.

When a wound is made in the upper part of the breaſt, the patients lying on the wounded ſide cannot at all let out the matter in the cavity; but an opening muſt be made in the lower part of the *Thorax*, between the ſecond and third rib, counting upwards, if it is on the left ſide; but if it is on the the right ſide then between the third and fourth rib, about a hand's breadth from the ſpine. The place where the opening is to be made ſhould be firſt marked with ink, and the inſtrument generally uſed to make it is the *trocar*, which muſt be driven above the rib into the *Thorax* with great caution, and gentleneſs; after it has penetrated, the ſteel inſtrument is to be drawn out, and the pipe left in as a paſſage for the extravaſated blood to be let out by; and if it does not readily make its way out by this, its evacuation may be forwarded by the ſuction of a ſyringe. The trochar is in common uſe on this occaſion; but as the lungs are very liable to be wounded by the paſſing of this inſtrument forcibly into the cavity of the *Thorax*, it is better to divide the common integuments with an inciſion-knife, as alſo the muſcles and pleura, carefully avoiding the lungs, which are very apt to adhere to the pleura in this part; when this perforation is properly made, it is carefully to be kept open as long as neceſſary, and the wound above to be healed up as ſoon as poſſible.

The cavity of the *Thorax* being thus cleanſed, the wound is to be dreſſed once every day, and the dreſſing performed with all poſſible expedition; and the utmoſt diligence uſed to guard the contents of the *Thorax* from the injuries of the external air. *Heiſter*'s Surg. p. 70.

THOS, Θως, in zoology, a name given to an animal of the wolf kind, but larger than the common wolf. It never touches men or cattle, and rather provides its food by cunning than open force; preying chiefly on poultry and water-fowl. *Hofm.* Lex. univ. in voc.

THOUGHTS, in a boat, a name given by ſeamen to the benches, on which the men ſit down to row.

THOWLES, in a boat, are thoſe pins in its gunnel, between which the men put their oars when they row.

THRACIA *Gemma*, a ſtone mentioned by Pliny, and deſcribed by him to be of three kinds; the one of a plain green, but a conſiderably deep and ſtrong colour, the other of a paler green without variegation, and the third ſpotted with blood-coloured ſpots. This is a ſhort deſcription, but the ſtone ſeems to have been a jaſper, of the nature of our green oriental jaſper and heliotrope.

THRACIUS *Lapis*, in the natural hiſtory of the antients, a ſtone often mentioned, and firſt called *benæ lapis*, from the place where it was firſt found, which was in the neighbourhood of Bina, or Bena, a town in Thrace.

It has been by ſome authors allowed a place in the catalogues of the materia medica; but it is impoſſible for us to ſay with any certainty which of ſeveral ſubſtances now known (which all anſwer in ſome degree to the accounts left us of it) is the real body they meant by that name.

It was an inflammable body, found in mines, and in the beds of rivers; and, in burning, afforded a very offenſive ſmell. Some of the late authors have ſuppoſed it was our common pit-coal, the antients expreſſed by this name; others, that it was jet; and others, the common cannel coal. *Hill*'s Theophraſtus, p. 34.

THRANITÆ, in the Roman trireme gallies, or thoſe which had three rows of rowers; thoſe of the upper row were called by this name, the ſecond the *Zygitæ*, and the loweſt *Thalamitæ*.

The *Zygitæ*, or middle row of men, in theſe veſſels took up but very little room, having a conveniency of moving their hands and oars under the ſeats of thoſe who ſat next before them.

Meibom, in his diſcourſe of the naval architecture of the antients, has proved that the builders of theſe veſſels found much better places for the ſeveral tires of rowers, than the commentators on the works of the authors who mention them have done; and that hence the vaſt height ſuppoſed neceſſary in theſe veſſels is much of it imaginary, and that the teſſaraconteris of Philopater, a veſſel ſaid to have forty tire of oars, may have been built and managed, though requiring four thouſand men to row it.

This author is of opinion, that according to the plan he has given of the Roman naval architecture, we might very much improve our own gallies and galleaſſes. He acknowledges our form indeed to be preferable in general to theirs; but would have the ſame proportions kept up by us that were by them in their long veſſels. *Meibom.* de Trirem.

THRASOS, a term uſed by Hippocrates, to expreſs a wildneſs and fierceneſs in the eyes of perſons, who approach to a delirium in fevers.

THRAUPIS, in zoology, the name given by many authors to the bird more commonly called *citrinella*; a ſmall bird of the ſize of a linnet, kept in cages in Italy for its ſinging, and of a green, yellow, and grey colour. See the article CITRINELLA.

THRAUSMA, a name given by the antients to a kind of gum ammoniacum, which was drier than the common, and more eaſily crumbled to pieces.

THRAUSTOMICTHES, in natural hiſtory, the name of a genus of compound earths. The word is derived from the Greek θραυστος, brittle, and μικθεις, mixt.

The bodies of this genus are loams compoſed of ſand and a leſs viſcid clay, and are therefore of a friable or crumbly texture.

The earths of this genus are generally uſed to make bricks; and there are ſeveral ſpecies of them. 1. A whitiſh one, dug in great plenty in Staffordſhire, and ſome other counties. 2. A brownish white one very plentiful about London. 3. A pale yellow one, common in moſt parts of England at ſmall depths. 4. A ſharp rough one, of a deep yellow, dug near the town of Hedgerley near Windſor, and commonly called Windſor loame: It is not found in any other place, and is of great value; it makes the bricks uſed for the iron furnaces, and ſerves at the glaſs-houſes and among the chemiſts as a very ſtrong and valuable lute; and is not only uſed in England, but carried to Holland and Germany, and many other parts of the world. 5. A deep duſky yellow one, dug in moſt parts of England, near the ſurface. 6. A hard brown one, found at ſome depth in Buckinghamſhire, and uſually found full of ſmall ſhells: It is uſed for covering the ridges of barns, and copings of walls; and makes very firm and durable barn-floors. 7. A light pale brown one, the looſeſt and moſt friable of all the genera, uſed in many places for making the bell-founders moulds. 8. A yellowiſh brown one: This is common in moſt parts of the kingdom, and makes the fine red bricks uſed for ornamenting buildings. *Hill*'s Hiſt. of Foſſ. p. 424.

THREAD (*Cycl.*)—The *Thread* of the Laplanders is very fine, white and ſtrong, but it is of a very different nature from ours; they know nothing of flax or hemp, nor of any other plant whoſe ſtalks might ſupply the place of theſe in making *Thread*, but theirs is made of the ſinews of the rain-deer. They kill of theſe animals a very great number continually, partly for food, partly for the ſkins which they uſe in cloathing themſelves, covering their huts, and on many other occaſions; the ſinews of all that they kill are very carefully preſerved, and delivered to the women, whoſe province it is to prepare this neceſſary matter. They beat the ſinews very well, after having ſteeped them a long time in water, and then they ſpin them out.

The *Thread* they thus make is of any degree of fineneſs they pleaſe; but it never is any longer than the ſinew from which it is made. They uſe this in ſowing their cloaths, ſhoes, gloves, &c. and the trappings of their rain-deer. The *Threads* of the ſame ſinew are laid up together, and are all of a length; and as the different ſinews afford them of very different lengths, they accordingly pick out ſuch as the preſent uſe requires, both in regard to length and fineneſs. This ſort of thread is made with much more labour than ours; but it is greatly ſuperior to it on many occaſions, where ſtrength is rather required than beauty.

Theſe people have, beſides this, a way of making a ſort of yarn

yarn of ſheeps wool, which they weave into garters and a ſort of ribbands, uſed by way of ornament; but they place no value on it, becauſe of its want of ſtrength. *Scheffer*'s Hiſt. Lapland.

Air-THREADS, a term uſed by ſome to expreſs thoſe fine long white filaments or thready ſubſtances, which we meet with in vaſt numbers floating about in the air, in Auguſt and September.

The world has been much perplexed about the generation of theſe, till it was known that they were the work of ſpiders, and that they ſerved theſe creatures to move from place to place by. They are long, downy, and very ſoft, and though they hold together when untouched, they ſtick to the fingers in handling, and eaſily break with a ſlight touch.

The greater number of ſpiders have the property of ſpinning this ſort of *Thread*. The long-legged field-ſpider, called the *ſhepherd*, and ſome others, want it; theſe have nothing to do with the *Air-threads*, ſo much wondered at; but all the others, that is, all thoſe which nature has endowed with a power of ſpinning, make them.

The general method of theſe creatures ſpinning and weaving their webs, is by letting down the thread and then drawing it after them, and ſo diſpoſing it as they think proper; but in the midſt of their work of this ſort, if they are cloſely obſerved, they will be ſometimes found to deſiſt, and turning the tail to the contrary way of the wind they will emit a thread with great violence, no leſs than that with which a jet of water is diſcharged from a cock. In this manner they continue darting forth the thread, which the wind takes, and carrying it forward it ſoon becomes many yards long. Soon after this the creature will throw herſelf off from the web, and truſting herſelf to the air with this long tail, will aſcend ſwiftly, and to a great height with it. The fragments of theſe lines, or the whole lines, and the ſpiders attached to them though unobſerved, make theſe *Air-threads*, and the uſe nature deſtines them for, is evidently the wafting the creature along the air, and giving it an opportunity of preying on gnats, and many other inſects that inhabit the air, out of the reach of theſe creatures by any other means.

The young ſpiders, as well as the old ones, have this property of ſpinning *Threads*, and ſailing in the air by means of them; and it is common to ſee very minute ſpiders at the ends of very long lines. No one particular kind is famous more than the reſt for this practice, but all that can ſpin, at the proper ſeaſon of the year do it.

The threads themſelves ſhew the uſe they are of to the creature in ſeizing its prey; for they, as well as the webs below, are uſually found filled with the fragments of devoured animals, the legs of flies, and the like.

When the *Threads* are newly ſpun, they are always ſingle, and are generally ſeen aſcending up higher and higher in the air; but when they are ſeen coming down, they are found ſometimes compoſed of three or four others, and either without any ſpider at the ends, or with two or three or more. It is plain that this happens from the meeting of theſe threads one with another in the air, and their tangling together; and this incommodes the creatures, and brings them down.

The whole proceſs of the workmanſhip of theſe threads is eaſily ſeen, by obſerving ſome of the ſpiders which have not yet mounted into the air, but ſeem to be meditating their flight. It is common to ſee one of theſe creatures at ſuch a time mount the top-moſt branch of a buſh, and from thence dart out at its tail one after another ſeveral of theſe long *Threads*, by way of aſſaying what it can do, and how it ſhall like them. When the creature has darted out a thread to the length of ſeveral yards, it will of a ſudden draw it all up again, and wind it up into a link with its fore-feet; but more frequently they break it off, and let it go. One ſpider will ſometimes dart out, and break off in this manner a great number of *Threads*, before it ſpins one that it will truſt to; but at length it will pleaſe itſelf with ſome one, and commit itſelf to the air on it.

Theſe broken *Threads* are what fill the air with the looſe threads we ſee in autumn; and as theſe ſoon entangle together, and bring one another down, it is no wonder that they are more frequent in the lower regions of the air, than thoſe with the ſpiders adhering to them, which uſually riſe to great heights, and ſuſtain themſelves there. And hence the origin of the *Threads* was much perplexed among the enquirers, becauſe they were found without any mark of the animal to which they owed their exiſtence. The buſineſs of feeding is not all the uſe of theſe *Threads*, but the creatures evidently ſport and entertain themſelves by means of them, floating about in the air, and changing height and place at pleaſure.

When a ſpider has once raiſed itſelf from the earth in this manner, it does not deſcend always on the ſame *Thread* it aroſe by, but draws that up at times, and winds it up into a hank with its fore-feet, and darts out another by way of ſupport; and the new *Thread* is made more or leſs long, as it is intended for a higher or lower flight.

Theſe *Air-threads* are not only found in autumn, but even in the depth of winter. The ſerene days about Chriſtmas bring out great numbers of them; but the *Threads* are at this ſeaſon only ſhort and ſlender. They are the produce of the young ſpiders, hatched only the autumn before, and are ſeldom uſed to ſuſtain the animal, but ſeem a mere ſporting of it, being thrown out and broke off at ſmall lengths. The thicker ropes of the autumn are the only ones intended for the ſupport of the old ſpiders in the air, when there is plenty of ſmall flies that inhabit the airy region, and make it worth the creature's while to take up its habitation among them. Phil. Tranſ. N°. 50.

THREX, among the Romans, an appellation given to gladiators, either becauſe they were natives of Thrace, or wore armour after the manner of that country. *Pitiſc.* in voc.

THRIFT, *Statice*, in botany. See the article STATICE.

The ſeveral more common ſpecies of this plant have been uſed to be raiſed promiſcuouſly for making the edges of flower-beds, inſtead of box; but the neceſſity of tranſplanting them every year to keep them within due bounds, has made them of late much diſuſed.

They are all propagated by parting their roots; the beſt time for doing which is in autumn, and they will grow with very little trouble, and flower in the May following, continuing in flower about three weeks or a month, if the weather is not too dry. *Miller*'s Gardener's Dict.

THRIO, Θρίω, in antiquity, a feſtival in honour of Apollo. *Potter*, T. 1. p. 405.

THRIPS, in natural hiſtory, a name uſed among the antients, to expreſs a ſort of worm hatched from the egg of a beetle; which, while in the worm-ſtate, eats its way into wood, and forms cells and cavities in it of various ſhapes, and in various directions, often reſembling the figures of letters or other things.

The antient Greeks are ſaid to have uſed ſmall pieces of the wood thus eroded in particular forms, as ſeals before the engraving of theſe utenſils was invented, and indeed they muſt very well have ſerved this purpoſe, ſince it is ſcarce poſſible to conceive how one of theſe pieces of corroded wood ſhould be counterfeited, or the impreſſion imitated.

Lucian mentions his marking his olives with a ſignature of one of theſe pieces of wood greatly eroded, and uſes the word *Thrips*, not as the name of the animal, but of the piece of wood eroded by it. Theophraſtus, Pliny and Ariſtotle, alſo uſe the ſame expreſſion; and we find that the word *Thrips* was as frequently uſed to ſignify the pieces of wood eroded, as the animal which eroded them.

THRISSA, in ichthyology, the name given by the Greeks and by the modern Latin writers, to the fiſh which we call the *ſhad*, or the mother of the herrings.

This is called by Artedi the clupea, with the top of the upper jaw divided, and with black ſpots on each ſide. This accurate author obſerves alſo, that the *agonus* or *agone* of Salvian, the *ſarachus* of Charleton, and the *aloſa minor* and *harengus minor* of Willughby, and others, which we call the pilchard, differ only from the *Thriſſa* in ſize; all being the varieties of the ſame ſpecies of fiſh, and all characterized by this ſpecific name.

THROAT (*Cycl.*)—*Sore*-THROAT, in medicine. See the article QUINZY, *Cycl.* and *Suppl.*

THROAT-*Wort*, in botany, the name of a plant of the bell-flower kind, called in Latin *Trachelium*. Its characters and ſpecies, ſee under that head.

This plant yields, when wounded, a milky juice in great plenty, and this if received into a ſhell or other ſmall veſſel, curdles immediately, and the whey runs from the thick part; this whey is of a brown colour, whereas that of the wild lettuce is of a fine purple, and dries into a cake that may be crumbled into a purple powder. The juice of the *Throat-wort* ſmells ſour, and its curdled part being dried burns like reſin at the flame of a candle. Phil. Tranſ. N°. 224.

THROMBUS, a word uſed by ſome medical writers, to expreſs a grume or clot of blood.

THROSTLE, an Engliſh name for the common mavis, or ſong-thruſh. See TURDUS.

THROWING, among bowlers. See the article BOWLING.

THRYALLIS, in botany, a name given by Nicander, and ſome other writers, to a ſpecies of mullein uſed in the coronæ and garlands of the antients; and, as he expreſsly ſays, different from the common wild mullein.

Dioſcorides ſeems to make this his third ſpecies, and calls it *lychnitis*, from its uſe in lamps; the Greeks beating out its thready ſtalks, and uſing them for the wicks of lamps. We have a kind of *verbaſcum*, or mullein, which we call *lychnitis*, in commemoration of Dioſcorides's name; but it does not appear to be the ſame ſpecies that Nicander and the other Greeks called by that name. Some alſo called it *nekeia*, or *necuia*, from its uſe in making a kind of torch; that was the thing with which they kindled the funeral piles of the dead.

THUMB, *Pollex*, in anatomy, one of the members, or parts of the hand. See the article HAND, *Cycl.* and *Suppl.*

The firſt phalanx of the bones of the *Thumb* is not like thoſe of the other fingers. Antient authors reckon it among the bones of the metacarpus, which it reſembles very much, and by this means allow only two phalanges to the *Thumb*, and

make five metacarpal bones. The convex ſide of this phalanx is very much flatted, and is much broader toward the head, than toward the baſis. On the concave ſide is a kind of angular line, which in ſome meaſure diſtinguiſhes it into two parts. Its head is like thoſe of the metacarpal bones, only flatted at top. The articular ſide of its baſis is proportioned to the digital ſide of the *os trapezium* of the carpus, and framed in ſuch a manner as that the ſigmoide cavities and eminences in the two bones croſs one another. This articulation has ſomething very particular in it; it is a kind of double ginglymus, which readily allows of flexion and extenſion, adduction and abduction, but with difficulty permits the oblique motions, becauſe then the two ſides run counter to each other.

The ſecond phalanx of the *Thumb* is ſhorter than the firſt; its body is convex or ſemi cylindrical on one ſide, flat on the other, and contracted between the edges. The articular ſide of the baſis is gently concave, and is ſurrounded near the edges by ſmall tuberoſities; as alſo near the angle of the phalanx. The head is the regular portion of a pulley, which projects more on the concave, than on the convex ſide; and on each ſide of it there is a ſmall foſſula, and ſome inequalities in form of tubercles. On the flat or concave ſide of the phalanx are two rough lines, one near each edge; they are the impreſſions or marks of the articular vaginæ. The connection of this phalanx with the firſt, is by a kind of arthrodia, or by a flat enarthroſis, which permits a motion in ſeveral directions, though more limited than in other articulations of the ſame kind. It is articulated with the third by a very perfect ginglymus.

The third phalanx of the *Thumb* repreſents the half of a ſort of cone, cut lengthwiſe, and by joining it to the ſame bone of the other *Thumb*, an entire cone is formed; the convex ſide is more even than the flat ſide, and on each edge there is a tuberoſity near the baſis: The baſis has two hollow ſides, which form a ginglymus with the head of the ſecond phalanx. The head is flat and ſmall, ending in a rough ſemi-circular border, which on the flat ſide of the bone repreſents a horſe-ſhoe. *Winſlow*'s Anat. p. 87.

THUNDER (*Cycl.*)—The noiſe of *Thunder* and the flame of lightning are eaſily made by art. If a mixture of oil or ſpirit of vitriol be made with water, and ſome filings of ſteel added to it, there will immediately ariſe a thick ſmoak, or vapour, out of the mouth of the veſſel; and if a lighted candle be applied to this, it will take fire; the flame will immediately deſcend into the veſſel, and this will be burſt to pieces, with a noiſe like that of a cannon.

This is ſo far analogous to *Thunder* and lightning, that a great exploſion and fire are occaſioned by it; but in this they differ, that this matter when once fired is deſtroyed, and can give no more exploſions; whereas in the heavens one clap of *Thunder* uſually follows another, and there is a continued ſucceſſion of them for a long time. Mr. Homberg explained this by the lightneſs of the air above us, in compariſon of that here, which therefore would not ſuffer all the matter ſo kindled to be diſſipated at once, but kept it for ſeveral returns.

THUNDER-*Stone*, in natural hiſtory, the ſame with that called by authors *Brontia*. See the article BRONTIA.

THUNDER-*Storms*. It is frequent in the *Thunder-ſtorms* in hot climates, to ſee a bituminous matter fall with the lightening to the ground, and there continue for ſome time burning in a maſs, or elſe burſt at once into a multitude of ſparks, which burn every thing they touch, and always leave a violent ſmell of brimſtone behind them.

Something of this nature, but concreted into a ſolid form and reſembling common brimſtone, was ſome years ago obſerved in the iſle of Wight; of which Mr. Cook, an inhabitant of Newport there, has given the following account:

The month of July, in the year 1737, had been very ſultry, and the nights often ſtormy, in particular there was one evening a very violent ſtorm of *Thunder* and lightening, attended toward the end with a great deal of rain. The morning afterwards, as a countryman was walking over a meadow near the ſea-ſide, he obſerved a yellow ball of a ſhining matter, lying looſe upon the turf or graſs. When he had taken it up, he found it to be no other than a lump of ſulphur, of an uncommonly ſtrong ſmell, and covered all over with a multitude of fine ſhining cryſtals of a yellowiſh colour, which fell off on the lighteſt touch. The whole ſubſtance appeared to be ſomewhat ſpungy, and it had a large hole in one part; it was near an inch long, and ſomewhat more than half an inch in diameter, and when put to the fire proved readily inflammable, and burnt with a whiter flame than common brimſtone, and with leſs acid and ſuffocating fumes.

The author of this account ſeems to think, that there is great probability that this ball was generated, not under ground but in the air, and that it was of the nature of thoſe maſſes of bituminous matter falling ſo frequently in *Thunder-ſtorms*, in the hotter countries, but that by ſome accident it miſſed taking fire, and was therefore left perfect in its ſolid form. It ſeems not to have been generated under ground, ſince if it had, it could never have been found on the ſurface ſo perfectly clean, with its pores all empty not filled with earth, and its covering of cryſtals untouched, though they adhered ſo very lightly to it that the gentleſt touch threw them off. Phil. Tranſ. N°. 450. p. 449.

THURIBULUM, among the Romans, a cenſer or veſſel, in which incenſe was burnt at ſacrifices. *Pitiſc.* in voc.

THURIFICATI, in church hiſtory, a deſignation given to thoſe, who, to avoid the perſecution of the Roman emperors, offered frankincenſe to the heathen gods. *Hofm.* Lex. in voc. See the article PERSECUTION.

THURSIO, in ichthyology, a ſpecies of fiſh, mentioned by Pliny, l. 9. c. 9. It is thought by ſome to be the *Phocæna*, or porpoiſe; and by others the *Sturgeon*. *Hofm.* Lex. univ. in voc. See the articles PORPOISE, and STURGEON.

THURUS, in natural hiſtory, the name of a creature deſcribed by Geſner, and ſome others, as a diſtinct ſpecies of wild bull; but the accounts of it ſeem either fabulous, or miſtaken deſcriptions of the wild bull. See the article BOS.

THUYA, *Tree of life*, in botany the name of a genus of trees, the characters of which are theſe: The embryo fruits are of a ſquammoſe ſtructure, and finally become a ſort of oblong fruit, between the ſcales of which there lie a ſort of marginated ſeed. To this it is to be added, that the leaves are ſcaly.

The ſpecies of *Thuya*, are the common *arbor vitæ*, and the Chineſe kind. *Tourn.* Inſt. p. 587.

THWART *the Hawſe*, in the ſea language. See the article HAWSE.

THYIA, Θυια, in antiquity, a feſtival in honour of Bacchus, celebrated by the Eleans. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 405.

THYITES *Lapis*, in the materia medica of the antients, the name of an indurated clay, approaching to the nature of a ſtone. It was found in Egypt, and uſed in diſtemperatures of the eyes.

This ſubſtance has been very much miſunderſtood by the late writers, and by moſt of them ſuppoſed to be loſt at this time; but this was wholly owing to their miſtaking the claſs of bodies among which they were to look for it. Some imagining it to have been a ſpecies of green marble; and others the turquoiſe-ſtone, that Dioſcorides meant by this name. It is very plain however, that it was no other than an indurated clay of the morochthus kind, and no more a ſtone than that ſubſtance, that being alſo frequently called *lapis morochthus*.

It is of a ſmooth, even and regular texture, very heavy, of a ſhining ſurface, and of a pale green, without the admixture of any other colour. It does not at all adhere to the tongue, nor ſtain the fingers in handling; but drawn along a rough ſurface, leaves a ſlender white line. It melts ſlowly in the mouth, and is of a ſharp acrid and diſagreeable taſte; and when rubbed down with water on a marble, it melts into a milky liquor of a pure white, not the leaſt greenneſs being ſenſible in it. It is found at preſent in the great mine at Goſſelar in Saxony, and ſeems to owe its colour to particles of copper; to which alſo it owes the virtues attributed to it by Dioſcorides, acting as a weak kind of verdigreaſe. *Hill*'s Hiſt. of Foſſ. p. 36.

THYLACION, a word uſed by the antient medical writers, to expreſs the bag formed by the membranes of the fœtus at the orifice of the pudenda, before the birth.

THYLLA, Θυλλα, in antiquity, a feſtival in honour of Venus. *Potter*, T. 1. p. 405.

THYMALLUS, in ichthyology, the name of a fiſh of the truttaceous kind, called in Engliſh the greyling, or umber.

It is of a long and flatted body, the belly is ſomewhat broad, and the back rigid and thin. It ſeldom exceeds a pound, or at the utmoſt a pound and half weight. Its back is of a duſky browniſh green, with a ſomewhat bluiſh caſt intermixed, and its ſides of a more blue ſhining gloſs with an admixture of gold colour. The ſcales are of a ſort of rhomboidal form, and the ſide-lines are much nearer the back than the belly. The ſides are variegated with black ſpots placed irregularly; but there are none of theſe near the tail. The back has two fins, and the tail is forked. The head is ſmall, the eyes large and protuberant; the mouth is moderately large, and the upper jaw larger than the under; it has no teeth, but the whole jaws are rough like a file.

It is caught in the freſh rivers in the mountainous counties of England, and in the like ſituations in Germany, and other kingdoms, and is one of the fineſt taſted of all the freſh-water fiſh. It feeds on worms, and ſpawns in May. See Tab. of Fiſhes, N°. 31. and *Willughby*'s Hiſt. Piſc. p. 187.

THYMBRA, in botany, the name of a genus of plants; the characters of which are theſe: The flowers and ſeeds are in all reſpects like thoſe of thyme, but that they are placed verticillately round the ſtalks.

The ſpecies of *Thymbra*, enumerated by Mr. Tournefort, are theſe: 1. The *Thymbra*, ſimply ſo called, and named by others *candy ſavory*. 2. The Spaniſh *Thymbra*, with leaves like marjoram, called *marum*, and *maſtichina*; and by ſome *clinopodium*. 3. The roundiſh-leaved Spaniſh *Thymbra*. 4. The Spaniſh *Thymbra*, with leaves like the coris, called by ſome *ſerpillum*; and by others a ſpecies of thyme. And, 5. The St. Julian *Thymbra*, or true ſavory, called alſo by ſome ſpiked ſavory, and the St. Julian's Savory. *Tourn.* Inſt. p. 197.

THYME, *Thymus*, in botany, *&c.* See the article THYMUS.

THYMELÆA, in botany, the name of a genus of plants, the characters of which are these: The flower consists of one leaf, and is funnel-shaped, and cut into four segments at the edges; from the bottom of this there arises a pistil, which finally becomes an oval fruit; which in some species is succulent, and in others is dry; but in all contains oblong seeds.

The species of *Thymelæa*, enumerated by Mr. Tournefort, are these: 1. The flax-leaved *Thymelæa*. 2. The African flax-leaved *Thymelæa*, with pale-coloured, and very sweet-scented flowers. 3. The African flax-leaved *Thymelæa*, with broad, obtuse, and shining leaves. 4. The African flax-leaved *Thymelæa*, with flowers collected into clusters. 5. The dwarf alpine flax-leaved *Thymelæa*, with purple sweet-scented flowers. 6. The dwarf alpine flax-leaved *Thymelæa*, with sweet-scented white flowers. 7. The small hairy knot-grass-leaved Portugal *Thymelæa*. 8. The common toad-flax-leaved *Thymelæa*. 9. The Spanish *Thymelæa*, with toad-flax-leaves. 10. The African *Thymelæa*, with very narrow, and short rosemary-like leaves. 11. The African *Thymelæa*, with long and narrow rosemary-like leaves. 12. The rosemary-leaved African *Thymelæa*, with long flowers. 13. The white-flowered shrubby African *Thymelæa*, with rosemary leaves. 14. The Spanish *Thymelæa*, with broad olive-like leaves. 15. The Italian silvery olive-leaved *Thymelæa*. 16. The olive-leaved rock *Thymelæa*. 17. The white-flowered alpine *Thymelæa*, with leaves hoary on both sides. 18. The smooth *Thymelæa*, with leaves like the polygala. 19. The hairy *Thymelæa*, with polygala-leaves. 20. The chamelæa-leaved *Thymelæa*, with short hairy leaves. 21. The woolly kali-leaved *Thymelæa*. 22. The juniper-leaved *Thymelæa*, with procumbent branches. 23. The Pyrenean juniper-leaved Thymelæa, with erect branches. 24. The African *Thymelæa*, with narrow heath-like leaves. 25. The *Thymelæa*, with white, soft, and silky leaves. 26. The African *Thymelæa*, with tufted flowers. 27. The woolly *Thymelæa*, with small houseleek leaves. 28. The Spanish *Thymelæa*, with hoary myrtle-like leaves. 29. The African *Thymelæa*, with butcher's-broom leaves. 30. The shrubby African *Thymelæa*, with milkwort-like leaves and jasmine flowers. 31. The narrow-leaved jasmine-flowered African *Thymelæa*. 32. The nepa-leaved prickly African *Thymelæa*, with small purple flowers. 33. The ever-green bay-leaved *Thymelæa*, called the *laureola mas*, or male spurge-laurel. 34 The bay-leaved *Thymelæa*, with deciduous leaves, called the female spurge-laurel. And 35. The bay-leaved *Thymelæa*, with deciduous leaves, with white flowers and yellow fruit. *Tourn.* Inst. p. 494.

THYMELÆÆ *Radix*, in the materia medica, the dried root of the *Thymelæa foliis lini* of Tournefort and other authors.

It is a light root of different sizes, of a reddish colour without, and greyish within, woody, and full of fibres, and tastes sweet at first, but is hot as fire when it has been held a little time in the mouth. It loses however both this fiery taste, and its acrid quality, in long keeping, and with them its virtues.

It is to be chosen new, well fed, and not worm-eaten. The fruit of this plant is the *granum cnidium* of the shops. They are both of an acrid quality, and are not in use in the shops at present. *Pomet*'s Hist. of Drugs, p. 46.

THYMELÆA is also a name by which some authors have called the *laureola*, or spurge-laurel, an ever-green shrub, common in our woods: But it is more usually made the name of the *mezereon*, or spurge-olive, and, with many, is understood only as the name of the spurge-flax. *Tourn.* Inst. p. 415. *Boerhaave*'s Index, vol. 2. p. 213.

THYMELE, in the antient theatre, a kind of pulpit, where the singers called *thymelici* performed. See the articles THYMELICI and LOGEUM.

THYMELICI, among the Romans, were musicians, who sung in the interludes, or who danced and kept time with their gestures. The place where they performed was called *Thymele*, whence Juvenal. VI. 66.

Attendit thymele, thymele nunc rustica discat.

THYMIAMA, Θυμιαμα, in antiquity, an offering of incense to God. See the article INCENSE, *Cycl.*

THYMIAMA, in the materia medica, a name by which some authors have called the *cascarilla bark*; called by some *cortex thuris*, or Indian bark. *Ray*'s Hist. Pl. vol. 2. p. 1841.

THYMIAMATA, a kind of fumigations among the antients, the ingredients of which were so various, that it appears they always consulted utility as well as pleasure, in their composition of them. Many of the ingredients, named in the oldest prescriptions for the making them, being the names of things not sweet-scented, the commentators have supposed that the antients expressed other things by those words, and not those which we at present mean by them; but all this is founded on the error of supposing these things intended only as sweet-scented preparations.

We find the gum ammoniacum of the antients used in them: And Neophytus reconciles the use of it in this manner very easily, by alledging, that it had the smell of coriander-seeds, which, as he observes justly, is an agreeable scent, and might do very well in mixture with others of this kind. It is pretty certain, that the ammoniacum of the antients was not the same gum which we now know by that name; but as the account of Neophytus, as to its smell, comes from an older Greek author, Dioscorides, we are to refer to him for the certainty of the expression; and by this it appears that Neophytus errs greatly, in attributing to ammoniacum the smell of coriander-seeds; for that the word used by Dioscorides, and which he has translated coriander, is κορίου; and this, as we find by many other passages of the same author, is an abbreviation of the word *castorei*, καστορίου.

The smell of castor is also attributed to ammoniacum by Theophrastus and others; whence it is evident that the antients used salutiferous as well as sweet-scented things in these fumigations. Galbanum is a worse smell than ammoniacum, and yet this also we find, together with myrrh, and other gums, is made an ingredient in the oldest prescriptions of this kind. And Pliny mentions the ammoniacum with the schænanth, and other sweets used for this purpose.

THYMOXALME, in the materia medica of the antients, was a composition used externally in the gout, and many disorders of the limbs, and was given inwardly in distemperatures of the stomach, a quarter of a pint for a dose. It operated as a purge, and was prepared in the following manner: Take two ounces of bruised thyme, as much salt, a little meal, rue, and penny-royal. These were to be put into a pot, and three pints of water, and fourteen ounces of vinegar are to be poured upon them; after which they are to be covered with a coarse cloth, and set in the sun for some time. *Dioscorides*, l. 5. c. 24.

THYMUS, *Thyme*, in botany, the name of a genus of plants, the characters of which are these: The flower consists of one leaf, and is of the labiated kind: The upper lip is erect, and usually bifid, and the lower is divided into three segments. The pistil arises from the cup, and is fixed in the manner of a nail to the hinder part of the flower, and surrounded by four embryos, which afterwards become as many seeds, and ripen in the cup of the flower. To these marks it may be added, that the stalks are usually hard and woody, and the flowers collected into heads.

The species of *Thyme*, enumerated by Mr. Tournefort, are these: 1. The common-headed *Thyme*. 2. The common broader-leaved *Thyme*. 3. The common narrow-leaved *Thyme*. 4. The white narrow-leaved strong-scented *Thyme*. 5. The white procumbent sweet scented *Thyme*. 6. The scentless *Thyme*. 7. The small-headed *Thyme*. 8. The Portugal *Thyme*, with narrow hairy leaves, and large long purple heads. 9. The Portugal *Thyme*, with narrow hairy leaves, and round heads of purple flowers. 10. The great-headed Portugal *Thyme*. 11. The small-headed Portugal *Thyme*. 12. The headed Portugal *Thyme*, with large scales. *Tourn.* Inst. p. 196.

We have three or four species of this plant propagated in our gardens, partly for use in the kitchen, and partly for curiosity. They are propagated either by sowing, or by parting the roots, both which should be done in March.

The seeds should be sowed on a bed of light earth, and must not be buried too deep. When they come up, they must be kept clear of weeds, and watered at times; and in June they should be thinned, leaving the plants at about six inches asunder. After this they will grow very fast, and will require no farther care.

If they are to be propagated the other way, the roots should be taken up, and parted into as many slips as can be, and each planted at six or eight inches distance, on beds of light earth, watering and shading them till they have taken root.

The common garden *Thyme* is a cephalic. It also is good in all obstructions of the viscera, in the rheumatism, and in flatulencies.

The serpillum, or wild mother of *Thyme*, is one of the greatest nervous simples of our own growth. An infusion of it alone will do wonders in tremors, lowness of spirits, and headachs. It makes a very agreeable liquor, drank in the manner of tea, and this, continued for some time, has proved a remedy in many cases where every thing else has failed. It is almost infallible in the cure of that troublesome disorder the nightmare.

THYMUS, (*Cycl.*) in anatomy. Dr. Pozzi says, that the *Thymus* of a calf, softened by maceration, discovers a lobe, from which a milky liquor runs out when wounded; and if air is afterwards blown into it, the whole *Thymus* is distended, and may be dried, when it plainly appears to be composed of cells communicating with each other; upon the sides of which muscular fibres are to be seen: From which structure he concludes, that the *Thymus* in fœtuses supplies the use of the lungs, serving as a receptacle for the chyle to be prepared in. Med. Ess. Edinb.

The *Thymus* is thought by some to furnish the liquor found in the thorax of fœtuses. See Mem. de l'Acad. des Scienc. Par. 1733.

THYNNIA, Θυννια, in antiquity, a sacrifice offered to Neptune by the fishermen, after a plentiful draught.

The word comes from Θυννος, a tunny, that being the sacrifice offered.

THYNNUS, in ichthyography, the name of a fish called in English the *tunny*, or Spanish mackrel, common in the Mediterranean,

diterranean, and others ſeas, and ſometimes, though not frequently, caught on the Engliſh coaſts.

It is a very large fiſh, growing ſometimes to ſeven or eight foot long, and more than an hundred weight. It is of a rounded and thick body, growing gradually ſmaller toward the tail, till it is at length extremely ſlender. It very much reſembles the *pelamys* in its whole figure, but that it wants the oblong black ſtreaks which that fiſh has on its ſides, and is much larger. The back is black, or, if held in ſome lights, is of a ſhining bluiſh or greeniſh hue. Its belly and half its ſides are of a ſilvery whiteneſs. Its ſcales are very ſmall. Its ſnout pointed. Its jaws both of equal length, and armed each with one row of teeth. The mouth is large and black within, except that part of the palate is red. The eyes are large. The larger black fins are two in number; the foremoſt placed near the head, and riſing out of a cavity in the back, and the other at a ſmall diſtance behind that; and, in ſome fiſh of this ſpecies, of a reddiſh or yellowiſh colour; and behind this laſt, there are eight, nine, or ten ſmall fins running down the ridge of the back at equal diſtances to the tail. The tail is very forked. The fins at the gills are black, ſmall, and terminate in a point. The belly fins are placed but at a ſmall diſtance hehind theſe, and are alſo ſmall; and both theſe, and the gill-fins have ſinuſes in the body of the fiſh, into which they may be depreſſed. Behind the anus is a fin like that on the back, and behind it eight more ſmall ones, anſwering to thoſe on the back alſo; and the ſkin of the ſides, near the tail, is extended into two fins; ſo that this part of the fiſh looks in ſome ſort ſquare. It is a good fiſh for the table, and is ſalted in vaſt quantities in Spain and Italy. See Tab. of Fiſhes, N°. 29. and *Ray*'s Ichthyography, p. 176.

THYOS, ΘυΘ, in antiquity, an offering of fruits, leaves, or acorns, which were the only ſacrifices at firſt in uſe. *Potter*, Archæol. Græc. T. 1. p. 213.

THYREOSTAPHILINUS, in anatomy, a name given by Douglaſs to a muſcle, called by Albinus and others, *palatopharyngæus*. See the article PALATOPHARYNGÆUS.

THYRRÆUM *Vinum*, a ſort of wine among the antients remarkable for its thickneſs and dark colour; it was ſweet, and luſcious, and not aſtringent.

THYRREUS *Lapis*, in natural hiſtory, the name of a foſſil, which the writers of the middle ages have called *ſyrus*.

It has many virtues aſcribed to it; but all the account we have of its real properties are from Pliny, who obſerves that it ſwam upon the water while whole; but when broken into ſmall pieces, theſe ſunk to the bottem. It ſeems to have been a ſort of bitumen of a ſpongy ſtructure.

THYSSELINUM, in botany, the name of a genus of umbelliferous plants, the flowers and fruit of which are the ſame with thoſe of the *petroſelinum*, or mountain parſley; from which it differs in nothing, except that it yields a milky juice when broken or wounded.

The ſpecies of *Thyſſelinum*, enumerated by Mr. Tournefort, are theſe: 1. The *Thyſſelinum* of Pliny, or milky parſley. 2. The marſh *Thyſſelinum*, called by ſome the *milky ſeſili*. *Tourn.* Inſt. p. 319.

TIBERIADES *Water*, the water of a hot ſpring near *Tiberiades* in Egypt.

Dr. Perry, when on the ſpot, tried ſome experiments on this water, which give us a much better idea of its nature, than we have from any other accounts of it. Half a dram of oil of tartar being mixed with an ounce and half of the water, it becomes turbid and muddy; and after twelve hours, three parts of the whole appear like white wool, only leaving a ſmall portion of clear water at the top. This white woolly matter dried, produced only a ſmall quantity of yellow ochre.

Spirit of vitriol added to the water in the ſame quantity, affords a large unctuous ſediment of a white colour. A ſolution of ſublimate being mixed in the ſame quantity, it became turbid and yellowiſh, and yielded an earthy ſediment in ſmall quantity; whence it ſeems evident, that it contains a ſal murale. Saccharum ſaturni being added in the ſame quantity, the water depoſited a lateritious ſediment in a ſmall quantity. Mixt with ſpirit of ſal armoniac, it turns to a bluiſh green turbid liquor, and finally yields a woolly ſediment. Sugar of violets mixed with it, turned it to a yellowiſh colour; and the ſcrapings of galls mixed with it, turned it to a deep purple; and on ſhaking, this became as black as ink.

It appears from theſe experiments, that the water contains a good deal of a groſs fixed vitriolic ſalt, ſome alum, and a ſal murale. It is too ſalt and nauſeous for internal uſe; but it muſt be of uſe as a bath in all cutaneous foulneſſes, eſpecially in ſcorbutic and leprous caſes; for it will powerfully deterge, ſcour and cleanſe the excretory pores, and it may, by its weight and ſtimulus, reſtore them to their natural ſtate and tone, and reſtore the true ſtate of the vitiated ſolids in general. Phil. Tranſ. N°. 462. p. 52.

TIBERIANUM *Marmor*, in the natural hiſtory of the antients, the name of the green and white marble, common in tables, *&c.* at this time, and by our artificers called *Ægyptian marble*. The Romans applied this name, however, only to one appearance of this ſpecies of marble, which was, when its white part was not arranged into regular lines, or arched figures, but diffuſed irregularly through the whole maſs; for where it was thrown into theſe ſort of arches, it was called the *auguſtan* marble. Theſe were, however, very idle diſtinctions, ſince the ſame block, to this day, often affords us the white veins, in both theſe diſpoſitions, in its different parts.

The antient Romans had it from Ægypt, and we alſo have the fineſt pieces thence; though the greater part of what we uſe is not brought quite ſo far. *Hill*'s Hiſt. of Foſſ. p. 481.

TIBERIANUM *Tormentum*, in medicine, a name given by ſome to the colic. See COLIC.

TIBIA (*Cycl.*)—*Cartilages of the* TIBIA. The *Tibia* has four or five proper cartilages, and two additional ones. The two proper cartilages which cover the two ſuperior ſurfaces of the head of the *Tibia*, are the thickeſt. Theſe are both gently hollow; but the internal, or that next the other *Tibia*, is more depreſſed in the middle than the other. The third proper cartilage covers the ſmall ſurface which lies on the lower part of the external condyle. The fourth covers the lower ſurface of the baſis of the *Tibia*, being continued over the outſide of the inner ankle. There are likewiſe ſuperficial cartilaginous incruſtations on the back part of this baſis, behind the inner ankle, and likewiſe on the backſide of the outer ankle, all for the paſſage of tendons.

The additional cartilages of the *Tibia* are two in number, called ſemilunar from their figure, and intermediate or interarticular from their ſituation; each of theſe cartilages is in the ſhape of a creſcent, or Roman C. Their convexity, or greateſt curvature, is very thick; their concavity, or ſmaller curvature, very thin, and ſomething like the edge of a ſickle. They lie on the two upper ſurfaces of the head of the *Tibia*; each cartilage is broad enough to cover about two thirds of the ſurface of the *Tibia* on which it lies, leaving one third bare in the middle; their under ſides are flat, their upper ſides hollow, and, together with the middle portions of the ſurfaces of the head of the *Tibia*, they form cavities proportioned to the convexity of the condyles of the os femoris. *Winſlow*'s Anatomy, p. 128.

Ligaments of the TIBIA. This bone is connected to the os femoris by ſeveral ligaments, two lateral, one poſterior, two middle, and one capſular. The innermoſt and broadeſt of the two lateral ones is fixed pretty low down on the inner ſide of the ſuperior part of the *Tibia*. The external, which is narrower and thicker than the former, is fixed partly in the *Tibia*, immediately above the fibula, and partly in the upper extremity of the fibula; both theſe ligaments lie a little behind the middle of the articulation. The poſterior ligament is fixed by ſeveral expanſions in the poſterior part of the head of the *Tibia*. One of the crucial ones is fixed by one end to the internal ſuperficial impreſſion in the notch of the os femoris, and by the other, to the notch in the head of the *Tibia*: The other is fixed by one end to the external impreſſion in the notch of the os femoris, and by the other between the anterior portions of the ſuperior ſurfaces of the head of the *Tibia*. The cornua of the ſemilunar cartilages degenerate into ligaments, ſhort and ſtrong, by which they are faſtened, and communicate by ſome ſmall portions with the crucial ligaments: They have likewiſe a common ligament, which like an arch runs tranſverſely between their anterior convexities, to the tuberoſity or ſpine of the *Tibia*. The patella is faſtened alſo by a ſtrong ligament; this runs directly down from the apex of the patella; and, beſide this, it has ſeveral ſmall lateral ligaments fixed in the lower part of its edge on each ſide, and inſerted anteriorly and a little laterally in the edge of the head of the *Tibia*.

The capſular ligament is fixed round the edge of the head of the *Tibia*, and in the edge of the patella. The crucial ligaments, and thoſe of the ſemilunar cartilages, are incloſed in this capſule; but the lateral and poſterior ligaments, and thoſe of the patella, lie without it. The capſule is alſo joined to a conſiderable portion of the circumference of the ſemilunar cartilages, and is ſtrengthened by many ligamentary fibres. Its inſide is ſmooth, and ſhining; and where it is not covered with tendons, is very thin. There is likewiſe a very thin ligament, fixed by one end to the lower part of the cartilaginous ſide of the patella, and by the other to the anterior part of the great notch between the condyles and the os femoris. The uſe of which ſeems to be, to prevent the articular fat from being compreſſed in the motions of the knee. *Winſlow*'s Anatomy, p. 129.

TIBIÆ *Quintus*, in anatomy, a name given by the old authors to a muſcle called the *biceps cruris* by Albinus and Winſlow, and the reſt of the moderns.

TIBIALIA, among the Romans, a kind of ſwaths with which they uſed to cover their legs. *Pitiſc.* in voc.

TIBIALIS (*Cycl.*)—TIBIALIS *Gracilis*, a muſcle of the leg, called alſo *plantaris*. It is a ſmall pyriform muſcle, ſituated obliquely in the ham, below the external condyle of the os femoris, between the poplitæus, and external gaſtrocnemius; and its tendon which is long, flat, and very ſmall, runs down on the ſide of the gaſtrocnemius internus all the way to the heel. The fleſhy body, which is no more than about two inches in length and one in breadth, is fixed by a ſhort flat tendon above the outer edge of the exterior condyle of the os femoris; from thence it runs obliquely over the edge of the poplitæus, and terminates in a very ſmall, but long flat tendon. This tendon runs between the body of the gaſtrocnemius externus and ſoleus all the way to the inner edge of the upper part of the tendo achillis, and from thence continuing

its courſe downward, it joins this tendon, and is inſerted, together with it, in the outſide of the poſterior part of the os calcis, without communicating with the aponeuroſis plantaris. Sometimes this muſcle is wanting, and in ſome ſubjects it is ſituated lower down. *Winſlow*'s Anatomy, p. 220.

TIBIALIS *Anticus*, a long muſcle, fleſhy at the upper part, and tendinous at the lower, ſituated at the fore-ſide of the legs, between the *Tibia* and the extenſor digitorum pedis longus. It is fixed above by fleſhy fibres in the upper third part of the external labium of the criſta tibiæ, and of the inſide of the aponeuroſis tibialis, or of that ligamentary expanſion which goes between the criſta tibiæ, and the anterior angle of the fibula. It is likewiſe fixed obliquely in the upper two thirds of the outſide of the tibia, or that next the fibula. From thence it runs down, and ends in a tendon, which firſt paſſes through a ring of the common annular ligament, and then through another ſeparate ring, ſituated lower down; afterwards the tendon is fixed, partly in the upper and inner part of the os cuboides, and partly in the inſide of the firſt bone of the metatarſus. *Winſlow*'s Anatomy, p. 217.

TIBIALIS *Poſticus*, a long fleſhy penniform muſcle, broader above than below, ſituated between the tibia and fibula, on the backſide of the leg, and covered by the extenſor digitorum longus. It is fixed above by fleſhy fibres, immediately under the articulation of the tibia and fibula, to the neareſt part of thoſe two bones, chiefly to the tibia, reaching to the lateral parts of that bone above the interoſſeous ligament, which is here wanting. From thence its inſertion is extended below the oblique line or impreſſion in the tibia, over all the neighbouring part of the interoſſeous ligament, and through more than the upper half of the internal angle of the fibula. Thro' all this ſpace it is fleſhy and penniform, and is covered by the extenſor digitorum longus. After this, it forms a tendon which runs down below the inner malleolus through a cartilaginous groove, and an annular ligament, and is inſerted in the tuberoſity of the lower part of the os ſchaphoides. *Winſlow*'s Anatomy, p. 220.

TIBICEN, in zoology, a fiſh of the cuculus kind, called by many authors, *lyra*, or the *harp-fiſh*; and in ſome parts of England, the *piper*.

The head of this fiſh runs out into two broad horns, which are ſerrated, or beſet with a ſort of teeth, or ſmall ſpines, all along their edges, which is its principal diſtinction from the hirundo or ſwallow-fiſh. Above the gill-fins it has on each ſide a long and ſharp ſpine. The forehead is elevated into a ſort of eyebrows over the eyes; and at the angles of theſe there are ſmall and ſhort ſpines; theſe are crooked; and the ſpines on the back of this ſpecies are longer than in any other of the cuculi. The ſide lines feel but very little rough to the touch, and the forehead between the eyes is not hollowed as in the other cuculi. The whole head is covered with a bony cruſt, which runs into two horns or ſpines behind. It has three fingers or filaments on each ſide, from the roots of the gill-fins; and its jaws are rough like files, but have no diſtinct teeth. The tail-fin, and the middle of the back in this fiſh are red. It is caught in the Mediterranean, and in ſome other ſeas. In our county of Cornwal, it is not unfrequently caught about the ſhores, and from the noiſe it makes when taken out of the water, is called the *piper*. *Ray*'s Ichthyography, p. 282. *Willughby*'s Hiſt. Piſc. p. 282.

TIBURO, in zoology, a fiſh very badly and falſely deſcribed by ſeveral authors, and proving, on a ſtrict enquiry, to be no other than the lamia or white ſhark. *Willughby*'s Hiſt. Piſc. p. 49. See the article LAMIA.

TICK, in the manege, a habit that ſome horſes take of preſſing their teeth againſt the manger, or all along the halter or collar, as if they would bite it.

TICKLISH, in the manege. A horſe is ſaid to be *tickliſh* that is too tender upon the ſpur, and too ſenſible, that does not freely fly the ſpurs, but in ſome meaſure reſiſts them, throwing himſelf up, when they come near and prick his ſkin. A *tickliſh* horſe has ſomewhat of the ramingues, *i. e.* the kickers againſt the ſpurs; but with this difference, that the latter put back, leap and kick, and yerk out behind, in diſobeying the ſpurs; whereas a *tickliſh* horſe only reſiſts for ſome time, and afterwards obeys, and goes much better, through the fear of a vigorous ham, when he finds the horſeman ſtretch his leg, than he does upon being actually pricked.

TIDE (*Cycl.*)—In the Philoſophical Tranſactions, N°. 4. we have an account of an extraordinary *Tide* near the weſtern iſles of Scotland. For ſome days one flood and ebb run twelve hours eaſtward, and the other twelve hours weſtward, till four days before the new and full moon, and then they reſume their ordinary regular courſe as before, running eaſt during the ſix hours of flood, and weſt during the ſix of ebb.

There is another uncommon irregularity in theſe *Tides*. Between the vernal and autumnal equinoxes, the courſe of irregular *Tides* about the quarter moons is to run all day, that is, twelve hours eaſtward; and all night, for twelve hours more, weſtward. But during the other ſix months, from the autumnal to the vernal equinox, the current runs all day weſtward, and all night eaſtward.

TIES, aboard a ſhip, are thoſe ropes by which the yards do hang; and, when the halliards are ſtrained to hoiſe the yards, theſe *Ties* carry them up.

TIFACOUM, a word uſed by ſome of the chemical writers to expreſs quickſilver.

TIFATUM, a word uſed by ſome of the chemical writers to expreſs ſulphur.

TIFFE *de Mer*, in natural hiſtory, a name given by Count Marſigli to a ſpecies of ſea plant, commonly but erroneouſly reckoned among the ſpunges, and called by authors, a *branched ſpunge*. This author has called it by this name from its reſemblance to the heads of the *typha paluſtris*, or cat's tail, when ripe in the month of September.

The ſpunges muſt be of a lax and cavernous texture; but this plant is ſmooth and firm, and has no inequalities on its ſurface, excepting a few ſhort hairs, which give it a velvety look, when firſt taken out of the water. It is a very elegant and beautiful plant; it grows to two foot in height, and is very elegantly branched. It grows on rocks and ſtones, and, when firſt taken out of the ſea, is full of a viſcous water, as yellow as the yolk of an egg; but when this water is preſſed out, and the plant comes to dry, it loſes its yellow, and becomes of a duſky brown colour. It is very tough and firm while in the water, but when dry it uſually breaks of itſelf into little pieces, and may be crumbled to powder between the fingers. This is a very ſtrong proof, among others, of its not being of the nature of the ſpunge.

When viewed by the microſcope, the whole ſurface is found to be covered with extremely fine and ſlender hairs; and, amongſt theſe, there are an infinity of little apertures, thro' which the ſea-water makes its way, for the nouriſhment of the plant. When a branch of it is cut tranſverſely, there are ſeen a number of long and fine canals, by means of which the water, received at theſe ſuperficial apertures, is conveyed to the whole ſubſtance of the plant; for theſe plants are all root, and imbibe their nouriſhment at every pore. *Marſig.* Hiſt. de la Mer, p. 82.

TIGEGUACU, in zoology, the name of a ſmall Braſilian bird, of the ſize of a ſparrow, and with a ridged and triangular bill, in which it reſembles the moucherolle. Its eyes are of a fine blue, and its legs and feet yellow. It is all over of a deep black, but that it has a large blood-red ſpot on the top of its head. Its tail is ſhort and black. *Marggrave*'s Hiſt. Braſil.

TIGER, *Tigris*, in zoology. See the article TIGRIS.

TIGH, in our old writers, a cloſe or incloſure mentioned in antient charters, and is ſtill uſed in Kent in the ſame ſenſe. Chart. Eccleſ. Cant. *Blount*.

TIGILLUM, a word uſed by ſome chemiſts to expreſs the tile with which they cover the mouth of their crucibles; and, by others, for the crucible itſelf. See the article TILE.

TIGRIS, the *Tyger*, or *Tiger*, in the Linnæan ſyſtem of zoology, makes a diſtinct genus of the quadruped claſs; the characters of which are, that it has four paps placed near the navel, and feet adapted to climbling. The author takes in the panther to this genus, and diſtinguiſhes the *Tiger* by the name *Tigris maculis oblongis*, and the panther by that of *Tigris maculis orbiculatis*. *Linnæi* Syſtem. Naturæ, p. 35.

The *Tiger* has its name from its ſuppoſed ſwiftneſs, and has been deſcribed by almoſt all authors as one of the ſwifteſt of all the wild carnivorous animals; but this has been wholly contradicted by ſuch authors as have ſeen the creature, who all declare that it is a ſlow and ſluggiſh animal, and is unable to overtake a man, or almoſt any animal that has an opportunity of running away from it. It will give two or three large leaps; but if it do not ſeize its prey in theſe, is but ill qualified to catch it afterwards. *Ray*, Syn. Quad. p. 165.

It exceeds the lion in ſize, and is of an unconquerable fierceneſs. It agrees with the panther in the variegation of its colours, but differs in the diſpoſition of them; for in the panther the colours are diſpoſed in round ſpots or eyes, and in the *Tyger* they are diſpoſed in long ſtreaks.

Marggrave deſcribes three ſpecies of American *Tygers*, the firſt called *jaguera* by the natives, and by the Portugueſe *onça*; the ſecond diſtinguiſhed by the natives by the name *jaguarete*, but called by the Portugueſe by the ſame name with the other; the third called by the Indians *cugua-cuarana*, and by the Portugueſe, the *Tyger*. But the two firſt ſeeming to be the ſame with what we know by the name of the *ounce*, and having round, not long variegations, ſeem properly of the panther, not of the *Tyger* kind.

It were much to be wiſhed that the antients had left us more certain marks, and fuller deſcriptions of the *Tyger* than they have.

The *Tyger* is found in the Eaſt Indies, in many parts of Aſia, and in America: But there ſeems ſome difference in ſpecies between the Aſiatic and American *Tygers*, and poſſibly fuller obſervation may prove, that the Aſiatic are ſwift, as the antients have deſcribed them, and the American ones, of the ſlowneſs of which we have accounts, may be a different ſpecies.

The manner of carrying off the young brood of this animal is deſcribed by Pliny as follows. The Hircanians and Indians bring up the *Tyger*, ſays he, an animal of a dreadful ſwiftneſs,

which is moſt put to the proof when going to be taken. The whole brood, which is always very numerous, is carried off upon a horſe, as ſwift as poſſible, and often removed to a freſh one. When the mother *Tyger* finds the neſt empty, and the brood gone, for the males take no care of them, ſhe traces the ſcent with furious ſpeed; and when ſhe is arrived within hearing of the perſon who is carrying off her young, he throws down one of them; this ſhe takes up in her mouth, and, as if made more ſwift by her load, carries it back, and then returning, is treated in the ſame manner till the perſon gets on board a ſhip, and leaves her to vent her rage on the ſhore. Vid. *Pitiſc.* Lex. Ant. in voc. *Plin.* Nat. Hiſt. l. 8. c. 18.

TIHOL, in natural hiſtory, a name given by the people of the Philippine Iſlands to a ſpecies of crane very frequent among them, and remarkable for its ſize, being taller than a man, when it ſtands erect, and holds up its neck. They call it alſo ſometimes *tipul*.

TIJEGUACU-*Paroara*, in zoology, the name of a Braſilian bird, of the ſize of a lark. It has a ſhort and thick beak, brown above, and whitiſh below. Its head, throat, ſides, and the lower part of its neck, are of a fine yellow, variegated with red in the female, and all over of a perfect blood-red in the male. The upper part of the neck, and the whole back, are grey, with a mixture of brown; the wings are brown, tipped with white; the tail is of the ſame colour; and the ſides of the neck, the breaſt, belly, and thighs, are white. *Marggrave*'s Hiſt. Braſil.

TIJEPIRANGA, in zoology, the name of a Braſilian bird of the ſparrow kind. It is a little larger than the lark. Its whole body, neck, and head, are of a very fine red or blood colour, and its wings and tail black.

There is another ſpecies alſo of this bird, which is of the ſize of a ſparrow, and is of bluiſh grey on the back, white on the belly, and of a ſea-green on the wings. The legs of this are of a pale grey. *Marggrave*'s Hiſt. Braſil.

TIKE, the Zetland name for an otter, of which there are many to be found about that iſland. Phil. Tranſ. N°. 473. Sect. 8.

TILE, or TYLE, (*Cycl.*) in aſſaying, a ſmall flat piece of dried earth, uſed to cover the veſſels in which metals are in fuſion.

Theſe are made of a mixture of clay and ſand, or powder of flints, or broken crucibles, made into a paſte, and ſpread thin with a rolling-pin, on a table, or flat ſtone. From theſe cakes or plates, pieces are to be cut with a knife, to the ſhape and ſize of the mouths of the veſſels to be cloſed. It is beſt then to pare away the borders of the under ſurface of the piece thus cut off, that this ſurface may immediately touch all the way the edge of the mouth of the veſſel, leaving a prominent rim, by which means the *Tile* ſits cloſe upon the veſſel, and is not ſo eaſily diſplaced by accidents, as a touch of the poker, or of the coals put on to mend the fire, as it otherwiſe would be. Finally, put on the middle of the outer ſurface a ſmall bit of the ſame matter, which ſerves as a kind of handle, by means of which it may be conveniently managed by the tongs, and eaſily taken off and put on again at pleaſure. *Cramer*, Art. Aſſ. p. 66.

TILIA, the *Lime-Tree*, in botany, the name of a genus of trees, the characters of which are theſe: The flower is of the roſaceous kind, and is compoſed of ſeveral petals, arranged in a circular form. The piſtil ariſes from the cup, and finally becomes an unicapſular huſk, containing oblong ſeeds.

The ſpecies of *Lime*, enumerated by Mr. Tournefort, are theſe: 1. The large-leaved common *lime*. 2. The common *Lime*, with ſmaller leaves. And 3. The hairy-leaved *Lime*, with red twigs and ſquare fruit. *Tourn.* Inſt. p. 611. See the article LIME-*Tree*.

Lime-tree flowers are eſteemed cephalic and cordial; they are alſo recommended in paralytic and nervous diſorders of all kinds.

TILLS, a name given by our farmers to the lentil, a kind of pulſe propagated in ſome parts of the kingdom; they are the ſmalleſt of all pulſe. They require but an ordinary ground, but they produce a vaſt quantity, tho' they lie in a ſmall compaſs. They make a fine ſweet fodder, and are the beſt of all things of this kind for calves, or any other young cattle. They are alſo the beſt of all ſorts of food for pigeons. *Mortimer*'s Huſbandry.

TILLÆA, in the Linnæan ſyſtem of botany, the name of a diſtinct genus of plants, the characters of which are theſe: The calyx is a flat perianthium, divided into three large oval ſegments. The flower is compoſed of three flat, oval, pointed petals, ſmaller than the ſegments of the cup. The ſtamina are three ſimple filaments, ſhorter than the cup. The antheræ are ſmall. The piſtillum has three germina. The ſtyles are three, and ſimple. The ſtigmata are obtuſe. The fruit is three long pointed capſules, of the ſame length with the flower, bent back, and ſplitting open longitudinally in their upper part. The ſeeds are of an oval figure; and two are contained in each of theſe capſules. *Linnæi* Gen. Plant. p. 36.

TILLAGE. The term *Tillage*, in its proper ſenſe, ſignifies the opening, breaking, and dividing the ground by the ſpade, the plough, the hoe, or other inſtruments which divide it by attrition, as the addition of dung does by fermentation.

Dung is only to be had in a limited quantity, and that in moſt places, except in the neighbourhood of great towns, too ſmall a quantity for the huſbandman's occaſions; but *Tillage* is in the power of the workman in every degree; and by this the field of ſubterranean paſture for the plants may be enlarged almoſt without limitation. Though the external ſurface is always confined to the ſame narrow bounds, *Tillage* may extend the earth's internal ſuperficies, in proportion to the diviſion of its parts; and as diviſion is infinite, ſo may alſo that extenſion of the ſuperficies be, which is the conſequence and effect of it.

Every time the earth is broken by any ſort of *Tillage* or diviſion, there muſt ariſe ſome new ſuperficies of the broken parts, which never has been open before; for when the parts of the earth are once united and incorporated together, 'tis morally impoſſible that they, or any of them, ſhould be broken again only in the ſame places; for, to do that, ſuch parts muſt have again the ſame numerical figures and dimenſions they had before that breaking, which, it is eaſy to ſee, will never happen.

Although the internal ſuperficies may have been drained by a preceding crop, and the next plowing may move many of the before divided parts, without new breaking them, yet ſuch as are new broken have, at ſuch places where they are broken, a new ſuperficies, which never was, or never exiſted before.

Tillage, as well as dung, is beneficial to all ſorts of land. Light land being naturally hollow, has larger pores, which are the occaſion of its lightneſs: This, when it is by any means ſufficiently divided, the parts being brought nearer together, becomes, for a time, bulk for bulk heavier; that is, the ſame quantity of it is made to lie in leſs room, and ſo it is made to partake of the nature and benefit of a ſtrong and firm land; that is, it will keep out too much heat and cold, and retain the roots of plants much more ſteadily than it could do before that *Tillage*.

The ſtrong and tough land being naturally leſs porous than it ought to be, is made for a time lighter, as well as richer, by a good diviſion: The ſeparation of its parts makes it more porous, and cauſes it to take up more room than it does in its natural ſtate, and then it partakes of the natural advantages of a lighter land. When ſtrong land is ploughed, but not ſufficiently, ſo that its parts are left groſs, it is ſaid by the farmers to be rough; in this caſe it has not the proper benefit of *Tillage*; for its pores and interſtices are left too large, and it has all the inconveniencies of a hollow land that is untilled. When the light land is ploughed but once, that is not ſufficient to diminiſh its natural hollowneſs or pores; and, for want of more *Tillage*, the parts into which it is divided by that once ploughing, remain too large, and conſequently the artificial pores are large alſo, and, in that reſpect, they and the ill-tilled ſtrong land are alike.

Light land having naturally leſs internal ſuperficies than any other kind, ſeems to require more *Tillage* or dung to enrich it: As when the poor hollow thin downs have their upper part, which is the beſt, burnt, whereby all, except a caput mortuum, is carried away; yet the ſalts of this ſpread upon that barren land, which is unburnt, divide it into ſuch very minute parts, that their paſture will nouriſh two or three very good crops of corn. But then the plough, even with a conſiderable quantity of dung, is never able to make another diviſion equal to that which thoſe ſalts had done; and therefore, after theſe two or three crops, the land always remains barren.

Artificial pores cannot be two ſmall, becauſe the roots of plants can the more eaſily enter the ſoil that has them; quite contrary to natural pores; for theſe may be, and generally are, too ſmall and too hard for the entrance of all weak roots, and for the free entrance even of ſtrong roots. Inſufficient *Tillage* leaves ſtrong land with its natural pores too ſmall, and its artificial ones too large; and it leaves light land, with its natural and artificial pores both too large. Pores which are too ſmall, in hard ground, will not permit roots eaſily to enter them; and pores which are too large in any ſort of land, can be of little other uſe to the roots of plants, but only to give them paſſage into other pores that are more proper for them; and if in any place they lie more open than they ought to the air, they are dried up and ſpoiled before they reach them.

The fine fibrous roots are the only parts of a plant which take in the nouriſhment, the larger part of the roots ſerving only to receive it of them, and convey it to the plant; and theſe fine and ſmall fibrous roots can take in no nouriſhment from any part of the earth, unleſs they are in contact with it, and preſs againſt the ſuperficies: This is the caſe in the ſmall pores in the earth; but by no means in large ones; for a fibrous root can never be compreſſed againſt the ſides of a cavity, whoſe diameter is much greater than its own, as is the caſe in all theſe large pores. The ſurfaces of great clods form declivities, which have large cavities at the bottom; theſe ſerve to receive and convey what rain and dew bring too quickly downward below the ploughed part.

The firſt and ſecond ploughing of land with the common plough, ſcarce deſerve the name of *Tillage*; they rather pre-

pare

pare the land for *Tillage*; the third, fourth, and every ſubſequent ploughing, are of infinitely more advantage to the ground, and are done at a much ſmaller expence; but the laſt ploughings will be moſt advantageouſly performed in the manner of hoeings. See the article HOEING.

The finer any land is made by *Tillage*, the richer it will become, and the more plants it will maintain; and it has been frequently obſerved, that in a large field, where at ſome time one part of the ground has been better tilled than the reſt, that part of the ground has produced the beſt crops, and been eaſily diſtinguiſhed by it from the reſt of the field, even ſix or ſeven crops after the time of the particular good *Tillage*. A piece of ground being once made finer than the reſt, will a long time ſhew the advantage of it; becauſe the dews have more power to enrich it, they penetrating farther than the ſuperficies, whereto the roots are able to enter. The fine parts of the earth are impregnated throughout their whole ſubſtance with ſome of the riches carried in by the dews, and there repoſited until, by *Tillage*, the inſide of thoſe fine parts become ſuperficies; and as the corn drains them, they are again ſupplied as before; but the rough large parts cannot have that benefit, and the dews not penetrating but to their ſurface, they remain poor. The experiments mentioned by Mr. Evelyn prove this beyond conteſt. Take of the moſt barren earth you can find, powder it well, and expoſe it abroad for a year, inceſſantly agitating it, and after this, without any other management, this earth will be the moſt fertile that can be conceived, and will readily receive any plant from the fartheſt Indies: All vegetables will proſper and flouriſh in this once barren earth, and bear their fruit as kindly with us, under a due degree of artificial heat, as in their native climates.

The artificial duſt will entertain plants which refuſe dung and other violent applications, and has a more nutritive power than any artificial dung or compoſt whatſoever: And by this pulveriſing and expoſing, the very nature of a ſoil may be changed, and the tougheſt clay made as light and friable as common light earth, and as fit for the nouriſhment of the tendereſt plants as any other; though, in its natural condition, its pores were too ſmall to give way to their tender roots, and had no communication one with another.

This is a ſort of improvement of land that cannot be practiſed in the large way, in fields, *&c.* but as it only conſiſts in dividing and breaking the particles of earth, and expoſing them thus broken to the air, it is plain that common *Tillage* approaches more or leſs to it, as more or leſs labour is employed; and the experiment proves, that the farmer need never fear beſtowing too much *Tillage* on any ſort of ground.

It is without diſpute, that what was one cubical foot of the original barren earth, and had in that ſtate only ſix cubical feet in ſuperficies, has after this powdering more than a thouſand cubic feet of ſuperficies in its internal parts. The very pooreſt land, and the very richeſt, in their natural ſtate, do not differ ſo much as one, and twenty; that is, a cubic foot of the richeſt land in the world will not produce more vegetables than twenty foot of the pooreſt; and as, in this method of pulveriſing, the ground is made greatly more than twenty times richer than it was before, it is a neceſſary conſequence that any poor land may, by proper *Tillage*, be made richer than the beſt land in the world naturally is.

There is alſo another very great advantage, when a ſoil has a large internal ſuperficies in a ſmall compaſs, as is always the caſe after much *Tilling*; which is this, that the roots of plants in it are then better ſupplied with nouriſhment; their food being nearer to them on all ſides, and more within reach than it can be when the ſoil is leſs fine, as in common *Tillage*, and the roots muſt extend much farther in the one than in the other, in order to reach an equal quantity of nouriſhment: They muſt range and fill perhaps twenty times more ſpace, in order to the coming in the way of an equal quantity of food.

Hard ground makes too great a reſiſtance to the paſſage of roots, and air makes too ſmall a preſſure upon their ſuperficies; in water they have a free paſſage to the utmoſt of their extent, and have every where an equal, proper, and even preſſure; and in light and fine earths, ſuch as thoſe divided by an equal and careful *Tillage*, they have much the ſame free paſſage and even preſſure as in water.

The general cuſtom of farmers is to leave off *Tillage* juſt when they have brought their lands into ſuch a condition, that *Tillage* would be of vaſt advantage to them. They uſually ſuppoſe the ſoil to be fine enough, when, with the help of harrows, they can cover the ſeed, and afterwards with a roller they break the clods, to the end that if a crop ſucceed, they may be able to mow it, without being hindered by theſe clods. *Tull*'s Horſehoing Huſbandry, p. 24.

TILMUS, a term uſed by ſome of the medical writers to expreſs the effect of a ſort of delirium, in which people pull the bedclothes, or pick out threads from the ſheets. This is uſually eſteemed a dangerous ſymptom.

TIMBER (*Cycl.*)—The uſes of *Timber* are ſo many, and ſo great, that the procuring a ſufficient ſupply of it, extremely well deſerves the care of every ſtate; as it muſt be a great diſadvantage to it to be obliged to have recourſe to its neighbours, and purchaſe at a very conſiderable and continually renewed expence, what might, by an eaſy œconomy, be ſufficiently ſupplied at home.

This œconomy, however, muſt be applied in time; for our natural indolence, our love to reap the advantages of every thing ourſelves, and our little care for poſterity, give great room to fear ſucceeding ages will want wood both for private and public exigencies. All our arts ſhould be employed on this ſubject, with two views, the one to preſerve and cheriſh our growing wood, the other to renew the trees which have been and are continually cut down.

The quantity of acorns that the oak bears, has made many people ſuppoſe, that nature has taken care for a renewal for us, and that of this vaſt quantity of ſeeds which annually fall, there will be always an over-ſufficient ſupply of young trees, which will grow up in the place of the old ones: But experience proves, that this is by no means the caſe. The greater number of theſe fallen acorns are devoured by a number of different animals, for whoſe nouriſhment nature has provided that abundance of them: And of thoſe which eſcape this fate, we are to conſider how few can come to good, from the natural accidents they are unavoidably expoſed to; they fall on a covered ground, where dead leaves, and decayed parts of branches of trees, uſually prevent their touching the earth, into which they are to ſhoot; or, if they can ſhoot here, it is merely from the ſurface, where they are, in their ſlow growth, liable, while very tender, to all the inclemencies of froſts; and add to this, that it is very difficult for ſuch tender plants as the young ſeedlings of theſe, to find room for growth or nouriſhment among the every way ſpreading roots of other trees; and the continual ſhade and want of free air, muſt render them very weakly and irregular in their growth, even ſuppoſing them to get over all the other difficulties.

It is very certain, that *Timber-trees* of oak are frequently met with among the underwood of foreſts; but we ſhall always find this to be the caſe, not in the cloſe places, but in certain ſpots where there has been a vacancy or opening; and that uſually where there are not, nor have at any time been, oaks in the neighbourhood of the ſpot. The acorns that fall from the oaks uſually come to nothing, from the before-mentioned accidents; and theſe trees which grow at diſtances, are owing to the acorns brought thither by birds, and accidentally dropped there. This is an inſtance familiarly verified, by obſerving, that there are frequently little buſhes near woods, which, though of white-thorn or other trees, are uſually ſurrounded and ornamented with young oaks; the jays and the like granivorous birds are the authors of this crop; for, bringing the acorns from the adjoining woods, to eat under theſe buſhes, they drop many by the way, which they do not trouble themſelves to look for on the ground, and which having here a freer ground to ſtrike root into, and an open air to grow in, ſeldom fail of coming to good, unleſs deſtroyed while young.

In order to the preſerving our growing *Timber-trees*, it would be a very uſeful law, that all who cut down any number of oaks, ſhould alſo leave a given number in good condition for after-cutting; and that no *Timber* ſhould be cut down, but at a proper age, in regard to the nature of the ſoil; ſince it is certain, that trees grow to their perfection at very different periods of time, in proportion to the depth of ſoil they have to grow in; and that as it is, on the one hand, not for the intereſt of the ſtate to ſuffer trees to be cut till at their perfection for ſize and ſoundneſs, ſo, after they are arrived at that perfection, it is equally certain, that they gradually decay.

The quality of the ſoil the tree ſtands in, may be neceſſary to be obſerved to this purpoſe; but the quantity or depth of it is the great ſubject of enquiry; and a great number of obſervations have proved, that the proper ſeaſon for cutting oaks in a ſoil of two foot and a half deep, is at fifty years old; thoſe which ſtand in a ſoil of three foot and a half deep, ſhould not be cut down before ſeventy years; and thoſe which ſtand in a ſoil of four foot and a half deep, or more than that, will encreaſe in goodneſs and in ſize till they are an hundred years old: And obſervation has proved, that after theſe ſeveral periods, the trees begin to decay.

This ſeems the beſt rule to eſtabliſh, in regard to the common ſoils; but thoſe which grow in a lighter or more ſandy ſoil, may have their periods changed from theſe to forty, to ſixty, and to eighty years at the greateſt depth; and after theſe times it is always beſt to fell the wood meant for public ſervice, whether then wanted or not, ſince it is much better to keep it in public magazines, than to leave it to be daily decaying.

Heaths, and other uncultivated places, where there is no regular growth of wood; but where fern, and uſeleſs plants alone ſeem to flouriſh, uſually afford alſo ſome ſtraggling trees of the oak. Theſe probably have had their origin from acorns dropped by birds; but theſe ſeldom grow tall or regular; ſince, not having been defended from the injuries of cattle, they are uſually browſed on, and ſtunted while young, and ſo become crooked and ſhort-trunked, or pollard trees. Theſe, though not of ſuch value as the more regular oaks, yet deſerve care, both with reſpect to their preſervation and felling; ſince they afford a number of trees naturally bent, and formed for many parts of ſhip-building.

The little care uſually taken of theſe trees, though on this occaſion

caſion of great value, ſeems to threaten a general loſs of them; but as trees, thus naturally crooked and bent, are of value, it is a laudable attempt to try at the finding a regular method of producing ſuch; and this is eaſily practicable, by following the ſame methods by which theſe wild ones become ſo. They wholly owe their figure to the cattle's biting off their tops while young, and afterwards biting off again the tops of the ſhoots from the firſt wound. In this manner, if a number of young trees, ſet apart for the experiment, have their tops cut off at two, four, ſix, eight, ten, and twelve feet from the ground, and four years afterwards the ſhoots from theſe ſtunted tops are again cut in the ſame manner, the trees will be found afterwards to grow up in all the irregularly crooked figures that can be conceived, and by this means a ſupply of naturally crooked wood may be raiſed for all the occaſions of ſhip-building, with infinitely greater eaſe and more certainty than by the method propoſed by ſome, of bending them down with weights tied to their tops while young.

As to the ſupply of young wood in the place of what is cut down, there are ſome circumſtances which have not had the attention paid to them which they deſerve. The ſpring froſts, which come on at a time when the ſhoots, by which nature is to raiſe the ſupply for what is cut down, are juſt preparing to grow, are of prodigious injury, and do not leſs miſchief to theſe than to the young ſhoots of garden plants, though the diſtant hope of the ſucceſſion to the proprietor, and uſually alſo the diſtance of place, and want of repeated obſervation, occaſions its not being perceived. This, however, may, in a great meaſure, be guarded againſt. Frequent experiments, and repeated obſervations, prove, that the miſchief done by theſe froſts, affect in a much greater degree thoſe ſhoots which are expoſed to the ſouth, than thoſe which face the north; and that it is greatly more powerful againſt ſuch as are wholly expoſed to the wind, than againſt ſuch as are ſheltered. Theſe known circumſtances may give the hint to a method of ſaving, at leaſt a great part of a wood to be felled, from this deſtruction, to its renewal, by the making it a rule to begin cutting down on the north ſide; and, as the whole felling is a work of ſome years, the ſtanding wood of every ſeaſon will defend the young ſhoots of the newly cut ſtumps the following ſpring, not only from the ſouth expoſure, but will ſhelter them alſo from the wind.

Many prudent managers have made fine eſtates of their coppice-woods, by regularly felling a certain portion every year, and providing for a renewal of the firſt cutting, againſt the felling of the laſt portion, by proportioning the time of growth to the quantity to be cut every year; and there is great intereſt to be made of a true knowledge of the growth of wood in this manner. Whoever obſerves the growth of young trees, will find that the ſecond year's growth is much more conſiderable than that of the firſt; the third year is more than that of the ſecond, and ſo on for many years; the yearly growths of young wood greatly encreaſing every ſeaſon up to a certain time or age of the tree, after which the increaſe in bulk, by growth, becomes gradually leſs. The great advantage to be made of coppice-wood, would be by knowing this intereſting period, and ſeizing on it, always to cut down the trees juſt at that time when they arrived at the end of their quick growth, and ſo ſetting nature to work with new ſhoots, to employ the ſame ſpeed on enriching again the owner. Regular obſervation and experiment alone can aſcertain this happy period; but any man who has much coppice-wood upon his eſtate, may aſſure himſelf of it, by cutting a given quantity every year, for ten years ſucceſſively, and then carefully reviewing the differences of the yearly produce. Memoirs Acad. Scienc. Ann. 1739.

Strength of TIMBER. The celebrated Monſieur de Buffon has attempted a rational calculation of the ſtrength of *Timber*, uſed in building, on the principles of his excellent demonſtration of the growth of trees. See the article WOOD.

He has proved that all wood conſiſts of a ſeries of woody cones laid in woody beds, all along the tree, and connected by a ſort of reticular work of much leſs ſtrength than their own ſubſtance. He infers hence, very juſtly, that when there are, in any ſpecies of wood, more of theſe cones, which ſhew themſelves in ſo many concentric circles in a tranſverſe ſection of the wood, and conſequently more of theſe weaker reticular ſubſtances which connect them, that wood muſt neceſſarily be weaker than ſuch in which, in an equal thickneſs, there are much fewer of theſe cones, and conſequently fewer alſo of theſe weaker inter-ſpaces.

If the irregularities of the ſtructure of wood were only theſe, it would be eaſy to compute, from the ſtrength of a ſtaff of an inch diameter, of any wood, what would be that of a beam of the ſame, of any given ſize; but this is by no means the caſe; for the diſpoſition of the cones, beds, and interſticial matter, is by no means the ſame in a large beam, formed by the workman, as in a little branch in its natural ſtate of growth.

This is eaſily conceived, when we conſider that, in order to make a beam of *Timber*, they ſquare a branch or part of the tree, or cut off four cylindric pieces from it, of what is called the blea. The heart of the wood lies now in the middle of the beam; this is the firſt woody bed, which all the others ſucceſſively cover, in form of ſo many concentric circles: The larger of theſe concentric circles is of the diameter of the whole piece of *Timber* now cut, and the circles, which naturally ſurrounded this, are now no longer perfect, but form only portions of circles, diminiſhing all the way to the ribs of the beam. A beam, thus ſquared, is therefore compoſed of a cylindric compleat piece of firm and hard wood, and of four angular portions, cut out of a much leſs ſolid and firm wood. This is the condition of a beam, ſquared out of a large arm of a tree, and made nearly of the diameter of that arm; but a beam of like ſize, cut out of the trunk of a larger tree, or out of one ſide of ſuch a trunk, is a very different thing, and is compoſed only of the longitudinal ſegments of the annual woody beds; and theſe ſegments ſometimes lie parallel to one of the ſurfaces of the beam, and ſometimes more or leſs inclined to one or the other ſide; they are alſo ſometimes longer, ſometimes ſhorter; and ſometimes more, ſometimes leſs, cut into the woody beds of the trunk of the tree they were cut from, and the beam is conſequently more or leſs ſtrong accordingly.

There are alſo two poſitions in a beam, the one of which is much ſtronger than the other; for theſe ſegments of the woody beds of the tree, form ſo many parallel flats. If you place the beam in ſuch a poſition that theſe planes or flats are vertical, it will reſiſt a much greater force than if they are placed horizontally in the poſition of the beam.

From theſe obſervations, it is eaſy to ſee how very fallacious the calculations and tables of the ſtrength of different kinds of *Timber* muſt be, while the authors have formed all their ſyſtems upon experiments made on pieces of one or two inches in diameter, and have given themſelves no trouble to enquire into either the number or diſpoſition of the woody beds in thoſe pieces, nor the directions in which the ſeveral beds were found on breaking them. Theſe, however, are extremely neceſſary and eſſential circumſtances; nor are theſe the only variations which they have omitted to obſerve; there are perhaps others equally neglected in all ſuch attempts, and yet equally neceſſary to make them of any real uſe. Young wood has always much leſs ſtrength than the older, and there is a great difference between the pieces cut out of the ſoundeſt part of the body of a tree, and thoſe from the young branches of the ſame tree. A piece cut out of the outer part of the trunk of a tree, near the blea, is alſo much weaker than one of equal diameter, cut out of the center or heart of a tree. The different age, and degree of dryneſs in wood, makes alſo great differences in its ſtrength; for a green branch of a tree is always more tough, and leſs eaſily broken, than a dry one: And the time employed in putting wood to the trial, as to its ſtrength, is alſo a circumſtance very neceſſary to be conſidered; ſince a beam of *Timber*, which will ſuſtain a certain weight for a few minutes, will not ſuſtain it perhaps for as many hours; and experiment has proved, that wood will often bear, for a ſhort time, a weight it cannot bear for a longer time; a beam having been found to bear a certain weight for one day, and the ſame beam afterwards having been broken in ſix months time by only two thirds of that weight. It is eaſily ſeen, from theſe conſiderations, that all the calculations in which theſe conſiderations have been neglected, can be of very little certainty; and that to make ſuch as may be certainly depended on, is a work of great difficulty.

As the advantages reſulting from ſuch calculations are, however, yet greater than the difficulties attending the attempt, this gentleman was encouraged to purſue the enquiry to the utmoſt. He cauſed certain pieces of wood to be broken by a determinate force, and calculating, according to that, what ought to be the force to break ſuch as were much larger; he tried afterwards what was the real force that would break them, and how far his calculations approached to the truth; in this he ever found extremely great differences between calculation and reality; and after many repeated trials, was never able to bring the fact any thing near the calculations. And trying, according to the ſame rules, others of greater lengths and thickneſſes, in proportion to the ſtandard piece, he found the calculations as far faulty as before. The diſappointment in theſe attempts determined him, however, to try a compleat courſe of experiments, from which a certain table of the force required to break the different kinds of wood might be eſtabliſhed, to which both himſelf, and the reſt of the world, might refer to upon occaſion. And this he executed in the following manner.

He began by chooſing in a certain ſpot of one of his own woods an hundred oaks, which were all found and lively growing trees, and ſtood as near to one another as they conveniently could. This caution was uſed, that the wood might be all of the growth of the ſame ſoil, ſince it is well known that the growths of different ſoils are in the ſame ſpecies of wood, of very different ſtrengths, and miſtakes of this kind might have rendered the whole attempt fruitleſs. Theſe oaks were all of the ſame ſpecies, and were in ſize from two foot and a half to five foot round. They were choſen purpoſely of different growths, or ſizes, that the experiments might be the

more ſimilar to the uſual cuſtoms of the workmen. For when a carpenter has occaſion for a piece of four or five inches ſquare, he does not for this purpoſe cut a tree that might have furniſhed a piece of a foot ſquare, becauſe of the expence; and it too often is their cuſtom to uſe ſuch pieces as have a very large ſhare of the blea on them. Not unfrequently indeed they uſe alſo rafters, ſawed out of large pieces of *Timber*; but theſe are, of all others, the very worſt; and the uſe of them in building ought to be prohibited, the ſmall wood being infinitely more advantageous for theſe purpoſes.

As the degree of dryneſs of wood alters its ſtrength very much, and as it is alſo very difficult to be aſſured with any degree of certainty, of the degree of drying or ſeaſoning of *Timber*; ſince two trees cut down at the ſame time ſhall often be found to dry very differently, it appeared to this gentleman much more eligible to take wood perfectly green for his trials, than that in any degree dried or ſeaſoned.

The trees were felled one by one, and were carried into a proper place; the day after they were felled the carpenters were employed to ſquare them, and the joiners to take their exact dimenſions; and on the day afterwards, the pieces were put to the proof; and the following is the method in which moſt of the experiments were made. Two ſtrong treſſels were taken, of ſeven inches ſquare, three foot high and three foot long, and ſtrengthened in their middle by a very ſtrong piece of *Timber*. On theſe two treſſels were placed the two extremities of the piece of wood which was to be broken; there were alſo ready ſeveral ſquare iron buckles, or rings, made of round iron work, the largeſt of which was nine inches wide, and was made of iron of ſeven inches about; the next was ſeven inches wide, and the iron it was made of was five inches round, and others of different degrees below theſe.

The piece of wood deſtined for the experiment, was paſſed through theſe rings; the larger of which ſerved for the thicker pieces, the ſmaller for the thinner. Every one of theſe rings had on its upper part and on the inſide, a rib nicely filed, of two or three twelfths of an inch broad.

The intent of this was to prevent the ring from inclining one way or other, when in uſe; and on its under part it had two hooks of iron, of the ſame thickneſs with the ring itſelf; theſe were placed at ſuch a diſtance from each other, as to form another ring of about nine inches in diameter, into which there was to be put a key of wood of the ſame diameter, and of four foot long. This key carried a ſtrong table of fourteen feet long, and ſix feet broad, which was made of rafters of five inches thick, nicely fitted one to the other, and ſecured by ſtrong bars of wood. This was ſuſpended to the ring by means of the large wooden key, and ſerved to place the weights on; theſe conſiſted of three hundred quarters of ſtones, which were all numbered, and weighed from twenty-five to two hundred pounds each. Theſe ſtones were put upon the table, and a heap of ſtones were placed together as long and wide as the table, and as high as was neceſſary for the breaking of the piece.

There was always great care uſed to place the piece and the treſſels on a level; and they were then faſtened, to prevent their diſplacing themſelves. Eight men were employed continually to fill the table, and began by placing in the center weights, firſt of two hundred, then of an hundred and fifty, next of a hundred; and ſo on to twenty-five pounds. Two men placed on a ſcaffold, ſuſpended in the air by cords, placed the fifty and twenty-five pound weights, which could not have been otherwiſe done, without danger of the mens being cruſhed to death; four other men held firm the four corners of the table, that they might not ſtir; and another, with a long ruler of wood marked how much the piece bent and gave way, as they loaded it with weights; while another marked the time, and wrote down the weight, which was often, twenty, twenty-five, or twenty-ſeven thouſand pounds.

Mr. Buffon cauſed more than an hundred pieces of wood to be broken in this manner; ſome regular ſquare beams, others rafters ſawn out of large trunks, beſide three hundred bars; and this great number was but barely ſufficient to give a regular ſcale of the force and ſtrength of *Timber*, in proportion to its ſeveral lengths and thickneſſes.

This gentleman obſerved, that a large piece of wood never broke, without firſt giving ſome notice of it; that green wood broke with much more difficulty than ſuch as was dry; and in general, ſuch ſort of wood as had a ſpring, reſiſted more than ſuch as had none. The blea of the wood, the wood of the branches, that of the top of the tree, and in general all the young wood, is weaker than that which is older.

The ſtrength of wood is not at all proportioned to its ſize; and a piece which is double or quadruple the thickneſs of another of the ſame length, is much more than of twice or four times its ſtrength; as for example, there required not quite four thouſand weight to break a piece of *Timber* of ten foot long, and four inches ſquare; and yet there required ten thouſand to break a piece of double that meaſure; and to break one of four times the meaſure, it required twenty-ſix thouſand weight; that is, to break a piece of ten foot long, and eight inches ſquare.

The ſame obſervation is alſo made good, in regard to the different lengths, as well as the thickneſſes. The laws of mechanics would inform us, that a piece of *Timber* of eight foot long, ought to bear juſt twice the weight of one of ſixteen feet. But experiment ſhews us here alſo, that the piece of eight foot long carries much more than the double of the other.

The wood which grows quickeſt, ſuppoſing the land the ſame, is always the ſtrongeſt: That which has grown more ſlowly, and the annual circles of which, that is, its ſeveral woody cones, are thin and ſlender, is always weaker than the wood in which they are thick.

The ſtrength of wood is proportionable to its weight, and a piece of wood of the ſame length and thickneſs with another, but conſiderably heavier than another, is found ſtronger alſo, and that very nearly in the ſame proportion. This is a remark of no ſmall conſequence; and, as the general weight of wood is eaſily known, it may ſave the expence of too much wood in building, as well as the danger from the greater error of uſing too little.

This accurate obſerver takes notice, that ſome may imagine his experiments to be the leſs concluſive, that the *Timber* he broke was looſe at the ends; and that in a wall, or building, it is uſually fixed at both ends. But he obſerves, that the difference of this circumſtance is not worth conſidering, for that the piece fixed in a wall is liable to bend in the middle, before it breaks; and that the fixures have no power to retain the ends, when they are pulled by this force.

This gentleman took no notice of any pieces which had faults, as many of thoſe he tried had, and broke with much leſs than their proportion of weight; but confined his obſervations and reaſonings only to ſuch pieces as were perfectly ſound and firm.

It might be ſuppoſed, that ſo great a number of trials as theſe, and that on ſo eaſy a ſubject, ſhould have left nothing farther to be done in it; but the author himſelf willingly acknowledges that there is yet much to be known. The proportion of the longitudinal ſtrength of wood to its tranſverſe, is a ſubject deſerving enquiry; as wood in buildings is often uſed in very different poſitions, and where the force acts upon it, not tranſverſely, but longitudinally or obliquely in different directions. Mem. Acad. Scienc. Par. 1740.

Seaſoning of TIMBER, a term uſed by our huſbandmen, to expreſs the preparing *Timber* after it is felled, for cutting and working up for uſe.

As ſoon as felled, it ſhould be laid up in ſome dry airy place, but out of the reach of too much wind or ſun, which, when in exceſs, will ſubject it to crack and fly. It is not to be ſet upright but laid along, one tree upon another, only with ſome ſhort blocks between, to give it the better airing, and prevent its becoming mouldy, which will rot the ſurface, and produce muſhrooms on it. Some perſons daub the trees all over with cow-dung, which occaſions their drying equally, and prevents their cracking, as they are otherwiſe very apt to do.

Some recommend the burying *Timber* in the earth, as the beſt of all ways of ſeaſoning it; and others have found it a fine preſervative to bury their *Timber* under the wheat in their granaries; but this cannot be made a general practice.

In Norway, they ſeaſon their *deal* planks, by laying them in ſalt-water for three or four days, when new ſawed, and then drying them in the ſun; this is found a great advantage to them; but neither this, nor any thing elſe, can prevent their ſhrinking.

The ſeaſoning *Timber* by fire is the beſt way of all, for piles and other pieces that are to ſtand under the earth, or water. The Venetians firſt found out this method, and the way they do it in is this; they put the piece to be ſeaſoned into a ſtrong and violent flame, in this they continually turn it round by means of an engine, and take it out when it is every where covered with a black coaly cruſt; by this means the internal part of the wood is ſo hardened, that neither earth nor water can damage it of a long time afterwards. This method is practiſed in many places for ſeaſoning the poſts for paling of parks, *&c.* and has this to recommend it, that in the very oldeſt ruins we have ever been acquainted with, there have been found many times pieces of charcoal, all of which has been found uninjured, though buried in the earth for ever ſo many ages. *Mortimer*'s Huſbandry, V. 2. p. 132.

When *Timber* has been properly felled, and ſeaſoned, by being expoſed to a certain degree of air and ſun, there is yet a method of preſerving it, much better than it could otherwiſe be, by external applications. When they are wrought and fixed in their places, the rubbing them over with tar or linſeed-oil, has been found of great uſe. The antients, particularly Virgil and Heſiod, adviſe the ſmoak-drying of all inſtruments made of wood, by hanging them up in the chimnies where wood fires are uſed. The whole benefit ariſing from this, ſeems to be the oil of the wood that is burnt, entering into the pores of the other as carried up in the ſmoak. But it would be a much more cleanly and eaſy method to apply ſome oil of this kind at once, and in any quantity that ſhould be judged requiſite. *Mortimer*'s Huſbandry, V. 2. p. 104.

The Dutch, who have *Timber* about their ſluices, and other buildings upon the water, more expoſed to the injuries of wet and weather than any other that is known; have a way of preſerving it, by coating it over with a mixture of pitch and tar, which they ſmear over the whole ſurface; and immediately, while it is moiſt, they throw on it as much ſand and powder of cockle-ſhells as it will retain. Thus it is coated over with a rough cruſt which will defend it from all kinds of injuries. See the article SULPHUR.

Green *Timber* is apt to ſplit and cleave in ſeveral places, after it is wrought into form. Workmen have different methods of remedying this deformity, for which ſee the article CLEFTS.

Felling of TIMBER. See the article FELLING.

Hardening of TIMBER. See the article HARDENING *of Timber*.

TIMBER-*Lode*, in our old writers, a ſervice by which tenants were to carry *Timber* from the woods to the lord's houſe. *Blount*.

Meaſuring of TIMAER, To meaſure round *Timber* without the help of inſtruments: let the mean circumference be found in feet, and decimals of a foot; ſquare it, multiply this ſquare by the decimal 0.079577 and the product by the length. For inſtance, let the mean circumference of a tree be 10.3 feet, and the length 24 feet; then $10.3 \times 10.3 \times 0.079577 \times 24 = 202.615$ = the number of cubical feet in the tree. The foundation of this rule is, that, when the circumference of a circle is 1, the area is 0.0795774715, and that the areas of circles are as the ſquares of their circumferences. Treat. Pract. Geom. p. 150.

The common way uſed by artificers for meaſuring round *Timber*, mentioned in the Cyclopædia, differs much from this rule. One fourth part of the circumference or girt, is by them reckoned the ſide of a ſquare, whoſe area is equal to that of the ſection of the tree; they therefore ſquare the girt, and then multiply by the length of the tree. According to this method the tree of the laſt example, would only be computed at 159,13 cubical feet.

TIME *(Cycl.)*—TIME, in the manege, is ſometimes taken for the motion of a horſe, that obſerves meaſure and juſtneſs in performing a manege; and ſometimes it ſignifies the interval between two of his motions. In the manege of a ſtep and a leap, the horſe makes by turns a corvet between two caprioles; and in that caſe the corvet is one *Time* that prepares the horſe for the caprioles.

The *Times* obſerved in making a ſtop, are nothing but ſo many falcades.

TIME alſo ſignifies the effect of one of the aids, thus, we ſay, a good horſeman diſpoſes his horſe for the effects of the heel, by beginning with one *Time* of the legs, and never runs precipitately upon his *Times*.

TIMOROSO, in the Italian muſic, intimates that the ſong is to be played or ſung, in ſuch a manner as to expreſs an awe or dread, either to ſhew reſpect, or to repreſent fear.

TIMOROUS, in the manege. See the articles STARTING, SKITTISH, *&c.*

TIN *(Cycl.)*—The combinations and ſeparations of metals, are ſubjects that have employed the thoughts of the moſt accurate chemiſts in all ages; yet new diſcoveries are ſtill to be made, and in theſe experiments as well as in many others, we are by no means yet arrived at the utmoſt perfection.

Mr. Groſſe in the memoirs of the academy of ſciences of Paris, has delivered a method he had invented of ſeparating *Tin* from lead or ſilver.

The advantages ariſing from the mixtures of different metals, are very numerous and of many different kinds; to this we owe the metal uſed for bronzes, for bells, for reflecting mirrors uſed in opticks, and a multitude of the like matters; a mixture of this kind makes braſs of copper, a little copper in the ſame manner, gives ſilver a hardneſs that greatly adds to its utility, and gives hardneſs and a more pleaſing colour to gold; a little copper or antimony give *Tin* a hardneſs, and render it more ſonorous: and a multitude of advantages beſides might be enumerated. But there is no leſs neceſſity and advantage alſo in the ſeparating metals, ſometimes when they have been joined by art, or are found united by nature: in theſe caſes ſometimes both the metals are preſerved, ſometimes the baſer or leſs valuable is deſtroyed.

Of theſe ſeparations of metals ſome are very eaſy: lead and mercury are ſeparated from gold and ſilver by heat alone, and ſo are antimony from gold, or zink from copper. On the other hand there are ſome ſeparations which cannot be effected without great trouble; of this kind are the mixtures of *Tin* with lead and with ſilver. It is not common to mix ſilver and *Tin* together on any occaſion; but they are ſometimes found mixed, and give the refiners great trouble; and even the chemiſts, who have often mixt *Tin* with ſilver to increaſe it, have always found it very difficult to ſeparate it again.

Mr. Groſſe happened to be preſent at the melting ſome ſilver, which plainly indicating that it contained ſome other metal, in the refining he ordered the workman to examine the lead which he uſed, and found that there was *Tin* among it. The ſcoriæ of the metal, which contained with the *Tin* a large quantity of ſilver, had on theſe occaſions been uſed to be ſold to the bell-founders, to the great loſs of the proprietor of the metal. Some indeed had adviſed different methods of recovering the metal from them, but without ſucceſs. It was on theſe ſcoriæ that Mr. Groſſe tried his experiment; it ſeemed to him that one great ſtep toward the ſeparation of the ſilver, was the haſtening the calcination of the *Tin*, and with this view he tried a mixture of charcoal, ſalt-petre, and earth, which he put together into the copel with the ſcoriæ. It is eaſy to ſee that a detonation would happen from this, and this muſt greatly add to the force of the fire, in acting upon the ſcoriæ, while the ferrugineous matter well known to be contained in the charcoal mixed itſelf with the *Tin*, and muſt greatly accelerate its calcination, divide its parts, and give the fire a new action over it. The conſequence of this perfectly anſwered expectation, and recovered a large quantity of ſilver from the ſcoriæ, in which the *Tin* had before held it firmly imbodied; repeated experiments proved the truth of this obſervation, and it was found to be eaſy by this means at any time to ſeparate ſilver from *Tin*, or to purify ſilver without loſs, by means of lead in which *Tin* has accidentally been embodied. The common method uſed by the plumbers to ſeparate their ſolder from old leaden pipes, *&c.* might ſeem an eaſy way of ſeparating *Tin* from lead, but this is not truly the caſe; the *Tin* in this inſtance not being ſeparated from the lead, but only a mixture of *Tin* and lead, which had been employed as ſolder is ſeparated from ſimple lead, which had been ſoldered with it. The method of making this ſeparation, is only by melting the ſolder off from the ſimple lead by a fire not ſtrong enough to melt the lead itſelf.

The ſcoriæ in which *Tin* is mixed with ſilver, are compoſed of *Tin* half calcined, and run into an opake vitrified ſubſtance, which forms a ſort of net-work, in which the ſilver is confined in extremely ſmall particles. If this is thrown into aqua fortis, the whole is diſſolved: but then it requires a very ſtrong fire to make the *Tin* loſe its metallic form; finally if the whole is finely powdered and then put into this menſtruum, the ſilver only is taken up or diſſolved, the *Tin* remaining untouched at the bottom of the veſſel.

The ſame gentleman found alſo a method of ſeparating *Tin* from ſilver, by means of corroſive ſublimate of mercury. To conceive the manner in which this ſeparation is effected, a piece of fine *Tin* need only be caſt into a ſolution of ſublimate; in which caſe the acid of the ſea-ſalt is ſeen to leave the mercury in order to fix upon the *Tin*.

And, according to the ſame principle, if ſublimate corroſive be added to a mixture of *Tin* and ſilver, the ſame effect is produced, the acid affixes itſelf to the *Tin*, and makes with it a butyrum joviale or butter of *Tin*, the mercury becomes diſſipated in the mean time by the action of the fire, and the ſilver remains pure and alone; but in this experiment, if too much corroſive ſublimate be added, there is danger of loſing ſome of the ſilver; ſince the abundant acid will prey upon and carry off a part of that metal, making a ſort of luna cornea which diſſipates itſelf in the air, or if the operation be performed in a cloſe veſſel, a butyrum lunare.

Gold may alſo be purified from *Tin* in this manner, and in this there is no riſk of loſs, ſince the acid which takes up the *Tin* has not the leaſt power over that metal: In all theſe proceſſes, however, the operator muſt avoid the fumes iſſuing from the crucible, for they are very dangerous.

Theſe methods of ſeparating *Tin* from ſilver are very certain and infallible, but they are too expenſive to be employed in common, and in larger works.

The ſeparating *Tin* from lead to be employed in the refining of ſilver is a matter of great importance; and this may be done in the following manner: Melt the lead, and when in fuſion throw into it a quantity of filings of iron, then increaſe the fire to a conſiderable degree, and the ſurface of the metal will be covered with a ſort of ſcum, which is no other than the iron and *Tin*. At this time there ſhould be a little alkali ſalt thrown in, and by this means the ſcoriæ readily ſeparate themſelves, and the pure lead remains in form of a regulus at the bottom. The ſame method may be uſed to ſeparate *Tin* from ſilver in the larger way, but it will be neceſſary for this purpoſe to add ſome lead, ſince otherwiſe the fuſion will be very ſlow and difficult, and the *Tin* will calcine without ſeparating from the ſilver. This is a very eaſy and very cheap method, and will obviate moſt of the miſchiefs which happen to the refiners, of which they would have much leſs frequent reaſon to complain, if they nicely examined the lead they were to employ. But if gold or ſilver be mixed with *Tin*, the ſhorteſt method in ſmall quantities is to calcine the whole very briſkly, and in order to compleat the vitrification and ſeparation of the *Tin*, to caſt in a little glaſs of lead, which will immediately join itſelf with it and carry it off from the maſs.

It may ſeem ſingular that iron being one of the hardeſt of the metals to melt, and *Tin* being of all the eaſieſt, they ſhould ſo readily and eaſily unite in theſe experiments; but this ſeems to be the reſult of one of thoſe natural and unexpected alliances which accident frequently diſcovers to us in bodies. There is one conjecture, however, that may be worthy a place in this reſearch, which is, that all *Tin* ore contains a quantity of arſenic, and it is well known that iron very readily mixes with arſenic, and is employed to ſeparate the arſenic from other ores, and a regulus may be formed of arſenic and iron. It is eaſy to ſuppoſe that *Tin* is in its metalline form, not wholly diveſted of the arſenic it contained when in the ore, and if this be allowed,

lowed, it is no wonder that the two metals are eaſily brought together by the mediation of that principle. Memoirs Acad. Scienc. Par. 1737.

Mr. Cramer gives the practical rules of ſeparating ſilver from *Tin*, thus: Divide one centner of *Tin* into two equal parts; put each of theſe into a ſeparate teſt, and add to each ſixteen centners of granulated lead, and one of copper; put the whole under the muffle, and make a very ſtrong fire; the *Tin* will be calcined immediately, and will ſwim upon the lead. Then diminiſh the fire a little, till the aſhes of the *Tin* that ſwim upon the ſurface do no longer ſparkle; when you ſees this, add with a ladle two centners of glaſs of lead to each teſt, in ſuch manner that it may be ſpread wide over the whole ſurface of the rejected calx; the calx will then change its form of powder into that of glaſs; then increaſe the fire to its higheſt degree, ſtir up the whole with an iron rod made warm; and when the ſcorification is perfected, pour out the maſs into a mould; the ſcoriæ being ſeparated, put both the regulus's into two coppels well heated; and into a third put ſixteen centners of lead, and one of the ſame copper uſed in the proceſs; examine all theſe beads after the coppelling is over; if the two firſt weigh exactly alike, 'tis a proof the proceſs has been well performed, and ſubſtracting the weight of the bead, ſeparated from the third pan, from the joint weight of the other two, the remainder is the weight of the pure ſilver contained in the quantity of *Tin* which was examined. *Cramer*'s Art of Aſſaying, p. 228.

Tin eaſily melts with ſilver, gold, or copper; but when they are mixt with it in equal or leſs quantity, it renders them extremely brittle. Silver is peculiarly ſuſceptible of this miſchief, and becomes almoſt as brittle as glaſs, by the admixture of a very ſmall quantity of *Tin*. Much greater quantities of *Tin*, however, in ſome metallic maſſes, leaves them ſtill pliant in ſome degree. Ten parts of *Tin*, and one part of copper, melted together, make a maſs more rigid than pure *Tin*, but ſtill ſomewhat tractable; and it is by this artifice, that veſſels and utenſils are made of tin, and yet are found conſiderably hard.

If to ten parts of *Tin*, and one part of copper, a little zink or braſs be added, it makes a very ſonorous metal, but brittle. This is ſometimes the mixture uſed as bell-metal, and cannons are in ſome places caſt of it. Lead becomes ſomewhat more rigid, or leſs ductile than before, by being mixed with *Tin*; but of all the metals it ſuffers the leaſt by the mixture.

If filings, or thin plates of iron, be made red hot in a crucible, and a double quantity of *Tin* put to them in a great fire, the whole will run into a brittle white regulus, which will yield to the magnet.

The vapours of *Tin* are very noxious to ſilver, gold, and copper, rendering them all brittle; nay, if only a little *Tin* be put into the fire, in which they are to be melted, they become brittle as ſoon as red-hot, and will break like glaſs under the hammer.

This metal, expoſed to the focus of a powerful burning-glaſs, melts, and emits a thick white fume, and, if held there a long time, wholly diſſipates itſelf in that fume. If, on the contrary, this metal be fuſed in a coppel by the ſame heat, it fumes conſiderably, and its ſurface becomes covered with a white calx, which greatly rarifies and expands, and there finally appear numbers of cryſtalline and bright ſtriæ like needles in that calx. If this be continued in the focus on a piece of free-ſtone, theſe cryſtals ceaſe to fume, and remain fixed while the ſtone itſelf melts and runs. And in the coppel there is uſually a part of theſe run into a reddiſh matter, reſembling a ſort of enamel. If the calx of *Tin* (that is, *Tin* reduced to a grey powder, by being diveſted of a part of its oil in the fire) be expoſed to the focus of the burning-glaſs, it fumes more than plain *Tin*, and is very ſoon transformed into cryſtalline ſtriæ, or needles. And if theſe are again expoſed to the ſame focus, placed on a piece of charcoal, they readily melt, and again aſſume the form of common *Tin*. The charcoal, in this caſe, furniſhes to the calx of *Tin* that oily matter which the fire had diveſted it of; and it is well known, that if the calx of *Tin* be made red hot in a crucible, and any fatty or inflammable matter be added to it, it immediately reſumes the form of *Tin* again; this reduction is wholly upon the ſame principle with the other, the oil of charcoal doing in the firſt, what the fat does in the laſt.

It appears, upon the whole, that *Tin* contains an oily matter, which is eaſily driven off by fire, and very eaſily received again on the mixture of any fat ſubſtance; that the earthy matter, which is the baſis of *Tin*, is of a cryſtalline nature, and very hard to fuſe, ſince no common fire can vitrify *Tin* alone; and even the focus of the moſt powerful burning-glaſs does it but with great difficulty, and imperfectly; this ſemi-vitrification is what throws the calx into needles, whereas were it perfect, the whole would be one uniform maſs, Mem. Acad. Par. 1709.

TIN, in medicine, though greatly celebrated by the writers of many paſt ages, is not much eſteemed at preſent. It is ſaid to be good in convulſions, epilepſies, and the madneſs ariſing from the bite of a mad dog. Its preparations are theſe: 1. *Stannum pulverizatum*, or powdered *Tin*. 2. *Sal Jovis*, or ſalt of *Tin*. 3. *Diaphoreticum Joviale*, or antihectic of Poterius. 4. *Aurum muſivum*, or, as it is commonly called, *moſaicum*, moſaic gold.

The powder of *Tin* is ſaid to be a good remedy againſt worms, particularly of the flat kind, which often elude the force of other medicines. See the article WORM.

TIN is alſo a word uſed by ſome of the chemical writers to expreſs ſulphur.

TIN *Floors*, a contrivance uſed by our huſbandmen who propagate hops, to dry them after the gathering. The common way of doing this, is either on a hair-cloth on a malt-kiln, or elſe by the ooſt. See the article OOST.

In both thoſe ways, however, the hops ſuffer very much; the beſt way is by the *Tin floor*. It is thus done: Let a ſquare brick room be built, with a door on one ſide, and a long fire-place of a foot wide in the middle, reaching almoſt acroſs it; let holes be made at the ſides of this fire-place, to let out the heat into the room; and at the height of five foot above this let a floor be made of laths of an inch thick, laid lattice-wiſe. Let this be covered with great plates of double *Tin*, taking care that the joinings of the *Tin* be well ſoldered, and lie upon the laths, not over the interſtices, which may be about four inches wide. Let a row of boards be fitted round the edge of this floor, to keep the hops from falling off, then lay on a covering of hops of a foot thick; then make a ſmall fire of charcoal in the mouth of the fire-place, and the hops will dry very quick and very regularly. They may be continually ſtirred about while drying, and when enough, a part of the boarded edge of the kiln may be taken down, and the dried parcel thruſt out, and a freſh parcel laid on in their place. A very ſmall quantity of fuel is ſufficient in this way, and any fuel will do, for the ſmoke never comes at the hops. There is a very great improvement ſtill upon this method of drying hops, uſed by ſome people; this is the making a wooden cover, of the ſize of the *Tin floor*; this is covered with plates of *Tin* nailed on, and is ſuſpended over the kiln in ſuch a manner, that it may be let down at pleaſure, when the lower parts of the hops are dry. This is to be let down within ten inches of their ſurface, and there it acts as a reverberatory, and drives back the heat on the upper ones, ſo that they are dried as ſoon as the lower ones. Thus all the trouble of turning is ſaved, and the hops are much better dried than in any other way. *Mortimer*'s Huſbandry, p. 186.

TIN *Hatch*, in mining, a term uſed by the people of Cornwall, to expreſs the opening into a *Tin* mine. They alſo call it a *Tin-ſhaft*.

They make ſeveral openings in the ſides of the hills where they ſuſpect veins of ore to be. All theſe, except that which opens on the head of the mine, are called *eſſay-hatches*; but that which does ſo, is made their entrance afterwards, and changes its name to that of the *Tin-hatch*.

TIN *Ore*. The firſt proceſs toward the ſeparating the metal from this ore, is the roaſting it, which the aſſayer performs in this manner: Put ſix centners of *Tin* ore in coarſe powder in a teſt, under a muffle made thoroughly red hot, ſhutting firſt the veſſel for a few minutes, and then opening it. If the fire is pretty ſtrong, the volatile part will be ſeen expelled in a thick white ſmoak, ſmelling like garlic. When this is over, take out the teſt, and when the ore is cold, beat it to powder, and roaſt it again in a ſomewhat ſtronger fire, till it exhales no more arſenic, which may be known by putting upon the teſt, when juſt taken from the fire, a thick cold plate of iron, which will be covered on its under ſurface with a ſmall whitiſh cloud, if the ore yet exhales any arſenic. *Cramer*'s Art of Aſſaying, p. 332.

When the roaſting is thus finiſhed, the ore may be run into malleable *Tin* in the common manner, as the common lead ore is, only with this caution, that the fire in the operation be carried as ſoon as poſſible to the higheſt degree that is neceſſary here, and the veſſel taken out of the fire, as ſoon as the operation is judged to be finiſhed.

TIN *Plates*, an article of manufacture very common among us, and vulgarly called *Tin*. It is iron plated over with *Tin*. The French call it *fer blanc*, white iron, as we ſometimes do in England. It was once known under a diſtinct name, *latin*. See the article LATIN.

TINA, a name given by the old medical writers to a bath made of a ſtrong decoction of many carminative ingredients, to be uſed in the colic.

TINCA, the *Tench*. See the article TENCH.

TINCA *Marina*, the *Sea-Tench*, in zoology, a name given by ſome authors to the common *turdus*, called in Engliſh, the *wraſſe*. *Willughby*'s Hiſt. Piſc. p. 320. See the article WRASSE.

TINCTURE *(Cycl.)*—A general rule for the properly making light *Tinctures* may be taken from the following bitter. Take half an ounce of Seville orange-peel ſhaved thin, half a dram of gentian-root thin ſliced, a ſcruple of the tops of Roman wormwood, half a dram of cardamum-ſeeds, and the ſame quantity of cochineal, each of them lightly bruiſed; put theſe ingredients into a pint of French brandy, let them ſteep for one night, and filter the liquor the next morning, and thus you have a fine light bitter.

Theſe

Theſe bitters are of the number of many other ſubſtances, where the goodneſs of a *Tincture* does not more depend upon the choice of the ingredients, than upon the manner of their being infuſed; for if ſuch be ſuffered to remain too long in the menſtruum, or if heat be uſed in extracting the *Tincture*, the groſs, terreſtrial, and nauſeous parts of the ingredients will be fetched out, and the *Tincture* will thus be loaded with a heavy indolent matter of little virtue. *Shaw*'s Lectures, p. 202.

If however, a greater ſtrength be required in the *Tincture* than can be procured by ſo ſlight an infuſion, when the ingredients are of this nature the matter ſhould never be ſuffered to be heated or ſtand long on the ſame ingredients, but ſhould be when ſtrained off, poured on freſh ones, and ſo on till of any ſtrength deſired, yet perfectly free from the groſſer parts.

Apothecaries uſually commit the ſame error in their finer *Tinctures*, that they do in their cordial waters, ſaturating the liquor in both caſes with the groſſer and more uſeleſs part of the ingredients: whence the cordial waters of the ſhops too often abound with a groſs heavy oil, and the *Tinctures* with a groſs heavy earth, or kind of bituminous matter, inſtead of the briſk, lively, and invigorating ſpirit, which alone is the thing required in both caſes.

To extract the *Tinctures* of hard, reſinous, or gummy bodies, however, requires a different treatment, and muſt be effected in another manner. See the article GUM-*Lac*.

A great variety of *Tinctures* may be given to common water, and many remarkable things occur in their changes on the addition of common menſtruums. Take a large ſpoonful of the ſyrup of pomegranate-flowers, mix it with five ſpoonfuls of water; the mixture will be of a very lively and brilliant red: for a violet colour, take the ſame quantity of ſyrup of violets and the ſame of water. When theſe *Tinctures* are thus prepared have at hand a vial in which is a ſmall portion of oil of tartar, which will only look like water remaining after the waſhing of the vial. Pour the red or the violet *Tincture* into this vial, and it immediately becomes a fine graſs green. Diſſolve the quantity of a walnut of crude ſal armoniac in a glaſs of water, pour all out except three or four drops at the bottom, and pour into this glaſs the fine red liquor, and it immediately becomes black as ink. In order to change the purple liquor red, only have a ſmall quantity of ſpirit of vitriol in the bottom of a vial, and pour into this; the violet water it immediately on this becomes of a florid red.

Steep Braſil wood in common water, or in white wine twenty hours, the liquor will then look of the colour of red wine; pour this into a glaſs waſhed with vinegar and it becomes of a fine yellow, like ſack. If this experiment be made with white wine, the wood and the vinegar make ſo little alteration in it, that it may be drank afterwards, and the whole proceſs ſeems a way of turning red port into ſack. Into this liquor when yellow, drop a few drops of a *Tincture* of benjamin made in ſpirit of wine, and it immediately loſes its yellow colour and becomes white. Beat ſome galls to fine powder, and rub the powder on a towel, then put into a baſon of water, in which any perſon is going to waſh their hands and face, a ſmall piece of common green vitriol, or copperas, after the perſon has waſhed, let them have this towel to wipe on, and the hands and face will be as black as if waſhed with common writing ink. The copperas in the water and the galls on the towel making real ink where they mix. This does no laſting injury to the ſkin, but will come off again upon waſhing with ſoap. Phil. Tranſ. N°. 238. p. 88.

TINCTURE *of Ambergreaſe*. See the article AMRERGREASE.

TINCTURE *of Antimony*, *Tinctura Antimonii*, is thus made; take ſalt of tartar a pound, antimony half a pound, rectified ſpirit of wine a quart; reduce the antimony to powder, and mix it with the ſalt by fuſion over a ſtrong fire. When it is cold, powder it, and pour on the ſpirit of wine; digeſt them together three or four days in a ſand heat, and then filtre off the clear *Tincture* for uſe. The ſalt of tartar yields a *Tincture* as well as the antimony. It is a diaphoretic and attenuant.

TINCTURA *Antiphthyſica*. See TINCTURA *Saturnina*.

TINCTURA FOETIDA, the ſtinking *Tincture*, a form of medicine in the late London Diſpenſatory prepared in this manner; take aſſafœtida four ounces, rectified ſpirit of wine a quart, digeſt them together for ſome time, and then ſtrain off and filtre the *Tincture* through paper.

TINCTURA *Martis cum Spiritu Salis*, a medicine thus prepared: take filings of iron half a pound, Glauber's ſpirit of ſea-ſalt three pounds; digeſt all together without heat, as long as the ſpirit will work upon the filings; then after the fæces have ſubſided, pour off the clear liquor, evaporating it to one pound, and adding rectified ſpirit of wine three pints.

This *Tincture* is good in all the caſes, in which the *ſal martis* is ſo. See the article SAL *Martis*.

TINCTURA SACRA, a *Tincture* of aloes, called alſo *hiera picra*.

The late London diſpenſatory have ordered this to be made of only eight ounces of aloes, and two ounces of winter's bark, powdered and put into five quarts of white wine, which is to be ſhook often, and kept in fuſion a week or more without heat, and then ſtrained off for uſe. *Pemberton*'s Lond. Diſp. p. 266.

It is a very good method to mix ſome clean white ſand with this, to prevent the aloes from running together in lumps.

TINCTURE *of Saffron*. See the article SAFFRON.

TINCTURA SATURNINA, the lead *Tincture*, a name given in the late London diſpenſatory to the *Tincture* before called *Tinctura Antiphthiſica*.

It is made of ſugar of lead and green vitriol, each two ounces; of rectified ſpirit a quart. The ſalts are ſeparately to be reduced to powder and then put into the ſpirit, then the whole is to ſtand ſome days without heat to extract the *Tincture*, and afterwards filtered through paper. *Pemberton*'s Lond. Diſp. p. 277.

Many perſons have found great perplexity in making this *Tincture*, it having at firſt begun to ſhew a good colour, but afterwards loſt it; this accident is owing to heat uſually employed in making the *Tincture*.

This *Tincture* is a powerful ſtyptic, and is often uſed with good ſucceſs in hectic fevers, ſpittings of blood, heat of the kidneys, ſimple gonorrhœas, fluor albus, and tabes dorſalis.

It was firſt recommended by Etmuller; who from its effect gave it the name of *Tinctura antiphthyſica*, which our college of phyſicians have changed to that of *Tinctura Saturnina*. We alſo find it in the pharmacopœa of Edinburgh, and in the beſt of the foreign ones. Mr. Boyle recommends it, and our moſt eminent phyſicians uſe it; notwithſtanding that ſome authors conſider it as a dangerous medicine, on account of its principal ingredient, the *ſaccharum ſaturni*, which ſome call a ſlow poiſon. Whether it be ſo or not when given in ſubſtance, it is certain, that there is a great difference between a corroſive ſalt ſo given, and a *Tincture* made of the ſame, in ſpirit of wine, and given in ſmall doſes, as Dr. Mead obſerves. Who adds, that in ſlow hectic fevers attended with a looſeneſs, profuſe ſweats, and a colliquation of the humours, he reckons two or three drachms, given at different times in cooling liquors every twenty-four hours, to be a convenient doſe. But the uſual doſe is thirty drops in Briſtol water, or ſome temperate or cool julep. See *Acc. of a medical controverſ. in the City of Cork*. p. 58, 59.

TINCTURA *Sénæ*, a form of medicine preſcribed in the new London pharmacopœa, and intended to ſtand in the place of the medicine commonly called elixir ſalutis, and Daffy's elixir. It is thus made, take ſtoned raiſins ſixteen ounces, leaves of ſena a pound, carraway ſeeds an ounce and half, cardamom-ſeeds half an ounce, proof ſpirit a gallon; digeſt all together without heat, and when the *Tincture* is well extracted preſs off the ſpirit and filtre it for uſe. *Pemberton*'s Lond. Diſp. p. 278.

TINCTURA *Styptica*, a form of medicine made with very little trouble and apparatus, and ſerving to ſupply the place of that elaborate preparation the *Tincture* of Helvetius; it is preſcribed in the late London pharmacopœa, and is to be made by mixing a dram of calcined green vitriol with a quart of French brandy *Tinctured* by the caſk, this is to be ſhook together that the brandy may turn black, and then ſtrained off for uſe. *Pemberton*'s Lond. Diſp. p. 280.

TINCTURA *Thebaica*, a name now given to the *Tincture* of opium, commonly called *laudanum*.

The method of making this is alſo much altered, as well as the name in the late London diſpenſatory, where the ſaffron being looked on as an uſeleſs ingredient is wholly left out, and the medicine ordered to be prepared in the following manner: Take of opium ſtrained two ounces, of cinnamon and cloves each a dram, white wine a pint, infuſe without heat a week and then ſtrain off the wine through paper. *Pemberton*'s Lond. Diſp. p. 266.

TINCTURES, in heraldry, a word uſed to expreſs colours, red, blue, green, and the like.

The writers on heraldry have had great diſputes about which of theſe colours or *Tinctures* are the moſt honourable. All agree in giving the pre-eminence to the metals gold, and ſilver that is to the yellow and white colours; as to the others, ſome eſteem them more noble as they approach more to light, that is to whiteneſs. Upton on this account ranges them thus; azure or blue, gules or red, purpur or purple, vert or green, ſable or black; others wholly diſſent from this, and prefer thoſe colours moſt which can be ſeen at the greateſt diſtance; with theſe, ſables or black is the moſt honourable or firſt colour; and they alledge the imperial black eagle, placed in a white field as an inſtance of this. Leigh prefers the red to the blue, as the red has ſome alliance to gold, and the blue to ſilver; the ſable is generally preferred to green and purple, by thoſe who give the red and blue the firſt places: it is in this eſteem on account of its ſtrong appearance; and green is preferred to purple, becauſe the latter is but of very late uſe in heraldry, and is called a new colour.

All the precedence given to *Tinctures* muſt however be conſidered with this ſpecial proviſo, that there is no particular reaſon for bearing them otherwiſe in the arms of kingdoms and families. In all coats of arms there ſhould be two colours or *Tinctures*; and it is the general rule that the field ſhould be of a nobler colour than the figures placed upon it: thus

thus in the arms of Scotland the field is yellow, and the lion placed upon it red: and if the field conſiſts of two different colours parted by feſs or by pall, then the nobleſt colour muſt always be in the beſt place, as on the upper part, or on the right hand of the ſhield; but all theſe rules are to be underſtood with this limitation, that there are no other ſpecial reaſons in the family for the contrary. *Neſbit*'s Heraldry, p. 19.

TINEA *(Cycl.)*—TINEA *Campeſtris*, the *field moth*, in natural hiſtory, the name given by Mr. de Reaumur to a ſpecies of inſect, which in all reſpects reſembles the *moth* ſo deſtructive of cloaths, except in its food; as that feeds upon woollen, and makes its neſt or covering of that ſubſtance; this eats the leaves of trees, and in the ſame manner makes itſelf a covering from the fibres and integuments of them.

Their changes are the ſame with thoſe of the common moth, and performed in the ſame manner; they only ſeem to differ in having a more moiſt food.

Mr. Reaumur firſt obſerved theſe on the leaves of the aſh. This creature for a great part of its life wants no covering, but like the aſcarides making its way through the upper integument of the leaf, it feeds on the parenchyma and juices; at length when it has eat away all the ſubſtance of the leaf, it bites out a piece from each integument of it, over and under its body, and faſtens the edges all round with threads of its own ſpinning; thus making a compleat caſe or covering, enabling it to bear the open air. This done, it marches from its place to find another leaf fit to ſupply it with more nouriſhment: thus it changes place ſeveral times during its life, and as often changes its covering, which requires but a very little time to make a new.

This creature may eaſily be found by the curious ſearcher in the ſpring; for at that time, if the leaves of the aſh are examined, many of them will be found flaccid and as it were dry, and the creature will uſually be found buried among the parenchyma of theſe, between their two integuments. Toward the end of ſummer theſe creatures paſs into the chryſalis ſtate, and from this, after a ſhort ſtay, into a ſmall ſort of moth, which flies about the leaves of the ſame tree; and is very beautiful when examined by the microſcope, but is too ſmall for obſervation by the naked eye. Theſe of the aſh are very common, and there is alſo another kind little leſs ſo, which at length changes into a two-winged fly, very ſmall but of very great beauty; theſe feed upon the leaves of the willow, and make their caſes of the downy matter which envelops its ſeeds.

Theſe are ſmall animals of this genus; but there are others which are conſiderably larger, and which make their coverings of various matters and of different ſtructure; they are uſually very rough and rugged, and ſeem made of any matter that happens to be in the way; ſome ſpecies uſually make them of pieces of ſtraw and particles of chaff, others of ſmall twigs of buſhes, others of the dry leaves of the oak, broom, and other plants. One ſpecies there is that erodes wood; but it never pierces deep into it, but only eats off a part of the ſurface to furniſh itſelf with matter for its covering. Several ſpecies of theſe alſo are inhabitants of the water in this ſtate: theſe form their caſes of various materials, in the choice of which they do not ſeem at all nice. Some of them make them principally of ſand; others take the fragments of water-plants, and the ſhells of ſmall freſh water ſhell-fiſh into their work. This caſe makes the ſhell, under which they ſuffer their change into the nymph-ſtate; and as according to the general rule of nature, in regard to the water nymphæ of winged animals, theſe have a neceſſity of taking in water at times, one end of this ſhell or caſe is never cloſed up, but only covered with a reticular cloſe work. In this ſtate they float upon the ſurface of the water, till the time of the perfect fly's appearing. There are beſide theſe, alſo a ſpecies of wall *Tinea*, which have been ſuppoſed by ſome to eat the very ſtones and other materials of which the walls they crawl upon are built. This however is an error, for they feed only on the liverworts and other plants which grow upon them, and make their caſes out of the integuments of their leaves, and of the fibres of moſſes and other things they find there. There is yet another ſpecies of theſe moths feeding on vegetables which differs from all theſe, in that it ſpins its covering of a ſort of ſilk, which it produces out of its own entrails in the manner of the ſilk-worm. Theſe caſes are not made ſo ſpeedily as the others, but are formed of ſeveral ſcales applied at different times one over another, and reſemble a ſort of coat of armour. Under the cover of this the creature feeds at large on ſeveral ſorts of vegetables, and when it has lived the deſtined time in this ſtate, it draws its whole body under this covering, faſtens up the apertures, and thus defended from injuries paſſes into the nymph ſtate, and after a proper time is ſeen iſſuing out of that in form of an inſect of a middle nature, between the fly and butterfly, called a muſco-papilio.

There is a ſpecies of *Tinea* or moth, found in the flowers of the lillies in many gardens, which uſes its own dung as the matter to form its caſe of. This ſpecies at length becomes a beetle.

Another ſmall beetle of a purple colour, and very remarkable for its beauty, is produced from a ſmall worm of this moth kind, which is as remarkable for its uglineſs; this has three pair of cruſtaceous feet, as the other worms of the beetle kind have: both theſe kinds, while in the *Tinea* or worm ſtate, collect together all their dung as they void it, and, by a very nice ſort of workmanſhip, form themſelves very compact and firm caſes of it, which they drag about with them where-ever they go.

Finally there is another field *Tinea*, the beetle produced by which is of a purple colour on the body, and black in every other part. This, while in the worm ſtate, covers itſelf with a caſe made of its own dung, but has this ſingularity, that when the time of its change approaches, it deſcends to the ground, and buries itſelf there till the time that it comes out in form of a beetle.

All theſe animals might have been deſcribed as the dependants on the beetle and fly kinds; but as they have this remarkable quality of feeding in the ſame manner, and making themſelves caſes of different materials in the manner of the *Tinea* or cloaths moth while in the worm ſtate, and in this ſtate they are much more obvious to the eye than the flies, beetles, *&c.* produced of them, many of which are ſo ſmall as to eſcape obſervation; this accurate author has choſen to deſcribe them together, and in this their impefect ſtate. He adds an account of another ſet of animals ſomewhat allied to them, which he therefore calls the *pſeudo-Tinea*, or falſe moth. *Reaumur*, Hiſt. Inſ. Tom. I. See the article PSEUDO-*Tinea*.

TINEMAN, in our old writers, a petty-officer in the foreſt, who had the nocturnal care of vert and veniſon, and other employments in the foreſt. Leg. *Canut.* ap. *Blount.*

TINET, *Tinettum*, in our old writers, is uſed for bruſhwood and thorns to make and repair hedges. In Herefordſhire to *tine* a gap in a hedge is to fill it up with thorns, that cattle may not paſs through it. Chart. *Blount.*

TINEWALD, the parliament or annual convention of the people of the Iſle of Man, of which this account is given; the governour and officers of that iſland do uſually ſummon the twenty-four keys, being the chief commons thereof, once every year, *viz.* Upon Midſummer-day at St. John's chapel, to the court kept there, called the *Tinewald*-court; where, upon a hill near the ſaid chapel, the inhabitants of the iſland ſtand round about the plain adjoining; and here the laws and ordinances, agreed upon in the chapel of St. John, are publiſhed and declared unto them. At this ſolemnity the lord of the iſland ſits in a chair of ſtate with a royal canopy over his head, and a ſword held before him, attended by the ſeveral degrees of the people, who ſit on each ſide of him, *&c.* *King*'s Deſcipt. of the Iſle of Man.

TINGING *of Marble*. The art of doing this has in ſeveral peoples hands been a very lucrative ſecret, tho' there is ſcarce any thing in it that has not at one time or other been publiſhed.

Kircher has the honour of being one of the firſt, who publiſhed any thing practicable about it. This author meeting with ſtones in ſome cabinets ſuppoſed to be natural, but having figures too nice and particular, to be ſuppoſed of nature's making, and theſe not only on the ſurface, but ſunk through the whole body of the ſtones, was at the pains of finding out the artiſt who did the buſineſs; and on his refuſing to part with the ſecret on any terms, this author with Albert Gunter a Saxon endeavoured to find it out; in which they ſucceeded at length very well. The method is this,

Take aqua fortis and aqua regia of each two ounces, ſal armoniac one ounce, ſpirit of wine two drams, about twenty-ſix grains of gold, and two drams of pure ſilver, let the ſilver be calcined and put into a vial, and pour upon it the aqua fortis, let this ſtand ſome time, then evaporate it, and the remainder will firſt appear of a blue and afterwards of a black colour. Then put the gold into another vial, pour the aqua regia upon it, and when it is diſſolved evaporate it as the former. Then put the ſpirit of wine upon the ſal armoniac and let it be evaporated in the ſame manner. All the remainders and many others made in the ſame manner from other metals diſſolved in their proper acid menſtrua, are to be kept ſeparate and uſed with a pencil on the marble. Theſe will penetrate without the leaſt aſſiſtance of heat, and the figure being traced with a pencil on the marble, the ſeveral parts are to be touched over with the proper colours, and this renewed daily till the colours have penetrated to the deſired depth into the ſtone. After this the maſs may be cut into thin plates, and every one of them will have the figure exactly repreſented on both ſurfaces, the colours never ſpreading: The niceſt method of applying theſe, or the other *tinging* ſubſtances, to marble, that is to be wrought into any ornamental works, and where the back is not expoſed to view, is to apply the colours behind, and renew them ſo often till the figure is ſufficiently ſeen through the ſurface on the front, though it does not quite extend to it. This is the method that of all others brings the ſtone to a nearer reſemblance of natural veins of this kind. *Kircher*'s Mund. Subter.

TINNITUS *Aurium (Cycl.)*—In the *Tinnitus*, the ear uſually receives ſounds which do not exiſt, or at leaſt which are not produced by the motion of the external air; and the ear be-

ing filled with a certain ſpecies of ſound, cannot admit other ſounds, unleſs they are very violent.

The antients imagined that this ſymptom was produced by the motion and agitation of the air which was included in the ear, and ſuppoſed this agitation to be occaſioned by flatulencies and vapours being conveyed into the ear, and that thoſe flatulencies aroſe either from the whole body, as in fevers; or from any particular part, as the ſtomach, or brain; or from pituitous humours lodged in the cavities of the ear; and from the differences of theſe they attempted to account for all the various noiſes heard in this diſorder, as if they were in ſome ſort real: but when we conſider the nature of the noiſes heard in this diſtemperature of the ear, ſuch as the loud roaring, or the murmuring of waters, and the jangling of bells, we ſhall eaſily conceive theſe can be no real ſounds; and it is indeed very evident that they do not ariſe from either wind, or any other matter, ſtriking the membranes externally.

As a *Tinnitus* conſiſts in the hearing a ſound which either is not real or exiſts only within the ear, in order to conceive the meaning of this, we are to conſider that the action of hearing conſiſts in the agitation of the immediate organ appointed for that purpoſe; and it is ſufficient to produce a ſound that that organ is agitated, whether it be by the air or not. In order to determine what may be the cauſe of this agitation, we need only examine what are the diſorders in which a *Tinnitus* uſually occurs; we ſhall find theſe to be inflammations, and abſceſſes of the tympanum and labyrinth, and the diſorders of the meatus auditorius. Inflammations of the tympanum and labyrinth neceſſarily produce agitations in the ſpiral lamina and in the ſemicircular ducts, either by tenſion of the membrances, or by the vapours which tranſpire, and mix themſelves with the air in the tympanum.

Acrid ſubſtances, worms, extraneous bodies, a conſtriction of the meatus ſucceeding a diſtenſion of the glands, and in general every thing that can cauſe in the meatus auditorius, pain, and the other ſymptoms before deſcribed, agitate the membrane of the meatus, and the membrana tympani; and this agitation is able to communicate itſelf to the immediate organ of hearing.

The ſecond ſpecies of *Tinnitus* is when we perceive a real ſound which is formed within the ear itſelf: thus we hear a humming noiſe when we ſtop our ears. This noiſe is cauſed by the friction of the hand, or by the compreſſion which influences the ſkin and cartilages, whoſe parts being put into motion may produce an agitation there. The elaſticity of the air alſo and the tranſpired matter from the hand, mixing with the internal air in the meatus, may alſo ſtrike the organ, tho' not ſtrongly, yet ſufficiently to occaſion a noiſe, as the offending matter is ſo near.

Commotions of the cranium, and diſorders which contract the meatus, may alſo cauſe a *Tinnitus* in the ear. Several perſons alſo are ſubject to a peculiar noiſe in the ear, which is plainly a pulſation; this uſually affects them moſt after exerciſe, and may very often be heard by other perſons, who place their heads near the diſeaſed perſon's ear: this is unqueſtionably the true pulſation of a dilated artery, ſince it always regularly keeps time with the heart.

There ſeem alſo to be ſome ſpecies of *Tinnitus*, in which, tho' the humming noiſe is very ſtrong, yet the organ of hearing is itſelf no way diſtempered; ſuch are thoſe of perſons in deliriums in fevers, and of ſuch as are ſubject to epileptic fits; theſe laſt uſually hear a humming in their ears, before they are attacked with a fit, and this ſeems wholly produced by the agitated ſpirits, which diſturb thoſe parts of the brain where the extremities of the auditory nerve terminate.

The *Tinnitus* are therefore of two kinds; the one proceeding from a diſtemperature of the organ of hearing, the other from a diſorder of the brain; and the cure is to be attempted accordingly. In the ſharper *Tinnituſſes*, which are uſually occaſioned by inflammations and pains in the ear, where the parts are uſually very tenſe and dry, we muſt uſe the ſame means as in acute pains, and tenſions of the membrana tympani; but in dull humming heavy noiſes, which are uſually occaſioned by rheums and ſuppurations, where the membranes are relaxed, we are to uſe the ſame remedies which give relief in pains occaſioned by cold: After which it will be no difficulty to chuſe the moſt proper, while we have a due regard to the circumſtances, from which the more juſt indications may be taken. *Du Verney.*

TINNUNCULUS, in zoology, the name of one of the long-winged hawks, called by others *Cenchris*, and in Engliſh, *Keſtrel*, *Stannel*, or *Windhover*.

It is about the ſize of a common pigeon. Its bill is ſhort, crooked, and very ſharp, and covered with a yellow ſkin at the top; near this the bill is white, elſewhere it is blue. Its tongue is bifid; its mouth very wide, and its palate blue. Its head is large and flatted, and is of an aſh-colour, with longitudinal ſtreaks of black. Its back and wings are brown, variegated with black ſpots; its rump is grey, with ſome tranſverſe black ſpots; and its breaſt and belly of a pale ruſt-colour, with a few longitudinal ſtreaks of black. Its tail is long and pointed, its tip of a pale ferrugineous hue, with a broad tranſverſe ſtreak of black over it; and the reſt of the tail is a mixed grey and brown, with black ſpots and ſtreaks. Its legs and feet are of a fine yellow. It builds in hollow oaks, and lays four egs, which are white, variegated with a number of ſmall red ſpots. It feeds on partridges and other birds. *Ray*, Ornithol. p. 50.

TINTINNABULUM, among the antients. See the article BELL.

TINUS, *Lauruſtine*, in botany, the name of a genus of trees, the characters of which are theſe: The flower conſiſts of only one leaf, and is of the rotated kind, and divided into many ſegments at the edges. The center of the flower is perforated by the pointal of the cup, which finally becomes an umbilicated fruit, of the ſhape of an olive, containing a pear-faſhioned ſeed.

The ſpecies of *Tinus*, enumerated by Mr. Tournefort, are theſe: 1. The common *Lauruſtine*. 2. The *Lauruſtine* with nervous leaves. And 3. The ſmall-leaved *Lauruſtine*. *Tourn.* Inſt. p. 607.

TIPHLE, in zoology, a name by which ſome authors expreſs the acus, or tobacco-pipe fiſh. *Bellon.* de Aquat. 446.

TIPIOCA, a name given by ſome authors to a ſort of cream or flower made from the yucca or manihot-root, by maceration of it in water, after expreſſing the juice.

TIPSARIA, or TAPSARIA, a word uſed by ſome medical writers for barley-water.

TIPUL, in natural hiſtory, a name given by the people of the Philippine iſlands, to a ſpecies of crane common there, and ſo tall, that when it ſtands erect, it can look over a man's head.

TIPULA, in natural hiſtory, the name of a genus of fly, remarkable for the great length of its legs, and uſually called by us the *long-legs*.

There are a great variety of kinds of the *Tipulæ*; and the ſmaller ſpecies ſo much reſemble gnats, that the generality of authors, not excepting even Goedart and Swammerdam, have confounded the two genera, and deſcribed theſe among the gnats. The external appearance, however, is all that conveys an idea of likeneſs between them; for the gnat is furniſhed with a trunk, and other offenſive weapons, by means of which it is able to pierce our fleſh; and, on the other hand, the *Tipula* has only a mouth without teeth, and has neither inclination, nor is in a condition to do any harm. It is indeed very happy for us, that this is the caſe, ſince the *Tipulæ* are greatly more numerous than the gnats, and were thoſe vaſt clouds of ſmall *Tipulæ*, which we ſee in marſhy places and elſewhere, and uſually call clouds of gnats, in reality ſuch numbers of thoſe miſchievous animals, we ſhould not eaſily eſcape a good deal of trouble from them.

The long form of the body, the poſition of the wings, and the length and poſition of the legs, are the circumſtances that make the reſemblance between the gnats and *Tipulæ*; but the ſtructure and organs of the head are alone a very ſufficient diſtinction. All the ſpecies of gnats have their origin from water-inſects, whoſe form they never quit, till they become winged; but the *Tipulæ* are not ſo regular, in this reſpect; ſome of them being produced from water-worms, and others from inſects of the like form, that have lived on earth, and preyed upon the juices of plants.

As the *Tipulæ* differ from the gnats in the figure of the mouth, and in being without a trunk, they differ as much from the other flies of that character, by their reſembling the gnat in the ſhape of their body. They differ alſo in the conformation of the mouth, and its ſeveral parts and organs. The opening of the mouth is a ſlit extending itſelf from the fore-part of the head toward the hinder part, and its lips cannot be called upper and lower; but they are lateral ones. When the body of the creature is preſſed, this mouth opens, and ſhews what ſeem to be a ſecond pair of lips within. Theſe are more firmly cloſed than the others, and reſemble only certain duplications of the fleſh. The exterior lips are cartilaginous, and are furniſhed with ſhort hairs; the interior are perfectly ſmooth, and of a fleſhy texture. The head of the *Tipula* is of a long and ſlender figure, and is of the nature of thoſe which we call the ſemi-trunk heads, as they much approach to the figure of the trunks of ſome other inſects. The lips are articulated at the extremity of this head, and on each ſide there ſtands, on the upper part, a ſort of beard, which, when nearly examined, is found to be articulated in the manner of the antennæ of inſects. Theſe two beards, in their uſual poſition, are placed cloſe together, and bent forwards over the head: Their office ſeems to be the covering the aperture of the mouth. Theſe ſeem conſtantly to be found in all ſpecies of the *Tipulæ*, and placed exactly in the ſame manner. They may therefore be uſed as a character of the creature; and if there ſhould be found any ſpecies wholly reſembling the *Tipulæ*, but wanting theſe, it may be very properly called a *protipula*. *Reaumur*, Hiſt. Inſ. vol. 9. p. 7.

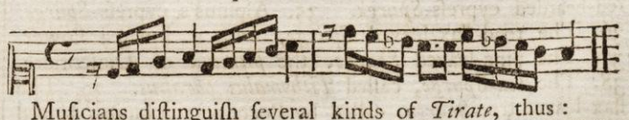
The larger ſpecies of *Tipulæ* are uſually found in our meadows, and theſe are in no danger of being confounded with the gnat kind, their ſize alone being a ſufficient obvious diſtinction. Theſe are often found of nearly an inch in length from head to tail; but their bodies are very ſlender, and are compoſed of only nine rings. The male *Tipula* is eaſily diſtinguiſhed, at ſight, from the female. It is much ſhorter in the body, and is thicker at the tail than any where elſe; this tail alſo uſually turns upwards, whereas that of the female is placed in the

ſame line with the body, and is ſlender, and compoſed of ſeveral ſcaly parts, proceeding from the laſt ring of the body. Theſe creatures are found in our meadows through the whole ſummer; but the end of September and beginning of October is the time when they are moſt of all plentiful: They are ſo common in ſome meadows, in theſe months, that there is no walking a ſtep without putting up whole flights of them. They are extremely well furniſhed by nature either for walking or flying. In the middle of a hot day they will often riſe to a great height in the air, and take long flights; but at other times they uſually only fly to one part of a field from another. They ſometimes uſe their wings alſo in the manner of the oſtrich, aſſiſting their legs with them in running; and ſometimes they make no ſmall uſe of their legs in their ſhort flights, the ſpring with which they throw themſelves off from a plant, carrying them to half the diſtance they are going to.

The legs of theſe creatures are greatly diſproportioned to the body, according to the common rules of nature, eſpecially the hinder pair, which are in the larger ſpecies uſually three times the length of the body. Theſe carry them ſafely and eaſily among the plants, and ſeem of the ſame uſe to them that ſtilts are to boys, in wading through dirt. This large ſpecies is a creature of no great beauty. Its body is of a browniſh colour, and its corcelet is ſo elevated, that the creature ſeems hump-backed. The head is ſmall, and the neck very ſhort. The reticulated eyes are ſo large, that they cover almoſt the whole ſurface of the head; theſe are of a greeniſh colour, with a caſt of purple, when viewed in ſome lights. Mr. Reaumur very carefully examined the head, to find out ſome of thoſe ſmaller ſhining eyes which other inſects of the fly kind have, and which reſemble thoſe of ſpiders: Theſe are uſually placed in a triangular figure on the head; but in this creature there are none of them in the common place; there appear indeed two lucid ſpecks, one at the origin of each of the antennæ, when the head is carefully examined with a microſcope: But Reaumur does not allow theſe to be eyes, he rather ſuppoſes that two very lucid ſpecks, on the anterior part of the breaſt, are eyes, though placed in ſo very ſingular a manner. The wings of this creature are long, but very narrow, and ſeem ſcarce well proportioned to the ſize of the animal; they are tranſparent, but have a ſlight caſt of brown; and their ribs, when viewed by the microſcope, appear beſet with ſcales, or feathers, in the manner of thoſe of the gnat kind. Some ſpecies of the *Tipulæ* have them alſo fringed, with theſe ſcales at the edges. There are no ailerons, or petty-wings, at the origin of theſe, as is the caſe in many of the other ſpecies of two-winged flies; but in the place of them there are two very fine balancers or mallets. Theſe have long pedicles, and roundiſh or oval heads. The ſtigmata of the corcelet are four; one pair are placed immediately underneath theſe balancers, and the other immediately below the firſt pair of legs. The firſt pair are very long, the others ſmall, and thoſe on the rings of the body, if there be any, are too ſmall for our ſight, even with good glaſſes. Each ring of the body is compoſed of two half cylinders, which are joined into one, by means of a membrane, which gives them room to diſtend or cloſe up at the creature's pleaſure. The large *Tipulæ* all carry two antennæ, or horns, upon their head; but theſe are of no remarkable ſtructure, they are only compoſed of a great number of joints, each covered with a fine downy hairyneſs; and at the joining of each to the next, there is a tuft of longer and more ſtiff hairs. This is the deſcription of the common large *Tipula* which we find in the meadows; and in almoſt all its parts, is applicable to the generality of the larger ſpecies of theſe inſects. *Reaumur*, Hiſt. Inſ. vol. 9. p. 13.

The ſmaller kinds are very numerous, and of great variety. Theſe are frequent in all places, and at all ſeaſons of the year: The ſpring ſhews us immenſe clouds of them, and even the coldeſt winter's day ſhews a great number of them in the ſunſhine about noon. Theſe creatures fly much better than the large *Tipulæ*; they ſeem indeed to be almoſt continually upon the wing, and their manner of flight is very ſingular; they are continually mounting and deſcending again, and that without quitting the direction of the line they go forward in; this they will often do for many hours together. In tracing theſe flies from their origin, they are all found to be produced from worms which have no legs, and have a regular ſcaly head. Thoſe from which the larger *Tipulæ* are produced, live under ground; they are moſt fond of marſhy places; but any ground will do that is not often diſturbed. They uſually are found at about an inch under the ſurface, and are ſo plentiful in ſome places, as greatly to injure the herbage. When they get into corn-fields, they cauſe whole acres of the corn to wither before it grows into the ear, and even in paſture-land the graſs is ſometimes ſo entirely deſtroyed by them, that there is no food for cattle in places where the herbage uſed to be ever ſo plentiful and ſtrong. It has been ſuppoſed from this, that they eat up the roots of the plants; but this is not the caſe; they feed only on the ſmall inſects which live under ground, and take in a large quantity of dirt with them into their ſtomachs. The miſchief they do, is by their being continually in motion, and looſening by this means the earth from about the roots, ſo that they dry up with the ſucceeding heat of the ſun.

Theſe creatures do not find it neceſſary to their living, that plants ſhould be upon the ſurface of the earth in which they live. There is frequently found in the hollows of the ſtumps of old trees, a ſort of earth which ſeldom produces any vegetables; yet the female flies of this ſpecies well know that their young will find a proper ſubſtance there; and there are uſually found great numbers of them in all theſe places. The hollow elms and willows, ſo common in our hedges, and by ditch-ſides, afford innumerable proofs of this: but it muſt be obſerved, that they are only found in ſuch earth of this kind, as is continually ſomewhat moiſt; that is, ſuch as is placed in a cavity which will retain the wet that falls into it; for when the earth lies in places where the water eaſily drains off, there never are found any of theſe inſects in it. Mr. Reaumur mentions a very ſingular ſpecies of large *Tipula*, which was produced with him from one of the worms found in the earth of an old elm; this was of the larger kind, and had ſome beautiful ſpots on the wings. It had alſo very elegant tufted antennæ; whereas, in the common large *Tipulæ*, theſe are plain and ſimply granulated ones, as well in the males as females. *Reaumur*'s Hiſt. Inſ. vol. 9. p. 17.



Mr. Ray, in his hiſtory of inſects, deſcribes fourteen ſpecies of this fly found in England. 1. The common *Long-legs*. This is about an inch long, and its antennæ are ſhort and ſlender, and its eyes black. The male of this ſpecies is more obtuſe at the tail than the female. 2. A very large kind, with large wings ſpotted with brown and white. 3. A large kind, with two large black ſpots on the wings. 4. A very beautiful *Tipula*, with black ſhoulders and back, a yellow belly, and ſome brown ſpots on the wings. 5. The yellow-winged *Tipula*, with ſpots on the wings, and a black and yellow body. 6. The common ſmall *Tipula*, with brown wings, ſpotted with white, and with opake dark brown ribs. 7. The middle-ſized black and yellow *Tipula*. 8. The long-legged *Tipula*, with ſhining black eyes. 9. The ſmall purple-winged *Tipula*, with a black back and yellow belly. 10. The middle-ſized green-eyed *Tipula*. 11. The browniſh-grey *Tipula*, with extremely long antennæ. 12. The elegant *Tipula*, with plumoſe antennæ. 13. The ſmall *Tipula*, with brown wings ſtreaked with black. And 14. The ſmall *Tipula*, with ſtriated wings, each having one very large black ſpot near the end. *Ray*'s Hiſt. Inſ. p. 72.

The white *Tipula* is a very beautiful little inſect; it is very common in gardens, and among buſhes in September and October; and tho' it appears all over white when ſeen at a diſtance, yet is not found to be ſo when examined more nearly. The wings, when the creature is ſitting, cover the whole body, and theſe are white; but the body itſelf is of a yellowiſh-green in that part next the head, and of a browniſh-black in the hinder part. The head of this creature is very ſmall, but the antennæ, or horns, are extremely long, and very beautifully feathered; they ſeem indeed a load to the creature to carry, and in their uſual poſition are croſſed one over the other in ſuch a manner, as to appear only one body together. *Reaumur*, Hiſt. Inſ. vol. 9. p. 20.

TIRATA, in the Italian muſic, is uſed to expreſs, in general, any quantity of notes, of whatever kind, provided they be of equal value, moving either upwards or downwards in conjoint degrees; thus they ſay, *Tirata di Semiminime*, when there are many crochets following one another in the manner above mentionod; *Tirata di Legâture*, when there are many notes of the ſame value following one another, among which the laſt of one bar, and the firſt of the next, are tied together by a ſemicircle, thus; ⌣ or ⌒.

Tirata is particularly uſed for a ſeries of quavers, or, in the modern notation, of demi-quavers or demi-ſemi-quavers, aſcending or deſcending by gradual intervals.

Theſe *Tirate* often, tho' not neceſſarily, begin with an unaccented note, and end on ſome accented one of greater duration. See the example annexed.

Muſicians diſtinguiſh ſeveral kinds of *Tirate*, thus:

1. *Tirata mezza*, or *mezza Tirata*, is that compoſed of three or four quick notes to aſcend, or deſcend to a note, a fourth, or fifth, higher or lower than the note from whence the *Tirata* begins; as in the examples before given.

2. *Tirata defectiva* is when theſe running notes go beyond the fifth, but do not reach the octave.

3. *Tirata perfecta*, is when it runs through the notes of a whole octave, aſcending or deſcending.

4. *Tirata aucta*, or *excedens* is when it goes beyond the compaſs of an octave.

The French call the *Tirata*, *Tirade*, and ſome call them *roulades*, but improperly, ſays Broſſard.

TIRSIO, in ichthyology, a name given by Gaza and ſome other authors to the phocæna of Willughby and others, the porpeſſe, or marſuin. It is a ſpecies of the delphinus, according to the Artedian ſyſtem; and is called the dolphin with a conic ſhaped body, a broad back, and a ſharp ſnout. Pliny, Bello-

Bellonius, and many others, call it *turſio*. See the articles TURSIO, PHOCÆNA, and DELPHINUS.

TIRSITES, a word uſed by ſome to expreſs foſſile coral.

TISRI, or TIZRI, the firſt hebrew month of the civil year, and the ſeventh of the eccleſiaſtical or ſacred year.

The Hebrews call it *Roſh-haſhanna*, that is, the beginning of the year. It anſwered to the moon of September. On the firſt day of this month was kept the feaſt of trumpets, becauſe the beginning of the year was then proclaimed by ſound of trumpets. On this day they refrained from all ſorts of ſervile buſineſs, and offered in ſacrifice a calf, a ram, and ſeven Lambs. Levit. xxiii. 24. Numb. xxix. 1. *Calm.* Dict. Bibl. in voc.

TITANIA, τιτανια, in antiquity, a feſtival in memory of Titanes. *Potter*, T. 1. p. 433.

TITANOS, a word uſed by ſome authors to expreſs lime, by others for the calx of burnt gypſum or plaiſter of Paris, and by others a lixivium of quicklime.

TITHENIDIA, τιθηνιδια, in antiquity, a Spartan feſtival, ſo called from τιθηναι, nurſes, who at this time carried the male infants committed to their charge to the temple of Diana Corythallia. For the ceremonies obſerved on this occaſion, ſee *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 432. ſeq.

TITHYMALOIDES, in botany, the name of a genus of plants, the characters of which are theſe: The flower compoſed of only one leaf, and in ſome degree reſembles a ſhoe; the piſtil finally becomes a fruit like that of the *Tithymal* or ſpurge.

The ſpecies of *Tithymaloides* enumerated by Mr. Tournefort are theſe: 1. The ſhrubby *Tithymaloides* with very large myrtle-like leaves. 2. The orpine-leaved ſhrubby *Tithymaloides*. 3. The nerium-leaved ſhrubby *Tithymaloides*. *Tourn.* Inſt. p. 654.

TITHYMALUS, *Spurge*, in botany, the name of a large genus of plants the characters of which are theſe: The flower conſiſts of one leaf, and is of the campaniform kind but globoſe, divided into ſeveral ſegments at the edge, and incloſed in two little leaves which ſeem to ſerve in the place of a cup to it. The piſtil ariſes from the bottom of the flower, and is uſually of a three-cornered ſhape; this ripens into a fruit of the ſame form, which contains many oblong ſeeds.

The ſpecies of *Tithymal* deſcribed by authors are theſe: 1. The myrtle-leaved tree-*Spurge*. 2. The broader-leaved tree-*Spurge*; this is evidently no other however than a variety of the firſt ſpecies, ſince, though very different in appearance, it ariſes from the ſeeds of that plant. 3. The turberoſe-rooted tree-*Spurge*, with ſmooth leaves, and a rough wart-like ſeed. 4. The leaf leſs African tree-*Spurge*. 5. The cotinus-leaved American tree-*Spurge*. 6. The cotinus-leaved tree-*Spurge*, with ſmaller leaves ſtanding in bundles about the ſtalk. 7. The blunt almond-leaved tree-*Spurge* of America. 8. The toad-flax-leaved tree-*Spurge* of America. 9. The box-leaved ſhrubby American-*Spurge*. 10. The pale flowered Æthiopian tree-*Spurge*, with leaves like thoſe of the German mezereon. 11. The red almond-leaved exotic-*Spurge*. 12. The wood-*Spurge*, with lunated flowers. 13. The hairy-leaved almond-*Spurge*. 14. The creeping-rooted almond-*Spurge*. 15. The gromwel-leaved *Spurge*. 16. The broad-leaved *Spurge*, called *lathyris* and *cataputia* by authors. 17. The broad-leaved Spaniſh *Spurge*. 18. The wild German broad-leaved *Spurge*. 19. The yellow-leaved *Spurge*, with hairy and finely indented leaves. 20. The ſoft hairy wood-*Spurge*. 21. The great broad-leaved *Spurge*. 22. The hoary meadow-*Spurge*. 23. The red-ſtalked willow-leaved and blite-leaved *Spurge* of Curaſſo. 24. The green ſtalked willow and blite-leaved *Spurge* of Curaſſo, with ſmooth leaves. 25. The little annual narrow-leaved *Spurge*, called by many authors *eſula*. 26. The little rock-*Spurge*. 27. The obtuſe-leaved little *Spurge*. 28. The annual *Spurge* with leaves like thoſe of flax. 29. The gentle mountain ſmall *Spurge*, called ſweet *Spurge*, and *eſula dulcis*. 30. The wart-*Spurge*, or rough-fruited *Spurge*. 31. The narrow-leaved wart-*Spurge*. 32. The narrow-leaved almond-*Spurge*, called *alypum* by ſome authors. 33. The cypreſs-*Spurge*, called alſo *humipinus*, and *eſula* in the ſhops. 34. The red-bearded cypreſs-*Spurge*. 35. Alpinus's cypreſs-*Spurge*. 36. The toad-flax-leaved *Spurge*, with a lunated flower. 37. The pine-leaved *Spurge*, the *pithiuſa* of Dioſcorides. 38. The ſea-*Spurge*, called *Tithymalus paralius*. 39. The flax-leaved tree-*Spurge*, called by Boccone the juniper-leaved ſea-*Spurge*. 40. The prickly ſea-*Spurge*. 41. The narrow-leaved almond-*Spurge*. 42. The jaggy-leaved almond-*Spurge*. 43. The almond-*Spurge*, with a thick pear-faſhioned root. 44. The little willow-leaved *Spurge*. 45. The tuberoſe or knotty-rooted *Spurge*, called by ſome *apios*. 46. The long-rooted tuberous *Spurge*. 47. The ſhrubby marſh-*Spurge*. 48. The broad-leaved triangular-fruited Portugal *Spurge*. 49. The olive-leaved bluiſh green *Spurge*. 50. The little ſmooth *Spurge*, with leaves like thoſe of money-wort, called *chamæſyche*. 51. The little hairy *Spurge*, with leaves like thoſe of money-wort. 52. The roundiſh-leaved not dentated *Spurge*, called by authors *peplus*, and *eſula rotunda*. 53. The common ſun-*Spurge*, or helioſcope-*Spurge*. 54. The annual *Spurge*, with oblong ſharp pointed leaves, called by Boccone the annual *peplis* with a moſſy flower. 55. The creeping annual *Spurge*, with a rounded yet pointed leaf. 56. The red ſea-*Spurge*, with obtuſe and auriculated leaves; the leaves and ſtalk of this plant are all red. 57. The green ſea-*Spurge*, with obtuſe auriculated leaves; both the leaves and ſtalk of this are green. 58. The many-fruited Sicilian *Spurge*, with leaves like thoſe of purſelain. 59. The perennial ſhort blunt-leaved kind. 60. The Spaniſh kind, with long heart-faſhioned leaves. 61. The Aleppo *Spurge*, with round hoary leaves. 62. The ſpreading American *Spurge*, with ſerrated leaves, and flowers ſtanding in cluſters in the alæ of the leaves. And, 63. The erect American *Spurge*, with ſerrated leaves, and cluſtered flowers ſtanding on long foot-ſtalks. *Tourneſ.* Inſt. p. 88.

TITILLARES *Venæ*, a name given by ſome Authors to the iliac veins.

TITILLICUM, a word uſed by ſome anatomical writers for the arm-pit.

TITMOUSE, in zoology. See the articles PARUS, and FRINGILLAGO.

TITT, in the manege. See the article NAG.

TIZRI, a Jewiſh month, anſwering to our September moon. See the article TISRI.

TIZZONAIOS, in the glaſs art, are two apertures, one on each ſide the working furnace, by which a ſervitor night and day puts in coals to maintain the fire. *Neri*'s art of Glaſs, p. 242.

TLAM, or SLAM, in the alum works, a word uſed by the workmen to expreſs a ſort of mud or foulneſs which does great hurt to the alum, rendering it foul and coarſe. The *ſlam* is a muddy ſubſtance ſettling to the bottom of the veſſels; but in the boiling the liquor it gives it a reddiſh colour, and diſorders the whole works when in any great quantity. They always paſs their liquor over four parcels of the alum rock, and the laſt if not carefully calcined generally gives it this diſadvantageous mixture. Phil. Tranſ. N°. 142.

TLAOLI, in botany, a name uſed by ſome authors for the plant called *maize*, *frumentum Indicum*, or Indian wheat. *Hernand.* p. 242. Piſo, Mant. Arom. p. 99.

TLAPALEZ-PATLI, in botany, a name uſed by ſome authors for the tree whoſe fruit is the ben-nut, and whoſe wood the Lignum Nephriticum of the ſhops. *Hernand.* p. 119.

TLAQUACUM, in zoology, the name given by the Spaniards and ſome others to a very remarkable animal in America, commonly known among us by the name of the *poſſum* or *opoſſum*. See the article OPOSSUM.

TLAQUATZIN, in zoology, a name by which the natives in ſome parts of America call the *opoſſum*. See the article OPOSSUM.

TLAQUATZIN *Spinoſum*, in zoology, the name by which Hernandez has called the cuanda, a ſort of Braſilian porcupine. See the article CUANDA.

TLATLANCUAYE, in botany, a name by which ſome authors have called the plant which produces the long pepper uſed in medicine. *Hernandez*, p. 126.

TLANHQUACHUL, in zoology, the name of a Braſilian bird, very much approaching to the nature of the European platea or ſpoonbill.

It is a very voracious bird, and feeds on live fiſh, but will not take or meddle with dead ones, and is all over of a beautiful red. It has a black ring round the upper part of its neck, and is common about the ſhores of the ſea and rivers. *Marggrave*'s Hiſt. of Braſil. See the article PLATEA.

TLAYOTIC, in natural hiſtory, the name of a ſtone found in new Spain, and uſed as a ſovereign remedy againſt the colic, and ſeveral other diſeaſes: it is a ſpecies of jaſper, approaching to the nature of the lapis nephriticus, and of a green colour. The natives cut it into ſeveral forms for uſe. See the article *Colicus* LAPIS.

TLEUQUECHOLTOTOTL, in zoology, the Mexican name of a bird of the wood-pecker kind, deſcribed by Nieremberg, under the name of the *avis ſalutiferus*; the feathers of a red creſt it carries on its head, being ſuppoſed a remedy for head-achs.

TLILZOCHITL, in botany, a name uſed by ſome authors for the plant whoſe pod is the fruit called vanilloes, and uſed in chocolate. *De Laët.* Ind. p. 230.

TMOLITES, the name of an excellent wine among the antients, like the Falernian.

TOAD, in zoology. See the article RUBETA.

TOAD-*Fiſh*, in ichthyology, an Engliſh name for the rana piſcatrix or lophius. See the article RANA.

TOAD-*Flax*. See the article LINARIA.

TOAD-*Powder*, *Pulvis Bufonum*. Dr. Kramer ſays, *pulvis bufonum*, when applied by way of pultice, with barley flour and urine, is an excellent remedy for ripening peſtilential buboes, but that it has no ſuch effect in venereal, or any other than peſtilential buboes.

TOBACCO (*Cycl.*)—In the iſland of Ceylon, there are two kinds of *Tobacco* cultivated for profit. They call both kinds *dunkol*, which ſignifies a leaf the uſe of which is to be ſmoaked. The one kind they call *hingele dunkol*, or *ſingele dunkol*; for they make no difference between the letters S and H in their pronunciation; the other they call *dunkol kappada*; *kappada* ſignifies gelding, and is a word of Portugueſe origin. This *kappada-Tobacco* is much ſtronger and more intoxicating than the other; but both kinds are the produce of the ſame plant; only the ſingle *Tobacco* has very little care

taken of it, being, after the ſowing, in a manner left to itſelf, while the other has great pains beſtowed upon it during the whole time of its growth, and till it is fit for uſe, in the following manner: They clear a little piece of ground, in which they ſow the ſeed of the *Tobacco*, and againſt the time that the young plants have got three leaves a-piece, they chooſe out another piece of ground into which to tranſplant them: This they hedge round, and turn their horned cattle into it, that their dung may fall upon it, and ſufficiently enrich it. The ground is then dug with a ſharp hoe, or ſpade, in the form of a pick-ax, and the dung, by this means, thoroughly worked into it. When the earth is thus prepared, they take up the young plants, and ſet them in this new ground, at about a foot ſquare diſtant from one another.

The manner of giving more or leſs ſtrength to this *Tobacco*, is by ſuffering the plants to grow to a greater or leſs height before they top them, or cut off the ſtalk at the ſummit. The uſual way is to cut off the top when the plant has fifteen leaves. If they intend the *Tobacco* to be a little ſtronger, they do this when it has only thirteen; and when they would have it ſtrongeſt of all, they do it when there are only eleven or twelve leaves. On the contrary, when they would have a milder *Tobacco*, they cut it not off till there be eighteen or twenty leaves; but in this way of counting the leaves, they never reckon the three or four loweſt, which do not grow ſo large and fine as the others. The cutting off the top, prevents the juices of the plant from being waſted in flowers and ſeeds, which are of no value; and, in conſequence of it, all being, after this time, employed to furniſh the growth of the leaves, they grow four times as large and thick as they otherwiſe would do.

To prevent all unneceſſary waſting of the ſap, theſe plants are tended every day; and as the young ſprouts appear in the joining of the leaves and ſtalk, they are continually cut off: This is done once in three days, till the leaves have their full bigneſs, which is about that time when the flowers would have been ripe, had the plant been ſuffered to grow in its natural way: They are immediately to be gathered when they are full grown, otherwiſe they waſte and decay. They cut down the whole plant, and bring them into their houſes, laying them on a heap. When they have lain a little time together, they begin to ſweat and grow hot: When they have been a little while fermenting, they turn them, bringing thoſe which were in the middle to the ſurface, and placing thoſe which were at the ſurface in the middle; by this means the whole quantity of leaves ferments equally. The longer they lie in this manner, the darker-coloured the *Tobacco* becomes. When they have left it thus to ſweat as long as they judge neceſſary, they hang every ſtalk ſeparately on cords; and when the whole is thoroughly dry, they carefully take off the leaves, and lay them by in bundles, till they have occaſion for them. This is the manner of their preparing the *kappada*.

The ſingle *Tobacco* is ſown in the ſame manner with this; but it is never tranſplanted nor tended, it grows as it pleaſes, and when the flowers are ripe, it is cut down, and laid careleſsly in heaps, where ſome of it ferments too much, and ſome too little. This is much weaker therefore than the *kappada*; and as both kinds are common in the place, the natives ſmoak them either ſeparately or together, mixed in different proportions, as they like. Some of the Ceiloneſe chew this ſtrong *Tobacco* with their beetle, and ſome, who ſmoke it alone, uſe no pipe, but, taking a long leaf of it, they roll it up into a long form, and cover it with the leaf of the wattukan-tree; they then light one end of it, and ſmoak by the other, till the whole is conſumed. Philoſ. Tranſ. N°. 278. p. 1145.

There are four or five kinds of *Tobacco* frequently raiſed by the curious in England. They are to be ſown in March, upon a moderate hot-bed, and when the plants are come up, they ſhould be tranſplanted to another hot-bed of moderate warmth, and ſet at four inches diſtance, watering and ſhading them till they have taken root: And as they grow ſtronger, giving them as much air as the ſeaſon will permit. In the beginning of May the plants will grow ſo large as to touch one another; and they are then to be taken up with a large ball of earth about their roots, and removed to a good ſoil, where they are to be planted at two foot aſunder every way. *Miller*'s Gardener's Dict.

Tobacco beat into a maſh with vinegar or brandy, and laid on the ſtomach, has ſometimes good effects in removing hard tumours of the hypochondria. We have the hiſtory of two cures made by ſuch applications in the Medic. Eſſ. Edinb.

The juice of this plant is ſaid to be good againſt ulcers and mortifications. *Boyle*, Works abr. Vol. 1. p. 56.

TOBACCO-*Pipe Fiſh*, the Engliſh name of the *acus*. See Tab. of Fiſhes, N°. 25. and the article ACUS.

TOBACTLI, in zoology, a name which Nieremberg ſays is often given to the American bird, more commonly called *Hoactli*. See the article HOACTLI.

TOBIANUS, in ichthyology, a name given by Schoneveldt and others, to the ammodytes, or ſand-eel.

TOBIS, in ichthyology, a name given by the Swedes to the ammodytes, or ſand-eel. The name *Tobianus*, given to this fiſh by Salvian, ſeems formed from its Swediſh name *Tobis*. Salvian is the firſt author who has deſcribed this fiſh, but his figure is not accurate, for he has given it two back fins inſtead of one.

TOCCATA, in the Italian muſic, is much the ſame as *Ricercata* or *Phantaſia*, *Taſtatura*, &c. But what diſtinguiſhes the *Toccata* from the other kinds of ſymphonies, is, firſt, its being uſually played on inſtruments that have keys, as organs, ſpinnets, &c. Secondly, that it is commonly compoſed to exerciſe both hands. Thus, ſometimes the baſs holds out a ſound, while the upper part makes diminutions, paſſages, or tiratas; and afterwards this part does the ſame, while the baſs moves in its turn. *Broſſard.*

TOCCATINA, in the Italian muſic, a ſhort reſearch, or *ricercata*. See the articles TOCCATA, *Suppl.* and RESEARCH, *Cycl.*

TOCCAVIENSIS *Bolus*, *Bole of Tokay*, in the materia medica, a fine medicinal earth, dug about Tokay in Tranſylvania, and eſteemed a powerful aſtringent. Kentman calls it the *bolus Pannonica vera*; and Crato, *bolus Hungarica*.

This laſt author eſteemed it ſuperior even to the bole armenic of Galen, and had a great opinion of it in malignant fevers. It is a fine and pure earth, and very heavy, moderately compact in its texture, but not very hard; and in colour of a conſiderably deep and ſtrong yellow. It is naturally of a ſmooth ſurface, and does not ſtain the fingers in handling. It ferments violently with acid menſtrua, and does not become red in burning. *Hill*'s Hiſt. of Foſſ. p. 7.

TOCKAY, in zoology, the name of a ſpecies of Indian lizard, diſtinguiſhed from the other kinds, by being ſpotted all over.

TOCMOL, in natural hiſtory, a name given by ſome to the common turtle.

TODDA-*Panna*, in botany, the name by which many authors call the *palma farinifera*, or ſago-tree. *Herm.* Cat. vol. 3. p. 9.

TODTENVOGEL, in zoology, a name by which Geſner and ſome other authors have called that ſpecies of œnanthe, known in England by the name of the *ſtone-chatter*, *ſtones-mich*, or *moor-titling*. *Geſner*, de Avib. See the article STONE-*Chatter*.

TOES (*Cycl.*)—*Adheſions of the* TOES. It is a frequent thing to meet with new-born infants with their fingers or *Toes* cohering or grown together, either by a ſtrict adheſion of the fleſh, or elſe by ſome looſe productions of the ſkin, as in the feet of ducks and geeſe; and a diſorder of the ſame kind is alſo ſometimes found in adults, from accidents; as when the fingers or *Toes* have been neglected, after an excoriation of them by burns or wounds. In both theſe caſes the ſurgeon's aſſiſtance is neceſſary, partly to remove the deformity, and partly to reſtore the proper uſe of the fingers.

Theſe adheſions, according to the nature of the diſorder, are to be ſeparated two ways, either by cutting out the intermediate ſkin with a pair of ſciſſars, or elſe barely by dividing them from each other with the ſame inſtruments. When this is done, to prevent their coheſions again, each finger muſt be inveſted ſeparately with a ſpiral bandage about an inch broad, dipped in lime-water and ſpirit of wine.

Sometimes the fingers, inſtead of adhering to each other, grow to the palm of the hand, from wounds or burns, ſo that they cannot be by any means extended, or drawn back to open the hand. The method of relieving this diſorder is firſt very carefully to ſeparate the fingers from their adheſions to the palm, without injuring their tendons, then dreſs them with a vulnerary balſam, and ſcraped lint, and extend them on a ferula or thick paſteboard; and let them remain in this extended poſture, ſeparately to be dreſſed till they are perfectly healed; but at every dreſſing they muſt be gently moved, to prevent a rigidity or ſtiffneſs of the joints. *Heiſter*'s Surgery. p. 330.

Bones of the TOES. Each of the *Toes*, except the greater one, conſiſts of three phalanges. The great *Toe* indeed has but two; but then there are five metatarſal bones, whereas there are but four metacarpal. The baſes of the phalanges remain for a long time epiphyſes. The firſt phalanx of the great *Toe* is very like the ſecond of the thumb; but its baſis is more hollow, anſwerably to the convexity of the firſt bone of the metatarſus, by which it is ſupported; its head is in form of a pulley, as in the thumb, but much broader: The ſecond, or laſt phalanx of the great *Toe*, is like the third of the thumb, but bigger and broader, eſpecially at its baſis. The tuberoſity, in form of a horſe-ſhoe, which terminates this bone, is alſo more unequal and more flat than in the thumb.

The firſt phalanges of the other *Toes* are the longeſt, but they are ſhorter and more convex than thoſe of the fingers. Their bodies are very narrow, and contracted in the middle, the baſes are generally excavated, and the heads made after the ſame manner as in the fingers. The ſecond phalanges are very ſhort, and almoſt without ſhape; both their baſes and heads are formed for articulations by ginglymi, but they are very imperfect. The bodies are of ſome length in the ſecond and third *Toes*; but they are very ſhort in the other two, eſpecially in the little *Toe*, in which the body is broader than it is long. The third phalanges are nearly of the ſame figure with thoſe of the fingers, but much ſhorter and thicker in proportion. In the two laſt *Toes* they are often united with

the ſecond phalanges, which is owing, perhaps, to the continual inaction and compreſſion occaſioned by ſhoes. *Winſlow*'s Anat. p. 103.

Ligaments of the TOES. The firſt phalanges of the *Toes* are tied to the heads of the metatarſal bones, by a ſort of orbicular ligament, ſet round the edges of the cartilaginous portions of the head, and thoſe of the baſes of the phalanges. In the four leſſer *Toes* of each foot, the inferior part of this ligament is very thick, and is cruſted over as it were with a cartilaginous ſubſtance, fixed to the baſes of the phalanges, and from thence continued over the head of the metatarſal bone next it. This ſubſtance grows hard with age like a ſeſamoide bone.

Of theſe ſeſamoide bones, as they are called, the great *Toe* has two belonging to the firſt phalanx, which are largeſt, ſooneſt formed, and moſt conſiderable of all. The ſecond and third phalanges of all the *Toes* being articulated by ginglymi, have lateral ligaments which go between the ſides of the baſes, and thence to the ſides of the heads: At the inferior edges of all theſe baſes there is a cartilaginous matter joined to theſe ligaments, which hardens with age in the ſame manner with thoſe of the firſt phalanges. *Winſlow*'s Anat. p. 135.

TOE, in the manege, is the ſtay of the hoof upon the fore-part of the foot, comprehended between the quarters.

We commonly ſay the *Toe* before, and the heel behind, in French, *Pince devant et Talon derriere*; implying, that in horſes, the *Toe* of the fore-feet is ſtronger than the *Toe* of the hind-feet: And, on the other hand, that the heels behind are ſtronger than thoſe before; and accordingly, in ſhoeing we drive higheſt in the *Toes* of the fore-feet and in the heels of the hinder feet. See the article DRIVE.

A horſe that does not reſt his hinder feet all equally upon the ſhoe, but raiſes his heels, and goes upon the *Toes* of his hind-feet, is called in French *Rampin*. See the article RAMPIN.

TOGA *Picta*, among the Romans, a purple gown embroidered with gold; which was worn during the ſolemnity of a triumph, by thoſe who had that honour conferred on them. It was an antient habit of the Etruſcans, and not brought to Rome till after *Tarquinius Priſcus* had ſubdued the twelve ſtates of that nation. *Hofm.* Lex. univ. in voc. *Picta*.

TOGOCH, in zoology, a name uſed by many for the umbla minor, or red charre, a fiſh caught in the lakes of Wales. The name is originally Welch. See the article CHARRE.

TOGULA, among the Romans, a narrow kind of *Toga*, uſed by the poorer ſort of people. See the article TOGA, *Cycl.* & *Suppl.*

TOKENS, in peſtilential caſes, thoſe livid ſpots which appear in the ſeveral ſtages of the diſeaſe, and are the certain forerunners of death. They generally appear only under the moſt deſperate circumſtances, and when the patient would otherwiſe be declared dying; but Hodges gives us inſtances where they appeared before any other ſymptoms of the diſeaſe, and came out without any pain or trouble; yet even in theſe caſes the perſon always died. Theſe *Tokens* are the mark by which the ſearchers conclude of the cauſe of the death of the perſon, and are the rule for ordering the houſe to be ſhut up, to prevent the ſpreading the diſeaſe. But the nurſes, and other crafty people have a way of diſguiſing this ſymptom after death, by covering the body with wet and cold ſheets. Theſe ſtrike in the ſpots, ſo that the perſon may be thought to have died by ſome other diſeaſe. *Hodges* de Peſt.

TOLCESTER, *Tolceſtrum*, in our old writers, an old exciſe or duty paid by the tenants of ſome manors to the lord, for liberty to brew and ſell ale. *Blount.*

TOLLENON, among the Romans, a warlike machine, formed in this manner: one beam was fixed very deep in the earth, and on the top of it another more than twice as long, and moveable upon a center. On one end of this croſs-beam were placed a covering of hurdles or planks, within which a few ſoldiers were put, and, by pulling down the other end with ropes, theſe were raiſed above the walls of a beſieged town. See *Pitiſc.* in voc.

TOLLENON, was alſo an engine for raiſing water out of a draw-well. *Pitiſc.* in voc.

TOLLES, or TOLÆ, names given by ſome to the tonſils, and by others to the glandular abſceſſes ſometimes affecting the limbs.

TOLSEY, in our old writers, denotes the place where merchants meet in a city or town of trade. *Blount.*

The word is compounded of the Saxon *Tol*, *tributum*, and *ſee*, *ſedes*.

TOLT, in law, a writ whereby a cauſe depending in a court-baron is removed into the *County-court*. Old. Nat. Br. 4. And as this writ removes the cauſe to the *county-court*, ſo the writ *pone* removes a cauſe from thence into the court of common-pleas, *&c.* *Terms of Law*, *Blount*, *Cowel.*

TOLTERCAIZTLI, in natural hiſtory, the American name of a ſtone, much reſembling the novacularum lapis, but variegated with red and black ſpots. They uſe the powder of this ſtone and cryſtal calcined together for diſeaſes of the eyes.

TOLUIFERA, in botany, the name of a genus of plants, ſo called from producing the balſam of Tolu. The characters are theſe: The perianthium conſiſts of one leaf, and is of a campanulated form, divided into five ſegments, and having one angle more remote than the others. The flower is compoſed of five petals, which are inſerted into the cup; four of theſe are ſtrait and equal in ſize, and are a little longer than the cup; but the fifth is twice as large as theſe, and is cordated at the end, and has an unguis of the length of the cup. The ſtamina are ten very ſhort filaments, but the antheræ are of the length of the cup, or ſomething more than that. The germen of the piſtil is oblong; there is ſcarce any ſtyle, and the ſtigma is acute. The fruit and ſeeds are yet unknown. *Linnæi* Gen. Plant. p. 182.

TOMATO, the Portugueſe name for the fruit of the lycopersicon, or love-apple; a fruit cultivated in gardens for the ſingularity of its appearance, and eaten either ſtewed or raw by the Spaniards and Italians, and by the Jew-families in England. See the article LYCOPERSICON.

TOMBAC, a name given by the French to a yellow metal, very nearly approaching to what we call prince's metal, and made by mixing and fuſing together a large quantity of zink with a ſmaller of copper.

TOMEION, a general name uſed to expreſs any ſharp or cutting inſtrument, uſed either in ſurgery, or in the mechanic arts.

TOMENTOSE-*Leaf*, among botaniſts. See the article LEAF.

TOMIAS, Τόμιας, in antiquity, an appellation given to the ſacrifice offered at the ratification of ſolemn leagues.

It was ſo called becauſe they cut out the teſticles of the victim, and took the oath ſtanding upon them. *Potter* Archæol. Græc. T. 1. p. 252.

TOMIN, in our old writers, a weight of twelve grains, uſed by goldſmiths and jewellers. *Blount.*

TOMINEIO, in zoology, a name by which ſome authors have called the guainumbi, or humming bird, the ſmalleſt of all birds. *Joſeph Acoſta*, Ind. Occ. L. 4. c. 37. See the article GUAINUMBI.

The name ſeems derived from the Spaniſh *Tomino*, a grain weight, as if they would call it a bird of a grain weight.

TOMOTOCIA, a word uſed by ſome authors, to expreſs the Cæſarean ſection.

TONE (*Cycl.*)—TONE, *in Muſic.* The word *Tone* is taken in four different ſenſes among the antients: 1°. for any ſound. 2°. For a certain interval, as when it is ſaid the difference between the diapente and diateſſaron is a *Tone*. 3°. For a certain *locus* or compaſs of the voice; in which ſenſe they ſaid the Dorian, Phrygian, Lydian *Tones*. 4°. For tenſion; as when they ſpeak of an acute, a grave, or a middle *Tone*. *Wallis*'s Append. ad Ptolem. Harm. p. 172.

In tempered ſcales of muſic, the *Tones* are made equal, but in a true and accurate practice of ſinging they are not ſo. Dr. *Pepuſch*, in Phil. Tranſ. N°. 481. p. 274.

It is uſual in the modern practice of muſic to divide the *Tone*, whether major or minor, into two *ſemi-Tones*. But a late learned muſician contends, that the diviſion of the *Tone-major* is harſh and in-elegant; ſo that, in dividing the fourth into its different ſpecies, the *Tone-major* ought either to be an individed interval, or make part of one. Phil. Tranſ. ibid See the article SPECIES.

According to Mr. Euler, the *Tone* contains two *ſemi-Tones*, taken in a large ſenſe; that is, including the greater and leſſer limma, under the term *Tone*. Thus the *Tone-major* is the ſum of the *ſemi-Tone major* and leſſer limma; as alſo the ſum of the leſſer *ſemi-Tone*, and greater limma. See the article LIMMA. And the *Tone-minor* is the ſum of the greater and leſſer *ſemi-Tones*. Laſtly, the greateſt *Tone*, *Tonus maximus*, is the ſum of two greater *ſemi-Tones*. *Euler*, Tentam. Nov. Theor. Muſ. p. 109.

But what Mr. Euler calls *Tonus maximus*, is more commonly known by muſicians under the name of a diminiſhed third. For thus they call the interval, for inſtance, between G♯ and B♭; it being compoſed of two diatonic intervals G♯ to A, and A to B♭. Vid. *Broſſard.* Dict. Muſ. p. 179.

TONE-*Major*—Six *Tones-major* exceed the octave by more than a comma. *Euler*, Tent. Nov. Theor. Muſ. p. 108.

TONGUE (*Cycl.*)—The *Tongue* is generally eſteemed a neceſſary organ in ſpeaking, ſwallowing, and taſting, yet a woman, who loſt her *Tongue* entirely by a cancer when four years old, ſpeaks diſtinctly, ſings prettily, ſwallows eaſily, and taſtes accurately. Phil. Tranſ. N°. 464. §. 11.

And this inſtance is not ſingle. Another occurs in *Lamberti*'s Memoirs; and a third, in the Memoirs of the Academy of Sciences.

TONGUE-*tied*, the popular name for a diſtemperature of the *Tongue* in children, when it is tied down too cloſe to the bottom of the mouth, by a ligament connected all along its middle, and called its frænulum, which requires to be divided, to give the *Tongue* its proper motion.

This is ſometimes the caſe in adults, but oftner in children, who cannot then exert their *Tongues* to ſuck. This is however, by no means ſo common as the women uſually imagine; not ſo much as one child in a thouſand being afflicted with it; nor is the operation in cutting it of little conſequence, ſince often bad accidents follow it, and ſometimes the loſs of a child's life. When the infant can put its *Tongue* out of its mouth, the frænulum wants no inciſion; but when the *Tongue* cannot be extended beyond the teeth, the operation is neceſſary. *Heiſter*'s Surgery, p. 466. *Heildan*, Cent. 3. Obſ. 28.

To perform this, the end of the *Tongue* ſhould be covered with a linnen rag, and held with the fingers to prevent its ſlipping, and the ligament of the *Tongue* running between the ranular veins and internal ſalival ducts, is to be divided by a pair of obtuſe pointed ſciſſars, till it give room enough for ſucking or ſpeaking, but in doing this great care muſt be taken not to wound the ſalival ducts, or the proper veins and arteries of the *Tongue*; for children have been known to periſh upon the ſpot from the cutting the ranular veins in this operation. Midwives often tear this ligament with their fingers as ſoon as a child is born; but this is a dangerous and bad practice.

TONGUE *Wounded.* The *Tongue* is frequently bit in fits of the epilepſy, and in violent falls; and is ſometimes wounded by a bullet.

If the wound is not very large, it will eaſily heal by the application of oil of almonds and ſugar-candy mixt together, or of honey of roſes and oil of myrrh made *per deliquium*; but large wounds of the *Tongue* will not unite without the aſſiſtance of the ſuture. It is therefore no wonder that wounds near the root of the *Tongue* always leave a fiſſure in the part, ſince their ſituation does not allow the uſe of the needle. To prevent the loſs of ſpeech enſuing upon large wounds on the fore part of the *Tongue*, the divided parts ſhould be brought together with the needle as ſoon and as neatly as poſſible, and afterwards anointed with oil of almonds and ſugar-candy, or honey of roſes and oil of myrrh; ſince ſticking plaſters cannot take place here. Gun-ſhot wounds on the *Tongue* can only be healed with theſe unctions, ſince the ſuture can be of no uſe in them: the patient ſhould be kept from talking, and live upon ſpoon-meats during the cure, but more particularly at the time when the wound is about to unite. *Heiſter*'s Surg. p. 81.

TONGUE *of Fiſhes.* All fiſhes have either a perfect *Tongue* or the rudiments of one in their mouths; but this organ is very different in the various ſpecies, in its figure, mobility, and other qualities and properties: as to the figure, it is in ſome pointed before, as in the clupeæ; in others it is rounded in this part, as the pearch and clariæ have it. And in others it is ſomewhat bifid, as in the pike. In ſome it is ſmooth on the upper part, as in the gadi, cyprini, and mackrel; in others it is rough and dentated in this part, as in the ſalmon, mullet, *&c.*

In many fiſh the *Tongue* is immoveable adhering firmly to the bottom of the mouth, as in the pearch, cyprinus, and indeed in the greater part of fiſhes; in others it is looſe, as in the whale.

In the cetaceous fiſhes the *Tongue* being looſe, as in quadrupeds, it is uſed by the animal in the ſame manner; but in other fiſhes it is of no uſe in the moving the food about in the mouth, nor is it the genuine organ of taſte, being in many of a cartilaginous ſubſtance, and therefore not proper for receiving the notices of that ſenſe. The principal uſe of the *Tongue* in theſe fiſh, ſeems to be in its ſerving as an aſſiſtant organ of ſwallowing, its being more elevated than the other parts of the mouth, rendering it fit for the toſſing the food down the throat. The true uſe of the *Tongue* in thoſe fiſhes which have it dentated, is that it ſerves to retain the prey from running out of the mouth, and afterwards in the ſwallowing it; what renders them the more fit for this uſe is, that, they have always the prickles turning inwards. It is the opinion of Mr. Ray, that the *Tongues* of the cartilaginous kinds have ſome ſenſe of taſte, and this is more probable, than that the more hard and rigid ones ſhould have any ſuch ſenſe. *Artedi*, de Piſcib.

It is but of late, that we have known enough of the anatomy of ſea-animals, to be able to refer to their proper origin many of the foſſile bodies which belonged once to them: an eminent inſtance we have of this in the *Tongue* of the fiſh called the *paſtinacha marina* by compariſon with which Sir Hans Sloane explained the nature of a very elegant foſſil, found ſometimes with us, but oftner in the Eaſt-Indies, ſometimes in the Weſt, and every where till then ſuppoſed to be a petrified muſhroom. The paſtinacha marina is a fiſh of a flat ſhape, and allied to the thornback kind. The *Tongue* of this fiſh is made up of many bones, all of them crooked, their two ſides making an obtuſe angle, ſuch as the ſides of the under mandible of a man do.

The uppermoſt ſides of theſe ſeveral bones, have furrows and pieces ſtanding together, after the manner of the teeth of a ſhort ſmall-toothed comb, or ſomewhat reſembling what we call the gills, on the under ſide of a common muſhroom; and to this furrowed appearance in the foſſile pieces, was owing the general error of taking them to be of the fungus kind. The extant parts of theſe toothed points in the *Tongue* anſwer to the like parts in the bones of the upper jaw of this fiſh; and between theſe and this bony *Tongue*, the food of the fiſh is cut and ground to pieces. The under ſide of the *Tongue* is, in the ſame manner as the upper, divided into ſeveral crooked pieces; but theſe have in this part no teeth or points: the whole *Tongue* of this fiſh is ſometimes found foſſile, converted into a ſort of ſtone, but this more frequently happens to the ſeveral joints or ſingle bones of which it is compoſed, and theſe are often mutilated or broken. The palate of the ſame fiſh is alſo ſometimes found either whole or in parts, and both the one and the other are of the number of thoſe things, called by Mr. Lluyd *ſiliquaſtra*, from a ſuppoſed reſemblance in them to the pods of the lupine, or ſome other ſuch plant; but he has diſtinguiſhed theſe from the reſt by calling them *ſiliquaſtra pectinata*, or the comb-like ſiliquaſtra. Phil. Tranſ. No. 230.

TONGUE *of a Muſcle.* What is vulgarly called the *Tongue* in this fiſh from its ſhape, is truly an organ by means of which it ſpins a ſort of threads in the manner of ſpiders or caterpillars; to fix itſelf to the rocks by. See the article MUSCLE.

TONGUE, in the manege. The aid of the *Tongue* or voice, is a ſort of agreeable clacking, or a certain ſound formed by the cavalier, in ſtriking his *Tongue* againſt the roof of his mouth, when he means to animate the horſe, and ſuſtain him, and make him work well in the manege. See the article AID.

To ſwallow the TONGUE, in the manege. A horſe is ſaid to draw in or ſwallow his *Tongue*, when he turns it down his throat, which makes him wheeze as if he were ſhort winded. This fault is cured by giving him a bitt with a liberty for the *Tongue*. See the article LIBERTY.

TONICUM *Diatonum.* See the article GENUS.

TONOS, a word uſed by Hippocrates to expreſs in general any nerve, whether ariſing from the brain or ſpinal marrow. It is alſo uſed to expreſs a tenſion in any part.

TONSÆ, among the Romans, the blades of oars, or that part of them which beats againſt the water. *Pitiſc.* in voc.

TONSILLS (*Cycl.*)—*Inflammation of the* TONSILLS. This is a very common complaint from taking cold, and in its different degrees requires different methods of cure: in general the ſame means are to be uſed as in quinſeys, except that ſuch copious bleedings are not neceſſary; nor indeed is there occaſion for bleeding at all unleſs the patient is of a plethoric habit, or the inflammation be very violent, for in that caſe, the taking away a moderate quantity of blood often prevents its coming to ſuppuration. The patient is firſt to be purged with an infuſion of tamarinds, ſena, and cream of tartar, and this repeated to the third or fourth doſe, if there be occaſion; in the intermediate times, the diaphoretic attemperating and nitrous medicines are to be given in powders, and a large quantity of diluting liquors allowed, which ſhould be gently acidulated, and have a ſmall quantity of nitre diſſolved in them. Gargariſms made of decoctions of biſtort root, red roſes, and other gentle aſtringents, are to be frequently uſed; and the frequent waſhing the feet in warm water often has a very remarkable good effect.

If after four or five days the diſtemper is found not to give way to theſe means, but the tumour ſtill remains; there is then but little hopes to be had of its reſolution, and a very different end is to be attempted; emollient gargariſms are now to be uſed and maturating plaſters externally applied, ſuch as diachylon with the gums, and the like; and ſuppurating cataplaſms are to be applied to the whole neck and throat: theſe methods are to be continued till the tumour either burſts of itſelf, or is ſo ripe as to be fit for opening by the hand of the ſurgeon. After this has been done, and the matter is diſcharged, gargariſms muſt be uſed of decoctions of ſome vulnerary herb, or common green tea, ſweetened with honey of roſes, may be uſed to ſerve the purpoſe. The mouth and throat are to be frequently waſhed with this till the part is healed. It is to be obſerved, however, that the reſolution of theſe tumours is never to be deſpaired of, not even during the uſe of the ſuppurating medicines, for it is often ſeen that the tumour has been wholly diſcuſſed even during the uſe of theſe means, the reſolution often being extremely ſlow.

This is a very troubleſome complaint, and with ſome perſons is apt to return very frequently; the beſt preſervative againſt it is a moderate diet and bleeding about the time of the equinoxes, either in the arm or foot. Some have found it neceſſary to open an iſſue in the arm, in this caſe, and have been by this means perfectly cured, but on its drying up have always found the diſeaſe return. *Heiſter*'s Compend. Med. p. 131.

TOOTH-*Ach* (*Cycl.*)—When this terrible pain will give way to no other remedy, it is ſaid it may be ſpeedily removed by cauterizing behind the ear underneath the protuberance termed antitragus. There are ſeveral methods of doing this: ſome uſe a cautery prepared on purpoſe, others only a common ſmall iron nail, or a piece of iron wire, and others heat a ſcalpel red hot and plunge into the part; others alſo affirm that as much ſervice is to be done by cutting there without cauterizing, ſuppoſing that the operation deſtroys a nerve going thence to the *Tooth*, which is the occaſion of the ſenſe of pain in it. But it is to be doubted whether this ſevere remedy be as certain of ſucceſs as ſome pretend. *Heiſter*'s Surgery, p. 434.

TOOTH-*drawing*. *Tooth-drawing* according to Cicero was invented by Eſculapius, in whoſe temple the antients hung up a pair of leaden pullicans, very properly ſignifying that no *Teeth* were fit to be pulled out, but ſuch as might be removed with a leaden forceps; that is ſuch as were looſe and ready to fall out of themſelves; for they very little conſult their own welfare, who pull out their *Teeth* while firm and ſound: for drawing the *Teeth* is not only a painful operation, but often brings on bad accidents, and ſometimes even hazards the patient's life.

Tooth-

Tooth-drawing, however wrong in many caſes, yet is certainly right and neceſſary in others. 1. In children for the removing their lacteal or deciduous *Teeth*, for when theſe are left too long in their ſockets, they diſplace the new ones and turn them awry. 2. In infants it is alſo neceſſary to draw ſuch *Teeth* as grow out of the palate, or out of improper parts of the mouth, and are placed ſo as to impede their ſpeaking or ſucking. 3. In the *Tooth-ach* proceeding from a *Tooth*'s being carious, and giving way to no medicines, drawing is the laſt reſort, and is abſolutely neceſſary. 4. Thoſe *Teeth* ought to be drawn which by their irregular figure and poſition lacerate the gums and lips, and cannot be brought into ſhape by the file. And laſtly, it is ſometimes neceſſary to draw a *Tooth* for the curing a fiſtula, or ulceration of the gums near the roots of the *Teeth*.

The regular method of drawing them is this: If the *Tooth* is in the lower jaw, the patient muſt be ſeated on a low ſeat, or on the floor, and if in the upper jaw, he muſt be placed on a high ſtool or table; then the proper inſtrument is to be ſelected, and the *Tooth* carefully drawn as a nail out of a piece of wood. But this muſt never be done while the gums are inflamed, ſwelled, or otherwiſe diſtempered. *Heiſter*'s Surgery, p. 456. See alſo *Fauchard*'s Chirurgien Dentiſte.

Wolf-TOOTH. See the article WOLF.

TOOTH-*Wort*, in botany. See the article PLUMBAGO.

TOP (*Cycl.*)—TOP *of a Ship*, a round frame of boards lying upon the croſs-trees near the head of the maſts, here they furl or looſe the *Top*-ſail, *&c.*

TOP-*Armours*, in a ſhip of war, are a kind of cloths hung about the round-*Tops* of the maſts for ſhow; and alſo to hide the men which are in the *Top* in a fight, who lie there to fling ſtink-pots, *&c.* or to fire ſmall ſhot down on the enemy in caſe of boarding.

TOP-*Maſts*, in a ſhip are four, which are made faſt and ſettled unto the heads of the main-maſt, foremaſt, mizzen-maſt, and bow-ſprit reſpectively.

TOP-*Gallant-Maſts*, in a ſhip are two, *viz.* *main-Top-gallant-maſt*, and *fore-Top-gallant-maſt*, which are ſmall round pieces of timber, ſet on their reſpective *Top-maſts*; on the top of which maſts are ſet the flag-ſtaffs, on which the colours, as flags, pendants, *&c.* hang.

TOP-*Ropes*, in a ſhip, are thoſe with which the *Top-maſts* are ſet or ſtruck. They are received through a great block, which is ſeized on one ſide under the cap, and then are reeved through the heel of the *Top*-maſt, where is a braſs ſhiver placed athwart ſhips; after this they are brought up and faſtened on either ſide the cap with a ring: the other part of them comes down by the ties, and ſo is reeved into the knight-head; and when it is to be heaved, it is brought to the capſtan. Theſe *Top-ropes* belong only to the main and fore-maſt.

TOP-*Sail-Lifts*, on board a ſhip. See the article LIFTS.

TOP-*Sails*, and TOP-*Gallant-Sails*, in a ſhip, are thoſe belonging to the *Top*-maſts, and *Top*-gallant-maſts.

TOP-*a-Starboard*, on board a ſhip, the word of command to hale upon the larboard liſt.

TOP *the Yard-Arms*, on board a ſhip, a word of command to make the yards hang higher or lower. See the article YARD.

TOPAN, in zoology, a name by which ſome have called the horned-beaked Indian raven, more uſually known by the name of the rhinoceros-bird, *Worm.* Muſ. p. 113. See the article RHINOCEROS-*Avis*.

TOPAZ, TOPAZIUS. The name given by the moderns to a gold-coloured gem, called by the antients the chryſolite, or gold-coloured gem.

This is a very valuable and beautiful gem, when pure and in its moſt perfect ſtate, but ſuch are very rare; and the leſs perfect ones common among our jewellers are of little beauty or price.

The *Topaz* is never found very large; the far greater number of the oriental ones are as ſmall as the head of a large pin, and it is but here and there one, which arrives at the ſixth of an inch diameter, and very few indeed exceed that ſtandard. The American ones are ſomewhat larger than theſe, and the European are the largeſt of all; but of the leaſt value. It is always found in a pebble-like form; roundiſh or oblong, and flatted on one ſide, and of an irregular and uneven ſurface, but uſually bright and of a good natural poliſh, unleſs where fouled by accidents. It is never found in a columnar or cryſtal-like form, notwithſtanding that our dealers in gems carry on a large trade with what they call *Topazes*, which are of this ſhape: but all theſe when brought to the wheel are found to be no more than common cryſtals, accidentally tinged to a yellow colour, as is very common for the cryſtals and ſpars to be, in and about mines, from an admixture of metalline particles; and almoſt all the common *Topazes* worn in rings are of this falſe kind.

The colour of the *Topaz* is ever a pure yellow; but, like the other gems, it has this in very different degrees: the fineſt *Topazes* are of a true and exact gold-colour, and are of great ſplendour; but they vary from this in degree, up to the deepeſt ſaffron-colour, and down to that of the paleſt amber.

The fineſt *Topazes* are of equal hardneſs with the ruby and ſapphire, and are ſecond only to the diamond; from this they degenerate down to the hardneſs of a garnet, and yet lower; but in all the genuine *Topazes*, even the very meaneſt are, when brought to the mill, found to be much harder than cryſtal. The fineſt *Topazes* have a luſtre at leaſt equal to any gem except the diamond; but the others are but dead and heavy: the oriental ones diveſted of their colour, by putting them in the fire, make a very cloſe counterfeit.

The *Topaz* is found in the Eaſt and Weſt-Indies, and in many parts of Europe: the oriental are greatly ſuperior to thoſe of any other part of the world; and the American are not much better than the German. The fineſt gem of this kind ever known, is in the poſſeſſion of the Great Mogul; its weight is ſaid to be 157 carrats, and its value more than twenty thouſand pounds. *Hill*'s Hiſt of Foſſ. p. 598. ſeq.

Counterfeit TOPAZ. To counterfeit the oriental *Topaz* in paſte: Take cryſtal prepared two ounces, ordinary minium or red lead ſeven ounces; put theſe into a crucible luted, and bake them twenty-four hours in a potter's kiln. If the maſs is not ſufficiently clear and fine, cover it up again and give a ſecond baking, and it will come out of a fine *Topaz*-colour. *Neri*'s Art of Glaſſ. p. 131.

TOPE, in ichthyology, an Engliſh name for a ſpecies of the ſqualus according to the Artedian ſyſtem, diſtinguiſhed from the other ſquali, by the noſtrils being placed extremely near the mouth, and by certain foramina, or apertures near the eyes. It is the fiſh called by the antients γαλέος κύων, *galeus canis* and *canicula*. See the article GALEUS *Canis*.

TOPIARIA, in botany, a name by which ſome authors have called the acanthus, or bear's breech, a plant common in the gardens of the curious. *Ger.* Emac. Ind. 2.

TOPICS (*Cycl.*)—*Topics* are ſuch medicines, as by the ſmallneſs and mobility of their particles, attended for the moſt part with a gentle acrimony, are able to make their way into the ſubſtance of the parts to which they are applied, without eroding or wounding any of the ſolids; and thence are juſtly called penetrating *Topics*.

It may be a queſtion how *Topics* in medicine act. It is commonly ſaid that this or that medicine penetrates the pores; but the ideas annexed to ſuch expreſſions do not ſeem very diſtinct. Writers on this ſubject have ſeldom been at the pains to tell us what pores they mean. We have an eſſay on this ſubject in the Medic. Eſſ. Edinb. Vol 2. Art. 4. by Dr. Armſtrong, who thinks that the effects of ſuch medicines are not owing to their particles entering the orifices of the abſorbent veins; nor to the opening of the exhalent veſſels on the ſurface of the body by theſe medicines; nor will he allow the particles of penetrating *Topics* to force their way through the coats of the veſſels; but he ſuppoſes, that ſubtile medicines are conveyed by the exhalant veſſels of the ſkin, to thoſe parts of the ſmaller arteries, where the circulation is choaked by obſtruction.

TOPIC, in rhetoric. See the article LOCUS.

TOPPING *the Lifts*, aboard a ſhip, the ſame as haling the top-ſail-*lifts*, and therefore they ſay *top-a-ſtarboard*, or *top-a-port*, that is, hale upon the ſtar-board, or larboard liſt. See the article LIFTS.

TORCH-*Thiſtle*, *Cereus*, in botany, a ſpecies of plants belonging to the *Cactus*-genus. See the article CACTUS, Append.

This plant conſiſts of a ſingle ſtem or body, twenty, thirty, or more feet high, and about five inches in diameter. It is of an angular figure, and armed with cluſters of ſharp firm ſpines, growing from tubercles placed along the ribs. The flowers, when open, are of the ſize of a large roſe, and conſiſt of forty or more petals; the outer ones purpliſh or greeniſh, the inner ones white.

It is a native of Surinam, and many parts of ſouth America. It has gotten the name *Torch-thiſtle*, from its being much uſed for *Torches*.

This plant is frequent in our ſtoves among the curious in exotic vegetables, but it ſo rarely flowers, that many who have kept ſeveral ſpecies of it in their ſtoves for their whole lives, have not happened to ſee it. Dr. Trew gives a particular account of the flowering of one of theſe plants, at Nuremberg, in the year 1730; which may be agreeable to the curious, who have not themſelves ſeen it.

The plant which flowered there was a branch ſeven years before ſeparated from another *Cereus* in the ſame garden, which had never flowered. It had in this time grown to be ſix foot high, and thirteen inches thick: it had ſeven angles near the baſe, eight in the middle, nine near the top. Its upper part appeared of a bluiſh green, from a duſty matter it was covered with; its lower part was of a fine graſs-green, and the down of the prickles was whitiſh near the top, and every where elſe brown. On the fifth of September, within an inch of its top, their appeared a round knot growing out of the trunk, this increaſed in ſize very faſt and grew out horizontally, on the fourteenth of the ſame month, it was eight inches long, and plainly ſhewed the rudiments of a flower, tho' as yet cloſed up, and ſome elegant ſtains of green, purple, and white were viſible on it.

The ſame evening the flower began to open, and at midnight was fully expanded, it was then ſix inches in diameter, and was of a ſtrong but not pleaſant ſmell. After midnight it began to contract; it grew leſs by half an inch in a few hours, and remained of this ſize till the next day at noon; it then ſoon con-

contracted to half its former diameter, and the next morning it was quite closed and withered, but it hung on the trunk till the thirtieth of September.

The beginning of the flower is a sort of tube, three inches long and about an inch diameter; of a colour between a yellow and a pale green: Its surface is channelled with several small furrows, between which there ran several blunt protuberances in a parallel order along the ridges; where the tube expanded itself, it divided into more than forty petaloide segments, ranked in six separate series; the three exterior and inferior whereof, here and there confounded their order, while the three superior and interior remained separate and unmixed. These several series differed in size and colour, the first or exterior series was of the same colour with the tube, that is of a pale yellowish green, but its upper part gradually inclining to purple. The second and third series had half their inner part greenish, and their edges of a more intense purple; the fourth was between yellow and white, terminating in purple tops; the tops of the fifth were likewise purplish. The petaloide segments of the sixth series were very tender and white, all the segments were of an oblong figure, and in the first series were terminated with blunt tops, in all the others with more and more pointed ones to the very innermost series. The innermost series, which contained thirteen of these segments, had all their edges lightly and irregularly cut and divided: the pistil was of equal height with the surface of the flower, and was a hollow tube, terminating at its upper part in a number of fine tender filaments, expanded in the form of a crown; these were as many in number as the segments of the innermost series, that is thirteen. The day before the flower dropped from the ovary, the place where it was to fall off was marked with a blackish circle, and at this the tube readily and evenly separated from the rudiments of the fruit. The pistil still firmly adhering to the ovary: the petaloide segments of the flower were found not be separated from the tube without tearing, and were really segments, not distinct petals as might have been guessed by a cursory view of the flower. The fruit did not come to its full growth, but grew so far as to shew that it would never have been prickly: upon dissection it afforded a viscous juice, and within it was a cavity, the sides of which were every where beset with small villi, except at the bottom; and at the end of each of these hairs hung a small white vesicle which was the rudiment of a future seed. The error of the common opinion of supposing the flower of the *cereus*, polypetalous, is evident from this description, and all that is observed of this strange and elegant flower, has been since verified by the flowering of the same species with us. About six years ago I was on a visit at the late Lord Petres at Therndon in Essex, when his gardener, who had been some time ordered to watch a *cereus* of this species which was about to flower, called us out at midnight to see it. It had opened three flowers at different heights upon the stalk, and they were all of the same size, something larger than the standard given by Dr. Trew, but in all other respects perfectly agreeing with his description. Philos. Trans. N°. 416.

The propagation of all the kinds of this remarkable plant is by cuttings, which must be laid in a dry place ten days or a fortnight before they are planted, or if it be three weeks, there is less danger of their miscarrying. They are to be planted in small pots, filled with a light sandy earth, with a mixture of lime rubbish, laying some stones at the bottoms of the pots to drain off the moisture. The pots are then to be placed in a gentle bed of tanner's bark, and once a week are to have a gentle watering; this is best done in June, or July: toward the middle of August, they must have air given them by degrees, and at the end of September they must be removed into the stove, where they are to remain the winter. They should always have a dry situation, and should never be exposed to the open air even in the midst of summer.

When the top of an old plant has been cut off for propagating; it always throws out several young shoots from its angles, which may all be easily propagated in the same manner, and it will continue to do this in such a manner, that there will be a continual supply even from one stock. They may be brought in small pieces from the West Indies packed up in straw, and will grow when planted here, as well as if cuttings from our own plants. *Miller*'s Gardener's Dict.

TORCHENES, in the manege, a long stick with a hole at the end of it, through which a strap of leather is run, the two ends of which being tied together, serve to straiten and closely tie up a horse's nose as long as the stick is stayed upon the halter or snaffle. This is done to keep the horse from being unruly, when he is dressed, or upon any other occasion.

TORDINO, in zoology, a name by which the Venetians call a bird of the lark kind common in their markets, and called by authors *spipolletta*. See the article SPIPOLETTA.

TORDO *Marino*, in zoology, the name of a bird of the starling-kind, called also the *codirosso maggiore*, or *ruticilla major*, and by the Austrians the *stein-reitling*. Aldrovandus has named it the *merula saxatilis*, or rock-blackbird. It is of the size of our starling, and much resembles it in figure, its breast is greyish and has a black transverse streak, and behind that the whole is of a yellowish hue. Its head and back are of a blackish hue with some slight variegations of grey, from the tip of the feathers being of that colour. The tail is long and of a reddish orange colour, and the under feathers of the wings are of the same hue; the females are of a less elegant colour than the males, viz. a mouse-colour variegated with white on the back, and ash-colour on the belly; what is yellow in the male birds is also very pale in the females. It is not uncommon in Germany, and may be taught like the starling to imitate the human voice. *Ray*'s Ornitholog. p. 145.

TORDYLIUM, in botany, the name of a genus of umbelliferous plants; the characters of which are these: The flowers are of the rosaceous kind, being composed of several heart-fashioned petals of irregular sizes disposed in a circular order on a cup which afterwards becomes a fruit nearly of an orbicular figure, being composed of two flattish seeds with a high and usually denticulated margin, which easily deposit their covering.

The species of *Tordylium* enumerated by Mr. Tournefort are these: 1. The greatest *Tordylium*, called by some the largest *caucalis*. 2. The smaller Narbone *Tordylium*, called by some the smaller Cretic *seseli*. 3. The least Apulian *Tordylium*, called the least *seseli*. 4. The small Syrian *Tordylium* with a granulated limb, called by some *gingidium*, and the great seeded *caucalis*. And, 5. The Portugal *Tordylium*, with hemlock-leaves, and striated seeds. *Tournef.* Inst. p. 320.

TORMENTILLA, *Tormentill*, in botany, the name of a genus of plants, the characters of which are these: The flower is of a rosaceous kind, consisting of four leaves disposed in a circular form: the cup is of the shape of a bason, consisting of one leaf, divided into several segments; the pistil arises from this cup, and finally becomes a globose fruit composed of several seeds closely laid together, and covered by the cup.

To these it may be added, that the leaves grow always more than three together, at the ends or summits of the stalks.

The species of *Tormentill* enumerated by Mr. Tournefort are these: 1. The common wild *Tormentill*. 2. The large Alpine *Tormentill*. 3. The creeping *Tormentill*, with gold yellow flowers. 4. The great *Tormentill*, with green deeply divided leaves. 5. The lesser *Tormentill*, with leaves deeply indented. *Tournef.* Inst. p. 298.

TORMENTILLÆ *radix*, in the materia medica, is the root of the common wild *Tormentill*, which is frequent with us in woods and on heaths, and flowers in June and July. It is a small trailing plant, and the leaves grow about seven at a joint; the flowers are small but of a lively yellow; the root is tuberous and often an inch thick, brown or reddish without, and of a flesh colour within, of a very astringent taste, and are to be chosen from the druggists large, plump, fresh dried. It is a cordial and a very valuable astringent; it makes a very good addition to the common white drink, changing it to a red colour and increasing its virtue. *Pomet*'s Hist. of Druggs, p. 48.

TORPEDO, (*Cycl.*) the *cramp*, or *numb fish*, in ichthyology, a name given to that species of ray-fish which is wholly smooth. See the article RAJA.

The phænomena of this fish are fully explained in the cyclopædia under the article TORPEDO.

TORQUATA, in zoology, a name given by many authors to the common or water-snake, from the remarkable ring it has about its neck. See the article NATRIX.

TORQUILLA, in zoology, the name of a species of woodpecker, more commonly known by the name jynx, and called in English the wry-neck, from its manner of twisting its neck about, and turning its head over its shoulders. *Ray*'s Ornitholog. p. 95. See the article JYNX.

TORTOISE (*Cycl.*)—It is said *Tortoises* will live some days after their heads are cut off, and that this is a preparation for dressing them in Pegu. *Boyle*'s Works Abridg. Vol. 1. p. 28. See the article TESTUDO.

TORTURA, a word appropriated by many medical writers, to express only the distortions of the face, and particularly of the mouth in convulsions.

TORUS, in architecture. See the article TORE, *Cycl.*

TORUSCULA, a word used by some medical writers to express a drop.

TORYNE, in pharmacy, the name of a kind of spatula intended for the stirring up the ingredients of decoctions while boiling.

TORYNETOS, a name given by some to a mixture of bread and water boiled together, whether meant as a kind of a panada, or for a pultice.

TOTANO, or TOTANUS, in zoology, the name of a bird, of the ægocephalus or godwit kind, common in the Italian markets, and more usually known by the name of vetola. See the article VETOLA.

TOTANUS, is also used by some for the limosa. See the article LIMOSA.

TOTAQUESTAC, in zoology, the name of a beautiful American bird, described by Nieremberg from Antonius Herera. It is said to be something smaller than a pigeon, and all over of a most beautiful green; its tail-feathers are of a very great length, and are greatly esteemed. The Indians value the bird so highly that it is death by their laws to kill it, so that when it is caught they only strip it and let it go again. *Ray*'s Ornithol. p. 303.

TOTTAVILLA, in zoology, a name by which ſome authors have called the *alauda arborea*, or common wood-lark. See the article ALAUDA.

TOUCAN (*Cycl.*)—TOUCAN, in zoology, the name of a very remarkable Braſilian bird, a kind of magpie, of a middle ſize between our common magpie and the thruſh, but having a beak thicker and longer than its whole body; this beak is hooked at the end, and is of a very thin ſubſtance, not exceeding the thickneſs of a membrane, and very light and hollow, yet bony in ſubſtance and very bright and ſhining. It has a ſort of toothed edge, which prevents its ſhutting cloſely, and giving paſſage for the air, enables the bird to live without noſtrils.

It is yellowiſh on the outſide and red within, and is covered with a ſort of ſcaly ſubſtance eaſily ſcraped off with a finger at the edge. Its head is large in proportion to its body, and is black on the crown, the reſt of it and the neck and back are ſlightly variegated with white; its breaſt is of a bright orange-colour, and its belly and thighs of a very fine and bright red, and the tail is black, but red at the end: it is on the whole a very ſingularly beautiful bird. It is ſaid that it feeds on pepper, and Thevet affirms that it devours it greedily and returns it again undigeſted, and that the natives gather up that pepper, and uſe it in their food, as leſs hot and acrid than the freſh pepper. See Tab. of Birds, N°. 11. and *Ray*'s Ornitholog. p. 88.

TOUCH-*Hole*, or VENT, in gunnery, is the ſmall hole at the end of the cylinder of a gun or muſquet, by which the fire is conveyed to the powder in the chamber. In a firelock, carabine, or piſtol, it is called the *Touch-hole*, but in a piece of cannon it is more properly called the vent.

TOUCH-*Needles*, ſmall maſſes of gold, ſilver, and copper, each pure, and ſimple, and in all the different combinations, proportions, and degrees of mixture, prepared for the trying gold and ſilver by the *Touch*-ſtone; by compariſon with the mark they leave on it.

The metals uſually tried by the *Touch*-ſtone, are gold, ſilver, and copper, either pure, or mixed with one another in different degrees, and proportions, by fuſion. In order to find out the purity, or quantity of baſer metal in theſe various admixtures, when they are to be examined, they are compared with theſe needles, which are mixed in a known proportion, and prepared for this uſe. The metals of theſe needles both pure and mixed, are all made into laminæ or plates, one twelfth of an inch broad, and of a fourth part of their breadth in thickneſs, and an inch and half long; theſe being thus prepared, you are to engrave on each a mark indicating its purity, or the nature and quantity of the admixture in it.

The manner of making the *Touch-needles* is by the proportions of the mark, a weight of half a pound, or eight ounces, being divided into ſixteen half ounces, the half ounces each into four drams, the dram into four penny-weight, and this into two half penny-weights.

Silver TOUCH-*Needles*, theſe muſt be only tempered with copper, and the proportion determined by the mark divided into half ounces and grains.

You muſt uſe therefore for this purpoſe one mark of ſuch a weight that it may conſtitute a ſufficient maſs of metal for the making one needle, let it weigh for inſtance one dram, then weigh ſuch a mark of the pureſt ſilver, wrap it up in a ſmall paper and upon this write ſixteen half ounces, which will ſignify that the whole mark of this metal is the pureſt ſilver, make the firſt needle of this maſs.

Next weight fifteen half ounces of pure ſilver, and one half ounce of pure copper, wrap theſe both in a paper, and write on it fifteen half ounces, which will ſignify that there are in that ſmall maſs fifteen parts of pure ſilver, and one part of pure copper; make of this the ſecond needle. In the ſame manner go on with the reſt, add two half ounces of copper to fourteen half ounces of ſilver, mark it fourteen half ounces, make the third needle of this, and in the ſame manner proportion the ſmall maſſes of ſilver and copper for making the other needles, and put inſcriptions upon every one in the following manner.

For the needle	1.— 16	half oz. of ſilver	0	halfoz. of copper.
	2.— 15		1	
	3.— 14		2	
	4.— 13		3	
	5.— 12		4	
	6.— 11		5	
	7.— 10		6	
	8.— 9		7	
	9.— 8		8	
	10.— 7		9	
	11.— 6		10	
	12.— 5		11	
	13.— 4		12	
	14.— 3		13	
	15.— 2		14	
	16.— 1		15	

When you have gone thus far, and have the metals in each of theſe proportions, wraped up in its ſeparate paper; put each ſeparately, into a new crucible never uſed for any operation, and adding a little borax melt them together in a very quick fire, which muſt be well kindled before with bellows: or what is yet better, throw them ſuddenly into a hot crucible, and as ſoon as they melt, ſtir them with a dry wooden peg, burnt at the end, and pour them immediately into an ingot. When this is done, wrap up each maſs, when cold, in its own paper again, and weight them ſingly, in a nice ballance. If they ſtill weigh a whole mark, they are good; but if there is any conſiderable deficiency in their weight, it is a ſign that your fire having been too weak, or of too long duration, has conſumed as much copper as is wanting in the weight; therefore this maſs muſt be eſteemed uſeleſs, and another made in its place in the ſame proportion.

When this is all finiſhed, make with a hammer out of each theſe ſmall maſſes, a *Needle*, making them a little hot; then engrave on each of theſe *Needles*, the number of half ounces it contains, as before marked on its paper; that is, upon the firſt 16, upon the ſecond 15, and ſo on, and then pierce them at one end, and running a ſilver wire thro' their eyes, collect them in order according to their different numbers. Theſe are the *Silver Touch-Needles*, made of the different allays of ſilver and copper.

In Holland they make uſe of the mint mark, divided into grains for the making their *Needles*. The firſt *Needle* made of pure ſilver is ſaid to be of twelve penny-weights. The ſecond is made of eleven penny-weights and eighteen grains, by the addition of ſix grains of copper. The third is made of eleven penny-weights and twelve grains, by the addition of twelve grains of copper; and ſo on, the proportion of ſilver decreaſing always ſix grains, that is, one quarter of a penny-weight at a time, and that of the copper being always increaſed in the ſame proportion, till at laſt the weight of the ſilver is reduced to one penny-weight, and that of the copper encreaſed to eleven penny-weights, which proportion conſtitutes the laſt *Needle*.

It is needleſs however, to go through the whole ſeries of the *Needles*, by ſo ſmall progreſſions to the very laſt, for very delicate proportions cannot be very accurately diſtinguiſhed in the operation.

Gold TOUCH-*Needles*. Theſe muſt be mixt either with ſilver alone, or with ſilver and copper, variouſly intermixed. This mixture is called allaying or carracting, and is determined with a mark divided into carracts, or weights of two ſixth parts of an ounce. There is nothing to be obſerved about the making of theſe *Needles*, beſide what has been already ſaid in regard to the *Silver Needles*; except that the proportions of the weights are determined in another manner. Theſe *Needles* are made according to the following diviſion and order; and they all weigh one mark.

The firſt is entirely of pure gold.

2.	23 Car. 6 Gr.	pure gold	6 Gr.	pure ſilver.
3.	23 Car.		1 Car.	
4.	22 Car. 6 Gr.		1 Car. 6 Gr.	
5.	22 Car.		2 Car.	
6.	21 Car. 6 Gr.		2 Car. 6 Gr.	
7.	21 Car.		3 Car.	
8.	20 Car. 6 Gr.		3 Car. 6 Gr.	
9.	20 Car.		4 Car.	
10.	19 Car.		5 Car.	
11.	18 Car.		6 Car.	

The decreaſe goes on thus, by whole carracts, till the weight of the gold is arrived at one carract, and that of the ſilver at twenty three; for after the ninth *Needle* you cannot make ſo exact a diſtinction of the half carracts.

This mixture of gold and ſilver is called the white allay; but when copper together with ſilver enters into the mixture of the gold, then it is called a mixt allay. The *Needles* for trial of pieces thus debaſed, are made of mixtures analogous to the former, except only that thoſe portions which in the firſt caſe were pure ſilver, here conſiſt of copper and ſilver mixt. Therefore you have here a double ſeries; for the mixture is either of two parts of ſilver, and one of copper, or of two parts of copper and one of ſilver. For inſtance,

The firſt is of pure gold.

2.	of pure gold.	23 Car. 6 Gr.	of pure ſilver.	4 Car.	of pure copper.	2 Gr.
3.		23 Car.		8 Gr.		4 Gr.
4.		22 Car. 6 Gr.		1 Car.		6 Gr.
5.		22 Car.		1 Car. 4 Gr.		8 Gr.
6.		21 Car. 6 Gr.		1 Car. 8 Gr.		10 Gr.
7.		21 Car.		2 Car.		1 Car.
8.		20 Car. 6 Gr.		2 Car. 4 Gr.		1 Car. 2 Gr.

and ſo on as in the foregoing.

If in this table you take pure copper inſtead of pure ſilver, and ſilver inſtead of copper, this gives you a third ſeries of golden *Needles*. And you may have a fourth by mixing with gold equal quantities of ſilver and copper in the ſame proportion. Theſe allays of gold are much in uſe, but workmen may eaſily employ a multitude of other variations, which compared with the already mentioned will be diſtinguiſhed in a thouſand different ways by an experienced perſon, ſo that it is neither poſſible, nor neceſſary to imitate them all.

But that theſe *golden Needles* may not be too expenſive, they

they may be made much ſhorter than thoſe of ſilver, and afterwards ſoldered to plates of copper, that may be ſufficiently long for uſe.

The uſe of theſe *Needles* is by means of the touchſtone; and ariſes hence, that every metal when pure muſt have its ſpecific colour, that diſtinguiſhes it from the reſt: but metals being the moſt opake of all known bodies, the ſpecific colour of every one appears moſt diſtinctly when you rub it againſt a very black hard ſtone; and if the colours of two or more metals are expreſſed by large lively ſpots, made near each other on the ſame plane, by rubbing them againſt the ſurface of the ſtone, you will by that means eaſily diſcern their difference, or their likeneſs.

The ſtone adapted to this uſe, and called from its office the *Touch-ſtone*, muſt have the following qualities. It muſt be of the deepeſt black, leſt the tincture of the metal ſhould be altered by ſpurious rays of light ſhining among it: it muſt be capable of being pretty well poliſhed, for when too rough, the colours of the metals rubbed againſt it cannot be neatly or regularly diſtinguiſhed; and if it is too ſmooth, the metals are but faintly, and too ſlowly abraded or ſcraped by it, eſpecially when gold is tried. It muſt alſo be neither too hard, nor too ſoft. Tripoli, coal-duſt, and tin aſhes are uſed in rubbing off the thin metalline cruſts, and in a ſhort time the ſtone when very hard is apt to acquire too ſmooth a ſurface; and when it is too ſoft it eaſily wears, throws off a duſt, and contracts furrows.

The black rough marbles, and the ſofter black pebbles from the beds of rivers, are moſt proper for this uſe, and are to be made into the form of a quadrangular priſm, about an inch thick, and two or three inches long.

The method of uſing your *Needles* and the ſtone is this: When you meet with a piece of metal to be tried; firſt wipe it very well with a clean towel, or piece of ſoft leather, that you may the better ſee its true colour; for from this alone an experienced perſon will in ſome degree judge before-hand what the principal metal is, and how, and with what debaſed. Then chuſe a convenient not over large part of the ſurface of the metal, and rub it ſeveral times very hardly and ſtrongly againſt the *Touch-ſtone*; that in caſe a deceitful coat or cruſt ſhould have been laid upon it, it may be worn off by that friction. This however is done more readily by a grindſtone or ſmall file if you have them at hand. Then wipe a flat and very clean part of the *Touch-ſtone*, and rub againſt it over and over, the juſt mentioned part of the ſurface of the piece of metal, till you have on the flat ſurface of the ſtone a thin metallic cruſt, an inch long and about an eighth of an inch broad: this done look out the *Needle* that ſeems moſt like to the metal under trial, wipe the lower part of this *Needle* very clean, and then rub it againſt the *Touch-ſtone* as you did the metal by the ſide of the other line, and in a direction parallel to it. When this is done, if you find no difference between the colours of the two marks, made by your *Needle*, and the metal under trial; you may with great probability pronounce that metal, and your *Needle*, to be of the ſame allay; which is immediately known by the mark engraved on your *Needle*. But if you find a difference between the colour of the mark given by the metal, and that by the *Needle* you have tried; chooſe out another *Needle*, either of a darker or a lighter colour than the former, as the difference of the tinge on the *Touch-ſtone* directs; and by one or more trials of this kind you will be able to determine which of your *Needles* the metal anſwers, and thence what allay it is of, by the mark of the *Needle*; or elſe you will find that the allay is extraordinary, and not to be determined by the compariſon of your *Needles*.

But if the metal under trial, has been altered by tin, arſenic, zink, or other ſuch admixtures, the workmen may be deceived by the colour, ſo as to take for pure gold, or ſilver, that which is not by any means ſuch. Deceits of this kind however are found out by the aſſiſtance of acid menſtrua. *Aqua fortis* anſwers this purpoſe, when the maſs is of the colour of gold, and *aqua regia* when it is of the colour of ſilver; for the firſt of theſe menſtrua diſſolves all metals except gold, and the latter all metals except ſilver. In this caſe then you are to pour upon your metallic ſtreak on the ſtone, one ſmall drop of either of theſe liquors, and extend it gently over it with a feather. If it is neither gold nor ſilver the whole ſtreak will be obliterated and conſumed, but if there is any gold or ſilver in it, this remains undiſſolved, and ſhews another colour, becauſe the other parts have been ſeparated from it by the ſolution. When theſe menſtrua are uſed, great care muſt be taken that there is no oil in the way; for that would ſpoil and deſtroy their effects.

Beſide theſe the following particulars are to be obſerved: Gold and ſilver when pure, whether ſeparate or both mixed together, without the addition of any other matter, when made hot in the fire, not only preſerve their colour, but if they were tarniſhed before, they recover their ſplendour there, not loſing the leaſt part of their weight: and by this quality in theſe two metals, the *caratura alba*, or white allay, made by the mixture of gold and ſilver alone, is diſtinguiſhed from all the others. If you have not liberty to try the whole maſs in the fire, you may make this experiment on a ſmall piece of it with a blow pipe.

If you find a *Needle* of the ſame allay with the metal under trial, the ſtreaks made by both upon the touch-ſtone muſt undergo exactly the ſame changes when *aqua fortis* is poured on them; and this ought always to be made a part of the trial by the *Touch-Needles*, that no fraud may be at the bottom.

All gold rendered brittle, when compared with the *Touch-Needles* by the ſtone, will appear leſs pure than it really is; and on the contrary all ſilver rendered brittle, has the whiteneſs of ſilver in a higher degree: nor is there any wonder in this, when rightly conſidered, ſince the bodies which make gold and ſilver brittle are only a few metals, and ſemi-metals, all of a very bright white colour, and neceſſarily adding to the whiteneſs of ſilver, and taking from the yellowneſs of gold, ſuch are tin, lead, regulus of antimony, biſmuth, zink, and arſenic. Theſe dilute the yellow colour of gold or copper, into a whiteneſs, ſo that the colour of copper mixed with the ſilver is hidden by admixtures of this kind, whereas gold on the contrary appears by them to have much more ſilver in it than it really has.

In a white allay, *aqua fortis* does not diſcover the preſence of ſilver from twenty-three, to ſeven carracts, becauſe *aqua fortis* does not ſeparate ſilver from gold, unleſs the maſs contains three times more ſilver than gold.

Metallic ſtreaks or cruſts which have been left ſome time upon the *Touch-ſtone*, cannot be compared with freſh ones, with any degree of uſe, becauſe their remaining long on the ſtone always alters their colour.

Silver when tempered with braſs appears whiter than it would do with a like quantity of copper, and as it may then be rendered ſufficiently ductile by a proper operation, you will hardly be able to find out the fraud with the *Touch-ſtone*, unleſs you make a ſecond time the ſame compariſon with the ſtreak of a *Needle* of the ſame colour, having previouſly poured *aqua regia* upon the metallic cruſt laid by rubbing on the touch-ſtone; nor are *Touch-Needles* tempered with braſs, of any great uſe on this occaſion, ſince this artificial metal is ſometimes more and ſometimes leſs yellow.

Laſtly, if the metal laid upon the *Touch-ſtone* by rubbing does not appear neat or diſtinct enough, lick it over with ſpittle that is not frothy; and the colours will be by that means more diſtinctly and livelily reflected. *Cramer*'s Art of Aſſaying, p. 116.

TOUCH-*Stone* (*Cycl.*) The *Iriſh* TOUCH-STONE, called *Baſanus Hibernicus*, by Molyneux and ſome others, is a black marble found in the county of Antrim in that kingdom, in angular columns, forming that amazing pile called by the vulgar, the giant's cauſeway.

This marble has the property of trying metals by the *Touch* beyond any other known ſtone; but it is not eaſily wrought into form, being ſo hard that it turns the edges of all the tools uſed to cut ſtones. Were it not for this it is admirably calculated for building, and for ornamental works; but nobody has attempted to uſe it in this manner, any where, except in the church of Ballywellan in the neighbourhood, and here the trouble of cutting is avoided, for the joints are taken as they found them, and the church is built of theſe in their natural ſhape, piled one upon another. The outer ſurface of this ſtone is of a whitiſh colour like lime-ſtone, but this is only the effect of the weather upon it; for where-ever it is broken it is found to be of a fine iron grey, and when poliſhed appears of a true and deep jetty black.

The accounts Pliny and others give of the *baſaltes* or *baſanus* found in Æthiopia and other places, agree extremely well in all reſpects with this Iriſh marble. They ſay it was always found in form of columns, and was much harder than the common marble, and of an iron colour: Kentman and other later writers, deſcribe alſo a pillared ſtone, found in Miſnia, the accounts of which agree perfectly well both with this and with the *baſaltes* of the antients: ſo that there is no great room to doubt but that both the Miſnian and the Iriſh columnar marble are the ſame with the *baſaltes* of the Greeks and Romans; and that this *baſaltes* is always found in the ſame columnar form, in whatever part of the world it is met with; and conſequently that the giant's cauſeway in Ireland, is no work of art as vulgarly thought, but only an immenſe congeries of this *baſanus* or *baſaltes* in its natural ſtate and form.

The columns of this marble are all regularly angular, but they conſiſt of a great number of ſides in ſome, and of a ſmall number in others. Some columns being octangular and others only triangular, and others of all the different numbers of angles between three and eight.

The Miſnian *baſaltes* is ſaid to have no columns of more than ſeven angles, or of leſs than four; by this account it appears that the Iriſh kind has two orders of columns which that wants, but this may be owing to want of due obſervation of the Miſnian kind: for Dr. Molyneux in his firſt account of this cauſeway, ſays, that its columns conſiſt of five angles at leaſt, or ſeven at moſt, but future obſervations alone can ſhew whether the Miſnian kind may not have other numbers of angles in ſome of its columns, from thoſe at firſt taken notice of, as well as this. Some of our Engliſh authors have been of opinion that the ſtone of the giant's cauſeway was of the *entrochus* or *aſteria* kind; but this is very abſurd, for the ſize of thoſe ſtones ſeems to be limited, as they are the remains of animals, and

nothing

nothing of that kind can be larger than the part of the animal it had its origin from, whereas we can never ſuppoſe any animal ſo monſtrouſly large to have at all exiſted, as that theſe columns ſhould have been only a part of it.

The ſubſtance of this ſtone is alſo an unſurmountable difficulty againſt the opinion of its being of the nature of the *entrochi* and *aſteriæ*, for they are all compoſed of ſpar, and are ſoft and crumbly; whereas this is too hard even for cutting in the common way of working other ſtones.

The columns of *baſaltes* in Miſnia, either are not jointed like thoſe in Ireland, or the joints have not been obſerved; but ſuppoſing that they really are not jointed at all, they may nevertheleſs be the ſame ſtone, ſince the joints may have been obliterated by the ſtones coming together while yet ſoft, and ſubject to injury by preſſure from above given by the ſucceeding addition of new joints: and, even in the Iriſh kind, the joints, tho' ſo very regularly formed in the way of ball and ſocket, in ſome are much leſs regular than in others, and, in ſome of the inland columns, are only two flat and ſmooth ſurfaces laid one upon another. It is not difficult to conceive that if theſe ſurfaces had met together in this cloſe contact, while a little moiſt, they would have cohered together; ſo as to have left no mark of the joining.

Agricola deſcribes a kind of marble found in the diſtrict of Hildeſheim in Germany; which alſo agrees very well with our *baſanus* of the giant's-cauſeway, and with the *baſaltes* of the antients; and an author, who has wrote on the ſame ſubjects ſince his time, confirms his account: he ſays, that the marble is black, and in form of beams and columns ſtanding up above the ſurface of the earth in the hills, and that being ſtruck forcibly againſt with a bar of iron, it gives a ſtrong ſmell like that of burnt horn. This agrees very well with the marble of the giant's cauſeway, which when put to the ſame trial has evidently the ſame effect. Philoſ. Tranſ. N°. 241.

TOURNEFORTIA, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: The cup is a ſmall *perianthium* divided into five ſegments, and remains after the flower is fallen; the ſegments are of a pointed figure. The flower conſiſts of a ſingle petal in form of an oval tube, longer than the calyx, divided into five ſlight ſegments, ſomewhat broad and pointed and ſpread open. The ſtamina are five tapering filaments of the lengh of the tube of the flower. The antheræ are ſimple and ſtand in the mouth of the flower. The germen of the piſtil is globoſe, and ſituated under the cup. The ſtyle is ſimple and of the length of the ſtamina, and the ſtigma is ſimple. The fruit is a globoſe berry, containing two cells, the ſeeds are of an oval figure, two in number, and ſeparated by the pulp. *Linnæi*, Genera plantarum, p. 62.

TOURNEQUET, in ſurgery, an inſtrument made of rollers and compreſſes with the help of a ſmall ſtick, and uſed to ſtop the effuſion of blood from large arteries in amputations by forcibly tying up the limb. The things neceſſary for this are a roller of a thumb's breadth, and of an ell in length, a ſmall cylindrical ſtick, a conglomerated bandage two fingers thick and four long, ſome compreſſes of a good length, and about three or four fingers breadth, to ſurround the legs and arms, and a ſquare piece of ſtrong paper or leather about four fingers wide.

The manner of applying this inſtrument is this, the rolled bandage is to be applied to the trunk of the wounded artery length-ways, covering it in a contrary direction with compreſſes ſurrounding the leg, foot, or arm, as it were with a ring; the roller muſt be paſſed twice round theſe applications, and faſtened in a knot, but ſo looſely that you may eaſily introduce your hand between it and the part: the leather or thick paper muſt now be nicely placed under it, upon the external part of the leg, and the roller tightened by degrees by turning round the ſtick, which is to be introduced into the knot; this to be done till the hæmorrhage is entirely ſtopped: the ſtick muſt now be kept in this ſituation till the wound is properly treated, and the return of the hæmorrhage prevented. When this end is acquired, the *Tournequet* is to be looſened, or entirely taken off, as ſhall be judged moſt convenient; but where it is applied to the arm, the rolled bandage is to be placed near the *axilla* in the internal part of the *humerus*, and the ſtick in this caſe is to be faſtened on the oppoſite ſide, the ſituation of the artery there requiring this poſition; and when it is to be applied to the thighs, the bandage is to be put as the caſe ſhall require, either to the upper part of the thigh, or juſt over the knee. *Heiſter*'s Surgery, p. 47.

TOW (*Cycl.*)—Tow-*Chain*, in huſbandry, a name given by our farmers to a chain, that makes a part of the ſtructure of the plough, faſtening the plough-tail to what they call the plough-head.

This is an iron chain of few links, and very ſtrong; it is fixed at one end to a collar faſtened to the middle of the beam of the plough, and at the other end paſſes thro' that part of the plough-head called the box, which is the timber thro' which the ſpindle of the two wheels run. The ſtake of the plough, which is an upright piece running parallel with the crow-ſtaves, pins this in at the bottom, running thro' that link which comes out by the box; this ſtake is faſtened by wyths or cords in two places to the left crow-ſtaffs, and the chain is thus kept firm. *Tull*'s Huſbandry.

TOWER, in glaſs-making. See the article Leer.

TOXICODENDRON, *poiſon-wood*, in botany, the name of a genus of plants the characters of which are theſe. The flower is of the roſaceous kind, being compoſed of ſeveral leaves diſpoſed in a circular form. The piſtil ariſes from the cup, and finally becomes a fruit of a roundiſh ſhape, dry, not juicy, and uſually of a ſtriated ſtructure.

The ſpecies of *Toxicodendron* enumerated by Mr. Tournefort are theſe: 1. The ſmooth trifoliate *Toxicodendron*. 2. The trifoliate *Toxicodendron*, with hoary ſinuated leaves. *Tourn.* Inſt. p. 610.

The moſt common American kind of this tree, is the aſh-leaved one; it grows in marſhy places, and is called by the common people marſh-ſumach; its leaves reſembling thoſe of the common ſumach, which are very well known to reſemble aſh-leaves in their pinnated ſtructure. It grows to about four inches in diameter, and at the utmoſt does not exceed twenty feet in height. It ſpreads much at the root, and where one has been at any time cut down, there are always ſeen a great number of young ones growing from its ſtump. It is of very quick growth, but is not durable. The inſide of the wood is yellow, and contains a juice which is as glutinous as turpentine; the wood itſelf has a very ſtrong and diſagreeable ſmell, but the juice ſtinks like carrion.

This tree poiſons two ways; by handling of it, and by the ſmell. The ſcent of it when cut down in the woods has poiſoned many people, and many more have ſuffered by it while burning in their fires. People with only handling it have been made blind for ſeveral days, and perſons who ſit near a fire when it is burning are often ſwelled and choaked up in all parts of the body in a terrible manner. It is very remarkable that the effect of this poiſon ſeems confined to ſome few perſons, and that one may handle it ever ſo long, and even chew it without hurt, while another is poiſoned by only touching it; and a whole company ſitting by a fire where it is burning, ſhall often all eſcape except one or two, who will be ſwelled with it. The poiſon of this tree is never mortal, but goes off of itſelf in a few days; and the people who ſuffer by it generally carry its effects off the ſooner, by uſing ſallad oil and cream to the parts. The firſt notice the perſon has of being affected by it, is by feeling a violent itching in the ſkin; this provokes ſcratching and rubbing; and in conſequence of this the part inflames and ſwells. Sometimes a perſon's whole body is ſwelled and poiſoned in this manner, and ſometimes only a particular part, as the legs; and, in this caſe, they often diſcharge a conſiderable quantity of water, and then grow well.

People who have been poiſoned by handling it, affirm that it is ſo much colder to the touch than other wood, and that it may be diſtinguiſhed by this in the dark; when it is burning ſome people are ſo affected by it as to ſwoon away, others yawn and ſeem uneaſy, while the reſt feel nothing of it. The fruit of this tree is a white roundiſh dry berry, growing in cluſters. Philoſ. Tranſ. N°. 367. p. 144.

TOXICUS, in botany, a name by which ſome authors have called the *arundo farcta*, of which the walking-canes are made. *Chabræus*, p. 193.

TOXOTÆ, τοξόται, among the Athenians, bowmen, a ſort of inferior officers, or rather ſervants, who attended the lexiarchi.

They were much like the Roman lictors: there were a thouſand of them in the city of Athens, that lived in tents, erected firſt in the forum and afterwards in the areopagus. *Potter*, Archæol. Græc. T. 1. p. 79. See the article Lexiarchi.

TOZZIA, in botany, a name given by Micheli and continued by Linnæus to a genus of plants, the characters of which are theſe: The perianthium is very ſhort; it conſiſts of one leaf of a tubular figure, divided into five ſegments at the end, and remaining when the flower is fallen. The flower is one-leaved and open; the tube is cylindric, and longer than the cup. The extremity forms two lips; the upper lip is bifid and the lower trifid, and all the ſegments are nearly equal in ſize and of a roundiſh figure. The ſtamina are four filaments hid under the upper lip of the flower. The antheræ are roundiſh. The germen of the piſtil is oval; the ſtile is capillary, of the length of the ſtamina; and the ſtigma is capitated. The fruit is a globoſe univalve capſule, having only one cell, in which is contained a ſingle oval ſeed. *Linnæi* Gen. Pl. p. 302. *Michel.* p. 16.

TRACHEA (*Cycl.*)—Tracheæ, in vegetables, are certain air-veſſels evident in many plants, but in none more beautifully or diſtinctly obſervable than in the melon.

Mr. Bulfinger obſerved that in cutting the root of the common melon tranſverſely, there appeared, beſide the bark and other commonly known parts of the root, a multitude of foramina, which were larger or ſmaller as the portions of the root were cut from a thicker or a thinner part. Theſe are eaſily viſible to the naked eye, for they are arranged into a number of faſciculi, which ſurround the axis of the root: there are uſually three circles of theſe diſtinguiſhable in the ſmaller parts of the root, and four in the larger; and the matter in which they

are

are placed is different from that which ſurrounds it, being much harder and more firm than that.

Moſt of theſe faſciculi or foramina finally become divided into two or three portions, and the interſtitial matter in that caſe is always the ſame with that which ſurrounds them. If any number of theſe faſciculi are examined, the order and diſpoſition of the foramina, and even their numbers, are found the ſame in all; they are ſo regularly continued along the root, that air, and light fluids, may be ſucked into the mouth thro' pieces of the root from two to nine inches long, and this even when they are contorted and crooked in their growth: the caſe is the ſame alſo, whether the piece be cut from the root or from the ſtalk of the plant, or from both; for when ſuch a piece is cut, half of which is root and half ſtalk, the continuation of theſe foramina is found to be the ſame, and the air paſſes, whether it be blown in at one end or the other: this is plainly ſeen on immerſing one end in water, and blowing in at the other; the bubbles of air ariſing readily and in great quantities. Comment. Petropolit. Vol. 4. p. 182.

In the trunk or ſtalk of the melon, there are always regularly twelve of theſe faſciculi with their regular foramina; and it is evident to the eye that theſe foramina are perfectly empty, if a ſmall ſegment of the root or ſtalk be placed between the eye and a ſtrong light. The number of faſciculi in the ſtalk is the ſame, whether it be cut near the root, or at ever ſo great a diſtance from it: the ſame in the ſmaller branches, and even in the pedicle which ſuſtains the fruit. The number of the cellules in the fruit alſo anſwers to that of theſe faſciculi in the ſtalk, there being always the ſame number when the fruit is perfectly and regularly formed, tho' ſometimes from accidents there are only ten or eleven to be counted. In the pedicle of the fruit there are indeed more than twelve to be obſerved, but theſe ſupernumeraries are only ramifications of the orignal twelve; on the contrary in the pedicles of the leaves there are only nine of theſe faſciculi to be counted; five of theſe are placed on the convex ſide of the ſtalk, and are greatly ſtronger than the others; and there are two middle-ſized, and two others very ſmall, in the other part. Theſe have their origin from the nine faſciculi of the ſtalk which are neareſt the pedicle; the other three run on without any divarication or without ſending off any branches, and form the pedicle of the next leaf; ſo that new leaves are produced by thoſe alternate faſciculi. The three which run on uninterrupted, form the three great middle ribs of the leaf into which the pedicle expands, and the two lateral ſmaller ribs are formed each of three other faſciculi taken in from the ſtalk; and in ſome of theſe the three faſciculi may be eaſily diſcerned on cutting them tranſverſely; in others only two ſhew themſelves on examination; and ſome part of one of theſe faſciculi may be always traced running out into every ramification of theſe ribs in the leaf, ſo far as the beſt glaſſes are able to carry the ſearch. Theſe faſciculi, as they are continued both thro' the ſtalk and pedicles and even thro' the ribs of the leaves, carry the external appearance of a white ligneous fibre; and as they are protruded to great lengths and run into very ſlender ramifications, their foramina become leſs and leſs apparent, and at length eſcape the obſervation with the very beſt miſcroſcopes.

If at any time the ſtalk near the inſertion of a leaf, and the leaf itſelf near that part, has happened to rot; it is eaſy to draw out theſe faſciculi regularly in the proper number; and theſe in their larger part ſhew all their foramina very beautifully, while in the ſmaller they become leſs and leſs diſtinct. The main ſtalk or trunk of the plant has a cavity or hollow in the middle, which is not continued to the root, nor to the pedicles of the leaves; and near the origin of the young branches, in that part of the ſtalk to which the inner part of the leaf correſponds, there is a greeniſh diaphragm which occupies the middle of the ſtalk, into which the fibres of the ſtalk, after making their ramification for forming the faſciculi of the pedicle, are inſerted laterally; after which, penetrating the ſtalk, and coming out at that part where the origin of the leaf is to be, they form a ſort of thin membrane, which covers the tender firſt ſhoot of the leaf and the young branch. This membrane finally ſhews its twelve faſciculi; and thus the true number is every where continued, unleſs in ſome few places where two of them have happened to cohere on their running too cloſe together; but in this caſe they ſoon divide again, and ſhew their true number. Comment. Petropol. Vol. 4. p. 184.

From the whole it may be concluded, that if the *Tracheæ* of plants are continuous canals, containing only air, and compoſed of a firm matter in their ſides, theſe faſciculi before deſcribed, as found in the root, ſtalks, &c. of the melon, are true *Tracheæ*: for it is plain that they are empty canals, or containing no other matter than air; neither need it be doubted that there are ſuch in all plants, becauſe in ſome even the beſt microſcopes cannot diſcover them: for we find in this very plant that thoſe *Tracheæ*, which in a part of their length are very conſpicuous, become ſmall and not to be diſtinguiſhed as hollow, in their finer and ſmaller extremities; and in ſuch plants as are ſuppoſed to have none of them, they may either be ſo minute as not to have a diſcernable hollow, or elſe their cavity, or at leaſt the new made orifice of it, may be occluded by the other veſſels of the plant throwing out their juices into it, on being wounded. We ſee that in the melon theſe *Tracheæ* are carried from the root to every part of the plant with great regularity, and that they are included in what we commonly call the woody fibres of plants, and have their ſides formed of the matter of thoſe fibres; whether theſe fibres have any juices circulating thro' other ſmaller canals, or are only deſtined to ſupport the *Tracheæ*, or air veſſels, is a queſtion not eaſily determined: they are much dryer than any other fibres of the plant, and ſeem to contain no juices, except thoſe deſtined for their own proper nutrition. They have by ſome been ſuppoſed to ſerve for the carrying back to the root ſuch juices as were not employed in the nouriſhing the plant; but all experiments ſeem to diſcountenance this conjecture, and it ſeems to have been built upon the obſerving this part of the vegetable without ſeeing its true uſe, or finding out the numerous *Tracheæ* which it ſuſtained. The cavity in the middle of the ſtalk may be attributed to the expanſion of the green fibres, and of the utriculi which form ſo great a part of the plant; and the motion of the juices in theſe may poſſibly be owing to the motion of the air in theſe *Tracheæ*, regularly dilating and contracting them. But the great eaſe and plainneſs with which they are followed in this ſearch is owing to their largeneſs, and the tenderneſs of the ſtalk.

It is eaſy to ſee in what manner the ligneous parts of plants contribute to vegetation, ſince in thoſe parts only the *Tracheæ* are ſituated: and hence alſo the reaſon appears very obvious, why grafts do not ſucceed unleſs the ligneous part of the ſtock be touched in the operation; all the *Tracheæ* of the ſtock being in this part, and it being impoſſible that the *Tracheæ* of the graft ſhould have any communication with them, unleſs brought into contact by opening this ligneous part of the tree. Act. Petropol. Vol. 4. p. 187.

Nothing ſhews the *Tracheæ* of plants in ſo beautiful a manner as a tranſverſe ſegment of a young ſhoot of the vine. They may be in this diſcovered in a good light even by the naked eye; but with the help of but a ſmall magnifying glaſs they appear very beautiful and diſtinct. In the generality of other trees, theſe *Tracheæ* are ſo ſmall, that even the largeſt magnifiers in our microſcopes cannot well diſtinguiſh them: ſo that Fontenelle and many other great men have doubted their exiſtence: but even where theſe are ſmalleſt of all, as in the petiola or middle ribs of the leaves of plants, they may, tho' wholly imperceptible to the ſight, be proved to exiſt, by experiments. If a ſmall cylindric glaſs be filled with water, and have all its air exhauſted from it by the air-pump, and the middle rib of a leaf be then cleared from the other parts, and cut off at both ends, and plunged at one end into this water, while yet in the exhauſted ſtate, the bottom of the petiolum being ſupported from touching the bottom of the glaſs, the ſituation and number of the *Tracheæ* in it will be eaſily diſtinguiſhed by a ſtring of bubbles, which, ariſing from each of them, will make a row of beads, as it were riſing in a continued chain to the ſurface. Act. Erudit. Ann. 1722. p. 24.

TRACHELAGRA, a term uſed by ſome medical writers to expreſs the gout in the neck.

TRACHELIUM, in Mr. Tournefort's ſyſtem of botany, the name of a diſtinct genus of plants the characters of which are theſe: The flower conſiſts of one leaf, and is ſhaped like a funnel, and divided into ſeveral ſegments at the edge. The cup of the flower is finally converted into a membranaceous fruit, which is uſually of a trigonal form, and is divided into three cells, which uſually contain a number of very ſmall ſeeds.

The ſpecies of *Trachelium* enumerated by Mr. Tournefort are theſe: 1. The blue-flowered umbelliferous *Trachelium*. 2. The jagged-leaved violet-coloured umbelliferous *Trachelium*. 3. The hairy *Trachelium* with flowers growing in cluſters from the alæ of the leaves. 4. The rock-*Trachelium* with flowers collected into heads. 5. The violet-coloured African *Trachelium*, with flowers growing ſcatteredly all upon the ſtalks. 6. The American ſow-thiſtle-leaved *Trachelium*, with very long white flowers. *Tourneſ.* Inſt. p. 130.

TRACHELOMASTOIDÆUS, in anatomy, a name given by Albinus to a muſcle, called by Winſlow and others the *complexus minor*, or *maſtoidæus lateralis*.

TRACHELOS, a word uſed by ſome anatomical authors to expreſs the neck.

TRACHIDNA, in ichthyology, a name given by Jovius and ſome others to the *draco marinus* of the old authors, called by us the *weever*.

It is a ſpecies of the *trachinus*, deſcribed by Artedi under the name of the *trachinus* without beards and with the lower jaw longer than the upper. See the next article.

TRACHINUS, in the Linnæan ſyſtem of zoology, the name of a genus of fiſhes, of the general order of the acanthopterygii: the characters of theſe are, that the opercula of the gills are pointed, and the eyes are placed near one another in the top of the head. *Linnæi* Syſtema Naturæ, p. 53.

The characters of this genus, according to Artedi, are theſe: There is one or more prickles at the upper angle of the coverings of the gills, and the head has ſome rough tubercles

on it. The eyes are placed near one another in the upper part of the head. There are two back fins. The foremoſt one is very ſhort. The appendices of the pylorus are from eight to twelve in number.

The ſpecies of this genus are only two: 1. The *Trachinus* with the lower jaw longeſt, without beards. This is the fiſh called the *draco* and *araneus marinus*, and by us the *weever*. The other is the *Trachinus*, with ſeveral cirri in the lower jaw.

This is the uranoſcope, or *Trachinus* of authors, called alſo *callionymus*. *Artedi* Gen Piſc. See the article URANOSCOPE.

The name is originally Greek, the word τραχεινος ſignifying rough, ſharp, or prickly. It was given to this fiſh from the rays of its back-fin being remarkably rigid, and ſharp like prickles.

TRACHINUS *Lapis*, a ſtone mentioned by the writers of the middle ages, as poſſeſſing many great medicinal virtues. It ſeems to have been a kind of *lapis nephriticus*, being deſcribed as bright, but not tranſparent, and being of two kinds, the one blackiſh, the other green.

TRACHURUS, in zoology, the name of a fiſh of the cuculus-kind, called in Engliſh a *ſcad*, and by ſeveral authors, *ſuro*, *ſaurus*, and *lacertus marinus*.

It very much approaches to the nature of the common mackrel in colour, ſhape, and taſte; inſomuch that the French call it *maquereau-batard*, or baſtard-mackrel; but it never grows to the full ſize of the mackrel, and is of a more flat ſhape. Its back is of a very ſhining blue. Its belly white, with a faint bluſh of reddiſhneſs. Some have erroneouſly ſuppoſed, that it had no ſcales; but it is covered with conſiderably large ones. Its ſide-lines are one on each ſide, and are made each of a row of bony ſcales. Theſe have all eminences in their middle, and riſe ſo high near the tail, as to make that part of the body of the fiſh appear ſquare. The eyes are large, and the lower jaw is a little longer than the upper. The jaws are rough like files. The back has two fins, a ſhort anterior one, and a long one behind it; and the tail is conſiderably forked. This fiſh uſually ſwims in large ſhoals, and is caught in the Mediterranean, and on the Engliſh coaſts in Cornwall, and ſome other places. It is eſteemed a very well taſted fiſh. *Ray*'s Ichthyography, p. 290.

TRACHURUS *Braſilienſis*, a name given by Mr. Ray to a fiſh of the cuculus-kind, commonly eaten in the Braſils, and known among writers on theſe ſubjects by its Braſilian name *guaratereba*. *Ray*'s Ichthyology, p. 291. See the article GUARATEREBA.

TRACING, in huſbandry, a term uſed by our planters for the method of preſerving the maize, or Indian corn. This, being a large grain, is apt to ſpoil, if not carefully preſerved.

Some thraſh out the corn as ſoon as the ears are gathered, and lay it up in holes of the earth, which are their granaries: But thoſe who have not opportunities of doing this, *trace* it, that is, they leave it in the ear, and weave, or faſten together a great number of ears by the ends of the huſks: Theſe *traces* of corn they hang up within doors, on ſuch ſupports as will keep them from one another; and they will, in this manner, keep good the whole winter.

This is a method of our introducing; but their own, of burying the clean corn, was at leaſt as good, and was the ſame practiſed by the Ægyptians of old, and by all the wiſeſt nations of the eaſt at this time. But whether we have improved their huſbandry in this particular, or not, it is certain that we have greatly aſſiſted them in the planting this corn, which we do by the plough, inſtead of the troubleſome method they had of doing it with the hoe. The manner of our planting it is this: We plough ſingle furrows the whole length of the field, and at about ſix foot diſtance one from another; we then plough others acroſs at the ſame diſtance, and then, wherever the furrows meet, the corn is thrown in; it is then covered either by the hoe, or by running another furrow behind it with the plough; and when the weeds begin to overtop the corn, they plough the ſpaces again, and by this means deſtroy and turn in all the weeds, and give the earth ſtirring, that greatly aſſiſts vegetation.

The famous method of horſe-hoing huſbandry, ſo celebrated by Mr. Tull in a book written on that ſubject, is no other than a bringing home this method of our American planters, in the culture of the maize, and applying it to our European corn, with which, however it can never ſucceed ſo well. The Indians, and our planters, join in the method of raiſing a hill of earth round every ſtalk of the maize; and when the ground is poor, or out of heart, they bury two or three fiſhes, of a kind called by them the *aloofe*, under every hill, and by this means they have a crop double to what would otherwiſe have been produced. The Engliſh have learned this manure from the Indians; and in New England, where they are near the fiſhing-ſtages, they bury the heads and garbage of the cods, which ſucceed as well as the aloofe, and coſt nothing but the carriage.

The lands on which the maiz or Indian corn has grown, are as well fitted for our European corn as if they had been laid fallow. The reaſon of this is, that the plants of the Indian corn ſtanding at ſix feet diſtance from each other, the far greater part of the ground has remained unoccupied, and at the ſame time has had the advantage of often ploughing to kill the weeds, which is a benefit equal to that of dung and reſt. All this, though it tends to prove the doctrine of horſe-hoeing huſbandry not new, yet it ſtrengthens the ſyſtem greatly.

The Indians, who do not intend an after-crop of European corn, occupy all the ground which they have been at the pains of clearing for the maiz, in another manner: They plant with the corn, in the ſame hill, a kind of kidney bean; this grows up with the corn, and its ſtalks climb up about thoſe of the maiz, which ſerve as well as ſticks or poles for it. In the center, at every vacant place between the hills, they plant ſquaſhes or pompions, which ſucceed very well; and often, after the laſt weeding of the ground, they ſprinkle in a quantity of turnep-ſeed; ſo that when the harveſt is over, they have a crop of turneps for the winter. Phil. Tranſ. N°. 142.

TRACING, among miners. See the article TRAINING.

TRACTORIÆ, among the Romans, were diplomas or tickets given by the emperor to ſuch as he ſent into or called out of the provinces, whereby they were entitled to the uſe of the public poſt, and to be maintained at the expence of the government. *Pitiſc.* in voc.

TRAGACANTH, or *Goat's-Thorn*, *Tragacantha*, the name of a genus of plants, the characters of which are theſe: The flower is of the papilionaceous kind, and its piſtil, which ariſes from the cup, finally becomes a bicapſular fruit, containing ſeveral kidney-ſhaped ſeeds: To this it is to be added, that the leaves ſtand in pairs upon the ribs, which uſually terminate in a prickly point.

The ſpecies of *Tragacanth*, enumerated by Mr. Tournefort, are theſe: 1. The common *Tragacanth*. 2. The woolly *Tragacanth*, ſuppoſed to be the *poterium* of Cluſius. 3. The purple-flowered ever-green Alpine *Tragacanth*. *Tourn.* Inſt. p. 417.

TRAGACANTHUM *venereum Indicum*, in natural hiſtory, a name given by ſome writers to the birds neſts ſo famous in ſoops in China, and in ſome parts of Europe, for their cordial reſtorative, and provocative virtues. They are the neſts of a kind of Indian ſea-ſwallow, and are made up of a ſubſtance reſembling gum-tragacanth, and, like it, melting in a jelly in any warm and watery liquor.

TRAGASIAN *Salt*, a term uſed among the antients for a ſort of ſea-ſalt, very little different from the common kind, being made by the evaporation of the water of ſome ſalt ponds near the ſea-ſhores.

TRAGELAPHUS, in zoology, the name of an animal of the goat-kind, of which there are two ſpecies, the one deſcribed by Geſner, the other by Bellonius.

The *Tragelaphus* of Geſner is a little larger than our common deer; its colour the ſame with that of this creature, and its hair of the ſame ſort and length; but its body is thicker; and its legs much ſhorter. Under its chin it has the beard of the goat; and all the way along the under part of its throat there runs a ſeries of long hairs, which hang down almoſt to its knees; the upper part of its neck has a mane of long hairs alſo, which are much darker-coloured than thoſe of the body. Its knees are covered alſo with long and thick tufts of hair, reaching a good way backwards. Its hoofs fall off every year. The horns reſemble thoſe of the ram, or rather of the goat, and are black, and bent backwards. The ears are ſhort. The eyes, the tail, and the parts of generation, are the ſame as in deer. It is a very gentle animal, and full of ſport and play, and is found wild among the rocks.

The *Tragelaphus* of Bellonius, is a creature with the hair of the goat, but without its beard; its horns do not fall of, and are of the ſhape of thoſe of the goat, but not unfrequently curled like thoſe of the ram. Its head, face, and ears, are very like thoſe of the ram; and its ſcrotum is very large, and hangs down in the ſame manner with that creature's. Its legs are of the length of the ram's; its hips under the tail are white; its tail black; and its neck, both on the upper and under part, and its breaſt alſo, are ſo hairy, with long hairs, that they look as if covered with one continued beard. The hairs on the ſhoulders and breaſt are long and black; it has on each ſide a remarkable grey ſpot; its noſtrils are black, and its mouth and the under part of its body white. *Ray*'s Syn. Quad. p. 82.

TRAGIA, in botany, the name of a genus of plants, the characters of which are theſe: It produces male and female flowers on the ſame plant. In the male the perianthium is divided into three ſegments, which are ovated, acute, and expanded. There are no petals. The ſtamina are three capillary filaments, of the length of the cup; and the antheræ are roundiſh. Plumier makes this cup a monopetalous funnel-faſhioned flower; but this does not appear to be really the caſe. In the female flowers the cup is divided into five ſegments, which are ovated and hollow. The germen of the piſtil is roundiſh, and furrowed with three lines. The ſtyle is ſingle, erect, and longer than the cup. The ſtigma is trifid and expanded. The fruit is a very large tricoccous capſule, of a roundiſh figure. The ſeeds are ſingle and roundiſh. *Linnæi* Gen. Plant. p. 448. *Plumier*, Gen. 12.

TRAGIC *Dance*, in antiquity. See the article EMMELIA.

TRAGICUS *Muſculus*, in anatomy, a name given by Albinus to one of the muſcles of the eye, called by Santorini and Winſlow, *Muſculus Tragi*.

TRAGIUM, in botany, a name by which ſome authors have called the fraxinella, or baſtard-dittany, the root of which is uſed in medicine. *Ger.* Emac. Ind. 2.

TRAGIUM *Germanicum*, in botany, a name given by ſome authors to the *atriplex olida*, or ſtinking orach. *Ger.* Emac. Ind. 2.

TRAGO-ORIGANUM, in botany, a name given by ſome authors to the *marum Syriacum*, or Syrian herb maſtic. *Pluk.* Alm. p. 374.

TRAGOPOGON, *Goats-beard*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the ſemifloſcular kind, being compoſed of a number of ſemi-floſcules placed on the embryo ſeeds, and contained in a cup divided into many ſegments; but not of the ſcaly kind. The embryos finally ripen into ſeeds, which are enveloped in a ſort of covering, and winged with down, and are all fixed to the thalamus of the flower. See Tab. 1. of Botany, Claſs 13.

The ſpecies of *Goats-beard*, enumerated by Mr. Tournefort, are theſe: 1. The great yellow-flowered meadow-*Tragopogon*. 2. The leſſer yellow-flowered meadow-*Tragopogon*. 3. The *Tragopogon*, with long ſinuated leaves. 4. The *Tragopogon*, with leek-like leaves, and pale violet-coloured flowers. 5. The leek-leaved *Tragopogon*, with bluiſh purple flowers, commonly known by the name of *artiſi*. 6. The leek-leaved *Tragopogon*, with blackiſh-purple flowers. 7. The leek-leaved *Tragopogon*, with blue flowers. 8. The leek-leaved *Tragopogon*, with white flowers. 9. The graſſy-leaved *Tragopogon*, with bright red flowers. 10. The crocus-leaved *Tragopogon*, with bluiſh purple flowers. 11. The yellowiſh purple ſmall *Tragopogon*. 12. The hairy *Tragopogon*. *Tourn.* Inſt. p. 477.

There are two or three ſpecies of this plant well known among us, the one wild in our meadows and paſtures, by the name of *go to bed at noon*, from its flowers always ſhutting up in the middle of the day; another kept in our gardens for its beautiful red flowers; and a third cultivated for its eſculent root, and known by the name of ſalſafy. This was originally from Italy, and is ſtill kept in many gardens as a good root; but is not common in our markets.

Theſe plants are propagated by ſowing their ſeeds in ſpring on an open ſpot of ground. The ſalſafy ſhould be ſowed in rows at nine or ten inches diſtance; and when the plants are come up, they ſhould be left at about ſix inches aſunder in the rows; they then require no further care but to be kept clear from weeds; and if the ſoil be light, and not too dry, they will grow to a conſiderable ſize by winter. The roots are to be taken up for uſe when the leaves are decayed, and continue in ſeaſon till March; and then the young ſhoots, which are very large and thick, are by many boiled as aſparagus, and make a very delicate diſh. *Miller*'s Gardeners Dict. in voc.

TRAGOSELINUM, in botany, the name of a genus of umbelliferous plants, the characters of which are theſe: The flower is roſaceous, conſiſting of ſeveral heart-ſhaped leaves, irregular in ſize, and diſpoſed in a circular form, and ſtanding on a cup which afterwards becomes a fruit, compoſed of two oblong ſeeds, which are gibboſe and ſtriated on one ſide, and flat on the other.

The ſpecies of *Tragoſelinum*, enumerated by Mr. Tournefort, are theſe: 1. The great *Tragoſelinum*, or pimpernel-ſaxifrage, with white flowers. 2. The great *Tragoſelinum*, or pimpernel-ſaxifrage, with red flowers. 3. The great *Tragoſelium*, or pimpernel-ſaxifrage, with burnet-leaves. 4. The leſſer *Tragoſelinum*, or common ſmall pimpernel-ſaxifrage. 5. The tall African *Tragoſelinum*, called by authors the great African pimpernel-ſaxifrage.

TRAGULA, among the Romans, a ſtrong kind of javelin, with a barbed head. *Pitiſc.*

TRAGUM, in ichthyology, the name given by Ariſtotle, and others of the old Greek writers, to the *trugum* of Elian, Athenæus, and Oppian. Both names are uſed to expreſs the fiſh called by authors the *paſtinacha marina*, and by us the *fire-flaw*, or *fire-flaire*. The fiſh is a ſpecies of the raja, and is diſtinguiſhed by Artedi by the name of the ſmooth-bodied ray, with no fin on the tail, and with a long ſpine placed on it, ſerrated before. See the articles RAJA and PASTINACHA.

TRAINING, or TRACING, (*Cycl.*) in mineralogy, a term uſed by our miners to expreſs the tracing up the mineral appearances on the ſurface of the earth to their head or original place, and there finding a mine of the metal they contain.

The principle on which this practice depends, is the change wrought in the face of the earth by the deluge, of the effects of which theſe remains are a very great proof. The ſuperficial, or upper part of veins, or loads of ore, is always the pooreſt, the richer ores lying deeper down, the poor ones only ſerving to lead the way. Theſe poor ores, or ſtones impregnated with the metalline matter of the mine, and called by our workmen, *ſhoad-ſtones*, were, probably, at the creation of the earth, brought regularly up to the ſurface, and ſhewed the places of the metals below. But at the time of the covering the earth by the waters of the deluge, they were, with the reſt of the ſurface, waſhed off, and carried, with the deſcent of the water, down into the plains, or into the beds of rivers, and there carried many miles down the ſtream. This being an allowed truth, the art of *Training* a mine is eaſy; for though this carrying the ſhoad-ſtones and poor ore, was done ſo many ages ago, yet all the way that ſome pieces were carried on, others would be depoſited by the way; and the heavieſt and richeſt falling firſt, the lighteſt would always be carried fartheſt, and there would be always left a ſtream of this matter all the way from the place where it was firſt produced, that is, where the mine now is; for the breaking of the ſurface of the earth, at this great cataſtrophe, was not ſo deep as to reach that; and this ſtream or *train* of matter will be found richer and richer as it approaches the mine, and finally will ſtop at the place where it is.

Where there is ſuppoſed to be a mine of any metal, the hills and country all about are diligently ſearched; the ſituations, and deſcent of the lands, and the earth, ſtones, and other foſſile bodies, are examined, particularly the colour and nature of the various ſorts of earths and ſtones which are found on the hills where the mine is ſuſpected to lie, that they may be readily known again if any of them are found in the neighbouring valleys. The ſtones which denote the loads, and are called *ſhoad-ſtones*, are found two, three, four, or even five miles from the hills, where they originally lay; but if the ſame ſort of ſtones are remembered on the hills, the *Train* is to be made out.

After any great land-flood, in which it is ſuppoſed there are uſually ſome new frets made in the banks of the rivers, theſe are carefully examined, to ſee whether any metalline ſtones may be found in their ſides and bottoms, all being then ſo clean, that the ſmalleſt ſhoad-ſtone may uſually be ſeen. If no ſtones of this kind are found, it ſometimes is of uſe, in order to farther reſearches, to examine whether any pieces of earth, of a different colour and nature from that of the reſt of the bank be found; for this being, if any ſuch is found, waſhed alſo from the neighbouring hills, it proves a great direction which ſide of the hill to ſearch into.

If no ſhoad-ſtone or grewt of a different nature from the reſt be found in theſe frets or newly worn banks, the miners leave the place for the preſent. For though the bed of the river afford many metalline ſtones, they never regard them, the continual change of place they receive from the current of the water rendering them only tokens that there is metal ſomewhere in the country; but they confound and perplex rather than inſtruct in the ſearch after the places where it is.

If there be found indeed ſtones of the ſhoad-kind, full of protuberances, or having ſharp angles, as if newly broken, it may be worth while to ſee whether they are not waſhed out of ſome part of the neighbouring banks by the late floods; as this ſort of appearance is a token of their having been newly taken into the bed of the river. But if they are rounded and ſmooth, it may be concluded that they have been long ſubject to the action of the water, and brought, perhaps, many miles from the places where they were originally lodged in the earth, and where only they could have been of any uſe to the *Tracer* of the mine.

When the frets in the ſides of rivers have been traced in vain, the ſearcher after a mine goes up to the ſides of the hills moſt ſuſpected to have mines in them, and there ſeeks for a convenience of bringing a little ſtream of water to run down. When this is found, he cuts a trench about two foot over, and as deep as the ſhelf. The water is turned into this cut, and after two or three days running in it, all the filth will be waſhed away, and the looſer part of the earth cleared off; and if any ſhoad-ſtones are lodged within the whole courſe of this cut, they will be found. If any ſuch are found, it is an unqueſtionable proof that there is ore in the higher parts of the hill; this encourages the work, and there is always found a mine, or at leaſt a ſquat, which will, without much danger, repay the expence and trouble. The ſquats are flat parcels of the ore, lying in different and diſtinct places of the hills, and not communicating with one another.

Sometimes a great deal of this labour is ſaved, and the ſhoad-ſtones are found on the ſurface of the ground, either turned up by the plough, or thrown up in ſmall quantities in mole-hills, or raiſed by ſome other accident; for they are ſeldom found naturally lying on the very ſurface of the earth; for the putrid remains of vegetable and animal ſubſtances, and other adventitious matter, has raiſed the ſurface of the earth in all places, ſince the time of the flood, and made indeed a ſort of new ſurface. Theſe ſtones were certainly laid bare on the ſurface of the ground, at the time of their being carried down from the mines; but this adventitious matter has buried them in this long tract of time, and they are generally found under about a foot of a ſort of vegetable mould. If, by any of theſe ſearches, a ſhoad is found, the miners have nothing to do but to follow it to its head, and there make the opening; but if no ſuch direction can be had, nor any ſhoad found, and there is yet ſuſpicion that there is a mine in the hill, the method is to make an *eſſay-hatch*, as it is called; this is ſunk near the

foot or bottom of the hill, and is an opening of about ſix foot long, and four foot broad, made in the ſearch of a vein as deep as the ſhelf; this is a caution that muſt be always carefully obſerved, for if they are made leſs deep than this, they may miſs of the vein tho' there is one. And the ſinking thus deep is always attended with certainty, for if no ſhoad is found on this, it may be concluded there is none there; except that ſometimes it is found that the ſhoad has been waſhed clean away, within two or three foot from the land: and then the load or vein is two foot farther or thereabouts up in the hill. If any ſhoad is found in the eſſay-hatch, there is a certainty of a vein of ore; neither doth it add a little toward the making a conjecture how high up the hill, or how far off the vein ſtring, or bonny is, carefully to mark how deep from the ſurface of the earth the ſhoad lies, for this is held an infallible rule, that the nearer the ſhoad lies to the ſhelf or faſt ground, the nearer the vein itſelf is, and *vice verſa*.

When there is no ſhoad or appearance of a mine found in the firſt eſſay-hatch, if the conjecture of a mine being in the hill has any tolerable foundation, the *tracing* it does not end here; but they go ten or twelve fathom up the hill and there open a ſecond eſſay-hatch, and if no ore or ſhoad-ſtone is found in this, they go as many fathom on each hand at the ſame height with the ſecond hatch; and there open a third and a fourth hatch, of the ſame depth and dimenſions with the firſt; if in neither of theſe there is found any ſhoad-ſtone, they aſcend proportionably with three more hatches, if the ſpace of ground require, at every ten or twelve fathom, and in this manner open them three abreaſt, at twelve fathom diſtance up to the top of the hill. If no ſhoad is found in any of theſe, it is concluded then that there is no *tracing* a mine there, and the hill is left.

If any ſhoad is found in any of theſe hatches or openings, the aſcending hatches from this are kept on in a direct line, and the deeper the ſhoad lies the nearer the vein is. The ſhoad grows gradually deeper from the ſurface, but nigher the ſhelf as they approach the mine; as ſuppoſe it be but half a foot from the ſhelf and ſeven foot deep from the ſurface, the vein is then concluded to be within a fathom or two; and on this the firſt proportion of twelve fathom between every hatch is leſſened, to ſix, four, two, one, or even leſs than that, as the vein is conjectured to be more and more near.

It often happens, for want of a good gueſs in this matter, that the diggers over-ſhoot the load; that is, they open their next hatch too high up the hill, or above the load or vein: this is a miſtake eaſily diſcovered and eaſily rectified. If a ſhoad is found lying near the ſhelf in one hatch, and in the hatch above there is no ſhoad at all, it is a proof that the hatch is too high, and the remedy is only to ſink a hatch at a middle diſtance between the laſt two, which will probably fall upon the very point of the load, and finiſh the work of *tracing*.

Sometimes it happens, that in continuing the *tracing* of the firſt ſhoad, a ſecond or new one is found; it is not uncommon for two ſhoads to be thus found in one hatch, and this is eaſily diſcovered without any danger of miſtake; for ſuppoſe in the laſt hatch the ſhoad which they *trace* lay at eight foot deep, and in this it lies at ten foot, and beſide this there is a ſhoad found at two foot depth; it is very certain that the ſhoad at ten foot deep is the ſame they were before *tracing*, and this is a new one pointing to another vein or load, which is now firſt diſcovered ſo near the ſurface of the earth. This has generally gravel or earth mixed with it, and is to be carefully examined; when the higher hatches are opened, this is continually found as well as the old load; and when the firſt is *traced* to the point of the vein, this ſecond is to be continued in the ſame manner, by other hatches opened at the ſame diſtances above: it often happens that in *tracing* this ſecond ſhoad, the hatches dug for it diſcover another new one or a third ſhoad; all theſe are to be *traced* one over the other by the ſame hatches, and will all be found worth the ſeeking after. The old writers on mineralogy agree with us in this obſervation, and tell us, it is not uncommon in ſome places to find as far as ſeven loads lying parallel to one another in the ſame hill. In theſe caſes, however there is uſually one maſter-load, or grand vein; the other ſix, that is three on each ſide, being the leſſer or concomitant veins. Five in the ſame manner, ſometimes lie in this order, the grand load in the middle and two on each ſide, but the more common method is three, a large one, and two ſmaller.

Every load has a peculiar coloured earth or grewt about it, which is found alſo with the ſhoad, and this always in a greater quantity the nearer the ſhoad lies to the load, and becomes leſſened by degrees to the diſtance of about a quarter of a mile, further than which that peculiar grewt is never found in any quantity with the ſhoad; ſo that this is a proof that the load or vein is near when it is found in quantity.

A valley may chance to lie at the foot of three ſeveral hills, in ſuch a manner, as to contain three ſeveral grewts, or that earth which was moved with the ſhoad in the concuſſion of the ſtrata at the deluge, with as many different ſhoads or *Trains* of ſhoad-ſtones in the midſt of each: in this caſe it will be very neceſſary to know the caſt of the country, and of each hill in reſpect to its grewt, for the ſurer *training* of them one after another as they lie in order: according to the foregoing rules of eſſay-hatching, the uppermoſt in this caſe always directs which hill to begin with firſt.

It ſometimes happens, that after having *trained* the ſhoad found in a valley up to the upper parts of a hill, there is only a ſquatt, or bonny found inſtead of a right vein of ore, for theſe detached parcels of ore have their ſhoads as well as the right veins. Theſe are uſually about two or three fathom long, and a fathom broad; few of them are larger, moſt leſs, and they never communicate with any other load or vein, nor ever ſend forth any of their own. The extremities of theſe beds of ore terminate without ſending out any ſtrings, not lying within walls as the loads; but tho' they are in the ſhelf or faſt ground, not moved by the flood, their ſurface is equal every where with that of the imaginary ſhelfy one, and they go down five or ſix fathoms deep and there terminate at once. The ore contained in theſe are rich, and they are always wrought out to the conſiderable advantage of the owners.

Theſe are the general rules of *tracing* mines, and tho' ſomewhat tedious and expenſive, they are certain, and never liable to the error and diſappointment the other ſhorter ways, as they are called, are liable to. Theſe ſhort ways are by the *virgula divinatoria* or the hazel-wand, whoſe bending in certain places without any external viſible force, is to point out the place where the vein of ore lies: the waters thought to iſſue from the particular loads are alſo uſed by ſome as a ſhort means of finding the veins; other of theſe ways are alſo by mineral ſteams and effluvia, by the barrenneſs of the ſoil, and the pitching of nocturnal lights on the ſuppoſed orifices of mines. But theſe methods are too extravagant or too uncertain to be uſed in caſes of ſo much conſequence. When the mine is found by the more certain rules of *tracing*, the digging it is a matter of leſs difficulty. Phil. Tranſ. N°. 69. See the article DIGGING.

TRAMELLED, in the manege. A horſe is ſaid to be *tramelled*, that has blazes or white marks upon the fore and hind foot of one ſide; as the far foot before and behind. He is ſo called from the reſemblance the white foot bears to a half *tramel*.

Croſs-TRAMELLED *Horſe*, is one that has white marks in two of his feet that ſtand croſs-ways, like St. Andrews croſs; as in the far-fore-foot, and the near hind foot, or in the near foot before, and the far-foot behind.

TRAMMELS, a kind of net uſed in fowling, the deſcription of which ſee under the article LARK.

TRAMIS, a word uſed by ſome medical writers, to expreſs the line running along the middle of the *ſcrotum*, from the *penis* to the *anus*.

TRANCHEFILE, in the manege, the croſs chain of a bridle that runs along the bit-mouth, from one branch to the other.

TRANSCENDENTAL (*Cycl.*)—TRANSCENDENTAL *Coſmology*. See the article COSMOLOGY.

TRANSFORMATION (*Cycl.*)—TRANSFORMATION *of Inſects*. It is well known that flies are not produced in that form, from the eggs of their parent fly, but undergo a change like that of the butterfly, and the like winged inſects; the egg hatching into a worm; and this after eating, and performing all the operations of animal life for a certain time, enters into a ſtate of reſt, and thence is changed into a fly.

Though the general courſe of nature is the ſame in this reſpect in flies and butterflies, yet the means and manner of it are different; the butterfly makes its coat for this *Tranſformation*; the fly-worms of many kinds have only a ſhell of their own proper ſkin to undergo this change in.

All the fly-worms of the firſt and ſecond, and many of thoſe of the third claſs, have their caſe thus made only of their own ſkin; the different ſpecies afford indeed ſome varieties in the manner of this, but a general idea of the work may be had from obſerving the worm or maggot of the common fleſh-fly in its ſeveral ſtages.

When this creature has arrived at its full growth, it finds it not convenient any longer to remain among the food it has till then lived upon; it quits it and now goes in ſearch of a place where it may wait for its metamorphoſis. To this purpoſe it creeps into the earth, where it remains two or three days without any change; at the end of this time, inſtead of its pointed figure, its white colour, and ſoft fleſhy ſubſtance, it acquires the figure of an egg, and becomes of a cheſnut colour, or ſomewhat rediſh, and looks opake and cruſtaceous; it is in this ſtate perfectly ſtiff, and deſtitute of motion, and the creature ſeems not only to have loſt its form, but wholly to have loſt its life alſo. *Reaumur*'s Hiſt. Inſ. Vol. 4. p. 288.

This however is not the caſe, all that is done, is that the creature has abſolutely quitted its ſkin, which is now become hard and of a determinate figure, and is within it compleating all its changes. Ibid. p. 289.

The manner in which this change of figure is given to the ſkin, is by the creature's drawing its head, and the two or three firſt rings of its body, within the reſt, and by that means making itſelf of this ſhape, ſhort and equally thick at each end. It does this within a few hours after it creeps into the earth, and if taken out after that time is always found of this ſhape, and ſeems to be *transformed*, only that its ſkin has not yet acquired

quired its brown colour. This however is not at all the caſe, for it can now walk as before, and thruſting out its head and the rings it had drawn in, can again acquire its former figure, which however it loſes afterwards at once, and becomes rigid in a few minutes, and in two or three hours the ſkin it has quitted, and which is now a ſhell, becomes reddiſh, and after a little more time acquires its proper cheſnut colour. Ibid. p. 290.

This coat is now no more a ſkin, but a ſhell, and fit to perform all the offices of one; it is no longer connected to the body of the animal, but is become hard, brittle, and rigid. It may however yet be diſtinguiſhed, eſpecially by the help of the microſcope, to be made up of a great number of rings, which may be more diſtinctly counted than they could be in the worm: there are nine of theſe between the caps, which make the two ends; two rings at leaſt, without counting the head, go to the forming the anterior cap, which is purſed or wrinkled up like the top of a bag when cloſely drawn together; but theſe folds or wrinkles do not abſolutely meet and cloſe up the end. The microſcope ſhews at each extremity of one of the diameters of this cap two little bodies not at all diſtinguiſhable by the naked eye; each of theſe is one of the anterior ſtigmata.

On the two rings which follow this cap immediately, underneath each of theſe ſtigmata; there may be obſerved a ſmall band, very little elevated above the ſurface of the reſt of the ſhell. Theſe ſeem the two ſtrongeſt parts of the ſhell, but they are in reality on the contrary the two weakeſt, and are the places where the ſhell is to ſplit and open to give paſſage to the fly. Ibid. p. 293.

On the cap which makes the other extremity of the ſhell may be ſeen, the two poſterior ſtigmata, theſe are the moſt conſiderable in the creature, and are each a collection of three oblong ſtigmata. Ibid. p. 294.

The *Transformation* in this ſhell is double, before the inſect becomes what it is to be finally, a fly like its parent; the firſt *Transformation* is into an oblong maſs of matter, void of all form, either of the worm it was, or of the fly it is to be; but from this it by degrees aſſumes the figure of the nymph, in which all the lineaments of the future fly are diſtinguiſhable. This *Transformation* (which is in theſe, and perhaps in all the worms that make a caſe of their own ſkin, prior to their change into the nymph ſtate) may be called the change into the long ball or ſpheroide, or into the ellipſoide. This fly-worm of the blue fly is one of thoſe, which with moſt difficulty ſhews this *Transformation*; but on boiling it at a proper time and afterwards carefully opening the ſhell, it will always be found in this ſtate. Ibid. p. 295, 296.

It is a very eaſy thing to be provided with theſe worms in their ſhell ſtate, in a ſufficient quantity; and it is a very pleaſing examination to boil and open ſeveral of them daily, to ſee the progreſs in their reſpective *Transformations*; by this means after two or three days one may diſtinguiſh the legs on the anterior part of the body, but very ſhort; the day following, the wings will begin to ſhew themſelves, and the ends of the legs will be found extended toward the hinder part; a day afterwards the end of the trunk may be diſtinguiſhed, and the head begins to ſhew itſelf. And finally the legs will be ſeen in their due length and proportion, and the reticular eyes will very plainly ſhew themſelves. Ibid. p. 299.

Several accidents, as the heat or cold, and dryneſs and wetneſs of the ſeaſon, contribute much to the forwarding or backwarding theſe ſucceſſive changes: in ſummer the worms will remain ſometimes in a moiſt earth ſix or ſeven days without changing; and others will acquire their ſhell-ſtate in a dry earth in two or three days: a moiſt earth may alſo very eaſily much impede the ſecond *Transformation*, from the ſtate of the oblong ball into the nymph. Since in order to this there is required an evaporation of a great deal of moiſture, which is in the ſhell; and this cannot be ſuppoſed to be ſo readily performed in a moiſt as in a dry place; and that ſuch an evaporation is required is very plain, from the change of weight in the ſhell in theſe two ſtates; for when the contained animal is in the form of its oblong ball, the ſhell is in the whole heavy enough to ſink in water; but when it has acquired the form of the nymph, it is ſo light that it ſwims. Ibid. p. 305.

The time required for theſe ſeveral changes often differs a little, and ſometimes conſiderably; but at a medium it ſtands thus: the worms which have been ſeen to creep into the earth on the 21ſt of April, have come out perfect flies on the 16th of May, and that in a cold ſeaſon for the time of the year.

The ſhells of ſeveral of this brood opened on the 28th and 29th of April, ſhewed the inſect in form of the oblong ball; the parts of the nymph were not diſcoverable in any opened before the 30th of April; but theſe ſhewed the legs of a third part of the length of the body: theſe nymphs had all a cavity on their anterior part; but thoſe opened on the 2d and 3d of May had not this cavity; but the dart and hooks viſible in it before were now applied againſt the ſurface of the cap, and the head of the future fly ſhewed itſelf: on the fourth of May the trunk appeared very fair, and the reticular eyes were become viſible, tho' all that was now viſible, was ſeen thro' a thin and delicate ſkin. Ibid. p. 306.

On the 6th of May the *antennæ* were diſtinguiſhable, and their form very perfectly finiſhed; on the 7th the ſmooth ſmaller eyes were diſtinguiſhable. The 8th of May the reticular eyes had acquired a reddiſh colour; the 9th the colour was yet more natural; the 10th theſe were become of a deep red, and the ſmooth eyes looked reddiſh; and on ſome of the ſtigmata of the nymph, the ſpots of the former worm were now eaſily diſcoverable; on the 11th the nymphs were all become hairy; on the 12th theſe hairs were more viſible, and of their natural colour, and the legs were become greyiſh, and of their full length. The lips of the trunk were of their natural colour, almoſt black; and the antennæ began to be coloured; and the whole ſhape of the fly was very diſtinct. The 13th, 14th, and 15th days made no great changes, as the parts were now already formed, and only wanted their proper ſtrength and conſiſtence; and on the laſt day, before their egreſs, and not before, did they appear to have any power of motion; which, as ſoon as they had it, was applied to the freeing themſelves from their ſhell, and coming out in the form of the parent fly. Ibid. p. 308.

The changes a multitude of other fly-worms undergo, and their ſhells made of their proper ſkin, are the ſame in all eſſential points with thoſe of the flies firſt mentioned. Some ſpecies have their ſhell more deeply annular, others almoſt entirely ſmooth; ſome have the two ends ſomewhat pointed, and others only one of them ſo; and in ſome this larger inflated end is the anterior, and in others the poſterior. Ibid. p. 309.

Swammerdam, to whom the world is indebted for the firſt true inſight into the wonders of the inſect world, has evidently proved, that what had before been called by the pompous and myſterious names of changes and *Transformations* of one animal into another, as of a worm into a fly, and the like, is, in reality, no more than a gradual and natural growth and evolution of the parts, not any metamorphoſis of them; and this growth reſembles very well, when judiciouſly conſidered, not only the increaſe of other animals, but alſo the natural budding and increaſe of plants.

The progreſs of theſe changes, as they are called, in inſects, is expreſſed by two different terms in their two moſt remarkable ſtates; the words are the *nymphæ* and the *chryſalis*.

Theſe words are often miſunderſtood, and even miſapplied and confounded by authors one with another. What the moſt accurate authors have originally meant by them, however, is this:

The nympha is the change of the worm, which carries the proper ſhape of the future little animal; and the chryſalis, or aurelia (for theſe words have the ſame ſenſe, derivation and meaning) the change of that caterpillar, which ſhews no parts at all of the animal that is to come.

This is the regular meaning of the two words; but Swammerdam proves them to expreſs, as the ſchoolmen call it, diſtinction without difference, for that he was always able to diſcover the ſeveral parts of the future animal, as well in the chryſalis as in the nympha; and that others had only made the difference from the want of due attention and application.

This author therefore makes no other difference between the nympha and chryſalis, but this; that ſince the parts of the future animal are not ſo plainly diſcernable in the chryſalis as in the nympha, and a fine golden colour is very common in the more obſcure ſtate of the animal, and is not found on any of thoſe ſo perfect, as to be vulgarly called nymph; it may be proper to expreſs, by certain forms of ſpeech, thoſe ſlight but obvious differences; but not to give them the pompous names of *Transformations*, and the like. The nymphs he therefore calls ſimply puppets, and the chryſalis's by the name of gilt puppets.

Swammerdam refers the general changes, as they are called, of the inſect tribe, into four claſſes, one or other of which takes in that of every known inſect, a very few excepted, whoſe progreſſions have not yet been ſufficiently inquired into, to aſcertain their nature. The four general claſſes, or ranks of changes, are diſtinguiſhed by four different ways of production, change, and growth.

The firſt rank, which he expreſſes by the name of nympha-animal, hath a little animal fully formed in the egg, which, after the evaporation of the ſuperfluous moiſture, comes forth perfect, and ſo grows up. Such is the louſe, and the like.

The ſecond claſs are diſtinguiſhed by the name of *nympha-vermiculus*. Theſe have the parts of the future inſect imperfectly ſhaped in the egg, and, after hatching, leave the creature to acquire its perfection viſibly by outward food. Of this kind are the graſshopper, the locuſt, the cricket, and many other the like creatures.

The third claſs he diſtinguiſhes by the name of the *nympha-chryſalis*, or *nympha-aurelia*. Theſe, after hatching, obtain their perfection darkly, and not till after the caſting off the laſt ſkin; ſuch are the butterfly and the like. The ſecond and third claſs agree in this, that not a perfect animal, but a worm is produced from the egg, and precedes the growing of the perfect parts; yet with this difference, that in the ſecond the little creature grows up manifeſtly and obviouſly to the eye; but in the third all is in darkneſs and obſcurity under the ſkin, and, as it were, within the body of the creature.

The fourth claſs is diſtinguiſhed by the phraſe *nympha vermiformis*; and the creatures of this claſs remain always ſhut up in the caſe of the worm or maggot, without any poſſibility of diſcerning the parts, till caſting both ſkins at once, it becomes a perfect and free animal, capable of propagating its ſpecies.

Thoſe inſects which come forth perfect, and in their own proper form, out of the egg, ſuffer no future changes, but only the caſting off their ſkins; but thoſe which come forth under the envelopement of a vermicular coat, do, beſide caſting their ſkins, after a proper time of eating and crawling about in that ſtate, become nymphæ; and that all inſects, as well thoſe which come out of the egg in the worm ſtate, as thoſe which come forth in their own form, are originally, in the egg, all in the nymph-form; and that thoſe which come out of the egg perfect animals, have no other difference in the manner of their productions, from the others, but that they have ſuffered in the egg, and out of the way of our inſpection, all thoſe changes which the others do undergo in the chryſalis or nymph-ſtate, in our ſight. The parts of the nymphæ of theſe animals protuberate and expand themſelves by degrees, much in the ſame manner that the buds of flowers of plants do; and the caterpillar is certainly the butterfly itſelf, only covered with a mantle which hides its ſeveral limbs from our eyes till thrown off.

Thus are the general tribes of inſects regularly reduced to theſe four claſſes, in regard to the manner of their production. Thoſe particular ſpecies which ſeem not reducible to theſe, or any other rules, or for which farther obſervation at leaſt is required, are the glow-worm, the ſcolopendra, the julus, the weavil or curculio, the dung-beetle or pilularius ſcarabæus, the ſmalleſt water-beetle, and the ſcorpion. See theſe under their ſeveral heads. *Swam.* Hiſt. Inſects.

TRANSFUGA, in antiquity, a deſerter. Among the Romans, deſerters were commonly puniſhed by cutting off their hands, it being thought, that living in ſuch a miſerable truncated condition, would ſtrike more terror than death itſelf.

We find, however, that deſerters were likewiſe crucified, burnt alive, thrown from the Tarpeian rock, or expoſed to wild beaſts at public ſhews. *Pitiſc.* in voc.

TRANSMUTATION (*Cycl.*)—TRANSMUTATION *of Metals*. Among the many things urged in favour of the belief of the poſſibility of this effect of chemiſtry, the experiment of Thurneiſſer, who, in the preſence of the Great Duke of Tuſcany, converted one half of a common iron nail into gold, by only dipping it, while hot, into a certain liquor, has given great encouragement to the ſearchers after that famous ſecret. The nail is ſtill preſerved in the repoſitory of the Great Duke of Tuſcany at Florence; and we have, in a very famous Engliſh collection, the blade of a knife, half iron and half gold, ſaid to have been effected in the ſame manner, and purchaſed by the preſent poſſeſſor at a very conſiderable price.

Tachenius, however, has diſcovered the cheat of the Florentine nail; and probably the matter does not ſtand much better, on examination, with the Engliſh knife. This author gives a proceſs by which iron may be ſo prepared as to be made to mix perfectly with gold. This was the whole ſecret of Thurneiſſer, who in this manner made his nail half iron and half gold, and then coating it all over with a ferrugineous matter, made it appear all iron. When this had been, in this ſtate, ſubjected to the examination of the prince, and a great many other perſons, he heated it red hot, and by that means burnt off the ferrugineous part of the golden end; and then dipping it into a certain oil, which he pretended to have great efficacy, the gold appeared, and was pretended to have been made by the oil from the iron. *Tachenii* Hippocrat. Chem.

Mr. Boyle thinks there is no impoſſibility in the nature of the thing, that one metal ſhould be *tranſmuted* into another: And in confirmation of this opinion, he mentions a *tranſmutation* of gold into ſilver, by means of his *menſtruum peracutum*. Monſieur Homberg declares, he has changed ſilver into gold by heat [a]. Mr. Boyle alſo mentions an anti-elixir, which, in very ſmall proportion, would conſiderably debaſe gold [b] in many reſpects, and particularly by reducing its ſpecific quantity from 19 to 15 $\frac{2}{3}$ times that of water.—[[a] Mem. Acad. Scienc. Anno 1709. [b] Works abr. vol. 1. p. 78.]

TRANSMUTATION *of Colours*. The change of colour of a decoction of the nephritic wood, according to the different lights it was viewed in, long perplexed the wits of thoſe who attempted to account for it; but Wolfius has carried the experiments on this decoction much further, and found a way of giving it its colours again, after taking them wholly away. If this decoction be held between the eye and the light, it appears of a blue colour; but if the eye be placed between it and the light, it appears then of a yellowiſh or a reddiſh colour. If a few drops of oil of vitriol be dropped into it, it will appear of a gold yellow in whatever light it is viewed; but if too much of this oil be added, the whole becomes foul and obſcure; and if a few drops do not produce the effect, it is a ſign that the decoction is too ſtrong, and that it muſt be diluted with water.

Oil of vitriol has the ſame effect upon many other decoctions of the woods, particularly on that of Braſil wood, which is of a fine red, but immediately becomes yellow on dropping a ſmall quantity of this acid into it. And, as in the other inſtance, ſo in this, it is neceſſary to the ſucceſs of the experiment, that the tincture be not over ſtrong. A few drops of oil of tartar added to this yellow liquor turn it red again, as at firſt; and if more oil of tartar be added, the colour becomes bluiſh, with a tinge of red, much ſtronger than the colour of the nephritic wood at firſt, when held between the eye and the light. In all experiments of this kind, the weakneſs of the tincture produces the greateſt beauty; and therefore it is beſt, inſtead of making a decoction, to make only a cold infuſion, by putting a ſmall quantity of the chips of the wood into water, and letting this ſtand cold for ſome time. Act. Erudit. Ann. 1718. p. 321.

A tincture of red roſes, made with common water and oil of vitriol, is well known to be of a very beautiful red colour; yet when the water has ſtood ever ſo long on the roſes alone, it has ſcarce any colour: If it be ſtrained off in this colourleſs ſtate, and the oil of vitriol then added, the red colour is produced as ſtrongly as if this acid had been dropped into the water while the roſes were yet in it. When the liquor is of this fine red colour, a ſmall quantity of oil of tartar makes it immediately green; and if more oil of vitriol be added to this green liquor, it becomes red again, but is muddy, and not ſo well coloured as before. If a few drops of a ſolution of corroſive ſublimate be added to this, it does not at all change colour; and on adding more water, with ſalt of tartar diſſolved in it, the liquor became red again, but of a very different red from what it was before in its muddy ſtate, being now clear and deeper. When the tincture of roſes has ſcarce any colour, a ſmall quantity of ſalt of tartar makes it green, but a large quantity makes it yellow. A few drops of oil of vitriol added to this yellow liquor, turned it to a pale red, and this could never be made green again by oil of tartar. Alum-water, added to a ſolution of ſalt of tartar, makes a white and opake fluid, though they are both ſeparately pellucid.

What is moſt obſervable in theſe experiments on the infuſion of woods, is, that oil of tartar, and a ſolution of ſalt of tartar in water, have a very different effect. Thus an infuſion of Braſil wood is red; and on dropping to it a few drops of oil of vitriol, it becomes yellow. If oil of tartar be added to this liquor, it only makes it yet more yellow; but if a ſolution of ſalt of tartar in water be added to this, it makes it red again. Act. Erudit. Ann. 1718. p. 322.

TRANSPIRATION (*Cycl.*)—TRANSPIRATION *of Plants*. It is evident that plants as well as animals continually ſuffer a loſs of their ſubſtance and juices, and that in two manners; by a ſenſible *Tranſpiration*, and by an inſenſible one. The latter of theſe is perceived very plainly in obſerving, that in the heat of ſummer, toward the cloſe of the day, thoſe plants which in the morning were very lively and vigorous, and in a perfectly good ſtate, are then found feeble, and, as it were, withering, and bending down toward the earth. It is with theſe plants juſt as it is with men and other animals, who are in the ſame manner faint and languid, by reaſon of their great *Tranſpiration* during the heat of the day.

The ſenſible *Tranſpiration* of plants is leſs eaſily proved than this inſenſible one, which ſeems ſomewhat ſtrange. By ſenſible *Tranſpiration* in a plant we underſtand an evacuation made by means of the pores of the leaves of a ſubſtance too thick and coarſe to be evaporated as ſoon as diſcharged, as the matter of the inſenſible *Tranſpiration* is. This matter is, however, not unfrequently found on the leaves of trees, though it is there uſually miſtaken for the remains of dew fallen upon them.

This, however, is not the caſe, as may be eaſily determined by the following conſiderations: 1. That the fluid matter upon the leaves of theſe trees is not merely aqueous, but is viſcid and glutinous, and ſweet to the taſte. 2. That it is always found in greater quantity on thoſe leaves which are expoſed to the ſun, than on thoſe which are ſhaded. 3. The leaves which abound in this appear lucid and gloſſy in ſeveral places, theſe lucid parts ſometimes appearing only in form of ſpots, and ſometimes in ſmall ſpaces of a twelfth of an inch long; and ſometimes leaves are found with their whole upper ſurface covered with one continued coat of it. 4. There is no appearance of this matter upon the leaves, either in the night, or before ſun-riſe in the morning; the occaſion of which is, that it is only drawn out by the heat of the ſun; and being in itſelf of the nature of manna, that is, being ſoluble in aqueous menſtruums, it is carried off and diſſolved by the dews which fall in that time. 5. The bees are often found collecting this matter from the leaves of trees, as carefully, and loading themſelves with it in the ſame manner, in order to make honey, as they do the ſweet ſubſtances from the baſes of flowers. This matter is the ſame with that in flowers, both are extravaſated in the ſame manner, and both are collected by the bee without injury to the plant. Since honey, therefore, is the matter of the ſenſible *Tranſpiration* of plants, it cannot be wonderful that it ſhould ſometimes have the flavour of that plant whoſe juices it once was a part of, or that the Narbonne honey ſhould have the flavour of roſemary; and ſo of others.

The trees which yield this ſenſible *Tranſpiration* in the moſt obvious manner, are the ſeveral ſpecies of maple and of lime. It is found more or leſs on a vaſt number of others; and many

plants and all flowers abound with it, almoſt without exception. It is in theſe moſt obvious in the bottoms of the monopetalous kinds, ſuch as the jaſmine and the meadow-trefoil; on ſucking of which there is always a great deal of it evident to the taſte. The leaves of any of the trees which afford this ſenſible matter of *Tranſpiration* being put into water renders it purgative, and in all things analogous to a ſolution of manna; but, in general, more agreeably taſted. Mem. Acad. Par. 1707.

TRANSPORTATION (*Cycl.*) — TRANSPORTATION *of Plants*. In the ſending plants from one country to another, great cautions are neceſſary. The plants ſent from a hotter country to a colder ſhould be always put on board in the ſpring of the year, that the heat of the ſeaſon may be advancing as they approach the colder climates; and, on the contrary, thoſe which are ſent from a colder country to a hotter ſhould be ſent in the beginning of winter.

The beſt way of packing up plants for a voyage, if they be ſuch as will not bear keeping out of the earth, is to have boxes with handles, filling them with earth, and planting the roots as cloſe together as may be; the plants ſhould be ſet in theſe boxes three weeks before they are to be put on board, and in good weather they ſhould be ſet upon the deck, and in bad removed or covered with a tarpaulin.

If they are going from a hotter country to a colder one, they muſt have very little moiſture; if, on the contrary, they are going from a colder to a warmer, they may be allowed water more largely, and being ſhaded from the heat of the ſun, they will come ſafe.

Very many plants, however, will live out of the earth a great while; as the ſedums, euphorbiums, ficoides, and other ſucculent ones. Theſe need no other care than the packing them up with moſs in a cloſe box; and there ſhould be a little hay put between them, to prevent them from wounding or bruiſing one another, and holes bored in the boxes to keep them from heating and putrefying. In this manner they will come ſafe from a voyage of two, or three, or even four or five months.

Several trees alſo will come ſafely in the ſame manner, taking them up at a ſeaſon when they have done growing, and packing them up with moſs. Of this ſort are oranges, olives, capers, jaſmines, and pomegranate-trees. Theſe, and many others, are annually brought over thus from Italy; and though they are three or four months in the paſſage, ſeldom miſcarry. And the beſt way of ſending over ſeeds, is in their natural huſks, in a bag, or packed up in a gourd-ſhell, keeping them dry, and out of the way of vermin. *Miller*'s Gardeners Dict.

TRANSTRUM, in the naval architecture of the antients, a term uſed to expreſs a ſort of croſs or tranſverſe ſeats that were placed in the polycrote gallies of thoſe times, and ſerved for the places of ſeveral of the rows of men, who could move and work their oars under the ſeats of the other or lateral rowers of the next tire.

Meibom, who has written expreſly on the naval architecture of the antients, has better underſtood the places and uſe of theſe *Tranſtra*, than any other author of late times; by a proper arrangement of theſe ſeats, and the lateral ones above and below each, he has taken off greatly from the height allowed by Scaliger, and others, to the polycrote veſſels. *Meibom.* de Trirem.

TRANSVERSALES *Abdominis* (*Cycl.*) — Theſe are muſcles nearly of the ſame breadth with the oblique; they take their name from the direction of their fibres, and each of them is fixed to the ribs above, to the os ilium, and ligamentum Fallopii below; and to the linea alba before, and behind to the vertebræ.

Its upper part is fixed to the lower part of the cartilaginous ſurface of the two loweſt true ribs, and of all the five falſe ribs, by fleſhy digitations; the fibres of which become tendinous, as they approach the linea alba. The middle part is fixed to the three firſt vertebræ of the loins, by a double aponeuroſis or two tendinous planes. The internal and external planes having incloſed in their duplicature the muſculus ſacrolumbaris, and quadratus luborum, unite in one ſtrong aponeuroſis at the edges of thoſe muſcles. The inferior part of this muſcle is fixed by an inſertion wholly fleſhy to the internal labium of the criſta of the os ilium, and a great part of the ligamentum Fallopii. *Winſlow*'s Anat. p. 168.

TRANSVERSALIS *Anticus primus Capitis*, a ſmall, pretty thick, and wholly fleſhy muſcle, about the breadth of a finger, ſituated between the baſis of the *os occipitis* and the tranſverſe apophyſis of the firſt vertebra.

It is fixed by one end in the anterior part of that apophyſis, and from thence turning up a little obliquely. It is inſerted by the other end in a particular impreſſion between the condyle of the *os occipitis* and the maſtoide apophyſis of the ſame ſide behind the apophyſis ſtyloides, and under the edge of the jugular foſſula. *Winſlow*'s Anat. p. 238.

TRANSVERSALIS *Anticus Capitis ſecundus*, a ſmall muſcle, ſituated between the tranſverſe apophyſis of the two firſt vertebræ of the neck. It is fixed by one extremity very near the middle of the ſecond apophyſis, and by the other near the root or baſis of the firſt.

TRANSVERSALIS *Colli major*, a long thin muſcle, placed along all the tranſverſe apophyſis of the neck, and the four, five, or ſix under apophyſes of the back between the complexus major and minor, and lying as it were on the inſertions of the firſt of theſe muſcles.

It is compoſed of ſeveral ſmall muſcular faſciculi, which run directly from one or more tranſverſe apophyſes, and are inſerted ſometimes in the apophyſis neareſt to them, ſometimes in others more remote, the ſeveral faſciculi croſſing each other between the inſertions of the two complexi, which are likewiſe croſſed by them. *Winſlow*'s Anat. p. 243.

TRANSVERSALES *Colli minores*, very ſmall and ſhort muſcles, found in the interſtices of ſeveral tranſverſe apophyſes in which they are inſerted, and called by ſome alſo *inter-tranſverſales*. *Winſlow*'s Anat. p. 244.

TRANSVERSALIS *gracilis Colli*, a long thick muſcle, reſembling the *Tranſverſalis* major in every thing but ſize, and ſituated on the ſide of that muſcle.

It is commonly taken for a portion or continuation of the ſacrolumbaris. Diemerbroek diſtinguiſhed it by the name of *cervicalis deſcendens*; and Stone, and others after him, have called it *acceſſorius muſculi ſacrolumbaris*. *Winſlow*'s Anat. p. 243.

TRANSVERSALES *Dorſi minores*. Some particular muſcles of this kind are found fixed to the extremities of the three loweſt tranſverſe apophyſes of the back: The reſt are all in ſome meaſure continuations of the *Tranſverſalis major*; but theſe few which are diſtinct, and lie in the interſtices between the apophyſes and diſtinct muſcles, are properly enough called by this name. *Winſlow*'s Anat. p. 248.

TRANSVERSALIS *Digitorum Pedis*, a ſmall muſcle which lies tranſverſely under the baſis of the firſt phalanges, and which at firſt ſight appears to be a ſimple muſcular body, fixed by one end to the great toe, and by the other end to the little toe. When carefully examined, it is found to be fixed by a very ſhort common tendon to the outſide of the baſis of the firſt phalanx of the great toe, conjointly with the antithenar, and by three digitations to the interoſſeous ligaments which connect the heads of the four metatarſal bones next the great toe. The three digitations are very ſlender, and gradually cover each other. *Winſlow*'s Anat. p. 225.

TRANSVERSALIS *Penis*, in anatomy, a name given by ſome writers, particularly Cowper, to a muſcle called by others *virgæ lateralis parvus*, and by Albinus the *Tranſverſus perinæi*. Winſlow calls it *Tranſverſus urethræ*.

TRANSVERSO-SPINALIS *Lumborum*, called by ſome *ſacer*, a muſcle compoſed of ſeveral oblique converging or tranſverſo-ſpinal muſcles, in the ſame manner as in the back and neck.

It lies between the ſpinal and oblique apophyſes of the loins reaching to the os ſacrum. The loweſt of theſe muſcles are fixed to the ſuperior lateral parts of the os ſacrum, to the ligamentum ſacro-ſciaticum, and to the poſterior ſuperior ſpine of the os ilium. The reſt are fixed to the three loweſt tranſverſe apophyſes, and to the four loweſt oblique apophyſes of the loins, and to their lateral tuberoſities; from thence they run up to all the ſpinal apophyſes of theſe vertebræ. The external, or thoſe that appear firſt, being longer than the internal, eſpecially toward the lower part. *Winſlow*'s Anat. p. 248.

TRANSVERSUS *Auriculæ*, in anatomy, a name given by Albinus to a muſcle of the ear, not allowed to be ſuch by other authors; but deſcribed by Santorini, and others, under the name of *fibræ tranſverſæ in gibbo auriculæ*, and *fibræ in convexa conchæ parte*. See the article EAR.

TRANSVERSUS *Naſi*, in anatomy, a name given by Santorini, and others, to that muſcle of the noſe called by Winſlow *Tranſverſalis ſive inferior*; and by Albinus, the *compreſſor naris*. See the article COMPRESSOR.

TRANSUM, in gunnery, is a piece of wood which goes acroſs the cheeks of a gun-carriage, or of a gun to keep them fixed together; each *Tranſum* in a carriage is ſtrengthened by a bolt of iron. See the article CARRIAGE.

TRAPA, in the Linnæan ſyſtem of botany, a genus of plants; the diſtinguiſhing characters of which are theſe: The cup is a perianthium compoſed of one leaf, divided into four at the edges, and remaining when the flower is fallen. The flower is compoſed of four petals larger than the ſegments of the cup, and placed vertically. The ſtamina are four filaments of the length of the cup; the antheræ are ſimple. The germen of the piſtillum is of an oval figure; the ſtyle is ſimple, and of the length of the cup; and the ſtigma is headed, and has a ridge round it. The fruit is an oval oblong ſtony capſule, containing only one cell, and armed with four thorns placed oppoſitely on the ſides; theſe are thick and pointed, and are what were originally the leaves or ſegments of the cup. The ſeed is a nut of an oval figure. *Linnæi* Gen. Plant. p. 50.

TRAPEZIUM, in geometry, a plain figure contained under four unequal right lines.

TRAPEZIUM *Os*, in anatomy, is one of the bones of the carpus; it is the firſt bone of the ſecond row, and has its name from its figure, which is a ſort of unequal ſquare. Its outer ſurface is rough, and makes a part of the outer or convex ſurface of the carpus. On its inner ſurface is an oblong eminence, which makes one of the four eminences on the concave ſide of the carpus; and on the ſame ſide it has a groove

groove or channel; there is likewiſe a ſmall tubercle on its outer ſurface.

This bone has ſeveral articular cartilaginous ſides, *viz.* one brachial, one digital, and two cubital. The brachial ſide, which is hollow, is articulated with the os ſcaphoides; the digital with the firſt phalanx of the thumb; one of the cubital with the os trapezoides, and the other with the firſt bone of the metacarpus. The ſide which is articulated with the firſt phalanx of the thumb, appears to be made up of two ſuperficial ſigmoide or ſemilunar half-ſides, diſtinguiſhed by an eminence of the ſame figure, being each more hollow towards the ſides than at the middle, which makes a portion of a ſort of ſuperficial pulley, with the edges much worn. One of the cubital ſides, which is articulated with the os trapezoides, is large; and the other, which joins the firſt metacarpal bone, is ſmall. *Winſlow*'s Anat. p. 83.

TRAPEZIUS (*Cycl.*)—This muſcle is a large, broad, thin, fleſhy plane, ſituated between the occiput and back, and thence extending to the ſhoulder, in figure of a large irregular ſquare, and, together with the *Trapezius* of the other ſide, it forms a kind of lozenge. Above it is fixed in the ſuperior tranſverſe line of the os occipitis, by a thin ſeries of fleſhy fibres reaching to the muſculus occipitalis, and ſeeming to cover that muſcle by a kind of aponeuroſis. Behind it is fixed to the five ſuperior ſpinal apophyſes of the neck, by means of the poſterior cervical ligament, and immediately to the extremities of the two loweſt ſpinal apophyſes of the neck, and of all thoſe of the back. From all theſe inſertions the fibres run in different directions, and terminate by one continued inſertion in about one third part of the clavicula, in the poſterior edge of the acromium, and through the whole ſuperior labium of the ſpine of the ſcapula, all the way to the ſmall triangular ſurface in that ſpine, over which ſurface the fibres ſlide and paſs freely, without being fixed therein. This muſcle covers immediately the ſplenius or maſtoideus ſuperior, part of the complexus major, the angularis, rhomboides, and part of the latiſſimus dorſi. The common inſertion of the two trapezii in the cervical ligament, is the reaſon that in pulling either of them toward one ſide of the neck, the other will follow it a little beyond the ſpinal apophyſes. *Winſlow*'s Anatomy, p. 173.

TRAPEZOID, in geometry, a plane irregular figure, having four ſides, no two of which are parallel to each other.

TRAPEZOIDES *Os*, in anatomy, is the ſecond bone of the ſecond row in the carpus. It has its name from its figure ſuppoſed to approach that of an unequal ſquare; but it might much more properly have been called os pyramidale, being in figure rather a kind of a pyramid, with its point broken off. Its baſis makes a portion of the outer or convex ſide of the carpus, and its truncated point a part of the concave ſide.

It has ſeveral articular ſides; one brachial, which is the leaſt of all, and is articulated with the os ſcaphoides; one digital, of a conſiderable length, notched on each ſide, and divided into two halves by a ſort of middle line or angle, which gives it the appearance of a pulley, articulated with the baſis of the firſt metacarpal bone; one radial, irregularly triangular, and articulated with the os trapezium; and one cubical, a little hollow, and articulated with the os magnum. *Winſlow*'s Anat. p. 84.

TRAPEZUNTINA *Laurus*, a name uſed by ſome botanical authors, for the *Lauroceraſus*, or common laurel. *Chabræus*, p. 51.

TRAPPINGS. Among the antients ſome will have the horſe *Trappings* to have been placed on their breaſts; others, on their forehead; and others again, on their cheeks. That on the breaſt was a ſmall kind of ſhield, finely poliſhed. *Hofm.* Lex. univ. in voc.

TRAQUENADE, in the manege. See the article ENTREPAS.

TRASCINA, in zoology, a name by which ſome authors have called the fiſh, more uſually known by the name of the draco marinus, and araneus. *Salvian* de Aquatic.

TRAVAIL, in the manege. See the article TRAVICE.

TRAVELLING. The common method of *travelling* in England being on horſeback, it may be proper to give ſome general rules for the keeping the creature ſound, and doing the buſineſs agreeably, and without many of the accidents which uſually attend it.

Care muſt be taken that the ſhoes be not too ſtreight, and do not pinch the horſe's feet any way; but be well ſhaped, and ſet eaſy. It is proper to have them put on freſh a few days before the journey, that they may laſt well, and that they may be ſettled to the feet before the ſetting out. The bridle is next to be examined; that the bit of it be proper, and not too heavy: for if it be, it will incline him to carry low when he grows tired, and reſt upon the rider's hand: This is what they call the uſing a fifth leg. It is a very diſagreeable thing, but may often be avoided, only by taking a proper care of the bit. The mouth of the bit ſhould reſt upon his bars, about a finger's breadth from his tuſhes, ſo as not to make his lips uneaſy. The curb ſhould reſt in the hollow of his head, a little above the chin; and if it gall him, the place muſt be defended with a piece of buff or other ſort of leather.

The next thing to be regarded, is the ſaddle; and proper care muſt be taken as to this, that it do not reſt either upon the withers, reins, or back-bone; and that one part of it do not preſs upon the back, any more than another. Some riders gall a horſe's ſides below the ſaddle with their ſtirrup leathers: This is moſt likely to happen to a lean horſe; and to prevent it, a leather ſtrap ſhould be fixed between the points of the fore and hinder bows of the ſaddle, and the ſtirrup-leathers ſhould be made to paſs over theſe leathers.

It is always beſt to begin a long journey by ſhort ſtages, and this is the more neceſſary if the horſe has not been exerciſed for ſome time before. If it be a horſe that is rid, he ſhould be ſuffered to ſtale as often as he likes, and even invited to it; but, if a mare, ſhe is to be leſs indulged in it as leſs neceſſary, and often diminiſhing her Strength. It is always adviſable to ride very ſoftly for a quarter of an hour, or half an hour before coming in to the inn at night, that he may not be over hot when put into the ſtable; but if the haſte of the journey will not admit of this, the horſe ſhould be walked in ſome perſon's hands, to cool him gently before he is put up.

If the weather is cold a cloth ſhould be laid over him while he is walked; and when taken in, his whole body ſhould be rubbed and dried with ſtraw. Some have a cuſtom of ordering their horſes legs to be rubbed well down, on their firſt coming in; but this is very prejudicial while the horſe is hot, and ſhould always be let alone till he is perfectly cooled.

As ſoon as the horſe is cooled, and ceaſes to heat in the flanks, the bridle is to be taken off, the bit waſhed, and hay given him that he may eat at pleaſure. The duſt in very dry weather will ſometimes clog up the tongue of the horſe in ſuch a manner, that he cannot eat without great difficulty; In this caſe ſome bran and water ſhould be firſt given him to waſh his mouth, or the ſervant ſhould do it with a wetted ſpunge.

Theſe are the proper methods, when the horſe has been rode moderately; but when he has been hurried at a great rate, the ſaddle is to be taken off as ſoon as he is put up, and the ſweat rubbed off with a ſweat knife; and then the whole body and legs are to be rubbed carefully down, and the head is to be wiped with a cloth, as alſo the back under the ſaddle, and the thighs; then the ſaddle ſhould be clapped on again, and the horſe gently led up and down, till cool and dry. The feet are alſo to be examined, to ſee if a ſhoe be wanting, or if any of them preſs upon the ſole; and the dirt, gravel, or other foulneſs is to be picked out from between the ſhoe and the foot. The openings of the feet may be ſtopped with cow-dung, and the hoofs if brittle ſhould be anointed with ſome fatty ſubſtance juſt at the ſetting on; and in dry weather they ſhould be greaſed, not only at night, but noon. Many horſes, as ſoon as unbridled, will lay themſelves down, inſtead of eating.

Many are apt on this to ſuppoſe the horſe ſick; but it is generally owing only to the heat and pain they find in their feet, which renders them unable to ſtand upon them: In this caſe if their eyes are examined, they will be found briſk and good, and the hay being offered them as they lie, they will eat it greedily. This ſhews there is no inward diſorder, and the heat and tenderneſs of the feet, if examined, will ſhew that they are the part in pain. The principal thing to be done in this caſe, is taking care that the ſhoes do not reſt upon the ſoles. This is not eaſily known but by taking off the ſhoes, which in caſes of extremity ſhould always be done; it will then be found where the ſole is touched by the ſhoe, being in that part more ſmooth and ſhining than elſewhere. In this caſe the feet are to be pared in thoſe parts, and then the ſhoes are to be fixed on again, anointing the hoofs, and ſtopping the ſoles with hot black pitch or tar.

Theſe are the means by which *Travelling* will be rendered eaſy and commodius both to the rider and the horſe; but there is ſome care alſo to be taken of the creature, after he comes off from a long journey. The firſt thing to be done is, that the two heel nails of the fore-feet are to be drawn, and if the ſhoe be large, then four ſhould be drawn; two or three days after the horſe ſhould be blooded, and for ten or twelve days after this he ſhould be fed with wet bran, without any oats; but he is to be kept well littered. The reaſon of drawing the heel nails is, that the feet are apt to ſwell after journies; and if this is not done the ſhoes preſs upon them in that part, and become very uneaſy to them; it is adviſeable to ſtop them alſo with cow-dung for ſome time; but they are in the wrong who pare them down after taking off the ſhoes, for the humours being all in motion after this, they are apt to fall into the feet.

If there appear any danger of the creature's legs ſwelling after the journey, it may be eaſily prevented by this means: Take a quantity of the dung of an ox or cow freſh made, mix it with ſo much vinegar as will reduce it to a ſoft paſte, and add to it a handful of ſalt; with this rub all the hips thoroughly up to the knees, and let it dry on; give the water in a pail that evening that the legs may not be wetted, and the next morning the horſe is to be led to water, and the whole remaining matter waſhed off. The jockies have a very cunning trick to recover the hoofs of a horſe injured by a long journey:

journey: They make a hole in the foot, and fill it with moiſtened cow-dung; they keep this in it a month, and the continual moiſture occaſioned by it makes the hoof grow very quick, and ſoon recover the proper dimenſions, but it ſoon after drys and ſhrinks ſo, that the foot is ſtreightned, and the whole hoof becomes brittle.

Cow-dung applied to a horſe's foot always moiſtens the ſole; but it drys up the hoof, if continued any length of time to it.

The beſt method of recovering a horſe's hoofs is to make a hole in the ſtable floor filled with blue clay a little wetted, in this the horſe ſhould keep his fore-feet a month; this will have more effect then a ſmall portion of cow-dung in the foot; and the effect will be of ſo different a nature, that the hoof will be rendered more tough than before, inſtead of being made brittle by it.

Moſt horſes that are fatigued, or overworked by long journies, have their flanks altered by it, without being purſy; eſpecially horſes naturally vigorous, which have been worked too violently. The beſt remedy in this caſe, is to give the horſe half a pound of honey in the morning, mixed among a feed of ſcalded bran: If he eats the half pound readily, give him a pound the next morning; continue this till the honey ceaſes to purge the creature; after this, powder of liquorice may be added to the ſcalded bran, and this continued ſome time, and two or three glyſters at convenient diſtances of time will be found very ſerviceable. If the horſe be very lean, it will be proper to give him ſome wet bran over and above his proportion of oats; and graſs is alſo very proper, if the creature be not inclined to be purſy. This caution, however, is to be had at all times, that exceſſive feeding may be bad, by ſubjecting the horſe to the farcy. When the horſe begins to drink heartily, it is a ſign that he will ſoon recover. Though this ſometimes fails, it is a good general rule.

TRAVERSE (*Cycl.*)—TRAVERSE, in the manege. A horſe is ſaid to *traverſe*, when he cuts his tread croſs-wiſe; throwing his croupe to one ſide, and his head to another.

TRAVERSE-*Board*, in a ſhip, a little round board hanging up in the ſteerage, and bored full of holes upon lines ſhewing the points of the compaſs: Upon it by moving of a little peg from hole to hole, the ſteerſman keeps an account how many glaſſes, that is, half hours, the ſhip ſteers upon any point.

TRAVERSE-*Table*, in navigation, is the ſame with the table of difference of latitude and departure; being only the difference of latitude and departure ready calculated to every degree, point, half-point and quarter-point of the quadrant; and for any diſtance under 100 miles, though it may conveniently ſerve for more.

This table is one of the moſt neceſſary things a navigator has occaſion for; for by it he can readily reduce all his courſes and diſtances, run in the ſpace of twenty-four hours, into one courſe and diſtance; whence the latitude he is in, and his departure from the meridian may be found.

TRAVERSE *the Yard*, on board a ſhip, is to brace it aft.

TRAVICE, in the manege, is a ſmall encloſure, or oblong quadrangle placed before a farrier's ſhop, and conſiſting of four pillars or poſts, kept cloſe together by croſs-poles. This encloſure is deſigned for holding and keeping in a horſe that is apt to be unruly or diſorderly in the time of ſhoeing, or of any operation.

This in ſome of the remoter parts of England goes by the name of a *break*; and is called in French *Travail*.

TREACLE (*Cycl.*)—Dr. Shaw, in his Eſſay on Diſtillery, has endeavoured to bring into uſe ſeveral ſorts of *Treacles*, which might be made at home, and would ſerve very conveniently for the diſtillation of ſpirits, or the making of potable liquors. Theſe are the inſpiſſated juices or decoctions of vegetables: Such as the ſweet juice of the birch, or ſycamore, procured by tapping or piercing the trees in ſpring, and the common wort made from malt, or from other vegetable ſubſtances treated in the ſame manner. Theſe liquors are ſeverally to be boiled down in a copper till they begin to inſpiſſate, and then to be poured into a balneum mariæ, when the remainder of the evaporation may be finiſhed without burning the inſpiſſated juices: Thus prepared it may be at any time reduced to the ſtate of wort, only by adding a ſufficient quantity of warm water. *Shaw*'s Eſſ. on Diſtill.

TREAD, in the manege. See the article PISTE.

TREASURER (*Cycl.*)—TREASURER *of the County*, he that keeps the county ſtock.

There are two of them in each county, choſen by the major part of the juſtices of the peace, *&c.* at Eaſter ſeſſions.

They muſt have 10*l.* a year in land, or 150*l.* in perſonal eſtate, and ſhall not continue in their office above a year; and they are to account yearly at Eaſter ſeſſions, or within ten days after, to their ſucceſſors, under penalties.

The county ſtock, of which this officer hath the keeping, is raiſed by rating every pariſh yearly; and is diſpoſed of to charitable uſes, for the relief of maimed ſoldiers and mariners, priſoners in the county gaols, paying the ſalaries of governors of houſes of correction, and relieving poor almshouſes, *&c.* And the duty of theſe *Treaſurers*, with the manner of raiſing the ſtock, and how it ſhall be diſpoſed of, is ſet forth particularly in the ſtatutes of 43 Eliz. c. 7. Jac. I. c. 4. 11 & 12 W. III. c. 18. 5 Ann. c. 32. 6 Geo. I. c. 23.

TREASURER, in cathedral churches, an officer whoſe charge was to take charge of the veſtments, plate, jewels, relicks, and other treaſure belonging to the ſaid churches. At the time of the reformation, the office was extinguiſhed as needleſs in moſt cathedral churches; but it is ſtill remaining in thoſe of Saliſbury, London, *&c.*

TREASURY (*Cycl.*)—The Athenian *Treaſury* was ſacred to Jupiter Σωτὴρ, or the ſaviour, and to Plutus the god of riches. Beſides other public monies, there were always a thouſand talents kept in it, which it was capital to touch, unleſs on the moſt preſſing occaſions. See the article OPISTHODOMUS.

The funds among the Athenians which ſupplied their *Treaſury*, were four, *viz.* the *tele*, τελη; the *phori*, φοροι; the *eiſphoræ*, εισφοραι; and the *timemata*, τιμηματα. Each of which ſee in its place.

The public *Treaſury* was divided into three parts, according to the uſe it was applied to; as, 1. The χρηματα τῆς διοικησεως, or that expended in civil uſes. 2. The Στρατιωτικα χρηματα, or money deſigned to defray the charges of war. 3. The Θεωρικα, or money intended for pious uſes; in which they included the expences at plays, public ſhews, and feſtivals, *&c.* *Potter*. Archæol. Græc. T. 1. p. 82.

To each of theſe branches of the public revenue there was a *Treaſurer* appointed, as Ταμιας τῆς διοικησεως, των στρατιωτικων and Θεωρικων.

TREATY (*Cycl.*)—in antiquity. For the ſolemn manner in which the Romans uſed to conclude *Treaties*, ſee Liv. l. 1. c. 24. The ceremonies obſerved by the Greeks in making *Treaties* may be ſeen in *Potter*, Archæol. Græc. l. 2. c. 6. T. 1. p. 252. ſeq.

In general it appears that the antients were very religious, grave and ſolemn in making *Treaties*; which were always confirmed by ſacrifices and mutual oaths, with horrid imprecations to the party that ſhould break the terms of agreement.

TREBIUS, in ichthyology, a name given by Joannes Cuba and ſome other writers, to the fiſh called *phycis* by Ariſtotle, Ælian, and Pliny; and *truca* and *tinea marina* by the later writers. It is nearly allied to the blennus claſs. See the article BLENNUS.

TRECHON, one of the many names by which the chemical writers, have called quickſilver.

TRECHEDIPNA, τρεχεδειπνα, in antiquity, a kind of livery or diſtinguiſhing habit worn by paraſites; the wearing of which was a ſufficient paſport to the tables of their patrons whoſe livery it was. *Pitiſc.* in voc.

The word comes from τρεχω, *I run*, and δειπνον, *a ſupper*.

TREE (*Cycl.*)—Heat is ſo eſſential to the growth of *Trees*, that we ſee them grow larger and ſmaller in a ſort of gradation as the climates in which they ſtand are more or leſs hot. The hotteſt countries yield in general the largeſt and talleſt *Trees*, and thoſe alſo in much greater beauty and variety than the colder do; and even thoſe plants which are common to both arrive at a much greater bulk in the ſouthern, than in the northern climates; nay, there are ſome regions ſo bleak and chill, that they raiſe no vegetables at all to any conſiderable height. Greenland, Iceland, and the like places, afford no *Trees* at all; and what ſhrubs grow in them are always little and low.

In the warmer climates, where *Trees* grow to a moderate ſize, any accidental diminution of the common heat is found very greatly to impede vegetation; and even in England, the cold ſummers we ſometimes have, give us an evident proof of this; for tho' the corn and low plants have ſucceeded well enough, and gooſeberries, currants, raſberries, and other low ſhrubs, have brought forth fruit in ſufficient plenty, yet the production of taller *Trees* have been found very much hurt; and walnuts, apples, and pears have been very ſcarce among us.

Heat is heat be it from what cauſe it will, and acts as well upon vegetation one way as another. Thus the heat of dung, and the artificial heat of coal fires in ſtoves, is found to ſupply the place of the ſun.

Great numbers of the Indian *Trees* in their native ſoil flower twice in a year, and ſome flower and bear ripe fruit all the year round; and it is obſerved of theſe laſt, that they are at once the moſt frequent and the moſt uſeful to the inhabitants; their fruits, which hang always on them in readineſs, containing cool juices, which are good in fevers, and other of the common diſeaſes of that hot country.

Plantations of uſeful *Trees* might be made to very great advantage in many places in every country, and the country greatly enriched by it, while the public would be alſo benefitted by it, ſince it would raiſe a continual ſupply of timber uſed in ſhip-building, and on other public as well as private occaſions.

We have in many places, heaths, and other barren and uncultivated lands, of very great extent; and how great an advantage would it be to the public to bring theſe to be truly valuable. Many, if not all of theſe heaths, would be found on trial capable of producing *Trees*; and ſome of them are truly

the remains of deſtroyed foreſts; and though the profit to be reaped from the planting them would come late, yet the expence of doing it would be very trifling in compariſon of that profit, and the means eaſy.

The authors who have given rules for planting, having employed themſelves only about ſmall ſpots of ground, the eſtabliſhing orchards or parks, are by no means to be ſuppoſed proper guides in attempts of this kind; and Monſieur de Buffon, who had a great opinion of the knowledge of our Evelyn and Miller, who ſeem to ſpeak of every thing from their own experience, found when he ſet about large plantations, that their opinions and rules were erroneous; and was obliged to have recourſe to experiments only; which he varied a thouſand ways: and though many of them proved unſucceſsful, yet they all gave hints toward others, by which the attempt might afterwards be brought to ſucceed.

This ſagacious enquirer into the operations of nature in the growth of vegetables, having ſet apart a conſiderable quantity of land for the trial, and procured a number of young *Trees*, firſt divided the whole quantity into a number of ſmall ſquares, and having made a plan of it, examined the nature, depth, and other circumſtances of the ſoil in each, and minuted the whole down on a proper part of the plan: that himſelf or whoever ſucceeded him might judge from the different growths of a number of *Trees* planted in the ſame ſtate in theſe different ſoils, the different advantages and diſadvantages of every circumſtance in the depth and nature of the ground, in regard to the growth of uſeful *Trees*. Different numbers of labourers were employed about different ſpots of this ground, and the acorns for the young growth planted at different ſeaſons; but the reſult in general was, that what ſhould ſeem the beſt methods ſucceeded the worſt; and thoſe pieces where many labourers had been employed, and the acorns planted before winter, were much thinner of young oaks, than thoſe where the leaſt labour had been beſtowed upon the ground, and where the acorns had been planted in the ſpring: but thoſe places which ſucceeded beſt from the ſowing, were thoſe which had the acorns planted in holes made by a pick-ax, without any preceding culture of the ground. And thoſe where the acorns had only been laid upon the earth, under the graſs, afforded a great number of vigorous young *Trees*, though the greater part had been carried away by birds and other devouring animals. Thoſe ſpots of ground where the acorns were ſet at ſix inches depth, were much worſe furniſhed with young ſhoots, than thoſe where they had been buried but at an inch deep; and in ſome places where they were buried at a foot deep not one ſhoot appeared, though in others where they had been buried at nine inches there were many.

Thoſe acorns which had been ſteeped for eight or nine days in wine lees, and in the water of the common ſewers, appeared out of the ground much earlier than thoſe which were put in without this previous management.

But the moſt ſucceſsful of all the trials, was that of planting in the ſpring ſuch acorns as had been ſown together in another place, and had time to ſhoot there; of theſe ſcarce any one failed, and the plantation was perfectly flouriſhing, tho' the growth of theſe young ſhoots was not ſo quick or vigorous as thoſe of the acorns, which had remained when firſt ſown; which was probably owing to the injury the tender radicles received in tranſplanting.

Thus ſucceeded the experiments by ſowing, while of thoſe made by planting young *Trees*, ſuch as had been brought out of woods and places under covert, ſucceeded much worſe than thoſe which had grown in more expoſed places.

The young *Trees* of the ſeveral parts of the plantation kept on their growth in the manner they had begun to ſhoot, thoſe of the more laboured parts continuing more weak, and lower than thoſe of the leſs laboured.

Thus were a number of neceſſary experiments carefully tried, and the reſult of the whole was, that to make a plantation of oaks, on a ſoil of the common clayey or loamy kind, the moſt ſucceſsful method is this: The acorns muſt be preſerved during the winter in the earth in this manner: let there be made a bed of earth of ſix inches deep, on this place a layer of acorns two inches deep, over theſe lay a bed of another half foot of earth, over that another layer of acorns, and ſo on ſucceſſively, till as many are employed as there will be occaſion for; the whole is then to be covered with a foot depth of earth, to preſerve all from the froſt. In the beginning of March theſe beds are to be opened, and the acorns which will by that time have ſhot out, and are then in reality ſo many young oaks, are to be planted out at a foot diſtance each, and the ſucceſs of a plantation of this kind need not be feared.

This is a manner of planting that is done at a ſmall expence, and even that might be in a great meaſure ſpared, were it not for the birds and other devouring animals; ſince, could the acorns be defended from theſe, they might be only laid on the ſurface of the ground under the graſs in autumn, and they would infallibly ſhew themſelves in ſo many young oaks the ſucceeding ſpring.

It is eaſy to continue the carrying the acorns, when taken out of their winters bed, to the place where they are to be planted, without doing them much injury; and the ſmall ſtop the tranſplanting puts to their growth, is in reality rather an advantage than an injury; ſince it only retards the young ſhoots for about three weeks, or leſs than that: and by that means ſecures them from the few cold mornings that may be expected about the time of their natural appearance. Memoires Acad. Scien. Paris 1739.

Trees in corn fields are a worſe enemy than any weeds, they ſuck up the nouriſhment from the corn about them, even to a great diſtance: nor is it peculiar to corn to ſuffer by them. Mr. Tull gives an inſtance of a ſingle *Tree* ſtanding in a field of turneps, which ſpoiled no leſs than half an acre of the crop. It has been ſuppoſed that *Trees* injured theſe lower herbs by their ſhadow; and ſome thought that the miſchief they ſaw from them, was owing to their droppings; but by this inſtance, it is plain both theſe conjectures are erroneous: the ſouth ſide of the *Tree*, where no ſhadow comes, is found to ſuffer as much as any other; and the droppings reaching only as far as the bows, and the miſchief ſo much farther, it is plain that the miſchief is owing to neither of theſe cauſes, but to the *Tree*'s drawing all the nouriſhment, by extending its roots ſo far, and in ſuch numbers, on every ſide the extent of ground through which the turneps were thus injured, probably ſhewing the extent of the roots of the *Tree*, which are found by this to run farther than is uſually ſuppoſed.

On felling of *Trees*, letters have ſometimes been found in the midſt of them. We have inſtances of this kind, mentioned in the Phil. Tranſ. N°. 454. Sect. 16. Where the trunk of of a beach being ſawed, diſcovered ſeveral letters in the wood, about one inch and an half from the bark, and near the ſame diſtance from the center of the trunk. It ſeems theſe letters had been formerly cut into the bark, and in proceſs of time theſe might be covered. See the place cited. See alſo the ſame number Sect. 17. in the remarks.

In the ſame Tranſaction, we have an account of the horn of a deer, found in the heart of an oak. Crucifixes have alſo been found in *Trees*, and were to be ſure ſhewn as miraculous to the ignorant. See p. 236. of the ſaid Tranſaction in the remarks.

TREES are often found buried in the earth. See the article *Foſſile* WOOD.

How TREES may be injured by froſt. See the article FROST.

Fruit-TREES. See the article FRUIT-*Trees*.

Juices of TREES. See the articles JUICE and SAP.

Diſtemperature of TREES. See the article DISTEMPERATURE.

Felling of TREES. See the articles FELLING and TIMBER.

TREES in a ſhip are of ſeveral ſorts, as, *Cheſs-Trees*, *Croſs-Trees*, *Roof-Trees*, *Waſte-Trees*, *Treſſel-Trees*. See the article CHESS-*Trees*, CROSS-*Trees*, &c.

Roof-TREES, in a ſhip, ſmall timbers that bear up the gratings from the half deck to the fore-caſtle, ſupported by ſtantions that reſt upon the half deck.

TREENELS, in a ſhip, long pins or nails of wood, whence they are called *Tree-nells*, or *Tree-nails*, made out of the heart of oak, to faſten the planks to the timber; and thoſe have always oakam driven into them to prevent any leak.

TREET, *Triticum*, in our ſtatutes, is uſed for fine wheat. See Statute 51. Hen. 3. *Blount*.

TREFOIL, *Trifolium*, in botany, the name of a genus of plants; the characters of which are theſe: The flower is of the papilionaceous kind: The piſtil which ariſes from the cup finally becomes a capſule, which remains covered with the cup, and uſually contains kidney-ſhaped ſeeds. To this it is to be added, that the leaves grow three on every ſtalk; though there are ſome inſtances of theſe plants truly of this genus, which have four or five on the ſtalk.

The ſpecies of *Trefoil*, enumerated by Mr. Tournefort, are theſe: 1. The bituminous, or ſtinking *Trefoil*. 2. The common purple meadow-*Trefoil*. 3. The larger purple *Trefoil*, with longer and narrower leaves, and deeper coloured flowers. 4. The common white-flowered *Trefoil*. 5. The ſmaller and ſmoother white-flowered meadow-*Trefoil*, called by ſome the female meadow-*Trefoil*. 6. The white meadow-*Trefoil*, with a bivalve pod, a hollow ſtalk, and leaves marked underneath with purple ſpots. 7. The bladder purple *Trefoil*. 8. The wild hop-*Trefoil*. 9. The ſmalleſt hop-*Trefoil*. 10. The mountain hop-*Trefoil*. 11. The large purple mountain-*Trefoil*. 12. The purple mountain-*Trefoil*, with ſharp-pointed and crenated leaves. 13. The purple mountain-*Trefoil*, with obtuſe-pointed crenated leaves. 14. The leſſer purple mountain-*Trefoil*. 15. The white mountain-*Trefoil*. 16. The *Trefoil* with a round red ſpike, called the greateſt lagopus or hares-foot *Trefoil*. 17. The *Trefoil*, with an oblong red ſpike. 18. The mountain-*Trefoil*, with a very long red ſpike. 19. The narroweſt-leaved ſpiked mountain-*Trefoil*. 20. The narrow-leaved Spaniſh *Trefoil*, with a pale red ſpike. 21. The narrow-leaved Spaniſh hares-foot *Trefoil*, with very red flowers. 22. The common ſmall-ſpiked field-*Trefoil*, called common lagopus, or hares-foot *Trefoil*. 23. The ſmall hares-foot *Trefoil*, with ſharp-pointed and not crenated leaves, and ſmall pale purple flowers. 24. The yelloviſh flowered hares-foot *Trefoil*, called the meadow-*Trefoil*, with ſulphur-coloured flowers. 25. The ſtarry-headed *Trefoil*, with globoſe huſks. 26. The common purple ſtarry-headed French *Trefoil*. 27. The ſmall ſtarry-headed *Trefoil*, or dipſacus-headed *Trefoil*. 28. The globoſe *Trefoil*, or round-

headed

headed hares-foot *Trefoil*. 29. The creeping globoſe headed *Trefoil*, or bur-headed *Trefoil*. 30. The ſmooth or woolly-headed *Trefoil*. 31. The larger ſoft-headed, or woolly-headed *Trefoil*. 32. The larger rough-headed *Trefoil*. 33. The ſmaller rough-headed *Trefoil*. 34. The thyme-headed *Trefoil*. 35. The *Trefoil*, with oblong rough heads. 36. The ſtrawberry-*Trefoil*, with heart-faſhioned leaves and red flowers. 37. The ſtrawberry-*Trefoil*, with deep violet-coloured heads. 38. The long-leaved purple ſtrawberry *Trefoil*, which ſeems only a variety of the former ſpecies. 39. The reticulated *Trefoil*, which buries its ſeed under ground. 40. The annual *Trefoil*, with heads like thoſe of dodder. 41. The little procumbent *Trefoil*, with heads covered with a thick woollyneſs. 42. The ſmall hairy *Trefoil*, with large ſeeds, and ſoft heads in the alæ of the leaves. 43. The *Trefoil*, with round heads at the knots of the ſtalks. 44. The blackiſh luxuriant *Trefoil*, with four, five, or ſix leaves on a ſtalk, called the quadrifolium hortenſe. *Tourn.* Inſt. p. 405.

Trefoil, or clover, is a plant greatly eſteemed by the Engliſh farmers, for the great improvement it makes upon land, the goodneſs of its hay, and the value of its ſeed. The great advantage of *clover*, or *Trefoil*, to the land on which it grows is, that it feeds a vaſt number of cattle at a time, and their dung is ſo rich a manure to the ground that in two or three years time it becomes fit for corn again, though it had been ever ſo much exhauſted before. Clayey lands, in particular, are greatly improved by it.

There are ſeveral kinds of *clover*, but the great ſort is eſteemed the beſt, whoſe ſeed is like that of muſtard, except that it is more oblong. The Engliſh ſeed is preferable to that of all other places, and the farmer ſhould chooſe ſuch as is of a greeniſh colour, with a caſt of red; that which is black never growing ſo well. An acre of land will require ten pound of ſeed, ſometimes twelve pound, and it is better to ſow too much than too little. It delights moſt in a rich warm ſoil, and always thrives beſt in thoſe lands which have been well dunged or manured; but the clay-lands, which are long in acquiring a coat of graſs, or ſwarding as the farmers expreſs it, and are little ſubject to weeds, are of all others the beſt land for *clover*; becauſe in thoſe lands, where the common graſs grows ſpeedily, it ſoon eats out the *clover*. Light lands are in general more ſubject to this ſudden growth of common graſs, and they have alſo another diſadvantage in regard to the *clover*, which is, that they eaſily waſh away from its roots after ſharp rains; and then the roots, being left bare, are killed by the firſt froſt that comes; in good grounds it will bear crops for three or four years; but not longer than that, even in the moſt proper ſoil, and with all the neceſſary cautions.

There is a very eaſy method of determining what is good *clover*-ſeed and what bad; it is only neceſſary to throw it into a glaſs of water, and that which ſinks is good, what ſwims is bad, and will never vegetate. It is eaſy, from this trial, to know what ſeed is to be depended upon, and what is not; and to know what allowance is to be made in bad ſeeds, for the quantity loſt in the proportion for every acre.

The beſt way of ſowing of *clover* is, either with barley or oats after the corn is ſown; and, upon this account, the corn is to be ſown ſomewhat thinner than ordinary. The uſual time of ſowing it, is in the end of March, or the beginning of April in a calm day; but if the land be very dry, it is better to ſow it with black oats, as early in the ſpring as may be, that ſo it may get up while the ſpring rains laſt, and be of ſome ſtrength before the dry weather comes. Some ſow it with wheat or rye at Michaelmas; this gives it an opportunity of ſhedding its ſeed on the ground, and by that means, the crop of the next year is rendered much ſtronger than it would have been made by any other means; but then it is beſt to be ſown upon dry lands, which will bear the ſowing both of the wheat and the rye upon broad ridges; which is uſually very ſucceſsful, if a mild winter follows; but if there are long and ſevere froſts, or deep ſnows, it is very hazardous. Some adviſe the ſowing it alone, at Michaelmas; which they ſay makes it come up the freer from weeds, than if ſown in the ſpring; and that it will get ſtrength enough before winter, to ſupport itſelf againſt the froſts, and will grow finely in the enſuing ſpring.

Some farmers ſow rey-graſs with the corn at Michaelmas, and early in the ſpring they ſow *clover*, which they only cover by rolling it. The beſt management of all ſeems to be the feeding it bare before winter comes on, and then it is ſafe; for the froſts, though they often deſtroy the leaves of the *clover*, yet never hurt its roots, unleſs they happen to lie bare. About the middle of May, or at the utmoſt toward the end of that month, is the time of mowing the *clover* for the firſt crop. This takes up more time and labour in the making into hay, than the common graſs, and muſt be well attended; but if it grow not too ſtrong, it will be found exceeding rich for the fattening of cattle. The exact time for the cutting this firſt crop is when it begins to knot, and after this ſome mow two other crops before winter. *Mortimer*'s Huſb. p. 32. ſeq.

Hop-TREFOIL, or *Hop-Clover*, the farmers name for the ſmaller ſpecies of *Trefoils*, or three-leaved graſs, which they ſow in many places inſtead of the large clover: it is eſteemed much finer and ſweeter than the large clover, and upon ſome land is a very great improvement, though 'tis reckoned to grow upon any ſoil.

Hartlip, in his legacy, ſays, there are twenty-three ſorts of it, and that every ſort loves a peculiar ſoil; ſome ſpecies thriving beſt on clay, ſome on ſand, ſome in watery places, and ſome on ſun-burnt grounds. The ſeeing one kind or other of it thus growing on all ſorts of ſoils, may have been the occaſion of the error of ſuppoſing that every kind of it would grow every where: there are very certainly ſometimes ſeen thin crops of it, and the moſt natural ſuggeſtion as to the reaſon of it, ſeems, that a wrong kind for the ſoil has been ſown there. It may be no ſmall improvement in this branch of the farmer's buſineſs, to find out which it is that particularly loves each ſoil, and always ſow the proper ſpecies in the proper places. *Mortimer*'s Huſbandry, p. 41.

It may be ſown either with corn, or alone on ploughed lands, or ſprinkled over meadows to make a better crop with the common graſs. They commonly allow twelve pounds of the ſeed to an acre; and when ſown alone, it is eſteemed much more laſting than the rey-graſs, eſpecially the yellow hop-clover. When ſown among the hay-graſs in meadows, it much improves the crop both in quantity and quality.

The laſt crop is, however, often damaged by the weather, and it ſeems, upon the whole, better for the farmer to make only one crop after that in May. This ſecond crop he ſhould alſo calculate to get ſeed from; and for this purpoſe he muſt let it ſtand till the heads are thoroughly ripe before it is cut, for it is a ſort of ſeed that is not eaſy to ſhed.

When the ſeed is firſt perceived in the head, it is a notice that in a month's time it will be ripe, and fit for cutting. It muſt be watched about this time, and the ſtalk will be found to turn brown, and the ſeed greeniſh, at the time when it is fit for cutting. It muſt be mowed in a dry ſeaſon, and kept carefully as dry as can be.

It ripens ſome years conſiderably ſooner than others, and therefore there can be no rule laid down for the time of cutting, but this muſt be guided by the ripening of the ſeeds in the heads.

If the clover is apt to wear out the ground, and become thin upon it, let it be mowed in May, and after that let it ſtand till the ſeed is ripe, and falls out of the huſks upon the ground; then cattle may be turned in to feed upon it, and it will riſe up as freſh and full from theſe ſcattered ſeeds, as if it had been new ſown with all the art and care in the world. One acre of this graſs will feed as many cattle as five acres of common graſs; but the moſt advantageous way of feeding them, is not to turn them in upon it, becauſe in that caſe they tread down more than they eat; but to cut it with a ſcythe, and give it them in racks.

If the cattle are to be turned in to feed at large upon it, this muſt be done gradually, and with great caution; for if they are at once removed from common graſs into this, they will over-feed upon it, and even burſt themſelves; they are therefore to be put in at firſt only for half an hour in the middle of the day; a ſecond day they may be left in an hour; and the third day two or three hours; and after this, for three or four days, they are to be turned in as ſoon as the morning dews are off the ground, and driven out again before the evening dews fall. After this, it may be ſafe to let them remain in it entirely.

Clover is apt to do harm to milch cows, more than to any other cattle; and it is a very good method ſome have, to take off from the too great richneſs of the crop, by ſowing rey-graſs among the *clover*. This upright graſs grows well among the branches of the *clover*, ſhooting up its ſtalks above it, and being eaten with the *clover*, takes off from its too great richneſs, at the ſame time that it makes the crop the larger.

The *clover* that is intended for ſeed is preſerved dry all the winter, and in March it is to be thraſhed for the ſeed: what ſeed firſt comes out is to be cleanſed from the ſtraw, and the huſks then are to be traſhed again. When all is obtained that can at one time, let the ſtraw be well dried in the ſun, and toſſed about with a rake, and then on the thraſhing it again, more ſeed in conſiderable quantity will be obtained: two buſhels of ſeed may thus be procured, out of the produce of an acre of good Land where the *clover* has throve. Id. ibid.

Shrub-TREFOIL. See the article CYTISUS.

TREMELLA, *Laver*, in botany, the name of a genus of ſmall and ſeemingly imperfect plants, the characters of which are theſe: They are a kind of plants ſeemingly of a ſort of a middle nature between the *alga* and *conferva*. Theſe produce no flower, nor ſeed, ſo far as has been yet obſerved, but are throughout of one uniform and tender texture, pellucid and membranaceous, and frequently gelatinous; they for the moſt part live in the water, and conſiſt of flat and plain leaves, often very broad, and ſometimes tubular. See Tab. of Moſſes, N°. 3. *Dillen.* Hiſt. Muſc.

There are ſeventeen known ſpecies of this plant. 1. The common ſea *Tremella*, called oiſter-green or ſea-*Laver*. 2. The freſh-water *Laver*: this is much ſmaller than the former, and of a very tender ſtructure. 3. The navel-*Laver*: this is diſtinguiſhed by having its leaves rounded and umbilicated in the center. 4. The marygold-leaved *Laver*: this is of a blackiſh green colour, and has all its leaves oblong, jagged, and growing on pedicles. 5. The leek-leaved *Laver*: this grows

grows to three or four inches long, and is of a pale green. 6. The faſciated, or double ribband-*Laver:* this is of a bright green, and finely undulated. 7. The gut-*Laver*, commonly called the ſea-chitterling: this is hollow and waved in various manners; it is common in ſalt-water ditches. 8. The thready and tape-like *Laver:* this is naturally of a fine green, but becomes white with long lying on the ſhores. 9. The ſmall cluſter-*Laver:* this conſiſts of ſmall and convoluted branches, forming a thick tuft; it is of a duſky green, and is common on pebbles near the ſea-ſhore. 10. The jelly-like buckthorn ſea-*Laver:* this is common on the ſides of ſmall ſalt-water ditches, and is of a fine bright green; the branches are ſomewhat diſtended, but not wholly cylindric. 11. The gelatinous fern moſs-like *Laver:* this is a very beautifully ramified ſpecies, and grows on ſmall pebbles; it is very tender and of a beautiful green. 12. The tender criſp or curled ground-*Laver:* this of a beautiful deep green, and is very common under old walls and pales, in January, February, *&c.* 13. The horned ground-*Laver:* this grows to three or four inches high, and is variouſly and elegantly divided into a number of branches, or horns; thoſe are of a membranaceous ſtructure, and of a pale green colour when growing, but a little yelloviſh when dried: while growing, it much reſembles ſome of the lichenoides. 14. The jelly rain-*Laver*, called *noſtoch*. See the article NOSTOCH. 15. The black gelatinous tree-*Laver*, called by the country-people witches butter: this is of a duſky-reddiſh black, and conſiſts of a thick wrinkled membranaceous ſubſtance; it is common in Herefordſhire, and ſome other countries on the barks of old trees. 16. The bladdery gelatinous river-*Laver:* this is corrugated in the manner of the meſentery, and is covered with granulous tubercles reſembling ſeeds; it is of a bright green, and is found in the rivers of Wales. 17. The bladder-headed-*Laver:* this ariſes from a greeniſh irregular cruſt, into a ſort of hollow tubercles or bladders, which at firſt lie cloſe upon it, but afterwards riſe upon ſmall pedicles; theſe heads or bladders are diſtended each by a drop of water, which when it is rarified by the ſun's heat often burſts the bladder, and the whole collapſes and looſes its form. *Dillen.* Hiſt. Muſc. p. 50.

TREMOLANTE, in the glaſs-trade, a name for the preparation of calcined braſs, otherwiſe called orpello, uſed either for a ſky-blue, or a ſea-green. *Neri's* Art of Glaſs, p. 35.

TREMOR (*Cycl.*)—TREMOR *Artuum*, in medicine, a diſtemper conſiſting in a violent agitation of the limbs in contrary directions, owing to a deficiency of the due tone and proper niſus of the affected parts. Medical writers diſtinguiſh this *Tremor* into the active and paſſive; the active is that which happens in violent paſſions of terror, anger, joy, *&c.* or in intermittent fevers, and is to be referred to the ſemi-convulſive motions; the paſſive are owing to a privative cauſe, and are allied to the ſemi-paralytic affections.

The paſſive *Tremors* of the limbs, when conſidered as a diſeaſe, are to be diſtinguiſhed from thoſe which are cauſed by external accidents, ſuch as the being plunged into cold water, the drinking tea, coffee, or other warm liquors, in many conſtitutions, and other ſuch accidental cauſes. The perſons ſubject to *Tremors* of the limbs are principally old people, in whom the vital principle is weak and languid.

Cauſes. The internal cauſes, are a flaccidity of the nerves and remiſſion of the tone of the parts; the external and accidental ones are the omiſſion of accuſtomed evacuations, a diaphoretic regimen, and an abuſe of ſpirituous liquors. *Junker's* Conſp. Med. p. 680.

Prognoſtics and Method of Cure. This is uſually in old people a very obſtinate complaint, and the more it is confirmed by being grown habitual, the more difficult is the cure; but if a caſe of this kind be taken in hand, as ſoon as it ſeizes the patient, and be treated in a rational manner, it is often perfectly cured. In order to this, the firſt ſtep muſt be the perfectly cleanſing the *primæ viæ*, by repeated doſes of rhubarb, or of an extract of black hellebore; if any habitual evacuation have been omitted, as bleeding or the like, this muſt be reſtored in the accuſtomed manner; and if any natural flux of blood by the hæmorrhoids or otherwiſe have ſtopped, this alſo muſt be recalled by proper medicines, or by the application of leeches: after this the due tone of the parts is to be reſtored by nervine medicines, as by wine impregnated with ſerpyllum, lavender, ſaſſafras, guaiacum, and the like ingredients; and externally by rubbing the parts with ſpirit of caſtor and ſerpyllum, and bathing them in decoctions of tanzy, ſavin, feverfew, and the like herbs. One great rule in the cure of this diſeaſe, is, that the patient is to abſtain from all hot things, otherwiſe an atrophy is eaſily brought on, and proves a much worſe thing than the original diſorder. *Junker's* Conſp. Med. p. 681.

TRENCHING *Plough*, (*Cycl.*) in huſbandry, the name of an inſtrument uſed to cut out the trenches, drains, and carriages in meadow and paſture-ground. It is alſo uſed for cutting the ſides of turf even, which are to be laid down again either in the ſame, or in ſome other places.

It conſiſts of a long handle, with a knob or button at the end, and at the other end it turns upward like the foot of a plough, to ſlide in the ground. In this part is placed a coulter, of the length proportioned to the depth to be cut, and with a ſharp edge; this has two wheels to make it run eaſy, and does a great deal of buſineſs in a very little time. *Mortimer's* Huſbandry.

TREPAN (*Cycl.*)—Where it is ambiguous whether there be an extravaſation of liquors, or a depreſſion of the ſkull, the operation of the *Trepan* is ſaid to be the ſafeſt method. Mr. Queſnay gives us ſome hiſtories of the *Trepan* being performed ſeveral times with ſucceſs, for the ſame diſeaſe; and of large parts of the ſkull being taken away, without loſs of the patient's life. See Mem. de l'Acad. de Chirurg.

We have the deſcription and figure of a *Trepan*, differing from and turning more equally than the common, by Mr. Monro, in the Med. Eſſ. Edinb. vol. 5. art. 41.

TREPANING (*Cycl.*)—Not only the head, but the ſternum, is ſometimes neceſſarily the ſubject of this operation, as abſceſſes are ſometimes formed under the ſternum between the membranes of the mediaſtinum, by a fall or blow, an inflammation, or other cauſes; in which caſes there is hardly a poſſibility of diſcharging the matter by any other method.

The great difficulty is to determine when and when not this is neceſſary; that is, when there really is an abſceſs formed there. When this is known to be the caſe, the operation is to be performed in the following manner: The patient is to be inclined backward, and a crucial inciſion made in the integuments upon the lower part of the ſternum, where the abſceſs ſometimes makes a point; then the integuments being freed from the ſternum, the *Trepan* is to be applied, and worked in the ſame manner as in *Trepaning* the cranium; and when the perforation is made, the patient is to be ſtooped forward, and ordered to cough or breathe hard, in order to promote the diſcharge of the matter; and the abſceſs is afterwards to be cleanſed with detergent injections, and healed in the uſual way. *Heiſter's* Surgery, P. 2. p. 21.

TREPIGNER, in the manege, the action of a horſe who beats the duſt with his fore-feet in managing, without embracing the volt; and who makes his motions and times ſhort, and near the ground, without being put upon his haunches. This is generally the fault of ſuch horſes as have not their ſhoulders ſupple, and at liberty, and withal have ſcarce any motion with them. A horſe may *trepigner*, in going upon a ſtrait line.

TRESSEL (*Cycl.*)—TRESSEL-*Trees*, in a ſhip, are thoſe timbers of the croſs-trees that ſtand along ſhips, or fore and aft at the tops of the maſts. See the article CROSS-*Trees*.

TRESSIS, among the Romans, a copper coin equal in value to three *aſſes*. *Pitiſc.* in voc. See the article AS, *Cycl.*

TREWIA, in botany, the name of a genus of plants, the characters of which are theſe: The perianthium is permanent, and is compoſed of three oval reflex and coloured leaves. There are no petals. The ſtamina are numerous capillary filaments, of the length of the cup. The antheræ are ſimple. The germen of the piſtil is placed under the cup. The ſtyle is ſimple, and of the length of the ſtamina, and the ſtigma is ſimple. The fruit is a three-ſquare turbinated coronated capſule, formed of three valves, and containing three cells. The ſeeds are ſingle, and are in figure convex on the one ſide, and angular on the other. *Linnæi* Gen. Plant. p. 236. Hort. Mal. vol. 2. p. 42.

TRIAD, *Trias*, (*Cycl.*) among the antient Mythologiſts. See the article FERNARY.

TRIANDRIA, in botany, a claſs of plants which have hermaphrodite flowers, with three ſtamina or male parts in each.

The word is formed of the Greek, τρὶς, three, and ἀνὴρ, male. Of this claſs of plants are the valerian, ſaffron, a great many of the graſſes, *&c.* See Tab. 1. of Botany, Claſs 1.

TRIANGLE (*Cycl.*)—Plutarch informs us, that Xenocrates the philoſopher reſembled the Deity to an equilateral *Triangle*, the genii to an Iſoſceles, and men to a ſcalenum. A *Triangle* has ſince been applied by Chriſtians to repreſent the Trinity, ſometimes ſingle, and at other times with additional lines, expreſſing a croſs. Thus we find them variouſly combined upon the medals of the popes, publiſhed by Bonanni. And nothing was more frequent formerly with printers, than to place theſe figures in the front of their books; at firſt, doubtleſs, with a religious intent, till at length, by common uſe, they became only preſs marks, and badges of diſtinction among the trade; as they now are with merchants, who mark their goods with them both here and abroad. Phil. Tranſ. N°. 474. Sect. 1.

TRIANGULAR (*Cycl.*)—TRIANGULAR *Leaf*, among botaniſts. See the article LEAF.

TRIANGULARIS (*Cycl.*)—TRIANGULARIS *Coccygis*, in anatomy, a name given by Santorini, and others, to the muſcle now generally called ſimply *Coccygæus*. See the article COCCYGÆUS.

TRIANGULARIS *Labiorum*, in anatomy, a name given by Santorini and Winſlow, to the muſcle called by Albinus *depreſſor anguli oris*, and by Cowper and others, *depreſſor labiorum communis*.

TRIANGULARIS *Penis*, in anatomy, a name given by Morgagni, and others, to a ſuppoſed muſcle, called alſo by ſome *dilatator penis*, and *dilatator poſticus urethræ*; and by others *levator ani*.

It is truly no diſtinct muſcle, but a proceſs of the *ſphincter ani* running into the perinæum.

TRIANGULARIS *Piſcis*, in zoology, the name of a ſea-fiſh of a very remarkable figure, called in Engliſh the *coney-fiſh*, of which there are two ſpecies, the one having two horns, the other wanting that character.

The horned kind is uſually ſix or ſeven fingers breadth long, and about three fingers broad. The tail ends in a ſomewhat long fin. The mouth is ſmall, and capable only of admitting a pea. It has twelve ſtrong ſerrated teeth in the upper jaw, and eight larger ones in the lower. The head riſes gibbouſly from the mouth to the horns; and the back is humped in the ſame manner in the middle. It has only one ſmall fin near the tail. Its eyes are large, and placed near the horns. Beſide the ſingle fin near the tail, it has four others, the tail making one, one more being ſituated on the back, and two on the belly. It has two horns like cocks ſpurs, growing ſtrait out of its forehead, and two others in a contrary direction, out of its belly near the tail. It has no ſcales, but has a hard ſkin, white on the belly, and brown every where elſe, and wonderfully marked with trigonal, tetragonal, and pentagonal and hexagonal figures. The ſpecies which has no horns, has a broader belly, a longer tail, and is marked all over its body only with hexangular figures, and innumerable ſmall tubercles. Its belly is yellowiſh, and the reſt of its body of a greyiſh or browniſh yellow. The mouth is narrow, and the teeth ſmall; five in the under, and eleven in the upper jaw. The eyes are large and round. It is hollow, and has very little fleſh. See Tab. of Fiſhes, N°. 68.

Both thoſe ſpecies are caught among the rocks, on the ſhores of the iſland of Java, and are ſometimes eaten by the inhabitants, being firſt ſkinned. *Cluſ.* Exot. L. 6. c. 27. *Willughby*'s Hiſt. Piſc. p. 150.

TRIANGULARIS *Splenii*, in anatomy, a name given by Spigelius and others, to a muſcle of the head called by Winſlow, the upper portion of the *ſplenius*, or *ſuperior maſtoidæus*, and by Albinus, the *ſplenius capitis*. The old authors have deſcribed it under the name of the *primus caput moventium*.

TRIBULASTRUM, in botany, a name given by Iuſſieu to a genus of plants, ſince called by Linnæus *neurada*. See the article NEURADA.

TRIBULOIDES, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the roſaceous kind, being compoſed of a number of petals, arranged in a circular form. From the cup ariſes a piſtil, which finally becomes, together with the cup, a roundiſh prickly unicapſular fruit, containing a ſeed like a cheſnut. The prickles of the fruit are only the leaves of the cup become rigid. There is only one known ſpecies of this plant, which is the water *Tribuloides*, commonly called the *water Tribulus*. The kernel of the fruit is eatable.

TRIBULUS, *Caltrop*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the roſaceous kind, conſiſting of ſeveral leaves, arranged into a circular form. From the cup ariſes a piſtil, which afterwards becomes a ſort of cruciform or turbinated fruit, compoſed of ſeveral parts, each ending in a prickly point, and all collected into a firm head, and containing oblong ſeeds.

The ſpecies of *Tribulus*, enumerated by Mr. Tournefort, are theſe: 1. The chich-leaved land *Tribulus*, with prickly ſeed-veſſels. 2. The great prickly-headed land *Tribulus* of Curaſſo 3. The long-leaved Armenian *Tribulus*, with turbinated heads. And 4. The vetch-leaved hairy *Tribulus* of the Eaſt-Indies. *Tourn.* Inſt. p. 265.

TRIBULUS *Marinus*, the *Caltrop-Shell*, in natural hiſtory, the name of a peculiar ſpecies of the purpura. It is of a whitiſh colour, and has three rows of ſpines. See the article PURPURA.

TRIBUNES *of the People*, (*Cycl.*) in antient Rome, by virtue of their office, claimed and exerciſed a power of ſummoning the ſenate at any time, whenever the affairs of the people required it, though the conſuls themſelves were in the city. It has been taken for granted, on the authority of Valerius Maximus, that the *Tribunes* of the people, on their firſt creation, were not admitted into the ſenate, but had ſeats placed for them before the doors in the veſtibule. But we may reaſonably conclude, that a magiſtrate ſo ambitious and powerful, who could controul, by his ſingle negative, whatever paſſed within doors, would not long be content to ſit without. *Dionyſ.* Halic. x. 31. *Middlet.* of Rom. Senat. p. 129. *Val. Max.* l. 2. c. 27.

A. Gellius ſays, that they were not made ſenators before the law of Atinius [a], who is ſuppoſed to be C. Atinius Labeo, *Tribune* of the people, A. U. 623. [b]; but that cannot poſſibly be true, ſince it is evident from the authority of Dionyſius, that near four centuries before, the *Tribunes*, by the mere weight, and great power of their office, had gained an actual admiſſion into the ſenate, within two years after their firſt creation [c]; in which we find them debating and enforcing, with great warmth, the demands of the commons, for a liberty of intermarriages with the nobles, and the choice of a plebeian conſul [d]. So that the intent of this Atinian law could not be, as it is commonly underſtood, that the *Tribunes* ſhould be ſenators in virtue of their office, for that they had been from the beginning; but that for the future they ſhould always be choſen out of the body of the ſenate, or, which is the ſame thing, out of thoſe who had already borne the office of quæſtor [e]. —[a] *A. Gell.* 14. 8. [b] V. *Pighil.* Annales, A. U. 623. [c] *Dionyſ.* l. x. 11. [d] *Dionyſ.* xi. 57. [e] *Middleton*, of Rom. Sen. p. 45.]

TRICEPS (*Cycl.*)—TRICEPS *Primus*, a fleſhy and flat muſcle, ſituated between the os pubis and the whole length of the os femoris; the firſt and ſecond croſs each other in ſuch a manner, as that the muſcle which is the firſt on the os pubis, becomes the ſecond on the os femoris; but the third keeps its rank.

The *Triceps primus* is fixed above by a ſhort tendon to the tuberoſity or ſpine of the os pubis, and to the neighbouring part of the ſymphyſis, its fibres mixing a little with thoſe of the pectineus. From thence it runs down, increaſing in breadth, and is inſerted by fleſhy fibres interiorly in the middle portion of the linea femoris aſpera. At the lower part of this inſertion a portion of the muſcle ſeparates from the reſt, and ſends off a long tendon, which, together with a like tendon of the *Triceps tertius*, is inſerted in the inner condyle of the extremity of the os femoris. *Winſlow*'s Anatomy, p. 208.

TRICEPS *ſecundus*, a fleſhy and flat muſcle, fixed above by fleſhy fibres below the ſuperior inſertion of the *Triceps primus* in all the outſide of the inferior ramus of the os pubis, as low as the foramen ovale; but ſeldom ſo low as the ramus of the os iſchium. This inſertion is broader than that of the former muſcle. From thence it runs down, and is inſerted in the upper part of the linea aſpera, between the pectineus and *Triceps primus*, mixing a little with each of thoſe muſcles. This inſertion appears ſometimes divided. *Winſlow*'s Anat. p. 208.

TRICEPS *tertius*, a fleſhy and flat muſcle, fixed above by fleſhy fibres to the anterior part of all the ſhort ramus of the iſchium, and to a ſmall part of the tuberoſity of that bone; this inſertion covers ſome part of the tendon of the ſemi-membranoſus; from thence it runs down and is inſerted by fleſhy fibres in the linea aſpera, almoſt from the little trochanter down to the middle of the os femoris.

It goes lower down than the firſt *Triceps*, ſending off a ſeparate portion, like that of the ſecundus. Theſe two portions join together and form a common tendon, which running down to the lower extremity of the os femoris is inſerted in the back part of the tuberoſity of the inner condyle; this ſeparate portion is ſometimes large enough to be miſtaken for a diſtinct muſcle, making a quadriceps inſtead of a *Triceps*. In all this progreſs this muſcle is joined to the vaſtus internus by a perforated aponeuroſis, through which the blood-veſſels paſs. *Winſlow*'s Anatomy, p. 208.

TRICHECHUS, in ichthyology, a name given by Artedi to the creature commonly called the manati, or ſea-cow. He makes it a diſtinct genus of the plagiuri or cetaceous fiſhes; the characters of which are theſe: The teeth are flat and ſtand in each jaw, and there is no fin on the back. This creature grows to twelve or fifteen foot in length, and to ſix or ſeven foot in breadth. The head is oblong and cylindric, and more reſembles that of a hog than any other creature's. The eyes are ſmall, there are ſmall apertures in the head by way of ears, and the lips are very thick; two teeth ſtand out on each ſide, of the thickneſs of a man's thumb, and five or ſix inches long. The pectoral fins are two, and ſtand on the breaſt; they are compoſed of five diſtinct bones reſembling fingers, joined together by a membrane; each bone has three articulations. The tail is placed horizontally, and there is no fin upon the back: In the females there are two round breaſts placed between the pectoral fins. The parts of generation are like thoſe of the human ſpecies in both the male and female; and there is a navel. The ſkin is hard, and almoſt impenetrable; the hairs are few, and of a greyiſh colour. The creature lives about the openings of great rivers into the ſea, and feeds on graſs and ſea-plants. The fleſh is white and well taſted. It makes a noiſe, and is ſaid to be eaſily tamed, and to love the human ſpecies. Its great enemies are the crocodile and the ſhark, both which are very fond of its fleſh. *Artedi* Gen. Piſc. 61. *Linnæi* Syſtem. Nat. p. 5.

The name is originally Greek, and is formed of the words θρίξ, a hair, and ἰχθύς, a fiſh. It is given this fiſh to expreſs its being hairy; as it is almoſt the only fiſh in the world that has a title to this adjective hairy.

TRICHERIÆ, in natural hiſtory, the name of a genus of foſſils, of the claſs of the fibrariæ; the characters of which are, that they are not elaſtic, and are compoſed of ſtrait and continuous filaments. See Tab. of Foſſils, Claſs 1.

The word is derived from the Greek τρίχες, capillaments or fibres. The bodies of this genus are divided into thoſe which have broader, and thoſe which have narrower filaments; and there are ſix known ſpecies of it: 1. The gypſum ſtriatum, or ſtriated plaſter-ſtone; ſee the article GYPSUM *Striatum*. 2. A yellowiſh white kind, found in the clay and gravel pits in Northamptonſhire, and elſewhere. 3. A white kind, with foliaceous flakes, made up of ſeveral conjunct ſeries of filaments, and emulating the external appearance of the talcs, though wanting their characters: This is found in the alabaſter pits of Derbyſhire. Theſe three are of the broad fi-

bred kind. Of thoſe with narrower fibres, there are, 1. A fleſh-coloured ſpecies, with very little gloſs, found in many parts of Yorkſhire, and worth enquiring after, as it readily burns to a very fine plaſter, like the gypſums. 2. A dull-looking white ſpecies, with very ſhort though continued filaments, found in the pits of red marl in Derbyſhire, and elſewhere. And, 3. A greeniſh white kind very gloſſy, with ſtrait narrow and continued filaments. This is a very ſcarce ſpecies, but is found ſometimes in the marl-pits of Derbyſhire and on the ſhores of Yorkſhire, having been waſhed out of the cliffs by the waves in high tides. All theſe ſpecies burn very readily to a fine plaſter, like the gypſums; and ſome of them are found in particular places in ſuch great abundance, that it would be a very advantageous thing to collect and burn them. *Hill*'s Hiſt. of Foſſ. p. 90.

TRICHESTRUM, in natural hiſtory, the name of a genus of foſſils, of the claſs of the ſelenitæ, but differing extremely in figure and ſtructure from the common kinds.

The word is derived from the Greek τρίχες, hairs or filaments, and ἀστὴρ, a ſtar; and expreſſes a ſet of bodies compoſed of filaments arranged into the form of a ſtar. The ſelenitæ of this genus are compoſed of filaments ſcarce any where viſibly arranged into plates or ſcales, but diſpoſed in form of a radicated ſtar, made of a number of disjunct ſtriæ. See Tab. of Foſſils, Claſs 2. *Hill*'s Hiſt. of Foſſ. p. 123.

Of this genus there is only one known ſpecies, which is of a pale brown, and is compoſed of extremely fine and ſlender filaments. It is formed like the lepaſtrum in the accidentally open cracks in the ſeptaria, or ludus Helmontii, and is no other way different from the bodies of that genus, than as in all the ſelenitæ the plates they are compoſed of are made up of filaments nicely arranged, in this as in ſome other of thoſe bodies, the filaments have never arranged themſelves into plates at all, but are diſpoſed into the form of a ſtar compoſed of ſingle threads. This body very readily and regularly ſplits according to the arrangements of the fibres, and is in ſome pieces tolerably pellucid. It is found only in one place, ſo far as is yet known, which is under the cliffs of Sheppy-iſland in Kent; where it is conſiderably plentiful, and makes a very elegant figure on the broken maſſes of ſeptaria, which are in immenſe numbers ſtrewed upon the ſhore. *Hill*'s Hiſt. of Foſſ. p. 150.

TRICHIASIS, in medicine, the name of a diſtemperature of the eyes, in which the eye-lids are inverted, and in which the eye-laſhes hurt and irritate the eyes.

The cilia or margins of the eye-lids are ſometimes inverted ſo as greatly to irritate the ſenſible coats of the eye, and bring on intenſe pains and inflammation, which, without timely aſſiſtance, may greatly injure, if not totally deſtroy the ſight. This diſorder is generally owing to accident, as the irregular cicatrix left on the part from a burn, the ſmall-pox, an ulceration, or wound, or ſome other external injury. But ſometimes a relaxation of the ſkin, and a paralytic diſorder of the eye-lids, are the chief cauſes of it.

Whatever cauſe it is from, it is always difficult enough to be remedied; for it is hardly poſſible for the ſurgeon to remove it, ſo as to prevent its returning, without extirpating the offending hairs; and if theſe be cut off cloſe, it will be to no purpoſe, becauſe the rigid ſtumps of the hairs will irritate the eye even worſe than the whole hairs did before. It is a very nice operation alone that can make a cure; here the hairs muſt be pulled up ſingly by the roots, and the places of their inſertion ſingly cauterized with a hot broad-pointed needle; but this the patient will ſeldom ſubmit to, and the only remaining method then, is to fill up the ſinus's out of which they were extracted with the lapis infernalis. But in this the greateſt care muſt be taken, that no part of that application get into the eye. The eaſieſt method is the touching the cavities, out of which the hairs have been pulled up, with a pencil-bruſh dipped in a mixture of ſpirit of ſal-armoniac and highly rectified ſpirit of wine, by which means they will cloſe up, and no more hairs will grow from them. *Heiſter*'s Surgery, p. 369.

TRICHIDES, in zoology, a name uſed by the antients, for a fiſh of the harengi-form kind, probably the pilchard, which they called alſo *Sardinia* and *Sardella*. *Willughby*'s Hiſt. Piſc. p. 224.

TRICHOMANES, in the Linnæan ſyſtem of botany, the name of a genus of capillary plants, deſcribed by Plumier; the characters of which are theſe: On the margin of the leaves ſtands a ſingle erect turbinated cup, and a ſtylus in the manner of a briſtle terminates at the capſule. The plants of this genus are very different from what other authors call the *Trichomanes*; which, according to Linnæus, is not a diſtinct genus of plants, but is a ſpecies of aſplenium. See Tab. I. of Botany, Claſs 16. and the article ASPLENIUM.

The characters of this genus, according to Mr. Tournefort, are theſe. The flowers are not diſcovered, but the ſeeds grow in cluſters on the backs of the leaves, as in fern. The leaves are compoſed of little uſually roundiſh leaves, which grow by pairs along a middle rib.

The ſpecies of *Trichomanes*, enumerated by Mr. Tournefort, are theſe: 1. The common *Trichomanes*. 2. The *Trichomanes*, with leaves elegantly jagged. 3. The ſmall tender *Trichomanes*. 4. The great branched *Trichomanes*. 5. The *Trichomanes* with round dents, ſurrounded by a black rim. 6. The *Trichomanes*, with leaves lightly prickly. 7. The *Trichomanes*, with triangular crenated leaves. 8. The *Trichomanes* with heart-faſhioned leaves. 9. The leſſer branched *Trichomanes*. 10. The *Trichomanes*, with leaves partly bifid, partly whole. 11. The broad-leaved dentated *Trichomanes*. 12. The pendulous ſoft and ſilky *Trichomanes*. 13. The ſilvery *Trichomanes*, black at the edges. 14. The *Trichomanes* with bifid indentings.

The fruit of the *Trichomanes* is a roundiſh capſule, of a membranaceous texture, and covered with a ſort of ſcales; theſe are ſurrounded with an elaſtic ring, by the contraction of which they are burſt, and the ſeeds thrown out. *Tourn.* Inſt. p. 539.

This plant ſerves with us, as a ſuccedaneum for the true adiantum, or maiden-hair, which is not a native of England, and by the careleſſneſs of our druggiſts is ſeldom brought over to us. The whole plant, ſtalks and leaves together are uſed, and the virtues are in their greateſt perfection, if it be gathered in the month of September; it it is ſpoken of by all authors, as a good medicine in diſeaſes of the breaſt and lungs, and is much recommended by ſome in the ſtone and gravel. *Dale*, Pharm.

TRICHOSANTHES, in botany, the name given by Linnæus to a genus of plants, called by Plumier, Micheli, and others, *anguina*: the characters are theſe: It produces male and female flowers, on diſtinct parts of the ſame plant; in the male flowers, the perianthium is one leaved, clavated, and very long; it is ſmooth on the ſurface, and has a ſmall mouth reflected backwards, and divided into five ſegments. The flower is divided alſo into five ſegments, it is fixed to the cup, and is plain and expanded; the ſegments are of a lanceolated oval figure, and are fringed at their edges, with a great number of long and branched hairs: the ſtamina are three very ſhort filaments, reaching to the top of the cup; and each anthera is an oblong erect cylindric body, ſurrounded above and below with a line containing a large quantity of farina. There are in this flower three ſtyles, which are very ſmall, and grow to the ſides of the cup, but they are always abortive. In the female flower, the perianthium is the ſame as in the male, but it ſtands in this upon the germen of the piſtil, and ſoon periſhes; the flower is the ſame with the male; the piſtil has an oblong and ſlender germen, and has a capillary ſtyle, ariſing from it, of the length of the cup; the ſtigmata are three in number, they are long, pointed, and gaping in the middle; the fruit is an extremely long pomum, and contains three cells, very remote one from another: the ſeeds are very numerous, and are compreſſed, and of an obtuſely oval form, and covered with a coat. *Linnæi* Genera Plant. p. 466.. *Micheli*, Nov. Gen. p. 9. *Plumier*, Rar. p. 100. Hort. Malab. Vol. 8. p. 157.

TRICHOSTEMA, in botany, the name of a genus of plants, the characters of which are theſe: The perianthium is compoſed of one leaf, and is bilabiated; the upper lip is divided into three ſegments, and is twice as large as the under one, which is divided only into two. The flower conſiſts of one petal, and is of the labiated kind; its tube is very ſhort; its upper lip is compreſſed and falcated, and the lower is divided into three ſegments, the middle one is oblong, and is the ſmalleſt of the whole; the ſtamina are four capillary filaments, they are crooked and extremely long, two of them are ſomething ſhorter than the others; the antheræ are ſimple; the germen of the piſtil is divided into four parts; the ſtyle is capillary and of the length of the ſtamina; and the ſtigma is bifid; the cup remains after the flower is fallen, and then becomes larger and the upper lip falls over the under one, it then becomes diſtended in the middle and cloſed at the mouth, and contains four ſeeds. *Linnæi* Gen. Plant. p. 265.

TRICHOURI, in natural hiſtory, a term uſed by ſome authors to expreſs ſuch flies, as have one or more hairs growing out at their tails; theſe are called alſo ſeticaudæ, and are diſtinguiſhed into three genera, as they have one, two, or three hairs growing out at the tail. See the article SETICAUDÆ.

TRICHRUS, in natural hiſtory, the name of a ſtone deſcribed by the antients, and ſaid to yield three colours; in their common way of preparing bodies of this kind for medicinal uſe, (which was by rubbing them down on a porphiry, or other hard ſtone with water) this firſt coloured the water black, then red, and laſtly white. It ſeems to have been a kind of hæmatites, or blood-ſtone.

TRICIPITIS *Caput Primum*, in anatomy, a name given by many authors to a muſcle of the thigh, called by Albinus *abductor femoris*; Douglaſs calls it *abductor primus femoris*, and Winſlow the *muſculus primus tricipitis*. It is the *pars octavi femoris* of Veſalius; that author, and indeed many others of the earlier anatomiſts, not eſteeming it a diſtinct muſcle.

TRICOR, a name, by which ſome of the chemical writers have called gold.

TRIDE, in the manege, ſignifies ſhort and ſwift; thus a *Tride pace*, is a going of ſhort and quick motions, tho' united and eaſy. A *Tride career*, is a very faſt gallop, with the times or motions ſhort and nimble; and ſo of other motions. Some apply the word only to the motion of the haunches.

TRIEDROSTYLA, in natural hiſtory, the name of a genus of ſpars.

The word is derived from the Greek τρεις, thrice, ἕδρα, a ſide, and στυλος, a column.

The bodies of this genus are ſpars, in form of trigonal columns, adhering by one end to ſome ſolid body, and terminated at the other by a trigonal pyramid. Of this genus there are four known ſpecies: 1. A ſlender one with a long obtuſe pyramid: this is one of the moſt common of all the the ſpars, and is found in almoſt all parts of the world; ſometimes in ſingle and large ſpecimens, but more frequently in large congeries, coating over the fiſſures of ſtone in form of cruſts. 2. One with ſhort but pointed pyramids: this is common on Mendip hills, and is found in ſome other parts of England. 3. A thick one with a longer pyramid, found in Northamptonſhire, and ſome other parts of the kingdom, encruſting the fiſſures of ſtone. And 4. One with a very ſhort column, and a long obtuſe pyramid: this is frequent in the mines of Germany, and not leſs ſo in thoſe of England, particularly in Derbyſhire. *Hill*'s Hiſt. of Foſſ. p. 222.

TRIEMERUS, the three-day fly, in natural hiſtory, a fly ſomewhat like the butterfly; it has four large yelloviſh wings, and a long body, with a head furniſhed with long antennæ, large eyes, and a ſpiral trunk. It is found among the nettles and mallows.

TRIENTALIS, in botany, the name of a genus of plants, the characters of which are theſe: The perianthium is compoſed of ſix leaves, and is permanent; the leaves are narrow, pointed, and wide expanded; the flower is of the ſtellated kind, and is compoſed of ſeven petals, which ſtand flat and open, and adhere together very ſlightly at the top, theſe are a little longer than the leaves of the cup; the ſtamina are ſeven capillary filaments, of the length of the cup, but inſerted into the flower; the antheræ are ſimple; the germen of the piſtil is globular; the ſtyle is capillary, and of the length of the ſtamina; and the ſtigma is headed; the fruit is a dry berry of a globular form, formed of an extremely thin cruſt, and having only one cell; the ſeeds are few in number, and are of an angular figure; the receptacle is large enough to hold a great number of them; the number of the leaves of the cup ſometimes varies. *Linnæi* Genera Plant. p. 187.

TRIERARCHI, τριηραρχοι, among the Athenians, commiſſioners choſen annually out of the richeſt citizens, who were obliged to provide all ſorts of neceſſaries for the fleet, and to build ſhips at their own charge. See *Potter*, Archæol. Græc. l. 1. c. 15. T. 1. p. 86.

TRIETERIS, τριετηρις, in the antient chronology, a cycle of three years. *Potter*, Archæol. Græc. T. 1. p. 459.

TRIEXAHÆDRIA, in natural hiſtory, the name of a genus of ſpars.

The word is derived of the Greek, τρις, thrice, ἕξ, ſix, and ἕδρα, a ſide.

The bodies of this genus, are perfect and pellucid cryſtalliform ſpars, conſiſting of thrice ſix planes, being compoſed of an hexangular column, terminated at each end by an hexangular pyramid: Of this genus there are three known ſpecies. 1. A clear one with narrow and oblong pyramids: this is found in the mountains of Germany, and in North-Wales; but with us it is ſmall and coarſe. 2. One with ſhort pyramids and a long column: this is found in the mines at Goſſelaer in Saxony. And, 3. One with ſhort pyramids, and a thick and ſhort column: this is found with us in the lead-mines of Yorkſhire. *Hill*'s, Hiſt of Foſſ. p. 204.

TRIFOLIUM *Trefoil*, in botany. See the article TREFOIL.

TRIFOLIUM *Paluſtre*, *Buckbean*. This plant, tho' mentioned by ſeveral writers, before Simon Pauli, yet he was the firſt who recommended it in ſcorbutic caſes. He ſays it is more ſubtle and penetrating than *naſturtium* or creſſes.

It ſeems at preſent to be coming into great repute in many chronical diſtempers; and frequently preſcribed among alexipharmics.

Many have got it into uſe in their families in the form of tea, and experience its conſtant uſe to be very effectual againſt ſcorphula's the king's evil, and obſtinate ſcorbutic diſtempers. Its taſte at firſt, is not very grateful, but time wears off that diſlike; its uſe in ſhop compoſitions is not yet known. Vid. *Quinc.* Pharm. P. 2. Sect. 4. p. 124.

Buckbean ſerves in Hampſhire to a very remarkable uſe; the brewers uſing it in their beer in the place of hops. It is as good a preſerver of the drink, and is a bitter of as agreeable a flavour: it has this advantage alſo, that one eighth part of the quantity is ſufficient, it is a very harmleſs plant, and is given by many as an antiſcorbutic, and by ſome in rheumatiſms, and other chronic caſes. It might be extremely worth while to try this practice in other parts, as the plant might be eaſily cultivated in any quantity, and that with this advantage, that it will grow on the worſt kind of boggy land, that will produce nothing elſe. *Mortimer*'s Huſbandry.

TRIFOLIUM *Acidum*, in botany, a name given by many authors to the oxys, or wood-ſorrel, from its having its leaves always three on a ſtalk, and being of an acid taſte. See the article OXYS.

TRIFAX, among the Romans, a javelin three cubits long, which was thrown by the catapulta. *Pitiſc.* in voc.

TRIGEMINI *Tertius*, in anatomy, a name given by Spigelius and others, to a muſcle called by Winſlow the *complexus minor* or *maſtoidæus lateralis*, and by Cowper and Albinus *trachelo-maſtoidæus*. See the article MASTOIDÆUS.

TRIGLA, in the Linnæan ſyſtem of zoology, the name of a genus of fiſhes, of the general order of the acanthopterygii: the diſtinguiſhing characters of theſe are, that the membrane of the gills has ſeven bones, and the pectoral fins have articulated appendages. Of this genus are the *lyra*, *hirundo*, *malvus*, *mullus barbatus*, &c. *Linnæi* Syſtema Naturæ, p. 53. See the article LYRA, HIRUNDO, &c.

The characters of this genus, according to Artedi are theſe: The branchioſtege membrane contains ſeveral bones; the head is very declivious, from the eyes to the end of the ſnout, and is large, aculeated, and as it were ſquare; the head is the broadeſt part of the fiſh, it thence grows gradually narrower, till it ends in a very ſmall tail: in many of the ſpecies of this fiſh, there are two or three articulated appendices growing under the pectoral fins: the eyes ſtand on the top of the head, and are covered with a ſkin; there are two back fins, the firſt of which is prickly; the pectoral fins in ſome of the ſpecies are very large.

Many of theſe fiſhes are capable of making a noiſe; and ſome of them by the help of their pectoral fins, can ſuſtain themſelves for a time out of the water, and fly to ſome diſtance. The appendices of the pylorus are from five to twenty.

Of thoſe *Triglæ*, which have continuous, obtuſe, and undivided ſnouts, the following are the ſpecies: The *Trigla* with a ſmooth head, and with two fins on the lower jaw: this is the *mullus barbatus* of authors. 2. The *Trigla* with a ſmooth head, with four yellow, not tranſverſe lines, on each ſide, parallel to one another: this is the *mullus major*, or ſurmullet of our fiſhermen. 3. The *Trigla* with a ſmooth head and and without beards, all over of a red colour: this is called by authors the *mullus imberbis*, or king of the mullets. 4. The *Trigla* with the head ſomewhat aculeated, and with a ſingle little pinnule at the pectoral fins: this is the *milvus* of authors, or the kite-fiſh; it flies four or five foot above the water, and that to a conſiderable diſtance. 5. The *Trigla* with a prickly head, and with three appendices on each ſide at the pectoral fins: this is the *hirundo* of authors, and is called by our fiſhermen the tub-fiſh. Of thoſe *Triglæ* which have the ſnout a little forked, the following are the ſpecies: 6. The *Trigla* with a ſomewhat biſid ſnout, and with the lateral line biſid at the tail: this is the *lucerna* of the Venetians, and the *milvus* of ſome authors. 7. The red *Trigla*, with the ſnout divided into two little horns, and with the opercula of the gills ſtriated: this is the *cuculus*, and *lyra* of ſome authors. This fiſh grunts when taken out of the water, and the noiſe has been ſuppoſed to be like that of a cuckow, whence the name.

Of thoſe *Triglæ*, which have the ſnout very deeply divided, and opened into two very broad parts; the following are the ſpecies: 1. The variegated *Trigla*, with the ſnout divided into two prickles, and with two little prickles to each part: this is *gurnardus griſeus* of Ray, or the grey gurnard. 2. The *Trigla* with the ſnout divided into two ſpines, and with tubulous noſtrils: this is the *lyra* of authors, called by our fiſhermen the *piper*. 3. The *Trigla* with many cirri, and with an octangular body: this is the *lyra cornuta* of authors: the body is rendered angular, by having ſix rows of acute and hard rhomboidal ſcales. *Artedi*, Gen. Piſc. p. 32.

TRIGONAL-*Leaf*, among botaniſts. See the article LEAF.

TRIGONELLA, in botany, the name of a genus of plants, including the fænugreek of authors; the characters are theſe: The perianthium is formed of one leaf, and is campanulated and lightly divided into five ſegments, which are pointed, and nearly equal in ſize; the corolla is papilionaceous, and ſeems compoſed of three petals; the vexillum is oval, obtuſe, and bent backwards; the two wings are of an oval oblong figure outwardly, by bending backwards, ſo that in the vexillum, they ſeem to compoſe a tripetalous flower of the common form; the carina is very ſhort and obtuſe, and occupies the middle of the flowers; the ſtamina are diadelphous and ſhort; the apices ſimple; the germen of the piſtil is of an oblong oval figure; the ſtyle is ſimple and erect, and the ſtigma is ſimple. The fruit is an oblong oval pod, of a compreſſed figure, containing ſeveral roundiſh ſeeds; the ſhape of the flower alone, ſufficiently diſtinguiſhes this from all the other genera of this claſs. *Linnæi* Gen. Plant. p. 362. *Tournef.* Inſt. p. 270. *Rivin.* p. 497.

TRIGONELLA *Foſſilis*, in natural hiſtory, the name of a foſſile ſhell, of the cockle-kind, but approaching to a triangular figure, having a broad bottom to which it deſcends, almoſt in ſtrait lines: on each ſide from the head or cardo, theſe are uſually found ſmall, but there are ſome met with of four or five inches round: they are found at different depths, in ſtone quarries, bedded in the matter of the ſtrata; and that often in the hardeſt ſtone. In ſome inſtances, the ſhells are found remaining in their native ſtate; but moſt frequently the ſhell itſelf is periſhed and gone, and there is a ſtony or ſparry matter depoſited in its place. *Hill*'s Hiſt. of Foſſ. p. 646.

TRILL-

TRILL-*Hooks*, thoſe uſed to hold the ſides of a cart up to the horſe. See the article CART.

TRILLETTO, in the Italian muſic, a little ſhort ſhake or quaver; it differs from *trillo*, only in point of continuance being its diminutive. See the next article.

TRILLO, in the Italian muſic, is often found marked with a ſingle T; or tr, and often alſo by a ſmall t, as well in vocal as inſtrumental parts. It is deſigned to intimate, that you beat quick upon two notes in conjoint degrees, as *e f*, or *d e*, alternately; beginning with the higheſt, and ending with the loweſt. This makes what the French improperly call *cadence*, and properly *tremblement*. But it is alſo very often found in the Italian muſic to give notice, that the ſame ſound be ſtruck many times over, beginning a little ſlow, and ending with all the quickneſs, that the throat or finger can form them. Thus, ſuppoſing the firſt two or three quavers, then as many ſemi-quavers, and then ending with demi-ſemi-quavers, all in the ſame pitch or tune.

The manner wherein we have deſcribed this, comes far ſhort of what able maſters can ſhew in practice: This *Trillo* is more particularly uſed, after a note has been long held out, to eaſe the voice; which ſo long a tenſion had weakened. *Broſſard.*

TRILOBOUS-*Leaf*, among botaniſts. See the article LEAF.

TRILOCULAR-*Capſule*, among botaniſts. See the article CAPSULE.

TRIMODIA, among the Romans, a bag like an inverted cone, in which ſowers carried their ſeed. It was ſuſpended from their necks, and was ſo called from its containing three buſhels. *Pitiſc.* Lex. Ant. in voc.

TRINGA, in the Linnæan ſyſtem of zoology, the name of a diſtinct genus of birds, of the order of the ſcolopaces: the diſtinguiſhing characters of this is, that the feet have each four toes, and the beak is ſhorter than the toes. *Linnæi* Syſtema Naturæ, p. 47.

There are three ſpecies of this genus: The firſt called by almoſt all authors *Tringa*; the others the *pinirole*, and our *ſandpiper*. See the article SANDPIPER and PINIROLE.

The firſt ſpecies, or *Tringa*, moſt uſually ſo called, has been however named *cinclus*, by Bellonius; and *gallinula*, *rhodopus*, *phœnicopus*, and *ochropus*, by Geſner. It is ſomewhat larger than the black-bird, the colour of all its upper-ſide, is a very gloſſy greeniſh brown; and its ſhoulders and the ſmaller feathers of its wings are ſpotted with white. In the male, there are numerous white ſtreaks, and ſpots on the head, but in the female theſe are wanting; the throat is white ſpotted with black; the breaſt and belly are of a pure ſnow white; the long feathers of the wings are brown, and thoſe of the tail variegated with brown and white; its beak is a finger and half long, and of a greeniſh colour; and its legs of a bluiſh green; the hinder toe is very ſmall. They live about the ſides of ponds and lakes; its legs are ſometimes ſeen reddiſh or yellowiſh. *Aldrovand.* Tom. 3. p. 481.

TRINGA *Minor*, in zoology, a name by which ſome authors called the bird, commonly known in England, by the name of the ſandpiper. See the article SANDPIPER.

TRINITY (*Cycl.*)—By a ſtatute of king William the 3d, if one educated in, or having profeſſed, the chriſtian religion, ſhall be convicted in any of the courts of Weſtminſter, *&c.* of denying any one of the perſons of the holy *Trinity* to be God, or maintaining that there are more gods than one, or of denying the truth of the chriſtian religion, or the divine authority of the ſcripture, he ſhall for the firſt offence be adjudged uncapable of any office; and for the ſecond diſabled to ſue any action, *&c.* Anno 9 and 10. *Will.* III. cap. 32.

TRINK, in our ſtatutes, is uſed for a fiſhing-net. 2 *Hen.* 6. c. 15. *Blount.*

TRIONUM, in botany, the name of a genus of plants, called by Ruppius *bammia*; the characters are theſe: The perianthium is double; the external one is compoſed of twelve ſlender leaves; the internal one is only compoſed of one leaf, and is inflated and divided into five ſegments at the end; the flower conſiſts of five petals, cordated at the top, and growing together at the bottom; the ſtamina are numerous, they grow into a cylinder at the bottom, and are free at the tops; the antheræ are kidney-ſhaped; the germen of the piſtil is roundiſh; the ſtyle is capillary and terminated, by five obtuſe reflex ſtigmata; the fruit is oval, but ribbed with five ridges, and is compoſed of five valves, and contains as many cells; the ſeeds are numerous and are kidney-ſhaped. It is plain from theſe characters, that this genus is nearly allied to the hibiſcus. *Linnæi* Gen. Plant. p. 383. *Ruppii* Flora Jenenſis, p. 16.

TRIOPHTHALMUS, a name given by authors to ſuch pieces of agate, or other ſemipellucid ſtones, as happen to have three ſmall circular ſpots, reſembling eyes upon them: theſe are of the nature of the common agate, *&c.* The ſpots are mere accidental varieties in the diſpoſitions of the veins, and do not make a diſtinct ſpecies of ſtone.

TRIOPTERIS, in botany, the name of a genus of plants, the characters of which are theſe: The perianthium is very ſmall and permanent, and is compoſed of one leaf divided into five ſegments; the flower is compoſed of ſix equal petals of an oval figure, and theſe are ſurrounded by three other ſmaller petals, which are alſo of an equal ſize one with another; the ſtamina are two filaments, beyond the petals of the flower, and are fixed to the cup; the external ones are ſomewhat ſhorter than the interior, and the antheræ are ſimple; the germen of the piſtil is divided into three parts; there are three erect and ſimple ſtyles; and the ſtigmata are obtuſe: there is no fruit to encloſe the ſeeds, but they ſtand naked, and are three in number, and are hollowed at the back, and edged with alæ, which when newly produced have the appearance of petals. Indeed what are called petals in this deſcription, are not ſo; but are the alæ of the germen, for the ſtamina are placed without them; but as they very much reſemble petals, a young botaniſt will more eaſily diſtinguiſh the genus, by their being taken for ſuch, than by any other means. *Linnæi* Gen. Plant. p. 195.

TRIORCHIS, a word uſed by ſome, to expreſs a man who has three teſticles.

It is alſo uſed as the name of a buzzard; and of a plant, called ladies traces.

TRIPENTAHÆDRIA, in natural hiſtory, the name of a genus of ſpars.

The word is derived from the Greek, τρὶς, thrice, πέντε, five, and ἕδρα, a ſide.

The bodies of this genus are ſpars, compoſed of thrice five planes; being made of a pentangular column, terminated at each end by a pentangular pyramid. Of this genus we only know one ſpecies; this has a moderately long column, and very ſhort and broad pyramids; it is found in Derbyſhire, Yorkſhire, and Cornwall, and is very frequent about Goſſelaer in Saxony. *Hill*'s, Hiſt. of Foſſ. p. 205.

TRIPHARMACUM, an ointment, in the late London diſpenſatory, ſo called from its being compoſed of three ingredients: the preſcription is this: Take common plaſter four ounces, oil olive two ounces, vinegar one ounce; ſet them over a a gentle fire, and ſtir them continually, till they become an ointment. *Pemberton*'s, Lond. Diſpenſ. p. 370.

TRIPOLI, (*Cycl.*) in natural hiſtory, the name of an earthy ſubſtance, uſed by the lapidaries to poliſh ſtones, and by the braſiers, and other the like artiſts to clean metalline veſſels. It is of two kinds, the yellowiſh, and reddiſh white; the yellowiſh white kind is called by authors, *alana gleba*, *tripolis* and *terra tripolitana*; this is the produce of Germany, Saxony, and France; there is alſo of it in the neighbourhood of Venice, but it is found in greateſt plenty in many parts of Africa. It is found a dry hard earth, of a very pale yellowiſh white, of a firm texture, and moderately heavy; it is ſometimes found of itſelf, conſtituting a ſtratum; but is more frequently met with in detached pieces among ſtrata of other matter. It is of a rough, irregular, duſty ſurface; it adheres ſlightly to the tongue, is dry, hard, and harſh to the touch, is not to be broken between the fingers, and ſlightly ſtains the hands: it makes no efferveſcence with aqua fortis, and makes a ſlight hiſſing noiſe on being thrown into water. The reddiſh *Tripoli* is of our own production, though not peculiar to ourſelves; it is found in great abundance on Mendip-hills in Somerſetſhire, nor leſs plentifully in many parts of Germany. This is well known in the ſhops as a ſubſtance of great uſe in poliſhing braſs, but is not applied to any of the other uſes of the yellowiſh kind: this like the former is moſt frequently found in detached maſſes, and while in the earth is tolerably ſoft, and eaſily falls into flakes. When dry it becomes of a conſiderable hardneſs, and is of a fine pale reddiſh white, of a looſe open texture, compoſed of a multitude of extremely thin plates or flakes laid evenly on one another, and conſiderably heavy; it is of a ſmooth and ſomewhat gloſſy ſurface; it adheres very firmly to the tongue, is dry and harſh to the touch, too hard to be broken between the fingers, and does not ſtain the hands: it makes no efferveſcence with acids, and burns to a paler colour, with ſome additional hardneſs. *Hill*'s, Hiſt. of Foſſ. p. 68.

TRIPUDIUM, in antiquity, a ſpecies of divination, in which omens were drawn from the rebounding of corn thrown to chickens. *Hofm.* Lex. Univ. in Voc.

TRIPYRAMIDES, in natural hiſtory, the name of a genus of ſpars.

The word is derived from the Greek τρὶς, thrice, and πυραμὶς, a pyramid.

The bodies of this genus are ſpars, compoſed of ſingle pyramids, each of three ſides, ſtanding on no column, but affixed by their baſes to ſome ſolid body.

Of this genus there are only two known ſpecies: 1. A ſhort and thick one, found on the ſides of the ſtacks of ſtone in Northamptonſhire and elſewhere; but this is not common, and is uſually ſmall. 2. A long one with a narrow baſe: this is not found in England, but is common in the German mines. *Hill*'s, Hiſt. of Foſſ. p. 226.

TRISACTIS, in natural hiſtory, a name of a genus of ſtar-fiſh, compoſed of a body and three rays, the more uſual number being five. See the article STELLA *Marina.*

TRIQUETRA *Oſſa*, triangular bones found in ſome craniums.

TRIQUETRUM *Folium*, among botaniſts. See the article LEAF.

TRISCÆDECACTIS, in natural hiſtory, a name given by Linkius, and ſome other authors, to a kind of branched ſtar-

fiſh

fish or astrophyte; whose rays are thirteen in number, where they first leave the body, and each divides into many more.

TRIS-DIAPASON, *Triple-Diapason*, in music, what is otherwise called a *Triple eighth*.

TRISE, at sea, the seamen's word, for haling up any thing with a dead rope, or one that doth not run in a block, but is pulled by hand or by main strength: thus if any cask, chest, or other goods hath only a rope fastened to it, and so without a tackle be pulled up into a ship by hand, they say it is *trised up*.

TRISETÆ, the *three-haired* flies, a term used by the writers in natural history, to express a certain genus of the seticaudæ, or bristle-tailed flies, which are distinguished from the rest, by having three hairs or bristles growing from the tail: there are several kinds of these flies, found frequently among our hedges.

TRISEUS, in ichthyology, a name given by Salvian, Benedictus Jovius, and others, to that species of the gadi, which we call the eelpout, and authors in general the *mustela fluviatilis*.

TRISPERMUM, in pharmacy, the name of a cataplasm or pultice, consisting of three ingredients, these are cummin, and opium seed, and bay-berries.

TRISSA, in zoology, a name used by some authors, for the fish more commonly known by the name of alausa, and called in English *shad*, or the mother of herring. *Rondelet*. de Pisc. p. 21. See the articles ALAUSA, and AGONUS.

TRISTO, a word used by Paracelsus, to express what he calls the material fire; lodged in the matter of all the four elements, and exerting upon occasion its influence, under the form of the proper effects of each element.

TRITÆOPHYES, a word used by the medical writers of the antients, to express a kind of fever, much of the nature of the tertian, and taking its rise from it.

TRITE (*Cycl.*) — This chord of the antient tetrachord, was so named from its being the third from the nete; and hence we might call it the anti-penultimate. It was otherwise in some tetrachords called parypate. See the articles PARYPATE, DIAGRAM, and NETE.

TRITE *Diezeugmenon*, in the Greek music, was the anti-penultimate note of the diezeugmenon tetrachord, and answers to Guido's c, sol, fa, ut. *Wallis*, Append. *Ptolem.* Harm. p. 157. See the article DIAGRAM.

TRITE *Hyperbolæon*, in the Greek music, was the anti-penultimate note of the hyperbolæon tetrachord, and answers to Guido's f, fa, ut. *Wallis*, Append. *Ptolem.* Harm. p. 157. See the article DIAGRAM.

TRITE *Synemenon*, in the Greek music, was the anti-penultimate note of the synemenon tetrachord; and answers to Guido's b, fa. *Wallis*, Append. *Ptolem.* Harm. p. 157. See the article DIAGRAM.

TRITHEITÆ, in church history, a name given to such heretics, as admit not only of three persons, but of three distinct substances and natures, in the holy Trinity. See the article TRINITY, and TRITHEISM, *Cycl.*

TRITICUM, *Wheat*, in the Linnæan system of botany, makes a distinct genus of plants, the distinguishing character of which is, that the calyx is a glume containing several flowers, composed of two valves, and containing the flowers arranged into a short spike; the valves are of an oval figure, and obtuse; the flower is bivalve and of the size of the cup; the valves are nearly of the same size, and the exterior is bellied, obtuse and pointed, and the interior smooth and flat; the stamina are three capillary filaments; the antheræ are oblong and split at the ends; the germen of the pistil is of a turbinated form; the styles are two, capillary, and reflex; the stigmata are plumose; the flower incloses the seed till ripe, and then opens and lets it out; the seed is single, oval, and oblong, obtuse at both ends, and convex on one side, and marked with a deep furrow on the other. Whatever plant has all these characters, whether the grain be eatable or not, is properly a wheat. *Linnæi* Genera Plantarum, p. 16.

TRITON *Avis*, in zoology, a name under which Nieremberg has described a bird of the West-Indies, famous for its fine singing, and found in Hispaniola; it is said to have three different notes, and to be able to give breath to sounds of all three kinds at the same time; it is also said to be a very beautiful bird. *Ray*'s Ornithol. p. 299.

TRITOPATORIA, τριτοπατορεια, in antiquity, a solemnity in which it was usual to pray for children, to the Θεοι γενεθλιοι, or *god's of generation*, who were sometimes called τριτοπατορες. *Potter*, Archæol. Græc. T. 1. p. 434.

TRITTYARCHI, τριττυαρχοι, among the Athenians, were magistrates who had the command or government of the third part of a tribe. *Potter*, Archæol. Græc. T. 1. p. 78. See the article PHYLARCHUS.

TRITURATION, (*Cycl.*)—Mr. Lindern relates two observations, which contradict the doctrine of violent *Trituration*, said to be performed by the stomach in digestion. 1. A dog having swallowed a die, vomited it up again eleven or twelve hours after, when the bony part of the die was much diminished, but the pins of wood, on which the spots are marked, were entire, and stood out a considerable way from the bone. 2. Three stomachs of swine, were crusted so thick over their interior surface with a stony substance, that all their cavity was filled, except a canal in the middle, of about an inch diameter. Notwithstanding this, the flesh of the creature was fair and sound, and sold well. Hist. de L' Acad. des Sciences. 1732.

TRIUMFETTA, in botany, the name of a genus of plants, the characters of which are these: There is no cup unless the flower itself be called so; this consists of five strait erect concave petals, obtuse at the ends and bending backwards, and have a prominent point within the leaf, below the apex; these fall soon after they open, whence they appear rather the petals of a flower, than the leaves of a cup; the stamina are sixteen erect subulated filaments, of equal height and of the length of the flower; the antheræ are simple; the germen of the pistil is roundish; the style is simple, and of the length of the stamina; and the stigma is bifid and acute; the fruit is a globular capsule, every way beset with crooked prickles, and containing within it four cells, in each of which are two seeds, convex on one side, and angular on the other. It is very rarely, however, that more than one seed comes to maturity in the same cell. *Linnæi* Genera Plant. p. 243. *Plumier*, Gen. 8.

TROADENSE *Marmor*, a name given by the antients, to a species of white marble, dug in mount Ida, and greatly used in building.

TROCHILUS, (*Cycl.*)—TROCHILUS, in zoology, a name used by Aristotle, Pliny, and others of the antient naturalists, for the *regulus cristatus*, or, as we call it, the golden-crowned wren. *Ray*'s Ornithol. p. 163. See REGULUS.

TROCHILUS is also the name of a remarkable water-bird, being very long legged, yet web-footed.

It is a very swift runner on the ground, and is thence called by the Spaniards *corriza*. Its beak is strait and black at the end, and the opening of its mouth very wide; it has black eyes, surrounded by a white naked membrane, and that by a brown one. On its under part it is white; its back, shoulders, and wings, are of a ferrugineous colour; its running is so very swift as to equal the flight of most birds. *Aldrovand*, de Avib. l. 19. c. 35.

TROCHISCI *e Nitro*, a form of medicine, prescribed in the late London dispensatory, the preparation is thus: Take purified nitre four ounces, fine sugar a pound, reduce them to fine powder, and make them up into *Troches*, with mucilage of gum tragacanth. *Pemberton*'s Lond. Disp. p. 323.

TROCHISCI *e Sulphure*, a form of medicine, prescribed in the late London pharmacopœia, and made in this manner: Take of flower of sulphur washed two ounces, of double refined sugar four ounces; beat them together, and by gradually adding mucilage of quince-seeds, form *Troches*. *Pemberton*'s Lond. Disp. p. 324.

TROCHITÆ (*Cycl.*)—These single joints of the entrochus are found in some places in such vast numbers, as to make people suspect that they could never have been so strangely collected together, if they ever had been of animal origin; but this is one of the many too rash conclusions of the modern naturalists.

If we consider the vast number of arms or branches, of which the star-fish consists, whence these are produced, it will not a little tend to solve the difficulty: but if after this we consider the manner of life of the animal, we shall find yet more reason to be satisfied, that the number of these fossils is no argument against their being its remains. The species of star-fish, whence they have their origin, is famous for the immense, and indeed amazing, number of its arms; each of these arms is composed of an immense number of these single joints, and the creatures while living usually herd together; and it frequently happens that in grasping after their prey, an arm or limb breaks off; the consequence of this is, that wherever the mutilated limb touches the arm of another fish of the same kind with its truncated end, it adheres and grows to it, so as never to be separated again: thus the two fish are for ever fastened together. As they are continually reaching out their arms in search of prey, this accident often happens among them; and it is not unusual to find a cluster, of twenty or more, of them thus growing together, and with their expanded arms forming a sort of net. Now if it be considered, what a large number of single joints or *Trochitæ*, go to the formation of the thicker part of one arm; and how immense a number of arms, such a cluster as this possesses, from so many fish, each furnished with so large a number, we shall find, that the dis-united joints of one such cluster as this, scattered over a stratum of clay, would appear an amazing number: how much more then, the produce of twenty, fifty, or a hundred such, which it is no wonderful thing should be found in one place, since they are gregarious animals.

The comparison of a single *Trochite*, or entrochus, with the arm of this recent star-fish, will at once evince the truth of this account of their origin, and the great error of those who have supposed them of a vegetable nature, and called them rock-plants. *Kepellus*, Epist. de Entroch. See the article ENTROCHI.

TROCHITIFER *Glans*. See the article GLANS *Trochitifer*.

TROCHLEARIS (*Cycl.*) in anatomy, a name given by Fabricius, and ſome other writers, to one of the muſcles of the eye, called by Albinus the *obliquus ſuperior oculi*; and by ſome, from its office, the *opifex circumgyrationis oculi*.

TROCHUS, in natural hiſtory, the name given by authors to a genus of ſhells; ſome of the ſpecies of which reſemble the figure of the *Trochus*, or top, which boys play with. As there are many ſpecies of this ſhell, however, which are flatted and have nothing of this form, the whole ſeries of them are much better named, by a denomination taken from the ſhape of the mouth, which is of an oval figure, and is alike in all theſe ſpecies, and different from all other ſhells. They are therefore aptly characterized by a late French writer under the name of *cochleæ ore depreſſo*. See the article COCHLEA.

TROCTUS, in ichthyology, a name given by Ariſtotle, Ælian, Atheneus, and others of the Greek writers, to the fiſh called *amia* by Pliny, and moſt other of the later as well as antient Latin writers; but by ſome, *lechia* and *glaucus*. It is properly a ſpecies of the ſcomber, and is diſtinguiſhed from the others by the name of the ſcomber with two fins on the back, and with the laſt ray of the hinder fin very long. This is an obvious character, by which it is eaſily diſtinguiſhed from all the other ſcombri, of which it is a genuine ſpecies. See the article SCOMBER.

TROGLODYTES, in the Linnæan ſyſtem of zoology, the name of a diſtinct genus of birds, of the order of the paſſeres; the diſtinguiſhing character of which is, that the beak is thread-like and pointed, and is crooked, and longer than the head. *Linnæi* Syſtema Naturæ, p. 49. See the article PASSER.

TROIS *Cinque*, in the French diſtillery, a term uſed to expreſs their brandy when of a peculiar ſtrength, conſiſting of five parts alcohol, and three parts phlegm.

The method of diſtilling the wines into brandy in France, is exactly the ſame with that uſed with us to draw the ſpirit from our waſh or fermented liquor of malt, treacle, ſugar, or whatever other kind. They only obſerve more particularly to throw a little of the natural lee into the ſtill, along with the wine; and the pooreſt wines are found to ſucceed beſt on the trial, making by much the fineſt brandies. We are apt to wonder, that we cannot from the wines of particular countries diſtil their particular brandies; but the whole myſtery conſiſts in this, that they do not ſend us over the ſame wines which they uſe in diſtilling, becauſe theſe latter would not be liked as wines, nor would keep in the bringing over. Sometimes in Scotland, they meet with the poor and prick'd wines, the ſame that the French diſtil their brandies from; and from theſe they diſtil a ſpirit, not to be known from the brandy diſtilled in France.

The lee, which the French add in the diſtillation, gives the brandy that high flavour, for which we ſo much eſteem it; but they themſelves like it much the worſe for it. The French notion of a proof ſtrength, determined by the chapelet or crown of bubbles, is the ſame with ours; and all their fine ſpirits are found of this ſtrength.

But they have one particular expedient for thoſe brandies, which prove foul and ſeedy, or retain the taſte of certain weeds which grow among the wines; they draw them over again, with a deſign to free them from that adventitious flavour. In this operation they always leave out the faints, or rather they change the receiver as ſoon as ever the ſtream comes proof; then mixing together all that run off before, they make a brandy ſtronger than the ordinary kind, and this is what they call *Trois-cinque*.

The diſtillers in France ſcarce ever bring their brandies higher than this; for they have the art to perſuade the foreign merchant, that the phlegm of French brandy is natural and eſſential to it: but the truth is, that the ſpirit alone contains the flavour and excellence of the brandy, and it might as well be reduced to half its bulk for exportation, and ſent over in the ſtate of alcohol, and then lowered with common water, to the proof ſtrength.

The French uſe no art in colouring their *Trois-cinque*, any more than their common proof-brandy, nor do they add any thing to give them an additional flavour. The thing which they principally value themſelves upon, both in regard to brandies and wines, being to make them perfectly natural: ſo that all the colour we find in their brandies, is acquired from the caſk, and the time they are left in it. This is often twelve or eighteen months, ſometimes two or three years; in this time they acquire a brown colour, and loſe their acrid taſte.

The greateſt adulteration of brandies is in England; the French have no temptation to do it, they having no cheaper ſpirit, ſince the prohibition of molaſſes in their country. The Dutch are in the ſame condition, having no melaſſes ſpirit; and only a very coarſe and nauſeous ſugar-ſpirit, and a yet worſe malt ſpirit of their own manufacture; a ſingle gallon of which, would ſpoil a whole piece of brandy. The French brandy alſo paying no duty in Holland, is as cheap, or nearly ſo, there as in France itſelf. The duties being high upon brandy in England, it is greatly adulterated, and that with all ſorts of ſpirits; as malt, melaſſes, cyder, and ſugar ſpirits; and when this is done in a dexterous and ſparing manner, the cheat is not eaſily found out. *Shaw*'s Eſſay on Diſtillery.

TROMBA, in the Italian muſic, either denotes the common trumpet, the buccina of the antients, or the modern ſacbut, but more properly our trumpet. See the articles TRUMPET, SACBUT, and BUCCINA, *Cycl.*

TROMBETTA, in ichthyology, a name given by the Italians to the fiſh commonly called *ſcolopax* by authors. See the article SCOLOPAX.

It is properly a ſpecies of the baliſtes, and is diſtinguiſhed by Artedi, by the name of the baliſtes with two ſpines in the place of the belly-fins, and another ſingle ſpine below the anus. See the article BALISTES.

TROMBETTA, in the Italian muſic, a ſmall trumpet, being the diminutive of *tromba*. See the article TROMBA.

TROMBONE, in the Italian muſic, a ſacbut. See the article SACBUT, *Cycl.*

TROMBONE, *picciolo*, *groſſo*, *primo*, *ſecundo*, &c. See the article SACBUT. Ibid.

TROMPE, in the manege. See the article DECEIVED.

TRONCO *per Grazia*, in the Italian muſic, by the French called *coup de grace*; is uſed to intimate to the voices, as well as inſtruments, that they are not to draw out the ſound to its natural length, but cut it ſhort; that is, only continue it long enough to be heard, by which means there is a ſmall ſilence between each ſound; which has a very good effect in expreſſions of grief, to make ſigns; and alſo in expreſſions of wonder and ſurpriſe, &c.

TRONE (*Cycl.*)—TRONE-*Pound*, in Scotland, contains twenty Scotch ounces. But becauſe it is uſual to allow one to the ſcore, the *Trone-pound* is commonly 21 ounces.

TRONE-*Stone*, in Scotland, according to Sir John Skene, contains 19½ pounds. Vid. Treat. Pract. Geom. p. 153.

TROOPER, in the military art, a private man in a troop of horſe.

TROPER, in our old writers, is uſed for a book of alternate turns and reſponſes in ſinging maſs. *Lindewode* calls it *liber ſequentiarum*. *Hoved*. Hiſt. p. 283.

TROPHY (*Cycl.*)—TROPHY, in architecture, an ornament which repreſents the trunk of a tree, charged or encompaſſed all round about with arms or military weapons, both offenſive and defenſive.

TROPIC (*Cycl.*)—TROPIC-*Winds*. Dr. Liſter has advanced a very ſtrange ſyſtem as to the nature and origin of theſe, which is, that they are owing to the halitus of ſea-plants, growing in great abundance in particular places; he ſuppoſes that the Levant breezes are briſkeſt about noon, becauſe the ſun at that time exhales moſt from the plant. The direction of this breeze from eaſt to weſt, he ſuppoſes may be partly owing to the general current of the ſea; for a gentle air will be led by the ſtream of our rivers, for example; and partly to this, that every plant is in ſome meaſure an heliotrope or turnſole, bending itſelf in ſome degree after the ſun, and conſequently emitting its vapours according to the courſe of the ſun. Phil. Tranſ. N°. 156. See the article TROPICAL, *Cycl.*

TROSSULI, among the Romans, a name given by ſome to the guards that attended the kings of Rome, otherwiſe called *Celeres*. See the article CELERES.

TROUSSEQUEUE, in the manege. See the article DOCK.

TROUT, (*Cycl.*) a very valuable river-fiſh, the diſtinguiſhing characters of which are theſe: Its body is long; its head ſhort and roundiſh; the end of its noſe or ſnout obtuſe and blunt; its tail is very broad; its mouth large; and each jaw furniſhed with one row of ſharp teeth; and in its palate there are three parcels of teeth, each of an oblong figure in the congeries, and all meeting in an angle near the end of the noſe; and the tongue has ſix, eight, or ten teeth alſo on it; and its ſides are beautifully variegated with red ſpots.

This delicious fiſh is obſerved to come in; and go out of ſeaſon with the ſtag and buck; the time of its ſpawning is remarkable; moſt other fiſh do this in warm weather, but the *Trout* in October or November. Among the ſeveral kinds of *Trout*, the red and the yellow are the beſt for the table; and in the ſame ſpecies the female has always the preference to the male; the head of the female is ſmaller, and the body deeper than in the male. They are known to be in ſeaſon by the bright colour of their ſpots, and by the largeneſs and thickneſs of their backs; which laſt is a general rule in regard to all fiſh, to know when they are in ſeaſon.

In the winter the *Trout* is ſick, lean, and unwholeſome, and very often is louſy. The louſe, as it is called, of the *Trout* is a ſmall worm with a large head, which ſticks very faſt to the ſides of the fiſh; they live upon the juices of the fiſh all the time of the cold weather, while he is poor and lies quiet in the deep waters; but when the warm weather in the ſpring comes on, and the fiſh leaves his lazy life at the bottom, and comes up to the ſhallow gravelly places, where the ſtream is ſwift, he ſoon ſhakes them off.

The *Trout*, at its firſt coming into the ſhallow waters, may be ſeen to rub his body continually upon the ſharp gravel at the bottom; it is by this means that he gets off theſe worms

or lice, as they are called. From this time he begins to feed on flies; but in May the peculiar fly that he is fond of is produced, and after feeding that whole month on this inſect, the fleſh of the fiſh becomes more red and firm, and its higheſt ſeaſon begins.

The general baits for a *Trout*, are a worm, a minnow, or a fly, whether natural or artificial: among worms there are ſeveral kinds which this fiſh is fond of; ſuch are the earth-worm, and dung-worm in particular; the lob-worm and branding-worm alſo are eſteemed: but the beſt of all is the ſquirrel-tail worm, which has a ſtreak down the back, a red head, and a broad tail. The brandling is commonly found in a old dung-hill, or under cow-dung, or elſe among tanners-bark; the others are found in the earth, and under large ſtones or ſtumps of trees: whatever worm is uſed, the longer it is kept to ſcower firſt, the better the *Trout* will take it: they are to be kept in an earthen pot among moſs, which is to be ſhifted once in three or four days, or oftner if the weather be very hot.

To take the *Trout* with a ground-bait, the angler ſhould have a light, taper, rod, with a tender hazel top; and may angle with a ſingle hair of three links, the one tied to the other, for the bottom of the line; and a line of three haired-links for the upper part: with this ſort of tackle, if the ſportſman have room enough, he will take the largeſt *Trout* in the river. Some fiſh with three haired-links at the bottom of the line, but there is very little ſport to be expected this way, for the *Trout* is very ſuſpicious and very quick ſighted. The angler muſt always keep out of ſight, and the point of the rod muſt be down the ſtream. The ſeaſon for fiſhing for the *Trout* with a ground-bait begins in March, and the mornings and evenings in general are the beſt time; but if the weather be cloudy, the ſport may be followed all day long. There muſt be a plummet at ten inches from the hook, which the angler muſt feel always touching the ground, and this muſt be heavier the ſwifter the ſtream is. The common worm is a good bait.

The minnow is a very good bait for the *Trout*, and with this the tackle need not be ſo ſlight, for the *Trout* will make at this bait with leſs conſideration, and ſieze it as ſoon as it comes in ſight; the upper part of the line with this bait, may be of three ſilks and three hairs for the upper part, and two ſilks and two hairs for the lower; and the hook may be moderately large. The whiteſt minnows and thoſe of the middle ſize are the beſt bait for the *Trout*, and they ſhould be ſo fixed on the hook, as to turn round when they are drawn up againſt the ſtream. The beſt way of baiting this fiſh, is to put the hook in at the mouth and out at the gills, then drawing it thro' about three inches, to put it again in its mouth, and let the point and beard come out at the tail, and then to tie the hook and his tail with a fine white thread, letting the body of the minnow be almoſt ſtrait down the hook; by this means it will turn, as it is pulled againſt the ſtream; and the more and quicker it turns the better: for want of a minnow, a ſmall loach or a ſtickle-back will ſerve.

The moſt agreeable manner of fiſhing for *Trout* is, however, with the fly, when the ſportſman has found the true method of doing it; the rod in this caſe muſt be light and pliable, and the line long and fine; if one hair be ſtrong enough, as it may be made, by proper ſkill in the angler, there will be more fiſh caught, than where a thicker line is uſed; and the fly-fiſher ſhould have the wind in his back, and the ſun before him.

TRUFFLES, (*Cycl.*) *Tubera*, in botany. See the article TUBERA.

The antients, it is evident from their writings, were not acquainted with the ſort of *Truffles* which we have in uſe at preſent; they deſcribe theirs to have been of a reddiſh colour, and ſmooth on the ſurface; we at preſent know this kind very well; it is common in Italy, and is called the wild *Truffle*, and diſregarded. They had indeed the white African *Truffle*, ſometimes brought to them, and held it in vaſt eſteem for its flavour. The Romans called it the Lybian *tuber*, and the Greeks the Cyrenean *miſy*; theſe people were very little acquainted with the African affairs, and called all the things they had from that part of the world by the name of Cyrenean.

Aviſenna recommends thoſe *Truffles* as the beſt which were of a whitiſh colour within; and this not being a clear white, he expreſſes himſelf by a word which ſignifies ſand-coloured, alluding to duſky white ſand, in common uſe at that time. Pliny has ſo far miſtaken the ſenſe of the author from whom he takes his accounts, that he ſays, the Lybian *tubera* or Cyrenean miſy were more fleſhy than the others: but Theophraſtus ſays only, that they had a rich fleſh-like ſmell, by which he diſtinguiſhes them from the inſipid *Truffle* in common uſe with the Greeks at that time. The word *ramul* which the interpreters of Aviſenna have rendered ſand-coloured, may be perhaps properly *ramad*, which is aſh-coloured; and if this be the true reading, we get over a great many difficulties, among the later writers about what the tubera arenoſa or ſandy *Truffles* of the antients were.

It is certain that the fineſt *Truffles* were called by ſome authors by this epithet *arenoſa*, with a very different meaning, only expreſſing that they were produced in ſandy countries: the European *Truffles* both then were, and now are moſtly produced in dry ground on the ſides of hills; but the Lybian were produced only in the burning ſands of that country, and theſe were therefore called ſand-*Truffles*. Serapio tells us, that the beſt of all *Truffles* were thoſe produced in ſand; and Martial alludes to theſe, where he deſcribes the fineſt *Truffles* as breaking the ſurface of the earth into cracks, and by that means directing people where to ſearch for them. This paſſage of Martial has been indeed ſeverely criticiſed on by many; and our own obſervation, and the teſtimony of Pliny called in to prove the poet in an error: we do not indeed ſee the ground burſt or crack where the *Truffles* are; and Pliny tells us expreſly, that the *Truffles* of his time never broke the earth where they grew, but remained quietly under it without giving any indication of their being there. This may all be true both of the common Roman *Truffle* and of ours; but as Martial here plainly ſpeaks of the fineſt kind, that is the Lybian *Truffles*, we muſt ſee whether the African *Truffles* do or do not break the ground where they lie, before we cenſure or applaud the poet. Leo Africanus is the moſt expreſs in the account of the Lybian-*Truffle* of any author, and he ſays, that the places where they are may always be known by the earth on the ſurface being raiſed into hillocks, and breaking in numerous cracks: thus we find the poet is ſo far from being culpable in his expreſſion, that he appears to have been better acquainted with the nature of the ſubject, than the author who wrote expreſly upon it.

The *Truffle* is moſt abundantly produced in dry fields of a reddiſh loamy earth, not too poor; and they are found to flouriſh moſt near the roots of elms, the ilex, and ſome other trees. They do not well bear the ſeverity of hard winters, but are uſually ſcarce all the ſeaſon after ſuch. The ſmalleſt are found about the bigneſs of a pear, and they grow from this ſize ſometimes to a pound weight, but ſuch are not common; what are taken up in the ſpring are diſtinguiſhed by their white colour, and inſipidity to the taſte, and are commonly called white *Truffles*: thoſe taken up in autumn are of a variegated colour within, and are called marbled *Truffles*; the inner ſubſtance having ſwelled extreamly and changed colour, and the white part now remaining only in form of a number of pipes or tubules, which ſeem in many places to run to the extremity, and terminate in the chaps and wrinkles of the back. The greyiſh ſubſtance, which is wrapped up among theſe tubules, when examined by the microſcope, appears to be a tranſparent parenchyma, compoſed of little bladders or hollow veſſels, in the midſt of which may be ſeen ſmall round bodies, which are unqueſtionably the ſeeds of the *Truffle*.

When the *Truffles* are arrived at this degree of maturity, which is generally in Auguſt, they are of a fine high flavour and agreeable ſmell; and the heat and rains at this ſeaſon greatly promoting their growth, has been the occaſion of the old error, that thunder produced them; after this they continue good to the middle of winter, and ſometimes even till March; but thoſe gathered from this time till the end of July are ſmall and only white, never marbled nor of their high taſte.

If the *Truffles* are not taken up when fully ripe, they always rot and burſt; whence it is plain that they are an annual plant, which lives no longer than till they have perfected their ſeeds. And if the place where the old ones have rotted and burſt be examined, the ſeeds will be found after ſome time to have vegetated, and a great number of young *Truffles* to be produced in the place: theſe, if not deſtroyed by the froſts, are what in the enſuing ſpring furniſh the younger white *Truffles*.

The *Truffle* is very apt to be pierced and eaten within by a worm, and this tho' a damage to the particular *Truffle*, is of ſome ſervice to the people, who make it their buſineſs to ſeek for them: for this worm, after a proper time paſſed in that ſtate, changes into its chryſalis ſtate in the body of the *Truffle*; whence he ſoon after comes out, in the ſhape of a beautiful violet-coloured fly; and wherever theſe flies are found, they are an indication that there are beds of *Truffles* near, as they are never bred in any other root.

Theſe communicate a bitterneſs to the whole *Truffle*, and and make it unfit for the table; tho', if the whole be carefully ſearched into, the part eaten by the worm, and the hole by which it made its way in, will be found to be in reality the only bitter parts, and the reſt of the *Truffle*, when theſe are cut out, as good as ever: but, beſide theſe deſtroyers, the microſcope uſually diſcovers on the ſurface of the *Truffle* a multitude of other devourers, which are ſmall white animalcules, continually eating, and ſearching the cracks of the bark, as the places where the pulp is moſt eaſily come at; theſe ſomewhat reſemble mites.

The earth that produces *Truffles* rarely affords any other plants, theſe taking up all the nouriſhment it can afford: the earth all about them ſmells ſo very ſtrongly of them, that they are eaſily found out by it, by the animals which carry their noſes near the ground: and thoſe who ſought after them

ſoon

ſoon found the way of uſing hogs to ſearch them out; but theſe being a ſort of unmanageable animal, dogs were found, which would ſupply their place with more certainty, and much leſs trouble. Mem. Acad. Scien. Paris, An. 1711.

TRUFFLE-*Worms*, in natural hiſtory, a ſpecies of fly-worm which is found in *Truffles*, and lives in and feeds on them, till the time it undergoes the common metamorphoſis of theſe creatures, for the production of a fly, like that from the egg of which it was hatched.

Theſe are a great nuſance to the *Truffles*, and often wholly ſpoil them: on preſſing them in this ſtate with the finger, one may uſually perceive ſome places give way, and on opening theſe the worms are found.

They are very ſmall, and have two brown ſpots, eaſily diſtinguiſhable near their hinder end; which are the two poſterior ſtigmata. They are all over white, and very tranſparent; and one may very eaſily diſtinguiſh the two black ſtalks of their two hooks, with which they tear the ſubſtance of the *Truffle*, as the other ſpecies do their food: the anus in theſe is very viſible, and is placed near the extremity, and under the belly; the creature ſecrets from this a whitiſh viſcid matter, which is a great means of haſtening the corrupting of the *Truffle*: while in the *Truffle*, theſe worms are always ſurrounded with this viſcid matter; but when they have arrived at their full growth, which is uſually in a few days, they then leave the *Truffle*, and go to ſeek ſome proper place, where they may reſt during the time of their transformation; they enter the earth for this purpoſe, and twelve hours after they have gone into it they are transformed into an egg-ſhaped ſhell, of a cheſnut-brown, of the ſame ſort with that of the blue fleſh-fly.

This ſhell is in theſe, as in all the other inſects of the ſame claſs, made of their proper ſkin; what it has particular is, that it is ſomewhat flatted, eſpecially at the anterior end; and all the way down this flatted part, on each ſide, it is bordered by a ſort of band or filament, like that on each ſide at the anterior end of the ſhells of the common fleſh-fly worm.

The ſtigmata are placed in a line with theſe, and the anterior ones terminate them; at the middle of the anterior end, there are ſeveral folds, like a purſe when drawn together, which encompaſs the opening by which the firſt ring is drawn in at the time of the formation of this ſhell.

Theſe are the worms in a manner peculiar to the *Truffles*; but beſide theſe, they often furniſh nouriſhment to another ſpecies, very common in muſhrooms of the ordinary eatable kind, and which has a yellow body and a black cruſtaceous head. *Reaumur*'s Hiſt. Inſ. Vol. 4. p. 374.

TRUMPE, in ichthyology, a name given by ſome of the Engliſh writers, to that ſpecies of whale, called by the generality of authors *cete*, and *balæna major*.

It is, according to the new ſyſtem of Artedi, one of the catodons; and is diſtinguiſhed from the other ſpecies of that genus, by having the fiſtula ſituated in the neck: the Dutch call this the pot whale-fiſh. See the articles CATODON, and BALÆNA.

TRUMPET (*Cycl.*)—TRUMPET-*Flower*, *Bignonia*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is compoſed of only one leaf, of a tubular form, wide open at the mouth; and ſeeming as if bilabiated: from the flower-cup ariſes a piſtil, which is fixed in the manner of a nail to the hinder part of the flower; this afterwards becomes a fruit or pod, divided into two cells by a longitudinal membrane, and containing flatted and uſually alated ſeeds.

The ſpecies of *Bignonia* enumerated by Mr. Tournefort are theſe: 1. The aſh-leaved American *Bignonia*, with great ſcarlet-flowers. 2. The aſh-leaved tree-*Bignonia* of America, with yellow flowers. 3. The ſhort-podded American *Bignonia*, with tendrils to the ſtalks. 4. The long-podded American *Bignonia*, with long tendrils to the ſtalks. 5. The two-leaved climbing American *Bignonia*, with long and broad pods, and broad ſeeds. 6. The bifoliate-climbing American *Bignonia*, with ſweet-ſcented, violet-coloured flowers, and dry, oval fruit. 7. The bifoliate-climbing American *Bignonia*, with purpliſh-yellow, ſcentleſs flowers, and hard, oval fruit. 8. The tree-*Bignonia* of America, with thin box-like leaves. 9. The tree-*Bignonia* of America, with ſingle undulated-leaves, and very long and narrow pods. 10. The heart-leaved tree-*Bignonia*, of the Eaſt-Indies. 11. The long-leaved Indian tree-*Bignonia*. 12. The five-leaved Indian tree-*Bignonia*, with a roſe-coloured flower, and flat pods. 13. The ſmaller five-leaved Indian tree-*Bignonia*, with a roſe-coloured flower, and angular pods. *Tourn.* Inſt. p. 164.

TRUMPET-*Shell*, *Buccinum*, in natural hiſtory, the name of a large genus of ſhells, the characters of which are theſe; they are univalve ſhells of the form of a *Trumpet*, according to old pictures; with a wide belly, and a large, broad, and elongated mouth. They have a diſtinct and regular tail, uſually long, tho' ſometimes ſhort; they have a crooked beak, and the clavcile is often elevated, tho' ſometimes depreſſed and contabulated. See Tab. of Foſſils, Claſs 9.

The family of the *Buccina*, when examined ever ſo ſtrictly, is very large; but according to the general cuſtom of authors, of confounding together ſeveral genera under the name, it is uſually made to appear much larger than it really is. Liſter has made it comprehend a vaſt number of ſhells, by confounding with it the families of the *murex* and *purpura*.

It is not indeed peculiar to this author, to have confounded theſe genera; thoſe who went before him have done the ſame: and Pliny has compriſed the *buccinum*, *murex*, and *purpura*, under the general name *ceryx*.

To avoid the general confuſion, which ariſes from not diſtinguiſhing the families of the *buccinum*, *murex*, *purpura*, and *vis*, or ſcrew-ſhell, it will be proper to obſerve, that there are regular characters, which diſtinguiſh them all, one from another: the characters are theſe:

The *buccinum* differs from the *purpura*, in that it has a very long mouth of an oval figure, and has an elevated head; whereas the *purpura* has a round mouth, and a head ſomewhat flatted. The tail of the *purpura* is alſo uſually furrowed, and is ſhorter than that of the *buccinums*.

The *buccinum* differs alſo from the *murex* in having a longer tail, by the ſmoothneſs and variety of colours of its coat, and by having a larger mouth leſs furniſhed with teeth; the *murex* having a ſmaller and longer-ſhaped mouth, its ſurface covered with points or ſpires, and ſeveral teeth.

It is eaſier to diſtinguiſh the *Buccinum* from the ſcrew-ſhell, as this is always more long and ſlender than the *buccinum*; it has alſo a flat mouth, and has rarely any tail. Theſe are all very large families in nature, and it is highly neceſſary for the naturaliſts to be well acquainted with them.

The moſt ſingular ſpecies of the *buccinum* claſs, is one that has its mouth turned the contrary way to all other ſhells: this has been thence called by authors, the *unique* and the *ſans pareille*. Aldrovand is of opinion, that the *buccina* may be ranked among the bivalve ſhells; becauſe they have an operculum, or ſhelly ſubſtance, fixed to the end of their body, which occaſionally ſtops up the aperture of the mouth; but if this were a ſufficient reaſon we ſhould have many more genera to add to the bivalves, particularly the ſnails of ſeveral kinds.

The *buccina* generate in the warm months, and ſome ſpecies of them are ſeen very frequently remaining in pairs together, upon the rocks deſerted by the tide on that occaſion. Theſe have been thence ſuppoſed to be of a different genus, and have been called *buccina littoralia*; they are uſually found in copulation early in the morning. *Rumphius*, de Teſt. *Aldrovand.* de Teſt. l. 3. c. 231. *Liſter*, Hiſt. Animal. Angl. p. 158.

The ſpecies of the *buccina* being very numerous, they are arranged under ſeveral diſtinct heads, according to certain obvious diſtinctions; and are as follow: 1. Of the *buccina* with long diſtinct tails and oblong mouths, there are theſe ſpecies. 1. The great browniſh white, contubulated, and tuberous *buccinum*. 2. The ſmall brown furrowed *buccinum*. 3. The *buccinum* with double and dentated lips. 4. The *buccinum* called the tower of Babel. 5. The red-ſpotted *buccinum*. 6. The Perſian *buccinum*. 7. The radiated *buccinum*, with broad, blackiſh-red ſpots. 8. The *buccinum* faſciated and undulated on each ſide, with a dentated columella. 9. The thick *buccinum*, with oblong and ſpotted tubercles. 10. The ſtriated and bottle *buccinum*. It is to be obſerved that when the laſt ſpecies but one is poliſhed, the loſs of its outer coat gives it a very different appearance; and it is found in many of the cabinets of the curious, variegated with blue and whitiſh-brown ſpots. 11. The *buccinum*, with a contabulated and pulvinated clavicle. 12. The ſtriated *buccinum*, with three tuberous eminences. 13. The coſtated and ſtriated *buccinum*.

Of the *buccina* with a ſhort tail and a wide mouth, we have the following known ſpecimens: 1. The hairy *buccinum* of Rumphius. 2. The thick *buccinum* called Midas's ear, with a dentated columella: this when poliſhed aſſumes a very different appearance, and is found in many cabinets under the name of the agate *buccinum*, as it carries a great reſemblance of that ſtone. 3. The grey wide mouth *buccinum*: this alſo when poliſhed aſſumes a very different appearance, and is ſpotted and lineated in an elegant manner; tho' wholly plain while it has its outer coat. 4. The undulated and ſtriated *buccinum*. 5. The *buccinum* covered with pointed tubercles placed in regular order. 6. The depreſſed umbilicated *buccinum*, with the lip and columella both dentated. 7. The yellow umbilicated *buccinum*. 8. The *ſans pareil*, or *buccinum* with the mouth opening the contrary way to all the other. 9. The alated and punctuated *buccinum*. 10. The tuberous *buccinum*, with two high ribs. 11. The rough furrowed *buccinum*, with a thick lip and an oval mouth. 12. The hermit *buccinum*: this uſually has the hermit-fiſh, a kind of ſmall crab in it, and has its clavicle full of ſmall balani.

Of the *buccina* which have long and erect clavicles, theſe are the following known ſpecies: 1. The Chineſe town ſhell, with a dentated columella. 2. The *buccinum* ſurrounded with red and white faſciæ. 3. The *buccinum* called tiara or papal crown, with the columella and lip dentated. 4. The mitre or plume *buccinum*. 5. The yellowiſh *buccinum*, with a dentated columella. 6. The *buccinum* with zones of brown and yellow. 7. The great triton *buccinum*. 8. The wide mouthed

mouthed *buccinum*. 9. The ſtriated *buccinum* with prickly ribs. 10. The reticulated *buccinum*, with oblong tubercles. 11. The red-mouthed ſpotted *buccinum*, with an irregularly ſtriated clavicle.

Of thoſe *buccina* which have leſs erect clavicles and crooked roſtra, there are the following known ſpecies: 1. The rough *buccinum*, called the Swiſs-ſhell. 2. The diſtortion or grimace ſhell, with a ſtriated lip and columella. 3. The *buccinum* with its lip elevated above the reſt of the ſurface. 4. The ſmooth-lipped *buccinum*. 5. The ſmoother bodied *buccinum*: theſe are all of the grimace kind. 6. The rough *buccinum*, with elevated tubes or pipes. 7. The tuberous *buccinum*, with a dentated wide mouth, and a long crooked and furrowed roſtrum. 8. The yellowiſh tuberous ſtriated *buccinum*, with a depreſſed clavicle, and with furrowed lips and columella. 9. The yellow *buccinum*, with an erect clavicle and a red mouth. 10. The ſtriated *buccinum*, with oblong tubercles. 11. The ſtriated gold-yellow *buccinum*. 12. The *buccinum* with brown, yellow, and white ſtriæ. Hiſt. Nat. Eclair. p. 263.

It appears from the writings of the antients, that the famous purple dye, which they obtained from a ſhell-fiſh was not peculiar to any one ſpecies; but was found in ſeveral of the ſmaller kinds of *buccina*; ſome of which they called *murices*, from the hollow ſpines, or long and ſlender proceſſes, which run in different directions from their ſhells.

Mr. Reaumur when on the coaſts of Poitou, found certain eggs of fiſhes, arranged in regular order, and in great numbers, on the rocks and ſalted banks, which had the ſame property with the purple-dying liquor of the *buccinum*; and which, as it is not yet known to what particular fiſh they belong, or what uſes they may hereafter be brought to ſerve, it may be proper to deſcribe here.

Each egg is of an elliptic ſpheroidal figure, the ſmalleſt part of which is about a twelfth of an inch in diameter, and the largeſt about one fifth, and it is attached to the rock or ſand by a pedicle reſembling that of a fruit; this is about a twelfth of an inch long, and a fourth part of its length in diameter. The egg itſelf is hollow, and is filled with the ſtaining liquor; its ſurface is only a membrane in the nature of parchment: at the end, oppoſite to that where the pedicle is fixed, there is a hole or aperture, reſembling the mouth of a glaſs-bottle; but that the liquor may not run out at this, it is ſtopped with a tranſparent ſubſtance, which ſerves as a cork to it; this however is placed exactly in a contrary direction to the corks of our bottles; for the larger end is on the inſide, ſo that all the force the included liquor can have on it, can be only to ſtop up the mouth the more firmly: beſide this alſo, it is cemented down all round by a ſort of glue. This egg contains two liquors, the one white and the other yellow; as the common eggs have their yolk and white: but the yellow liquor in this, is not collected all into one body; but ſwims about freely in the white in eight diſtinct drops. The glutinous liquor by which the pedicles of theſe eggs are faſtened to the ſtone or ſand, is of ſuch force, that it is not eaſy to pull them off without breaking the eggs; but by help of the thin blade of a knife, they may be taken off without injury. As there are always a great number of the *buccinas* of the ſmaller kinds, about the places where theſe eggs are found, Mr. Reaumur was led to believe that they were the eggs of this fiſh; in favour of which ſuppoſition, the colour they afford in common with that fiſh, is alſo no ſmall argument; what made this opinion appear leſs probable to him, was the largeneſs of theſe eggs in proportion to thoſe animals; but we are ſo well aſſured of the largeneſs of many ſhell-fiſhes eggs, in proportion to their own ſize, that this ſeems but a weak argument againſt ſo probable an opinion. Mem. Acad. Par. 1711.

Pliny ſeems to derive the name *buccinum* from *buccina*, a kind of muſical inſtrument[a]; but it is more probable that inſtrument took its name from the ſhell to which it bore a reſemblance, and of which it might probably have been antiently made[b].—[a *Plin.* Hiſt. Nat. l. 9. c. 36. b Phil. Tranſ. N°. 282. p. 1277.]

Buccina are of ſome uſe in phyſic; when calcined they have a drying cauſtic quality. *Liſter*, Ap. Phil. Tranſ. N°. 197. p. 645. See Tab. of Shells, N°. 9. and Tab. of Foſſils, Claſs 9.

Buccinum lapidoſum is a figured ſtone, ſhaped like the former, and probably only a petrifaction of the ſhell above-mentioned. *Mercat.* Metalloth. Arm. 9. loc. 36. c. 33. p. 301.

Ray ſpeaks of a *buccinum* which not only petrified, but after petrifaction was converted into a pyrites. *Ray*, Phil. Lett. p. 202. See PYRITES, *Cycl.* and *Suppl.*

TRUMPETER, (*Cycl.*) in zoology, a name given in England, to a particular ſpecies of pigeon, called by Moore the *columba tibicen*.

This ſpecies is of the middle ſize of the common pigeon, and made conſiderably like it; but it is pearly-eyed; is of a mottled black, and is feathered down the legs and feet, and is turn-crowned like the nun, and ſome of the other ſpecies; ſometimes like the finnikin, but much larger: this ſeems to be the beſt ſort as being the moſt melodious. The beſt character to know them by, is a tuft of feathers growing at the root of the beak; and the larger this tuft is, the more they are eſteemed. The reaſon of their name is, that they imitate in their cooing the ſound of the trumpet; but to be often entertained with their melody, it is neceſſary to feed them frequently with hemp-ſeed. *Moore*'s Columbarium, p. 45.

TRUMPETER, in a man of war, one whoſe office is always to attend the captain's command, and be ready at the entertainment of ſtrangers. In the time of an engagement his proper ſtation is on the poop.

TRUNGIBIN, in natural hiſtory, a name given by Rawwolf, Tournefort, and others; to a ſort of manna collected from the *alhagi maurorum*, as the common manna is from the aſh; and uſed in the eaſtern parts of the world as a purge. It is what we call the *manna perſicum*, and tho' in itſelf a very fine and clean kind of manna, yet it is uſually ſo careleſly collected, and mixed with ſo much filth, that it requires to be given in three times the doſe of ours, in order to purge. The name ſeems very evidently to be a corruption of the *tereniabin* or *teren-jabin* of the Arabians, which was the word uſed by all their authors to expreſs the *manna perſicum*.

TRUNCATED *Leaf*, among botaniſts. See the article LEAF.

TRUNK, (*Cycl.*) in natural hiſtory, a pointed, hollow, ſlender, and oblong body; joined to the fore-part of the heads of many inſects, and ſerving them for ſucking the blood or juices of the animals or vegetables, on which they feed.

The *Trunks* of flies ſerve for diſtinguiſhing many genera of thoſe little animals, from their different form and other accidents. Some of theſe are a tube formed all of one ſimple piece, and others compoſed of ſeveral ſhorter pieces, nicely joined together: ſome are thin and as it were ſhelly, others thick and fleſhy; thoſe of ſome flies are terminated by a ſort of broad foot, or by a ſort of thick lips; and thoſe of others have no lips, or at leaſt no ſenſible ones; and others are made in form of a ſpindle hollowed at the end.

It is often neceſſary to have recourſe to the microſcope, to diſtinguiſh with nicety and exactneſs between theſe; and how indeed is it poſſible to do any thing without the help of glaſſes, in the diſtinctions of the parts of animals, the whole bodies of which are ſo very minute.

Without the aſſiſtance of glaſſes, however, it is eaſy to diſtinguiſh among the flies of different genera, three different manners of carrying this organ when in a ſtate of inaction. Many flies have *Trunks* which they can ſhorten, when they are not uſing them; theſe are fixed in the fore-part of the creature's head, where there is a cavity deſtined to receive them when they are not in uſe. In many ſpecies, this cavity is no more than a mere ſinus or hole, in the fore-part of the head; but in others it is more nicely contrived, the anterior part of the head lengthening itſelf, and forming a kind of arched vault for its reception. Other flies have *Trunks*, which in the time of inaction are turned, or ſomewhat folded from above downwards; the *Trunks* of bees are of this kind. Ibid.

There are others alſo, which have their *Trunks* contained entirely in a ſort of caſe, where they lie ſtrait at length, without being either turned or folded; but they are able to encline them in any direction, in regard to the poſition of their legs: of this kind are the *Trunks* of the cicadæ, gnats, &c.

Among the butterfly claſs, a great number are furniſhed with a *Trunk*; but there are alſo a great number that have it not: the fly of the ſilk-worm, and many, as well larger as ſmaller kinds, are without this, (as it ſeems neceſſary) organ, by which they ſuck the juices from flowers; and which is the only way of their taking in nouriſhment. Thoſe ſpecies which have it, ſhew it to the firſt view; it is placed in the middle of the head directly between the two eyes. And tho' in ſeveral ſpecies it is very long, yet it takes up even in theſe but very little room; when it is not in uſe, it is always rolled up in a ſpiral form, in the manner of the ſpring of a watch; and even the ſhorteſt of them are thus turned as well as the longeſt. Some of them make only one or two turns of this kind, others of a middling length make four; and finally the longeſt of all frequently make eight turns. In the rolled ſtate, we can ſee only a ſmall part of one of the outer turns of the ſpiral; the origin and extremity, with a great part of the intermediate ſpires, being hid under a remarkable ſort of hood or mitre; which is formed of two hairy bodies, following the contour of the eyes, and ariſing from their under-part in form of pieces of the ſkin of ſome animal, with the hair upon it. Theſe are moveable at the pleaſure of the animal, and ſeem intended by nature only as a caſe, for the defence of this tender and neceſſary organ to the creature. *Reaumur*, Hiſt. Inſ. vol. 1. P. 1. p. 287.

This is the caſe in moſt of the ſpecies, but in ſome others the office of theſe hairy bodies is ſupplied by two rounded and very prominent parts, which in the ſame manner follow the contour of the lower part of the eyes, and fill up a great part of the front of the head; leaving only a ſort of channel or furrow between them as a place for the *Trunk*. Theſe parts the French naturaliſts call the beards of the butterflies, and in ſome ſpecies they are of a very ſingular figure; extremely different from thoſe which have been here deſcribed. If one is deſirous to know in what manner this *Trunk* is uſed, he need only follow a butterfly to a flower, and there obſerve its motions. As ſoon as it is ſettled on the verge, it unrols

roſs this *Trunk*, and extends it into a perfectly ſtrait piece; it then directs it into the flower, and thruſts its extremity to the very bottom, where it is affixed to the cup; this is the caſe, however deep the flower be. When it has been a few minutes in the flower, it draws it out and rolls it up; and after a few moments, it extends and plunges it into the flower again: this it repeats four or five times, and then flies away to another flower. This is the thing that has occaſioned the poets to make the butterfly the emblem of inconſtancy, in its flying immediately from one flower to another; but the truth is, that the flower it leaves is no longer capable of affording it the nouriſhment it wants.

There are among the butterflies, ſome which never ſettle upon any thing, but are eternally upon the wing in the manner of ſwallows: theſe feed on the wing as thoſe birds do. We often ſee them buzzing about a flower in the manner of a bee, and in that caſe they ſuſtain themſelves in the air with their wings, while they unrol their *Trunk*, and thruſt its extremity into the flower, to ſuck from its bottom the honey-dew, which is the common food of them, of the bees, and of many other inſects.

The *Trunk* of the butterfly is a flat body, being broader than it is thick, and is formed of a matter ſomewhat reſembling horn; if the head of the creature be ſqueezed, it becomes neceſſitated to unrol the *Trunk*, and may thus at any time be made to ſhew it at its length. Its origin is juſt in that part of its face, where the noſe in other animals takes its origin; and hence ſome authors who have obſerved it when unrolled, have called thoſe butterflies which are poſſeſſed of it the long-noſed ones; but this is very improper, as it aſſuredly ſupplies the place of a mouth. It is always largeſt at the inſertion, and thence gradually decreaſes to a point at the other end.

The *Trunk* of the butterfly may alſo be unrolled, by getting the point of a pin between the circles at the center, and then drawing it gently from the head, the *Trunk* will by this means be drawn out to its full length; and if we tieze the creature a little, by gently preſſing any part of it, it immediately opens a crack, in the middle of which it runs up by degrees to the origin or baſe, and ſplits it in a manner into two.

It has been much diſputed, among the curious obſervers of nature; whether the *Trunk* be originally compoſed of two parts, or two *Trunks* laid cloſe to one another; or whether it were owing to its tender ſtructure, that it was eaſily ſplit by breaking its parts.

Mr. Bonani was of the firſt opinion, and Mr. Riget agreed with him at firſt, but he afterwards became of the contrary ſentiment; and thought that they really broke in this ſplitting, being originally only one: but Reaumur has determined the queſtion in favour of Bonani; having, by repeated obſervations, found them compoſed of two parallel *Trunks*, nicely and evenly laid ſidewiſe together. This indefatigable ſearcher after truth, examined the *Trunk* in the butterfly, while yet in its cryſalis, and when juſt iſſuing from it: he obſerves that, in the firſt caſe, the *Trunk* is not rolled up, but is laid evenly lengthwiſe along the body, and in this ſtate it is eaſily ſeen to be made up of two parallel *Trunks*; but in the ſucceeding ſtate, of juſt hatching from the cryſalis, one may ſee that it is compoſed of two: for one of the firſt efforts of the creature, is to roll this organ up into its ſpiral form, and in doing this, the two pieces often gape ſo wide aſunder, and are rolled up ſo irregularly, that it is ſcarce to be conceived how the animal will be able to lay them even afterwards. This however is done by ſeveral times rolling and unrolling it; they join firſt regularly at the baſe, and then by degrees all the way along to the point. It ſometimes happens that there are difficulties in this, and the parts become folded, wrinkled, or otherwiſe injured in their figure; and if all this be not ſet right in a few minutes, by the action of rolling and extending it; it never is done afterwards, but the organ dries in that form, and the creature loſes the whole uſe of it, and is doomed ſoon to periſh by hunger. Mr. Ray mentions a butterfly with a double *Trunk*; but Mr. Reaumur never having been able to find any ſuch, it is very probable, that as Mr. Ray was unacquainted with this ſtructure of the *Trunks* of all theſe creatures, he only found one whoſe *Trunk* had never cloſed. *Reaumur*, Hiſt. Inſ. vol. 1. P. 1. p. 293.

The union of the two parts, of which the *Trunk* in theſe creatures is formed, is too ſtreight to be owing merely to their contact; were they no better joined, they would frequently open and ſeparate, in the frequent rolling and unrolling of the whole, for the taking in of food. It is evident, on the contrary, that they are faſtened together by a nice joining, and a very viſcous fluid.

There are among the *Trunks* of butterflies, only two ſuch eſſential differences, as to deſerve a general diſtinction; the one kind of theſe are longer, flatter, and rolled up into more ſpirals; the others are ſhorter, thicker, and make fewer turns. The firſt reſemble a ſort of thin blades, the others reſemble a cord; ſome of the flat ones are two or three inches long, and thick in proportion: theſe are the propereſt for a microſcopic obſervation, in order to know their true ſtructure; and when examined in this manner, they are found to be formed in an elegant manner, and made up of fibres, which divide themſelves into a number of rings, and reſemble the annular ſtructure of the *aſpera arteria* in large annimals. Some of the *Trunks* of theſe animals are bright and gloſſy, both on the under and upper ſide; and ſome of them have a number of ſmall flat bodies iſſuing from them which are uſually placed at the extremity, tho' ſometimes at a diſtance from it; theſe have been ſuppoſed by ſome, to be a ſort of fingers, whoſe uſe was to collect together the nouriſhment fit to be received into the *Trunk*; and others have ſuppoſed them the organs of ſuction: but they appear rather to be only intended by nature, as ſupports to the end of the *Trunk* while employed in ſucking, as they have no organization proper for anſwering either of the other purpoſes aſſigned to them, and as they are obſerved only in the more weak and tender *Trunks*, the ſtrong and thick ones having none of them. The two bodies which form the *Trunk* of the butterfly, have each of them a hollow running all the way along them, or are each of them properly a ſeparate canal, capable of receiving a fluid and conveying it up into the body of the animal. *Reaumur*, Hiſt. Inſ. vol. 1. P. 1. p. 301.

Mr. Reaumur found out their ſtructure with great eaſe, by moiſtening or ſoaking them in water after the creature was dead: after this treatment they became much more manageable and pliant than before, and could be rolled and unrolled at pleaſure, and cut tranſverſely or in any other direction. The matter of which theſe *Trunks* are formed ſeems more of the nature of whalebone, than of any other known ſubſtance; and, like that, if thus ſuppled by ſoaking in water, they are in ſome degree tranſparent, from the thinneſs of their ſides; and when they have been long enough in water, if they are preſſed with the finger, there may be ſeen a ſeparate column of water moving about in each. And as this obſervation is moſt eaſily made on ſuch *Trunks* as have been cut off tranſverſely from the head, theſe receiving the water the moſt readily, the whole may in theſe be at pleaſure preſſed out at the ends where they are cut; and the joining of the two canals, or parts of the *Trunk*, along the middle, is more like that of the feathered part of a bird's plume, than any other combination in the parts of the animal world; and the joining of the two parts is ſo nice, that there is another or third canal formed by it, which is nearly as cloſe at the ſides as the other two: this may ſerve the creature for the conveying its food as well as the other two, but it appears more probable that its office is to convey the air for the creature's reſpiration, and that the *Trunk* in this manner ſerves in the office both of a mouth and a noſe.

The other kind of *Trunks* of the butterfly claſs, are the ſhort and thick ones; theſe are not flat, but rounded like a cord; they are very robuſt and ſtrong, and they terminate in a ſharp point, which in ſome ſpecies is capable of wounding the finger if preſſed againſt it: in all, however, it is capable of wounding and making its way into the tender ſubſtance of the leaf of a flower. The manner of the creature's getting its nouriſhment is this: it plunges the end of the *Trunk* into the ſubſtance of the flower, by means of the hole made by this ſharp end, ſo far, that its apertures are in the place where the juices extravaſate themſelves, from the wound the point has made; the point itſelf being often on the other ſide, having pierced quite through. When it has thus drained away all the juice it can, it flies to another flower, and acts in the ſame manner. There is a ſpecies of butterfly, remarkable for having a ſort of a figure of a death's head on its breaſt; this ſpecies has a thick *Trunk* of this kind, ſo very ſharp at the point, that it is capable of wounding the hand.

The action of the *Trunk* in ſucking is eaſily ſeen on giving a piece of ſugar to a butterfly, that has been kept without food for ſome days, after its being produced out of the cryſalis; many of the ſpecies will in this caſe feed on the ſugar in the ſame manner that they would on the juices of flowers, and will ſhew that the uſe of their rolling up their *Trunk* at times, is the ſwallowing what they have received into it. The *Trunks* of the ſeveral ſpecies of butterflies are as different in colour as in ſhape; ſome are black, others reddiſh, many of a cheſnut colour; ſome are alſo of a pale brown, and ſome of a beautiful yellow; many of them alſo are hairy on the under ſide, and many are ſmooth. The thicker *Trunks* are always ſhorter than the flat ones, and have only one canal. *Reaumur*, Hiſt. Inſ. Vol. 1. P. 1. p. 309.

TRUNKS *of Gnats*, the inſtrument by means of which, the gnat ſtrikes the fleſh, and ſucks the blood from animal bodies.

This is a machine well worth an attentive obſervation. As fine and ſmall as this inſtrument appears, it is nevertheleſs of a very complex ſtructure. The piercer, or more properly piercers of this inſtrument, are all entirely hid in the ſheath which makes what we call the *Trunk*; and is the only part we naturally have offered to our view. *Reaumur*, Hiſt. Inſ. Vol. 4. p. 580. ſeq.

This *Trunk* appears to be cylindric, in the greateſt part of its length; and is covered with ſcales, not unlike thoſe on the nerves of the wings of the creature; and reſembling ſmall leaves. Near its end, it has a little ſwelling, where there is an oblong button, broader at its inſertion than at its point: the end of this button is furniſhed with an aperture, out of which the creature occaſionally thruſts a fine point. Many naturaliſts have obſerved this point; Swammerdam conſidered

it as a ſingle pointed body, formed to pierce the ſkin; but Lewenhoek diſcovered that it was made up of a vaſt number of pointed bodies. There is no occaſion, however, for all the accuracy of obſervation of Swammerdam, nor all the power of the magnifying glaſſes of Lewenhoek, to diſcover that this is a complex body; a common ſmall magnifying-glaſs, and a careful examination, will at any time diſcover it.

If a gnat be held by the corcelet between the fingers, and a little ſqueezed, the ſheath or caſe of the *Trunk* will be frequently ſeen to open itſelf lengthways on each ſide, ſometimes only a little way, and at others almoſt along its whole length; and a fine gloſſy reddiſh filament ſhews itſelf at the opening of this caſe. This filament is bent and turned inwards, and one very ſoon diſtinguiſhes that it is indeed a congeries of a great number of filaments: theſe one may eaſily ſeparate, in ſome meaſure, from one another, by means of any pointed inſtrument; and very often the filament ſeparates of itſelf into ſeveral in the bending. It is plain, therefore, that the inſtrument deſtined to pierce the ſkin, and ſuck the blood, is of a complex ſtructure; that what we might naturally take for this inſtrument, is only its caſe or ſheath, and that this caſe, inſtead of a plain cylindric body, is really a compoſition of two ſemi-cylindric ones, which have the power of ſeparating from one another for the animal's occaſions.

The beſt way to get a regular ſight of the *Trunk* of this creature, and of its manner of uſing it, is to ſuffer a gnat to ſettle upon the hand, and not diſturb him in the operation; but with a magnifying glaſs in the other hand, to obſerve all his motions. In this caſe, we may firſt ſee a ſmall and ſlender point thruſt out at the end of the caſe, and try ſeveral different parts of the ſkin with this ſharp inſtrument; when it has done this, it chooſes that part which is moſt eaſily pierced; and where there lies a veſſel underneath, capable of furniſhing as much blood as he will have occaſion to ſuck.

As ſoon as he has made his choice, the wound is immediately given; and ſince the point of the compound piercer cannot be protruded ſo far out of the caſe as it is neceſſary it ſhould to ſtrike to a proper depth, the uſe of the ſlit in this caſe is ſeen; for while the button at the end of this remains firmly applied to the orifice of the wound, where the piercer is introduced, and ſupports that delicate and feeble inſtrument from bending, the caſe opens at the ſlit, and its two ſides bend to give room to the piercer to penetrate; and at length, when the piercer is ſunk to its utmoſt depth, the two extremities of each piece touch, and the ſides are brought cloſe together.

Sometimes alſo one may obſerve in peculiar ſpecies of the gnat kind, when they are about to ſtrike the fleſh, a more complex ſtructure of this ſheath; for one may ſee, inſtead of the two antennæ which all the gnats have, an appearance of four, while the creature is in the act of ſucking. It will be eaſy for any one to gueſs, that the ſecond pair of theſe, which do not appear at any time, except when the creature is thus employed, are not true antennæ; and on a nice examination, they appear indeed to be no other than parts of the caſe of the piercers, which, as ſoon as the gnat of this ſpecies ſtrikes the ſkin, are ſeparated from the upper part of the caſe, and are two ſlender oblong bodies, of the ſame length with the caſe, except that part of it which we call the button. Theſe two pieces of the caſes at this time ſtand always in a parallel direction with the true antennæ, and are very nearly of their length. Each of theſe, examined in this ſtate, has the appearance of a regular cylinder, but, probably, in its ſtate of reſt, is hollowed, and of a proper ſhape, to encloſe and ſurround a part of the ſurface of the caſe; and this muſt of neceſſity be their real ſhape, ſince when the *Trunk* is in a ſtate of reſt, they are no other way diſtinguiſhable on it, than by the making it a little thicker; whereas, were they really cylindric bodies, as they appear in the ſtate of action of the *Trunk*, they muſt, when it was at reſt, be ſeen in form of two prominent lines on its ſurface.

The ſeveral ſpecies of gnats have great variety in their *Trunks*; and in the obſerving many kinds, the true ſtructure of that organ in all will be moſt regularly and eaſily found. Some have the caſe of the piercers only one ſingle tube ſplit lengthwiſe along its upper part; others have this ſlit made by the junction of two caſes, which cover cloſely a great part of its circumference; and others have the two tubes ſo well adjuſted, and nicely fitted to one another, that a good glaſs cannot diſcover them from the reſt of the *Trunk*, when in a ſtate of reſt; but in others this ſtructure is eaſily diſcoverable, as the extremity of one of them, when beſt fixed, is ſtill to be diſcovered ſomewhat ſeparated from the *Trunk*, and adorned with a pencil of ſmall hairs, like thoſe of the antennæ. The male gnats, which have their antennæ feathered, are thoſe which have the plumes at the extremities of theſe additional pieces of the caſe of the *Trunk*; and theſe have not the beards which are found ſituated over the *Trunks* of the other ſpecies of gnats.

There is, beſide all theſe, one ſpecies of gnat whoſe piercer has no need of the button at the end of the caſe, common to all the reſt, to ſupport it while it enters the fleſh. This has a caſe on which it reſts itſelf as on a ſeventh leg, from which it darts a piercer, which, without any ſupport, is of ſufficient ſtrength to penetrate the fleſh, and do its office for the animal. This ſpecies of gnat has two very long beards placed above its *Trunk*, and terminated by an end, covered with white ſcales; what remains of theſe beards is covered with brown ſcales, and the body of the gnat is brown, and the corcelet reddiſh.

Tho' it is eaſy to find that the *Trunk* of a gnat is compoſed of ſeveral pieces, yet it is by no means eaſy to ſay what the number of them is. The beſt microſcopes often ſhew the whole a ſingle body, its ſeveral parts are ſo extremely well joined; and when they have been found to be more than one, it is very difficult yet to ſay how many they are. Lewenhoek imagined them to be four in number; and Swammerdam, who had firſt believed the whole a ſingle filament, afterwards thought he diſcovered ſix pieces going to its compoſition.

After ſeparating the piercer of the gnat wholly from its ſheath, if it be cut tranſverſely near its baſe or inſertion in the head, and the ſection laid upon the plate of a microſcope, and there touched with an extremely fine pointed inſtrument, it may be divided into four, and ſometimes into five ſeparate pieces. Two of theſe may often be ſeen to come out of a third, as out of a canal or tube: the ſeeming neceſſity of a tube in this inſtrument, for the ſucking the blood, has made many ready to perſuade themſelves that they have ſeen one: but if we follow the analogy of nature in her other works, we ſhall find there is no abſolute neceſſity for ſuch an organization in this part; ſince, in the gad-fly, the ſeveral pieces of which the piercer is compoſed are of themſelves able to form a tube for the paſſage of the blood.

The figures of the ſeveral conſtituent parts of this inſtrument are as difficult to be determined as their number; thus much is certain, however, that the points of all the pieces are by no means alike, for ſome are much longer than others.

Out of the immenſe number of gnats that one ſees in ſummer, in wet places, it is eaſy to determine that very few have any chance, even once in their lives, to ſuck the blood of larger animals. The reſt, however, are far from being doom'd to perpetual famine; the herbs of the field afford them a ſufficient nouriſhment; for theſe, like many other of the inſect tribes, are partly carnivorous, partly otherwiſe, and feed equally on fleſh and vegetables. *Reaumur*, Hiſt. Inſect. vol. 4. p. 580. ſeq.

TRUNK-*Manna*. See the article MANNA.

TRUNSCHIBIL, a word uſed by Tournefort, to expreſs the manna Perſicum, called alſo by ſome *Trungibin*; both evidently corruptions of the terenjabin of the Arabians. See the article TRUNGIBIN.

TRUSSED, in the manege. A horſe is ſaid to be *well truſſed*, in French *bien gigoté*, when his thighs are large and proportioned to the roundneſs of the croupe. On the contrary, a horſe with thin thighs, that bear no proportion to the breadth of the croupe, is ſaid to be *ill truſſed*.

TRUTTACEOUS, in zoology, the name of a genus of fiſhes of the trout kind, which are diſtinguiſhed from all other fiſhes by a ſmall fat fin, which they all have near the extremity of the back, and which has no rays or nerves. Of the fiſh of this genus, ſome live only in freſh waters, never entring the ſea or ſalt rivers: others frequent both the freſh and ſalt waters, and are therefore called *anadromi* or *catanadromi*. Theſe leave the freſh waters while young, and go into the ſalt waters to feed and grow, and again return into the freſh rivers at the time of their full growth and ſpawning, that their offſpring may have the ſame advantages themſelves have had, of being hatched into life in freſh water.

The *truttaceous* fiſhes are divided into two orders, thoſe which have, and thoſe which have not teeth. Of the edentulous kind, or ſuch as have no teeth, are the lavaretus, ferra, thymallus, oxyrynchus, and albula; and of the toothed kind, are the ſalmo, umbra, trutta, carpio, *&c.* In diſſection, the *truttaceous* fiſhes have all apophyſes to the pylorus, and are all a high-taſted and fine ſet of fiſh for the table. *Ray*'s Ichthyography, p. 182.

TRY (*Cycl.*)—TRY, at ſea. A ſhip is ſaid to *try*, when ſhe has no ſails but her main-ſail aboard; when her tacks are cloſe aboard, the bowlings ſet up, and the ſheets haled cloſe aft; when alſo the helm is tied cloſe down to the board, and ſo ſhe is let lie in the ſea. And ſometimes when it blows ſo hard that they cannot maintain the main-ſail, as they ſay, that is, cannot bear it out, they make her lie a *Try* under a miſſen-ſail only.

TRYBLION, a word uſed by the old medical writers, to expreſs the pot or diſh in which the medicines uſed in fumigations were placed at the time of uſe.

TRYCHNUS, in botany, the ſame as *Strychnus*, the name of the nightſhade. The Greeks called it τρυχνος, and the Latins, as well as themſelves, often left out the initial σ, as they do in many other words; thus they write *milax* for *ſmilax*, *maragdus* for *ſmaragdus*, *&c.*

Pliny uſes the word *Trychnos* as the proper name of the plant; and Dioſcorides, willing to diſtinguiſh the mad nightſhade from the ſleepy nightſhade, which are the two poiſonous kinds, ſo called from their different effects, calls the one *Trychnos* and the other *Strychnos*. But this is a trivial difference in the name, and would never be eſteemed any difference

ference by thoſe who know the Greek language, in which this is familiarly done without any intent of diſtinguiſhing.

Theocritus mentions the plant *Trychnus*; but he is to be underſtood of a third kind, differing from both theſe poiſonous ones, and bearing an eſculent fruit. This was the plant we now call *lycoperſicon*, or *pomum amoris*. The writings of Theophraſtus warrant the poet in calling this plant, as well as the others, by the common name *ſtrychnus*, or *Trychnus*; for he expreſsly ſays, there are three kinds of *Trychnus*, one which cauſes ſleep, another which cauſes madneſs, both poiſonous, and a third, which is eſculent.

The *poma amoris* are at this time eaten by the Jews with us, and by ourſelves in ſoups, and the like. The Italians, Spaniards, and Portugueſe, all eat them, and eſteem them a very delicate diſh. The later Greek writers have left off the uſe of the word *ſtrychnus*, and uſe the term *melintzanion* for this plant. See the article MELINTZANIUM.

TRYGUM, in ichthyology, the Greek name given by Elian, Athenæus, and Appian, to the fiſh which we call the *paſtinacha marina*, or fire-flaire. Ariſtotle and ſome others write it *tragum*. The fiſh is a ſpecies of the ray, and is accurately diſtinguiſhed by Artedi by the name of the ſmooth-bodied ray, with no fin on the tail, and with a long ſpine ſerrated on the anterior parts. See the article RAJA.

TRYING, in pharmacy, the purifying fat ſubſtances, by means of melting, and ſeparating them from their membranes, *&c.* In the college diſpenſatory, the method laid down for the purifying lard, ſuet, *&c.* is this: Melt them at a gentle fire, with the addition of a little water intermixed, and, when melted, ſtrain them from the membranes. The addition of water in this keeps the fat from burning and becoming black, which it would otherwiſe do; for the water, not being capable of receiving any greater degree of heat than that of boiling, will keep the bottom of the veſſel from growing too hot, much better than the niceſt management of the fire could do. *Pemberton*'s Lond. Diſp. p. 146.

TSAPHARI, in the materia medica of the antients, a name given by ſome to the cadmia, called by Dioſcorides, *placitis*, and by others of the Greek writers, *zonitis* and *onychitis*. It was a flat kind, forming a ſort of coat or cruſt on the walls or ſides of the furnace: hence it had the name *placitis* or *cruſtaceous*; and it was called *onychitis* and *zonitis*, becauſe, when broken tranſverſely, it appeared made up of ſeveral ſucceſſive plates, which had the appearance of ſo many belts or zones. Serapio tells us that this and the botryoide cadmia were dug out of the mines; that is, that they were natural productions; but this is erroneous, and contrary to all the accounts of the antients.

TSHINKA, in the materia medica, a name by which ſome authors have called the clove-tree, the tree which produces the ſpice of that name. *Piſo*. Mant. A. p. 117.

TSIA, in botany, a name taken from the Japoneſe, and uſed by ſome authors for the tea tree.

TSIAM *Pangam*, in botany, a name uſed by ſome authors for the tree whoſe wood is the logwood uſed in dying and in medicine. Hort. Malab. vol. 6. p. 3.

TSIANA *Cua*, in the materia medica, a name given by ſome authors to the coſtus root. Hort. Malab. vol. 4. p. 15.

TSIN, in natural hiſtory, the name given by the Chineſe to a ſtone which they make great uſe of in their manufacture of porcelain ware. It is of a deep blue colour, much reſembling Roman vitriol in appearance, and is found in lead mines, and ſuppoſed to contain ſome particles of lead; its effects being the ſame in the porcelain manufacture as thoſe of ceruſs or white lead; in making the other colours penetrate into the ſubſtance of the veſſels. The deep violet colour that we ſee ſo beautiful on the China ware, is uſually made with this ſtone. They find it about Canton and Peking; but the latter place affords the beſt, and it ſells at greatly the beſt price.

The painters in enamel melt this ſtone in their way, and uſe it very much; they form many beautiful works, by laying it upon ſilver; but it is apt to come off in time. When the *Tſin* is uſed in the porcelain manufacture, it is only uſed to the vaſes that paſs a ſecond baking, and are intended as the beſt kinds.

The *Tſin* is prepared by only beating it to powder, not roaſting it in the common way. They mix the powder with large quantities of water; and ſtirring it together, they let it ſubſide a little to ſeparate any earthy or extraneous matter that might be among it. They then let the powder ſubſide. The water which is thrown away has no colour from this matter; and the powder itſelf is not of that fine blue it was in the lump, but of a pale aſh-colour; but this recovers all its beauty when it is laid on the China, and baked. The ſettlement taken from the water is dried and preſerved in powder, and when it is to be uſed, they only mix it up with gum-water, or a ſolution of glue, and lay it on with a pencil. Obſervations ſur les Coutumes del' Aſie.

TSUBAKI, in botany, a name by which Kæmpfer calls the concellia. See the article CONCELLIA.

TUB (*Cycl.*)—TUB-*Fiſh*, in ichthyology, an Engliſh name given to a ſpecies of the *trigla*, commonly called the *flying fiſh*, and by authors *hirundo*, *corvus*, and *milvus*.

It is diſtinguiſhed by Artedi from the other fiſh of the ſame genus, by the name of the *trigla* with a prickly head, and with three appendages on each ſide to the pectoral fins. This is the only name to be judged ſpecific for this fiſh; for the others are ſo vague in their ſignification, that they have been applied by different authors to fiſh of different ſpecies, and even different genera, which had a power of ſuſtaining themſelves out of the water by means of their long pectoral fins. *Artedi*, Gen. Piſc. p. 74. See the articles HIRUNDO and TRIGLA.

TUBA, in natural hiſtory, a name by which many old authors call the buccinum.

TUBBER, in mining, a name given in Cornwall to that mining inſtrument, which is in other parts of England called a *beele*. It is an iron inſtrument, pointed at each end, and having a hole in the middle for the handle. See the article DIGGING.

TUBBER-*Men*, are, in Cornwall, the people who work with this tool, and who are, from its other name of *beele*, called in other places *beel-men*. See the article BEELE.

TUBE *of a Flower*, among botaniſts. See the article PETAL.

Glaſs TUBES. See the article GLASS *Tubes*.

TUBEL, a word uſed by ſome chemical writers to expreſs ſcales of copper or braſs.

TUBEROUS, or TUBEROSE *Roots*, among botaniſts, ſuch as are large and fleſhy, thicker than the ſtalk of the plant, of an irregular figure, and wanting the characters of the bulbous. See the article ROOT.

TUBERA, *Truffles*, in botany, the name of a genus of plants, the characters of which are theſe; they are of a fungous fleſhy ſtructure, and are of a roundiſh figure, growing ſometimes ſingle, ſometimes many together, and always remaining under ground.

The ſpecies of *Truffles* are only two. 1. The common *Truffle*; and 2. The teſticulated *Truffle*. *Tourn.* Inſt. p. 565. See the article TRUFFLE.

TUBIPORA, in botany, the name given by Linnæus to the ſea plants uſually called by authors *tubularia*. See the article TUBULARIA.

TUBOR *Terræ*, a name uſed by ſome botanical authors for the cyclamen or ſow-bread. *Ger.* Emac. Ind. 2.

TUBULARIA, in botany, the name of a genus of plants, the characters of which are theſe: That it grows under water, and is of the ſtony hardneſs of coral, and compoſed of a congeries of hollow pipes or tubes.

There is only one known ſpecies of this, which is the purple *Tubularia*. *Tourn.* Inſt. p. 575.

TUBULARIA *Foſſilis*, in natural hiſtory, the name of a ſpecies of coral found very often foſſile in Germany and Italy, and compoſed of a great number of tubes, or longitudinal pipes, often reſembling ſo many worms ranged perpendicularly in the maſs. See Tab. of Foſſils, Claſs 7.

They are uſually found either in maſſes of a lax ſtone, or in ſingle tubules in thoſe of the harder and firmer texture. In theſe two ſtates this foſſil makes two very different appearances; and, according to the different directions in the maſs, or the different views of them that the ſections of it place them in, they make a number of very elegant figures. *Hill*'s Hiſt. of Foſſ. p. 641.

TUBULATED *Flower*, *Tubulatus Floſculus*, in botany, a term uſed by authors to expreſs thoſe ſmaller flowers, a great number of which go to compoſe one large compound flower. Theſe are called tubulated in diſtinction from another kind of them, which are, from their ſhape, called ligulated. The tubulated floſcules generally compoſe the diſk, and the ligulated ones the radius of the compound flowers. The tubulated ones are formed into a hollow cylinder, which expands into a mouth at the top, and is divided into five equal ſegments, which ſtand expanded, and in ſome meaſure bent backward. See Tab. 1. of Botany. Claſs 1.

TUBULUS (*Cycl.*)—TUBULI *Concamerati*, in natural hiſtory, the name of a genus of the *Tubulus marinus*, diſtinguiſhed abundantly from all the others by its figure and inner ſtructure.

They are long ſhelly bodies, uſually either of a conic or cylindric form, or elſe reſembling the dentales in ſhape; and ſometimes, but that very rarely, they have their ſmaller end bent and twiſted round. They are compoſed within of a number of hollow compartments, each of which communicates with the next by means of a ſiphunculus, which runs through the whole length in the manner of the thick nautilus, or the cornu ammonis. We know not theſe in their recent ſtate at this time, but frequently meet with them foſſile in the ſtones brought from Sweden for pavements, and in ſome others.

Some authors have called theſe by the name *alveoli*, confounding them with the conic body found in the belemnitæ. See ALVEOLUS. Others have called them *pyramidal entrochi*, others *obeliſci marmorei alveolares*; and they are the bodies deſcribed by Geſner and Aldrovand under the names of *lapides caudæ cancri* or *cancrites*. Some late authors have called them alſo *polythalamii*, and other *cone-ſtones*. *Klein.* de Tubul. p. 7.

TUBULI *Foſſiles*, in natural hiſtory, the name given by authors to the caſes or *tubules* of ſea-worms, found buried in the earth.

They

They are in their native ſtate of very various kinds, but by different accidents attending them in their accidental one, they are ſubject to a multitude of other appearances. They are found of very various ſizes, ſometimes compleat, and buried in the ſtrata of earth or ſtone; ſometimes they are more or leſs perfect, and are immerſed in maſſes of the *ludus helmontii* or *ſeptariæ*, and in this ſtate, they make one kind of *lapis ſyringoides*, or pipe-ſtone; but the moſt beautiful *ſyringoides*, or pipe-ſtones, are the parts of the bottoms of ſhips, or poſts fixed in the ſea, which have been pierced, in their original ſtate of wood, by theſe ſea worms, and afterwards, petrified with the caſes or *Tubuli* of the worms remaining in them; theſe are uſually of a pale yellow or whitiſh wax colour; and the body of the maſs of a browniſh or blackiſh hue, but retaining the ſtructure of the wood: of theſe, there are beautiful ſpecimens in great abundance on the ſhore of the iſland of Sheppy. We have the very ſame ſubſtances alſo buried in our clay-pits, about London and at Richmond; but in theſe the wood is highly ſaturated with the matter of the common vitriolic pyrites, and the pipes often filled with the ſame ſubſtance.

Thoſe *Tubuli* called *dentalia* and *entalia* are not leſs frequent, and are found of various ſizes; ſmall ſmooth ones are common in our clay-pits about London; and the larger ſtriated ones are not unfrequent in the hills of Yorkſhire; but they are much more plentiful in thoſe of France and Italy. *Hill*'s Hiſt. of Foſſ. p. 648.

TUBULUS *Marinus*, or *Canalis*, in natural hiſtory, the name of a genus of univalve ſhell-fiſh; the characters of which are theſe: It is of an oblong figure, terminating in a point, and hollow within; ſo that it reſembles a tube or horn. Theſe are alſo called by the older writers *dentalia*, from their reſembling the tooth of a dog.

It has been a common error of authors to confound under the general name of *Tubulus marinus*, theſe ſhells, and thoſe very different ones of the *vermiculi marini*, which make a number of pipes or tubes joined together; theſe by their number and joinings, have induced a late French author to place them among the multivalve ſhells, while the *canales* are uſually ſingle and ſeparate, and can have no title to any claſs, but the tubular univalve one. Aldrovand obſerves, that the *Tubuli* called *dentalia*, and thoſe called *antalia*, differ only in ſize; and he thinks they have no title to the name *conchæ*, ſince they are neither of the nature of the common bivalve, nor univalve ſhells, ſuch as the patella and *auris marina*; but this is very idle, ſince by this rule the ſnails, and many other families, might be excluded as well as theſe. This author ſays, in another place, that the *antale* is formed of many circumvolutions; whence he ſeems to have taken in the *buccina* under this name; but later writers have more nicely diſtinguiſhed in theſe caſes. The ſea pencile is evidently of this genus, tho' extremely different from all the other ſpecies of it, in having its head pierced with a multitude of holes, in the manner of the head of a watering pot. Some authors, from the figure of the ſhell, call this *phallus marinus*, and the French call it *le priape*. *Aldrovand*, de Teſtac. l. 3. p. 382.

Of this general claſs of the *Tubuli* or *Canales*, there are four ſubordinate diſtinctions: 1. Some are ſtriated. 2. Some are ſtrait. 3. Some are bent like a horn: and, 4. Some are ſmall and even on the ſurface, and are bent a little into a figure approaching to that of a creſcent; theſe are now called by many *antalia*.

Of the ſtriated *Canalis*, we ſeem to have at preſent only one known ſpecies; tho' this varies ſo greatly in ſize and colour, that it might in its ſeveral ſtates be miſtaken by many for ſeveral ſpecies. There is alſo another very different form it aſſumes in our cabinets; this is owing to its being poliſhed, the ridges being by this manufacture taken off, and the ſhell made to appear extremely different.

Of the ſtrait kind we ſeem alſo to have only one ſpecies, tho' varied by accidents into ſeveral different appearances.

Of the crooked kinds we have. 1. The horn *Canalis*: this is a *Tubulus marinus* exactly of the ſhape of a horn moderately inflected. 2. The root-ſhaped *Canalis*. 3. The biſtort *dentalia*, or *Canalis*, of the figure of the biſtort-root. 4. The rape-*dentalia*, or *Canalis*, of the figure of the rape-root. 5. The *Canalis*, called vulgarly *dens-canis*, or the dog-tooth ſhell. 6. The *dens elephantis* or elephant's-tooth ſhell. 7. The whitiſh *Canalis*. And, 8. The greeniſh *Canalis*. To theſe is to be added, the *phallus* or *priape* of the French; called alſo by ſome of that nation the *arroſoir* or watering-pot; it is an oblong and ſtrait ſhell, with the head pierced full of ſmall holes like the head of a watering-pot.

Of the *Canalis* called by the French *antales*, we have only two ſpecies. 1. The white: And, 2. The yelloviſh *antalis*. Hiſt. Natur. Eclairc. P. 2. p. 245. See the articles PENICILLI *Marini*, DENTALIS, SOLEUS, BELEMNITES, and TUBULUS *concameratus*.

TUBULOSE-*Leaf*, among botaniſts. See the article LEAF.

TUCANA, in zoology, a name given by ſome to the toucan, a very remarkable American bird of the magpye-kind; but having a beak as long and thick as its whole body. *Ray*'s Ornithol. p. 88. See the article TOUCAN.

TUCK *of a Ship*, the truſſing or gathering up the quarter under water; which if ſhe lie deep, makes her have a broad, or as they call it, fat quarter, and hinders her ſteering, by keeping the water from paſſing ſwiftly to her rudder; and if this truſſing lie too high above the water, ſhe will want bearing for her works behind, unleſs her quarter be very well laid out.

TUFECSI, a body of the Spahis, or horſe, in the ſervice of the Grand Seignior. *Pocock*'s Egypt, p. 166.

TUFFO, in botany, a name given by the people of Guinea to a plant common in that country, and uſed in decoction to waſh ſore eyes with. It is of the ſun-flower kind, and is called by Petiver, *flos ſolis Guineenſis folio ſcabro flore minore*. It much reſembles ſome of the American ſun-flowers. Philoſ. Tranſ. N°. 232.

TUFTED *Duck*, in zoology, the Engliſh name for the *capo negro*, a ſpecies of duck with a blackiſh head, and a tuft of feathers hanging from it. See the article CAPO *Negro*.

TUGUS, in botany, the name of a ſweet aromatic plant, much eſteemed in the eaſtern parts of the world, and ſuppoſed by father Camelli, who very ſtrictly compared it with the accounts given by Dioſcorides and the antients of their amomum, to be that very plant. The cluſtered manner of growing of the fruit, together with its oblong ſhape, and the aromatic taſte of the ſeeds, ſeem greatly to countenance this opinion.

The *Tugus* is a plant of conſiderable height, growing up ſometimes to eight or nine cubits. Its leaves are of an oblong form, marked with large veins and ribs, covered with a ſoft hoary down underneath, and of a very agreeable aromatic ſmell. The flowers are red, and grow in cluſters, of a hand-breadth or more in length, in a kind of ear, ariſing either from the root, or from the main trunk of the plant. The fruit follows theſe flowers, and is no other than the inflated or enlarged cup of the flower, containing the ſeeds: this makes but a very thin and tender covering for them; and they, being delicious to the taſte, are much ſought after by birds, inſects, and field mice. One or other of theſe creatures uſually devours them before they become really ripe; and this makes the fruit ſcarce, even in the places where the plant grows, ſince very little of it can be collected.

Each fruit of the *Tugus* contains five or ſeven ſeeds; theſe are of an oblong figure, of a reddiſh colour, and of an agreeable aromatic taſte, but not too acrid.

The natives ſeem as fond of theſe, as the antients were of the amomum; and the young women ſtring them on threads, and wear them as bracelets; ſometimes they make the bracelets of the ſeeds alone; but more uſually they ſtring them alternately with pearls, and pieces of red coral: theſe bracelets they call *caropi*, as well as the fruit itſelf.

In ſome places, where the *Tugus* is ſcarce, they uſe the ſeeds of the abelmoſch, the cannacorus, or the ſago, inſtead of theſe of the *Tugus*; but the true are much more eſteemed. They are ſuppoſed, when worn by way of a necklace, to keep off the effects of a bad air, and to preſerve them from the bites of ſerpents or the centipes. If not a preſervative, they are however found, upon experience, to be a very good remedy in the laſt caſe, the common application for the bite of this animal being ſome of the ſeeds of the *Tugus* chewed in the mouth to a ſort of paſte.

The cluſter of fruit of the *Tugus*, or true amomum, when newly formed and unripe, ſomewhat reſembles the pſeudo-amomum of Garcias; but this likeneſs wears off as they ripen. Camelli, who hath given this excellent account of the *Tugus*, has added a figure of it in the Philoſophical Tranſactions, from which ſome at firſt ſight may object to the juſtice of his making it the ſame plant with the amomum; ſince Dioſcorides, and from him Pliny, affirm the leaves of the amomum plant to be like thoſe of the pomegranate; this no more agrees with his figure, than with his general deſcription of the common leaves of the *Tugus*, which are not at all like thoſe of that tree, but greatly larger and longer in their ſhape: but this is a difficulty eaſily cleared up, by obſerving that Dioſcorides, Pliny, and the reſt of the antients, when they deſcribe the amomum, never concern themſelves about the plant which produces that precious fruit, which probably they never ſaw; but all they mean by its leaves, are thoſe ſmall and ſhort leaves which they found adhering to the cluſter of the fruit, as brought over to them for ſale. Theſe are the leaves of the ear only, and theſe are not unlike thoſe of the pomegranate, on the plant while growing. Philoſ. Tranſ. N°. 248. p. 2.

TUI, in zoology, a name by which ſome call the *paroquette*.

The word is originally Braſilian; and the names of ſeveral of the Braſilian ſpecies of this bird, deſcribed by Marggrave, have the word *Tui* as a part of them; as the *tuiete*, the *tuipara*, the *tuitirica*, and *tuiaputejuba*. See the article TUIETE, *&c.*

TUIAPUTEJUBA, in zoology, the name of a Braſilian ſpecies of paroquette, all over of a green colour, but in different ſhades, very deep on the wings, very pale and ſomewhat yelloviſh on the belly, and of a faint colour all over the reſt of the body. Its tail is very long; it is about the ſize of a ſwallow;

ſwallow; its eyes are large and black, and have a circle of yellowiſh green feathers round them, and over the beak, which is black and crooked; and on his head he has one ſpot of gold yellow feathers. *Marggrave*'s Hiſt. Braſil.

TUIETE, in zoology, the name of a Braſilian ſpecies of paroquette, of the ſize of a lark, and all over of a pale green colour, variegated with blue. The origin of its wings is blue, as are alſo all the ends of the wing-feathers, ſo that when the bird ſits ſtill, there is, as it were, a blue line ſeen running down each ſide; on its rump there is alſo a blue ſpot; its tail is but ſhort; its beak ſmall, crooked, and of a pale red; and its legs and feet grey. *Marggrave*'s Hiſt. Braſil.

TUITIRICA, in zoology, the name of a Braſilian paroquette, which is a little larger than the common kind; all over of a fine beautiful green, but deeper on the back and wings than elſewhere. Its beak is very hooked, and of a pale red; its eyes black, and its feet blue; its tail is but a little longer than the wings when cloſed. This is a ſpecies much eſteemed in the Braſils, as it eaſily learns to talk, and becomes ſo tame, as to eat out of any one's mouth. *Marggrave*'s Hiſt. Braſil.

TULACUM, in natural hiſtory, a name given by the people of the Eaſt Indies to a ſpecies of yellow orpiment, of the coarſer kind, variegated with red. They prepare this by ſeveral calcinations, and then give it internally in fevers, and many other diſorders, eſteeming it a ſort of panacea. They ſay that gold may be extracted from it, which is not improbable; for it is well known, that ſome of the Roman emperors did actually procure gold from one of the other kinds of orpiment, which is now found at Goſſelaer in Saxony.

TULIP, *Tulipa*, in botany, a large genus of plants, the characters of which are theſe: The flower is of the liliaceous kind, and is compoſed of ſix leaves, and ſomewhat of the form of a pitcher; the piſtil occupies the center of the flower, and finally becomes an oblong fruit, divided into three cells, which contain flat ſeeds, arranged in a double order; the root is tunicated, and the fibres grow from its bottom.

The ſpecies of *Tulip*, enumerated by Mr. Tournefort, are theſe: 1. The yellow early-flowering *Tulip*. 2. The red early *Tulip*. 3. The purple early *Tulip*. 4. The amethyſtine early *Tulip*. 5. The early *Tulip*, with a duſky blackiſh purple flower. 6. The purple *Tulip*, with a pale cup. 7. The bright red *Tulip*, with a yellow cup. 8. The early white *Tulip*. 9. The early ſcarlet *Tulip*, with pale red edges, and red heart-faſhioned ſpots at the bottoms of the leaves. 10. The early *Tulip*, with a crimſon and red flower. 11. The variegated amethyſtine early *Tulip*. 12. The early *Tulip*, with a bright red flower, with white edges. 13. The early crimſon *Tulip*, with white edges. 14. The variegated white and reddiſh early *Tulip*. 15. The early variegated red *Tulip*. 16. The variegated roſe-coloured many-flowered early *Tulip*. 17. The early yellow variegated *Tulip*. 18. The early yellow *Tulip*, with red edges. 19. The early *Tulip*, of a blended red and yellow colour. 20. The beautiful ſcarlet *Tulip*, with yellow edges. 21. The broad-leaved yellow *Tulip*, with crimſon edges. 22. The yellow *Tulip*, with edges ſtriated with red, and a green bottom. 23. The yellow *Tulip*, with numerous ſmall ſpots. 24. The yellow *Tulip* with gold-coloured ſpots. 25. The yellow *Tulip*, with roſe-coloured edges. 26. The yellow *Tulip*, with red ſpots. 27. The yellow *Tulip*, with a red mark near the cup. 28. The yellow *Tulip*, with bright red ſpots. 29. The greeniſh yellow *Tulip*. 30. The pale lemon-coloured *Tulip*, with green ſtreaks on the back. 31. The brimſtone coloured *Tulip*, with deep red edges, and roſe-coloured ſpots near the ſtamina. 32. The bright ſtraw-coloured *Tulip*, with red edges. 33. The early purple variegated *Tulip*. 34. The roſe-coloured *Tulip*, with yellow veins. 35. The bright red *Tulip*, with greeniſh ſtreaks. 36. The *Tulip*, with reflex flowers of a bright red throughout within, and on the outſide of a greeniſh colour, with a bright vermillion edge. 37. The early white *Tulip*. 38. The white *Tulip*, with green veins. 39. The white *Tulip*, with roſe-coloured ſpots. 40. The white *Tulip*, with broad red ſpots. 41. The white *Tulip*, with red edges. 42. The ſilvery white *Tulip*. 43. The yellowiſh white early *Tulip*, with long red ſtreaks. 44. The reddiſh white *Tulip*, with red edges. 45. The white wide-open *Tulip*, with red ſtreaks. 46. The early narrow-leaved *Tulip*. 47. The early hyacinth-leaved *Tulip*. 48. The late flowering yellow *Tulip*. 49. The plain gold yellow *Tulip*. 50. The yellow *Tulip*, variegated with red and green. 51. The late-flowering ſcarlet velvety *Tulip*. 52. The late globoſe *Tulip*, ſpotted with gold colour. 53. The white *Tulip*, with a ſcarlet edge. 54. The white *Tulip*, variegated with a yellowiſh purple, and with yellow bottoms to the leaves. 55. The ſnow-white *Tulip*, with purpliſh-red edges. 56. The ſnow-white *Tulip*, with deeper purple edges. 57. The late-flowering ſtellate *Tulip*. 58. The changeable white-flowered *Tulip*, with red edges. 59. The ſcarlet *Tulip*, with white edges. 60. The late-flowering globoſe vermillion *Tulip*. 61. The late deep red *Tulip*. 62. The red changeable *Tulip*, with greeniſh ſpots in the middle of the petals. 63. The great branched late-flowering *Tulip*. 64. The ſmaller late-flowering branched *Tulip*. 65. The late green-flowered *Tulip*. 66. The late green *Tulip*, with double flowers. 67. The late flowering green *Tulip*, with white edges. 68. The late *Tulip*, with double red flowers. 69. The double late yellow *Tulip*. 70. The large dubious *Tulip*. 71. The largeſt dubious *Tulip*. 72. The middle-ſized dubious *Tulip*, with ſulphur-coloured flowers. 73. The yellow *Tulip*, with bright red ſpots. 74. The yellow *Tulip*, with red edges. 75. The large dubious *Tulip*, with orange-coloured flowers. 76. The middle-ſized dubious *Tulip*, with variegated flowers. 77. The *Tulip* which bears bulbs in the alæ of the leaves. 78. The dwarf broad-leaved white *Tulip*. 79. The dwarf broad-leaved yellow *Tulip*. 80. The dwarf broad-leaved red *Tulip*. 81. The dwarf narrow-leaved *Tulip*. 82. The dwarf graſſy-leaved *Tulip*. 83. The little yellow Italian *Tulip*. 84. The ſmall broad-leaved *Tulip*. 85. The little red *Tulip*. 86. The cottony cretic *Tulip*. 87. The little French yellow *Tulip*. 88. The little yellow and purple *Tulip*. 89. The Perſian variegated *Tulip*. 90. The Candey *Tulip*, with ſhining leaves. 91. The middle-ſized changeable *Tulip*, with curled leaves adhering to the baſe of the flower. 92. The many-leaved yellow *Tulip*, called by ſome the monſtrous double yellow *Tulip*. And 93. The great yellow *Tulip*, with jagged flowers, and ſpots of yellow and blood-red, in different parts of them. *Tourn.* Inſt. p. 373. ſeq.

The characters of a good *Tulip* are theſe: 1. It muſt have a tall and ſtrong ſtem. 2. The flower ſhould conſiſt of ſix leaves, three within, and three without; and the former ſhould be larger than the latter. 3. The bottom of the flower ſhould be proportioned to the top, and the ends of the leaves ſhould be rounded, not pointed. 4. The leaves, when opened, ſhould neither turn inward, nor bend outward, but ſtand erect; and the whole flower ſhould be of a middling ſize, neither too large, nor too ſmall. 5. The ſtripes muſt be ſmall and regular, and ſhould all ariſe from the bottom of the flower: The chives alſo ſhould not be yellow, but of a brown colour.

Tulips are generally divided into three claſſes, according to their times of flowering; the early, the middling, and the late.

The early ones are not near ſo high as the late, but they are valued for their earlineſs, as they flower in February. The roots of theſe are to be planted in the beginning of September, under a warm pale or hedge. The proper ſoil for them is paſture-land with the turf rotted among it, and a mixture of one fourth part ſand; this ſhould be laid about ten inches deep, and ſhould be renewed every year. If the weather is very ſevere when they firſt appear, they ſhould be covered with mats; as alſo at nights, when they are in flower, if it be very froſty. When their flowering is over, and their leaves decay, the roots ſhould be taken up and laid in a dry place, and afterwards cleaned and laid up in a ſafe place from vermin, till the September following.

The late blowers are propagated from what they call breeders, which are plain flowers, brought over principally from Flanders, which is the great mart for flower-roots; and theſe by culture, are changed into ſtriped and variegated ones. They are alſo propagated by ſowing the ſeeds; but this requires great care, as in the raiſing all the other fine flowers from ſeeds.

The ſeeds muſt be ſaved from the choiceſt flowers, and ſowed in ſhallow pans or boxes of earth, in September. The ſpring following they appear like the leaves of graſs, or young onions, and after ſtanding two or three months theſe decay. The boxes are to be kept clear of weeds, and removed to different ſituations where they may enjoy the morning-ſun, and be defended from ſharp winds and froſts; at the Michaelmas of the following year they are to be removed out of the boxes into beds, where they ſhould be planted two inches deep, and at two inches diameter from one another. In October, an inch depth of new earth ſhould be ſifted on them, and they are to remain two years in theſe beds; at the end of this time they will flower, and the beſt of them muſt be marked with ſticks, that their roots may be diſtinguiſhed when the leaves are decayed.

But there is no judgment to be paſſed either on *Tulips*, or any other flowers, on their firſt flowering; becauſe the next year the good ones are often found to have degenerated, and the bad to have improved: After this, however, they may be concluded good or bad.

The breeders, as they are called, being thus raiſed, are to be ſhifted every year into freſh earth, and they will in time break out into very fine ſtripes. The earth they are planted in ſhould be every year of a different kind, and the beſt general ſoil is made of a third part paſture-land with the graſs rotted in it, a third part fine ſea-ſand, and a third part lime-rubbiſh; theſe ſhould be mixed half a year before they are uſed, and often turned. The beds muſt be laid eighteen inches deep with this earth. This ſhould be laid in firſt ten inches thick, and on this the roots ſhould be placed in regular order, and at even diſtances; and then the other eight inches ſhould be laid over theſe, the top of the bed being a little rounded to throw off the wet. Thus they are to remain till the buds appear, and then if the nights are very ſevere they are to be ſheltered by covering them with mats. The flowers which break out into fine ſtripes here, ſhould be ſeparated

afterwards from the reſt, and if they hold on their beauty to the laſt, which the floriſts call dying well, they will never return to plain flowers again; and the off-ſets from the roots of theſe will always produce ſuch flowers, and often more beautiful than thoſe of the parent root.

When the *Tulips* have flowered, their heads ſhould be broken off to prevent their ſeeding, which would make them flower much the worſe the next year. *Miller*'s Gardener's Dict.

The Dutch have always been admirers of flowers, and before the preſent faſhion of cultivating the auriculas and carnations came up among them to the height it now is at, they took the ſame care of *Tulips*. The prices they ſold theſe at among one another, are amazing. Munting tells us, that in the years 1634, and the four or five following, they not only purchaſed them at extravagant rates beyond credibility, but many of the burghers, ſhopkeepers and tradeſmen, quitted their ſhops and trade, and addicted themſelves ſolely to the culture and cure of their *Tulips*. The fineſt of them were then valued above gold or gems; and there is an account of one bargain for the purchace of that *Tulip* which they call the viceroy, preſerv'd: The perſon who purchaſed this, not having money, paid for it the following things; two laſts of wheat, four laſts of rye, four fat oxen, twelve fat ſheep, eight fat hogs, two hogſheads of wine, four tons of beer, two ton weight of butter, a thouſand pound weight of cheeſe, a bed, a ſuit of cloaths, and a large ſilver beaker; the whole valued at two thouſand five hundred gilders. We have another account about the ſame time, of twelve acres of good land offered for one *Tulip* root. And at a publick ſale of a private perſon's collection there was made ninety thouſand gilders. This madneſs would have run yet higher among them, but the ſtates at length took it into conſideration, and finding it very detrimental to ſubſtantial and neceſſary trade, put a ſtop to it, and reduced the price. *Munting*. de Plant.

TULIP-*Tree*, a very beautiful American tree, which produces flowers ſuppoſed like thoſe of the *Tulip*. Theſe trees uſed to be kept in tubs, and houſed in winter with great care; but ſome of them having been planted out in the open air at Lord Peterborough's at Fulham, they throve much better than thoſe which were ſo carefully nurs'd up, and ſoon produced abundance of flowers.

The tree is commonly found wild in all the northern parts of America, where its timber is of very great uſe. The flowers are not in reality much like thoſe of the *Tulip*, tho' vulgarly ſaid to be ſo. The flowers are ſucceeded by canes, which are often ſent over from America; and the trees are frequently raiſed with us, from the ſeeds contained in them. The ſeeds muſt be taken out of the canes in ſpring, and ſown in pots of light earth, which muſt be placed in a back bed, and covered with mats, and frequently refreſhed with a little water. When the young plants appear, they ſhould be placed, during ſummer, in a ſhady ſituation; and in winter they ſhould be put into a frame, where they may have the benefit of the open air in mild weather, and be ſheltered from ſeverity of froſts. In the ſpring following, the plants ſhould be tranſplanted into ſmall pots, and taken the ſame care of for four years, as while they were in the ſeed-pots; after this they will be ſtrong enough to tranſplant finally into the places where they are to remain: it ſhould be planted on a light loamy ſoil near other trees, but not over-ſhaded by them. Some raiſe them from layers, but they are two or three years before they take good root, and then never make ſuch ſtrait and regular trees. *Miller*'s Gardiner's Dict.

TULIPIFERA, a name given by Cateſby, to the *liriodendron*. See the article LIRIODENDRON.

TULOS, a word uſed by ſome medical writers to expreſs a callus.

TUMBABA, a word uſed by chemiſts, to expreſs *ſulphur vivum*, or crude ſulphur.

TUMBALA, a word uſed by ſome authors, to expreſs the *ſquammæ* or ſcales of any metal.

TUMBLER, (*Cycl.*) a name given to a particular ſpecies of pigeon, called by Moore the *columba revolvens*.

It has its name from its peculiar property of *tumbling*, when it is in the air, which they are very fond of doing; and effect exactly in the ſame manner as our poſture-maſters do it; by throwing themſelves over backward. It is a very ſmall pigeon, and is always ſhort bodied, full breaſted, thin neck'd, narrow beak'd, and has a ſmall ſhort head; the iris of the eye in this ſpecies, is uſually of a bright pearl-colour.

The Engliſh *Tumbler* is uſually of one plain colour; black, blue, or white: the Dutch is much of the ſame make, but has different colours, and is feathered on the legs ſometimes; it has alſo a larger head, and thin ſkin round the eye. Some of the fineſt pigeons of this ſort are bred from a mixture of the Dutch and Engliſh kinds. Theſe pigeons are remarkable for the height they fly to; they never ramble far from home, but will riſe almoſt perpendicularly, till they appear no larger than a ſparrow, or become quite out of ſight; they will often keep at this height five or ſix hours, and then come gradually down again: they never tumble when they are at any great height, but only as they aſcend or come down again. There are particular times alſo, at which theſe birds will take much higher flights than at others; but they ought to be kept by themſelves, and practiſed to it by the company of one of their own ſpecies; for if they mix while young, with other pigeons, they will learn to fly as they do: a flight of a dozen of theſe birds ſent out together, will keep ſo cloſe, as to be all in a compaſs that might be covered with a handerchief; but they ſhould never be turned out in foggy weather, or in high winds; in the firſt caſe, they loſe ſight of their home, and perhaps never find it again; and in the others, they are blown away; and if they return, it is not till another day; in the mean time lying out, they are in danger of cats, and other accidents.

Laſtly, the hen ſhould never be turned out with egg, for ſhe is then ſick, and not fit for flying; and beſide often drops her egg, and the breed is loſt by it. *Moore*'s Columbarium, p. 39.

TUMEX, in the materia medica of the antients, a name given by authors to a ſort of tutty, the ſame with the *cadmia placitis* of Dioſcorides and the Greeks. This was a worſe kind than the *botrytis*. The *botrytis* was formed on the roof of the furnace, and hung down thence in form of cluſters of grapes; this was the pureſt kind.

The *Tumex* or *cadmia placitis*, was a heavier and coarſer ſort, which not being volatile enough to aſcend to the top of the furnace, applied itſelf to the ſides, and there formed a ſort of coat or cruſt, which was taken off at times, and reſerved for the more common uſes. This ſort of cadmia, being formed by the ſucceſſive application of new coats of matter, at different times, was found to be of a cruſtated texture, when broken tranſverſely, and reſembled, in ſome ſort, the onyx, with its different zones or belts. It was therefore called by ſome, *cadmia onychites*; and by Aviſenna *mantheca*, which ſignifies in the Arabian, *zonites*, or compoſed of plates or zones.

TUMORS *of the Breaſts*, *Mammarum* TUMORES. *Tumors* and inflammations of the breaſts are a diſorder that very frequently afflicts child-bearing women, and almoſt conſtantly happens, in ſome degree, a few days after their delivery.

If the milk be impelled into the breaſts too plentifully and forcibly, which frequently happens at that time, and the mother be at the ſame time ſeized with a violent cold, or indeed be but affected by any violent paſſions, the veſſels become obſtructed, and the breaſts tumified, with great heat, redneſs, reſiſtance, and violent pain. The ſame thing happens alſo very frequently to women who give ſuck after their lying in, and often to ſuch whoſe milk is very ſmall in quantity. Women at other times are alſo ſubject to them, and even men have been known to have the ſame diſorder, from no other cauſe than a great fright. One breaſt of a man, opened on ſuch an occaſion, has afforded above two pounds of matter. This ſort of abſceſs is uſually attended with a fever, thirſt, head-ach, and difficult reſpiraton, and is often preceded by ſhiverings.

Tumors of this kind are generally prevented in thoſe who do not intend to ſuckle their children, by applying, ſoon after their delivery, plaſters of ſperma-ceti warm, all over the breaſts, but perforated with a hole for the nipples. A moderately tight bandage ſerves alſo as a help to keep away milk; and cooling plaſters are of ſervice to the ſame purpoſe, applied between the ſhoulders. But if the lying-in woman intend to ſuckle the child, there is no better way to prevent theſe *Tumors*, than very carefully to avoid colds, and violent paſſions of the mind, and to let the child ſuck very frequently, to prevent the milk from ſtagnating. Plenty of ſmall broth, and thin fluids, muſt alſo be taken, which will prevent the milk, for the firſt two or three weeks, from being too abundant, or from ſtagnating in the breaſts. But when the milk has once ſtagnated, and a *Tumor* is begun, all endeavours are to be uſed to diſcuſs what has ſtagnated in the ſmall veſſels, with all poſſible expedition, both by internal and external remedies, in order to prevent the *Tumor* from running to a ſuppuration, or into a ſchirrus.

The beſt external application, on theſe occaſions, is the ſperma-ceti plaſter, covered with a warm bag, or cataplaſm of ſalt and bran, or of chamomile, elder, and melilot flowers. The carminative ſeeds of fennel, anniſe, *&c.* are alſo very good external applications over a plaſter, on theſe occaſions. A calf's bladder, filled with a warm decoction of elder and chamomile flowers in milk, applied to the breaſt, and renewed as often as neceſſary, is alſo found of excellent ſervice. Theſe not proving ſufficient, recourſe muſt be had to Venice treacle, rob of elder, litharge vinegar, cummin vinegar, and lime water, which muſt be all applied hot to the breaſts by means of linnen cloths dipped into them, and put to the breaſts, as warm as can be conveniently borne.

If the breaſts are very full of milk, part of it muſt be diſcharged by ſucking, or by a glaſs pipe; and this, with the other means, often repeated, till the pain and *Tumor* diſappear.

If the *Tumor*, however, proves large, and will not be diſperſed in four or five days by theſe methods, or when, as it very frequently happens, the ſurgeon is called in too late to put this method in practice, the beſt method is to forward its maturation and ſuppuration as quick as poſſible, leſt it turn to

a ſchirrus or cancer by delay. The plaſter of diachylon, with the gums, or ſome other ſuch ripening plaſter is to be applied forthwith; and with all convenient ſpeed the proper cataplaſms are to be uſed, to digeſt the matter; theſe are to be applied hot to the breaſts, and very frequently renewed, keeping them on with large compreſſes and bolſters, the better to retain the heat. The *Tumor*, when the matter is ripe, will by this means either break of itſelf, or elſe it muſt be opened by the ſcalpel, the inciſion being always made in the lower part of the breaſt; and after the matter is all diſcharged, the wound is to be cleanſed with the common digeſtives, incarned with the ſarcotic, and healed with the balſam of Peru, or ſome other ſuch vulnerary balſam. But where the ſuppuration has run very deep, the wound muſt be waſhed by means of a ſyringe, with vulnerary decoctions; and to prevent the opening from cloſing, before the bottom is healed, and filled up with new fleſh, a ſort of tent of ſcraped lint muſt be introduced, which may be ſhortened at every dreſſing, as the wound fills up, and at length wholly laid aſide. *Heiſter*'s Surgery, p. 187.

Encyſted TUMORS, *Tumors* ariſing in different parts of the body, but contained in certain membranous coats: Theſe are ſometimes harder, ſometimes ſofter, of a paliſh colour, and uſually attended with little pain. Theſe *Tumors* ariſe from obſtructions either in the glands, or in the adipoſe membrane, more eſpecially about the face and neck, where they occaſion great deformity.

The membranous coat with which theſe *Tumors* are inveſted, is often of a conſiderable thickneſs, and is uſually the coat of the diſordered gland, or ſome of the adipoſe cells. At their beginning they are uſually very ſmall and moveable; but encreaſing by ſlow degrees, they grow ſometimes to an enormous bulk.

The conſiſtence of ſome of theſe *Tumors* is ſoft and fluctuating, and of others more hard and firm. They are of all ſhapes and ſizes, and ſome of them become hard as a callus, and unmoveable, while others are, for the generality, ſoft and moveable.

They are diſtinguiſhed according to the conſiſtence of their contents; ſome are called *atheromata*, from their contents reſembling paſte, others, which have them of the conſiſtence of honey, are called *meliceres*; but if they are of a fatty ſubſtance, like ſuet or lard, they are called *ſteatomata*. If they happen in a gland which becomes indurated, they are called *ſchirrous*; and laſtly, when they are of a fleſhy conſiſtence, they are called *ſarcomata*. Some of theſe *Tumors* have been found alſo full of hair.

They are diſtinguiſhed by others according to the places where they are ſituated. Thoſe ſeated under the ſcalp are called *talpa*, *teſtudo*, or *lupia*. Thoſe in the neck, *ſtrumæ* or *ſcrophulæ*; and thoſe in the hands and feet, eſpecially if among the tendons, are called *ganglions*.

There is no general method for the cure of them; but the ſurgeon, according to their different circumſtances, attempts this by diſcuſſion, ſuppuration, or extirpation. *Heiſter*'s Surgery, p. 323.

Fungous TUMOURS, in ſurgery, are a ſort of ſwellings much approaching to the nature of the œdema, and are often diſorders of very bad conſequence.

Theſe are *Tumors* of a limb, taking their riſe at the joint; they look pale, are void of heat and pain, eaſily yield to the preſſure of the fingers, but riſe again inſtantly on removing the finger, leaving no pit or impreſſion behind; tho' no joint of the upper or lower limbs can be ſaid to be ſecure from this diſorder, yet the knees are ever moſt ſubject to it, and that becauſe they abound in fat and glandular bodies, which are concealed among the ligaments and tendons. It is what we commonly know by the name of white ſwellings or ſcrophulous *Tumors* in the joints, and is of ſeveral ſpecies; for ſome *Tumors* of this kind are larger, ſome ſmaller, ſome ſofter, ſome harder; and with regard to the ſtate of the inſpiſſated fluid, ſome are more, ſome leſs glutinous. The noxious humours are uſually ſituated without the joint, and are, in that caſe, properly what we are here treating of. But in ſome they are collected and retained in the joint itſelf, as the ſerum is contained in the teſticle in an hydrocele. This laſt diſorder is not improperly to be called a dropſy of the joint; and this may be commonly diſtinguiſhed from the external fungous *Tumors* of the joints, by the inlargement which appears all round the joint; whereas the fungous *Tumor* is uſually ſituated more on one or the other ſide of it.

The proximate cauſe of theſe *Tumors* is, doubtleſs, the viſcidity of the ſerum about the ligaments of the joints, which is apt to ſtagnate after the ligaments have received any conſiderable violence from a fall or a blow. The *Tumor* ſometimes riſes in the external parts, ſometimes in the articulation itſelf, by which the ligaments being weakened, the part loſes its natural motion; and when the nerves or blood-veſſels are greatly preſſed upon by the *Tumor*, the parts below are uſually deprived of nouriſhment; and while the joint, by degrees, becomes greatly enlarged, the parts below it diminiſh and waſte.

In order to render the cure of recent and milder *Tumors*, of this kind, the more eaſy, by diſperſing remedies, it will be proper to rub the diſordered part with warm cloths every day, fomenting it afterwards with tartarized ſpirit of wine; and this method is to be carefully purſued, till the natural ſtrength and form of the limb are reſtored. Purmannus's fomentation is excellent for this purpoſe. It is made of ſix ounces of roch-alum, an ounce and half of Roman vitriol, and two handfuls of ſage leaves, boiled in a quart of herring-pickle, mixed with a pint of the ſharpeſt vinegar; it is to boil together for about half an hour, and then to be uſed as the before-mentioned.

When the tumours begin to diſperſe, and the parts to recover their ſtrength, it will be a great forwarding of the cure, to foment the limb well ſeveral times every day with tartarized ſpirit of wine, or with the fœtid oil of tartar, laying the bandages carefully on every time afterwards, to defend it from the injuries of the external air, of which it is very ſuſceptible: And laſtly, the following is an application by which many of theſe *Tumors* have been perfectly and happily cured. Take litharge half a pound, bole armenic an ounce, maſtic and myrrh of each half an ounce, white wine vinegar a pint; mix theſe together, and let them boil for a quarter of an hour, and let coarſe linnen rags be dipped in this liquor, or fine ones often doubled, and applied morning and night in bed to the part; and at the ſame time the patient is not to omit the proper internal remedies, which are the attenuants and ſudorifics.

But if the *Tumor* be of long ſtanding, and will not give way to any of theſe remedies, all the hope left is to make an inciſion into the dependant part of it, taking great care to avoid wounding the ligaments or tendons of the joint; and by this means the ſtagnating ſerum, if contained in one cavity, is inſtantly evacuated, and if it be lodged in ſeveral different cells, it will yet make its eſcape through the ſame orifice in the ſpace of a few days. Before the inciſion is made, in this caſe, the *Tumor* ſhould be pulled down as low as may be with the fingers, and a tight bandage made above to retain it in that ſituation; by this means the moſt convenient part for the inciſion to be made in will lie fair, and when the opening is made, the ſerum will readily burſt forth like blood on the opening a vein, or lymph in the tapping for the hydrocele or aſcites. When this is done, if any *Tumor* ſtill remains, the part is to be dreſſed with diachylon or oxycroceum plaſters, and waſhed with lime-water or ſpirit of wine. By continuing the applications, what remains inſpiſſated in the *Tumor* will entirely diſperſe. When the limb is reſtored to its natural ſhape, the wound is to be healed with vulnerary balſams, diligently avoiding the uſe of fatty or oily medicines, as they are hurtful to the tendons and ligaments, with which thoſe parts abound. If the ſerum, contained in the *Tumor*, is ſo glutinous that it cannot diſcharge itſelf for want of fluidity, throw up attenuating injections at every dreſſing. The beſt for this purpoſe are thoſe prepared from a decoction of agrimony, birthwort, or ladies mantle, mixed with honey, in which roſemary or celandine have been infuſed. Notwithſtanding that ſuch of theſe *Tumors* as are opened by the knife are ſooneſt diſcharged and healed, yet ſome ſurgeons prefer the application of cauſtic medicines to the knife, diſcharging the ſerum upon the falling off of the eſchar. In either caſe it would be proper to warm and invigorate the ligaments and tendons, eſpecially when the diſorder falls upon the knee, by the uſe of ſome nervous ointment, or aromatic ſpirit.

It too frequently happens, however, that after the wound has been cauterized, the inſpiſſated ſerum having been firſt ever ſo carefully evacuated, that there will be a freſh collection of a vitiated fluid in the part. In order to prevent therefore an accident of this kind, let the patient be kept in a ſtrict courſe of purging, ſudorific and attenuating medicines, and the wound be kept open with tents, cleanſing it thoroughly every day, by throwing up an injection, ſuch as has been before directed. It may be proper alſo ſometimes to inject lime-water, and afterwards to cover up the part with a warm plaſter, or foment it with ſome liquor of the ſame intention. It is, however, finally to be obſerved, that it is not every fungous *Tumor* of the joints that can be opened with ſafety; for if the *Tumor* is of a very long ſtanding, hard, or of a very large ſize, or the patient is of an infirm weakly habit of body, the knife muſt not be thought of, as it would occaſion diſorders worſe than the firſt; to wit, caries, fiſtulas, and gangrene. *Heiſter*'s Surgery, p. 285.

We have an account of a very extraordinary *Tumor* in the knee of a perſon, whoſe leg was taken off by Mr. Peirce at Bath. The leg and foot weighed ſixty-nine pounds. See Phil. Tranſ. N°. 452. Sect. 4.

Windy TUMORS. Theſe *Tumors* are formed by the air incloſed under ſome membrane, which is dilated more or leſs by that air, according to its quantity, and from within which it cannot eſcape, at leaſt not of a certain time.

Theſe *Tumors* are uſually round, circumſcribed, or determinate, and if they are ſtruck with a finger, they give a ſound like that of a blown bladder. They have no particular ſeat in any part of the body, but almoſt every part is more or leſs liable to them.

The great difficulty in accounting for theſe *Tumors*, is to ſay how the air comes to be collected there; but the moſt probable cauſe ſeems to be the collecting together of a quantity of a

fluid in ſome adjoining part where there is ſome obſtruction. The air, which is naturally mixed with all the fluids in the human body, always remains in them while they continue in their fluidity, and in their natural motions; but when they are amaſſed together in any particular part, and their fluidity and motion become impaired, the air that was in them becomes immediately in a ſtate of diſengaging itſelf from them; and it uſually does ſo diſengage itſelf. The membranes of the part where this collection of the fluids is made, are relaxed by it, and their pores conſequently enlarged, and the air which has diſengaged itſelf, eſcapes eaſily by theſe pores, while the fluids are much too thick to be able to follow it, ſo that it eſcapes alone.

The air, thus ſeparated, runs under ſome other adjoining membrane, which it immediately elevates and diſtends. As the liquors amaſſed in the other place are not yet ſo far altered, but that part of them are continually received again into the road of circulation, and conſequently more freſh fluids left in their place: theſe freſh fluids contain more air, which is, by degrees, ſeparated from them, as from the others, and finds its way, in the ſame manner, to the place where the reſt of the air is; and hence is the continual increaſe of the *Tumors*; and it is very evident, that when a *Tumor* is once formed in this manner, it cannot go down, even though the firſt extravaſation, which occaſioned it, ſhould wholly diſappear, and all the fluids be again received into their veſſels again; but, in fine, the air included in the *Tumor* may dilate the membrane, which encloſes it, ſo far, that its pores may be ſufficiently opened to let it eſcape; this, however, wholly depends on its quantity, and on the cloſer or laxer texture of the membrane.

Thoſe acute pains which we call ſtitches in the ſide, and which are principally felt on the ſides, and about the region of the breaſt, may poſſibly be ſometimes occaſioned by acrid humours, which prick the nervous fibres; and the pain, in this caſe, is ſometimes very acute, and even attended with a ſharp fever; but very often this pain is occaſioned only by air included between the fibres, where it occaſions a violent tenſion and pain; but often the relief from this is ſudden, the natural elaſticity of the parts reſtoring all to their priſtine ſtate, and the air being condenſed again almoſt as ſoon as dilated. Very often the natural ſpring of the parts either entirely ſends off the air, or elſe drives it to another place; and this is the reaſon why pains of this kind are often found to ſhift about and change place ſo ſuddenly.

But of all the effects of air in the body, none is ſo great as that found in the bodies of thoſe who have died by loſs of blood, whether that has been occaſioned by wounds or natural hæmorrhages. There may, in this caſe, often be perceived, through the coats of ſome of the veins, little bubbles of air floating on the ſurface of the blood contained in them; and this is no way to be wondered at, ſince as a great part of the blood has been loſt out of the body by the hæmorrhage, the remainder has been by this much injured in its power of motion, as well by loſs of quantity to impel it, as of animal ſpirits to enliven it; and by the want of ſtrength in the arteries to perform their pulſations, in order to the keeping it in motion; the conſequences of theſe joint cauſes, according to the principles before laid down, muſt be, that the air muſt eſcape out of the blood, and appear freed as we ſee it.

If we perceive this only in the veins, the reaſon is plain, ſince there is no blood any where but in the veins of perſons who have died in this manner, the arteries having been already drained; whereas, in other bodies there always remains ſome blood, though but little, in the arteries. Another conſequence of dying by an hæmorrhage is, that the ventricles of the heart are always found empty of blood; which is not the caſe in thoſe who have died by other means. The cauſe of this is, that the force with which the veins drive up the blood from their extremities toward their larger trunks, and thence to the heart, is much weaker than that by which the arteries throw the blood they contain toward the extremities. This being allowed, a great loſs of blood cannot but diminiſh the force of the arteries and veins both; but its effect will certainly be greater on the veins; ſo that they may wholly loſe their force before the arteries have loſt theirs; and theſe laſt making at length one general contraction, may throw off all their contents into the veins, while they, having already loſt all their power, can no longer move it forwards; ſo that, in this caſe, it all remains there, and conſequently what blood remains in the body, muſt, on opening it, be found lodged in the veins.

It is ſometimes obſerved in bodies which have died of hæmorrhages, that the ſmaller veſſels, at conſiderable diſtances from the heart, have been all full and diſtended with wind; in this ſtate it is not impoſſible that they may have been ſometimes miſtaken for lymphatic veſſels; but in tracing them up to their trunks, they ſoon diſcover what they really are. After a large quantity of blood has been loſt, it is plain that there can be but little in the lungs, while the quantity of air is always equal there; and as the air always eaſily diſengages itſelf from the blood, when it is leſs fluid, and in ſmaller quantity than before, the air may, in this caſe, paſs from the lungs to the heart with the blood, without being ſo intimately mixed with it as at other times; when the arteries have, after this, not power enough to impel the blood into the veins, their power may yet be ſufficient to drive this wind into them, it being much lighter, and more ſuſceptible of motion; and this alone ſeems a very natural and eaſy ſolution of this phænomenon. This ſuppoſes, indeed, that the motion of the blood being ſtopped, death comes on, as well by this means, as by the ſtoppage of reſpiration. Mem. Acad. Par. 1714.

TUMORS *of the Teſticles*. See the article TESTICLES.

TUNA, in botany, the name by which ſome authors have called the *opuntia*, the Indian fig, or *ficus Indica*, as it is uſually called. *Jonſ.* Dendr. p. 57.

TUNALLUS, in ichthyology, a name given by Albertus, and ſome others, to that ſpecies of the coregoni called by the generality of authors the *thymallus*, by us the *grayling*, or *umber*. Artedi diſtinguiſhes it by the name of the *coregonus*, with the upper jaw longeſt, and with twenty-three rays in the back fin. See the article COREGONUS.

TUNG, in natural hiſtory, the name given by the Indians to a little inſect, called by the Spaniards *Piqué*, which is very common, and very troubleſome in ſome parts of the Eaſt and Weſt Indies.

It is of the ſize of a ſmall flea; its place of laying its eggs is within the ſkin of the human body, and it diligently ſearches opportunities of doing this, and often ſucceeds in the attempt, to the great pain and trouble of the perſon who ſuffers it. The creature, knowing that it ſhall be ſoon cruſhed to death under the ſkin, generally makes its way either under the nails, or where there is ſome callus on the ſurface; there it eats its way along, and, in fine, lays its eggs, which hatch into ſo many young ones, and ſpread themſelves between the fleſh and ſkin all over the finger and hand, if not prevented by taking out the old one in time.

The perſon often does not perceive the creature's getting in, it enters ſo gradually and eaſily; but he is ſoon adverti ſed of the place where it is by a violent gnawing pain, the creature really eating its way as it goes along. The only remedy in this caſe is, to enlarge the orifice at which it entered, and take it out whole; the wound ſoon heals up, and there is an end of the matter. This may often be done with the point of a needle; but if not, it is much better to ſubmit to the opening it with a lancet, than to the ill conſequences which otherwiſe will attend it. Obſerv. ſur les Coutumes de l'Aſie. p. 184.

TUNICA (*Cycl.*) TUNICA *Albuginea*, the name of the membrane that covers the body of the teſticles. It is of the ſame ſubſtance with others of the thicker membranes of the body, and is ſupplied with proper veſſels for its nouriſhment; but under this the body of the teſticle is, on a ſtrict examination, found to be only a congeries of veſſels rolled up in regular and even folds, without any intermediate ſubſtance of whatever kind. It is neceſſary to have recourſe to the uſe of glaſſes to ſee this ſtructure; and there is one caution neceſſary to the perſons who would make the experiment, which is, that as theſe veſſels all contain a liquor, which being ſomewhat thick and whitiſh, ſoon dries when expoſed to the air, and, in drying, acquires ſomewhat of the appearance of fleſh, it is very apt to deceive the inſpector into an opinion, that there is really a fleſhy matter in the ſubſtance of the teſticle, diſtinct from the veſſels: What will ſet this right, will be the obſerving, that the object, when newly cut, and immediately viewed, has none of this fleſh-like matter about it; but only a mucous humour may be ſeen ouzing from the mouths of the rolls or folds of the veſſels where cut; and that afterwards, when the fleſh-like matter becomes viſible, it is only ſeen about the ends and edges of the piece of the teſticle that is examined, and only in thoſe places where it was before ſeen ouzing out in form of a fluid from the apertures of the veſſels.

Theſe veſſels, of which the ſubſtances of the teſtes are compoſed, are extremely tender and fine; yet, while the ſubject is freſh, they may, by a delicate hand, be drawn out, and will ſometimes be extended to half a yard long without breaking. The ſingle veſſel, when thus extended, has much the appearance of the external coat of the epididymis, and its corrugations. Theſe tubes receive their contents in ſome ſort from the arteries, and have a communication with them, inſomuch that on injecting a coloured matter into the *arteria preparans*, and afterwards opening the teſticle, this matter will be found to have made its way into ſeveral of the tubes compoſing the rolls or folds of the ſubſtance of the teſticle.

It might be ſuppoſed, that this colouring of the tubes was only external, and that the matter of the injection had only ſpread itſelf on their ſurface, or penetrated into the plexus of veſſels that cover them; but, on trying to waſh off the colour with ſpirit of wine, it proves ſo permanent as not to give way to that; and, on curiouſly examining a part of a ſingle tube pricked with a fine needle, the coloured matter of the injection may be diſtinctly ſeen ouzing out of the puncture. The glands in general are no other than the teſtes; and the pancreas, and many other parts of the body, have no parenchyma or intermediate fleſhy ſubſtance between the veſſels, but are made up of veſſels or tubes filled with peculiar liquors, and generally owe their colour to that of the liquor they contain. No reputed gland is any other thing than a mere congeries of veſſels, through which peculiar juices come and go; and the very

coats of the larger veſſels ſo much approach to this ſtructure, that, though not wholly compoſed of other veſſels, they have ſo many in them, that the far greater part of their ſubſtance is made up of thoſe veſſels, and of the fluids which are continually paſſing through them, and which keep open their paſſages.

Theſe liquors being deſtined for the ſupport of the coat of the veſſel, are in general the ſame with that which flows within it.

As to the teſticles being wholly compoſed of theſe veſſels or tubes, without any other ſubſtance, it is, perhaps, carrying the matter too far, to aſſert it in ſuch abſolute terms. That there are certain membranes, connecting ſeveral of the veſſels into, as it were, one roll or tube, appears in the nice examination of the teſticles of the rabbit, and ſome other animals; and though there be no parenchyma, or fleſhy ſubſtance, yet it is very probable, by the lubricous appearance of theſe veſſels on the outſide, that there is originally among and between them a mucous or ſlimy matter, which may ſerve in the place of a parenchyma. Philoſ. Tranſ. N°. 53.

TUNICATED *Roots*, among botaniſts, ſuch as are formed of a multitude of coats ſurrounding one another. See the article ROOT.

TUNNEL-*Net* (*Cycl.*)—This net muſt be made of three-twiſted thread, and muſt not be too thick: It ſhould be dyed green, that the colour may give no ſuſpicion to the birds, and the meſhes ſhould be about two inches and a half broad.

Into the hind meſhes, at the larger end, there muſt be put a ſmooth wooden rod, about the bigneſs of a gun-rammmer; of this muſt be made a ſort of hoop, both ends being tyed together, and at different diſtances from one another, there muſt be placed many more ſuch, which are to be rounded in the ſame manner, and are to ſupport the net its whole length in the tunnel form. Two ſtakes, or ſtrong pegs, muſt be faſtened at the ſides of the entrances into the net, and one at the farther end, or narrower part; the two firſt are to keep the mouth of the net ſufficiently extended, and the laſt is to keep it pulled out lengthwiſe to its full dimenſions, the hoop preventing its falling in.

There muſt be uſed with this net two others of that kind, which they call *halliers*. Theſe are long and ſtrait nets, and are to be faſtened down to the mouth of the *Tunnel-net* on each ſide, extending ſeven or eight fathoms on each ſide from it, ſo as to take in fourteen or ſixteen fathoms in front, beſide the breadth of the mouth of the *Tunnel-net*, and to direct all that ſhall move forward within that compaſs into the net.

In order to uſe this net, a covey of partridges is to be found, and then the net is to be placed at a conſiderable diſtance behind them: When this is fixed, the ſportſman is to take a compaſs, and get before the birds with a ſtalking horſe or ſtalking ox, and then to move forward, driving them towards the net. This is to be done gently, and carefully, they are not to be driven at once ſtrait forwards; but the ſportſman is to wind and turn about, and, at times to ſtand ſtill, as if the horſe was grazing. If the partridges, in the time of driving, make a ſtand, and look at the machine, it is a ſign they ſuſpect it, and are ready to take wing: In this caſe the ſportſman muſt ſtand ſtill, or even go back a little; and when they are become compoſed again, he is again to advance upon them. If any ſingle bird lies remote from the reſt, the ſportſman muſt take a compaſs round him, and fetch him in; for if he takes wing the reſt will all follow; in this manner, with patience and caution, the whole covey may be driven like a flock of ſheep up to the nets. A real horſe, trained to the purpoſe, is, however, much better than a ſtalking machine.

The halliers, or wings of the *Tunnel* muſt not be pitched ſtrait, but in a ſort of ſemicircle; and the birds, when they ſtop their march, will run along them to the middle, where the mouth of the *Tunnel* is open.

When they come to the mouth of the *Tunnel*, the old ones will make a ſtand, as if to conſider what was before them; but on preſſing gently on them with the horſe, the young ones will run in, and then all the reſt will follow.

The ſportſman muſt then make all the haſte he can to the mouth of the net, to ſecure them from coming back again.

The ſtalking-horſe is to be made of canvas or linnen, painted in the figure of a horſe, and ſupported by two croſs ſticks, by which the ſportſman carries it before him, ſo that his own body is compleatly hid by it. There are to be holes made through it, by which the ſportſman ſees his game; and the tail is to be made of hair, and to hang looſe from the body, that it may play in the wind in moving.

TUNNY, a name given by us to the Spaniſh mackrel, a larger fiſh of the ſcomber kind, called by authors *thynnus* and *arcynus*, by Salvian *limoſa*, and *pelamys* by Ariſtotle, Ælian, and the other old writers. See Tab. of Fiſhes, N°. 29.

It is properly a ſpecies of the ſcomber, and is expreſſively named by Artedi, the ſcomber with eight or nine fins in the hinder part of the back, riſing out of a furrow; and a furrow at the place of the belly-fins. See the articles THYNNUS and SCOMBER.

TUNUPOLON, in zoology, the name of an Eaſt Indian ſpecies of viper, found principally in the iſland of Ceylon. It is of a ſmall ſize, and of a fine ſattin-like gloſs, beatifully variegated with different ſhades of brown. *Ray*'s Syn. An. p. 332.

TUPUTA, in zoology, a name under which Nieremberg has deſcribed an American bird, which, he ſays, is like a pheaſant in ſhape, and loves low buſhes and ſedgy places, never flying into high trees, and which has no fleſh, but merely a vaſt aſſemblage of living worms between the ſkin and the bones. Mr. Ray has ſufficiently laughed at the abſurdity of this account; which probably had its origin from the diſtempered ſtate of one bird of ſome well known ſpecies; though Nieremberg thinking the worms a ſufficient character, has given no farther account of it. *Ray*'s Ornithol. p. 298.

TURBAN-*Shell*, *Cidaris*, in natural hiſtory, the name of a genus of the echinodermata, which are of a hemiſpheric or ſpheroidal figure, and have their name from the Latin *Cidaris*, a *Perſian Turban*, as in ſome degree reſembling that headdreſs. See Tab. of Teſtaceous and Cruſtaceous Animals, N°. 1, 2, 3, 4.

Of this there are ſeveral kinds: 1. The *Cidaris miliaris*, ſo called from its eminences or tubercles, being as ſmall as the grains of millet. Of this there are three known ſpecies; one with a high top, a ſecond with a flatter and more of a hemiſpheric figure, and a third which is ſomewhat angular.

The ſecond kind is the *Cidaris variolata*. The eminences of this are of a middle ſize, between thoſe of the miliary and mammiliary kinds, and ſomewhat reſemble the puſtules of the ſmall-pox when ripe, whence they have their name. Of this kind there are three known ſpecies: 1. The briſly echinus of Rumphius. 2. The ſmall ovarius of Langius. And 3. The Turk's *Turban* of moſt authors. And to theſe may be added a fourth, a very remarkable one of an elliptic form, with very few tubercles, and a large mouth. *Klein*'s Echinod. p. 17.

The third kind is the *Cidaris mammillata*, or the mammillary echini. The tubercles of theſe are very large, and imitate the appearance of breaſts, with nipples to them. Of theſe alſo there are two known ſpecies. 1. The fingered echinometra of Rumphius. 2. The ſpecies called the *moor's Turban*.

The fourth kind is the *Cidaris coronalis*; the tubercles of which are ſo diſpoſed as to make it repreſent the diadem of antient kings. Of this there is only one known ſpecies, and that extremely rare.

The fifth kind is the *Cidaris corollaris*; the tubercles of which are ſo diſpoſed, as to imitate the garlands made of flowers. Of this there are two known ſpecies, the one thicker, and the other thinner.

The ſixth kind is the *Cidaris aſteriſans*. Of this there is only one known ſpecies, the tubercles of which are diſpoſed in form of a radiating ſtar.

The ſeventh is the *Cidaris aſſulata*, or tiled *Cidaris*. This is ſo called, becauſe the ſeveral parts of the ſhell are joined tranſverſely to one another. Of theſe there are eight known ſpecies. 1. Olearius's ſpecies, compoſed of twenty orders of aſſulæ. 2. Aldrovandus's *echinometra maxima pelagica Sardica*. 3. The flammated kind, the vertex of which has ten rays, like ſo many flames. 4. The variegated kind, whoſe tubercles are variegated with white, and a fine roſe colour. 5. The puſtuloſe kind, which is thick beſet with tubercles, reſembling ripe puſtules. 6. The granulated kind; the tubercles of which are very ſmall. 7. The ſmooth kind, with a flat crown. 8. That ſpecies called by Mercatus *anachytis*, which has a very gibboſe back.

The eighth kind is the *botryoide Cidaris*. Of this there is only one known ſpecies, which bears a very great reſemblance to the central part of the ſea ſtar-fiſh, with contracted fragments of the rays.

The ninth kind is the *Cidaris toreumatica*. This has its name from the Latin *toreuma*, ſignifying a chaſed or wrought plate, the ſuperficies of this being as if chaſed and engraved into figures. There is only one known ſpecies of this genus.

This claſs of the echinodermata is made out by the aſſiſtance of the foſſile, as well as the recent animals; many of the kinds being now unknown on any ſhores. Id. Ibid.

TURBINATA *Oſſa*, the name of the turbinated bones of the noſe. See the article NOSE, *Cycl.*

TURBINATUM, a name given by ſome to the glandula pinealis.

TURBINES, in natural hiſtory. See the article TURBO.

TURBINITÆ, foſſile ſhells of the turbo kind, or ſtones found in thoſe ſhells. Among the people who have objected to the ſhells found buried in the earth being the remains of real animals, it has been alledged by ſome, that theſe in particular are always of a blackiſh or aſh-colour, when found in chalk or clay, and white from the rocks, or when they have been bedded in ſtone.

To this Auguſtino Scilla has very judiciouſly anſwered, that the *Turbinitæ* found in chalk and clay, are not the real ſhells, but are ſtones which have been formed in thoſe ſhells, the ſhells themſelves, which gave ſhape to them, being decayed and gone; whereas thoſe found bedded in ſtone, are, at this time, the ſhells themſelves, preſerved in their natural beauty by the hardneſs of the bed they lie in; or, if not real ſhells, that the only ſtone which can form itſelf there being ſpar, that is white, and the ſhells giving origin to ſuch a ſtone will

appear

appear as white in its ſubſtance, or more ſo, than they would in their own. *Auguſtino Scilla*, de Petrifac.

TURBAT, in ichthyology, the ſame with *Turbut*. See the article TURBUT.

TURBIT *Pigeon*, a particular ſpecies of pigeon, remarkable for its ſhort bill, and called by the Dutch *cort bek*, that is, ſhort-beak. Moore calls it in Latin, *columba fimbricata*: And its Engliſh name ſeems no other than a bad pronunciation of its Dutch one. It is a ſmall and ſhort-bodied pigeon, and has a beak no longer than that of a partridge; the ſhorter this is, the more the pigeon is eſteemed: It has a ſhort round head, and the feathers upon the breaſt open, and reflect both ways, ſtanding out like the frill of the boſom of a ſhirt. This is called by many, the *purle*, and the more the bird has of it, the more it is eſtemed. The tail and back are generally of one colour, as blue, black, red, yellow or dun, and ſometimes chequered. The flight feathers, and thoſe of all the reſt of the body, are white. They are a light nimble pigeon, and, if trained to it, will take very high flights, in the manner of the tumblers. *Moore*'s Columbarium, p. 53.

TURBITH (*Cycl.*)—There is great uncertainty and confuſion among the old writers, in regard to the drug called by this name. Aviſenna, and the reſt of the Arabian phyſicians, all preſcribe *Turbith*; and we are apt to believe, that they mean our *Turbith*-root; but it does not appear ſo either from the form or virtues of that medicine.

All the writers of later ages have placed the *Turbith*-root among the things of value and uſe, brought as merchandize from the Eaſt Indies; and Garcias juſtly deſcribes the plant: But his deſcription plainly proves, that it cannot be the *Turbith* of the Arabians; for all that they have ſaid about the *Turbith* is tranſlated from Dioſcorides, and he has ſaid it of the tripolium.

The tripolium of the Greeks is therefore the *Turbith* of the Arabians, and this is a very different thing from the *Turbith* of our times. Meſue indeed ſeems to make the *Turbith* a different thing from what all the others have made it; he ſays, that it is the root of a plant of the lacteſcent kind, which had leaves like the ferula or fennel giant. This is a deſcription that can by no means agree either with the tripolium of the Greeks, or the *Turbith* of Garcias; and proves, that if Meſue was right in ſaying it belonged to the plant, of which what he calls *Turbith* was the root, then his *Turbith* is different from both the one and the other of theſe. Some other of the writers on theſe ſubjects have alſo called two roots, different from all theſe, by the names of white and black *Turbith*. The black *Turbith* is the pityuſa-root, a kind of ſpurge; and the white *Turbith* the root of the alypum.

Aviſenna calls the *Turbith*, *terbadh*. Some have ſuppoſed this word expreſſed a thing different from all the others; but this is by no means the caſe, for the *Turbith*, or *turbadh* of Aviſenna is the ſame with the *Turbith* of Serapion, that is, with the tripolium of Dioſcorides.

From this *turbadh* of the Arabians, the later Greek writers have formed the word τερβιθ; but they have applied it, in a very looſe and vague manner, to ſeveral very different things. Neophytus makes the *Turbeth* a ſpecies of myrobalan; but in this he errs, no other author having ever underſtood the word in that ſenſe. Upon the whole, it appears, however, that there are three different plants, called *Turbith* by authors, the tripolium, the pityuſa, and the alypum; but all theſe are different from the Indian *Turbith*, which is the *Turbith* of Garcias, and the *Turbith* of our ſhops. There is alſo in one part of Aviſenna an account of *Turbith* different from all theſe, and making it a kind of wood.

TURBITH-*Mineral* has been uſed as a ſternutatory, and is ſaid to have made wonderful cures in diſtempers of the eyes. Mr. Boyle relates a cure of this ſort, performed by the famous empiric Adrian Glaſs-maker on Mr. Vatteville, a Swiſs officer of diſtinction in the French ſervice, and totally blind. This gentleman was ordered to ſnuff about a grain of *Turbith* up each noſtril, which immediately operated in a violent manner by vomit, ſtool, ſweat, ſalivation, and the lacrymal glands, for twelve hours together; and alſo cauſed his head to ſwell greatly; but within three or four days after this ſingle doſe had done working, he recovered his ſight. *Boyle*'s Works abr. vol. 1. p. 103.

TURBO, the *Screw-Shell*, in natural hiſtory, the name of a genus of ſhell-fiſh, the characters of which are theſe: They are univalve ſhells, with a long, wide, and depreſſed mouth, in ſome ſpecies approaching to a round ſhape, and in ſome having teeth, in others not. They all grow narrow toward the baſe, and are auriculated, and terminate in a very long and ſharp point. See Tab. of Shells, N°. 11.

Aldrovand, and many others of the old authors, make no difference between the *Turbines* and ſcrew-ſhells, though the diſtinction of the genera is very obvious; the ſcrew-ſhells having a long, large, and dentated mouth, which terminates toward the baſe in a narrower aperture than elſewhere: And the ſhell itſelf always runs to a very ſharp point at the end; whereas the *Turbines* terminate in a leſs ſharp point, and have thicker bodies, and always much wider mouths. The ſcrew-ſhells are indeed very eaſily confounded with the buccina; and it requires more accuracy to diſtinguiſh them, than has fallen to the ſhare of the generality of writers on theſe ſubjects an age or two ago. Aldrovand and Rondeletius have confounded theſe genera, and have brought in a third among them, by the epithet *muricatum*, which, when applied to the buccinum, is generally obſerved to bring into that family a ſhell of the murex claſs, and which might have been very properly called by that ſhorter name.

That theſe may be, however, more juſtly diſtinguiſhed for the future, it may be proper to add the genuine character of the *ſcrew-ſhell*; which is, that it is of a very long and ſlender ſhape, and ends in a very ſharp point. Its ſpires run on imperceptibly, without any great cavity, and the baſe is ſmall and flat, as is alſo the mouth. Liſter, who was for making all the long ſhells buccinums, calls the ſcrew-ſhell, the intervals of the ſpires of which are deep, a long twiſted buccinum, with a flat mouth. Fabius Columna has confounded yet more the genera of ſhells together; he brings in the trochus into the family of the buccina; and tells us, that the words *ſtrombus*, *trochus*, *rhombus*, and *Turbo*, which he calls the poetical name, are all ſynonymous terms, and expreſs the ſame ſort of ſhell. *Liſter*, *Fabius Columna* Aquat. & Terreſtr. P. 59. p. 65.

To avoid the obſcurity which muſt naturally ariſe from ſuch confuſion of words, it is proper to obſerve, that *Turbo* and *ſtrombus* are derivatives of the ſame Greek word στρεφω, to turn, and therefore are, properly, but one word in ſenſe, and always to be accepted as ſynonymous terms, and ſignifying a long and ſlender ſhell, whoſe baſe and apex are both very ſmall. *Bonani* Recreat. Ment. & Occul. p. 126.

The trochus has a ſmall mouth, but then its baſe is large and flattiſh, and its conic figure is one of the characters of its genus. Thus is this diſtinguiſhed from the former; and as to the *rhombus*, when we have obſerved, that, though the word properly ſignifies a lozenge figure, it is uſed in ſhells for the name of a cylindric kind; it will appear, from the whole, that theſe four words are not all ſynonymous, but that three diſtinct genera are meant by them, the firſt two only being of the ſame ſignification.

The moſt remarkable ſpecies of the *Turbo* or ſcrew-ſhell, is that called *ſcalare* by Rumphius, from its ſpires running up hollow, or with a ſpace between them. This is a very ſcarce and valuable ſhell, when large, but is often found ſmall in the Adriatic.

The ſpecies of the *Turbo* are ſo numerous, that it is proper to arrange them under different heads.

1. Of the *Turbines* which have a long and toothleſs mouth, and a wrinkled columella, theſe are the following ſpecies: 1. The nail-*Turbo*, variegated with blue ſpots. 2. The awl-*Turbo*, with yellow perpendicular lines. 3. The *Turbo*, with points diſpoſed in circles. 4. The ſpotted and lineated needle-*Turbo*. 5. The ſcrew-*Turbo*, with variegated lines and ſpots. 6. The whitiſh reticulated and granulated *Turbo*. 7. The virgated and corded *Turbo*.

2. Of thoſe *Turbines* which have dentated mouths and a wrinkled columella, we have the following ſpecies: 1. The faſciated contabulated *Turbo*. 2. The *Turbo*, called the child in ſwadling clothes.

3. Of thoſe *Turbines* which are of a pyramidal figure, and have depreſſed mouths, we have the following ſpecies: 1. The teleſcope-*Turbo*, with tranſverſe furrows. 2. The whitiſh *Turbo*, with yellow circular lines. 3. The Chineſe pyramid or obeliſk *Turbo*. 4. The rough *Turbo*, with elated rows of tubercles. 5. The granulated and lineated little tower *Turbo*.

4. Of thoſe *Turbines* which have long and erect mouths, we have the following ſpecies: 1. The alated borer *Turbo*. 2. The whitiſh borer *Turbo*. 3. The variegated borer *Turbo*. 4. The lineated borer *Turbo*.

5. Of thoſe *Turbines* which have a flat mouth, and are of a longer ſhape, theſe are the following: 1. The contabulated and roſtrated caterpillar-*Turbo*: this is covered with tubercles, and has blue ſpots and lines. 2. The white roſtrated caterpillar-*Turbo*, with many tubercles and ſpires.

6. Of thoſe *Turbines* which have a large oval mouth, we have the following: 1. The *Turbo* called *vitta*, with black, yellow, and red veins. 2. The claviculated and variegated agate-coloured *vitta*. 3. The whitiſh *vitta*, with a variegated clavicle.

7. Of the round-mouthed *Turbines*, we have the following ſpecies: 1. The hollowed wreathed *Turbo*. 2. The bone-coloured *Turbo*, with twenty wreaths, depreſſed into ſeveral ſinuſes. 3. The yellow and white thick-wreathed *Turbo*. 4. The *Turbo* with ſeventeen furrowed wreaths. 5. The ſcalar *Turbo* of Rumphius, with white lines. 6. The aurited *Turbo* of Rondeletius. Hiſt. Nat. Eclairc. p. 271.

TURBO *Cochlea*, in natural hiſtory, a name by which ſome authors have called the Perſian ſhell, a ſpecies of *concha globoſa* or *dolium*.

Many have been puzzled with this ſhell, not knowing in what claſs to rank it; and Aldrovand has placed it at the end of his work, ſaying, that it would ſeem to belong to the turbinated kinds, but that it wants the *Turbo*. See the article DOLIUM.

TURBUT, in ichthyology, a name given by us to the fiſh called by authors the *hippogloſſus*, *paſſer major*, and *paſſer Britannicus*.

According to the new ſyſtem of Artedi, this is a ſpecies of the pleuronectes, and it is diſtinguiſhed by him by the name of the wholly ſmooth pleuronectes, with the eyes on the right ſide. See the articles HIPPOGLOSSUS and PLEURONECTES.

TURCICA *Terra*, *Turkey Earth*, in the materia medica, a very fine bole or medicinal earth, dug in great plenty in the neighbourhood of Adrianople, and uſed by the Turks as a ſudorific and aſtringent, and famous among them in peſtilential diſeaſes. It is ſometimes brought over to us alſo, made up into flattiſh orbicular maſſes, of two or three drams weight, and ſealed with ſome Turkiſh characters. This earth is of a ſomewhat lax and friable texture, yet conſiderably heavy, of a greyiſh red colour, but always redder on the ſurface than within; extremely ſoft, and naturally of a ſmooth ſurface. It breaks eaſily between the fingers, and melts freely in the mouth, with a conſiderably ſtrong aſtringent taſte. It adheres but ſlightly to the tongue, raiſes no efferveſcence with acids, and burns to a duſty yellow colour. *Hill*'s Hiſt. of Foſſ. p. 15.

Many authors who have written of the materia medica, and of foſſils in general, have indiſcriminately called the various kinds of Lemnian earth by this name; but the true *Terra Turcica*, deſcribed by Schroder, Wormius, *&c.* is a different ſubſtance, though not ſufficiently characteriſed by thoſe authors to diſtinguiſh it from all the other earths.

TURCOIS (*Cycl.*)—See the Appendix.

TURDUS, in the Linnæan ſyſtem of zoology, the name of a genus of birds, of the order of the paſſeres. The diſtinguiſhing characters of this genus are, that the tongue is jagged, and has a rim or margin round it; the bill is of a conic pointed figure, a little convex, and naked at the baſe. *Linnæi* Syſt. Natur. p. 49.

This genus comprehends the thruſh, black-bird, and ſtarling. The diſtinguiſhing characters of this genus, according to Mr. Ray, are theſe: They are of a middle ſize between the pigeon and the lark. Their beak is moderately long and thick, and is a little bent downwards; their mouth yellow within; their tail long; and their food both vegetable ſubſtances, and inſects in common. Moſt of theſe birds ſing very melodiouſly, and may be taught to imitate the human voice in ſpeaking. *Ray*'s Ornithol. p. 137.

There are three ſubdiſtinctions of the *Turdus* kind: 1. The thruſh, called by authors ſimply *Turdus*. 2. The merula, or black-bird, diſtinguiſhed by its dark colour: And 3. The ſtrurnus or ſtarling, known by the breadth and flatneſs of its beak. We have four ſpecies of thruſh in England: 1. The *Turdus viſcivorus major*, or miſſel-bird. 2. The *viſcivorus minor*, or ſong-thruſh, or mavis. 3. The *Turdus pillaris*, or field-fare. And 4. The *Turdus iliacus*, or ſwine-pipe. See the articles MISSEL-*Bird*, MAVIS, FIELD-*Fare*, and SWINE-*Pipe*.

The two firſt of theſe build and remain the whole year with us, the others only viſit us in winter. Id. ibid.

TURDUS *Chiappæ*, in zoology, the name of a bird of the Weſt Indies, oddly and imperfectly deſcribed by Nieremberg, and ſaid to be very dexterous at filling a pine with acorns, which are its only food, by making holes in its bark. Theſe it fixes in ſo nicely, that it is not eaſy to get them out; and theſe are its ſtore, which it eats occaſionally. It is, from this practice, called alſo *paſſer faber*. *Ray*'s Ornithol. p. 303.

TURDUS, in ichthyography, the name of a genus of fiſhes, of the claſs of thoſe which have only one back-fin, the anterior rays of which are prickly; the hinder ones ſoft and ſmooth.

Of theſe fiſhes there are ſeveral ſpecies, which may properly be divided into two orders; the firſt, of thoſe which are ſmaller and broad; the ſecond, of thoſe which are larger and oblong.

Of the firſt order are the *tinca marina*, or wraſſe. See the article WRASSE. The *merula*, or *Turdus niger*. See the article MERULA. The *lepros*, and *pira pixanga*, which ſee. And the *Turdus viridis* or *verdone*. See the article VERDONE. *Ray*'s Ichthyogr. p. 320.

Of the ſecond order are the *pavo*. See the article PAVO. And the *Turdus viridis major*, and *Turdus fuſcus maculoſus*.

The *Turdus viridis major*, or great green *wraſſe*, is of a fine green on its back and ſides, even to the ſide-lines; and the lower part of the ſides and belly are of a pale whitiſh yellow, variegated with greyiſh and pale blue ſpots. Its body is long, and not much unlike that of the pike in figure. Its back-fin is long, and has thirty-two ribs, the anterior nineteen of which are rigid and prickly, the hinder twelve ſoft, flexile, and ramoſe. The ſcales are large, the eyes ſmall, and the teeth very large and ſtrong.

The *Turdus fuſcus maculoſus*, or brown ſpotted wraſſe, ſcarce at all differs from the other, except in colour. It is of a duſky hue on the back and ſides, variegated with blue ſpots; and on the belly blue, with lines and ſpots of red. All the fins, except thoſe of the gills, are of a red colour, ſpotted with blue; the tail alſo is of this colour, and the gill-fins are yellow. *Ray*'s Ichthyogr. p. 322.

TURF (*Cycl.*)—TURF *Sweating*, an Indian method of curing diſeaſes, which has been found to ſucceed very happily on many trials.

Paul Dudley, Eſq; gives an account of a man of ſeventy-four years old in New England, who drinking cold water when very hot, had a pain ſettled in one ſide and arm, which baffled all art to remove; till after nine weeks confinement to his bed, when he was given over by every body, it was propoſed to try this method of cure upon him.

An oven-full of *Turf* was ordered to be cut; the *Turfs* were of about eighteen inches ſquare each, and were of the nature of the Engliſh *Turf* uſed in Gardens.

The Indian doctor, before the *Turf* was put into the oven, rubbed over their graſſy ſide with ſome ſort of oil or ſpirit, and then putting the two graſs ſides together, placed them in the oven. When they had been two hours there, and were well baked, he took them out, and made a bed upon the floor, the place for the head being a little raiſed: The old man was then taken out of bed without his ſhirt, but wrapped in a ſheet, and being laid on the *Turf*-bed, ſuch another parcel of the hot *Turf* was laid over him. The *Turf* was laid thickeſt on that ſide where the pain was, but none of it was put upon his breaſt or head.

He was then covered with a blanket to keep in the heat; and while he was in this warm bath, he was continually ſupplied with warm cordials to keep him from fainting, of which he was in great danger. After he had lain in this bath about three quarters of an hour, which was as long as he could bear it, he was put into a bed very well warmed, without his ſhirt, where he ſoon fell aſleep, and ſweated to that degree, that it run through the pillow and bed on the floor. After about two hours ſweat, they rubbed and dried him, and put on his cloaths; and the old gentleman found himſelf much eaſed and refreſhed. The operation was performed in the morning, and before night he walked about the houſe comfortably, his pain being almoſt all gone. The cordials were, after this, repeated, and, on the fourth day, the ſweating was performed again; the day after which the old gentleman was well enough to go about his buſineſs. He lived eleven years afterwards in perfect health, and free from pain.

Great care is to be taken in this operation, that the patient do not lie too long in the *Turf*: In many caſes, a quarter of an hour is found to be long enough; and the general rule is, that as ſoon as the patient begins to fetch his breath ſhort or faint, he muſt be put to bed immediately, and the cordials muſt by no means be omitted; for the life of the patient is endangered without them. Philoſ. Tranſ. N°. 384. p. 129.

TURKEY, in zoology. See the article MELEAGRIS.

TURKINS, in our ſtatutes, is uſed for a ſky-coloured cloth. Stat. 1 R. 2. c. 8. *Blount*.

TURMERIC (*Cycl.*)—A plaſter of *Turmeric*, well bruiſed, top and roots, is thought to be good againſt the bite of the ratttle-ſnake. See Phil. Tranſ. N°. 479. p. 144.

TURN, (*Cycl.*) in mining, is a pit ſunk in ſome part of a drift. If the mine be deep, there are many of theſe *Turns* one below another. *Houghton*'s Compl. Miner, in the Explan. of the Terms.

TURN, in the manege, is a term commonly uſed in directing to change hands. See the article CHANGE and ENTIER.

TURN, in the ſea language. See the article LAND-*Turn*.

TURNEP, *Rapa*, in botany. See the article RAPA.

It is but of late years that the farmers have brought *Turneps* into uſe, as an improvement of their fields. All ſorts of land, when made fine either by dung and tillage, or by tillage alone, will produce *Turneps*, but not all equally.

Chalky land is too dry for them, and they are ſo long on it before they get into the rough leaf, that the fly often takes them, and they are deſtroyed. Sometimes, however, they ſucceed well in this ſort of land, though rarely. Charlock is a weed very apt to infeſt *Turnep*-lands, and when the *Turneps* and this are both young, they are ſo alike, that there have been inſtances of the people ſent to weed, miſtaking one for the other, and cutting up all the *Turneps*, and leaving all the charlock.

Sandy and gravelly land are found to be the beſt for *Turneps*, becauſe theſe ſoils are moſt eaſily pulverized, and have a warmth that makes the *Turneps* grow much faſter than they would in a colder ground. By this means they are preſerved from the danger of the fly, which only infeſts them while not yet grown into the rough leaf; and this ſort of ſoil, when well tilled and hoed, never wants moiſture even in the hotteſt weather. The dews reach as deep as the plough or hoe penetrates, which is ſix or eight inches; and the ſun's heat with us is never ſo great as to exhale it wholly from that depth. *Tull*'s Horſehoing Huſbandry, p. 44.

When *Turneps* are ſowed by hand, and hoed by hand-hoers, the plants grow too cloſe, and the operation is never half performed, the workers uſually leaving one half of the land unhoed, and covering it with the earth they cut up from the other parts; ſo that the weeds there being only buried an inch or two deep, grow more vigorouſly than before. The true method is to ſow them by the drill, and horſe-hoe them afterwards. By this means the plants are kept at a proper diſtance, and the earth opened between them. The effect of this, upon a fair trial, has been proved to be, that the drilled *Turneps*, when gathered, have been twice the quantity of the ſown ones, upon an equal quantity of ground, though the hand-hoing of the latter had coſt at the rate of ten ſhillings an acre.

In the method of drilling, they are ſure to come up quickly, becauſe in every row half the ſeed is planted at four inches

deep, from which, or even a greater depth, this ſeed will come up well; and the other half is planted exactly over that at half an inch depth, falling in upon the earth that has covered the firſt half. Thus planted, if the ſucceeding weather be ever ſo dry, the deep half of the ſeed will certainly come up; and if it chance to rain much ſoon after the ſowing, then the ſhallow half will be up firſt. The plants may alſo be made to come up at four ſucceſſive times, by mixing the ſeed half new and half old, for the new will be ſure to come up two days, or thereabout, before the old.

Turnep-ſeed ſhould always be ſown in this manner, in order to its eſcaping the danger of the fly, which otherwiſe often deſtroys whole fields of the young plants; but theſe four chances ſecure it; for though one coming up ſuffers, another eſcapes it, being often found, that the ſeed ſown over-night has been ruined by the fly, while that ſown the next morning has wholly eſcaped.

When the fly is found likely to devour them, they may be horſe-hoed; this will bury the greateſt part of thoſe animals; or they may be drilled in another row, without new ploughing the land. This fly feeds only on the two firſt or ſeed-leaves of the *Turnep*, which are very ſweet; the following leaves are rough, and do not ſuit its taſte; ſo that if the plants eſcape being eaten up while in the ſeed-leaves, they eſcape entirely.

The moſt infallible of all methods of preventing the miſchief from this fly, is to make the ground very fine, and then roll it with a heavy roller acroſs the ridges, after it is drilled; this method cloſes up the cavities in the earth, and prevents the fly's entrance or exit to lay the eggs, hatch, or bring forth the young ones, to prey upon the *Turneps*. This rolling always diſappoints the fly; but it ſometimes alſo diſappoints the owner, if he has ſown the crop by hand in a ſcattering manner. Theſe ſeeds, lying near the ſurface, are injured, and the ground, hardened by the rolling, will not let them grow well, but they become yellow, dwindle, and come to no perfection, unleſs they have a thorough hoing, as ſoon as the rough leaves appear. The drilled *Turneps*, being in ſingle rows, with ſix-foot intervals, may be rolled without danger; for, be the ground ever ſo hard, the hand-hoe will eaſily ſingle them out to a proper diſtance, at the expence of ſix-pence an acre, or leſs, if not in harveſt, and the horſe-hoe will plough in thoſe wide intervals to great advantage, whether the ſeaſon be wet or dry. Three or four ounces of ſeed in the drill way, anſwers for as much land as three or four pounds in the hand-ſowing; and there is this other advantage, that the plants, all ſtanding in rows, will be eaſily diſtinguiſhed, and properly ſingled out to their due diſtances, while very young; which is a thing of great advantage, as they thrive much the better for being early ſeparated from their uſeleſs neighbours. The ſix-foot ridges, whereon *Turneps* are drilled in ſingle rows, may be left higher than for double-rowed crops; becauſe there will be more earth in the intervals, as the ſingle rows take up leſs.

There is no prefixed time for planting *Turneps*, becauſe the nature of the ſoil muſt be conſulted; ſome land will bring them as forward when planted in Auguſt, as other land will when planted in May; but the uſual time is the middle between theſe, that is, about Midſummer. It is a practicable ſcheme, when *Turneps* are planted in rows, with theſe large intervals, to ſow wheat between. In the latter end of September, when the *Turneps* are full grown, a ridge is to be ploughed in the middle of each of the intervals, taking the earth to the ridge in ſuch quantity, as only to leave enough with the *Turneps* to keep them alive; wheat is to be drilled on this ridge: Toward ſpring the *Turneps* are, in this caſe, to be pulled up, and carried off the ground. The wheat being now left alone, the land is to be well horſe-hoed in the intervals. In Spring the wheat may be ſown in treble rows, and will afford a good crop. If the *Turneps* ſtand ſo thick in theſe ſingle rows as to touch one another, when half grown, provided the intervals between the rows be well horſe-hoed, they will yet attain to their full bigneſs; and they are often found to have thruſt one another out of ſhape, and become oval inſtead of round.

It is beſt to give the firſt hoing alternately; that is, to hoe only every other interval; this keeps them from being ſtunted, and it proves better thus to give them their food at twice, than to do it all at once. Id. Ibid.

In horſe-hoing it is not well to come nearer than within three inches of the ſides of the rows; but where the *Turneps* are planted in double rows, as ſoon as their roots are grown as large as a finger, the prong-hoe is to be uſed between the plants; and even in that little ſpace of three inches, left by the horſe-hoe, when they are in ſingle rows. Four of the alternate hoings in the intervals are found, on trial, to be equal in uſe to four whole hoings, though they are done at half the expence; for this half-hoing furniſhes the *Turneps* with as much nouriſhment as they require, and 'tis in vain to give more.

Dry weather is very injurious to *Turneps*, when ſown in the common way, and only hand-hoed; becauſe the hoe, in this caſe, does not penetrate deep enough to keep the ground moiſt; but in horſe-hoing the earth is cut ſo deep, that it is always kept moiſt, and a dry ſeaſon does the crop no hurt. Dung and tillage will, in all caſes, do their buſineſs quicker than tillage alone. On this principle, *Turneps* have more occaſion for dung than any other plants, becauſe they have leſs time to grow.

Twelve pound weight may be eſteemed the middle ſize for the great *Turneps*, and they ſometimes grow to ſixteen or nineteen pound weight. The farmers great intereſt in them is their ſize; and it ſeems evident that every *Turnep* in a field may be made to grow to its full ſtandard, or the largeſt ſize that nature has allotted it, provided it be properly managed, and nouriſhment ſupplied in a due manner. The greateſt inconvenience that attends *Turnep* huſbandry, is, that when they are to be eaten off in the Spring, which is their chief uſe, they do not leave time for bringing the land in tilth for barley; and the loſs of a crop of this is more than the gain by the *Turneps*; but this is wholly remedied by the horſe-hoing huſbandry, in which the land may be almoſt as well tilled before the *Turneps* are eaten off, as afterwards.

If the *Turneps* be ſown in June, the moſt experienced farmers will have only thirty plants left to a ſquare perch in the hand-hoing, finding that if more are left, they ſtarve one another, and the crop will be worſe; but in drilling the rows at ſix foot intervals, there will be at leaſt ſixty left to the perch, and theſe will thrive well, if the ſoil be rich, and well broken.

Sixty *Turneps* to a ſquare perch, at five pound each, which is but a third part of the ſize of ſheep-*Turneps* at their full growth, will make a crop of above eighty quarters to an acre.

When *Turneps* are planted late upon poor ground, they may be left more numerous; becauſe they will not have the advantage of heat for the hoing, that would make them grow larger, when ſet out at greater diſtances.

The greateſt *Turnep* improvement of the farmer is for his cattle in winter; one acre of *Turneps*, at this ſeaſon, will maintain more than fifty of meadow or paſture land. Moſt cattle will eat *Turneps*, and they breed milk better than any other food whatever. Sheep always refuſe them at firſt, and, unleſs they have eaten them while lambs, they will be ready to ſtarve before they will touch them; but as ſoon as hunger compels them to fall to, they are ſoon fattened by them. Lambs of three weeks old will eat them, ſcooping them very prettily, while thoſe of a year old, which are called *tegs*, will not touch them of three or four days, till almoſt famiſhed.

In ſome places, the greateſt uſe of *Turneps*, except for fattening oxen and ſheep, is for ews and lambs in the ſpring, when natural graſs is not grown up on poor grounds. Sometimes the farmers are obliged to keep their ews and lambs upon them till April, though they were run up to ſeed in the mean time. Id. Ibid.

There are three manners of ſpending *Turneps* with ſheep. See the article SHEEP.

The white and purple-rooted *Turnep* are the two kinds raiſed for the uſe of the table in England. They thrive beſt in a dry ſandy ſoil, that is not too rich; if the ground be too rich, they are apt to grow ſticky; but they are always the beſt taſted when produced on freſh, not on worn-out lands. The common time of ſowing them is from the beginning of July to the middle of Auguſt; but the gardeners about London ſow them every month from March to Auguſt, that they may have a conſtant ſupply; thoſe ſown early always ſucceed beſt when ſown on a moiſter ſoil than the others; for when on a dry one, they are ſubject to great damages, and are often almoſt wholly deſtroyed by a fly.

Turneps muſt always be ſown in an open place, for if they ſtand near hedges, or under ſhelter, they run up into tall ſtalks, and do not grow at the root. *Miller*'s Gardener's Dict.

TURNESOL, a plant of conſiderable uſe by the colour prepared from it, and known under its name. The root of theſe plants is long and white; the leaves reſemble in ſhape thoſe of the xanthium, or leſſer burdock; they grow on long pedicles, and are of a whitiſh or aſh-coloured green. The flowers form a ſort of cluſter, and grow out of the alæ of the leaves; they are of two kinds on the ſame plant, barren and fruitful, or, as botaniſts expreſs it, male and female.

The barren, or male flowers, occupy the top of every cluſter, and are placed each in a cup, divided into five ſegments, and themſelves conſiſt each of five ſmall yellowiſh leaves, with a bundle of ſtamina in the middle. The female, or fruitful flowers, are placed at the bottom of the cluſter, and are ſurrounded each by a cup, divided into ten ſegments; they are compoſed of five ſtamina, which ſurround a piſtil which is furniſhed with three forked filaments. This piſtil, which is fixed in the bottom of the cup, finally becomes a round fruit, of a rough ſurface, and green colour, its protuberances only appearing a little whitiſh. This fruit is divided into three cells, and each of theſe contains one round ſeed. The whole fruit is attached to the cup by a very long pedicle, ſo that when the flowers are withered, and it has arrived at its maturity, it is found hanging from the alæ of the leaves, and ſeems to have been produced without any flower; and this is what has led ſome writers into the error of imagining, that the flowers and fruit of this plant grow on different ſtalks.

Some have tranſlated *Turneſol* by the Engliſh word *ſun-flower*, which has led many to ſuppoſe that the great yellow ſun-

flower which we keep in gardens, was the plant that afforded the *Turneſol* colour: But this is a miſtake; and it is to be obſerved, that the true *Turneſol* plant here deſcribed, is very common in the fields of France and Germany, but does not grow wild with us in England.

The juice of the berries of the *Turneſol* rubbed upon paper or cloth, at the firſt appears of a freſh lovely green, but preſently changes into a kind of bluiſh purple. The ſame cloth, afterwards wet in water, and wrung out, will turn the water into a claret-colour: And it is to be obſerved, that theſe are the rags of cloth uſually called *Turneſol* in the druggiſts ſhops. *Boyl*'s Works abr. vol. 2. p. 79.

The lixivium of this plant in lime-water and urine, or in the volatile ſpirit of wine, turns marble blue. See the article *Colouring of* MARBLE.

TURNESOL, in botany, *&c.* See the article HELIOTROPIUM.

TURNING (*Cycl.*)—TURNING-*Evil*, in cattle, a diſeaſe that cauſes them frequently to turn round in the ſame place. It is alſo called the *ſturdy*.

The common remedy, recommended by Mr. Markham, is to throw the beaſt down, and bind him; then to open his ſkull, and take out a little bladder, filled with water and blood, which uſually lies near the membrane of the brain, and then gradually heal the wound. *Boyle*'s Works abr. vol. 1. p. 87.

TURNO *Vicecomitum*, a writ that lies for thoſe that are called to the *ſheriff's turn*, out of their own hundred. Reg. orig. 173. *Blount*, *Cowel*.

TURNSTONE, in zoology, the Engliſh name of a bird called by authors the *morinellus marinus*, or ſea-dotterel.

It is a little larger than the blackbird; its head moderately thick, and its body of a longiſh ſhape; its beak a finger's breadth long, thick at the baſe, and ſharp at the point; and its head, neck, ſhoulders, wings, and the upper part of its breaſt, are of a browniſh colour; its throat and belly are ſnow-white; the middle of its back has a very large white blotch; and its rump is variegated by a broad tranſverſe ſtreak of black; its legs are ſhort, and of a reddiſh yellow or orange colour. *Ray*'s Ornithol. p. 231.

TURONILLA, in zoology, a name given by ſome authors to the common little prickly fiſh called the *ſtickleback* or *barnſtickle*, and more uſually known among authors by the names *pugnitius* and *aculeatus piſciculus*. *Rondelet*. de Aquat. p. 9. See the article PUGNITIUS.

TURPENTINE (*Cycl.*)—In the diſtilling of *Turpentine* and other balſams by a gentle heat, it has been obſerved, that there ariſes firſt an acid ſpirit, that will mix with water; which ſpirit, except the fire be very gentle, is loſt. This grateful acid ſpirit, that firſt comes over, is, as a learned chemiſt and phyſician informs us, highly refrigeratory, diuretic, ſudorific, balſamic, or preſervative from putrefaction, excellent in nephritic caſes, and for quenching thirſt; all which virtues the biſhop of Cloyne thinks contained in the cold infuſion of tar, which draws forth only its fine flower, or quinteſcence, or the native vegetable ſpirit, together with a little volatile oil. See the article TAR-*Water*.

Turpentine is a fine reſin, whereof there are four kinds in uſe; the *Turpentine* of Chios or Cyprus, which flows from the *Turpentine*-tree; the Venice *Turpentine*, which is got by piercing the larch-tree; the Straſburgh *Turpentine*, which Mr. Ray informs us is procured from the knots of the ſilver fir; it is fragrant, and grows yellow with age. The fourth and laſt kind is common *Turpentine*, which is neither ſo tranſparent nor ſo liquid as the former; and this Mr. Ray takes to flow from the mountain pine. All theſe *Turpentines* are uſeful in the ſame intention. Theophraſtus ſays, the beſt reſin or *Turpentine* is got from the terebinthus growing in Syria, and ſome of the Greek iſlands. The next beſt is that from the ſilver fir and pitch-pine.

Turpentine may be of uſe to preſerve the bodies of inſects. Mr. Boyle [a] took clear Venice *Turpentine*, and evaporating to two thirds, obtained a reddiſh tranſparent gum, clear of bubbles, eaſily ſoluble by heat, and as eaſily rendered brittle by cold. Having firſt pulverized it, he melted it for uſe, with a gentle heat, and dipped the body to be preſerved ſeveral times therein, till it acquired a caſe of due thickneſs.—[[a] Works abr. vol. 1. p. 29, 30.]

Oil of TURPENTINE. The *oil of Turpentine*, taken in too large a doſe, hath often very bad conſequences, ſuch as a ſtrangury, bloody urine, and its total ſuppreſſion, with a fever, violent thirſt, and vomiting.

In the Medic. Eſſ. Edinb. vol. 2. art. 5. we have an account of ſuch ſymptoms produced by the taking two drams of this oil in warm ale. The patient was cured by a warm bath, and drinking plentifully of Fuller's *emulſio Arabica*.

TURPENTINE-*Tree*. This tree, beſides its proper fruit which ſucceeds the flowers in the uſual way, is remarkable for producing what authors of little curioſity have named another fruit, called its *horn*. This horn is a membranous production, of the length and thickneſs of a man's finger; and what ſurprized thoſe authors who eſteemed it a ſort of pod, was to find that it produced not ſeeds, but living animals, which they called flies.

The true hiſtory of this horn is, that it grows from the ſurface of the leaves, not from the ſtalks in the manner of fruit; and is no natural production of the tree, but a mere accidental thing, occaſioned by the wound of an inſect on the leaf. There are a genus of ſmall animals called *pucerons*, ſome of which have wings, others not, and which we ſee very frequently in vaſt cluſters on the leaves and ſtalks of ſeveral plants. A certain ſpecies of theſe animals is peculiarly fond of the juices of the *Turpentine*-tree, and always takes its abode upon its leaves. The female of this animal, ſoon after it is produced from its parent, makes its way under the covering or upper membrane of the leaf, and there lives ſecure till it produces its young. Theſe, as ſoon as they are brought forth, begin to ſuck, and fixing uſually upon the ſides and top of the cavity in which they are placed, they occaſion a great derivation of juices to that part of the membrane of the leaf which covers them; and the conſequence of this is, that it riſes up from the leaf, and begins to grow into a long body; the formation of this afterwards is the ſame with that of all other galls, and is owing to the ſame cauſe, a wrong derivation of juices. This gall-horn, or bladder, which ever it be called, continues to grow in length, till it burſt ſomewhere at the ſides, and then the winged and creeping brood appear. This, though eſteemed ſo great a wonder by many, is far from being peculiar to this tree, for our common elm affords galls much of the ſame kind. See the article PUCERON.

TURPENTINE-*Tree*, in botany. See the article TEREBINTHUS.

TURREBA, the *Earth-Apple*, in natural hiſtory, a name given by the people of Guinea, and ſome other parts of Africa, to a very fine kind of truffle, which they find in great plenty in their barren deſarts, four or five inches under the ſand.

TURRITIS, *Tower-Muſtard*, in botany, a genus of plants which have four-leaved cruciform flowers, ſucceeded by long pods, containing a number of ſeeds. The plants of this genus differ from the heſperis, in that they have flat pods; from the leucoium, in that the ſeeds are not marginated; and from the cabbage, both in the flatneſs of the pods, and in the whole appearance of the plant.

The ſpecies of *Turritis*, enumerated by Mr. Tournefort, are theſe: 1. The common or larger *Tower-Muſtard*. 2. The ſmaller *Tower-Muſtard*. 3. The branched *Turritis*. 4. The leucoium-leaved *Turritis*. 5. The cut-leaved alpine *Turritis*. 6. The *Turritis* with the lower leaves like thoſe of ſuccory, the others perfoliate. And 7. The purple ſpring *Turritis*. *Tourn.* Inſt. p. 223.

TURSIO, in zoology, a name by which Bellonius, Scaliger, and ſeveral others, have called the *phocæna* or *porpeſſe*, diſtinctively from the dolphin, with which it is confounded by the vulgar. *Willughby*'s Hiſt. Piſc. p. 31. See the articles DELPHINUS and PHOCÆNA.

TURTLE, in zoology. See the article TURTUR.

TURTLE, in ichthyology, the name by which we commonly call the great ſea tortoiſe. See the article TESTUDO.

TURTUR, in zoology, the *Turtle-Dove*, a very beautiful little bird of the pigeon kind. The head, neck, and back, are of the bluiſh-grey colour of the common pigeon, with ſome mixture of a reddiſh brown near the rump, and at the bottom of the neck. Its breaſt and belly are white; but its throat of a fine bright purple; and the ſides of the neck are variegated with a ſort of ringlet of beautiful white feathers, with black baſes. It feeds on hempſeed, and other vegetable matters. *Willughby*'s Hiſt. Avium. p. 134.

TURTUR, in ichthyology, a name given by Paulus Jovius, and ſome other writers, to the fiſh called the *paſtinacha marina*. It is the *tragon* and *trygon* of the old writers, and is a ſpecies of the rayfiſh diſtinguiſhed by Artedi by the name of the ſmooth-bodied ray, with no fin in the tail, but with a bony ſpine in it, ſerrated on one ſide.

TURTUR, the *Turtle-Shell*, in natural hiſtory, the name given by the collectors of ſhells to a very beautiful ſpecies of murex, common in the cabinets, but not found any where on the ſhores. This is owing to its having greatly altered its appearance in the poliſhing; for it is no other than the white and brown-mouthed murex, which is common in its rough ſtate, with its outer coat taken off. See the article MUREX.

TUSHES, in the manege, are the fore-teeth of a horſe, ſeated beyond the corner teeth, upon the bars; where they ſhoot forth on each ſide of the jaws, two above, and two below, about the age of three, three and a half, and ſometimes four: and no milk or foal-teeth ever come up in the place where they grow. See the article TEETH.

TUSSILAGO, *Coltsfoot*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the radiated kind. The diſk is compoſed of floſcules; and the outer circle of ſemi-floſcules; theſe ſtand upon the embryo ſeeds, and are all contained in a ſcaly cup. Theſe embryos finally become ſeeds winged with down, and adhering to the thalamus of the flower. To this it is to be added, that the flowers appear before the leaves. *Tourn.* Inſt. p. 487.

There is no other known ſpecies of this plant but the common *Coltsfoot*. See Tab. 1. of Botany, Claſs 14.

The common *coltsfoot* ſtands generally recommended as a very great medicine in coughs, and all diſorders of the breaſt and lungs. It is alſo ſometimes uſed externally in inflammations.

TUSSIS, the *Cough*. Medical writers define a *Cough* to be a diſcuſſory and eliſory motion of the breaſt, by means of which nature attempts to throw off ſomewhat that is offenſive to her.

Phyſicians diſtinguiſh *Coughs* into the idiopatic and the ſymptomatic; the firſt is truly pectoral; the other only affects the breaſt, by means of the conſent of parts. Of the ſymptomatic, or, as ſome expreſs themſelves, the conſenſual *Coughs*, ſome have a catarrhal diſpoſition, and have a coryza for their origin or attendant, or, more ſtrictly ſpeaking, a gravedo; ſometimes a bronchus, hoarſeneſs, and inflammation of the tonſils; others are called hypochondriacal, which ſometimes ariſe from diſorders of the ſtomach, and are therefore called dry ſtomachic coughs; and ſometimes from ſchirroſities of the liver, whence they are common to people in cachexies, and in hectics and dropſies.

A *Cough*, which riſes from internal cauſes, is to be carefully diſtinguiſhed from one that riſes from external. The dry and the moiſt *Cough*, that is, thoſe in which matter is ſpit up, and thoſe in which nothing is evacuated, differ alſo greatly, as well in regard to their ſymptoms, as to the perſons they attack. The dry *Cough* is always more tedious in cure than the moiſt, and more eaſily returns. The ſtomachic *Cough*, which is owing to conſent of parts, is known by the quantity and thickneſs of the matter that is ſpit up, which is always moſt frequent after meals, and gives a tendency toward a reaching to vomit. This moiſt ſtomachic *Cough* differs in this manner, in all particulars, from the dry cough of the ſame name and origin with it, as mentioned before.

The hypochondriac *Cough* is abundantly diſtinguiſhed from the other kinds, by its dryneſs, and by its vehement violence, for it always leaves a hoarſeneſs behind it; this always is moſt violent after eating, and after drinking large draughts of cold liquors, or aſcending ſteep places. As alſo by its bearing very well a cold and humid air, and not being exaſperated by it, as the pectoral *Coughs* are; and finally, by a ſenſation of a concuſſion of the diaphragm, when the effects in coughing are violent. *Junker*'s Conſp. Med. p. 514.

The common habitual dry *Cough* is diſtinguiſhed from the other kinds by its remarkable dryneſs; and the common moiſt habitual *Cough* by its abundant quantity of matter diſcharged, and by its appearing pulpy and greeniſh, and not ſanious, or ſtreaked with blood, and continuing in the ſame degree uſually for a conſiderable time. In this habitual *Cough* there is no waſting of the fleſh, nor is there that violent exacerbation on the taking of opiates, which is always found in the phthiſical *Coughs*, to which all opiates ſeem the greateſt enemies. This *Cough* alſo always receives great benefit from purging medicines, but the phthiſical *Cough* none at all: But both theſe differ greatly, according to the age and temperament of the body of the perſon afflicted with them.

Perſons ſubject to Coughs. The ſimple idiopathic *Cough*, ariſing from internal cauſes, whether it be of the moiſt or dry kind, is almoſt peculiar to young people, and thoſe of plethoric habits. The catarrhal ſymptomatic *Cough*, which ariſes from external accidents, is common to perſons of all ſtates and ages; but is more frequent among old men than among others. The perſons moſt ſubject to the common dry *Cough* are young people of a florid conſtitution and dry habit of body; and men of the middle or more advanced ages are ſometimes alſo afflicted with it, from ſuppreſſions of the hæmorrhoidal diſcharges, or from omiſſions of habitual bleedings; as are alſo people who are badly conformed, gibboſe or crooked, and ſuch as are afflicted with the evil, or have calculi in the bronchia, or nodes of a ſchirrous nature in the lungs; and finally, ſuch as have been ill-treated in the ſmall-pox, or have had the itch, or any other violent cutaneous eruption ſtruck in upon them. People moſt ſubject to a common moiſt *Cough* are thoſe of a phlegmatic habit, ſuch as are apt to cool their neck and breaſt in autumn in damp cold air in evenings; ſuch as have omitted their habitual bleedings, and ſuch as have drank too freely of ſpirituous liquors, or taken too much of acids. The idiopathic pectoral *Cough* ariſes from a congeſtion of humours in the breaſt; and the hypochondriac *Cough* is either owing to a fault in the ſtomach, or to a ſchirroſity in the liver. *Junker*'s Conſp. Med. p. 515.

Prognoſtics in Coughs. The ſimple idiopathic pectoral *Cough* very frequently goes off of itſelf, without the aſſiſtance of medicines, or with no farther aſſiſtance to nature than bleeding, judiciouſly managed; but though thus gentle while recent, yet when it is become habitual, and fixed upon a perſon, it is very obſtinate; and though at firſt it is far from a conſumptive *Cough*, yet there is no certainty but that it may, at ſome time or other, occaſion ulcerations in the lungs. A dry *Cough* in young people is much to be feared, when of long ſtanding, for it not unfrequently degenerates into a ſpitting of blood, or into a conſumption: This kind ſometimes alſo changes into what authors call the *ferine Cough*, which is ſo violent, that perſons afflicted with it are ſcarce able to recover themſelves after a fit of it. In general, any *Cough* that ſeizes a perſon in the Spring, is much eaſier cured than one that attacks in Autumn. Periodic *Coughs*, that have been long uſed to return upon people at certain times, are always to be ſuſpected of danger, if they leave them ſuddenly, and no natural or artificial evacuation is made in their place; for they too often bring on faults in digeſtion, and ſometimes ſuffocative catarrhs, and paralytic diſorders: A moiſt habitual *Cough*, when it ſuddenly changes into a dry one, is alſo a bad prognoſtic. A violent dry hypochondriac *Cough*, that frequently remits and recurs again, and is uſually worſt in the night, gives great reaſon to ſuſpect a ſchirroſity in the liver; and the more regularly it returns at ſtated times, the more certain is the defect of this or ſome other of the viſcera; ſo that the prognoſtic is very fatal and very certain from it. *Junker*'s Conſp. Med. p. 518.

Method of Cure. In caſe of a moiſt pectoral *Cough*, it is proper firſt to give a purge, not violent, but yet moderately ſtrong, to derive the matter from the breaſt; and the catarrhal matter muſt then be prepared for evacuation; when it is ſimply mucous, the common reſolvent and diſcutient catarrhal medicines are to be depended upon; ſuch are decoctions of the roots of pimpernel and iris, with the leaves of hyſſop, horehound, ſcabious, and ſpeedwell; with theſe are to be given the attenuant gums, as ammoniacum, benjamin, and ſagapenum, with the warm carminative ſeeds. When the matter is too tough and viſcous, the buſineſs then is, on the contrary, to incraſſate and reduce it to a ſoft pulpoſe body. This is effected by liquorice-root or juice, with gum arabic, figs, ſtarch, together with all the ſulphureous medicines. If, on the contrary, the matter is thin and acrimonious, and irritates violently, then the cure is to be effected by ſuch things as obtund and ſweeten it; of this kind are emulſions of almonds, and the cold ſeeds, with barley-water, water-gruel, the mucilages of quince, and fleawort ſeeds, and the like; and to theſe are to be added occaſionally, ſperma ceti, and oil of ſweet almonds: When the *Cough* is habitual, laxatives are to be given after theſe, or in the intermediate times, during the taking them; and if the *Cough* returns, when the matter of it is no longer the cauſe, it is to be quieted by gentle opiates, ſuch as the ſtorax pill; and finally, corroborants are to be given to reſtore the due tone of the lungs.

In the dry *Cough* the gentleſt purges only can properly have place, and nothing is ſo proper as to begin with ſmall doſes of rhubarb; after this, to diſcuſs the ſtagnating blood about the breaſt, decoctions of the pectoral herbs are to be taken in large quantities, ſuch are coltsfoot, ſcabious, maiden-hair, and the like. While the patient is taking theſe, he ſhould frequently waſh his feet in warm water; and finally, the cure is to be compleated by ſuch corroborants as reſtore the due tone of the lungs; of this kind, Stahl's tonico-nervine mixture is a very excellent medicine.

In the hypochondriacal *Cough*, as there is generally a fault in the liver, the *Cough* can never be cured, unleſs that defect can be removed. The *Cough* is therefore to be judged, in this caſe, only a ſymptom of the diſeaſe, and the method of treatment muſt be the ſame as in the infarctions of the liver. See the article HEPATIS *Infarctus*.

When this obſtruction is removed, the *Cough*, occaſioned by it, goes off of itſelf. In caſes where the hypochondriac *Cough* depends on a fault in the ſtomach, the firſt conſideration to be had, is, whether it be dry or moiſt; when it is dry, we may conclude that the fault is not ſo much in the ſtomach, as in the parts about it; and hence the motion of the congeſtions of blood toward the vena porta are to be regarded.

The moiſt ſtomachic *Cough* always brings the breaſt into conſent, and is hence often called a *ſtomachico-pectoral Cough*; for the mucous matter which lies in the fauces, and is daily evacuated rather by hawking than coughing, probably aſcends up the œſophagus, and cauſes a ſlight *Cough* in the day-time; but in the night, when that excretion ceaſes, it is eaſy for ſome little humidity to ſlip down the aſpera arteria; and this will be again thrown up by coughing in the morning. In the cure of this, there muſt be firſt given ſome gentle purges; after theſe, ſuch medicines as reſolve viſcoſities in their firſt formation; in which intention the roots of elecampane and pimpernel, with that of florentine orrice, are of great effect; and in the food it will be proper to eat large quantities of ginger, pepper, and the other ſpices; and at night, going to bed, drink a ſmall glaſs of brandy. When the diſeaſe begins to mitigate, the eſſence of amber is a medicine that will do the greateſt ſervice.

Bleedings in *Coughs* in general, when the conſtitution is plethoric, and they are done at proper times, are of great ſervice in breaking the force of the diſeaſe; nay, in caſes of a true phthiſis, bleeding often greatly retards, and keeps off the bad ſymptoms. It is to be obſerved, however, in all theſe caſes, that, when the conſtitution will bear it, the quantity taken away ſhould be larger, for otherwiſe they only invite a larger afflux of blood to the breaſt, and ſo increaſe inſtead of mitigating the force of the diſeaſe.

Bleeding is always more neceſſary in a dry *Cough* than in a moiſt one, unleſs the ſuppreſſion of ſome natural hæmorrhage, or the omiſſion of the habitual bleedings, have been the occaſion of it. Bleeding is alſo the more neceſſary in *Coughs*, as they

they return at times with renewed violence, and hurt the breaſt and lungs; and, in this caſe alſo, if cupping has been frequently uſed, and lately omitted, it muſt be had recourſe to again. Purging medicines have the moſt ſpeedy effects in moiſt *Coughs*, and indeed in dry ones they are not always ſafe, or, at the moſt, very gentle purgations alone are proper in this laſt caſe, where there is not a load of attending matter to be evacuated, as in the firſt. Sweating medicines are by ſome preſcribed in *Coughs*; but they have no proper place in any judicious regimen for theſe caſes, unleſs after the *Cough* is cured, and the matter carried off, when they may perhaps be of ſome ſervice to compleat the reſtoration of the conſtitution to its priſtine ſtate, by an equal diſtribution of the humours through the whole body. In ſimple *Coughs* there is occaſion for very few medicines, and, in general, inciding things, which diſpoſe the matter to an eaſy evacuation, with gentle laxatives, do the whole buſineſs.

The commotions occaſioned by humid *Coughs* are never extremely violent, nor of any great danger, and therefore it is not neceſſary to be at any great pains to allay them by opiates; but theſe are very ſucceſsfully given in caſes where the emotions are greatly too violent for the quantity of matter, or where they continue after the matter is carried off and evacuated. In this caſe the ſtorax pill is of great ſervice. *Junker*'s Conſp. Med. p. 520.

TUTSAN, in botany, *&c.* See the article ANDROSÆMUM.

TUTTI, in the Italian muſic, is uſed to ſignify that all the parts are to play together, or to make a full concert.

In this ſenſe *Tutti* ſtands oppoſed to *ſoli* or *ſolo*. See the article SOLO.

It is often found expreſſed by *omnes*, *ripieno*, *da capella*, *choro*, &c.

TUTULUS, among the Romans, a manner of dreſſing the hair, by gathering it up on the forehead into the form of a tower. *Pitiſc.* in voc.

TUTULUS likewiſe ſignified a woollen cap with a high top.

TUTTY, *Cadmia fornacum* (*Cycl.*)—Dioſcorides and Pliny differ conſiderably in their accounts of this ſubſtance, though they and all other authors agree in the material part of its hiſtory, *viz.* That it is a recrement of metals collected in the furnaces where they are melted.

Pliny mentions a kind called *capnitis*, or the *ſmoak Cadmia*. This is not mentioned by Dioſcorides. This *Cadmia capnitis* was the fineſt and moſt ſubtile of all the kinds; it was found at the mouths of the furnaces, where the flames burſt out on ſtirring up the fires.

The botryoide *Cadmia* was eſteemed a very good kind. This was, according to Pliny, of two colours, grey and red. The red, he tells us, was very much the better kind. Dioſcorides mentions no ſuch thing as a red *Cadmia*, but only ſays, that the grey botryoide kind, when broken, appeared of a ruſty colour, and ſpotted within. This is the worſt kind, according to Pliny.

Dioſcorides no where mentions his red kind, but he names after this a blue ſort, which was greatly preferable, and which was white within.

As Pliny does not mention this blue *Cadmia*, nor Dioſcorides the red, it is probable that they are the ſame thing, eſpecially as both agree in their being the moſt excellent kinds. The Greeks had a way of expreſſing all things that were blue by the word *cyanizuſa*, or reſembling the *cyanus* in colour. This word κυανιζουσα ſeems to have been the word that Pliny miſtook in his deſcription taken from this or ſome other Greek author, for the other or better kind of botryoide *Cadmia*, and reading φοινισσουσα for κυανιζουσα, tranſlated it red inſtead of blue. We have ſo many inaccuracies of this kind in Pliny, that it is much better to reconcile his account of the cadmia thus, than to ſuppoſe he was acquainted with a ſpecies of that ſubſtance, which no body elſe ever knew.

TWAITE, in our old writers, a wood grubbed up and converted into arable land. Co. Litt. 4. *Blount*.

TWENTY *four Men*: Men choſen every half year to redreſs the grievances of the mines and miners; but every man generally ſerves his year when choſen. *Houghton*'s compl. Miner. in the Explan. of the Terms.

TWISTED, (*Cycl.*) in the manege, called in French *Biſtourné*, is uſed for a horſe reduced to the ſame ſtate of impotency with a gelding, by the violent wringing or *twiſting* of his teſticles twice about; which dries them up, and deprives them of nouriſhment.

TYGER, or TIGER, *Tigris*, in zoology. See the article TIGRIS.

TYING *Courſe*, among brick-makers. See the article BRICK.

TYLOS, in zoology, a name by which many authors have called the *turdus iliacus*, or red-wing. See the article RED-*Wing*.

TYMPANA, Τυμπανα, among the Athenians, a capital puniſhment, wherein the criminal being affixed to a pole, was beaten to death with cudgels. *Potter*. Archæol. Græc. l. 1. c. 25. T. 1. p. 134.

TYMPANOTRIBA, among the antients, a deſignation given to an effeminate perſon, who could do nothing but play on the tympanum. *Pitiſc.* in voc.

TYMPANUM (*Cycl.*)—The *Tympanum*, or barrel of the ear, is a cavity irregularly ſemicircular, the bottom of it being turned inward, and the mouth joined to the circular groove of the external auditory paſſage. It has both eminences and cavities obſervable in it. The remarkable eminences are three in number, a large tuberoſity lying in the very bottom of the barrel, a little toward the back part, and a ſmall irregular pyramid, ſituated a little above the tuberoſity, and a little more backward; the apex of it is perforated by a ſmall hole, and on one ſide of the baſis, two ſmall bony filaments are often found in a parallel ſituation. They are ſeldom found to be wanting, on a careful inveſtigation, though their tender ſtructure expoſes them to be very often broken. In the third eminence is a cavity ſhaped like the mouth of a ſpoon, ſituated at the upper, and a little toward the anterior part of the bottom of the *Tympanum*. This cavity is part of a half canal, and at a very ſmall diſtance from its point, is a little bony ridge, which goes from one edge of it to the other, but is ſeldom found entire. The principal cavities are the openings of the cells of the maſtoide ſinuoſities, the opening of the euſtachian tube, the bony half canal, the feneſtra ovalis and rotunda; and to theſe may be added the ſmall hole in the pyramid. The opening of the maſtoide cells is at the poſterior and upper part of the edge of the barrel; the cells themſelves, which end there, are dug in the ſubſtance of the maſtoide proceſs, being very irregular and full of windings and turnings. The opening of the euſtachian tube is at the anterior, and a little toward the upper part of the edge of the barrel. This tube, which in France is uſually termed the aqueduct, runs from the *Tympanum* toward the poſterior openings of the naſal foſſæ and arch of the palate. The bony portion of it, the only part ſpoken of here, is dug in the apophyſis petroſa along the duct of the carotide apophyſis; and when it leaves that, it is lengthened out by the ſpinal apophyſis of the os ſphenoides. Theſe too cavities, the maſtoide cells, and the euſtachian tube, are, in ſome meaſure, prolongations of the *Tympanum*, one anterior, the other poſterior. The bony half canal, of which the cavity, like the mouth of the ſpoon, is the extremity, lies immediately above the euſtachian tube, toward the upper ſide of the apophyſis petroſa, or rather in the very ſubſtance of that upper ſide, and in a natural ſtate a ſmall muſcle is lodged in it. *Winſlow*'s Anatomy, p. 47.

TYMPANY (*Cycl.*)—This diſeaſe has been generally accounted, both by the antients and moderns, a ſpecies of dropſy, but very improperly; for though it is often productive of, or complicated with an aſcites, yet it is in itſelf a perfectly diſtinct diſeaſe, and accompanied with no extravaſation of water in the abdomen, perſons who have died of it having been found, on opening the body, with the abdomen as dry as in a ſtate of health; but the ſtomach has been found, in ſome, greatly diſtended with flatulencies, and containing a viſcid humour, though in no great quantity. The inteſtines are alſo uſually found diſtended, and, as it were pellucid, and, on being pricked, they collapſe, without the appearance of any water. And, in ſome caſes, on opening the abdomen, the whole ſwelling has ſubſided, on the excluſion of a groſs flatulence which had diſtended it. The inteſtines have, in ſome ſubjects, been found diſtended to the bigneſs of a man's thigh, in ſome parts, and in others lower down, ſo contorted and twiſted together, that there could be no paſſage either for the wind or the excrements. It is not uncommon alſo, on diſſection, to find great numbers of worms, of the common long kind, in the inteſtines.

A *Tympany*, without a dropſy, is moſt incident to women after labour, when the lochia have been ſuppreſſed by colds or otherwiſe, or diſcharged in too ſmall quantities; a bad regimen during the lying in, and the omitting to ſwathe the belly properly down, has alſo often a bad effect this way. In caſes of this kind, women find ſoon afterwards the abdomen inflated, with a conſiderable uneaſineſs, a difficulty of breathing, coſtiveneſs, and an unaccountable anxiety. Theſe are the breeding ſymptoms of the approaching *Tympany*; and the ſame often happens after unſkilful treatment in abortions, and after the leaving a part of the lochia behind, or the injuring the uterus in delivery.

Children are alſo ſubject to *Tympanies*, when violently afflicted with worms, and ſometimes after the meaſles and ſmall-pox; and if due care is not taken of theſe caſes, at their beginning, the ſuperior parts ſoon become extenuated, and the patients die. Extream voracity of children alſo, and their eating great quantities of food at a time, when the ſtomach is weak, ſometimes brings on this diſorder.

The *Tympany* is juſtly accounted one of the more dangerous kinds of diſeaſes, ſince the perſons afflicted with it much oftener die than recover. When it is accompanied with a dropſy, it is ſcarce ever cured; and a ſimple *Tympany* in women and children, if neglected at firſt, degenerates into a chronic diſorder, and hardly admits of a cure. Some, indeed, have gone ſo far as to ſay, they never knew a patient, afflicted with a *Tympany*, recover; but this ſeems too raſh a judgment. That diſtention of the abdomen, which is properly called a flatulent colic, is by ſome accounted a ſpecies of *Tympany*; but this is not naturally dangerous, and is eaſily cured, except

when it is attended with ſpaſms of the viſcera, in which caſe the medicines, given to reſtore the due tone of the inteſtines, are by no means proper in regard to the ſpaſms.

In curing flatulencies of the ſtomach and inteſtines, the proper method is to promote the diſcharge of the vapours by the anus, and to attenuate and carry off by ſtool the viſcid matter which is the occaſion of them. To this purpoſe diſcutient and evacuating glyſters are very ſerviceable: theſe ſhould be prepared of chamomile, hyſſop, juniper-berries, and the carminative ſeeds, a little quantity of ſal gem, crude ſal ammoniac, or Epſom ſalt, in veal broth. After theſe, laxative medicines are to be given, with balſamic and carminative ingredients; and then the powders of zedoary, orange-peel, tartarum vitriolatum, are to be given; and, when neceſſary, the pillulæ de ſtyrace at proper intervals. In the mean time much ſervice may alſo be done by external applications; ſuch as the oils of mint, rue, nutmeg, and the like, with balſam of Peru; and the rubbing the belly with Hungary-water is often of immediate relief: By theſe means the ſlighter inflations of the ſtomach and inteſtines are uſually cured with eaſe, and often beginning *Tympanies* yield to a continuance of them. *Hoffman.* Opera. T. 4.

TYPHIUM, in botany, a name uſed by ſome authors for colts-foot. *Ger.* Emac. Ind. 2.

TYPHLE, or TYPHLINE, a name by which ſome authors have called the fiſh, more uſually known by the name of the *acus*. *Willughby*'s Hiſt. Piſc. p. 158. See the article ACUS.

TYPHLINUS, in zoology, the name by which the Greeks, and from them ſome others, have called the *cæcilia*, or ſlow-worm. See the article CÆCILIA.

TYPHOS, the name of a diſeaſe deſcribed by Hippocrates and the old writers, and by them diſtinguiſhed into five kinds.

The firſt kind of *Typhos* is a legitimate and continual fever, impairing the perſon's ſtrength, and accompanied with pains in the abdomen, and a preternatural heat and weakneſs of the eyes, and a failure of ſpeech.

The ſecond kind begins with a tertian or quartan fever, and is attended with a pain in the head, and a large diſcharge of ſaliva, and ſometimes worms. The feet, and other parts of the body, are afflicted with ſoft ſwellings, the eyes are painful, and the voice tremulous and faint, from the ſticking of the ſaliva in the throat. The belly and back are alſo often in pain.

The third kind is diſtinguiſhed by the intenſe pains it gives in the joints, and ſometimes over the whole body, and often with a lameneſs.

The fourth is known by the violent tenſion and pain of the abdomen which attends it; this is uſually followed by a diarrhœa, and ſometimes by a dropſy.

The fifth kind is diſtinguiſhed by an unnatural paleneſs all over the body, and a ſort of tranſparence, as if the whole ſkin were only a bladder, containing a watery juice, though not inflated; the eyes are hollow in this caſe, and the patient is continually feeling about the bed-cloaths, as if picking out threads. There is always an uneaſineſs after eating, and frequent nocturnal pollutions.

The word *Typhos* is alſo uſed in a more general ſenſe for *Typos*, to import the remiſſions and exacerbations of diſeaſes.

TYPIC *Fevers*, an appellation given by medical writers to thoſe fevers which are regular in their attacks, and in their general period: They are thus called by way of diſtinction from the erratic, which obſerve no regular type, or determinate appearance.

TYRANNUS, in zoology, a name given by ſome to the lanius, or butcher bird, a ſpecies of hawk, not larger than a thruſh, but a very fierce and fatal enemy to the ſmall birds. *Ray*'s Ornithol. p. 52. See the article LANIUS.

TYRBE, Τυρβη, in antiquity, a feſtival celebrated by the Achæans, in honour of Bacchus. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 434.

TYRIUM *Marmor*, a name given by the antients to a ſpecies of marble of a beautiful white, ſometimes free from veins, and ſometimes variegated with duſky blackiſh grey ones. When pure, it was little inferior to the Parian, and often was uſed inſtead of it by the ſtatuaries.

TYROSIS, a name given by the antients to a diſorder in the ſtomach, occaſioned by milk curdling in it, from the too great acidity of the humours.

TYRUS, a word uſed by ſome of the barbarous writers for a ſerpent or viper.

TZANATL, in zoology, the name of an American bird deſcribed by Nieremberg, which, he ſays, has all over very long and beautiful feathers, of a fine green, and of the ſhining gloſs of the feathers of the peacock. The upper ſide of the wings is black, but their under part is of a very fine and ſhaded green. It has a very beautiful creſt on its head; its throat and breaſt are of a fine ſcarlet. The wing feathers are very long, and very beautifully variegated with ſeveral colours. The Indians eſteem the feathers of this bird more valuable than gold; they dreſs up the images of their gods with them. *Ray*'s Ornithol. p. 303.

TZANGÆ, among the antients, a kind of Parthian garments, according to ſome; but others will have them to have been ſhoes ſet with precious ſtones, formed into the figure of eagles, and deſigned for the emperor's uſe. *Pitiſc.* in voc.

TZANPAU, in zoology, the name of an American bird, deſcribed by Nieremberg, and kept by the Spaniards in cages for its melody. It is famous for the modulations of its voice, and is by many eſteemed the female of the polyglotta avis, or cencontlatolli of the Indians.

It is of the ſize of our ſtarling. Its breaſt and belly are mottled with white, grey, and black, and its back with white, black, and a duſky brown. *Ray*'s Ornithol. p. 305. See the article POLYGLOTTA *Avis*.

TZICATLINA, in zoology, a ſpecies of ſerpent, ſaid to be found in America, and reckoned among the moſt beautiful of that kind of animals. It is nine inches long, about the thickneſs of a man's little finger, and variegated with alternate ſwaths of white and red, croſſing its body. It is likewiſe one of the harmleſs kinds of ſerpents.

The name ſignifies the *ſerpent of ants*, becauſe it lives always in their neſts, and comes out along with them. *Hofman.* Lex. in voc.

TZINITZIAN, in zoology, the name of a very beautiful American bird, deſcribed by Nieremberg, of the ſize of a ſmall pigeon, and ornamented with variouſly-coloured feathers. The beak is ſhort, crooked, and of a pale colour; the head and neck are like thoſe of the pigeon; the breaſt and part of the belly are red; but that part which is next the tail is of a fine elegant blue, and a bright white, beautifully intermixed with one another; the tail is green on the upper part, and black underneath; the wings are variegated with white and black; the feet and legs are grey; and the ſhoulders of a very beautiful green. It is moſt frequent near the South-ſea, and feeds on vegetables. It is kept in cages for its beauty, but never ſings. The Indians make ſeveral beautiful works of its feathers. *Ray*'s Ornithol. p. 303.

TZTACTZON, in zoology, an American name under which Nieremberg has deſcribed a ſpecies of duck, remarkable for the variable and beautiful colours of its head, which are purple, blue, white, and green, and ſhine like ſattin. Its body is variegated with black, grey and white. Its legs are red, and is eaten as the other water-fowl. It is common in the lakes of Mexico; and has feet much more adapted to ſwimming than to walking. *Ray*'s Ornithol. p. 299.

V

V, in muſic, is often uſed to ſhew that a piece is deſigned for the violin; and VV, for two violins, or more.

V. S. is an abbreviation for *Volti Subito*. See the article VOLTI *Subito*.

VACCA, in zoology, the female of the ox-kind. See the articles BOS and OX.

VACCARY, *Vaccaria*, in our old writers, a houſe or place to keep cows in; a dairy-houſe, or cow-paſture. *Flet.* lib. 2. *Blount*, *Cowel.*

VACCINIUM, in botany, a name by which ſome authors have called the great bilberry, or *vitis idæa magna* of other writers. *Dale.* Pharm. p. 294.

VACUNALIA, among the Romans, a feſtival kept in honour of the goddeſs Lacuna.

It was celebrated in December by the country labourers, after the fruits were gathered in, and the lands tilled. *Pitiſc.* Lex. Antiq. in voc.

VADIATION, *Vadiatio*, in the civil law. See the article VADARI, *Cycl.*

VA-EMBU, in the materia medica, a name given by ſome authors to the *acorus Aſiaticus*, or Aſiatic ſweet flag. Hort. Malab. vol. II. p. 99.

VAGINA (*Cycl.*)—VAGINÆ *Femoris Tenſor*, in anatomy, a name given by Albinus to a muſcle of the thigh, called by others the *membranoſus*, and the *muſculus faſciæ latæ*; and by ſome *muſculus aponeuroticus*. See the article MEMBRANOSUS.

VAGINANS *Folium*, among botaniſts. See the article LEAF.

VAGUE *Acid*, a term much uſed by the modern chemiſts, and ſignifying a certain volatile fluid ſalt or acid, ſuppoſed to be found every where in mines, and in combination with different other ſubſtances, to form many of the ordinary compound foſſils.

This mixing with foſſile oil, petroleum, oleum terræ, or the like, probably conſtitutes the various ſorts of native foſſile tranſparent ſulphurs; uniting with ſemi-metals, it forms cinnabar, antimony, and other foſſils, both ſolid and fluid; uniting with metals, it forms divers kinds of vitriols; with calcarious earths, different alums; and laſtly, with pyrites, which is the matrix of vitriol, calcined in a wood-fire, it produces common ſulphur.

It may probably be held much of the ſame nature with that acid, which burning ſulphur diffuſes from its blue flame, ſo ſuffocating and fatal to all animals. Certainly the analyſis ſeems to intimate as much. And hence this may probably be looked upon as a male ſalt, ſerving to impregnate the female ſalts and earths. *Boerhaave*, Chem. 112.

There ſeems to be a certain *vague* ſalt or acid diffuſed in all parts of the earth, which, when alone, is volatile; but when it has a body, or proper ſubject to adhere to, it becomes fixed. The idea of this ſalt we are at a loſs how to convey, otherwiſe than by its effects; it ſeems to come neareſt the nature of ſpiritus ſulphuris per campanam, and is diſcovered in all ſulphur, in all vitriol, in all alum, in all nitre, in all foſſile coal, and many other ſubſtances; and is, perhaps, that pernicious fume or damp found in mines, and the ſmoke which flies from bituminous turf, and other the like bodies.

It is looked upon as an indeterminate principle, diſtributed through every part of the globe, both inſide, and out. It is this acid that diſſolves iron and copper near ſome hot baths. It is this that, meeting with foſſile oil, becomes coagulated, and is converted into ſulphur; that being received into the earthy part of the lapis calcarius, converts it into alum; and inſinuating itſelf into the ſubſtance of iron, produces green vitriol; into that of copper blue vitriol.

This doctrine of a *vague* acid may ſeem a little hypothetical, till the actual ſeparate exiſtence of ſuch an acid can be ſhewn; of which we do not know any clear inſtances. The argument for it ſtands thus: We find ſeveral mineral bodies that afford acids upon their analyſis; or appear to contain acids; and therefore nature makes uſe of theſe acids in the compoſition of ſuch mineral bodies: But to render this argument concluſive, the acids ſhould be ſhewn to exiſt in the earth, and inſtances be produced of nature's working in this manner, with the ſeveral ſteps of the proceſs. Inſtead of this direct proof, we only find a prejudged theory in authors, ſupported indeed by probable reaſonings, and a plauſible ſolution of phænomena: But all this may poſſibly be no more than a bare accommodation to the mind. *Shaw*, Chem. 112.

VAI-*Hio*, in the materia medica, a name uſed by ſome authors for a kind of lignum aloes, which is brought from China, and is very black, and ſcented. *Dale*, Pharm. p. 448.

VAISSEAUX *Enfilez*, a term uſed by the French writers in chemiſtry, for thoſe veſſels uſed in diſtilling in an open fire, or in ſand, which do not conſiſt in the common way of a retort, joined immediately to a receiver, but have a receiver with a double opening, and a neck at each end, placed between the retort and the ordinary receiver. The neck of the retort is let into one of the necks of this middle veſſel, and its other neck is thruſt into that of the receiver; by this means the receiver, into which the liquor is to fall, ſtands at a greater diſtance than it otherwiſe would from the fire, and the vapours are more eaſily condenſed in it by its coolneſs, while they have alſo a double or treble ſpace to expand in, and by that means are not ſo likely to burſt the veſſels.

VALDIA, in botany, a name given by Plumier to a genus of plants, ſince called by Linnæus, *ovieda*. *Plumier*, Gen. 24. See the article OVIEDA.

VALE *of a Pump*, at ſea, a term for the trough by which the water runs from the pump along the ſhip-ſides, to the ſcupper-holes.

VALERIAN, *Valeriana*, (*Cycl.*) in the Linnæan ſyſtem of botany, makes a diſtinct genus of plants, taking in the *valerianella* of Tournefort, and the *valerianoides* of Vaillant.

The characters of this genus are, that the cup ſcarce deſerves the name of one, and is only a ſort of rim or foliaceous edge, ſurrounding the germen. The flower conſiſts of a ſingle petal, in form of a tube, prominent in its inferior part, and containing a honey juice, divided into five ſegments at the edge, all which are obtuſe. The ſtamina are three, or fewer, pointed, erect filaments, and of the ſame length with the flower. The antheræ are roundiſh. The piſtillum has its germen below the receptacle. The ſtyle is thread-like, and of the ſame length with the ſtamina; and the ſtigma is ſomewhat thick. The fruit is a capſule, that ſplits and falls off. The ſeeds are ſingle and oblong. Theſe are the characters of the genus; but there is great variation among the different ſpecies. *Linnæi* Gen. Plant. p. 8.

The characters of this genus, according to Tournefort, are theſe: The flower conſiſts of one leaf, and is ſhaped like a funnel, and divided into ſeveral ſegments at the edge. This ſtands upon a cup, which finally becomes an oblong ſeed, of a flattiſh form, and winged with down.

The ſpecies of *Valerian*, enumerated by Mr. Tournefort, are theſe: 1. The great Pyrenean *Valerian*, with the leaves of cacalia. 2. The ſcentleſs Alpine *Valerian*, with undivided leaves, and a creeping root. 3. The middle marſh *Valerian*, with ſlightly divided leaves. 4. The firſt Alpine *Valerian* of Caſpar Bauhine. 5. The other Alpine *Valerian*, of the ſame author. 6. The figwort-leaved Alpine *Valerian*. 7. The roundiſh-leaved mountain *Valerian*. 8. The Alpine *Valerian*, reſembling the celtic Spikenard. 9. The cretic *Valerian*, with the dropwort-root. 10. The celtic *Valerian*, commonly called celtic ſpikenard. 11. The common broad-leaved red *Valerian*. 12. The ſmall narrow-leaved red ſea-*Valerian*. 13. The common narrow-leaved red *Valerian*. 14. The great broad-leaved ſea *Valerian*. 15. The ſmall narrow-leaved, white-flowered ſea *Valerian*. 16. The garden *Valerian*. 17. The great wild *Valerian*. 18. The great wild *Valerian*, with ſhining leaves. 19. The great marſh *Valerian*. 20. The ſmaller marſh *Valerian*. 21. The little marſh *Valerian*, with a ſmall flower. 22. The little Alpine *Valerian*. 23. The annual *Valerian*, with leaves like thoſe of the calcitrapa. 24. The broad-leaved annual jagged Portugal *Valerian*. *Tourn.* Inſt. p. 131.

The *Valerians* may be known, when not in flower, by their roots being ſcented, and their leaves always ſtanding two at a ſtalk.

The great garden *Valerian* is an alexipharmic, ſudorific, and diuretic. The root is the only part of it uſed in medicine; this is to be taken up in September, and carefully dried. It is then given in powder in aſthmas, pleuriſies, coughs, obſtructions of the liver and ſpleen, and in the plague, and all malignant and petechial fevers. It is alſo recommended by ſome as a vulnerary, and by others as one of the greateſt medicines in the world for weakneſſes of ſight.

The wild *Valerian* root is much more famous than this, but in a different intention. It is of a ſtrong diſagreeable ſmell, and is given in nervous caſes with very great ſucceſs. There are not wanting inſtances of perſons cured of confirmed epilepſies by it. In all convulſions it is a very ſucceſsful medicine.

VALERIANELLA, in botany, the name of a genus of plants, the characters of which are theſe: The flower conſiſts of one leaf,

leaf, ſhaped like a funnel, and divided into ſeveral ſegments at the edge. This ſtands upon a cup, which afterwards becomes a fruit, always containing one ſeed only, but yet is of very various figures; one ſort is like a ſpear-point in ſhape, being compoſed of two flat pieces, containing a ſeed in one or the other of them; another is of an oval ſhape, umbilicated, and terminated by three points; others have beautifully regular hollows cut in each for a ſingle ſeed; others are longer, fungoſe, and lunated, containing a cylindric ſeed; and finally, others terminate in three hooks, and contain a ſomewhat crooked ſeed.

The ſpecies of *Valerianella*, enumerated by Mr. Tournefort, are theſe: 1. The low early field *Valerianella*, with flatted ſeeds. 2. The low early field *Valerianella*, with ſerrated leaves. 3. The taller late-flowering field *Valerianella*, with more turgid ſeeds. 4. The *Valerianella* with naked round umbilicated ſeeds. 5. The *Valerianella* with naked umbilicated ſeeds. 6. The *Valerianella*, with large hairy umbilicated ſeeds. 7. The *Valerianella*, with ſmall hairy umbilicated ſeeds. 8. The Indian *Valerianella*, with a galeated, purple, or white flower. 9. The ſtarry ſeeded *Valerianella*. 10. The great Portugal *Valerianella*, with ſeeds like thoſe of ſcabious.

The ſeveral ſpecies of this genus may be known, when not in flower or ſeed, by their ſtalks being always divided regularly into two, and their leaves being ſmooth, veiny, and and placed two at each joint. *Tourn.* Inſt. p. 132.

VALET, (*Cycl.*) in the manege, a ſtick armed at one end with a blunted point of iron, to prick and aid a leaping horſe.

Formerly a *Valet* was called *Aiguillon*, *i. e.* goad, and ſome of them had ſpur-rowels upon them, only the points beaten down: And when a horſe was firſt begun round a pillar, without a rider, they uſed to prick his flanks with the *Valet*, to make him know the ſpur, and obey it, without reſiſting. At preſent the *Valet* is not uſed for that purpoſe, and the name of *goad* is ſuppreſſed, as being only proper for oxen.

VALIGA, a name given by ſome medical writers to an infuſion or tincture of jalap in ſpirit of wine, or ſpirit of citron, with the addition of a little ſaffron.

VALVULÆ *Conniventes*. Mr. du Vernoi is of opinion, that the *Valvulæ Conniventes* of the inteſtines are formed by the arched veſſels and fat in the internal cellular coat, and covered by the villous or nervous coat. See Comment. Acad. Petrop. Tom. 4. p. 192.

VAN (*Cycl.*)—VAN *of a Fleet*. See the article SQUADRON.

VANDOSIA, in zoology, a name by which ſome authors have called the *leuciſcus*, the common dace, or dare. *Willughby*'s Hiſt. Piſc. See the article LEUCISCUS.

VANELLUS, in zoology, a name given by many to the lapwing, more commonly known by the name *capella*. See the article CAPELLA.

VANILLA (*Cycl.*)—This fruit is principally brought to us by the Spaniards, who traffic with the Americans for it. It grows in the warmer parts of America, and that uſually in places where there is water near. The natives diſtinguiſh it into three kinds, which the Spaniards call the *pompona*, the *ley*, and the *ſimarona*.

The pods of the *pompona* kind are thick and ſhort; thoſe of the kind called *ley*, are longer and ſlenderer; and thoſe of the *ſimarona*, which is alſo called *baſtard Vanilla*, are the ſmalleſt of all the kinds.

The *ley* kind is the only good *Vanilla*. It ought to be of a good reddiſh brown, neither too black nor too red, and neither too dry nor too moiſt; when perfect they always appear full, though dry; and a parcel of fifty in number ought to weigh above five ounces.

There is a kind which is larger, fifty pods of which uſually weigh eight ounces; this is called the *ſobre buena*, and is eſteemed of all others the moſt excellent.

The ſmell of the *Vanillas* ought to be penerating and agreeable. And when the pods are freſh, and in good condition, they are found, when opened, to be full of a blackiſh oily balſamic liquor, in which there ſwim a great number of very ſmall black ſeeds. The ſmell, when the pod is freſh opened, is very lively, and in ſome degree intoxicating.

The *pompona Vanilla* has a ſtronger, but leſs agreeable ſmell than the former, and when taken, gives men violent headachs, and women diſorders of the womb. The liquid ſubſtance in the *pompona* is thinner than in the *ley*, and the ſeeds much larger, being nearly of the ſize of thoſe of muſtard.

The *ſimarona*, or *baſtard Vanilla*, has very little liquor, and has few ſeeds in the pod, and has ſcarce any ſmell.

The *pompona* and *ſimarona* are no ſaleable commodities, nor ever brought to market, except cunningly by the Indians, who mix them among the pods of the *ley*, or true kind. It is not yet certainly known, however, whether theſe three kinds are the produce of different ſpecies of plants, or whether they differ only as to age, or the ſoil where the plant grows.

They never put *Vanilla* into chocolate in any part of New Spain. There has been ſent over into France *Vanilla* from Caracca and Maracaybo. The pods of this are ſhorter than thoſe of the true *Vanilla*, and thicker than the *pompona* kind. It is, however, plainly a ſpecies of *Vanilla*, and is of a very good ſmell and taſte. There is alſo mention made by ſome of a *Vanilla* of Peru, the dried pods of which are two fingers wide, and above a foot in length; but of a much inferior ſcent to the *Vanilla*, and not retaining any long time even what it has.

The leaves of the *Vanilla* plant are about a foot long, and three fingers breadth wide. They are obtuſe at the end, and of a very dark duſky green. The flowers are ſingle, and of a whitiſh colour, variegated with red and yellow. The pods appear as ſoon as theſe fall, and are green at firſt, but grow of a yellowiſh colour as they ripen. It is at this time that they gather them. The whole ſhrub is a climber, of the nature of the vine, and muſt be three or four years old before it produces any fruit.

The time of gathering the pods for ſale is from September to December. They require no other management than to be gathered in a dry ſeaſon, and laid twenty days, to dry away the ſuperfluous humidity, and, at times, preſſing the pods gently with the hands.

The plant climbs up the talleſt trees, and its main ſtock, in time, becomes woody and hard as that of the vine; the root ſends up many off-ſets, which are planted by the natives, near the foot of a tree, and thrive very eaſily; and it is thus that the ſhrubs are propagated; and the time for doing this is in winter, or toward the beginning of ſpring.

It is remarkable that the young ſhoot is not to be planted into the ground as with us, but on the bark of the tree; this is, however, no ſingular caſe in the hot countries, for nature ſhews the way; the branches of trees, broken off by winds, often being blown againſt other ſpecies, and yet always taking hold on them, and growing; this is owing to the great abundance of the ſap in trees in theſe climates. Memoirs Acad. Scien. Par. 1722.

Vanillas are accounted cordial, carminative, ſtomachic, and reſtorative; they are alſo ſaid to be diuretic, and to promote the menſes.

VANNING-*Shovel*, among miners, an inſtrument uſed for waſhing the ores of any metal, after being reduced to powder, thereby to diſcover the richneſs and other qualities of the ore. See the article SHOAD.

VAPOUR (*Cycl.*)—*Fiery* VAPOURS, *Halitus Ignei*, a term uſed by ſome to expreſs thoſe exhalations from the earth, which either take fire of themſelves on the burſting forth into the air, or are readily inflammable on the bringing a candle to them.

Many of the ſuppoſed burning lakes are owing to theſe fumes burſting up through the water, and not to any quality of the water itſelf. Our famous burning well at Wigan in Lancaſhire is of this kind. The common people affirm, that the water of this ſpring burns like oil; but there is nothing of truth in this. There burſts up a *Vapour* through the earth in this place, which keeps the water bubbling, as if boiling over the fire, though it is not warm; and the ſtream of this breath may be felt iſſuing up in theſe places like a ſtrong wind. This breath alone is inflammable, and takes fire at the approach of a candle, burning with conſiderable violence for ſome time.

There are coal-pits in the neighbourhood, and the air is certainly of the ſame kind with that inflammable *Vapour*, often met with in thoſe places, and which may alſo be prepared from iron diſſolved in a proper menſtruum. The water itſelf, taken from the place, does not burn; and if the bottom be made dry, the vapour which aſcends from it will burn as ſtrongly as if the water were there. The flame is not diſcoloured like that of ſulphureous bodies, nor has it any bad ſcent; and the fumes, as they are felt burſting out of the earth, by the hand held over the place, are not hot. Phil. Tranſ. N° 20.

VAPPA, a word uſed by the antients to expreſs dead wine, or wine deprived of all its ſpirituous part.

The word is alſo metaphorically uſed to a peculiar ſtate of the blood, when it is in a low, diſpirited condition, as is the caſe even in healthy perſons, when worn out with exceſſive labour, and in cachectic and ſcorbutic perſons.

VARA, in commerce, a long meaſure uſed in Spain and Portugal. It is of various lengths in different places. That of Seville is $33\frac{127}{1000}$; that of Madrid, $39\frac{166}{1000}$; that of Portugal, $44\frac{11}{1000}$ inches Engliſh meaſure. Treat. Pract. Geom. p. 8.

VARIA, in zoology, a name by which ſome authors have called the leopard, or *pardalis*, from the beautiful variegations it is marked with. See the article PARDALIS.

VARIATION (*Cycl.*)—VARIATION *of Curvature*, in geometry, is uſed for that inequability, or change, which happens in the curvature of all curves, except the circle. And this *Variation* or inequability conſtitutes the quality of the curvature of any line. *Newton*, Meth. of Flux. and Inf. Series. p. 75.

Sir Iſaac Newton [a] makes the index of the inequability, or *Variation* of curvature, to be the ratio of the fluxion of the radius of curvature, to the fluxion of the curve; and Mr. Maclaurin, to avoid the perplexity that different notions, connected with the ſame terms, occaſion to learners, has adopted the ſame definition; but he ſuggeſts [b], that this ratio gives rather the *Variation* of the ray of curvature, and that it might have been proper to have meaſured the *Variation* of curvature, rather by the ratio of the fluxion of the curvature

itſelf,

itſelf to the fluxion of the curve; ſo that the curvature being inverſely as the radius of curvature, and conſequently, its fluxion as the fluxion of the radius itſelf directly, and the ſquare of the radius inverſely, its *variation* would have been directly as the meaſure of it, according to Sir Iſaac Newton's definition, and inverſely as the ſquare of the radius of curvature. According to this notion, it would have been meaſured by the angle of contact contained by the curve and circle of curvature, in the ſame manner as the curvature itſelf is meaſured by the angle of contact contained by the curve and tangent. The reaſon of this remark may appear from this example [c]. The *variation* of curvature, according to Sir Iſaac Newton's explication, is uniform in the logarithmic ſpiral, the fluxion of the radius of curvature in this figure being always in the ſame ratio to the fluxion of the curve; and yet, while the ſpiral is produced, though its curvature decreaſes, it never vaniſhes, which muſt appear a ſtrange paradox to thoſe who do not attend to the import of Sir Iſaac's definition. — [[a] Meth. of Flux. and inf. Series, p. 76. [b] Fluxions Art. 386. [c] Phil. Tranſ. N°. 468. ſect. 6. p. 342.—]

The *variation* of curvature at any point of a conic ſection, is always as the tangent of the angle contained by the diameter that paſſes through the point of contact, and the perpendicular to the curve at the ſame point, or to the angle formed by the diameter of the ſection, and of the circle of curvature. Hence the *variation* of curvature vaniſhes at the extremities of either axis, and is greateſt when the acute angle, contained by the diameter, paſſing through the point of contact and the tangent, is leaſt.

When the conic ſection is a parabola, the *variation* is as the tangent of the angle, contained by the right line drawn from the point of contact to the focus, and the perpendicular to the curve.

VARICULA, a diminutive of the word *varix*, a term applied by ſome authors to the intumeſcence of the veins of the tunica adnata in the eye, ariſing from thick blood.

VARIETIES, in natural hiſtory, a word uſed to expreſs an accidental change in ſome body which is not eſſential to it, and therefore does not conſtitute a different ſpecies.

The naturaliſts of former ages have run into great errors, in miſtaking the accidental *varieties* of plants, animals, and minerals for diſtinct ſpecies. Many of them have called a plant a new ſpecies, becauſe its flower, which ſhould have been blue or red, is white on account of the poorneſs of the ſoil, or ſome other ſuch reaſon. Mr. *Ray* has eſtabliſhed a very good teſt for *varieties* in botany; he allows every thing to be a diſtinct plant which will propagate itſelf in its own form by its ſeeds; but ſuch, as when ſown, loſe their difference, and run back to the old ſtandard, he accounts *varieties*, however great their diſtinctions may appear. In the hiſtory of fiſhes as much confuſion has been introduced by miſtaking *varieties* for diſtinct ſpecies as in botany. Artedi is the only author who has rationally attempted to bring this part of natural hiſtory into order in this reſpect, and to ſettle regularly the rules by which to diſtinguiſh real and eſſential, from accidental differences.

The principal grounds of the error of ſuppoſing *varieties* diſtinct ſpecies of fiſh, have been theſe: The variable and inconſtant colour of fiſhes has been miſtaken for a ſpecific difference; in this manner Rondeletius has deſcribed many *varieties* of the turdi, labri, and other fiſhes, under the names of diſtinct genera.

Others have paid the ſame too great regard to the more conſtant *varieties* of colour, which are found only to differ in degree, in the ſeveral individuals of the ſame ſpecies, and their differences to be only in the degrees of the ſame colour, which is much more intenſe in ſome, and more remiſs in others. Theſe differences can only make *varieties* of the ſame fiſh, the ſpecies remaining always the ſame. Of the ſame kind are the miſtakes of thoſe who eſteem ſize or magnitude a ſpecific character: and thus, out of the *varieties* of the ſame fiſh, occaſioned by ſcarcity or plenty of food, or other ſuch occaſions, make larger or ſmaller ſpecies. The place where fiſh are caught, is alſo another occaſion of making new ſpecies, with theſe ſort of authors; thus though the *perca fluviatilis* of Bellonius, and the *perca marina* of other authors be the ſame fiſh, yet they are pretended to be different ſpecies. The time of ſpawning is alſo with ſome made a diſtinction of ſpecies; and thus we find the common pike divided into three ſpecies, according to its ſpawning, in ſpring, ſummer, and autumn, which it does according to the heat or coldneſs of the climate. See the article SPECIFIC *Names*.

All theſe differences are falſe and frivolous, and the utmoſt they can do, is to make what are properly called *varieties*, though few of them are ſufficient even for that. A ſalmon caught at ſea, is not different from one of the ſame brood caught in a river: and if the *perca marina*, falſly ſo called, be a little different from the *perca fluviatilis*, yet if its ſpawn will produce regular *percæ fluviatiles*, its difference can only amount to a *variety*, not a diſtinct ſpecies.

The trifling nature of diſtinction by colour, is ſeen by the variety we daily ſee in the colours of ſome of our moſt common fiſh; as the tench, the eel, the ſalmon, and ſome others, which vary more or leſs, from every change of the water; all the other diſtinctions, of ſize and place, are as frivolous; and the giant and the dwarf, the black and the white man, the Aſiatic and the European, may as well be called diſtinct ſpecies of men, as theſe of fiſhes.

Finally, the time of ſpawning is no eſſential difference; for we daily ſee the change of climate make changes of that kind in all creatures; and even in the ſame climate, and under the ſame circumſtances, the ſame ſpecies of birds will afford ſome individuals much earlier or later in laying their egg sthan others. *Artedi* Ichthyol.

VARIUS, in zoology, a name uſed by moſt authors for a ſmall freſh-water fiſh, common in brooks and running waters, and well known in England, by the name of the *minow*, or *menow*; and called *Phoxinus lævis* by ſome other writers.

It is diſtinguiſhed from other fiſh of its ſize, by being of a duſky browniſh olive colour on the back, by its having a yellow line running on each ſide, from the gills to the tail, below which the belly and ſides are of a very varying colour; in ſome white, in others of a fine bright red, and in others, there is a line of a fine blue running on each ſide; and in others, the ſides are variegated with yellow, brown, and red lines. Its ſcales are ſo extremely ſmall, that it has been generally ſuppoſed to have none. Its mouth is very large. It is a very well taſted fiſh, and if but a little larger, would be very much valued. *Ray*'s Ichthyogr. p. 268.

VARIUS *Mus*, in the old authors of zoography, a name uſed for the ſame creature they otherwiſe called *mus ponticus*; which ſeems to have been no other than our ſquirrel. See the article SCIURUS.

VARNISH *(Cycl.) Amber* VARNISH. *Amber Varniſh* is prepared in the following manner: Put four ounces of amber into a crucible, and melt it with a ſmall degree of heat, and pour it out upon an iron plate, when cold, reduce it to powder, and add to it two ounces of drying oil, that is, linſeed oil thickened by boiling it up with litharge, and one pint of oil of turpentine, and diſſolve the whole together into a liquid *Varniſh*. *Shaw*'s Lectures, p. 424.

This has been long a great ſecret in the hands of the traders in theſe things; but deſerves to be made public, as a leading experiment towards the perfecting the arts of *varniſhing* and japanning.

China VARNISH. The *China Varniſhes* have been always famous; the manner of making which is ſaid to be as follows: Take crude *Varniſh* ſixty ounces, common water the ſame quantity, mix them well together till the water diſappears; afterwards put this into a wooden veſſel five or ſix palms long, and two or three broad; mix them together with a wooden ſpatula, for a whole day in the ſummer's ſun, for two days if in winter, and afterwards keep it in an earthen veſſel, covered with a bladder. The water will not unmix itſelf again: this is called the ſun *Varniſh*. See VARNIH *for Porcelain*, *infra*.

The oil of wood, called by the Portugueſe *azeile de Pao*, is made in the following manner: Take twenty ounces of that oil, which they call oil of wood, and ten drams of the oil of the fruit; boil theſe a little together, and the oil will look yellow; then let it cool, and add to it five drams of quick lime powdered. To make the firſt grounds called *camiſeca*, take ſwine's blood and quick lime powdered, of each an equal quantity; ſpread this mixture upon the wood, and when it is dry, ſmooth it with pumice-ſtones.

To make the black *Varniſh*, take of the *Varniſh* prepared in the ſun ſixty ounces, ſtone black alum (ſuppoſed to be a ſort of copperas) diſſolved in a little water, three drams, and ſeventy drams of lamp-oil, called by the Portugueſe *azeile de Candea*. Theſe things are all to be mixed together in a wooden veſſel, putting the lamp oil in at twice, and ſtirring the whole together with a wooden ſpatula.

The pitch-coloured *Varniſh* is made in the following manner: take oil of wood, crude, forty drams; called *da Pao*, of the lamp-oil, called *da Candea* crude, forty drams; mix them together in the ſun in a wooden veſſel, in the ſame manner as the common *Varniſh* and water are ordered to be mixed in the firſt proceſs.

To make the red *Varniſh*, take ten drams of cinnabar, twenty drams of prepared *Varniſh*, and a little lamp-oil; mix, them all together.

To make the yellow *Varniſh*, take of the yellow colour ten drams, prepared *Varniſh* thirty drams, a little lamp-oil; mix all together: and

To make a *Varniſh* of a muſk colour, take of the red *Varniſh* ten drams, and of the black *Varniſh* four drams; mix them well together. Philoſ. Tranſ. N°. 261. p. 524.

Theſe are the accounts ſent to the great duke of Tuſcany by the jeſuits in China: Dr. William Sherard communicated them to the royal ſociety; and to render the accounts uſeful to the world, he preſented with them the ſeveral ſubſtances mentioned; theſe are depoſited in the muſæum of the ſociety, and may ſerve as inſtructions to all who are curious in this art.

VARNISH *for Porcelain*. The Chineſe have of late years diſcovered a new kind of *Varniſh* for their ware: they call this *Tſekinyeou*, that is to ſay, the browniſh gold varniſh; it is of the colour of the brown images, or of what we call coffee colour. The novelty of this has made it much eſteemed: it is made in the manner of all their other varniſhes, by diſſolv-

ing the finer part of an earthy ſubſtance in water. The ſubſtance which they make it of is a common yellow earth: this they diſſolve in water, and letting the coarſe parts ſettle, they pour off the yet thick liquor, and what afterwards ſubſides from this, is the pure and fine part, which they keep in form of a ſoft paſte, or thick cream. They uſe this only to the thinneſt and moſt delicate porcelain ware.

The manner of uſing it is this: they mix a quantity of this fine ſediment with ſo much water as renders it thin and liquid, like the common *Varniſh*: this and the common kind are to be uſed together, ſo that care muſt be taken that they are nicely of the ſame degree of thickneſs: this the workmen try by dipping a petunſe or brick of their earth into both, and ſeeing which comes out moſt covered, that which lies on the thickeſt, is to be diluted with more water, or the other to be heightened with more of the earth, to bring them to the ſame ſtandard. They are both judged to be ſufficiently liquid when they enter the pores of the petunſe. They then mix ſome of the oil of fern aſhes and lime, (ſee the article FERN-*Oil*) along with the brown *Varniſh*, and add as much of this mixture to the common *Varniſh* as they find upon trial will give ſuch a colour as is required. The common proportion for the brown colour moſt eſteemed at preſent, is two pints of the brown *Varniſh* to eight pints of the common; and to four pints of this mixture they add one pint of the *Varniſh*, or oil of fern. It might puzzle a ſtranger to their terms, to underſtand what theſe people meant by oil; but it is a word with them in uſe for any thing liquid; and they call all their *Varniſhes* ſo, though made of the powders of earths and ſtones mixed with water. They apply this *Varniſh* to the veſſels by dipping them into it, and ſo compleatly covering them inſide and out before they put them into the oven; and the baking gives a great brightneſs to the colour. This is the niceſt part of the whole manufactury of the porcelain, and other wares of that kind. The *Varniſhes* uſed by the Chineſe are two; the one they call *oil of ſtones*, the other, *oil of fern*; which ſee. They mix theſe together, and with great caution and delicacy apply them to the veſſels all over equally, with a ſteady hand and a fine pencil. Obſervat. ſur les Coutum. de l'Aſie, p. 304.

When the porcelain is very thin and fine, they give it two beds of the *Varniſh*, the one over the other, when dry; theſe are to be very thin, and they anſwer to the ſingle covering of *Varniſh* given to the common good China, that is thick and ſtrong. They give theſe coats by dipping, and uſe the foot of the veſſel to hold it by: after this, they hollow the foot, and paint the circle that we ſee round it, or mark it with ſome Chineſe character.

The *Varniſh* they lay on is ſo thick, that it often hides the colours, till the baking afterwards brings them out again: this is the caſe with the fine deep blues; we ſee none on the beſt china; it is all hid under the coat of white, and the veſſel appears plain, till it has paſſed through the fire again; but then the colour appears deeper than when at firſt laid on. Obſerv. ſur l'Aſie.

VASTUS *(Cycl.)*—VASTUS *Externus*, a very large fleſhy muſcle, almoſt as long as the os femoris, broad at the extremities, and thick in the middle, and lying on the outſide of the thigh.

Its upper inſertion being ſomething tendinous, is in the poſterior or convex rough ſurface of the great trochanter. It is likewiſe fixed by a fleſhy inſertion along the outſide of the os femoris, for above two thirds of its length downward, in the correſponding part of the linea aſpera, and in the neighbouring portion of the faſcia lata. From all this extent, the fleſhy fibres running downward, and a little obliquely forward, towards the rectus anterior, terminate inſenſibly in a kind of ſhort aponeuroſis, which is fixed in all the neareſt edge of the tendon of the rectus, in the ſide of the patella, in the edge of the ligament of that bone, and the neighbouring lateral part of the head of the tibia. The body of this muſcle is bigger than its extremities, and its loweſt fibres run a little below the rectus. *Winſlow*'s Anatomy, p. 213.

VASTUS *internus*, a muſcle very like the *vaſtus externus*, and ſituated in the ſame manner on the inſide of the *os femoris*.

It is fixed above by a ſhort flat tendon in the anterior rough ſurface of the great trochanter, and by fleſhy fibres in that oblique line, which terminates the baſis of the collum of the os femoris anteriorly on the foreſide of the inſertions of the pſoas and iliacus, in the whole inſide of the os femoris, and in the linea aſpera on one ſide of the inſertions of the three tricipites, almoſt down to the internal condyle. From all this extent, the fibres run downward, and a little obliquely forward, and the body of the muſcle increaſes in bulk: it terminates below in an aponeuroſis, which is fixed in the tendon of the rectus anterior, in the ſide of the patella, and of its tendinous ligament, and in the ſide of the head of the upper extremity of the tibia. *Winſlow*'s Anatomy, p. 214.

VATERIA, in botany, the name of a genus of plants; the characters of which are theſe: The perianthium is ſmall, acute, and permanent, and is compoſed of one leaf, divided into five ſegments; the flower conſiſts of five oval expanded petals; the ſtamina are numerous filaments, ſhorter than the flower; the antheræ are ſimple; the germen of the piſtil is roundiſh; the ſtyle is ſimple and ſhort, and the ſtigma is headed; the fruit is turbinated and trivalved; the ſeeds ſingle and oval. *Linnæi* Gen. Plant. p. 235. Hort. Mal. vol. 4. p. 15.

VATICANÆ *Pillulæ*, the name of an old form of medicine, intended as a purge. The recipe is in the Old London Pharmacopœa; but the late ones have diſcarded it.

VAULT *(Cycl.)*—VAULT, in the manege. To *vault* a horſe-ſhoe, is to forge it hollow, for horſes that have high and round ſoles; to the end that the ſhoe, thus hollow or *vaulted*, may not bear upon the ſole that is higher than the hoof; but after all, this ſort of ſhoe ſpoils the feet; for the ſole being tenderer than the ſhoe, aſſumes the form of the ſhoe, and becomes every day rounder and rounder. In Mr. Solleyſel's Compleat Horſeman, may be ſeen the true method of ſhoeing for high and round ſoles.

VAUNING, in mineralogy, a term uſed by our miners to expreſs a coarſe and expeditious way of waſhing ores, for the examination of their nature and richneſs.

This inſtrument called the *Vaun*, is a long and moderately deep wooden ſhovel; into this they put the earthy or ſtony matter, which they ſuſpect to contain the metal, in powder: they then add water many times, and ſhaking and ſtirring it thoroughly about, they throw out the water, and add freſh, till at laſt the matter is ſeparated; the earthy part is waſhed away, and the ſtony and mineral matter only remain, the one at the hinder part, the other at the point of the ſhovel. This laſt is collected ſeparate; and on being examined either by the eye or teſt, they are able to judge very nearly of the general profit of the mine.

This method is often uſed with the ſtones and earths found in the ſhoads, or trains of mines. Phil. Tranſ. N°. 69.

VAZABU, in the materia medica, a name by which ſome authors have called the *Acorus Aſiaticus*, or Aſiatic ſweet flag. *Herm.* Muſ. Zeyl. p. 56.

UBIRRE, in zoology, a name given by ſome to the anguilla marina, or ſmall ſea eel, a long fiſh of the eel kind, living among rocks about the ſea ſhores, and growing to be very fat and well taſted. *De Laet*'s Ind. occident. See the article EEL.

UDNON, in botany, the name by which Theophraſtus and Dioſcorides have called the truffle commonly uſed at table in their time.

Dioſcorides tells us, that it was a root dug up at ſmall depths under ground, and had neither ſtalks, nor flowers, nor leaves; and that it was of a reddiſh colour, and ſmooth ſurface. By this, which is alſo the account of Theophraſtus and Athenæus, we find, that the *Udnon* was indeed the truffle; but we alſo find that they were not acquainted with the better kind of truffle, which we cultivate at preſent.

This ſmooth reddiſh-coated truffle is common in Italy at this time, and is eſteemed of no value, and called the wild truffle: the ſort that is eaten there, and in all other parts of Europe, is the blackiſh and rough-coated kind. In Africa they have a yet finer kind than ours; it has a white coat, and is of the moſt delicious flavour. The Greeks were alſo acquainted with this, and denominated it Cyrenean, as they did almoſt all the things they had from Africa: they alſo gave it the name *miſy*; but this word being alſo the name of a vitriolic mineral, allied to the *ſory* and the *melanteria*, ſome confuſion has been thereby introduced. Many having thought, that the Cyrenean miſy was only a finer kind of the mineral of that name. See the article MISY.

UDO, in the materia medica, a name given by the *Portugueſe* to the lignum aloes. See the article LIGNUM *Aloes*.

It ſeems only a corruption of the monoſyllable *Ud*, by which the Arabian phyſicians have called that drug; and even this *Ud* poſſibly was only a contraction of the orthography of the word *Heud*; which ſeems to have been the original name of this drug among the Arabs. See the article HEUD.

VEERING, in huſbandry, a term borrowed of the ſailors, and uſed for the turning two furrows toward each other, as they muſt do to begin a ridge; they therefore call the top of a ridge a *Veering*; and they call the two furrows that are turned from each other at the bottom between two ridges, a *henting*, that is, an ending, becauſe it makes an end of plowing ridges.

VEGETABLE *(Cycl.)*--- *Vegetables*, according to the analyſes made of them by chemiſtry, are diſtinguiſhable into two grand tribes, the acid and the alkaline; the firſt affording a volatile acid, and the ſecond a volatile alkali, upon a dry diſtillation: thus guaiacum, cedar, box, cinnamon, cloves, ſorrel, mint, balm, &c. afford an acid; but garlick, leeks, onions, horſe-radiſh, ſcurvy-graſs, muſtard, &c. afford an alkali, which, when rectified, is hardly diſtinguiſhable from that of animal ſubſtances, ſo as nearly to reſemble the ſpirit and ſalt of hartſhorn.

For the analogy between the animal and *vegetable* world. See the article ANIMAL.

Muſcles of VEGETABLES, ſee the article MUSCLE.

VEGETABLE *Salt*. In the Philoſophical Tranſactions we have ſome very curious proceſſes and obſervations by Redi, on the ſubject of the ſalts of *Vegetables*. Burn any wood, herb, fruit, or flower to aſhes; make a lye with theſe aſhes with common water, not heated; filtre this through paper till it is clear as rock-water; then evaporate this lye to a proper degree in a balneum mariæ, in a glaſs veſſel. This degree of evapora-

tion muſt be carefully obſerved, according as the congelation of the ſalt is intended to be haſtened or retarded. In the common way of evaporating lixiviums of this kind in earthen veſſels over a naked fire, a great quantity of the ſalt is always loſt; part of this is carried off with the vapours raiſed too haſtily in this manner, and part penetrates the ſides and bottom of the veſſel, though it be ever ſo well glazed. The quantity of water neceſſary, is, in moſt caſes, about five pints to two pound weight of the aſhes. After all the ſalt that can be got is extracted by this operation, the aſhes being calcined again in a kiln, will afford more ſalt of the ſame kind, but in a much ſmaller quantity.

The ſalts of *Vegetables* made in this manner, are ſubject to run into water in damp weather, unleſs very carefully kept; but in this, art may be employed, and the running in a great meaſure prevented. Thus, if ſome ſulphur be added to the aſhes, when their burning is almoſt over, and conſumed by burning among them, very little difference will be made in the nature of the ſalts, but they will be more white and cryſtalline, and will keep much better. The proportion of ſulphur is to be in ſome meaſure regulated by the quantity of ſalt the aſhes are known to yield; but on a medium, five ounces of ſulphur is enough to add to a hundred pounds of aſhes. When the *vegetable* ſalts are thus made, they have each their peculiar figure, and this they retain, though diſſolved and cryſtalized again ever ſo often. If two or three of theſe ſalts, thus carefully made, and which have each their determinate figure, be diſſolved together in water, they will each of them ſhoot again ſeparate, and in their reſpective figures, not mixing and forming different figures, as might be expected.

This experiment holds good alſo, not only in theſe ſalts, but in all other kinds, which have naturally their determinate figures: thus, if in a veſſel of water, there be diſſolved together ſome blue vitriol, ſome roach alum, and ſome ſalt petre, the whole liquor will be of a blue colour from the vitriol; but when it is carefully evaporated to a proper ſtandard, the ſalts will all form themſelves again into their own regular and natural cryſtals: the vitriol will be blue as before, but all the reſt, though found in a coloured fluid, will be as colourleſs as at firſt, and each will have its own determinate ſhape. Though the lixivial ſalt of every plant thus treated, have its own peculiar figure, when diſſolved, and regularly ſhot again; yet, as in the ſea ſalt, and ſome other natural ſalts, there appear, on cryſtallization, maſſes of different figures, ſo in ſome of theſe the ſame ſalt will have two or three different figures, all peculiar however to itſelf. Two ſorts of cryſtals have been obſerved in the ſalts of the lettuce, the ſcozonera, the melon, and ſome others: three ſorts in the black pepper, and in the flowers of the red roſe; and four ſorts in the ſalts of the roots of white hellebore.

Beſides this diverſity of figures in many of the kinds of ſalts, there is one kind of cryſtals which run through the ſalts of almoſt all the kinds, in a greater or leſſer proportion: theſe are certain cubic grains or cryſtals. It is probable, that theſe are cryſtals of ſea ſalt, which is a ſalt found mixed among many others, and is naturally of this cubic figure in its firſt or ſimple concretions. It ſeems alſo a general rule, that the different parts of the ſame plant form cryſtals of a different figure; for the leaves of laurel form cryſtals very differently ſhaped from thoſe procured from the wood of the ſame tree; and the figures of the cryſtals in the ſalt of the pulp of a gourd are very different from thoſe of the ſalts made from the rind of the ſame fruit. See Tab. of Microſcopical Objects, Claſs 3.

Many ſalts made from different ſubſtances, have either abſolutely the ſame or very ſimilar figures in their cryſtals. The ſalt of the cucumber has a figure very like that of the ſalt of eye-bright; and the ſame form is obſerved in the cryſtals of orange-flowers, endive, liquorice, and many other plants.

In order to obtain theſe ſeveral cryſtals of the lixivial ſalts, determinate and exact in their figures, and not mixing one with another, it is neceſſary to uſe great caution in the evaporating the lye; for if it be totally evaporated, there remains only a cruſt of ſalt at the bottom of the veſſel, if it be only too far evaporated, though not totally: the ſalts ſhoot into large cluſters, and are never regular and perfect; and finally, if the lye is left too weak, then the evaporation afterwards, in order to the forming the cryſtals, is ſo tedious, that few can have patience to attend to it. Nothing but practice and experience can dictate when to ſtop the evaporation; but when this has been learned, the veſſel is to be taken out of the *balneum mariæ*, and the clear liquor is to be poured out of it into ſeveral ſmall vials. Theſe are to be ſtopped to keep out duſt and moiſture; and, after a time, the ſalts will congeal into cryſtals, which will be fixed to the ſides and bottoms of the vials, in their true and proper ſhapes, and in the likeneſs of rock-cryſtal, as to brightneſs and tranſparency.

Different plants and trees yield aſhes, which are impregnated in a different degree with ſalts. The ſame plants, at different ſeaſons of the year, contain alſo different quantities; and all theſe varieties make it neceſſary to attend carefully to the time of ſtopping the evaporation. It is alſo to be obſerved, that there is a great difference in the quantity of aſhes, to which plants and their flowers and fruits burn, as well as in that of the ſalt they yield; and what is moſt remarkable, is, that theſe have no connection one with the other. There are various inſtances of this kind in Redi's paper; he obſerves particularly, that an hundred weight of orange flowers reduced to aſhes, yielded only four pounds ſix ounces of them, and theſe aſhes only five drams of ſalt: that eight hundred weight of gourds made only four pounds of aſhes; but theſe yielded no leſs than ten ounces of ſalt, while an hundred weight of maiden-hair yielded nine pounds of aſhes, and theſe only four drams of ſalt. A great number of other proceſſes of this kind are mentioned in the ſame place; to which we refer the curious.

It was obſerved, that all theſe ſalts thus cryſtallized, had a purging virtue, from whatever plant they were made; and the ſalt drawn from pomegranate peels, or other aſtringents, is as ſtrongly purgative, as that from the moſt purgative drugs. The doſe in which theſe ſalts are to be taken, is from half an ounce to an ounce diſſolved in warm water; and it is all the ſame thing what *Vegetable* they are made from; the ſharp-pointed cryſtals and the blunt ones having the ſame degree of virtue. Garlick, and the like ſhop *Vegetables*, yield no ſalt at all of this kind. Philoſ. Tranſ. N°. 243. p. 296.

VEGETATION (*Cycl.*)—The great attention of all who ſtudy botany, is at preſent placed on the diſcovery of new plants; but we are yet unacquainted with many peculiarities in the moſt common ones, which may prove not a leſs worthy employment for our thoughts.

The irregularities in the *Vegetation* of the ſeveral parts of plants ſeems a ſubject well deſerving our attention; and Mr. Marchand has laid before us an inſtance of this in one of our moſt vulgar plants, the common garden radiſh.

In the month of July, this gentleman obſerved a plant of this ſpecies, which had accidentally fixed itſelf in an open place, and was then full of flowers and pods. Toward the end of one of the branches, he obſerved a kind of tuberoſity of an oblong ſhape, which looked ſomewhat like one of the pods of the plant, but that it was too long, and was very oddly twiſted and contorted; this daily increaſed in ſize, and in a week was come to its full growth, which was, in the whole, about two inches and a half in length, and three quarters of an inch thick. It was of a very rough and knotty ſurface, and like the reſt of the ſtalk, had ſeveral pedicles of flowers growing on each ſide from it; it terminated in a ſmooth end, divided into three parts, which all turned upwards.

The longeſt of theſe points terminated in a green cartilaginous flower of the ſame ſubſtance with the protuberance which produced it; in this there were all the regular parts of the flowers of the more perfect kind; there were four leaves which ſerved for a cup; four more within theſe, which repreſented the petals; ſix other ſmall bodies there ſtood in the middle of the flower, which repreſented the ſtamina; and among theſe another body which repreſented the piſtil; ſo that, here was in this irregular *Vegetation*, a repreſentation at large of every part of the perfect flower of the radiſh, excepting only the apices; but theſe were all very different in their nature and ſtructure, from their ſimilar parts in the natural flowers, being all of a hard, thick, and tough cartilaginous ſubſtance, and in colour of a greeniſh brown.

The ſhorteſt of the three points which terminated this tuberoſity, had alſo at its end a reſemblance of a flower compoſed of all the parts mentioned in the former, and of the ſame colour and ſubſtance with it, only differing in being a little ſmaller: and the third point had no regular reſemblance of a flower, but was of the ſame cartilaginous ſubſtance, and of a ſemi-circular figure, and had its upper ſurface ornamented with ſeveral irregular protuberances. This irregular *Vegetation* remained in vigour till October, when it gradually faded away, and there was no appearance of ſeeds in any part of it.

The radiſh, when its ſtalks are wounded by the pucerons, or other inſects, will often throw out a protuberance of ſome irregular figure; but the reſemblance of flowers in this, was a ſingularity never before obſerved.

To explain this, it will be neceſſary to obſerve, that every organized part of a plant contains in it a number of inviſible ſeminal principles, capable of producing plants like that to which they have owed their origin; and this is a truth of which the ſucceeding inſtances will all bring very familiar and obvious proofs.

The graft of a tree, which from only one ſingle bud, produces a tree like that from which it was taken, certainly acts upon this principle; for the whole tree is quite different from the ſtock on which it is grafted, which ſerves for no other purpoſe but merely to convey to it a proper nutritive juice for the developing its parts.

We very well know, that there are many roots, which being cut into little ſlices of only a quarter of an inch thick, each of theſe will propagate its ſpecies, and ſend up new plants, like that which the root belonged to; and ſome roots being ſplit longitudinally into four quarters, each of theſe will in the ſame manner grow and flouriſh, and ſhoot out roots from one part, and ſtalks from another, ſo as to furniſh perfect plants the ſame year: and how can this be, but by their having been ſeminal points in all theſe pieces and ſections of roots, which being dilated, and put in action by the humidity of the earth, have grown into perfect plants. Several of the bulbous rooted plants produce off-ſets from the ſeveral ſcales of their roots, and from the

ſides of their ſtalks; theſe in three years time produce perfect plants with their flowers; and what are theſe but ſo many ſeminal points ready upon occaſion to be developed.

Nothing is ſo obvious, as that the ſlips, or cuttings of trees, when planted in the ground, produce roots in one part, and buds for branches from another, and ſo finally become trees, like thoſe from which they were cut; and this, though the piece that is planted, has no viſible appearance of any bud in any part of it.

We alſo know, from daily experience, that many plants ſhoot out roots from their ſtalks as they grow, and that though this uſually happens in places where there is ſome ſolid ſubſtance for theſe new roots to faſten themſelves to, yet it happens alſo in ſome plants where there is no ſuch uſe for them; and what are theſe roots in a new part of a plant, but the effect of ſo many ſeminal points, ready to grow both into roots and into branches, in all thoſe places.

Among the thick and fleſhy leaved plants, as the opuntia, and other of the ſucculent plants of the Indies, there needs no more to produce a new plant, but to cut off a part of a leaf, and ſtick it into the earth, where it will at once take root, and produce a new plant in a very ſhort time. A thouſand other inſtances of this kind might be given; but theſe may be ſufficient to prove, that there are, in almoſt all parts of plants, certain ſeminal points, which, like the plantula ſeminalis, incloſed in the perfect ſeed of each, need only humidity, and a proper degree of warmth, to develop and unfold themſelves into perfect plants.

We are not therefore to wonder at the imitation of perfection in any irregular productions of vegetables, ſince it appears that there are numbers of perfect plants contained in every part of a growing plant, of the ſame kind. Mem. Acad. Par. 1709.

The perpendicular aſcent of the branches and trunks of trees, while their roots are at the ſame time running perpendicularly downwards, has been a ſubject of admiration to all who have conſidered the laws of *Vegetation*; and none ſeem to have well underſtood or explained it, till Mr. de la Hire, in the memoirs of the Paris Academy in 1708. He ſuppoſes that, in all vegetables, the root is furniſhed with juices of a much thicker and coarſer kind than thoſe of the trunk and branches, and that the juices of this part are heavy and denſe; while thoſe of the upper parts of the ſame vegetable are much more light and fine.

In effect, the root of the plant paſſes with all naturaliſts as a part analogous to the ſtomach in animals, where the nouriſhment is digeſted, and refined to ſuch a degree as is neceſſary for its being received into the finer and tenderer veſſels of the trunk and branches.

This difference of the juices for the ſervice of the different parts of the plant, neceſſarily ſuppoſes a different ſhape and ſize of veſſels for its reception, and, in a word, a different contexture in the parts; and there is no doubt but that this contexture is preſerved in its different manner, even in the firſt rudiments of the plant or tree, in the ſeed.

We are therefore to conceive, even in this embryo plant, a ſort of diviſion between the root and the ſtalk; ſo that all that is to be on the one ſide of that diviſion, is to receive a finer juice for its nouriſhment, and all that is on the other ſide, a coarſer. Now ſuppoſing that the plantula ſeminalis, or embryo plant in the ſeed, be turned the wrong end upwards, in the ſowing or placing that ſeed, ſo as to have its root turned upward, and its ſtalk downward; yet the veſſels of the root being larger than thoſe of the ſtalk, and conſequently capable of receiving coarſer and heavier fluids; theſe weighty fluids muſt always bend its tender fibres downwards, though their natural poſition in the ſeed would point them upward; they will always be bent downward alſo by the greater force, the longer they grow. For, ſuppoſing the fixed point, already mentioned, to be at firſt at any given diſtance from the extremities of the roots, and they bending downward, it is plain that, as they increaſe in length, they will be of more force, as the arms of a lever are always more powerful the longer they are.

While all this is doing in the root, the communication being open between that and the ſtalk, the finer juices are received there, and theſe as naturally throw the ſtalk into an erect poſture, as the others bend down the root; ſo that, in a few days the whole plant becomes turned right, the fixed point between the root and ſtalk having remained unmoved, and all on the one ſide of it having conſtantly had a tendency upwards, while all on the other had the ſame tendency downward.

From this time forward the root puſhes with more regularity downward, and the ſtalk upward, than before. There is, however, this great difference in their growth, that the ſtalk and branches find no reſiſtance to their ſhooting up, while the roots find a great deal to their ſhooting downward, by means of the ſolidity of the earth, whence the branches advance much faſter and farther in their growth than the roots; and theſe laſt, often finding the reſiſtance of a tough earth unſurmountable, turn their courſe, and ſhoot almoſt entirely horizontally. Mem. Acad. Par. 1708.

Artificial VEGETATION. Many of the proceſſes and operations in chemiſtry afford productions, whether of ſalts or metals, or of whatever other ſubſtance, which very much reſemble plants of one kind or other, whence they have been called *metallic Vegetations*. But though many have been hence induced to believe, that theſe productions were formed in the manner of vegetables, there is not the leaſt ground for ſuch an opinion from reaſon or experiment.

Mr. Homberg, who has treated very accurately of the ſeveral kinds of theſe *chemical Vegetations*, divides them into three different claſſes.

Thoſe of the firſt claſs are ſuch as conſiſt of a pure maſſy metal, without the mixture of any foreign matter whatever. Thoſe of the ſecond claſs are compoſed of a diſſolved metal, which, though it has concreted afterwards, yet retains a part of the menſtruum in it: And the third claſs contains thoſe which have no metal in them, but are merely compoſed of ſalts, oils, or earths, or of combinations of theſe.

All the productions of the firſt kind are made without the admixture of any liquor, and are merely owing to the force of fire. Theſe are of a firm and ſolid texture, and may be taken out of the veſſels in which they were made, without danger of breaking them. On the other hand, the *Vegetations* of the ſecond kind are all formed in a fluid, and are all ſo brittle, that they are not to be touched without breaking. Of the third kind, ſome are formed, or will ſubſiſt at leaſt, in the dry air; others are very tender, and are formed only in fluids, the very ſtirring about of which deſtroys them.

Examples of the firſt kind may be ſeen in the following proceſſes: Make an amalgama, with an ounce or two of fine gold or ſilver, with ſix times the weight of pure mercury revived from cinnabar; break the amalgam to pieces, and waſh it ſeveral times with river water, till it leaves no longer any colour or foulneſs in the water; after this, let it be dried, and, putting it into a glaſs retort, diſtil it in a gentle ſand heat, which ſhould be continued two days. The longer the heat is preſerved, before all the quickſilver is raiſed and carried over, the more beautiful and perfect will the *Vegetation* be. At the concluſion of the operation, the fire muſt be raiſed to ſuch a degree, as to carry over all the mercury, after which, let the fire go out. All the mercury will be found in the receiver, and all the gold or ſilver will be left in the retort. It will be ſoft and pliable, and of the moſt beautiful colour the metal is capable of receiving; and from the main maſs, at the bottom, there will be thrown out a number of beautiful branches, of different heights, and differently ramified, ſo as to repreſent ſhrubs or plants. Theſe may be ſeparated from the maſs at the bottom, and preſerved. They really reſemble, with great exactneſs, ſome ſorts of vegetables; but when we conſider the fortuitous riſe of theſe, and the regular organized bodies of the true vegetables, with their manner of explication from the ſeed, there is but a very faint reſemblance to be perceived between the one and the other.

Another of theſe *Vegetations* of the firſt claſs, is this: Melt an ounce or two of pure ſilver in a crucible, and when it is in fuſion, caſt upon it, at different times, an equal weight of common ſulphur in powder. Stir the whole about with an iron rod, and, taking it from the fire, let it cool. Beat the maſs to powder, and put it into another crucible. Set it in a ſmall fire, or in a ſand heat, to drive off the ſulphur in fumes, without running the metal into fuſion. As the ſulphur riſes into vapour, it will carry up along with it a part of the ſilver, above the ſurface of the reſt, in form of fine ſlender filaments, or flat and thin plates, which will remain fixed at their lower end to the maſs out of which they are raiſed, and will be very ſoft and pliable, and extremely bright and gloſſy. The filaments will often riſe to two inches high in this proceſs, and the flakes or plates will be of the length and breadth of a card uſed in play.

A third *Vegetation* of this claſs is the following: Melt together two ounces of ſilver, and ſix ounces of lead. Put the mixture into a copel under a muffle in a furnace, and give ſuch a fire as is neceſſary to purify ſilver by the copel. When the ſilver appears fine, take the copel out of the fire, and leave it to cool. Soon after it is taken from the fire, there will ariſe out of the ſurface ſome filaments of melted ſilver, of the thickneſs of a hog's briſtle, and of three quarters of an inch high. They are often larger and thicker than this, and not unfrequently emulate the figure of branches of coral. They are uſually hollow within, and are fixed at the bottom of the maſs of the ſilver.

Of the ſecond claſs, of metallic *Vegetations*, is the famous arbor Dianæ, and the ſeveral other ramifications of metals after ſolution. See the article DIANÆ *Arbor*, *Cycl.* & *infra*.

The third claſs, that is, of ſuch chemical *Vegetations* as contain no metallic matter, the following proceſs gives an inſtance: Take eight ounces of ſalt petre, fixed by coals; ſet it in a cellar, and let it run into an oil per deliquium: Filtre this liquor, and pour on it, by a little at a time, as much oil of vitriol as will perfectly ſaturate it. After this, evaporate all the humidity, and there will remain a compact ſaline maſs, which will be hard, very white, and of an acrid taſte; powder it groſsly, and pour upon it a ſufficient quantity of water, in an earthen veſſel; the water will begin to evaporate, after it has ſtood uncovered

a few

a few days; and, as this is effected, the ſalt will vegetate in ſeveral places into branches; theſe will ſurround the whole ſurface of the water, and will continue to form themſelves anew as the water evaporates, till it is all gone; after which they will ceaſe; but if more water be added to the ſalt, they will appear again in all their beauty, as that afterwards evaporates.

Another example of theſe ſaline *Vegetations* is ſeen in the branched cryſtallizations of ſalts, naturally produced on the ſhore of the Spaniſh and other ſeas, and which may eaſily be imitated by art: This is no other than a natural conſequence of the ſea plants growing on the ſhore, being, when their leaves are decayed, cruſted all over their branches with cryſtals of ſea-ſalt, left by the evaporation of the water, which had been left upon them by the receſs of the ſea; this proceſs being very frequently repeated on them, every wetting leaves a freſh coat of ſalt over them; ſo that, at length, the whole appears a mere plant of ſalt. Very beautiful ſpecimens of this kind are often met with on the ſhores; and may be imitated by art by means of ſea-ſalt diſſolved in water, and the ſolution carefully filtred. But, in doing this, it is neceſſary to peel off the bark of the plant which ſerves for the mould; for as the bark is uſually brown or green, or of ſome colour different from that of the ſalt, it diſcovers itſelf too plainly, and takes greatly off from the beauty of the whole.

A third very ſingular inſtance which Mr. Homberg gives of theſe *Vegetations* is this: He collected about three pints of rain-water from the bottom of an old wooden trough, in which it had ſtood about half an hour, after running down from the tiles of an old houſe. This water had fallen in the time of a tempeſt, attended with thunder. He had ſet this bottle of water, careleſsly ſtopped with a piece of paper, in a window, which looked toward the ſouth, where it ſtood three months. The water had appeared tolerably clear, when it was firſt ſaved; but, by degrees, as it ſtood, there ſubſided to the bottom a greeniſh ſediment, of about a quarter of an inch in thickneſs. There was apparently a fermentation in this matter, and it appeared ſpongy and cavernous, and had frequently air-bubbles riſing up from it. In the middle of a hot day, in July, Mr. Homberg obſerving this bottle, ſaw that there was no muddy ſediment at the bottom, but only a clear and beautiful green *Vegetation*, part of which had alſo raiſed itſelf to the ſurface of the water, and part remained ſuſpended, in form of ſlender filaments, in the middle. The extremity of every one of theſe filaments was furniſhed with a ſmall round globule, which appeared white and bright as ſilver, and reſembled a ſort of fruit at the top of the branch.. On ſhaking the bottle about, the whole *Vegetation* diſappeared, and the matter of it blended itſelf among the water in a looſe irregular manner. About ten o'clock the next morning, when the ſun began to warm the bottle, the *Vegetations* appeared again in their former ſhape, and were only owing to ſmall bladders of air which, in their riſing from among the green mud at the bottom, drew up long ſtrings of it along with them, and appearing in form of ſmall round pearls at the tops of the branches. This appearance continues ſo long as the ſun ſhines upon the bottle; after which the bubbles, and their pedicles, gradually ſink together, and lie confuſedly at the bottom, till the morning ſun of the ſucceeding day raiſes them again in the ſame manner from the bottom to the ſurface. Mem. Acad. Par. 1710.

The moſt beautiful of all metallic *Vegetations* is the *arbor Dianæ*, or ſilver-tree. A great many proceſſes for the making this have been publiſhed; but ſome of them are not found to ſucceed, upon experiment; and others are too tedious to follow. Mr. Homberg gives a ſuccinct account of the method by which he uſed to make it, and this is never known to fail. Make an amalgam in the cold, with four drams of pure ſilver, and two drams of crude mercury; diſſolve this in four ounces of aqua fortis; mix this with a pint and half of water, and ſet it by in a bottle well ſtopped. When there is occaſion to uſe it, pour about an ounce of it into a little vial; put into this a piece of the bigneſs of a ſmall pea of the common amalgama, either of gold or ſilver, made as ſoft as butter. Leave the vial to reſt for two or three minutes; and in that time there will begin to ariſe a number of little upright ſtalks from the ball. Theſe will viſibly increaſe in length every moment, and, ſoon after, will throw out ſeveral ſide branches. Thus, by degrees, the whole will have the form of a little tree; the ball of amalgama will be of a dead whitiſh colour; but the trees will be like the brighteſt ſilver. The whole of this beautiful *Vegetation* will be performed in a quarter of an hour: But it is to be obſerved, that the liquor which has ſerved once, will not do again.

The matter which forms the tree is not formed by the amalgam put into the liquor; but by the firſt amalgam which was diſſolved in it, the water added afterwards having ſo much weakened the diſſolvent, that it is not able to keep the matter ſuſpended, when there is offered any opportunity for its precipitating; and the mercury, thus diſſolved, meeting here with mercury undiſſolved, quits the diſſolvent, and applies itſelf to it; but that not in its own form of globules, but in ſuch ſhapes as the mixture of ſilver, and of the ſalts of the nitrous acid in the diſſolvent, determine it to.

This proceſs may be varied a great many ways, as to the thickneſs or thinneſs of the branches, and the ſlow or ſpeedy manner in which they are formed, according to the nature of the liquor, and of the amalgama. The weaker the liquor is, the ſlower will the branches be formed; and they will, in this caſe, be longer, and fewer in number, and by that means the more imitate a tree. On the contrary, when the liquor is too ſtrong, the whole ſurface of the globule of amalgam thrown into it, will, in a few minutes, be covered with a low and ſhort tuft of buſhes; and that water, which is ſtrong enough of the ſolution to produce trees upon a thick amalgam, will not be able to produce any thing upon ſimple mercury, and but very little upon a thin amalgam. And, on the contrary, that liquor which is ſtrong enough to produce a ramification upon ſimple mercury, will, on a thin amalgam, produce only a few ſhort buſhes; ſome yet lower than theſe will be formed by it on a thicker amalgam, and it will, in fine, diſſolve the amalgam.

It appears from the whole, that there is in this nothing of true *Vegetation*, but merely a ſimple cryſtallization in this form. There is alſo another *Vegetation* formed by cryſtallization, without the aſſiſtance of mercury; but it is more ſlow, and wants the beautiful metalline colour of the laſt. It is thus performed:

Diſſolve one part of fine ſilver in three parts of aqua fortis, evaporate half the diſſolvent, and add to the remainder of it twice its weight of diſtilled vinegar, well dephlegmated; ſet this mixture by for a month, and at the end of that time there will be found, in the middle of the vial, a tree, in form of a fir, with its branches reaching up to the ſurface of the water. This is no other than a cryſtallization of the diſſolved ſilver, whoſe parts have been thrown into this form by the mixture of the ſalts of the vinegar with thoſe of the nitre. This therefore has not the colour of ſilver, but is white and tranſparent, in the manner of a genuine ſalt, and makes a very elegant figure in the menſtruum.

A third *Vegetation* of the metallic kind is thus performed: Take a quarter of a pound of common white river pebbles, calcine them two or three times over, quenching them every time in water; after this, beat them to a fine powder, and mix them exactly with twelve ounces of ſalt of tartar. Melt the whole in a ſtrong fire, and let it cool, it will be a vitrified maſs. Powder it, and lay it on a marble in a cellar, it will diſſolve into an oil per deliquium: Keep this in a vial; then take any metal you pleaſe; diſſolve it in aqua-fortis or aqua-regia; evaporate the diſſolvent, and there will remain a grey powder. When you have a mind to ſee the *Vegetation*, put a ſmall piece, about the bigneſs of a pea, of this calx into ſome of this liquor. In three or four minutes there will iſſue out of it a ſtalk, which will grow longer and thicker every moment; and finally will ſhoot out two or three branches from its ſides, and each of theſe, as well as the main trunk, will be terminated by a large round air-bubble.

This is a *Vegetation* extremely different from either of the others. In them the branches were only cryſtallizations of the diſſolved metal; and the little maſs of matter, thrown into the liquor, furniſhed nothing to them. In this, the whole is owing to the matter thrown in, and is the mere effect of a fermentation. The calx of the metal yet contains ſome acids. The alkaline liquor ferments with theſe; the fermentation indeed is but ſlow, becauſe the metalline particles envelope the acid ſalts. But as, in all fermentations, there is air diſcharged; ſo in this air-bubbles are ſent upward from the maſs; but the metalline particles riſing with them, detain them, and make their aſcent very ſlow, while they are compelled to draw up a long filament of the metallic matter with them. The metal is ſoftened during the time of the fermentation, otherwiſe it could not be thus drawn up with the air-bubbles; but it immediately hardens again, when out of the ſtate of ferment, and becomes able to ſupport itſelf in the branched form, even when taken out of the liquor it is formed in.

There is another metallic *Vegetation*, which is formed by merely amalgamating a metal with mercury, without the mixture of any acid liquor. Take three or four parts of mercury, purified by five or ſix ſublimations, and one part of fine gold or ſilver; make an amalgam without heat; ſet this amalgam to digeſt for fifteen days in a ſlow heat, in a matraſs hermetically ſealed; the amalgam will in this time harden, and all its ſurface will be covered with branches and trees, ſome of them riſing to an inch high; the quantity of mercury muſt be nicely adjuſted in this experiment, for otherwiſe there will be no *Vegetation*, whether the quantity be too much or too little; and if the veſſel be not perfectly cloſed, the proceſs will fail, though the quantities and the degree of fire have been ever ſo well obſerved. This *Vegetation* is only made by the fire heating the mercury, and raiſing it, in order to its flying off; in which riſing it lifts up parts of the metal with it, and leaves them in that poſture, in the forms of trees and plants. Mem. Acad. Par. 1692.

VEGETATION *of Salts*, a name given by Mr. Petit, of the academy of Paris, to the concretions which ſalts form, after ſolution in water, when ſet in the air to evaporate.

Theſe concretions always appear round the ſurface of the liquor, affixed to the ſides of the veſſel, or ariſing above its top,

and are very different in the different ſalts, and in moſt of them very beautiful.

This gentleman acknowledges that the obſervation was owing to accident; for having ſet out ſeveral ſmall veſſels full of ſolutions of ſalts, in order to obſerve the progreſs of their *Vegetation*, he was greatly pleaſed and ſurprized to find this remarkable accident attending them. The firſt ſalt he obſerved it in was nitre; but ſoon after, finding that the ſolution of ſal armoniac did the ſame, and that with different-figured concretions, the figures which the reſt would aſſume appeared to deſerve an enquiry. He choſe to call theſe figures, not before obſerved, *Vegetations*, in the language of the chemiſts; not that he ſuppoſed them to be produced as plants, by a regular aſcent of juices, but merely by appoſition of ſaline particles one to another. Theſe are all properly of the third claſs of the chemical *Vegetations*, according to Mr. Homberg's diſtinctions.

The ſeveral ſalts he choſe to experiment upon, were refined ſalt-petre, ſal prunellæ, ſal armoniac, ſea-ſalt, ſal ex duobus, or the impregnation of the caput mortuum, left after the diſtillation of aqua-fortis, *&c.*

Theſe ſalts were diſſolved in the ſeveral following liquors; common water, lime water, white wine, red wine, ſpirit of nitre, ſpirit of ſalt, ſpirit of vitriol, oil of tartar per deliquium, ſpirit of ſalt, and the volatile ſpirit of urine, and mixtures of oil of tartar per deliquium, with ſpirit of vitriol, and with ſpirit of nitre.

Salt-petre, diſſolved in common water, produced *Vegetations* reſembling the rugged points of rocks; and the more the water is ſaturated with this ſalt, the more beautifully the *Vegetations* are formed: For this purpoſe, one part of ſalt may be diſſolved in three parts of water, in warm weather; but in colder weather the proportion of the water muſt be increaſed to four times, or four and a half, the quantity of the ſalt.

Salt-petre, diſſolved in lime-water, affords the ſame *Vegetation*; but the points are finer, and the whole bodies of the concretions ſmaller. Wine diſſolves a ſmaller quantity of ſalt-petre than water; and though the *Vegetations* are ſmaller from this ſolution, yet every particle compoſing theſe is granulated in manner of the ſurface of a mulberry; and the whole concretions reſemble ſome of the botryoide mineral bodies in miniature, or grapes thick ſet upon the bunches.

Spirit of nitre, and oil of tartar, being mixed together to the point of ſaturation, and the ſalt formed by this diſſolved in a quantity of water juſt ſufficient for this purpoſe, and the ſolution expoſed in a glaſs or earthen veſſel to the ſun, there are formed concretions of the ſame kind with thoſe of the common ſalt-petre diſſolved in water, except that they are more fine and more ramified. It need not appear wonderful, that this mixture ſhould produce the ſame concretions with pure nitre, ſince it is well known, that true and proper nitre is the reſult of it.

An ounce of crude ſal armoniac being diſſolved in three ounces of common water, and expoſed to the ſun, there form, upon the edges of the veſſel, *Vegetations* more thick and leſs pointed than thoſe from nitre, and more reſembling rude maſſes of flints thrown confuſedly one upon another. This ſolution being ſet out in veſſels of tin, the appearances are much altered, the concretions are all of a roundiſh figure, and are covered on their outſides with numbers of fine points.

The ſame ſalt, diſſolved in lime-water, produces a different ſort of concretion; thoſe in glaſs veſſels are compoſed of round heads, beſet with ſeveral tolerably large points; and in veſſels of other kinds, the concretions vary a little, but always keep the ſame general form.

Spirit of ſalt, and ſpirit of urine, mixed to the point of ſaturation, and expoſed in earthen veſſels, produce concretions very little differing from thoſe of ſal armoniac, when they are nicely examined; on a careleſs view, however, they appear very different, the ſeveral granules they are compoſed of being much ſmaller than in the common ſolution of that ſalt.

It is not ſtrange that this mixture produces theſe concretions, as well as the ſimple ſolution of ſal armoniac, ſince this mixture produces a true and genuine ſal armoniac.

Sal armoniac diſſolved in white or red wine, and expoſed, produces, inſtead of theſe roundiſh concretions, a ſort of oblong ones, ſomewhat irregular in form, and granulated all over their ſurfaces, in the manner of a mulberry. Theſe are faſtened to a ſort of tails, and by this means are made to reſemble, upon the whole, cluſters of grapes. This might give perſons of warm imaginations an opinion, that the wine was ſhewing itſelf again in the form of the grape, whence it was made; but it is to be obſerved, that the flowers of ſal armoniac, which riſe in the diſtillation of the volatile ſpirit with ſalt of tartar, being diſſolved in water, produce the ſame grape-like cluſters. And the common ſal armoniac, diſſolved in an impregnation of the caput mortuum of aqua-fortis, affords the ſame grape-like concretions as when diſſolved in wine.

The concretions of theſe ſalts will form themſelves in the ſhade, but they are always much more beautiful when the veſſels have been expoſed to the ſun; they are alſo much ſooner formed by aſſiſtance of the ſun's heat: It will take a month at leaſt to produce good *Vegetations* of either in the ſhade; but in the ſun, a week, or, at the utmoſt, ten or twelve days, will be found ſufficient. There are many ſolutions of ſalts, however, which have no occaſion for the ſun's heat to form them. Of this kind are the following:

A mixture of ſpirit of vitriol, and oil of tartar per deliquium, being made up to the point of ſaturation, add ſo much water as will be ſufficient to diſſolve the ſalt precipitated to the bottom of the mixture; if this ſolution be ſet to *vegetate*, the concretions will form themſelves into a ſort of little buſhes: Theſe are very beautiful; but ſo many accidents muſt concur to their formation, that they will not always appear, even from the ſame quantities of the ingredients, managed ſeemingly in the ſame manner.

One of the moſt ready and moſt beautiful of all the ſaline *Vegetations*, is that formed by a ſolution of the ſalts in the caput mortuum of aqua-fortis, with common water. If a pint of water be put to half a pound of this caput mortuum, and the whole boiled together, that the ſalts may be diſſolved, and the liquor afterwards filtrated, and expoſed in an earthen veſſel, there will be formed, in about eight and forty hours, *Vegetations* wholly like thoſe from the mixture of ſpirit of nitre and oil of tartar, except that theſe from the caput mortuum are more ramified and more beautiful. When the ſolution is expoſed in a glaſs veſſel, they form themſelves on the ſurface into very beautiful figures of trees, ſhrubs, and buſhes; and this not only on the ſurface, but on both the inſide and outſide of the glaſs. Theſe can be compared to no known concretions, except to the *Vegetations* of iron, deſcribed by Mr. Lemery; they differ indeed in nothing from theſe, but that the *Vegetations* of the metal are of a browniſh colour, whereas thoſe of the ſalt are white.

This impregnation ſucceeds beſt in dry weather, for in a moiſt ſeaſon the *Vegetations* form themſelves more ſlowly, and are much leſs beautiful. Glaſs veſſels are alſo eſſential to the *Vegetations* being formed in their greateſt beauty; they are never nearly ſo beautiful in earthen ones; and even in the former the *Vegetations* ſucceed much better in ſome ſorts of glaſs, than in others. The caput mortuum of aqua-fortis alſo is very different, from the different diſtillations; and all of it does not ſucceed alike in this *Vegetation* of the ſalt. That which looks lighteſt, and of the reddeſt colour, ſeems the beſt for this purpoſe. An impregnation of this caput mortuum in red wine, produces no *Vegetations*, but only forms a cruſt with ſmall eminences on the ſides of the veſſel; and ſalt-petre, diſſolved in the impregnation of this caput mortuum in water, produces a much more beautiful *Vegetation* than that of ſalt-petre alone; but at the ſame time much leſs beautiful than that of the impregnation alone. Sea-ſalt, diſſolved in the ſame impregnation, ſometimes will produce beautiful *Vegetations*, but ſometimes only a rough cruſt. Common rough ſalt-petre forms no *Vegetations*, but only cruſts over the veſſel, as is the caſe with the ſolutions of many of the metals in different acid menſtruums. And the ſame is the caſe in regard to many ſalts from which it might be natural to expect concretions of this kind. Memoirs Acad. Par. 1722.

VEGI, or UGI, the names given by the Arabian phyſicians to the acorus. Theſe writers ſeem not to have been acquainted with the plant itſelf in its growing ſtate, but only to have known that part of it which was uſed in medicine in their time; but the Greeks deſcribe the plant in ſome ſort.

Serapion mentions the *Vegi* or *acorus* as a medicine; but he quotes no one Arabian who has named it, but tranſcribes his account of it from Dioſcorides; and Aviſenna ſays it is the root of a plant much reſembling the alburdi, that is, the paper-reed of the river Nilus. Aviſenna adds, that the acorus grows only in wet places; and the old manuſcripts of Dioſcorides have the epithet *papyraceum* for the *acorus*, though imperfectly expreſſed; and thence probably this author took the hint of reſembling it to the paper-reed.

VEIENTANA *Gemma*, in natural hiſtory, the name of a gem deſcribed by Pliny, and ſaid to be found in Italy; he ſays it was black, but ſurrounded with a circle of white; it was probably a ſtone of the camea kind.

VEIN (*Cycl.*)—*Pulſations of the* VEINS. The pulſations of the arteries are well known; but though no ſuch motion be natural to the *Veins*, yet there have not been wanting inſtances in which a morbid ſtate has been able to produce them. The pulſations of the arteries anſwer to the motions of the heart, that throws the blood into them; but when this fluid has once got into the *Veins*, it uſually returns through them to the heart again in an uniform and equable motion; and this is not only the caſe in the human body, but alſo in other animals, whether they be in health or in ſickneſs. One of the inſtances in which the contrary has been obſerved, and where the *Veins* have had a pulſation, is a caſe related by Mr. Homberg to the Paris Academy. The patient was a lady of about thirty-five years old, afflicted with a grievous aſthma, a pain in the head, a continual want of reſt, and terrible palpitations of the heart.

On opening her body after death, the heart was found of twice its natural dimenſions, its cavities very large, and its ſides very thin; and in each trunk of the arteries there was a fleſhy polypus fixed to their internal ſurface. That in the trunk of

the aorta was found to be two foot long, and plainly of a fibrous fleshy substance, for six or seven inches of its length; but from that downwards, it became only like clotted blood.

At the time that this lady was most violently afflicted with her asthma, the veins of her arms and neck were plainly perceived to have a pulsation wholly like that of the arteries, and plainly followed the motion of the heart: She had, in the latter time of her life, usually two of these fits in four and twenty hours; and when they were over, the pulsations in the *Veins* ceased. Mem. Acad. Par. 1704.

VEINS *of plants*, a term used by Dr. Lister, to express certain vessels in plants, which are analogous to the *Veins* of animals, and have been observed in some degree, by the naturalists of almost all ages, though differently described by authors. Pliny has described these parts of a plant under the names of *venæ* and *pulpæ*; and Dr. Grew calls them *fibres* and insertments on the ligneous body, interwoven with that substance which he takes to be the cortical body, that is, the several distinctions of the grain. This author also calls them the pores of the ligneous body; but that they are not merely such, may be plainly seen in cutting off a transverse piece of the stalk of some large wild plant, as the great wild angelica, or the like. In the cut stalk of this plant, the *Veins* every where shew themselves to be distinct from fibres, observable in the parenchyma of the same cortical body with themselves, the milky juice always rising beside the fibres not in any fibre: also in a transverse cut of the root of the common burdock, the like juice springs on both sides of the several radii of the woody circle, that is, in the cortical body, and the pith only.

Again, where there is no pith, there is none of this juice to be observed, and consequently none of these *Veins*, as in the roots of plants, and trunks of trees, but even in the bark of either. The sphondylium, the cicutaria, and many of the thistle kind, are instances of this. Dr. Grew describes pores in the cortical body, and pith; but these vessels are not of the number of the things designed by those pores; these pores are extended by the breadth of the plant; but the pores of this juice are extended lengthwise. The pith of a dried fennel stalk will shew these very beautifully, and with due care, they may be traced all along the whole length of that pith.

It remains therefore, that if these are pores, they must be of those pores of the cortical body, that are supposed to be extended the length thereof; but it is much more proper to call them *Veins*, or vessels, analogous to those of the human body, and covered with their proper membranes; for they are to be found in the pith, and sometimes in the cortical body of the plant, not included within the common tunicle of any fibres, but having their own proper membranes; which indeed, if they had not, the porous and spungy parts of the pith and cortex would be in all places filled alike with the juice; but on the contrary, it is found to rise in a few set and determinate places only, that is, according to the disposition and order of the vessels. If a ligature be made on the trunk of the spurge, and the trunk wounded, the juice bursts immediately out in large quantities; but if not wounded, none is discharged by means of the ligature: now the exterior part of the trunk of these plants is allowed by all observers to be perforated in almost innumerable places; and therefore, if this milky juice were not contained in its peculiar vessels, there is nothing to hinder, but it should rush out at these pores on the ligature made above; but it is evident, that it does not do this till the containing vessels are wounded.

The juices of plants are probably then all contained in these *Veins*, or distinct and proper vessels, covered with their own membranes, and not loosely distributed through the substance of the plants. Those things which are essential to *Vegetation*, are alike allotted to all plants; and it is to be supposed, that all plants have these vessels, though we cannot alike distinguish them in all. Those plants, whose juices are white or yellow, or of any other colour different from that of the body of the trunk, are always distinctly seen, pouring out those juices at separate holes in a wound. Those whose juices and stalks are of the same colour, do not so readily shew them; but there is a time, when they are, in some parts of these plants, if not in all, sufficiently plain to the naked eye.

The tender shoots of the greater and lesser maple, in May, are full of a milky juice, which is the known liquor of these *Veins*; and if a clean knife-blade be applied to a transverse cut of a young shoot of elder, and then raised gently away, the liquor of those *Veins* will be drawn up into strings, answering to the orifices of the *Veins* made by the wound. The pedicles of the leaves of our garden rhubarb, frequently shout out a sort of white and transparent gum: this must be an accidental exsudation of a gum, very constantly contained in the *Veins* of the plant, though not distinguishable in these stalks: this, and many other like instances, prove the existence of such vessels, though they are not obvious to the eye; and there remains no doubt but they are to be found in all plants by some trials. Even the mushrooms, the lowest class of plants, are not destitute of these vessels; there is one which shews them very evidently, this is the wood mushroom, whose stalk, when broken, or cut, discharges a milky juice, as hot as pepper, or more so; and this does not exsudate from the whole spungy substance of the stalk, but is plainly discharged from the mouths of certain wounded vessels.

The primary use of these *Veins* is certainly to carry the nutritious juice of plants; and this appears plainly in that where they are not, there is no vegetation, as is seen if an engrafted branch or arm is bared, or the clay stripp'd off; in this case, all the course of the vegetation will appear to have been made only by the bark, the wood having had no share in it. The bark is the place where these *Veins* lie, not the wood; and therefore, it is no wonder that the vegetation, if dependant on these *Veins*, is carried on only where these *Veins* are. The vegetable drugs of our shops are all of this nature, the juices contained in these *Veins* being evidently what give them their virtue. Phil. Trans. N°. 79.

VEIN, among miners, is that space which is bounded with woughs, and contains ore, spar, canck, clay, chirt, croil, brownhen, pitcher-chirt, cur, which the philosophers call the mother of metals, and sometimes soil of all colours. When it bears ore, it is called a *quick vein*; when no ore, a *dead vein*. *Houghton*'s Compl. Miner, in the Explan. of the terms.

The *Veins* of Mines differ greatly from one another in depth, length, and breadth; some stretch obliquely, from the surface toward the central parts of the earth; and these the miners call deep *Veins*; others lie shallow, and circular, so as to encompass a large space; and these are termed spreading *Veins*; others possess a great part of the space they lie in, both in length and breadth; and these are called accumulated *Veins*, being no more than a space possessed by a large group of fossils of one kind. To give the compleat history of *Veins*, and fibres which are smaller *Veins*, their differences, their directions, their interstices, their discontinuations, their risings and fallings, and their goodness, would be a large work. Let it be oberved, however, that these things seem all to proceed in a certain order, though that order, and the laws and rules of it, are not perfectly understood, so as to afford sure directions for practice; whence it sometimes happens, that after a *Vein* has been successfully traced for some time, it dips, breaks off, or takes a different course, leaving the workmen as it were at a fault.

When the *Vein* is found, a pit is to be sunk upon it, and a crane fixed at the top of the pit for craning up the ore. Burrows, or adits, are also to be cut horizontally through the hill in one or more places, reaching to the mine, and serving to wheel out the ore, instead of craning it up. *Shaw*'s Lectures, p. 246.

The manner of digging varies according to the nature of the *Vein*. If this be soft, it is dug with the spade, and turned out into wooden trays, placed to receive it. If the *Vein* be harder, it is to be knocked out with the hammer and chissel. If it be too hard for this method, they soften it by fire, which makes all stones brittle; but the most expeditious of all mine working, is that by gunpowder, which tears up, and breaks to pieces vast rocks in a moment.

VELITIS, in the natural history of the antients, the name of a peculiar sort of sand used in the making glass.

The antients, in their different ages, made glass of different materials. These, however, were principally thin natrum, which was, in most respects, the same thing with our alkali salts used in glass-making, mixed with flints, shells, or sand. Sand was the most universal mixture; and for this purpose, they always chose such sand as was found washed clean on the banks of rivers; and this they therefore called glass-sand, or *Velitis*, or *hyalitis*. *Hill*'s Theoph. p. 11.

VELLA, in botany, the name of a genus of plants; the characters of which are these: The perianthium is of a cylindric figure, and erect, and is composed of four slender and obtuse leaves, which fall with the flower; the flower is composed of four petals, and is of the cruciform kind; the petals are of an oval figure, and of the length of the cup; the stamina are six filaments of the length of the cup, only two of them are a little shorter than the other four; these two stand opposite to one another; the antheræ are simple; the germen of the pistil is oval; the style is conic; the stigma is simple; the fruit is a globose, cristated, pendulous pod, containing two cells, divided by a membrane, twice as large as the pod itself, and of an oval figure; the seeds are roundish. *Linnæi* Gen. Plant. p. 317.

VELLIA, in zoology, a name used by some authors for the *lanius minor*, or *lanius tertius* of Aldrovand, called in England the *flusher*. *Ray*'s Ornithol. p. 54. See the article FLUSHER.

VELOCE, in the Italian music, is used for quick.

VELOCISSAMENTE, or VELOCISSIMO, in the Italian music, is used for very quick, or with great rapidity. It is seldom met with; *presto*, or *prestissimo*, being mostly used in its stead. *Brossard.*

VELOCITY, (*Cycl.*) — In the doctrine of fluxions it is usual to consider the *Velocity* with which magnitudes flow, or are generated. Thus, the *Velocity* with which a line flows, is the same as that of the point, which is supposed to describe or generate the line. The *Velocity* with which a surface flows, is the same as the *Velocity* of a given right line, that, by moving parallel to itself, is supposed to generate a rectangle, always equal to the surface. The *Velocity* with which a solid flows, may be measured by the *Velocity* of a given plain surface, that

that by moving parallel to itſelf, is ſuppoſed to generate an erect priſm, or cylinder, always equal to the ſolid. The *Velocity* with which an angle flows, is meaſured by the *Velocity* of a point, ſuppoſed to deſcribe the arc of a given circle, which ſubtends the angle, and meaſures it. See *Mac Laur.* Fluxions, B. 1. ch. 1.

All theſe *Velocities* are meaſured at any term of the time of the motion, by the ſpaces which would be deſcribed in a given time, by theſe points, lines, or ſurfaces, with their motions continued uniformly from that term. *Mac Laur.* ibid.

The *Velocity* with which a quantity flows, at any term of the time, while it is ſuppoſed to be generated, is called its *fluxion*. See the article FLUXION.

VELVET (*Cycl.*)—*Colour of black* VELVET. The manner of giving this deep and fine colour to glaſs, is this: Take of cryſtalline, and pulverine frit, of each twenty pounds, of calx of lead and tin four pounds; ſet all together in a pot in the furnace, well heated; when the glaſs is formed and pure, take ſteel well calcined and powdered, ſcales of iron that fly off from the ſmith's anvil, of each an equal quantity; powder and mix them well; then put ſix ounces of this powder to the above deſcribed metal while in fuſion; mix the whole thoroughly together, and let all boil ſtrongly together, then let it ſtand in fuſion twelve hours to purify, and after this work it. It will be a moſt elegant *Velvet* black.

There is another way of doing this, which alſo produces a very fair black. It is this: Take an hundred weight of rochetta frit, add to this two pound of tartar, and ſix pound of manganeſe, both in fine powder; mix them well, and put them to the metal while in fuſion, at different times, in ſeveral parcels; let it ſtand in fuſion after this for four days, and then work it. *Neri*'s Art of Glaſs, p. 95, *& ſeq.*

VELUM, in eccleſiaſtical writers, the ſame with what is otherwiſe called *brandeum*. See the article BRANDEUM.

VELUM *quadrageſimale*, a veil, or piece of hangings, antiently drawn before the altar in *Lent*, as a token of mourning and ſorrow. *Blount.*

VENABULUM, in antiquity, a long kind of ſpear uſed in hunting wild beaſts. *Hofm.* Lex. Univ. in voc.

VENCU, in botany, the Chineſe name for an excellent fruit found in that country, which the Portugueſe call *jamboa*, and the Dutch *pompehinoes:* It grows on prickly trees, like the limon-tree, only larger. Its flowers are white, exactly the ſame in ſhape with thoſe of the limon, and have an exceeding ſweet ſmell; a very fragrant water is diſtilled from them. The fruit itſelf far exceeds the citron in bulk, being in ſize equal to, and ſometimes exceeding a man's head. The rind is like that of the golden rennet; the pulp is of a reddiſh colour, and its taſte partakes of ſweet and acid, reſembling that of grapes not fully ripe. A liquor is preſſed from it, as in Europe, from apples, pears, &c. It will keep for a whole year. *Hofm.* Lex. Univ. in voc.

VENDITOR *regis*, the *king's ſalesman*, or perſon who expoſed to ſale, goods and chattels ſeized or diſtrained to anſwer any debt due to the king. This office was granted by king Edward I. to Philip de Lardimer, in the county of York, *Ita quod ipſe, vel certus ſuus attornatus, ibit ad mandatum vicecomitis de loco in locum infra com. præd. ſumptibus ſuis ad venditiones faciendas, & capiat de unaquaque venditione pro feodo ſuo* xxxii. Den. but the office was ſeiſed into the king's hands for the abuſe thereof. Anno 2 Ed. 2. *Blount.*

VENENUM *cocci*, a term uſed by many of the antients for the purple tinge, which the kermes berry, as it is uſually called (ſee the article KERMES) gave to linnen, or other things.

The word *Venenum* being generally underſtood to expreſs poiſon, it has been ſuppoſed by many, that the kermes was eſteemed poiſonous, or that there were two ſorts of this drug; the one a harmleſs medicine, and the other poiſonous. But there is no warrant for this in any of the old writers, and the whole ſeems indeed but a miſtake about the ſenſe of the word *Venenum*, which we find by many paſſages of the beſt authors, ſignified a ſtain, as well as a poiſon.

The antients called the veſtments dy'd ſcarlet with the kermes indifferently, by the names of *flammeæ*, or *venenatæ*. Servius tells us, that in certain ſacred ceremonies, it was neceſſary that the prieſt ſhould be clothed in a ſcarlet robe; and he uſes the word *venenato* to expreſs it in ſome places, and *flammeo* in others.

VENER, one of the many names by which the chemiſts call Mercury.

VENEREA *concha*, in natural hiſtory, the name of a very large and elegant genus of ſhells, more uſually called the *porcellanæ*. See the article PORCELLANA.

VENETA *bolus*, a fine red earth uſed in painting, and called in the colour-ſhops *Venetian red*.

It is improperly denominated a bole, being a genuine ſpecies of red ochre. It is of a fine bright, and not very deep red, approaching, in ſome degree, to the colour of minium, or red-lead, and is moderately heavy, and of an even and ſmooth texture, yet very friable, and of a duſty ſurface: it adheres firmly to the tongue, is very ſmooth, and ſoft to the touch, eaſily crumbles to pieces between the fingers, and very much ſtains the ſkin in handling. It has a ſlight aſtringent taſte, and makes no fermentation with acids.

It is dug in Carinthia, and ſent from Venice into all parts of the world, being an excellent colour, and very cheap; our colour-men, however, find too many ways of adulterating it. *Hill*'s Hiſt. of Foſſils, p. 59.

VENISON, *Cycl.*—The old huntſmen have determined, that every beaſt of the foreſt, that is food for man, is *Veniſon*. In many parts of the world, the bears are as regularly hunted, as the hare and buck, *&c.* are with us, and there are called *Veniſon*; but with us, at preſent, the word *Veniſon* ſeems limited to the fleſh of the hart, the hind, the buck, the doe, and the other creatures of that kind.

Some have extended the ſignification of the word to the beaſts of the foreſts, which were chaſed as game, and afforded the diverſion of hunting, whether their fleſh were eaten or not; thus, in ſome places, the wolf and the fox are reckoned among the *Veniſon* beaſts. See the article FOREST.

VENOSA *arteria*. See the article ARTERIA *venoſa*.

VENOSE *Leaf*, *Venoſum folium*, among botaniſts. See the article LEAF.

VENTININA, a term uſed by Paracelſus and his followers, to expreſs the art of divining, or knowing by the winds and their courſes, the good or ill effects of ſeaſons.

VENTRICULUS *ſuccenturiatus*, in medicine, a name given by ſome to the duodenum, when very large. Medic. Eſſ. Edinb. abridg. Vol. 2. p. 34.

VENUS (*Cycl.*)—A ſmaller ſtar having been obſerved by Mr. Short near *Venus*, which had the ſame phaſis as that planet, has given ſome ſuſpicion of its having a ſatellite. See Phil. Tranſ. N°. 459. ſect. 23. where it is ſaid, that M. Caſſini, in his Elemens d'Aſtronomie, mentions a like obſervation.

VER-*puceron*, in natural hiſtory, a name given to a kind of inſects which are fond of eating the *puceron*, and deſtroy them in vaſt numbers. See the article PUCERON.

They are thus called, as the ant-eater is, *formica leo*, from their deſtroying great numbers of them.

Theſe *Ver-pucerons* are a ſort of worms produced from the eggs of flies, and are of two principal kinds; the one having legs, the other none.

When we obſerve the vaſt number of young produced by every puceron, and the quick progreſs they make in their multiplication, we are apt to wonder, that every plant and tree in the world is not covered with them; but on the contrary, when we obſerve the deyaſtation theſe devourers make among them, we are apt to wonder how any of them eſcape at all, to perpetuate the ſpecies. Theſe worms indeed ſeem created for no other purpoſe but to deſtroy them; and this they do in ſo violent a manner as is ſcarce to be conceived. As the flies of many kinds lay their eggs on meat and other ſubſtances, which they know will afford food for the young ones, when hatched from them: ſo the parents of theſe worms lay their eggs on the branches and leaves of trees loaded with pucerons, on which they know they will feed. The worms produced from them are devourers from the very inſtant they are hatched, and find themſelves placed in the midſt of prey, being every way ſurrounded by a nation of creatures which are their proper food, and which are furniſhed with no weapons, either offenſive or defenſive, and which never ſo much as attempt to fly from them, but ſeem wholly ignorant of their danger, till ſeized upon by the devourers. *Reaumer*'s Hiſt. of Inſects, Vol. 6. p. 111.

Theſe worms are very large in proportion to the pucerons, the difference not being leſs than that between the lion and the ſmalleſt quadruped. Their figure is varied at pleaſure; but ſeems, in its moſt natural ſtate, to be much larger at the poſterior part than at the anterior; the poſterior part alſo uſually remains fixed, while the other is twiſted about various ways; but the creature can, at its pleaſure, ſhorten the body, by drawing in the ſeveral rings, and then it appears of an oval figure.

Theſe worms are of different colours, and different ſpecies; thoſe which are found on the elder are green, with a white ray down the back; thoſe on the ſloe and gooſeberry-tree are whitiſh, variegated with yellow undulations. Other ſpecies are of a pale yellow, others of a ſomewhat deeper yellow, with two ſtreaks running down their backs of a bright cheſnut colour, between which there is one black one. Some have reckoned theſe ſeveral ſpecies among the caterpillars, but very improperly, as they have no one character of this kind, but every way reſemble the worms or maggots, produced from the eggs of the common flies. Theſe creatures have at their head a dart of a brown colour and hard ſubſtance, ornamented with two ſmaller points at the baſe, ſo that it repreſents, in ſome degree, a flower-de-luce: this is the weapon with which they deſtroy the pucerons, and this they either draw back within the head, or thruſt out at pleaſure. The mouth of the creature is placed under this dart, but is not eaſily diſcovered, the creature uſually keeping it very cloſely ſhut; there are times however, when the creature is ſeen bending its head down ſeveral times towards its belly; and if the anterior and under part be then examined, the place of the mouth will be diſtinguiſhed by means of a yellowiſh liquor which it throws out of it.

All theſe worms have two ſtigmata or apertures for the receiving air at the hinder part of the body. Theſe are very di-

ſtinctly

ſtinctly ſeen, and are either round protuberances, placed at the two ſides of the upper part of the ring; or two tubes or cylinders, either ſo placed or joined together, and elevated above the reſt of the ſurface. They have alſo two ſtigmata near the head; theſe are called anterior, as the others are poſterior; but theſe are ſmaller than the others, and have been generally overlooked by authors. There are ſeveral ſpecies of theſe worms that are hairy, and ſome are prickly. One very ſingular ſpecies is ſo much ſo, that it reſembles a hedgehog; it is of a greeniſh white colour, but has three lines running along the back, compoſed of three ſeries of ſpots, thoſe of the middle line being black, and thoſe of the others brown. The ſpines or prickles upon this ſtand in the number of ten or twelve on every ring, and are all hooked, and have their points turned toward the hinder part of the body. They only are placed on the back and ſides, the belly being perfectly ſmooth. See Tab. of Inſects, N°. 24.

Theſe creatures have no legs; there are indeed certain fleſhy eminences on the under part of the rings of ſome of them, which aſſiſt them in walking; but their common method of moving is by fixing their head to any part, and then drawing the reſt of the body to it. This creature, however, has very little occaſion for motion; its whole buſineſs, in this ſtate, is to eat, and its parent has ſo placed it, that it need not hunt its food ſingly, like other creatures of prey; but it finds itſelf every way ſurrounded with the creatures it is to feed upon, and touched by them before, behind, and on every ſide; nay, they often walk upon its back without any apprehenſion of the danger: They remain in their places till he has cleared them away, by eating them; and when he has devoured all within his reach, it is then only that he need move his quarters, and that but a little way; for he ſeldom has farther to go than to the fartheſt place his head could reach, while he remained fixed in the former place. *Reaumur*'s Hiſt. Inſ. vol. 6. p. 117.

The way to ſee him eat, ſo as to diſtinguiſh the manner of it, is to keep one a few hours without food, and then placing him on a paper, or on the hand, and placing ſome of the pucerons about him, the manner of his feeding on them will be ſeen. It appears evidently that he has no eyes, for he tries to find them only by feeling, ſtretching out his head, and trying every where with it, before, behind, and on every ſide, while his hinder part remains fixed. As ſoon as he perceives a puceron, he darts his triple weapon into it, and ſticks it juſt as we do a mouthful of meat upon a fork; he then draws back the dart into the firſt ring, and that ring into the ſecond, and then uſes his mouth, which has a kind of trunk, with which he ſucks the juices of the puceron.

When the *Ver-puceron* is of the white, or otherwiſe pellucid kinds, it is a very ſurpriſing ſight to obſerve the manner of the feeding, which is clearly ſeen through the ſkin. The puceron being drawn into the ſecond ring of the body, there is ſeen juſt below that an oblong body, which is, at times, darted up to the body of the puceron, and down again from it. The movements of this are very ſwift, and the ſpace of reſt between them but ſhort. This is a ſort of pump, which ſucks in the parts and juices of the animal, and delivers them again to the œſophagus or ſtomach, placed behind it. During the ſhort ſpace of reſt, we ſee it diſtinctly diſcharge from its hinder part what it had before received from the animal, into this paſſage. This is ſometimes only its juices, which look like ſmall bubbles of air, and ſometimes a great number of little roundiſh granules, which are evidently the embryo pucerons, with which we know the body of all the grown ones to be loaded, all the pucerons being breeders.

When the worm is hungry it feeds very voraciouſly, when not ſo, it eats more at its leiſure. The ſkin of the puceron is always thrown out of the mouth, as ſoon as its juices and entrails have been ſucked, and it then looks perfectly like the exuvia, which the pucerons naturally throw off when they change their ſkins. The worm will ſuck one of theſe creatures thus dry in leſs than a minute, and then loſes no time, but throws it out, and immediately ſeizes another. In this manner Mr. Reaumur ſaw one worm eat twenty of theſe creatures in twenty minutes, and ſuppoſes that he continued the ſame ravage long afterwards; for having put him among an hundred pucerons, there was not one left after two or three hours.

When the worm is placed at its eaſe among vaſt quantities of them, it does not eat ſo very quick, but ſeems to amuſe itſelf by eating one in two or three minutes. This manner of feeding, however, deſtroys prodigious numbers, for they ſeldom reſt, but are almoſt continually at it; and it is hard to find one of them, at any time, without a puceron in its mouth. So that a branch of elder, which is covered on every part with theſe animals for four or five inches, ſhall be found wholly cleared in three or four days, by only three or four of theſe worms. *Reaumur*'s Hiſt. Inſ. vol. 6. p. 127.

The pucerons are never free from their enemies; there is no place where they are ſeen in any conſiderable number, where theſe worms are not alſo found; and their ſecureſt retreats do not preſerve them. The bladders of the elm, and other trees; the galls of the leaves and pedicles of the poplars, and the folded leaves of the ſame trees, which are all inhabited by the pucerons, are all ſubject to be viſited by theſe worms alſo. They do not always immediately make their way into them; but as ſoon as one of the winged pucerons has eſcaped out of the place, the hole at which he came out, lets in one of theſe worms, which ſoon deſtroys all the remainder of the family. Another great misfortune to theſe poor creatures, is, that the worms are not confined to any one ſpecies of them, but eat all indifferently.

The anus of the worm is placed in the fold of the two laſt rings of the body, and is almoſt continually voiding a blackiſh liquid excrement.

Theſe worms, when full grown, are greatly an over-match for the pucerons; and it is odd to obſerve the young worms in their attacks upon them. A worm juſt hatched, and not a third part ſo big as the puceron, will immediately, however, attack any one that is next it: The puceron, feeling itſelf wounded, will immediately run away; but the worm keeps its hold, and, raiſing its body by the head, ſticks to the puceron, and even kills and ſucks its juices while it is carried away. When it has done with this, it gets upon another, and ſo on, till it grows and gains ſtrength and ſize enough to reſiſt the force of the puceron, in endeavouring to carry it away, and then fixing itſelf by the tail among the heaps of them, it feeds at pleaſure. When it has eaten till it has arrived at its full growth, the time of its transformation into the fly ſtate approaches: It then ceaſes to eat, and crawling along the leaf or ſtalk of the plant, ſeeks out a proper place where it may be at reſt during its cryſalis ſtate.

When it has pitched upon the place, it begins to void the viſcous liquor before-mentioned in great quantity from its mouth. It extends this over a ſpace equal to its body, and then placing itſelf on the place, it becomes fixed there, and moves no more. It draws back its head, and the ſkin of the whole body hardens ſo as to form a ſhell, under which it paſſes the cryſalis ſtate. In this ſtate it makes a very beautiful appearance; for the ſkin, though become as hard as horn, yet has loſt nothing of its tranſparence, but, on the contrary, has gained a yet greater degree of it; and the nymph of the fly is ſeen clearly within it, the motion of the heart being very diſtinctly viſible.

After this, as the nymph grows every day more and more perfect, the eyes, the antennæ, and the ſeveral other parts, may be diſtinctly ſeen: And this indeed would prove the beſt of all ſubjects to convince thoſe who ſuppoſe, that maggots are ſuddenly changed into flies, and caterpillars into butterflies, of the error of their opinion; as they might here ſee, by the cleareſt occular demonſtration, that the change is very ſlow and regular.

The flies which are produced from theſe worms, are all of the two-winged kind; but there are ſeveral different ſpecies of them; the generality of them reſemble waſps, and have a very flat body. Goedart, who has deſcribed ſome of theſe flies, was ſurprized to ſee them very ſmall, when firſt produced from the cryſalis, yet growing very large in a quarter of an hour's time, and that without taking any nouriſhment; but this was only owing to their ſeveral parts having been greatly ſqueezed while in the cryſalis, and expanding themſelves when they were at liberty from the compreſſion. Theſe are the changes of this kind of *leo puceron*; but the other devourer of theſe creatures, which has ſix legs, is of a different kind, and indeed is in itſelf reducible to ſeveral ſpecies, ſome of theſe ſix-legged worms becoming four-winged flies, and others a kind of beetles. Theſe, from their near reſemblance to the formica-leo, are by Reaumur diſtinctly called *puceron-lions*. *Reaumur*, Hiſt. Inſ. vol. 6. p. 131. See the article PUCERON-*Lion*.

VER *Polipe*, in natural hiſtory, a name given by Reaumur, and ſome other authors, to a ſpecies of water-worm, by no means to be confounded with the creature called ſimply the *polype*, and which is ſo famous for its reproduction of parts cut off, and for many other ſingular properties. See the article POLYPE.

This *Ver-polype* is a ſpecies of water-worm, produced from the egg of a tipula, and had this name given it from ſome remarkable productions, placed at the anterior and poſterior parts of the body, which are ſuppoſed to have ſome analogy with the parts of the ſea-fiſh called the *polypus*.

Theſe worms are found in muddy ditches, uſually either crawling upon, or buried in the mud. They are of various ſizes, from more than an inch in length, to a fifth of an inch, and are ſmooth and even on their ſurface; they are compoſed of ſeveral rings, as other inſects of this kind, and have a brown ſcaly head, of a regular figure, and much harder than the reſt of the body. Juſt below the head, on the under part of the body, there are placed two membranaceous productions, which ſeem fragments of arms; they are conſiderably thick, and are cut off obliquely at the ends, and furniſhed with many hairs. At the other extremity of the body there are placed four other productions, reſembling four pieces of cords; two of theſe are affixed to the middle of the lower ſide of the laſt ring but one, and the other two, at the joining of this to the laſt ring. The anterior pair ſerve the creature greatly in its moving, and theſe hinder ones have their uſe in fixing that part of the body in the earthy caſe the creature ſometimes makes for itſelf, while the head is at liberty to move every where about in

ſearch of prey. Theſe hinder ones are broadeſt at their inſertion, and ſomewhat narrower at the point, and are very flexile and moveable every way.

The anus of the creature is placed near the end of the laſt ring of the body, and is of a ſquare figure; it is ſurrounded with a number of rigid hairs or ſpines, and at each corner has a fleſhy tubercle, which ſtands out a conſiderable way from the level of the body; the two under ones are much larger than the other two, and the creature evidently uſes them to puſh itſelf forward in its moving about. Probably, however, theſe parts have ſome other more important uſe. The taking in of air or water is likely enough to be the uſe they are aſſigned for.

The cells which theſe creatures uſually live in are compoſed principally of fragments of a light and ſpungy earth, and to this they add the broken pieces of ſticks and leaves, and other ſuch ſubſtances as are juſt heavy enough to ſink in water. Mr. Reaumur ſuſpects that they have a method of ſpinning ſome glutinous fluid out of their bowels, to fix theſe things together with. But though they uſually reſide in theſe caſes, they often quit them, and are found ſwimming about the water, or with their tails at the top, and playing about with their bodies; or at the bottom, crawling on the ſurface of the mud.

When the creature has lived its deſtined time in this ſtate, it changes into a nymph, in the caſe in which it had lived to the time of this change; it throws off the head, and the productions that ſerved as arms, and to faſten it at the botttom of the caſe. Nature has generally made the nympth and cryſalis ſtate of animals a time of reſt and incapacity of motion; but in this, as in the great worms, has given even the nymph a locomotive power, and that a very briſk one. The creature, in this ſtate, had ſufficient need of it, and could never arrive at its laſt change without it. When the time of this final change comes on, the nympth riſes to the ſurface of the water, and a crack opening on the back, the winged inſect begins to appear. The getting thoroughly out is a work of time; and this is the moſt perilous period of the creature's life; for if the weather be windy, it is commonly blown into the water, and drowned, before the hinder parts are looſe. *Reaumur*, Hiſt. Inſ. vol. 9. p. 49.

VERANO *Ave*, or *Ave de* VERANO, in zoology, the name by which the Portugueſe in the Braſiils call a large bird of the thruſh kind, approaching to the ſize of a ſmall pigeon, remarkable for its loud noiſe; and more commonly known by its American name, *guirapanga*. *Ray*'s Ornithology, p. 145. See the article GUIRAPANGA.

VERATRUM, *white Hellebore*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the roſaceous kind, conſiſting of ſeveral petals, arranged in a circular form. The piſtil ariſes from the middle of the flower, and finally becomes a ſeed-veſſel, compoſed of three capſules joined together, and containing oblong ſeeds, ſomewhat reſembling grains of wheat, and alated or ſurrounded with a foliaceous edge.

The ſpecies of *white Hellebore*, enumerated by Mr. Tournefort, are theſe: 1. The greeniſh-flowered *Veratrum*. And 2. The earlier-flowering *Veratrum*, with blackiſh purple flowers. *Tourn.* Inſt. p. 272.

VERBASCULUM, in botany, a name given by many authors to the primroſe, and with the title of *odoratum* to the cowſlip. *Dale*, Pharm. p. 187.

VERBASCUM, *Mullein*, in botany, the name of a genus of plants, the characters of which are theſe: The flower conſiſts of a ſingle leaf, rotated, and divided into many ſegments at the edge. From the cup there ariſes a piſtil, which is fixed in manner of a nail to the middle part of the flower, and finally becomes a fruit or caſe of an oval pointed figure, divided by an intermediate ſeptum into two cells, which uſually contain a number of ſmall angular ſeeds fixed to a placenta.

The ſpecies of *Mullein*, enumerated by Mr. Tournefort, are theſe: The common broad white-leaved yellow-flowered *Mullein*. 2. The white-flowered common *Mullein*, called by many the female *Mullein*. 3. The great female *Mullein*, with a large yellow ſcented flower. 4. Branched *Mullein*, with narrow thick leaves, and a gold-coloured flower. 5. Black *Mullein*, with a purpliſh yellow flower. 6. Annual green-leaved *Mullein*, with yellow flowers. 7. The black *Mullein* of Dioſcorides. 8. Black *Mullein*, with leaves like the yellow horned poppy. 9. The powdery *Mullein*, with ſmall yellow flowers. 10. The taper *Mullein*, with ſmall white flowers. 11. The branched perennial French *Mullein*. 12. The perennial Alpine black *Mullein*, with white flowers, and purple ſtamina. 13. Branched *Mullein*, with ſmall white flowers. 14. Low perennial Alpine *Mullein*, with leaves and flowers like thoſe of borrage. 15. Hoary Alpine borrage-leaved *Mullein*, with white flowers. *Tourn.* Inſt. p. 146.

VERBENA, *Vervain*, in botany. See the article VERVAIN.

VERBENA *Femina*. See the article ERYSIMUM.

VERDELLO, in natural hiſtory, the name of a green marble, uſed in Italy as a touch-ſtone, for the trying of gold, *&c.*

VERDETUM, the name of a green ſubſtance, uſed as a colour in painting. It is a very pure kind of verdegreaſe, being an ærugo of copper, produced by the vapour of vinegar.

VERDITER *Cycl.*—Mr. Boyle informs us, that the London refiners, to part ſilver and copper, diſſolve the mixture of them in aqua-fortis, and afterwards dilute the ſaturated menſtruum with water, and then with copper plates ſtrike down the ſilver. But as much copper remains in the menſtruum, to improve their liquor to the beſt advantage, they pour it upon whiting, that is, white chalk or clay finely powdered, cleanſed, and made up into balls, wherewith the tinged parts incorporating themſelves, will in ſome hours conſtitute a ſort of *Verditer* fit for painters, leaving the reſt of the menſtruum an indifferently clear liquor; whence they afterwards, by boiling, obtain a kind of ſalt-petre, fit, with the addition of vitriol, to yield them a new aqua-fortis. But he obſerves, that ſometimes the refiners could not make this *Verditer* for a great while together. But a remedy was found at laſt, which is, to warm the menſtruum well before it be poured on the whiting. *Boyle*'s Works abr. vol. 1. p. 169.

We have a way of making this colour in England by a mixture of powdered verdegreaſe and whiting. This is much inferior to that *Verditer* which is made with the copper-water uſed in the waſhing of ſilver; but its cheapneſs, and readineſs of preparation at all times, has recommended it into general uſe.

VERDONE, in zoology, the name of a fiſh of the turdus or wraſſe kind, called by ſome authors *turdus viridis minor*.

It is of a fine green colour in all parts of its body; the back, ſides, and belly, have all plainly the ſame colour; but in ſomewhat different degrees, the back being of the deepeſt dye; the belly has ſomething of yellowneſs with the green, and the ſides are variegated with lines of a fine blue. It has only one long fin on the back, which has thirty rays or ribs, the eighteen foremoſt of which are rigid and prickly, the others ſoft and flexile. It is caught in the Mediterranean, and ſold in the markets in Italy. *Salvian* de Aquat. p. 88.

VERGADELLE, in zoology, the name of a fiſh of the mullet kind, called by others the *chelon*, remarkable for the thickneſs of its lips. *Rondelet.* de Piſc. See the article CHELON.

VERITH, in ichthyology, a name given by Iſidore to the fiſh commonly called by authors, *thriſſa*; by us, the *ſhad*, or the mother of the herrings. See the article THRISSA.

It is eaſily diſtinguiſhed from the herring, by the top of the upper jaw being bifid, and the ſides ſpotted; but it is the opinion of that accurate obſerver Artedi, that it differs only in ſize from the pilchard, and the agone, alauſa, and ſardina, or ſmall pilchard.

VERKENS *Viſch*, in zoology, the Dutch name of a fiſh caught in the Eaſt Indies. It is about ſeven inches long, of a blackiſh-green colour, with fins and tail wholly black, and with yellow iriſes to the eyes. It is caught in freſh waters in the Eaſt Indies, and is a very delicate fiſh. It is very near related to the capriſcus, if not the ſame ſpecies. *Ray*'s Ichthyogr. Append. p. 1. 3. See the article CAPRISCUS.

VERMELHO, in zoology, the name of an American fiſh, more uſually known by the name of the *pudiano*. It is a ſmall fiſh, of the ſhape of the pearch, with a purple back, and yellow ſides and belly. *Willughby*'s Hiſt. Piſc. p. 339. See the article PUDIANO.

VERMES, *Worms*. See the articles VERMIS and WORMS.

VERMICULARIS *Cruſta*, a term uſed by ſome anatomical writers, to expreſs the internal hairy and corrugated coat of the inteſtines.

VERMICULUM, a word uſed by ſome chemiſts to expreſs a tincture or elixir.

VERMICULUS *Marinus*, the *Sea-Worm*, in natural hiſtory, the name of a genus of ſhell-fiſh of the multivalve kind.

The characters are theſe: They are multivalve ſhells, formed in the ſhape of tubes or pipes, and are rounded, wrinkled, and uſually crooked, though ſometimes ſtrait. Theſe ſhells are called *vermiculi*, or ſea-worms, from the fiſh contained in them, which is always a ſort of worm. They uſually are found in great cluſters together, interwoven oddly with one another.

Bonani calls them ſea-ſerpents, incloſed in ſhells, from the various twiſted forms in which they adhere to ſhips and rocks. The author eſtabliſhes them among the multivalves, becauſe they are never found ſingle, but always in theſe cluſters; in this ſenſe he looks upon the whole cluſter as the ſhell-fiſh under conſideration, not any one of the ſingle tubes: Though he acknowledges that each of theſe tubes is a perfect ſhell, independant of the reſt, and has its proper inhabitant. Strictneſs in natural hiſtory therefore would not bear him out, in arranging them among multivalves, for they are certainly an univalve ſhell, though many of them happen always to be found together.

Care muſt be had not to confound theſe with the *dentalia* and *entalia*; for theſe laſt are always found ſingle; and the *vermiculi*, of the kind here treated of, are always found together in great numbers, forming cluſters of ten inches, and often much more in diameter.

Of the *Vermiculi*, which are ſtrait, we have the following ſpecies: 1. The *Tubularia Purpurea*, by many eſteemed a ſpecies of coral. This is called by ſome the *ſea-organ*, and has greatly the appearance of common red coral, but is in reality only a maſs of theſe tubes of worms. 2. The pale red

Tubularia. 3. The thicker *Vermiculus*, called the *great organ-pipe.* 4. The ſmooth *Vermiculus.* 5. The ſtriated *Vermiculus.* 6. The canaliculated or deep furrowed *Vermiculus.*

Of the crooked kind we have the following ſpecies: 1. The gut *Vermiculus.* This ſpecies always forms a large cluſter, and reſembles the inteſtines of animals. 2. The variouſly curled *Vermiculi.* 3. The *Vermiculi*, terminating in elegantly twiſted ends. 4. The brown wrinkled *Vermiculus.*

Of thoſe *Vermiculi* which are diſpoſed in a ſort of circles, we have the following: 1. The earth-worm *Vermiculus.* 2. The concamerated *Vermiculus.* This is a ſpecies of *Vermiculus*, divided in the inner part into a number of chambers or cells, in the manner of the nautilus, and having a ſiphunculus of communication running through the whole. 3. The mud-*Vermiculus.* This ſpecies lies under the mud of the bottom, and adheres to ſtones. 4. The oiſter *Vermiculus.* 5. The muſcle *Vermiculus.* 6. The buccinum *Vermiculus.* Theſe are three diſtinct ſpecies, which always take up their abode on thoſe peculiar ſhells. 7. The red cancellated *Vermiculus.* 8. The brown twiſted *Vermiculus.* 9. The roſe-coloured and white *Vermiculus.* Hiſt. Nat. Eclairc. p. 354.

VERMINA, a word uſed by many of the medical authors to expreſs a tormenting pain in the bowels, feeling as if worms were gnawing them.

VERMIS, *Worm*, in natural hiſtory. See the article WORM.

VERMIS *Cæruleus*, a name given by the antient naturaliſts to an animal they deſcribe as living in the Ganges, and ſome other rivers in the Eaſt Indies, and of an enormous length. Pliny tells us that they are ſeventy feet in length; but he at the ſame time convinces us, that they were not properly worms; for he tells us they had gills like thoſe of fiſhes, and ſays they were called *Vermes*, only becauſe they were like worms. Cteſias mentions theſe Indian water-worms, and ſo do many other old writers, all giving them the ſame characters, but differing ſomewhat in the length, which the laſt-mentioned Greek author makes to be only ſeven feet, not ſeventy. Solinus has miſtaken this account of the gills of this creature, and has tranſlated or copied the authors he took his account from ſo ill, as to call them arms, and gives them the length the other authors attribute to the whole animal. This creature was of a blue colour, and lived in the deep waters; but would, according to their accounts, riſe up to the ſurface near the ſhore, to ſeize upon cattle that came to drink. They even tell us of its ſeizing on the elephant in this manner; and, at this rate, the whole ſeventy foot length is neceſſary. Inſtead of ſeventy feet, ſome copies of Pliny have it ſixty; and the later authors from this have made it only ſix: And Solinus has miſtaken what Pliny ſays of the creature, being called *Vermis* from its having the ſhape of a worm, and ſuppoſes he means that it was called *cæruleus*, becauſe of its being of a blue colour; but we find nothing of this in the old authors, nor any other name for it but *Vermis.* The naturaliſts of late ages have given no account of any ſuch animal as this; and it is very probable that the authors who firſt deſcribed it meant nothing but the crocodile, which they had heard of as a terrible voracious reptile, living in the Ganges, as it does to this day; but had never had any tolerably accurate account of it. See the article CROCODILE.

VERMIS *Cerebri*, the *worm* in the brain, a name given by ſome writers to an epidemical fever in Hungary, attended with terrible deliriums.

VERONICA, *Speedwell*, in botany, the name of a genus of plants, the characters of which are theſe: The flower conſiſts of one leaf, and is rotated and divided into ſegments at the end. From the cup there ariſes a piſtil, which is fixed in the manner of a nail to the middle part of the flower, and afterwards becomes a membranaceous fruit, divided into two cells, and containing uſually ſmall, but ſometimes larger ſeeds. *Tourn.* Inſt. p. 143.

The ſpecies of *Veronica*, enumerated by Mr. Tournefort, are theſe: 1. The common ſmall procumbent *Veronica*, called *male Speedwell.* 2. The longer-leaved ſmooth creeping Pyrenean *Speedwell*, 3. The upright male *Speedwell.* 4. The broad-leaved ſpiked *Speedwell.* 5. The purple ſpiked *Speedwell.* 6. The narrow-leaved ſpiked *Speedwell.* 7. The long-leaved ſpiked *Speedwell.* 8. The ſmall ſpiked *Speedwell.* 9. The ſmall rock *Speedwell*, with naked ſtalks. 10. The common meadow *Speedwell*, with leaves like ſerpyllum. 11. The ſmooth erect Alpine male *Speedwell*, with lightly indented leaves. 12. The ſmaller Roman ſmooth *Speedwell*, with leaves like the ſmall baſil. 13. The ſmall creeping *Speedwell*, with roundiſh hollowed leaves. 14. Hairy daiſy-leaved Alpine *Speedwell.* 15. The Alpine ſhrub *Speedwell.* 16. The hard ſhrubby *Speedwell*, with a long germander-like leaf. 17. The ſhrubby Alpine *Speedwell*, with a roundiſh ſmall leaf. 18. The ever-green rock *Speedwell.* 19. The Auſtrian *Speedwell*, with finely divided leaves. 20. The greateſt *Speedwell.* 21. The greateſt ſingle-ſtalked not-branched Pyrenean *Speedwell.* 22. The great ſhrubby *Speedwell.* 23. The procumbent *Speedwell*, with the appearance of meadow teucrium. 24. The ſmaller *Speedwell*, with the lower leaves round. 25. The white-flowered ſmall *Speedwell*, with round-bottom leaves. 26. The little narrow-leaved branched procumbent *Speedwell.* 27. The many-ſtalked *Speedwell.* 28. The leaſt mountain erect, ſquare-ſtalked *Speedwell.* 29. The creeping *Speedwell*, with teucrium leaves. 30. The common *Speedwell*, with flowers growing to the ſtalks. 31. The great round-leaved water *Speedwell.* 32. The ſmaller round-leaved water *Speedwell.* 33. The larger long-leaved water *Speedwell.* 34. The ſmaller long-leaved water-*Speedwell.* 35. The creeping olive-leaved water *Speedwell.* 36. The narrow-leaved water *Speedwell.* 37. The round-leaved Pyrenean *Speedweed.* 38. The ivy-leaved ſpring *Speedwell.* 39. The germander-leaved *Speedwell*, with flowers ſtanding on long ſtalks. 40. The germander-leaved *Speedwell*, with flowers ſtanding on long ſtalks, and with leaves placed alternately on the ſtalks. 41. The common ſpring *Speedwell*, with trifid or quinquifid leaves. 42. The white-flowered annual knot-graſs-leaved *Speedwell.* And 43. The branched upright American ſhrubby *Speedwell*, with vervain-like leaves. *Tourn.* Inſt. p. 144.

In the Linnæan ſyſtem of botany, *Veronica* likewiſe makes a diſtinct genus of plants; the characters of which are, that the cup is a perianthium, divided into four ſegments, and remaining after the flower is fallen. Its ſeveral ſegments are narrow and pointed. The flower conſiſts of a ſingle petal, in form of a cylindric tube, of the length of the cup, or nearly ſo; flat in poſition, and divided into four ſegments at its extremity, each of an oval ſhape, and the lower the narrower. The ſtamina are two filaments, narroweſt at the bottom, and bending toward the top. The antheræ are oblong. The piſtillum has a compreſſed germen; a thread-like ſtyle, bent, and of the length of the ſtamina; and a ſimple ſtigma. The fruit is a turbinated and heart-faſhioned capſule, flat at the top, containing two cells, with four valves, and full of a great number of roundiſh ſeeds. *Linnæi* Gen. Plant. p. 4.

VERONUS, in zoology, a name given by many to a ſmall river-fiſh, well known in England by the name of the minow. *Ray's* Ichthyogr. p. 268. See the article PHOXINUS.

VERSIO *Chemica*, a term uſed by chemical writers to expreſs a change, wrought by their art, of manifeſt forms into occult ones, which, they ſay, is done by a corruption of the ſpecific form, and the generation of a more general one; that is, by a converſion of decompounded elements into compound bodies, and of impure into ſuch as are perfectly pure. Theatr. Chem. vol. 1.

VERTEBRÆ (*Cycl.*)—Anatomiſts, in the deſcription of theſe bones, divide them into the body, apophyſes, and cavities.

The body of the *Vertebræ* is that principal part or large maſs, ſituated anteriorly, and ſupporting all the other parts. In moſt of the *Vertebræ* the body repreſents a portion of a cylinder cut tranſverſely, the circumference of which is more or leſs round on the fore-part, and ſloped on the back-part. It has two ſides, the upper and lower, each of which is, as it were, bordered by a thin lamina, in form of an epiphyſis.

The apophyſes of moſt of the *Vertebræ* are ſeven in number; one poſterior, called the ſpinal apophyſis, which ends in a ſmall epiphyſis, and has given the name to the whole ſyſtem of the *Vertebræ*; two lateral, called *tranſverſe apophyſes*, and four others, which are likewiſe lateral, two on each ſide; one above, and one below. Theſe are called by the common name of *oblique apophyſes*, and diſtinguiſhed into the ſuperior or aſcending, or inferior or deſcending. Theſe four are the leaſt of all the apophyſes of the *Vertebræ*, and each of them has a cartilaginous ſide. It would be more proper to call them *articular*, inſtead of *oblique apophyſes.*

The cavities in the *Vertebræ* are theſe: A large middle hole between the body and apophyſes; four notches, two on each ſide, one ſuperior and ſmall, the other inferior and large. The great foramen is part of the vertebral or ſpinal canal; and the notches in one *Vertebra* meeting thoſe in another, form the lateral holes which communicate with the canal. The inner ſubſtance of the *Vertebræ* is ſpongy, or like a diploe, covered with an outer compact ſubſtance; which in the body of the *Vertebra* is very thin, but thicker in the proceſſes. The *Vertebræ* are joined together by their bodies, and by their ſmall apophyſes. The bodies, in a natural ſtate, are principally united by a cartilaginous ſymphyſis; that is, by the intervention of a pliable and elaſtic cartilage, as is very manifeſtly ſeen in the freſh bones. This cartilaginous connection makes the lateral holes of the ſpine larger in the body than they appear in the dry ſkeleton, where theſe cartilages are wanting. Their connection, by the ſmall apophyſes, is by arthrodia, and not by ginglimus. And theſe two articulations are ſecured by very ſtrong ligaments. *Winſlow's* Anatomy, p. 54.

The cartilages between the *Vertebræ* of the back yield conſiderably to the preſſure of the body, in an erect poſture, and expand themſelves in the night when perſons lie down. Hence ariſes a very ſingular phænomenon, but a very true one: which is, that a man is conſiderably taller at his riſing in a morning, after the expanſion of theſe cartilages, during the abſence of preſſure for ſeveral hours, than at night, when they have been preſſed down all the day.

The reverend Mr. Waſſe ſeems to have examined this difference more ſtrictly than any other perſon. He found that ſeveral perſons, enliſted as ſoldiers in a morning, had been diſcharged for want of height, on their being meaſured again

before the officers in the evening; and on this occaſion meaſured ſeveral other people, and found the difference in many caſes to be not leſs than an inch. This gentleman obſerved in himſelf, that fixing a bar of iron where he juſt reached it with his head on getting firſt out of bed in the morning, he could loſe near half an inch in an hour, or leſs, if he employed that time in rolling his garden, or any other exerciſe of that laborious kind. He obſerved alſo, that riding often took off the height very ſuddenly; and what was more particular, that in ſitting cloſe to ſtudy for five or ſix hours without any motion, he loſt often a whole inch in height. People who uſe hard labour, ſink rather leſs in the whole, than thoſe of ſedentary lives; and the height once loſt, is never to be recovered that day, not even by the uſe of the cold bath; but a night's lying down alone can reſtore it. Philoſ. Tranſ. N°. 383. p. 87.

This difference in height takes place only in the human ſpecies, as we are the only creatures who walk erect, and throw the preſſure of our whole weight upon the back-bone. This gentleman meaſured horſes before and after riding, and could find no difference, even after the longeſt journeys.

The alteration in height, is much greater in young people, than in thoſe who are more aged. It is evident from this change happening to perſons when they ſit, as well as when they ſtand, that it is brought about merely by the back-bone; and we muſt admire the ſtructure of that part of the body, which owes its giving way thus, to its being formed together in that manner which alone could ſuit it to the ſeveral purpoſes it was intended for. The thickneſs and ſhortneſs of the bones, with the intervening cartilages, aſſiſted by the bony proceſſes, diſpoſe it to a motion peculiar to itſelf; whereas, had the bones been of any conſiderable length, upon bending the body, the articulations muſt have made a large angle upon their inmoſt edges, and the ſpinal marrow would have been continually liable to be injured; and had the cartilages been intirely wanting, it would have been as uſeleſs as if it were but one bone, whereby the trunk of the body being rendred incapable of bending, muſt have remained for ever in an erect poſture. Another particular, which beſpeaks the utmoſt wiſdom and deſign in the contrivance of this part is, the remarkable difference there is in the cartilages placed betwixt the ſeveral bones of the ſpine.

The *Vertebræ* of the back require but little motion, and the cartilages there are for that reaſon ſmall and thin, in compariſon with thoſe of the loins, which being very thick, the loweſt more eſpecially, the motion is much greater there, and much better to be borne. This being the ſtate and diſpoſition of the parts, during the whole ſpace of time in which we are uſually employed about our ſeveral buſineſſes, till the time that we diſpoſe ourſelves to reſt, the cartilages of the ſpine, will, by their compreſſible and yielding properties, become more cloſe and compact from the preſſure they ſuſtain, and conſequently the ſpine, which is the only ſupport of the trunk of the body, will become ſhorter; but when this ſuperior weight ſhall be intirely removed, by placing the body in an horizontal poſture, as it always is when we are in bed, the compreſſed cartilages will, by their natural elaſtic power, begin gradually to enlarge themſelves, till they, by degrees, recover the expanded ſtate they had before they gave way.

The cartilages between the ſeveral *Vertebræ*, are twenty-four in number, and every one of theſe is preſſed ſomewhat in our daily employments, ſo that when they all come to expand, the aggregate of their ſeveral expanſions cannot be ſuppoſed leſs than about an inch. Now, if this be the difference occaſioned by the preſſure of the common weight of the body alone upon itſelf, it muſt neceſſarily be much greater in thoſe perſons whoſe conſtant employment it is to carry heavy burdens. The compreſſion and expanſion of the cartilages in older people being leſs than in younger, is a neceſſary conſequence of the cartilages in time of age growing harder, and leſs capable of compreſſion; for they often grow almoſt bony in length of time; and hence it is, that old people are obſerved to loſe ſomewhat of their former height, the cartilages in them ſhrinking to a ſomewhat ſmaller compaſs as they grow bony; and this ſhortening is therefore not imaginary, as many have believed, but real, and owing to this plain cauſe. Phil. Tranſ. N°. 383. p. 90.

VERTEBRÆ *fractured.* When any of the *Vertebræ* are fractured without hurting the ſpinal marrow, we may reaſonably ſuppoſe, that the fracture is confined to ſome of the oblique, or ſpinal proceſſes, and therefore the patient will be in no great danger; but when the body of the *Vertebra* is either broke or ſplit, and the contiguous ſpinal marrow bruiſed or compreſſed; all parts of the limbs and viſcera beneath that *Vetebra* become immoveable and rigid, and death often follows. Laſtly, if the tranſverſe proceſſes of the *Vertebræ* are broken, which incline toward the cavity of the thorax, it is ſcarce poſſible, that the heads of the ribs which are connected there, ſhould eſcape being fractured alſo, which makes the caſe very deplorable. When only the proceſſes of the *Vertebræ* are broken, it will be the beſt way to reduce the bones into their places with the fingers, placing narrow compreſſes dipped in warm ſpirit of wine on each ſide the *Vertebræ*, and over them thick pieces of paſtboard, to be kept on by the proper bandages; for by this means the bones of the *Vertebræ*, which are very ſoft and ſpungy, will very quickly and eaſily grow together again.

If in theſe fractures the ſpinal marrow be divided, death is generally an inevitable conſequence; all that the ſurgeon can attempt in this caſe, is to lay bare the fractured *Vertebra* with the ſcalpel, and replace, or elſe remove, ſuch fragments as injured the ſpinal marrow; and the wound muſt be afterwards gently cleanſed, and treated with the vulnerary balſams, to be kept on with the napkin and ſcapulary bandage, till either the wounds ſhall be terminated by a perfect cure, or by death. *Heiſter*'s Surgery, p. 125.

VERTEBRÆ *luxated.* The luxations which happen to the ſpine, and *Vertebræ* of the back, are generally imperfect ones; for it appears from an accurate conſideration of the ſtructure, and articulations of theſe bones, that none of the *Vertebræ* can be intirely diſplaced without being fractured, and alſo compreſſing and wounding the ſpinal marrow, which muſt produce danger of inſtant death. Even the imperfect luxations of theſe bones are very dangerous; which happen either between the two ſuperior *Vertebræ* of the head and neck, or between the reſt of the *Vertebræ*, when they are forced from each other. Such as have a luxation between the head and upper *Vertebra*, ſeldom eſcape being carried off by a ſudden death; for by this means, the tender medulla, which joins immediately with the brain, and is lodged in the ſpine, the brain itſelf, and the nerves which ariſe from beneath the occiput, are too much diſtended, compreſſed, or lacerated. The two condyloide proceſſes of the occiput uſually ſlide out of their glenoide ſinuſſes in the firſt *Vertebra* of the neck, when a perſon falls headlong from an high place, or from on horſeback, or when he receives a violent blow upon the neck. People die uſually very ſuddenly by this accident, and are uſually ſaid to have broke their necks, though there is really no more than a bare luxation; though it does really ſometimes happen, that the *Vertebræ* of the neck are broken. If life ſhould remain after ſuch an accident, which very rarely happens, the head muſt neceſſarily be diſtorted, commonly with the chin cloſe down to the breaſt, ſo that the perſon can neither ſwallow, ſpeak, or move any part that is below the neck; therefore, if ſpeedy aſſiſtance is not had, death enſues, from the compreſſure, or hurt of the medulla.

In order to reduce this luxation, the patient muſt be laid flat upon the ground, then the ſurgeon kneeling down with his knees againſt the patient's ſhoulders, muſt bring them together, ſo as juſt to contain the patient's neck between them; this done, he is quickly to lay hold of the patient's head with both his hands, and ſtrongly pulling and extending it, he muſt gently move it from one ſide to another, till he finds by a noiſe, the natural poſture of the neck, and a remiſſion of the ſymptoms, that the diſlocation is properly reduced.

The imperfect luxations of the *Vertebræ* of the back, are no more than their two upper or lower proceſſes being diſplaced, and that often but on one ſide: this happens ſometimes to only one of the ſpinal *Vertebræ*, ſometimes to more. Theſe luxations are generally very difficult to reduce; the beſt method of doing it is thus: When the apophyſes of the *Vertebræ* are diſlocated on both ſides, the patient is to be laid leaning on his belly over a caſk, drum, or ſome other gibbous body; and then two aſſiſtants are ſtrongly to preſs down both the ends of the luxated ſpine on each ſide; by this means the bones of the ſpine will be ſet free from each other, lifted, or puſhed up in form of an arch, and ſo gradually extended: this done, the ſurgeon puſhes down the luxated *Vertebræ*, and at the ſame time nimbly puſhes the ſuperior part of the body upwards, and by this means the luxated bones are ſometimes happily reduced into their places; if ſucceſs does not attend the firſt attempt in this way, the operation is to be repeated. When the *Vertebra* comes out on one ſide, the patient is to be placed inclining in the prone poſture now mentioned; but ſo, that when the left apophyſis is diſplaced, one aſſiſtant may preſs the lower *Vertebræ* inward to the right, and another may depreſs the right humerus, and *vice verſa*: After the *Vertebræ* are reduced, the part is to be bathed with ſpirit of wine camphorated, or to have compreſſes dipped in the ſame ſpirit laid on it, and the napkin and ſcapulary bandage is to be applied. *Heiſter*'s Surg. p. 153.

VERTEBRÆ *of fiſhes.*—The *Vertebræ* of fiſhes are extremely different in ſhape in the ſeveral kinds, and even vary in number in the different ſpecies of the ſame genus. The anterior *Vertebræ* in ſome have three apophyſes, as in the cyprini, eſoces, pleuronecti, &c. and in the clupeæ they have no leſs than ſeven of theſe apophyſes, but they are ſlender and capillary. *Artedi* Ichthyol.

VERTIBULUM, a word uſed by ſome writers to expreſs the round head of a bone, which, in its articulation, is inſerted into the ſinus, or cavity of another bone.

VERTUMNALIA, among the Romans, a feſtival celebrated in honour of the god Vertumnus in the month of October. *Pitiſc.* in voc.

VERU, a comet, according to ſome writers, reſembling a ſpit, being nearly the ſame kind as the lonchites, only its head is rounder, and its train longer and ſharper pointed.

VERVA, a word uſed by ſome authors to expreſs an ivory amulet to be worn for the epilepſy.

VERVAIN, *Verbena*, in botany, the name of a genus of plants; the characters of which are these: The flower consists of one leaf, and is of the labiated kind. The upper lip is erect, and divided into two segments, the lower into three; and these are so disposed, that at first sight the flower has not at all the appearance of a labiated one, but seems only divided into five segments. The pistil arises from the cup, and is fixed in the manner of a nail to the lower part of the flower. It is surrounded by four embryos, which afterwards become four slender oblong seeds, which ripen in the cup, and fill it almost wholly up. To these marks it may be added, that the flowers of the *Vervains* grow in spikes, or sometimes in short heads, but never verticillately.

The species of *Vervain*, enumerated by Mr. *Tournefort*, are these: 1. The common *Vervain*. 2. The common *Vervain* with white flowers. 3. The taller broad-leaved Portugal *Vervain*. 4. The fine leaved *Vervain*. 5. The nettle-leaved *Vervain* of Canada. 6. The nettle-leaved *Vervain*, with jagged leaves, and larger flowers. 7. The narrow-leav'd nettle *Vervain*, of America, with blue flowers, and branched spikes. 8. The very narrow-leaved nettle *Vervain* of America, with numerous spikes and purple flowers. *Tournef.* Inst. p. 200.

Vervain was used among the Antients at their sacrifices, and was thought to contain something divine. The Romans, in the beginning of the year, made a present of this herb to their friends. *Danet.* in voc.

VERVISE, in our statutes, is used for a kind of cloth, Stat. 1 R. 3. cap. 8. *Blount*, *Cowel*. See the article PLONKETS.

VERULCA, the same as *Verva*, a name for an amulet of ivory worn on the arm as a cure for the epilepsy. *Scribonius Largus*.

VERZELLINO, in zoology, the name of a bird common in Italy, and kept in cages for its singing, called by authors *citrinella*, and *thraupis*. See the article CITRINELLA.

VESICARIA, a name given by Rivinus to a genus of plants, the same with the *corindum* of Tournefort. *Rivinus*, 4. 144. See the article CORINDUM.

VESICULÆ *seminales*. These vessels are very evident in fishes; the females of most fish have double ovaria, though in some they are single, as in the osmerus, and perca fluviatilis of Bellonius; but the *Vesiculæ seminales* in the males are two in number in all fish, not excepting the males of these here mentioned. They differ, however, very much in regard to their figure and situation. As to their situation, they in some fish occupy almost the whole length of the abdomen, as in the spinose kinds in general, and in the petromyzum, accipenser, and many of the other cartilaginous kinds. In some fish, they are placed only in the lower part of the abdomen, as in the cetaceous kinds, *&c.* As to figure, in the generality of fish, they are oblong, and compressed, but in some they are round, as in the cetaceous kinds. The other parts of generation are wanting in most fish. *Artedi* Ichthyolog. See the article TESTES.

VESP, or WASP, *Vespa*, in the history of insects. See the article WASP.

VESP-*Ichneumon*. Of this insect, Mr. Ray mentions a great number of species; the greater part of which are common on the sides of mud banks in the borders of fields. These have all slender bodies, and are armed with stings.

The origin of this creature is very strange; it is usually found issuing from the body of the common cabbage caterpillar. The occasion of which is this: The parent fly strikes her tail through the skin of the back of this caterpillar, and deposits her eggs in the creature's flesh. The eggs hatch into small maggots of the carnivorous kind; and these prey upon the flesh of the caterpillar till they arrive at their full growth: the creature that supports them, keeping itself alive all this time by the vast quantities of nourishment it is continually taking in. At length, when these worms are arrived at their full growth, they spin themselves a webb, under which they change into chrysales, and soon after come out in form of the fly that laid the egg. This is not peculiar to this single species of fly; but many are educated thus in the bodies of caterpillars of several kinds: some of these spin their webs under the skin of the caterpillar, and eat their way through it, when arrived at their perfect state; but others crawl out while yet in their worm state, after having eaten their full time, and bury themselves under ground in order to spin their webs.

The species are these: 1. The red-tailed *Ichneumon*, with long wings spotted with black. 2. The black-tail'd *Ichneumon*, with a long and slender body, variegated with annular marks of red and black. 3. The black *Ichneumon*, with three hairs at its tail; the body of this species is intirely black, without the least variation. 4. The black *Ichneumon*, with a white circle on the legs, and on the antennæ. 5. The *Ichneumon* with a thick breast, and a body beginning by a slender filament, and terminating in a thick tail. 6. The great large winged *Ichneumon*, with a yellow body, and large yellow spots on the wings. 7. The smaller large-wing'd *Ichneumon*, with black wings, and a black body and tail. 8. The red-leg'd *Ichneumon*, with a body red at the beginning, and a white large spot upon the back. 9. The large *Ichneumon*, with a black head, breast, and legs, a red body, and black tail. 10. The flat-body'd *Ichneumon*, with a black back, and greenish white belly. 11. The slender body'd *Ichneumon*, brown on the back, with one yellow transverse line, and yellowish on the belly. 12. The small three-haired *Ichneumon*, with long antennæ.

13. The small black *Ichneumon*, with a white cross upon its back. 14. The reflex horned *Ichneumon*, with its anterior feet clypeated. 15. The black body'd *Ichneumon*, with two broad circles of yellow on the middle of the back. 16. The black body'd *Ichneumon*, with a white tail, and a white triangular spot on the shoulders. 17. The long bodied *Ichneumon*, with a yellow body and black tail: this is an inch and quarter in length, and is a very beautiful species. 18. The large caterpillar *Ichneumon*, with the anterior half of the body of a bright orange colour, and the other half black. This is produced in the body of another species of caterpillar. 19. The black *Ichneumon*, with orange coloured legs. 20. The small *Ichneumon*, with yellow legs, and a yellow back, and three hairs at the tail. 21. The small *Ichneumon*, with three hairs at its tail, with shining wings. 22. The black *Ichneumon*, with several narrow yellow circles on the hinder part of the body. 23. The black breasted *Ichneumon*, with the anterior part of the body yellow, and the hinder part black. 24. The caterpillar *Ichneumon*, with no hairs at the tail, and with very long horns. 25. The long-bodied caterpillar *Ichneumon*, with only one hair at the tail: these are produced of worms lodged in the bodies of different kinds of caterpillars. 26. The black and yellow *Ichneumon*, with purple wings. 27. The slender bodied *Ichneumon*, with purple wings. 28. The orange-coloured *Ichneumon*. The whole body in this species, is of a reddish yellow, with no spot, or variegation in it. 29. The black bodied *Ichneumon*, with red legs, and shining wings; each marked with one spot. 30. The variegated leg'd *Ichneumon*, with a white circle on each antenna. The legs of this species are partly black, and partly red. 31. The large *Ichneumon*, with a yellow body and black tail: and, 32. The inky wing'd *Ichneumon*. *Ray*'s Hist. of Insects, p. 254, *& seq.*

VESPERTILIO, the *bat*. In the Linnæan system of zoology, this animal makes a distinct genus; but that not as a bird, as the vulgar esteem it, but as one of the quadruped class. The characters of the genus are these: That the creature is viviparous, whereas all the birds are oviparous: that it has two paps: its feet have five toes on each; and the four feet are expanded into a sort of wings. Under this class, the author takes in the canis volans, and glis volans; the flying dog and flying dormouse, as they are called by other authors. *Linnæi* System. Nat. p. 37.

Bontius describes a very strange kind of *Vespertilio*, or bat, as he calls it, found in the East-Indies; and Piso, who has thoroughly considered the subject, doubts much, whether it can properly be referred to the bat kind or not. Indeed, it seems more properly to belong to the class of the flying squirrel. *Bontius* calls it the *Verspertilio admirabilis*, and describes it as being of the size of a cat, and of a fleshy body; and says, that it flies by means of membranes annexed to the sides of its body, and to its fore-legs; and that it can expand these to a vast compass. From all this it appears to be of the squirrel kind; but he adds, that they fly in flocks, like our wild geese, which seems very improbable; and it seems rather, that the creature was intended only for long leaps. If Scaliger had known this animal, it would be very natural to believe he meant it under the name of the *felis volans*, or flying cat; which is generally supposed another name only for the common flying squirrel.

VESPERTILIO, in conchyliology, the name of an elegant species of voluta, supposed to have some resemblance to the colour of a bat. See the article VOLUTA.

VESPIVORUS *buteo*, in zoology, a name given by some authors to the bird, called in English, the honey-buzzard, from its feeding its young with the maggot worms out of honey-combs. *Willughby*'s Ornithol. p. 39. See the article APIVORUS *Buteo*.

VESSEL (*Cycl.*)—*Extraordinary* VESSELS, in anatomy. It is not uncommon to meet in the bodies of dissected persons remarkable variations from the common course of nature in the structure of the body; and among these, sometimes duplicates of parts naturally single: thus Kerkring mentions a double *vena cava*, and a treble ductus thoracicus in different bodies, as also four spermatic arteries in one body, with no spermatic veins: there are accounts also of defects of parts usually judged essential; but it is to be observed, that the ends of nature being much more easily answered by the excess, than by the defect of parts, the accidents of excess are greatly more common than those of defect. *Kerkring*'s Spicil. Anat.

Chemical VESSELS. See the Appendix.

VESSIGON, in the manege, a wind-gall, or soft swelling, on the in and outside of a horse's hough, that is, both on the right and left of it.

VETCH, *Vicia*, in botany. See the article VICIA.

Horse-shoe VETCH. See the article FERRUM *equinum*.

Bitter VETCH, in botany. See the article AROBUS.

VETO, in Roman antiquity, was the solemn word used by the tribunes of the people, when they inhibited any decree of the senate, or law proposed to the people, or any act of other magistrates. *Liv.* 6. 37. *Middlet.* of Rom. Sen. p. 160. See the article INTERCESSION.

VETOLA, in zoology, a name used by the Venetians, and from them by many others for a water-bird of the godwit kind,

kind, called by Aldrovand, the *Totano*, and by Geſner, the *Fedoa ſecunda*.

It uſually weighs about nine ounces; its beak is ſhaped like that of the woodcock, and is red all over, except at the end, where it is blackiſh; its neck is grey; its belly and breaſt white; its head of a browniſh grey; and its back brown; but its rump has a white ring on it; its tail is compoſed of black and white feathers. *Ray*'s ornitholog. p. 216.

VETTONICA, in botany, the antient way of ſpelling the word *Betonica*, the name of a plant called in Engliſh, *Betony*.

It is called *Vettonica* by Pliny, who ſays, it obtained that name from a people of Italy ſo called, among whoſe woods it grew.

We are far from being certain what plant the antients mean when they preſcribe *Betony*, ſome having applied the name to the ſame plant, which we at this time call by it; others calling the *ſerratula* or ſaw-wort, by this name, and others roſemary.

Dioſcorides mentions only one kind of *Betony*, which he calls *ceſtra* and *pſuchrotropha* in the Greek, and which his tranſlators explain by *Vettonica vel roſmarinus*; and this is countenanced in expreſs words by the author himſelf, in one place, where he ſays the plant *ceſtra* is called *pſuchrotropha*, from its being produced in damp places; and that the Romans called it *Betonica*, or *roſmarinus*.

This ſeems abſolutely confounding the two plants *roſemary* and *Betony*.

The *Betony*, ſaw-wort, and roſemary, of the preſent times, are three very different plants; and we are therefore not to cenſure the antients, if any one of them wants the virtues they aſcribed to *Betony*, but to try them all round.

However, if any thing certainly can be judged of the *betonica* of the antients, it is, that it was our *ſerratula*. See the article SERRATULA.

VEXILLARII, among the Romans, were veteran ſoldiers, the ſame with thoſe the old Romans called *triarii*. There were ſix hundred of them in every legion. See the article TRIARII, *Cycl.*

VIATORES, among the Romans, officers whoſe buſineſs it was to go into the country, and acquaint the ſenators of the extraordinary days on which they were to meet. See Mem. de l'Acad. vol. 1. p. 405.

VIBA, VUBA, or VABA, names by which ſome botanical authors call the common ſugar-cane. *Piſo*, p. 119. *Marggrave*, p. 82.

VIBEX, (*Cycl.*) a word uſed by ſome to expreſs a black mark upon the ſkin, from a bruiſe.

VIBRANT, or VIBRION, in natural hiſtory, the name of a claſs of flies, commonly known by the name of the *ichneumons*.

The word is derived from the Latin *vibro*, to ſhake or quiver, and is applied to theſe flies, from the continual vibrating motion obſerved in their antennæ.

VIBRISSÆ, a word uſed by medical writers to expreſs the hairs in the noſtrils.

VIBURNUM, in botany, the name of a genus of trees, the characters of which are theſe: The flower conſiſts of only one leaf, and is of the rotated kind, and divided into ſeveral ſegments at the edges. The center of this flower is perforated by the pointal of the cup, which finally becomes a roundiſh, ſoft and juicy berry, containing a hard ſtriated ſeed, of a flattiſh figure.

There is only one ſpecies of this tree, which is the common *Viburnum*. *Tourn.* Inſt. p. 607.

VIBURNUM *Galls*, in natural hiſtory, the name of a ſpecies of galls, or ſmall protuberances, frequently found on the leaves of the *Viburnum*. Theſe are of a very ſingular nature, and ſeem to be compoſed of a different ſubſtance from that of the leaf. They appear in form of brown circular ſpots, of which there are ſometimes forty or more on one leaf. Theſe are about a fifteenth of an inch in diameter, and they riſe a little above the ſurface of the leaf, as well on the under as the upper ſide; each of theſe has alſo a ſmall prominence in the center, on each ſide of the leaf, looking like a nipple ſtanding on the breaſt.

Theſe are found in great plenty in the months of June, July, and Auguſt, and, when opened, each contains one inſect, which is a ſmall worm of a white colour, with ſix legs, and two hooks of a brown colour at the head. The manner of watching the changes of this inſect is this: Place ſeveral of the leaves of this ſhrub, with their pedicles, in a veſſel of water; ſet this upon a ſheet of white paper, on a ſmooth table, and cover it with a box, the edges of which muſt touch the paper every where; by this means the leaves will be kept freſh, ſo long as is neceſſary for the feeding of the animal in the galls; and this, after its proper changes, eſcaping out of the galls, muſt be found within the outer box. Mr. Reaumur tried this method with ſucceſs, and found that theſe worms became, in fine, a very ſmall ſpecies of beetle, ſeveral of which he found crawling upon the paper. They were of a cinnamon colour, and had conic and granulated antennæ of a beautiful figure. *Reaumur*'s Hiſt. Inſ. vol. 6. p. 209.

VICARDI, the name of an office in the iſland of Candia.

The word is probably a corruption of the Latin *vicarii*. The *Vicardi* is the governor of a village, and is ſometimes the pariſh-prieſt; his office is to levy the public taxes, and to ſend offenders to the cadic. This office is always appointed yearly. *Pocock*'s Egypt, vol. 2. p. 2. p. 12.

VICARIO *Deliberando occaſione cujuſdam recognitionis*, &c. An antient writ that lies for a ſpiritual perſon impriſoned. Reg. Orig. 147. *Blount*, *Cowel.*

VICES, a term uſed by the dealers in horſes to expreſs certain faulty habits or cuſtoms in that creature, which render him troubleſome to the rider, and are never to be worn off, but by attention to the regular methods.

The following are the tricks generally underſtood as *Vices* by dealers, and their methods of preventing, correcting, and curing them.

1. If a horſe carry his head or neck awry, ſtrike him twice or thrice with the ſpur on the contrary ſide; but if he be very ſtiff-necked on the right ſide, and very plying or bending on the left, the rider is to hold the right rein ſhorter than the other, and give him ſudden checks every time he inclines that way, having a ſharp wire faſtened in the reins, that ſtriking in his neck, he may be compelled to hold it ſtrait; but in this care muſt be always taken to check him upwards, for otherwiſe he will get a habit of ducking his head, which will prove very troubleſome.

2. If a horſe is apt to ſhake his head and ears, upon the leaſt occaſion, or move his ears, when he is going to kick or bite, or caſt his rider; the way of curing this, is to ſtrike him on the head with a wand, as ſoon as he ſhews the firſt attempt to it; and, at the inſtant of ſtriking him, he is to be checked with the bridle, and be ſtruck with the ſpur on the contrary ſide; this will put him out of his pace, and he is then to be ſtopped, that he may have leiſure to underſtand the rider's meaning. Every time that he ſtarts or winches, which are ſignals that he is going to bite, or to ſtrike with his heels, the ſame is to be done, and he will, by degrees, be broke of theſe habits.

3. If a horſe is ſubject to ducking down his head frequently, the rider muſt, every time he is guilty of it, check him ſuddenly with the bridle, and at the ſame time ſtrike him with the ſpurs, in order to make him ſenſible of his fault. If he be ſtanding, he is thus to be made to bring his head in the right place as he ſtands; and when he does ſo, he is to be cheriſhed, that he may underſtand the rider's meaning, which, in time, he will certainly do.

4. If a horſe be ſkittiſh, and apt to ſtart, ſo that the rider is never free from danger, while on his back, the cauſe of the malady is firſt to be carefully enquired into: If it be found to proceed from a weak ſight, which repreſents objects to him other than they really are; the method of curing him is, every time he does it, to give him leiſure to view the things, and ſee what they really are; he muſt have time to view them well, and then be rid gently up to them. If, on the contrary, his ſkittiſhneſs depends on his being naturally fearful, and alarmed at every noiſe, he is to be cured of it by the inuring him to loud noiſes of many kinds, as firing of guns, drums, trumpets, and the like; and he will, in time, come to take delight in what he was before afraid of.

5. If a horſe be reſtive, and refuſe to go forward, the rider is to pull him backwards, and this will often occaſion his going forward; this is uſing his own fault, as a means of reclaiming him. The rider is firſt cautiouſly to find whether this *Vice* proceeds from real ſtubbornneſs, or from faintneſs; if from the latter, there is no remedy but reſt; but if actual ſtubbornneſs be the fault, the whip and ſpur, well employed, and perſiſted in, will, at length, be found a certain cure.

6. If a horſe rear up an end; that is, if he riſes ſo high before as to endanger his coming over the rider, the horſeman muſt give him the bridle, and bear forwards with his whole weight. As he is going down, he ſhould have the ſpur given him very roundly; but this muſt by no means be done as he is riſing, for then it will make him riſe higher, and, probably, come over.

7. If a horſe be ſubject to lie down in the water, or upon the ground, there is no better remedy than a pair of ſharp ſpurs reſolutely applied. But there is ſome caution to be uſed in the applying them, for bad horſemen generally are the occaſion of the faults in horſes, by correcting them out of due time. The proper moment of ſpurring is juſt when he is going to lie down; but when this has diverted him from the thought of it, he is not immediately to be ſpurred again. For the doing this frightens the creature, and puts him into confuſion to that degree, that he at length becomes reſtive, and thus one fault is only changed for another, and that perhaps a worſe.

8. If a horſe be apt to run away, very cautious means muſt be uſed to break him of it. The rider muſt be gentle, both with a ſlack curb, and keeping an eaſy bridle-hand. He is firſt to be walked without ſtopping him; but only ſtaying him, by degrees, with a ſteady, not a violent hand, and always cheriſhing him when he obeys: When he is thus made very manageable in his walk, he is to be put to his trot, and finally to his gallop; and from theſe he is to be brought into a walk again, always by degrees, and ſtaying him with a ſteady hand. By uſing this method from time to time, with

judgment and patience, it is probable he may at length be cured.

9. If a horſe is apt to fly out violently, it is certain, that the more the bridle-rein is pulled, and the more he is hurt by tugging the curb, the faſter he will run: The beſt method is therefore, if there be field-room enough, to let him go, as ſoon as he is going, by ſlackening the bridle, and giving him the ſpur continually and ſharply, till he ſlacken of his own accord. Thus, by degrees, he will find that himſelf is the ſufferer, by all his flights, and he will then leave them off, tho' he could be never broke of them any way elſe.

10. Some horſes will not endure the ſpurs when they are given them, nor ever go forwards; but faſtening themſelves to them, they will ſtrike out and go back; and if they are preſſed more hard, they will fall to piſſing without ever going out of the place. If the horſe who has this *Vice* be a gelding, it will prove very difficult to cure him of it. A ſtone-horſe, or a mare are much eaſier cured; but even theſe will be trying at it again afterwards; and if ever they get the better of their rider, they will not fail to keep it up in this particular.

Every horſe, of whatever kind, that has this fault of cleaving to the ſpurs, as the jockies call it, and not going forwards with them, is to be rejected, in the buying for any gentleman's riding, for it is a ſign of a reſtive nature, and is a fault generally accompanied with many others.

VICIA, *Vetch*, in botany, the name of a large genus of plants, the characters of which are theſe: The flower is of the papilionaceous kind; and the piſtil, which ariſes from the cup, finally becomes a pod, furniſhed with roundiſh or angular ſeeds; to this it is to be added, that the leaves ſtand in pairs on the rib, and that terminates in a tendril.

The ſpecies of *Vetch*, enumerated by Mr. Tournefort are theſe: 1. The common cultivated *Vetch*, with black ſeeds. 2. The common cultivated *Vetch*, or tare with grey ſeeds. 3. The cultivated *Tare*. 4. The great wild buſh *Vetch*. 5. The buſh-*Vetch*, with roundiſh, but pointed leaves, and with black ſeeds. 6. The buſh-*Vetch*, with roundiſh, but pointed leaves, and with ſpotted ſeeds. 7. The buſh-*Vetch*, with narrower-pointed leaves, and a ſmall black ſeed. 8. The many-flowered *Vetch*. 9. The hoary perennial many-flowered *Vetch*. 10. The great-many-flowered *Vetch*, with variegated blue and white flowers. 11. The hairy perennial many-flowered *Vetch*, with pea-like pods. 12. The white-flowered hairy wild *Vetch*. 13. The great early French hairy wild *Vetch*, with red flowers. 14. The buſh *Vetch*, with a roundiſh, ſhort, and blunt-pointed leaf. 15. The corn *Vetch*, with numerous hairy pods. 16. The corn *Vetch*, with ſingle ſmooth pods. 17. The leaſt *Vetch*, with numerous ſmooth pods. 18. The long-leaved *Vetch*, with longer pods. 19. The narrow-leaved violet purple-flowered *Vetch*, with broad ſmooth pods. 20. The many-leaved *Vetch*, with ſmooth pods. 21. The *Vetch* that buries many of its pods under the ground. 22. The leaſt early French *Vetch*. 23. The procumbent *Vetch*, with broad, not ſerrated leaves. 24. The procumbent *Vetch*, with very broad leaves, and with ferrugineous-coloured flowers and fruit. 25. The procumbent *Vetch*, with very broad ſerrated leaves. 26. The largeſt wild *Vetch*, with the appearance of the wild pea. 27. The wild yellow *Vetch*, with a hairy pod. 28. The perennial late-flowering yellow *Vetch*, with hairy pods. 29. The perennial late-flowering yellow *Vetch*, with ſmooth pods. 30. The yellow-flowered *Vetch*, with a brown galea to the flower. *Tourn.* Inſt. p. 397.

VICOMAGISTER, among the Romans, an officer whoſe buſineſs it was to take care of the ſtreets, that nothing might obſtruct, or render them anywiſe incommodious. *Hofm.* Lex. Univ. in voc.

VICTORIATUS, among the Romans, a coin with victory repreſented on one ſide, equal in value to half the *denarius*. See the article DENARIUS, *Cycl.*

VICTORIOLA, in botany, a name uſed by ſome authors for the hippogloſſum, called in Engliſh the *Alexandria-laurel*, *horſe-tongue*, or *double-tongue*. *Ger.* Emac. Ind. 2.

VIDIMARUM, in botany, the name of the tree which bears the ſebeſtens, a medicinal plum, of Aſia and Ægypt. Hort. Mal. vol. 4. p. 77.

VIELLE *ridée*, the *wrinkled old Woman's Shell*, a name given by the French authors to a ſpecies of *chama* of the mutilated kind, very much reſembling the famous *concha veneris*, but longer, and without that peculiarly-ſhaped oval aperture to which that ſhell owes its name.

It has ſeveral ſpines about the lips, as the *concha veneris* has, but they are ſhorter and more obtuſe than in that ſhell. The whole ſurface of this ſpecies is deeply and irregularly wrinkled. It is of a whitiſh colour, variegated with brown.

VIELLEUR, in natural hiſtory, the name of a ſpecies of fly, common in Surinam, and ſome other places. It is moderately large, though leſs ſo than the lanthorn-fly, ſo common in that place, and has a long head, and ſome other particulars, in which it reſembles that creature. Mrs. Merian has given a figure of it, and reports it as the opinion of the natives, that it changes at length into a lanthorn-fly. See the article LANTHORN-*Fly*.

VIGOROSO, or VIGOROS AMENTE, in the Italian muſic, is uſed to direct a performer to ſing or play with vigour, ſtrength, and firmneſs.

VIGESIMA, among the Romans, a tax of the twentieth part of the yearly incomes of all inheritances. It was firſt eſtabliſhed by Auguſtus. *Pitiſc.* Lex. in voc.

VIGESIMA was likewiſe a cuſtom paid for ſlaves ſold, as alſo for one made free. *Pitiſc.* in voc.

VIGESIMARIUS, among the Romans, an officer who had the management of collecting the *vigeſima*. See the article VIGESIMA.

VILLANELLA, in the Italian muſic, a ſort of air or tune to which the peaſants of that country dance. There are ſome of theſe *Villanellas* very agreeable, having ſomething gay and enlivening in them, well adapted to their deſign. The firſt couplet is uſually played plain and ſimple, afterwards come an infinity of variations, diminutions, *&c.*

VILLEIN *Fleeces*, in our Statutes, are bad fleeces of wool, ſhorn from ſcabby ſheep. 31 Ed. 3. c. 8. *Blount*, *Cowel.*

VILLOSE *Stalk*. See the article STALK.

VILTRUM, a word uſed ſometimes alone to expreſs a filtre, inſtead of the word *filtrum*. But *Viltrum* is more commonly joined with the word *philoſophorum*, and then expreſſes the common alembic for diſtillation.

VIMMALA, in natural hiſtory, a name given by the people of the Eaſt Indies to a kind of pyrites, of a braſſy appearance, and of a cubic figure.

They alſo give it in the ſame places to the *pyritæ* in general, when ſmall and of a ſimple internal ſtructure.

VINAGO, in zoology, a name given by ſome authors to the wood-pigeon, from the colour of its breaſt, ſhoulders, and wings, reſembling that of red wine. Its more uſual name among authors is *OEnas*. See the article ŒNAS.

VINDICTA, among the Romans, the prætor's rod or ſwitch, with which he touched a ſlave's head when he was affranchiſed. *Danet.* in voc.

VINCETOXICUM, in botany, a name uſed by many authors for the aſclepias, or ſwallow-wort, from its ſuppoſed virtues as an antedote. See the article ASCLEPIAS.

The people of Stiria and Carinthia are more ſubject than any other nation to ſcrophulous diſeaſes; but nature has provided them alſo with a very ready and ſafe remedy, which is the *Vincetoxicum*, or ſwallow-wort. This grows in vaſt abundance all over theſe countries; and the common people know it as a certain cure for this terrible diſeaſe. It is alſo found of excellent uſe in dropſies; and as it might be cultivated with us, or its roots imported in any quantities, it is wonderful that we do not uſe it.

VINE, (*Cycl.*) *Vitis*, in botany. See the article VITIS.

All the ſorts of *Vines* are propagated either from layers or cuttings. The former is the method uſually practiſed with us, but the latter ſeems much the better.

In order to propagate them by cuttings; theſe muſt be choſen ſuch as are ſtrong and well-ripened ſhoots, of the laſt year's growth, and ſhould be cut from the old *Vine*, juſt below the place where they were produced, taking a knot of the two years wood, which ſhould be pruned ſmooth. The upper part of the ſhoot ſhould then be cut off, ſo as to leave the cutting about ſixteen inches long. Theſe cuttings are to be placed with their lower part in the ground, in a dry place, laying ſome litter about their roots to prevent them from drying. In this place they ſhould remain till the beginning of April, which is the time to plant them. They are then to be taken up and wiped clean, and if they are very dry, they ſhould ſtand with their lower parts in water ſix or eight hours. Then, having prepared the beds for them, they are to be ſet at about ſix foot diſtance from each other, and making their heads ſlant a little toward the wall. The cutting is to be ſo buried in the ground, that only the uppermoſt bud be upon a level with the ſurface; the earth is then to be well cloſed about the plant, and a little mould heaped up over the eye of the bud, to keep it from drying. After this, there is no more trouble neceſſary, but to keep the ground clear from weeds, and to nail up the ſhoot as it grows, to the wall, rubbing off all the ſide-ſhoots.

The Michaelmas following, if the cuttings have produced ſtrong ſhoots, they ſhould be pruned down to two eyes. In the ſpring following the ground is carefully to be dug up about the ſhoots, and the ſtalks to be earthed up to the firſt eye. During the ſummer all the lateral ſhoots muſt be rubbed off as they appear, and only the two from the two eyes which were left, muſt be encouraged; theſe, as they grow, are to be nailed up againſt the wall; and in the middle of July theſe ſhould be ſhortened, by nipping off their tops, and this will greatly ſtrengthen the ſhoot. At the Michaelmas following theſe ſhould be pruned, leaving them each three eyes, if they are ſtrong; but if they are weakly, only two. The next ſummer there will be two ſhoots from each ſhoot of the laſt years wood; but if there ſhould be two from one eye, which is ſometimes the caſe, then the weaker is to be rubbed off. At midſummer the ends of the ſhoots are to be pinched off as before; all the weak lateral ſhoots are to be diſplaced, as in the preceeding ſummer, and the whole management is to be the ſame. This is all the culture neceſſary to young *Vines*.

As to the management of grown *Vines*, it is to be obſerved that theſe rarely produce any bearing ſhoots, from wood that is more than one year old; the great care muſt therefore be always to have plenty of this wood in every part of the tree.

The bearing ſhoots for the following year ſhould be left at the pruning with four eyes each. The under one of theſe does not bear, and conſequently there are only three which do. Many leave more eyes on the ſhoots, that they may have more fruit, which is the conſequence; but then the fruit is much poorer; and this is ſo well known in the wine countries, that there are laws to direct that no more than ſuch a number of eyes are to be left on each ſhoot, for the grapes would elſe be of a poor juice, and deſtroy the reputation of their wine. Each of the three eyes left, will produce two or three bunches; ſo that each ſhoot will give ſix or nine bunches, which is as much as it can bring to any perfection. Theſe ſhoots muſt be laid in at about eighteen inches aſunder on the wall; for if they are cloſer, when the ſide-ſhoots are produced, there will be no room to train them in upon the wall; and the largeneſs of the leaves of the *Vine* requires alſo that the ſhoots ſhould be at a proportionable diſtance.

The beſt ſeaſon for pruning *Vines* is the end of September, or beginning of October. The cut is always to be made juſt above the eye, and ſloped backward from it, that if it bleed, the juice may not run upon the bud; and where there is an opportunity of cutting down ſome young ſhoots to two eyes, to produce vigorous ſhoots for the next year's bearing, it ſhould always be done. In May, when the *Vines* are ſhooting, they ſhould be looked over, and all the ſhoots from the old wood ſhould be rubbed off, as alſo the weaker, whenever there are two produced from one eye. During the month of May the branches muſt be nailed up againſt the wall as they ſhoot, and toward the latter end of this month, the ends of the bearing branches ſhould be nipped off, which will greatly ſtrengthen the fruit. Thoſe, however, which are to bear the next year, ſhould not be ſtopped before the beginning of July.

When the fruit is all gathered, the *Vines* ſhould be pruned, whereby the litter of their leaves is all removed at once, and the fruit will be forwarder for this the ſucceeding year. *Miller*'s Gardener's Dict.

The *Vine* is one of the trees moſt liable to be injured by froſts with us; its trunk is often ſplit in froſty weather, and that moſt frequently when it ſtands in the warmeſt aſpects. In the year 1683, the great froſt ſplit almoſt all our timber-trees; but this was owing to defects in them, by which the ſap was detained in very large quantities in particular places, from their being wind-ſhaken, coltie, or otherwiſe diſtempered; but the *Vines* ſuffered the ſame accident, ſeemingly from another cauſe.

Thoſe *Vines* were moſt ſplit this year, which were expoſed to a ſouth aſpect, and planted againſt the warmeſt walls. The ſun, their uſual friend, now proved their enemy, and daily thawing the ſap in the trunk, it was again frozen every night. This often bending and unbending, ſoftening and hardening the vivid ſpirituous juice of this plant, deſtroyed it; and the ſap, being the ſame year diſordered, and not gradually ſeaſoned, but even ſtopped before Michaelmas-day, and the freſh ſap wholly detained by the ſucceeding froſts from ariſing, the frozen and hard earth alſo denying its juices, even though the veſſels of the plant had been in a condition to receive them; the trunks and branches of the *Vines* were filled only with a thin, watery, and mortified ſap, and this moſt of it extravaſated by the burſting of the veſſels it was frozen in, many of them ſuffered as much as if cut off from the root. Thus periſhed the greater part of the *Vines* expoſed to the ſun's action; while the other, which ſtood in more ſhady places, not having their juices thawed and frozen daily, ſuffered but one change, and often eſcaped. It was alſo obſerved this year, that the red grap-trees eſcaped in general much better than the white, being hardier than they.

Other wall-trees, containing viſcous juices, eſcaped very well, while the *Vines* thus ſuffered, even though expoſed in the ſame manner. Among others, the plums, apricots, peaches, and wall-cherries, had very little damage. It is eaſy to conceive why plants with viſcous juices ſhould ſuffer leſs by froſt, than thoſe with more thin ones; and we ſee that this is the caſe between theſe two ſorts of trees, the plums, *&c.* often exſudating their juices in form of gum-arabic; but the *Vines*, when they throw out any, ſhew that theirs is as thin as common water. The different kinds of trees have, doubtleſs, all their different conſiſtences in their juices; and it may have principally been owing to that diverſity in others, as well as in the plum and *Vine*, that ſome eſcape, while others periſh by froſts. Phil. Tranſ. N°. 165.

VINE *Gallinſect*, an inſect of the *gallinſect* claſs, principally found on the *Vine*, though capable of living on ſome other trees, and ſometimes found on them. It is much of the ſame ſhape, figure, and manner of life with the other animals of this claſs; but differs from them in this; that as they lay their eggs all under their body, and continue abſolutely to cover them, till they are hatched; theſe protrude them from their body, and they are found in prodigious abundance, lodged in a ſort of cottony or ſilky bags all over the ſtalks and branches of the *Vines*; the dead animal is ſometimes found covering them in part; but more frequently they are abſolutely naked, and often are ſo numerous as to appear like thin cobwebs hung one over another all over the *Vine*. See Tab. of Inſects, N°. 32.

Theſe eggs might be eaſily miſtaken for thoſe of ſmall ſpiders; they always hatch well, and come to maturity on the *Vines* they are found on; but if removed to others, they ſeldom come to any thing, which is very ſingular, ſince the *Gallinſects* of almoſt all other trees may be removed and propagated either on the ſame or on different trees. Theſe neſts of eggs, covered with down, and thus lodged on the *Vine*, are of no certain ſhape or form; ſometimes they are convex and roundiſh; but that is not always the caſe, they ſtick to the fingers on touching, and are pulled away in ſmall irregular threads; if theſe are pulled away to any conſiderable diſtance, the eggs come among them; they are oblong, reddiſh, and of ſmooth ſhining ſurfaces, and are amaſſed in vaſt numbers in the center of each of theſe little packets.

The inſect, as it lays theſe eggs, directs them under its body toward its head, and thence downward toward the tail again; they are all arranged like the beads of a necklace, and make long chains or ſtrings, thus directed, and running backward and forward with ſeveral ſinuoſities; and the cottony matter in which they are enveloped, is not like that of ſpiders, produced from certain particular organs appointed for the ſpinning it, but ſweats out, as it were, from every pore of the creature's body; but moſt of all from its ſides; it ſeems to be produced in extremely ſmall and ſhort filaments; but, being of a viſcous nature, will draw out on the touch like glue or warm reſin; and long threads of it are originally formed by the courſe of the chains of eggs before deſcribed, which take it up in their courſe, and form it into numerous threads of their own length, as it goes on.

Theſe *Vine* inſects are of the boat-faſhioned kind; but, beſide theſe, there are ſome other ſpecies which lodge their eggs in a cottony neſt of the ſame kind. The common thorn affords a ſhorter and more convex kind that this does; theſe are a very ſmall ſpecies; others are ſomething larger; but the oak affords a ſort equal in ſize, if not exceeding thoſe of the *Vine*; ſome of theſe are brown, others bluiſh, and others reddiſh; and there are ſome minute differences in their ſhape. *Reaumur*, Hiſt. Inſ. Tom. 4. p. 61.

VINE *Grubs*, in natural hiſtory, a name given by ſome authors to the pucerons, or little inſects, which are uſually of a green colour, and are found often in prodigious numbers, ſticking to the leaves of trees and plants, and to their young ſtalks.

Mr. Reaumur has been very curious in his inveſtigation of the nature of this inſect; but its manner of propagating its ſpecies was never clearly obſerved, till Mr. Bonet diſcovered it.

Reaumur obſerves, that in every family of pucerons, there are ſome that have wings, and ſome that have not; and that, according to the uſual courſe of nature, the winged ones ſhould be males, and the others females; but, on the contrary, that both the winged and the unwinged *Vine-grubs* are females, all being viviparous, and each kind producing a number of living young; ſo that the males of theſe pucerons were never diſcovered, even by that careful obſerver; nor could he ever find out what it was that impregnated the one and the other kind. He leaves us queries on this ſubject, whether there is no copulation among them, and whether they are all hermaphrodites, each having in itſelf the organs of both ſexes, as is the caſe in the river muſcles.

Mr. Bonet, in order to inform himſelf of the proceſs of nature in theſe creatures, brought up one of them in perfect ſolitude from its birth; he had an opportunity of obſerving it in the place where it was kept, and watched it very ſtrickly for many months together. At the end of twelve days this creature, without having had any copulation with a male, began to breed. She produced in the whole ninety-five young ones, all alive, and conſtantly under the eye of the obſerver. This experiment was repeated ſeveral times with the ſame ſucceſs; and, at length, repeated upon the young ones produced in this manner, and they were found to breed at the ſame period, and in the ſame manner with their parent, without having had any copulation with a male, as far as to the fourth generation.

A haſty obſerver would immediately conclude from this, that there was no copulation among the pucerons; but farther enquiry proves, that this is not the caſe; for the ſame obſerver has found a ſpecies of them in which there is copulation; ſo that both the winged and the unwinged kinds are truly females, and the male is a ſmall fly, of a very different ſhape, as is the caſe in regard to many other inſects. This male is the moſt ſalacious creature imaginable, copulating a vaſt many times ſucceſſively, with the ſame, and with different females. As this is the caſe in regard to one ſpecies of this creature, it doubtleſs is ſo alſo in regard to the reſt, though that has not yet been obſerved: And the ſingularity ſeems to be this, that after the male has copulated with the female, ſhe not only becomes prolific, but her young ones are born ready impregnated, as far as to the fourth generation; after which, probably, there is a neceſſity for the copulation with the male again.

There is another very ſingular obſervation alſo in the production of the young pucerons; the females are properly viviparous, and uſually bring forth live young; but they ſometimes produce only a ſort of fœtus's, which are laid in long ſeries one beſide the other, as the caterpillar-eggs are laid by the

the butterfly; and they are left to hatch, as it were afterwards, by the heat of the sun. Philos. Trans. N°. 469.

VINEGAR (*Cycl.*)—It is plain that the original component matter of *Vinegar* is sugar, which, in the art of acetification, seems wholly converted into a fluid tartar, and if the aqueous liquor be separated from *Vinegar*, we find the *Vinegar* is thereby made the stronger, insomuch that if *Vinegar* were to be highly concentrated by congelation, it would become almost solid, or a kind of actual tartar.

Whence the rule is easy, that, in order to make an almost solid *Vinegar*, we should endeavour to dissolve tartar in an aqueous liquor, whence to perfect the art of acetification. The dissolving of tartar largely with sugar or treacle, and the strongest *Vinegar*, by repeated imbibitions, that and a proper management is much to be recommended to the persons concerned in this trade. *Shaw*'s Lectures, p. 205.

It is very well known that a very large quantity of water, or mere insipid phlegm, is contained in *Vinegar*, and that what we call *Vinegar*, would be infinitely stronger, if cleared of that. It is for this reason, that a great quantity of *Vinegar* will saturate but a very small portion of an alkaline salt; and a great deal of this aqueous acid is, for the same reason, required to dissolve a small portion of metal. A pint of the strongest *Vinegar* will scarce dissolve more than two drams of iron, and will not saturate more than the same quantity of pure salt of tartar.

It has been wished by many, that some method could be contrived of concentrating *Vinegar*, so as to give it more strength; this must depend alone on the extracting the aqueous humidity; and this has been attempted several ways. Of all others, however, that succeeds best which we find recommended by Stahl, which is by freezing. This method so far deprives *Vinegar* of its superfluous water, and so far collects its acetous penetrating sharpness, as to render it an extremely powerful menstruum, throwing out five or six parts of phlegm, which scarce tastes at all sour, and having one sixth or one seventh part possessed of all the virtues of the whole. Dr. Shaw assures us, that he has repeated this experiment, and found it to answer perfectly upon the trial.

This condensed *Vinegar*, toward the end of the operation, or in the last congelations, lets fall a white shining powder, which is a tartar that, though dissolved in great quantity in the whole aqueous fluid, could not be retained in this concentrated one. *Stahl* de Condensat. Vini.

The thicker *Vinegar* is, the less fit it proves for distillation, as there is always the greater danger of an empyreuma, or burnt smell, which would spoil the whole process, and as it usually in this case comes over oleaginous. And the purest white salt of tartar, saturated with this distilled *Vinegar*, being afterwards ignited, turns black, and yields a smell extremely like that of crude tartar in the calcination. *Shaw*'s Chemical Essays.

On the other hand, the more the *Vinegar* is diluted immediately before distillation, the less danger there is of burning: And if the thick remaining mass, when the thinner part is distilled from it, be again diluted with water, it may, by a second distillation, be brought to afford an acetous substance; though this latter be by no means comparable to this former volatile part. This Vigani justly suspects to be a thing known but to very few. And even when the *Vinegar* it distilled with the utmost labour and care, it still has this effect in a higher degree, and contains an immense quantity of phlegm, in proportion to its acid salt.

In this case, the method of condensation by freezing is of the utmost service; first of all separating the more aqueous part, and in the next place, that which is somewhat acetous, tho' not comparable to what remains behind; so that, by this means, a most concentrated and subtle spirituous distilled *Vinegar* may be produced, *viz.* by freezing the whole parcel of distilled phlegm and distilled *Vinegar* together, a thing of great moment to the curious in the *chemia sublimior*, and particularly to those who understand Hollandus. And when the *Vinegar* is froze without distillation, by this means you have a noble rob, or a rich concentrated *Vinegar*, freed from its distillating aqueous and useless part. *Vigani*, Medull. Chem.

Vinegar, when applied to sores in animal bodies, stimulates and resists putrefaction. When weak, it also enjoys the virtues of water; when strong, approaches in its effects to those of salts and acid spirits. Med. Ess. Ed. vol. 5. art. 24. See the articles SALT and SPIRIT.

Portable VINEGAR, a name given by the chemists to a sort of *Vinegar*-powder, or *Vinegar* in a dry form. It is a preparation of tartar with *Vinegar*, and is made in this manner: Take white tartar, half a pound; let it be carefully washed, then dried and powdered; infuse this powder in the strongest wine-*Vinegar*, then dry it, and infuse it again, repeating this operation ten times. After this the dry powder is to be kept for use; at any time a sort of extemporaneous *Vinegar* may be made by dissolving a small quantity of this powder in any proper liquor.

Eels in VINEGAR. The common opinion, from the discovery of eels in *Vinegar*, that its sharpness to the taste was occasioned by these animals, occasioned the accurate Lewenhoek to attempt a careful examination of it by the microscope.

Some of the strongest and sharpest *Vinegar*, after having been exposed for some hours to the air, and afterwards examined by the microscope, entertains the sight with a number of corpuscles, called the salts of *Vinegar*, which are acute at both extremities, and have many of them in the middle an oblong figure of a brownish colour, and others were altogether clear, pellucid, and bright as crystal. Others of these particles appeared of an oval figure, and some of the half of such a figure, hollowed like a small boat, or the half of a nut-shell. The more perfect figures, pointed at both ends, and pellucid, are so very minute, that some thousands of them are comprehended in a small drop.

These seem to be what affect the tongue with the acid sharpness, when we taste of *Vinegar*; and it is very probable, that beside these, minute as they are, there are multitudes of others equally pointed, and infinitely smaller than these.

If *Vinegar* be placed in an open glass, and suffered to remain some weeks, the surface of it will be found, on examination with good glasses, to be full of the same figures, double-pointed, and very pellucid; and in these, very often, there may be cavities plainly discovered; but examining the liquor a little deeper down, there are found numbers of minute eels; yet these, though minute, are prodigiously larger than the salt particles, and can never be supposed to be the occasion of the sharpness of *Vinegar* to the taste, by any who rightly consider, since it is not all *Vinegar* that contains them; nay, the much greater part of *Vinegar* is wholly without them, and in winter they all die; yet *Vinegar* is not less sharp at that season, than in the summer.

If *Vinegar* be impregnated with crabs-eyes, or any other alkaline substance, which blunts, and in a great measure destroys its acidity, these double-pointed figures are no longer found in it, on a microscopical inspection; but in their places we find others with an oblong quadrangular base, from which they shoot up into pyramids, and appear like polished diamonds. These are also so very minute, that six thousand of them are computed to be contained in a drop of the liquor, no larger than two corns of barley. And these will be usually found all of the same size, or very nearly so, which is by no means the case with the other salts of *Vinegar* in its natural state.

Mr. Mentzelius was so lucky as to see these undergo their last metamorphosis, and change into small flies: And though this is a single instance, in regard to the microscopical world of animalcules, yet it is highly probable that the whole race of those, whose appearance in medicated fluids we have been so long puzzled to account for, may, like these, be the worm state of some winged aerial insect, and have owed their origin, where we see them, to the eggs of parent flies, too small for our sight. *Reaum.* Hist. Inf. vol. 4. p. 404.

VINNET, in our statutes, is used for a flower or border, which printers use to ornament printed leaves of books. Stat. 14 Car. 2. c. 33. *Blount.*

VINOUS (*Cycl.*)—VINOUS *Liquors.* All sorts of *vinous* and fermented liquors, both before and after the fermentation, consist not of similar, but heterogeneous parts, which are joined together in one certain and determinate order; thus the action of fermentation being a separation and destruction of the former connection of the subject, and transposing its parts anew, there must of necessity have been a kind of firm or durable texture in the subject so disjoined, separated, and new-ranged.

For example: Grapes being laid upon dry straw, in a cold place, will, for some time after they are separated from the vine, preserve that texture, which gives them their saline, unctuous, and slimy sweetness; which the juice also retains after pressing, and becomes a clear and transparent must, without separating itself into parts, but continuing regularly and uniformly mixed, so as to preserve the different matters it consists of, intimately connected among themselves. In this firmly connected state they may be kept many months, if a cask be filled with this juice, and set in a cool place, as we evidently see in stum. *Shaw*'s Essay on concentrating Wines.

Wine, in the precise chemical or philosophical notion of it, is a saline clammy oleaginous matter, diluted with a large proportion of water, whereby 'tis expanded, or set at a distance from itself, while the saline parts are saturated with, and interspersed among the subtile earthy ones that make the slimyness; thus they together imbibe, detain, and hold the grosser parts, beside which there are other oily parts vastly more subtile, which, by means of the highly attenuated saline portion adhering closely to them, remain as much connected with the water as the rest; and these are what we call the spirituous parts; but the connection of them all together is so strong and durable, that they move for a long time as one body, without separating, if carefully preserved. An acquaintance with the true nature, history, and effects of *vinous* fermentation, will fully explain and justify these positions.

If the spirituous part be once separated and drawn away from the wine by distillation, though it were immediately to be returned back to the remaining mass from whence it came, and ever so well shook again with it, the whole by no means retains its former taste, odour, and durability, but turns to a confused turbid mixture, of a different and nauseous taste, and a disagreeable smell; and, on the whole, approaches nearly to

a ſtate of vapidity. The only objection to this general rule, is, that if a new fermentation, or even but a fret be raiſed, when the ſpirit is newly joined to the remainder in the ſtill, the ſpirit may be thus re-inſtated, and the wine rendered perfect. The proceſs is different and uncertain; but a nice management, and a proper intermedium, will bring it about.

If an inflammable ſpirit diſtilled from the ſame, or any other *Wine*, be put to a parcel of *Wine* which is too ſaline, or not ſufficiently ſpirituous, the bare addition, or tumultuous admixture thereof, very far from giving the fine and intimate ſoftneſs of a good *Wine*, will rather manifeſt its own burning acrimony and nidorous flavour to the ſmell and taſte, and will add a nauſeous bitterneſs to the former tartneſs or acidity. This is an obſervation of Stahl's, and is allowed by Dr. Shaw to be true in general; but he obſerves, that, under a nice and proper management, a fine and taſteleſs ſpirit may be prepared and introduced into *Wines*, and will, after a time, become intimately mixed with their other part, and remain abſolutely undiſcoverable to the taſte or ſmell, unleſs by the excellency and the ſtrength it gives. *Stahl*'s Schediaſma de concentrat. Vini. See the article WINES, SPIRIT, &c.

VINUM *Aloeticum Alkalinum*, a form of medicine in the late London Diſpenſatory, intended to ſtand in the place of Helmont's elixir proprietatis: It is prepared in this manner: Take of bay fixed alkaline ſalt eight ounces, aloes, myrrh, and ſaffron, of each an ounce, purified ſal armoniac ſix drams, white wine a quart; infuſe them together without heat for a week, or longer, and then filtre the wine through paper for uſe. *Pemberton*'s London Diſpen. p. 262.

VINUM *chalybeatum*, *Chalybeate Wine*, is thus prepared: Take filings of iron four ounces, cinnamon and mace, of each half an ounce, of Rheniſh *Wine*, two quarts; infuſe a month without heat, often ſhaking the veſſel; then filtre it off for uſe. This is the preſcription of the new London Diſpenſatory, and is vaſtly preferable to that of the former, where only ſaffron was ordered.

This *Wine* is an excellent ſtomachic and aperient; it may be drank a moderate glaſs once or twice a day, or mixed in apozems of the aperient vegetables.

VINUM *Eſſatum*, in chymiſtry, a term uſed by Paracelſus, and ſome others, to expreſs *Wine* concentrated by freezing, after a long and low heat; the method of making it was this: They ſet the *Wine* in horſe-dung three months in a glaſs, hermetically ſealed, and then expoſed it to the froſty air for a month, after which they threw away the ice, and ſaved the unfrozen liquor.

This was their *Vinum Eſſatum*, called alſo eſſence of *Wine*; and ſpirit of *Wine*, and it is in this ſenſe, that Paracelſus ſays, ſpirit of *Wine* is a not-inflammable liquor, a paſſage that very few have underſtood.

Moſt of the antient chemical philoſophers profeſs, that they uſed ſpirit of *Wine* for the diſſolving of gold. We know very well, that what we call ſpirit of *Wine* has no ſuch power; and if we may judge from Rolfink, the emperor Rudolphus employed the *Vinum Eſſatum*, or concentrated *Wine* of Paracelſus, for that purpoſe. *Vigain*, in his *Medulla Chemiæ*, has ſaid a great deal of the virtues of the ſpirit of *Wine*, ſome of which deſerve to be carefully enquired into; the others are evidently idle and imaginary. What Paracelſus delivers on the ſame ſubject, deſerves alſo to be conſidered. *Vigain* Medul. Chem. *Paracelſ.* de Archidoxis.

Stahl, who has written a great deal on the concentration of *Wine* by freezing, concludes his eſſay, by telling us, that he who has this ſecret, by means of a little dry powdry body of turning water into wine, will not perhaps eaſily divulge the capital uſe he may make of ſuch a ſecret.

Dr. Shaw obſerves, that the author of this treatiſe intimates ſomewhat conciſely, but candidly and philoſophically enough, the poſſibility of doing wonders with a thing that is not difficult to be had with us: the myſtery lies in the words, little, dry, and powdery; and Dr. Shaw, tho' he does not perfectly explain himſelf upon the ſubject, ſays, that the body is common, and that England abounds with it; that it is totally and tranſparently ſoluble in water, fermentable, perfectly white, and ſweet as ſugar; the other goes not ſo far as this, nor is it certain that this is his meaning; but if not, it is at leaſt a very remarkable fact, and comes atteſted by a very good hand. Whatever may be the uſes of concentrated *Wine* in chemiſtry, it is plain, that it may be of the greateſt ſervice in the common affairs of life, as it may be eaſy to have it prepared in ſufficient qantities in the *Wine* countries, and imported hither, where a very ſmall portion of it will render the loweſt and worſt of our *Wines* very rich. *Shaw*'s Chem. Eſſay.

VINUM *extemporaneum*, a name given by Dr. Shaw and others, to a ſort of extemporaneous vinous liquor, made without fermentation, from the melaſſes ſpirit, lemons, water, and ſugar, in the following manner: Some good ſound lemons are to be cut into ſlices, rind and all, and put into a quantity of pure and fine melaſſes ſpirit; when they have ſtood in infuſion three or four days, the liquor is to be ſtrained clear off, and filter'd; and having before prepared a very thin ſyrup of the fineſt ſugar diſſolved in ſpring-water; the two liquors are to be mixed together. The proportions of this mixture can only be hit by repeated trials, but when once found, it will be eaſy to continue them; and a vinous liquor will thus be prepared not inferior to many foreign wines.

VINI *Oleum*, *oil of wine*, a very precious liquid, kept as a ſecret in the hands of ſome dealers in ſpirits, and uſed to give the brandy flavour to ſpirits of leſs price. It is certain, that all the ſpirits we uſe take their flavour from the eſſential oil of the ſubſtance they are made from, that of malt is very nauſeous and offenſive, and renders the ſpirit horribly diſagreeable, if not carefully kept back in the diſtillation of it; that of the grape, on the other hand, is extremely agreeable, and is what gives the delicious flavour to French brandy: this therefore is to be carefully brought over among the ſpirit in diſtillation.

This is that *oil of Wine* ſo much celebrated among our diſtillers, and is for their uſe made ſeparate, and is of ſuch effect, that half an ounce of it will determine a pure and clear malt ſpirit to be French brandy, ſo as to ſtand the teſt of the niceſt palate; and all the trials that can be invented, provided the oil and the ſpirit have both been carefully made.

The manner of making the oil is this: They take ſome cakes of dry wine lees, ſuch as are uſed by our hatters, and diſſolving them in ſix or eight times their weight of water, they diſtil the liquor with a ſlow fire, and ſeparate the oil by the ſeparating pot, reſerving for this nice uſe only that which comes over firſt, the oil that follows being coarſer, and more reſinous. To render this buſineſs perfectly ſucceſsful, there muſt be ſeveral things obſerved: 1. The lee muſt be of the right kind, that is, of the ſame nature with the French brandy propoſed to be imitated. 2. The malt ſpirit muſt be extremely pure. 3. The doſe of the oil muſt be very well proportioned: and, 4. The whole muſt be artificially united into one ſimple and homogene liquor. Theſe cautions all regard only the taſte, and beſide theſe, in order to come up to a nice counterfeit, ſeveral other particulars muſt be attended to; ſuch as the colour, proof, tenacity, ſoftneſs, and the like; ſo that, in ſhort, the operation has too much nicety in it to be hit of by every ordinary dealer. When this fine *Oil of wine* is procured, it may be mixed into a quinteſſence, with pure diſtilled alcohol, or the totally inflammable ſpirit of wine, to prevent its growing diſtaſteful, rancid, or reſinous; and thus it may be long preſerved in full poſſeſſion of its flavour and virtues.

The ſtill bottoms, or remaining matter after the diſtillation of this oil, will yield many productions to advantage, particularly tartar, and ſalt of tartar, as alſo an empyreumatic oil, and a volatile ſalt, like that of animals. Some kinds of lees afford all theſe in much greater quantity than others; the lees of canary and mountain wines yield very little of them, and indeed, ſcare any tartar, or fixed ſalt at all; but the white French lees of thoſe thin wines, that afford the ordinary brandies, yield them all very copiouſly, inſomuch, that ſometimes a ſingle hogſhead of dry and cloſe-preſſed lees will afford by this proceſs, three gallons of brandy, forty pounds of clean tartar, a large proportion of empyreumatic oil, and volatile ſalt, beſide full four pounds of good ſalt of tartar. It is not to be expected, however, that every parcel of this lee ſhould yield fully in this proportion. *Shaw*'s Eſſay on Diſtillery.

Chium VINUM. See the article CHIUM *Vinum*.

VIOLA, the *Violet*, in botany, the name of a genus of plants; the characters of which are theſe: The flower is of the polypetalous, anomalous kind, much reſembling the papilionaceous ones. The piſtil ariſes from the cup, and finally becomes a ſeed veſſel, uſually of a trigonal form, which opens in three places when ripe, and contains roundiſh ſeeds.

The ſpecies of *Violet*, enumerated by Mr. *Tournefort*, are theſe: 1, The common purple ſweet-ſcented *Violet*. 2. The ſweet-ſcented garden purple *Violet*, with large leaves. 3. The common wild ſcentleſs *Violet*, with larger and rounder leaves. 4. The common wild ſcentleſs *Violet*, with longer, narrower, and more pointed leaves. 5. The common white *Violet*. 6. The blue flowered *Violet*, with ſmaller flowers, and ſmaller leaves. 7. The double purple *Violet*. 8. The double red *Violet*. 9. The double white *Violet*. 10. The double variegated red and white *Violet*. 11. The greyiſh flowered double *Violet*. 12. The double *Violet*, with very large flowers. 13. The double *Violet*, with very deep purple ſmall flowers. 14. The round-leaved marſh *Violet*. 15. The mountain *Violet*, with leaves divided into many ſegments. 16. The purple alpine *Violet*, with very ſmall leaves. 17. The round-leaved yellow flowered alpine violet. 18. The leſſer round-leaved yellow flowered alpine *Violet*. 19. The dwarf narrow-leaved mountain *Violet*, with ſnow-white ſcentleſs flowers. 20. The purple-tree *Violet*. 21. The tree *Violet*, with blue and white flowers. 22. The yellow-flowered tree *Violet*. 23. The ſweet-ſcented three-coloured mountain *Violet*, or heart's-eaſe. 24. The great flowered yellow mountain *Violet*. 25. The great flowered white mountain *Violet*. 26. The yellow mountain *Violet*, with roundiſh crenated leaves. 27. The blue three coloured mountain *Violet*, with roundiſh crenated leaves. 28. The great flowered blue mountain *Violet*. 29. The yellow mountain *Violet*, with leaves not crenated. 30. The mountain three coloured *Violet*, or panſie, with variegated flowers. 31. The common creeping garden panſie. 32. The creeping garden panſie, with yellow and white flowers. 33. The creeping garden panſie, with white and blue flowers. 34. The

The creeping garden panſie, with purple and yellow flowers. 35. The creeping garden panſie, with plain white flowers. 36. The creeping garden panſie, with *violaceous* velvety flowers, of a deep purple and gold yellow. 37. The creeping garden panſie, with a large blackiſh purple flower. 38. The creeping garden panſie, with a pale velvety flower. 39. The creeping garden panſie, with a gold, yellow, and ſtraw-coloured velvety flower. 40. The two coloured, or white and yellow field *Violet*. 41. The two coloured field *Violet*, with blue and yellow flowers. 42. The two coloured field *Violet*, with blue and white flowers. 43. The field *Vielet*, with wholly yellow flowers. 44. The field *Violet*, with wholly white flowers. 45. The long leaved ſhrubby Spaniſh *Violet*. 46. The American *Violet*, with paſſion-flower leaves. 47. The Teucrium leav'd Pyrenean *Violet*, with a long tail to the flower. 48. The rock *Violet*, with a thick, crenated, leaf, like that of baſil, and a large ſcentleſs flower, of a blue colour with white ſtreaks. 49. The purple ſcentleſs *Violet* without a ſtalk, and with leaves like the panſie, but ſcarce at all ſerrated. 50. The ſmall hairy-branched erect two coloured *Violet*. 51. The ſmalleſt alpine *Violet*, with leaves like *nummularia*. 52. The great hairy cucumber leav'd Virginian *Violet*, with blue flowers. 53. The great hairy cucumber leaved Virginian *Violet*, with yellow flowers. *Tourn.* Inſt. p. 420.

Violet flowers, freſh gathered, are emollient, and gently purgative. They are greatly recommended by authors in fevers, head-achs, pleuriſies, and peripneumonies. A ſyrup of them made in a ſtrong infuſion in water, is the only preparation kept in the ſhops: it is given to children as a gentle evacuant, and ſerves as a teſt to diſtinguiſh acids from alkali's, the former turning it immediately red, and the latter green.

VIOLA, in ichthyography, a name by which ſome authors have called the ſmelt, from its ſweet ſmell, which has been ſuppoſed to reſemble that of the *Violets*. *Willughby*'s Hiſt. Piſc. p. 202. See the article EPERLANUS.

VIOLA *ſerotina*, the *late Violet*, a name given by the antiens to a garden-flower, not properly of the *Violet* kind, but to which we, as well as they, have connected the name *Violet*, though with a diſtinctive epithet, we call it *Viola matronalis*, or dames *Violet*.

Pliny is very expreſs in this diſtinction, but is not ſufficiently attended to in it; and by this means is miſunderſtood in ſome other parts of his works, where he alludes to this flower in his deſcription of the colour called by the Romans *conchylius*, or *conchyliaceus color*; he ſays, that the deepeſt degree of it was that of the flower of the *Viola ſerotina*. The commentators on his works have generally explained this into his ſaying, That the deepeſt colour of this name was a blue purple, like that of the *Violet*; but he only means that it is of a deeper red than the colour of the mallow flower, and with a proportionate mixture of purple, as there is in that flower. See the article CONCHYLIACEUS *color*.

VIOLARIS *Lapis*, in natural hiſtory, a foſſile body, called by the Germans *Violſtein*, and by many authors, *Lapis odore Violarum*, from its having a ſweet ſmell when freſh broken, which has been ſuppoſed to reſemble that of the *Violet*.

The Germans have many ſtones, which have more or leſs of a ſweet ſmell when freſh broken, as they have many which ſtink very ſtrangely; the latter of theſe they call all by the common name of *ſwine-ſtone*, and the former, all by that of *Violet ſtone*. The ſubſtance, however, which poſſeſſes this quality in the higheſt degree of all others, and is therefore moſt proper to be called diſtinctly by this name, is a ſpecies of talc, of the genus of the bractearia, called by Dr. Hill *bractearium niveum lucidiſſimum bracteis undulatis*, or the ſnow-white ſhining bractearium, with undulated ſcales. This is found in maſſes of an extremely rude and irregular ſtructure, but very compact and firm, uſually of a roundiſh, or oblong figure: theſe are of various ſizes, from an inch or two, to a foot in diameter, and are compoſed of almoſt an infinite number of thin extremely beautiful and ſnow-white plates, which are all broad, thin, and flaky, and of various ſizes, and perfectly irregular in ſhape and figure, and are naturally waved, bent, and curled: its ſmell, when broken, is not like that of any of the known perfumes, but is a ſort of mixed one, reſembling that of roſes and *Violets* together: it is very heavy, and will neither give fire with ſteel, nor ferment with acid menſtruums. It is common on the ſhores of rivers in Italy, and in the mountains in Germany. *Hill*'s Hiſt. of Foſſ. p. 83.

VIOLET, *Viola*, in botany. See the article VIOLA.

VIOLONCELLO. See the article VIOLIN, *Cycl.*

VIOLONE. See the article VIOLIN, *Cycl.*

VIPER, *Vipera*, (*Cycl.*) a poiſonous ſpecies of ſerpent, well known in moſt parts of the world.

Its ſize is uſually two foot and a half in length; its upper part is of a duſky colour, with an admixture of a reddiſh tawney; and in the females with a great deal of whitiſhneſs. Along the middle of the back there runs a broad dentated black line, or a long ſeries of conjunct rhomboidal ſpots, reaching from the head to the tail. A little below this, there is on each ſide a ſeries of ſmall black ſpots; and in the lower part of each ſide there runs a continued line, made by a ſeries of white ſpots, which are very ſmall; then another of larger black ones, and next to this another of ſmall white ones; again, the belly is covered with long black ſcales placed tranſverſely.

This ſeems the general diſpoſition of the colours of the *Viper*, but it is by no means fixed and unalterable; for there are *Vipers* whoſe back is wholly black. The belly however ſeems to be black in all, and the tail does not run to more than a fifth part of the length of the body beyond the anus, and is terminated in a very ſharp point. Wormius ſays, the *Viper* feeds on herbs; but this aſſuredly is not its only diet, ſince there are frequently found in its ſtomach, mice, beetles, ſmall birds, and the like; many of which are often found whole: And it is ſurpriſing to conceive how they were ſwallowed, ſince they are often three times as thick as the whole neck of the ſerpent.

The canine teeth of the *Viper* are only two, and thoſe hollow from the apex to the root; and theſe are not poiſonous in themſelves, but ſerve to make the wound by means of which the poiſon they contain is mingled with the blood. This poiſon ſeems to be a matter ſecreted like ſaliva, by peculiar glands placed in the bags at the roots of theſe dog-teeth. *Ray*'s Syn. Quad. & Serp. p. 285.

By Mr. Boyle's experiments made upon *Vipers in vacuo*, it appeared, that on the withdrawing the air from the veſſel where the *Viper* was put, ſhe began to ſwell, and after ſome time ſhe opened her mouth very wide, and frequently; but on continuing two hours and a half in the receiver, ſhe did not appear to be quite dead. The gaping of the jaws was attended with a loſs of the ſwelling, obſerved at firſt in her whole body; but after every time cloſing them ſhe ſwelled again, and thus became lank and plump reciprocally many times in an hour. During the firſt moments this creature crawled about, as if in ſearch of air, and afterwards foamed at the mouth.

The neck and body continued ſwelled longer, in a ſecond experiment with another *Viper*, and a bliſter appeared on the back. This creature lived an hour and a half. The mouth remained vaſtly diſtended after death, and the internal parts of it were much diſtorted, and thruſt forwards. After the admitting the air the mouth cloſed, and opened again after a time; and in fine, on pinching the tail there was ſome motion perceived in the body, that ſeemed to argue life. The common ſnake bears the exhauſted receiver better than the *Viper*, and after many hours remaining in it, and ſeeming dead, will give ſigns of life on being warmed by bringing the glaſs to the fire; but a longer continuance in the rarified air abſolutely kills it, as it does all other creatures. Phil. Tranſ. N°. 62.

The ſtory of the rattleſnake's charming its prey has been laughed at by many, and by others the effects of the animal's fear have been ſuppoſed the reſult of a previous bite; but we have a great deal of reaſon to believe, that this ſort of faſcination is juſt what it is related to be, from an experiment mentioned in the Philoſophical Tranſactions, of a like thing in regard to a *Viper*. It is well known, that no *Viper* will feed while in confinement, except a female which is with young, but that ſuch a one will. A *Viper*-catcher, who had more than ſixty living *Vipers* in a cheſt, put a living mouſe in among them; there happened to be one female big with young among theſe, none of the others at all regarded the mouſe, but ſhe raiſed up her head a little, and looked furiouſly at it. The mouſe was terrified, and ſtood ſtill for a conſiderable time, though the *Viper* continued rolled up in a ſpiral, only raiſing up its head and looking at it, and vibrating its tongue; the mouſe at length recovered of its fright, and began to move, but without running away, only walking in a terrified manner round and round the *Viper*, and often ſqueaking; at length ſhe came before the head of the creature, which was ſtill raiſed, and the mouth open. The mouſe, after ſome time, went up to the creature, and crept into its mouth, where ſhe was gradually ſwallowed without the *Viper*'s altering its poſture.

The poiſon of *Vipers* is neither in their teeth, their tail, nor their gall, but in two veſicles or bladders which cover their teeth, and which upon compreſſion when the *Vipers* bite, emit a certain yellowiſh liquor, that runs along the teeth and infects the wound.

The poiſon of the *Viper* is only noxious when immediately conveyed into the blood. Nor is it mortal to eat the fleſh of creatures killed by *Vipers*, or to drink the wine in which they have been drowned, or to ſuck the parts they have wounded. On the contrary, Signior Redi ſays, ſucking the wound is a ſovereign remedy againſt the bite of *Vipers*. This author denies, what had been affirmed by Ariſtotle and Galen, that the ſpittle of a faſting perſon kills *Vipers*. Phil. Tranſ. N°. 9. p. 160.

Vipers are viviparous. Phil. Tranſ. N°. 84. p. 138.

The bite of the *Viper* having been ſuppoſed certainly curable by oil of olives alone, and a *Viper*-catcher in England having ſuffered himſelf to be bitten by one of theſe creatures, and having recovered after many dangerous ſymptoms; and the cure being attributed to the oil alone, though other medicines were given him internally; Meſſieurs Geoffroy and Hunauld of the Royal Academy of Sciences at Paris, made a number

of experiments, by which it appeared that this oil was not the great remedy that was pretended. (See the article OIL *of Olives*.) And added to their accounts, ſome others of perſons bitten, in which all the dreadful conſequences of that poiſon are ſhewn, and the remedies by which they were cured are mentioned. Philoſ. Tranſ. N°. 443, 444, 445.

Their firſt inſtance is in the caſe of Mr. Piron, who was bitten at the end of the fore-finger by an enraged *Viper*; there immediately iſſued a drop of blood from the wound, and the firſt application made to it was the covering up the whole finger with a quantity of Venice-treacle; the finger, however, ſwelled violently, and was ſcarified in ſeveral places, and the patient was made to eat the body of the *Viper* boiled, and drank after it a glaſs of wine with ſome Venice-treacle, and with a few drops of the volatile ſpirit of *Vipers*; and the finger was wrapped round with compreſſes and bandages, wetted in aqua vitæ. Soon after this the patient began to have inclinations to vomit, he vomited very plentifully, the ſwelling increaſed, and his arm, which was now very much diſtended, was ſcarified in twenty places, and compreſſes of linnen dipped in aqua vitæ laid on the wounds; he afterwards took volatile ſalt of *Vipers* in repeated doſes, had more ſcarifications made on his arm, and he drank in the ſpace of an afternoon and evening a quart of ſtrong wine. He ſlept very ſound after this, and the ſymptoms all diſappeared, he was almoſt recovered by ſix o'clock the next morning, only the ſcarifications took two months to heal, and after that time he enjoyed a perfect ſtate of health.

A ſecond inſtance, is that of a young lad of a robuſt conſtitution bitten by a *Viper*, enraged and kept for ſome time in a very hot place near the fire; he felt a pain like that of oil of vitriol dropped on a wound, but without delay he cut off the head of the *Viper*, bruiſed it, and applied it to the wound, and tied the finger on which he was bitten very tight round with a binder: He after this had ſome ſcarifications made, and rubbed into them a quantity of the fat of the *Viper*; he killed four *Vipers*, and uſed all their fat, and took three drams of Venice-treacle in ſome wine. His whole arm ſwelled, he perceived a violent heat over his whole body, and the other hand was ſo ſwelled at length that he could ſcarce ſhut it: On this he took a large doſe of Venice-treacle, camphor, volatile ſalt of *Vipers*, of amber and of ſal-armoniac, and a dram of volatile ſpirit of ſal-armoniac, and ſal volatile oleoſum; this he repeated at ſome diſtance of time, he was blooded in the oppoſite arm, the patient vomited violently, and an inciſion being made all along the finger, there followed no blood. The hand, arm, and breaſt were embrocated with a mixture of ſpirit of lavender, camphor, Venice-treacle, and the fat of *Vipers*. After having vomited plentifully, and been embrocated with this warm mixture, he found himſelf much eaſier, at eight o'clock at night he took another doſe of his volatile medicines, and ſlept till four in the morning, he then took a large glaſs of wine and ſlept till ſix, and at ſeven eat a part of a chicken with a good appetite. The ſurgeons would have made more ſcarifications on the arm, but he would not ſuffer it; and three days afterwards an eriſipelas appeared, to which he applied a mixture of aqua vitæ and ointment of marſhmallows, and finally was perfectly recovered.

Theſe are two inſtances in which the ſymptoms of the bite appeared in much the ſame manner with thoſe of the man who ſuffered himſelf to be bitten in England, in order to be cured by the oil. The ſleep came on in all in the ſame circumſtances, and they were all cured, as well he who uſed no unctuous application at all, as he who uſed the fat of the *Vipers*, or the Engliſhman who depended upon the oil. The internal medicines given to them all were of much the ſame kind; and all that can be concluded from the whole, is, that either theſe bites would not have proved mortal in themſelves, or that the cordial medicines, which they took internally were the remedies that prevented the miſchief that would have enſued; and theſe ſeem to have acted not as ſpecifics againſt the bite of this animal, but merely as medicines that would ſtop the ſpreading of a gangrene; the unprevented increaſe of which is the thing that proves fatal from this creature's bite.

The diſſections of the animals which had died by the bite of the *Viper*, whether they had or had not been rubbed with oil, afforded all the ſame appearances. The limb which had received the wound was in all ſwelled and livid, and theſe ſymptoms uſually were carried along the thigh to the belly, and ſometimes up to the breaſt. Inciſions made along theſe parts always diſcovered the cellules of the membrana adipoſa full of a bloody-coloured water, and the membrane itſelf was ſwelled, blackiſh, and gangrened. And this appeared always more plainly in the belly, than in any other part; the membrana adipoſa in all other parts of the body was in its natural ſtate. The injured parts often had a cadaverous ſmell; the muſcles of the wounded limb were alſo found of a browniſh colour, and their fibres had loſt their conſiſtence, and ſeemed ready to give way to the approaching gangrene. Nor is this effect confined to the external parts alone; a gooſe that had been bitten had three gangrenous ſpots on its heart, and all the indications of a beginning gangrene in other parts of it; the concave ſide of the liver was alſo gangrened, and had wholy loſt its conſiſtence; and the lungs of a fowl that had been bitten on the wing, were found in part gangrened. The effects however were different in degree, from the bites of the ſeveral *Vipers*; and there ſeems no reaſon to doubt, but that the bites of different animals, though of the ſame ſpecies, under different circumſtances, either in regard to the creature wounding, or the creature wounded, may be followed with very different conſequences; ſo that remedies are not to be depended on from their ſucceſs in one or two trials. Mem. Acad. Scienc. Par. 1737.

VIPERA, *Viper*, in zoology. See the article VIPER.

VIPERA *Pileata*, or *Vittata*, in zoology, a name by which ſome authors have called a remarkable ſpecies of Indian ſerpent, more uſually known by the name of *Cobra de Capella*. See the article COBRA *de Capella*.

VIPERARIA, in botany, a name given by ſome authors to the *Scorzonera*, or vipers-graſs. *Dale*'s Pharm. p. 83.

VIRGA (*Cycl.*)—VIRGA *Aurea*, *golden Rod*, in botany, the name of a genus of plants; the characters of which are theſe. The flower is of the radiated kind; its diſk is compoſed of floſcules, and its outer circle of ſemi-floſcules. Theſe all are placed upon the embryo fruits, and are contained in a common ſcaly cup: Theſe embryos finally ripen into ſeeds, winged with down. To this it is alſo to be added, that the flowers uſually ſtand in long ſeries towards the tops of the ſtalks.

The ſpecies of *Golden-rod*, enumerated by Mr. Tournefort, are theſe: 1. The broad-leaved *Golden-rod*, with ſerrated leaves, called the ſaracens conſoud. 2. The broad-leaved *Golden-rod*, with ſerrated leaves, variegated with white. 3. The common broad-leaved *Golden-rod*. 4. The white-flowered *Golden-rod*, with narrower and leſs ſerrated leaves. 5. The mountain *Golden-rod*, with broad ſmooth leaves. 6. The mountain *Golden-rod*, with broad hairy leaves. 7. The alpine *Golden-rod*, with rigid bay-like leaves. 8. The alpine *Golden-rod*, with long ſoft and ſharp-pointed leaves. 9. The narrow-leaved Canada *Golden-rod*, with a ſpecious panicle. 10. The narrow-leaved hairy Canada *Golden-rod*, with a leſs ſpecious panicle. 11. The ſea lavender-leaved *Golden-rod*, with the flowers all placed on one ſide the ſtalks. 12. The large flowered dwarf *Golden-rod*. 13. The annual white-flowered toad-flax-leaved acrid *Golden-rod*, called acrid annual ſleabane. 14. The great *Golden-rod*, with viſcous and ſtrong-ſcented leaves. 15. The great *Golden-rod*, with viſcous and ſtrong-ſcented leaves, and with excreſcences like galls. 16. The leſſer *Golden-rod*, with viſcid and ſtrong-ſcented leaves. 17. The ſhrubby Portugal *Golden-rod*, with long, narrow, and viſcous leaves. 18. The pale purple-flowered *Golden-rod*, with broad auriculated leaves. 19. The purple-flowered *Golden-rod*, with broad and not auriculated leaves. 20. The broad-leaved *Virga-aurea*, with deep violet-coloured flowers. 21. The broad and undulated leaved *Golden-rod*, with pale purple flowers. 22. The Tripolium-flowered *Golden-rod*. 23. The Canada *Golden-rod*, with ſmooth, roundiſh, and ſerrated leaves. 24. The Canada *Golden-rod*, with extremely broad ſmooth leaves. 25. The tall Canada *Golden-rod*, with leaves hoary underneath. 26. The New-England *Golden-rod*, with broad rigid leaves. 27. The dwarf Canada *Golden-rod*, with toad-flax leaves. 28. The dwarf Canada *Golden-rod*, with the leaves of the ſmaller willows. 29. The great flowered American *Golden-rod*, with aſphodel roots. *Tourn.* Inſt. p. 483.

The common *Golden-rod* is an aſtringent, and its root is given in powder with great ſucceſs in diarrhœas, dyſenteries, and in hæmorrhages of all kinds; particularly in ſpittings of blood.

VIRGA *Paſtoris*, in botany, a name given by ſome authors to Dipſacus. Vid. *Lemery* & *Miller* in voc *Dipſacus*; alſo *Tourneſ.* Inſt. Bot. p. 466.

Where the name *Virga paſtoris* occurs in the tranſlation of the Arabian writers, it is not to be ſuppoſed to mean the plant we call *Virga paſtoris*.

It is indeed the literal tranſlation of the haſſalelrheir of Serapion and Aviſenna; but they called the common horſetail by this name, when they applied the adjective female to it; and when they added male, they meant by it the common knot-graſs.

Both theſe plants poſſeſſed the common virtues of aſtringents and agglutinants, and were for that reaſon placed together by the old Greek writers, and were both called *Polygonum* by them, having both an equal title to that name, as it expreſſes no other than a plant that has many joints; and they diſtinguiſhed the knot-graſs by the name of the male *Polygonum*, and the horſe-tail by the name of the female; as the Arabians did by the names male and female *Virga paſtoris*.

VIRGA *Sanguinea*, in botany, a name given by Mathiolus, and ſome other authors, to the cornus fæmina, or dogberry-buſh, common in our hedges. *Ger.* Emac. Ind. 2.

VIRGÆ *Lateralis Minimus*, in anatomy, a name given by ſome writers to a muſcle, called by others *levator ani parvus*, and by ſome *tranſverſus ani*. It is called by Albinus the *tranſverſus perinæi*, and by ſome *tranſverſalis penis*.

VIRGATA *Sutura*, a term uſed by ſome anatomiſts for the ſagittal ſuture of the cranium.

VIRGILIAN *Huſbandry*. See the article HUSBANDRY.

VIRGINALE *Clauſtrum*, a term uſed by ſome writers to expreſs the hymen.

VIRGINS-*Bower*, *Clematitis*, in botany, the name of a genus of plants; the characters of which are theſe: The flower is of the roſaceous kind, and uſually conſiſts of four leaves arranged in a circular form, and without a cup. The piſtil ariſes from the center of the flower, and finally becomes a fruit compoſed of ſeveral ſeeds arranged into a ſort of head, and each ending in a long plume.

The ſpecies of *Clematitis*, enumerated by Mr. Tournefort, are theſe: 1. The common broad-leaved wild *Clematitis*, with leaves indented. 2. The broad-leaved wild *Clematitis*, with leaves not indented at the edges. 3. The pear-tree-leaved indented *Clematitis*. 4. The creeping *Clematitis*, called by many authors flammula. 5. The creeping ſea *Clematitis*. 6. The white flowered upright *Clematitis*. 7. The early red-ſtalked upright *Clematitis*. 8. The geranium-leaved alpine *Clematitis*. 9. The blue-flowered upright *Clematitis*. 10. The white-flowered upright *Clematitis*. 11. The blue-flowered procumbent *Clematitis*. 12. The purple procumbent *Clematitis*. 13. The double blue flowered *Clematitis*. 14. The double purpliſh-blue *Clematitis*. 15. The double pale-red *Clematitis*. 16. The upright dwarf Spaniſh *Clematitis*, with white flowers. 17. The narrow-leaved Portugal *Clematitis*, with ſmall blue flowers.

Authors have added to this genus, the *Clematitis* trifolia flore roſeo, which is properly a granadilla; and the *Clematitis* Daphnoides, which is a pervinca. *Tourn.* Inſt. p. 293.

The ſeveral ſpecies of this plant make a very fine ornament in the quarters of gardens allotted to flowering ſhrubs. They are all propagated, by laying down their branches in ſpring, as is practiſed in vines and other ſuch ſhrubs; and in a year's time they will have taken ſufficient root, and may be taken up and removed to the places where they are to remain. This ſhould be done in ſpring, and a little mulch muſt be laid about their roots, and they muſt be watered in dry weather. In two years after planting they will make very ſtrong ſhoots, which are to be trained up to ſtakes, that they may not trail upon the ground. After this, they require no farther care, than to cut out their dead branches every year, and in the ſpring to ſhorten ſuch branches as are too long and rambling.

They may alſo be raiſed from ſeeds, ſown either as ſoon as ripe, or in the ſpring; but this is a more tedious way, as they lie ſix or twelve months in the ground before they appear, and after that require two years care in a nurſery-bed before they are fit to be planted out where they are to ſtand.

VIRIDELLUS, a word uſed by ſome medical writers, to expreſs the epilepſy; and by ſome of the chemical ones, as a name for the common green vitriol.

VIRILIS *Teſtis Muſculus*, in anatomy, a name given by Veſalius, and others, to the muſcle generally known by the name of the *Cremaſter*.

VIRITES, a name by which the writers of the middle ages have called the Pyrites.

VISCAGO, in botany, the name of a genus of plants, deſcribed by Dillenius, and ſince called by Linnæus *Silene*. *Dillen.* Hort. Elth. p. 309. See the article SILENE.

VISCAGO is alſo uſed by ſome pharmaceutic writers, to expreſs a mucilage.

VISCERA (*Cycl.*)—*Wounds of the* VISCERA. If any of the *Viſcera* ſituated in the abdomen, as the liver, ſpleen, or kidney, has received a wound from a ſharp inſtrument, at the firſt dreſſing the wound muſt be filled as tenderly as poſſible with lint well ſaturated with highly rectified ſpirit of wine, or ſpirit of turpentine, ſecuring the dreſſings with compreſſes and a bandage; by this means the hæmorrhage will be ſtopped, if no large veſſel is divided. When this part is gained, the wound muſt be treated in the common manner, and the patient kept very low; bleeding him, if of a plethoric habit, and giving daily two or three doſes of Lucatellus's balſam; for balſams of this kind are of great ſervice in healing internal wounds. This is the method to be taken with wounds of the *Viſcera*, which may be diſcovered by the eye or touch. But in ſuch of them as are hidden, and not to be thus diſcovered, all that can be done is to inject vulnerary decoctions, and keep a paſſage open for the evacuation of ſordes, or grumous blood. *Heiſter's* Surg. p. 68.

VISCERALIA, a term uſed by phyſicians, to denote ſuch medicines as impart ſtrength and firmneſs to the ſanguineous *Viſcera*, ſuch as the liver, ſpleen, *&c.*

VISCERATIONES, among the Romans, a feaſt conſiſting of the intrails of animals, given to the people at the burial of great men in Rome. *Danet.* in voc.

VISCUM, *Miſletoe*, in botany, the name of a genus of plants; the characters of which are theſe: The flower conſiſts of one leaf, hollowed into the ſhape of a baſon, and uſually divided into four ſegments at the edge, and ſprinkled over with apices in the form of little protuberances. The embryo fruits do not ſucceed there, but appear on other plants of the ſame ſpecies, and are ſurrounded with four little leaves; theſe finally become round berries full of a glutinous juice, and containing flatted and heart-faſhioned ſeeds.

The ſpecies of *Miſletoe*, enumerated by Mr. Tournefort, are theſe: 1. The common, or white-berry'd *Miſletoe*; and 2. The *Miſletoe* with red berries. *Tourn.* Inſt. p. 609. See the article MISLETOE.

VISCUM is alſo uſed for *Birdlime*. This was eſteemed a poiſon among the antient Greeks, and is ſeldom omitted under the claſs of deleterious things enumerated in their writings.

It is called by theſe authors *Ixias*; but this word has occaſioned great errors in late writers, the word *Ixias* having been applied for the white camelion thiſtle, not becauſe of any poiſonous quality it had; for they all declare it to be innocent, but becauſe of its yielding a viſcous, or clammy juice. The black chamæleon thiſtle was always eſteemed poiſonous among them; and hence ſome have ſuppoſed the word *Ixias* to be applied to that, and the poiſon *Ixias*, mentioned by the Greeks, to be the root of that plant. Paulus Ægineta indeed ſeems to have underſtood it ſo, the poiſon *Ixias* being by him placed among the roots; but Galen, who calls it a ſlow poiſon, and ſays, that it kills by ſtopping up and glewing together the inteſtines, plainly enough means *Birdlime*, not the root of any plant.

VISCUM *Caryophylloides*, a name given by Sir Hans Sloane, and many other authors, to a genus of plants of a very peculiar kind. They are called *Viſcum* from their growing upon other trees, in the manner that the miſletoe does with us; and *Caryophylloides*, from their leaves, in ſome degree reſembling thoſe of our pinks or carnations; but the plant itſelf, in all its ſpecies, is wholly different, both from the miſletoe and pink, in all other reſpects.

The ſeveral ſpecies of theſe plants differ greatly alſo from one another; the moſt fragrant ſpecies in Jamaica is a very large one called by the common people, the wild pine. The root of this plant is compoſed of a great number of brown filaments, which encompaſs the whole branch of the tree on which it grows; theſe are very different from the roots of our miſletoe, for they enter into the ſolid ſubſtance of the tree, but the roots of the miſletoe are expanded over its ſurface, and are often confuſedly interwoven one with another. The roots of *Viſcum* give a very firm baſis for the plant, and from theſe there ariſe the rudiments of the leaves, which at length grow to the likeneſs of thoſe of leeks, or of the leaves of ſome of the aloes, being folded one within another; they in ſome ſort alſo reſemble thoſe of the pine-apple, or ananas, and it is on this account that the plant is called the wild pine. Theſe leaves are between two and three foot long, and are three inches broad at the baſe, from whence they run tapering all the way, till they terminate in a point; they are very round or convex on the outſide, and very hollow within; by means of this ſhape of the leaves is formed a very fine reſervatory of water in every plant of this kind.

All the leaves being thus hollow within, and ſtanding in a circle at the bottom, form a round hollow maſs, which ſwells out into a ſort of bulb, looking like a turnep, except in colour, and very large; they afterwards draw nearer to the ſtalk, and form by that a ſort of neck to this bottle cavity, which is cloſe and firm on all ſides: in the rains, the trees on which theſe plants grow, drop off vaſt quantities of water from their leaves, and this is in great plenty catched by one or other of the long leaves of this plant; each of which is a ſort of hollow pipe, conveying all that it receives into the bottle, or reſervoir at the bottom; this ſoon runs over, but in conſequence of this, it is at laſt left full, and this water it retains a long time, by means of the narrow neck they form above, which prevents the evaporation that would otherwiſe naturally happen by the ſun's heat: this water gives a continual ſupply of juices to the leaves, which are of a pale green in the bottle part, and as green as a leek above.

In the midſt of theſe leaves riſes a ſmooth branched and ſucculent ſtalk of about three foot long; this, when wounded, yields a white mucilaginous juice; the flowers are numerous, and conſiſt each of three leaves, ſtanding in a three-leaved green cup; after theſe come three corner'd capſules; at the baſe of this are three ſmall and ſhort leaves, and within it are contained ſeveral ſeeds, of an oblong, pyramidal form, ſmall in themſelves, but winged with a very long and fine down. The plant is very common in woods and foreſts, and grows uſually to the branches, but ſometimes to the trunks of the trees, eſpecially when they are ſomewhat decayed, their bark then more eaſily receiving the ſeed, and giving a free paſſage to the roots. Phil. Tranſ. N°. 252. p. 114. See the article SOWING.

VISION (*Cycl.*)—*Diſtinct* VISION, that by which an object is ſeen diſtinctly. An object is ſaid to be ſeen diſtinctly, when its outlines appear clear and well defined, and the ſeveral parts of it, if not too ſmall, are plainly diſtinguiſhable, ſo that we can eaſily compare them one with another, in reſpect to their figure, ſize, and colour. Dr. *Jurin's* Eſſ. on diſt. and indiſt. Viſion.

In order to ſuch *diſtinct Viſion*, it has hitherto been commonly thought, that all the rays of a pencil, flowing from a phyſical point of an object, muſt be exactly united in a phyſical, or at leaſt, in a ſenſible point of the retina. But it ſeems certain,

certain, from the experiment mentioned by Dr. Jurin, that such an exact union of rays is not always neceſſary to *diſtinct Viſion*.

Hence the doctor divides *diſtinct Viſion* into two ſpecies, *viz.* into *Viſion perfectly diſtinct*, or *perfect Viſion*, and *Viſion imperfectly diſtinct*; which he calls ſimply by the name of *diſtinct Viſion*. The former, is that in which the rays of each pencil are collected into a ſingle phyſical, or ſenſible point of the retina; the other ſpecies, is that in which thoſe rays occupy ſome larger ſpace upon the retina, yet ſo far as the object is diſtinctly perceived.

Perfect *Viſion* in a given eye, and a given diſpoſition of that eye, depends only upon the diſtance of the object; it has no dependance upon the magnitude of the object; but diſtinct *Viſion*, in a given eye, and a given diſpoſition of the eye, depends upon the diſtance and magnitude of the object jointly. There appearing therefore a real difference between perfect *Viſion*, and what we call *diſtinct Viſion*, the learned doctor has enquired very particularly into the reaſon why an object may be ſeen diſtinctly without perfect *Viſion*; for which we refer to his eſſay at the end of Dr. *Smith*'s Opticks.

VISITATION (*Cycl.*) — The *Viſitation* of the Virgin Mary is a feaſt inſtituted firſt by pope Urban IV. in the year 1389. and ordained to be kept on the ſecond of July. *Hofm.* Lex. in voc.

VISITATION is likewiſe an order of monks founded by Francis de Sales and his mother Chantalia. Id. ibid.

VISPELLIONES, among the Romans, were ſlaves who could not be manumitted. *Pitiſc.*

VISTAMENTE, in the Italian muſic, is uſed to give notice to play, or ſing, quick, briſkly, &c.

VISTE, in botany, a name given by ſome authors to the common white mountain coralloides: it is the Lapland name for the ſame plant; the rain-deer, and many other creatures feeding on it when all other vegetables are deſtroyed.

VITA (*Cycl.*)— VITA *longa*, a name given by ſome botanical authors to the *piper Æthiopicum*, or Æthiopian pepper. Gen. Herb. p. 1335.

VITALBA, in botany, a name given by ſome authors to the viorna, or traveller's joy, a tall climbing plant with white flowers, common in the hedges. *Ger.* Emac. Ind. 2.

VITALIA, a name given by ſome authors to the cardiac medicines.

VITALIS, in botany, a name given by ſome authors to the common telephium, called in Engliſh *Orpine*, and live-long, from its quality of living and flouriſhing a long time after it is taken from the root. *Ger.* Emac. Ind. 2.

VITEX, the *chaſte Tree*, in botany, the name of a genus of trees; the characters of which are theſe: The flower conſiſts of one leaf, and is, as it were, bilabiated, and tubular behind; the piſtil ariſes from the cup, and is fixed in the manner of a nail to the hinder part of the flower; this finally becomes a roundiſh fruit, divided into four cells, each containing oblong ſeeds.

The ſpecies of *Vitex*, enumerated by Mr. Tournefort, are theſe: 1. The *Vitex*, with broad ſerrated leaves. 2. The *Vitex*, with narrower leaves, diſpoſed in the manner of thoſe of hemp. 3. The narrow hemp-like leaved *Vitex*, with bluiſh flowers. 4. The white flowered *Vitex*: and 5. The *Vitex*, with extremely narrow leaves. *Tournef.* Inſt. p. 603. See the article AGNUS *Caſtus*.

VITIFERA, in zoology, a name by which many have called the common œnanthe, a bird well known in England by the name of the wheat-ear; and called in ſome places the fallow-finch and white-tail. See the article WHEAT-*Ear*.

VITILIGO, a diſeaſe frequent among the Arabians: it is the ſame with what is otherwiſe called *Alphos*. *Hofm.* Lex. in voc. See the article ALPHOS, *Cycl.* & *Suppl.*

VITIS, the *Vine*, the name of a genus of plants; the characters of which are theſe: The flower is of the roſaceous kind, and is compoſed of ſeveral petals, arranged in a circular form; from the middle of the flower there ariſes a piſtil, which is ſurrounded by a number of ſtamina; this finally becomes a round, ſucculent, or juicy berry, containing uſually four pear-faſhioned ſeeds. See the article VINE.

The ſpecies of *Vine* enumerated by Mr. Tournefort, are theſe: 1. The common, or wild *Vine*. 2. The Corinthian, or currant *Vine*. 3. The parſley *Vine*, or *Vine* with deeply laciniated leaves. 4. The early *Vine*. 5. The damaſk *Vine*. 6. The muſkatel, or Apian *Vine*. 7. The Pergulane *Vine*, with fruit of the ſize and ſhape of plums. 8. The African *Vine*. 9. The Allobrogic *Vine*. 10. The large bunched *Vine*, with white ſweet and firm grapes. 11. The large bunched *Vine*, with rediſh, or blackiſh ſweet grapes. 12. The large bunched, with whitiſh oval grapes. 13. The hairy *Vine*. 14. The climbing five-leaved Canada vine. 15. The maple-leaved Canada *Vine*. 16. The abutilon-leaved Canada *Vine*, with purple grapes. 17. The American *Vine*, with ſerrated ivy-like leaves. 18. The round leaved American *Vine*, with blue cluſtered grapes. 19. The great, trifoliate, American *Vine*, with ſmall round grapes in large cluſters. 20. The ſmaller trifoliate American *Vine*, with larger turbinated grapes diſpoſed in cluſters. 21. The ſow-bread leaved American *Vine*, with racemoſe corymbi of black grapes. *Tourn.* Inſt. p. 613. See the article VINE.

VITIS *Idæa*, the *Whortle*, in botany, the name of a genus of plants; the characters of which are theſe: The flower conſiſts of one leaf, and is of the globoſe campaniform kind. The piſtil ariſes from the cup, and is fixed in the manner of a nail to the hinder part of the flower; the cup finally becomes a ſoft umbilicated berry, juicy, and containing ſmall ſeeds.

The ſpecies of *Vitis Idæa*, enumerated by Mr. *Tournefort*, are theſe: 1. The *Whortle*, with oblong crenated leaves, and black fruit. 2. The *Whortle*, with roundiſh, and not crenated leaves, and with red fruit. 3. The long leaved white berry'd *Whortle*. 4. The great round leaved *Whortle*. 5. The ſweet-ſcented *Whortle* of Ceylon. 6. The pyrola-leaved Canada *Whortle*: and 7. The myrtle-leaved Canada *Whortle*. *Tourn.* Inſt. p. 608.

VITISALTUS, a word uſed by ſome medical writers for the *Chorea ſancti Viti*. See the article VITUS's *Dance*.

VITRAGO, in botany, a ſpecies of plants, reſembling that of which the glaſs is made. It is otherwiſe called *Helxine*. *Hofm.* Lex. in voc. See the article HELXINE.

VITREA *Tabula*, a name given by ſome authors to the internal table of the cranium.

VITREUS *Humor*, the *vitreous humour* of the eye. See the article EYE.

VITRIOL (*Cycl.*)—The manner of making the common green *Vitriol*, or copperas, at Brickleſy in Eſſex, is this: They gather the pyrites, or copperas ſtone on the ſhores of Shepey-Iſland, and in other places; and this they lay upon a large bed, or floor prepared in the open air, underneath which there are gutters, or troughs diſperſed to receive and carry away the liquor impregnated with the mineral, to a ciſtern where it is kept till worked.

The air and weather diſſolves, and breaks theſe ſtones; and the rain falling on them, waſhes gradually out all the *Vitriol*; which is thus ſeparated from it: they boil the liquor in large leaden pans, putting in a great quantity of old iron, and when ſufficiently evaporated, they let it out into troughs, where the *Vitriol* ſeparates itſelf, and cryſtalizes, ſticking to the ſides of the troughs, and to ſticks and bars placed acroſs them. The remaining liquor they call the mother of *Vitriol*, and ſave it to be afterwards boiled and evaporated again. *Ray*'s Engliſh Words, p. 139.

There is contained in the original liquor, of which *Vitriol* is made from the pyrites, a white, acrid, and pungent ſalt. This is ſeparated from the mother liquor, or brine, when no more *Vitriol* will ſhoot; and is called by the chemiſts, the ſaline principle of *Vitriol*.

Common green *Vitriol*, when diſſolved in water, and ſeparated from its metalline, and ochreous, or earthy particles, by zink, or any other of the imperfect metals, added in filings to the ſolution, is then much of the nature of this white ſalt, called the ſaline principle: it is white, not green, more unctuous than the common *Vitriol*, and has a grain rather appearing like nitre than like *Vitriol*.

The native white *Vitriol* of Goſſelaer has alſo ſomewhat of this nature in it, having leſs metal, and much leſs mineral ſulphur than the common green, or blue *Vitriols*. The common *Vitriol*, thus ſeparated from its earthy and metalline parts, will yield its ſpirit eaſily, and with the gentle heat of a ſand furnace; as the white ſalt extracted from the mother liquor of *Vitriol* will: whereas, in the common *Vitriol*, the metalline part ſo detains the ſaline, that it cannot be driven off in form of vapour, till that compages is broken, by a very intenſe and violent heat; what remains in the retort after the diſtillation of either this or the other ſalt, is not red like colcothar of *Vitriol*, but is white and ſpungy, and rather reſembles burnt alum, than any other ſubſtance, in its appearance. It is inſipid when firſt taken out of the veſſel; but on being expoſed to the air, it receives ſtrange impreſſions and alterations. Phil. Tranſ. N°. 103. See the article SALINE *Principle*.

There is great reaſon to believe, that *Vitriols* are no other than metals of different kinds, penetrated and reduced into a new form by ſulphur. If thin plates of copper be cemented with beds of brimſtone between, and the operation repeated four or five times with freſh brimſtone every time, moſt of the copper will be converted into *Vitriol*; and this diſſolved in water, filtrated and cryſtallized, will afford elegant rhomboidal blue cryſtals, no way diſtinguiſhable from common blue *Vitriol*.

The ſame proceſs may be repeated with iron inſtead of copper, and the *Vitriol* will then be the common green kind, or copperas; or if the acid liquor, called ſpirit, or oil of ſulphur by the bell, be rubbed on plates of iron or copper, and ſuffered to dry away in the air, or over a gentle heat, and this repeated three or four times, the metal being afterwards put into water, will be ſo far corroded and diſſolved by it, that there will be a liquor produced, which will yield, on a proper evaporation, blue or green cryſtals, according as iron or copper have been uſed. This ſhews evidently, that the metal thus corroded by the acid of *Vitriol*, is ſoluble in water, ſo far as it has been ſo corroded; and that this ſolution affords true *Vitriol*. Such may be the formation of *Vitriol* about the copper mines in many countries, and ſuch the formation of the common green *Vi-*

triol or copperas in the pyrites with us in England. That ſtone is well known to contain ſulphur and iron, both in large quantity; and the combination of theſe in the earth, or in the air, where moiſture enough can get at them, may very well be underſtood to form *Vitriol*, which is the natural reſult of ſuch a ſolution. Phil. Tranſ. N°. 104.

It is obſervable, that before metallic *Vitriols* are diſſolved in water, they cannot be perfectly dried without changing their nature; and when diſſolved, they conſtantly let fall much ochre to the bottom; ſo that by repeated ſolution and cryſtallization of *Vitriol* in water, all the *Vitriol* is at length turned into ochre, and an unctuous liquor, that cannot eaſily be dried. Whence the eaſier, the quicker, and with the leſs water, ſome ſalts are diſſolved, the more eaſily they retain their water.

There is alſo ſomething particular in the ſolution of metals by water, for certain ſalts are required to diſſolve them; and when they are diſſolved into cryſtals of *Vitriol*, they then readily and eaſily diſſolve in water, ſo long as theſe cryſtals retain that ſalt which is the ſolvent of the metal; but when this ſaline ſolvent is wanting in the *Vitriols*, water will ſcarce diſſolve them at all, but ſuffers the metallic part to precipitate; but when the metal is previouſly diſſolved by its own ſolvent ſalt, it readily yields to water, and may thus, by a gentle evaporation, be reduced to cryſtals, wherein the metal, its ſolvent, and water always concur in a certain proportion. By this method metals are made potable, and act in the body as well, according to the acid ſolvent, as to the nature of the metal diſſolved. The action of all *Vitriols* depends thus upon theſe two principles united with water; and of this kind are the *Vitriols* of gold, ſilver, copper, iron, lead, and tin.

This rule does not extend, however, to all the *Vitriols*; for thoſe of the ſemi-metals, though they are firſt diſſolved by their acid ſolvents, ſo as to appear in a ſaline form, cannot therefore be diluted with water like the ſalts of the true metals: Thus pure regulus of antimony, perfectly diſſolved in ſpirit of ſea-ſalt, adhering to the mercury ſublimate, in the diſtillation of the butter of antimony, is a true *Vitriol* compoſed of antimony, diſſolved in ſpirit of ſea-ſalt: Whence one might ſuſpect, that it would diſſolve in water; but, on the contrary, as ſoon as water touches it, the acid ſolvent quits the regulus, mixes with the water, and lets fall the metallic calx entire. *Boerhaave*, Chem. part 1. p. 451.

Liquamen Pyriticum, or mother of *Vitriol*, is of an acrid and firey taſte, very different from that of *Vitriol*, and has been proved by ſome late experiments, to contain a ſalt very different from the *Vitriol*. The method of ſeparating this pure, is to evaporate a quantity of the water, impregnated with *Vitriol*, and received from the beds of the pyrites; this being evaporated to a pellicle, the *Vitriol* will ſhoot in the cold, and a quantity of ochre will be precipitated. After this, ſucceeding evaporations will yield more *Vitriol* and more ochre, to the fifth time; but if the experiment be continued after this, the firſt ſucceeding ſhooting of the liquor yields, inſtead of *Vitriol*, a yellow ſalt.

This contains the laſt portion of the ochre remaining in the liquor. After this, the matter yielding no more *Vitriol*, is called the waſh, or *Liquamen of Vitriol*. It taſtes acrid and firey, and the quantity left from a gallon of the well impregnated liquor from the bed, is about a pound. From this may be procured a white pungent ſalt, by ſubſequent evaporations. This is the ſaline principle of *Vitriol*, according to the chemiſts, and is contained in ſo large a quantity, that near thirteen ounces of it may be ſeparated from a pound of the liquor; the remaining liquor, after this, is what is called *Liquamen Vitrioli* by ſome chemiſts, but not properly. It will never coagulate into ſalt, but is very firy and acrid to the taſte, and extremely ponderous, not leſs ſo than oil of *Vitriol*, nor leſs pungent; and is the ſtrongeſt liquor any way obtained from a natural ſubſtance without diſtillation. This liquor being expoſed to the air in a veſſel not cloſed, will in a little time attract double its weight of water from it. All corroſive and ſaline liquors have ſomewhat of this property of imbibing moiſture from the air, and weakening themſelves by it; but this liquor attracts it faſter and in greater quantity than any other. This liquor receives moſt moiſture, and inceaſes moſt quickly in wet weather, leſs ſo in dry; and this may have given occaſion to that error ſo common among the chemiſts, that ſeveral preparations of *Vitriol* derive moiſture from the moon, and have more or leſs of it, according to her different phaſes. The changes of the conſtitution of the air have effected what, in this caſe, they ſuppoſed to be done by the different phaſes of the moon. Phil. Tranſ. N°. 103.

VITRIOL *of Copper*. The glaſs-makers have a method of making this without corroſives, which was originally practiſed by Neri, and with which they make ſome very fine colours in glaſs, particularly a fine ſea-green.

The method of making the preparation is this: Take little thin pieces of braſs, and lay them *ſtratum ſuper ſtratum* in a crucible, with powder of brimſtone. When the veſſel is full, ſet it luted and covered in an open wind furnace, with burning coals over it, and let it ſtand two hours; then let the furnace cool of itſelf, and take out the crucible, the maſs within will be of an obſcure blackiſh purple; powder and ſift it fine, and then mixing with every pound of it ſix ounces of powdered brimſtone, take a round veſſel of earth, that will bear the fire, place it upon iron bars ſet acroſs in an open wind furnace, fill it with coals, and then put in the powder; keep it burning and ſtirring about till all the brimſtone is burnt up; then take out the pan, and powder the calcined maſs again; ſift it fine, and proceed with it thrice as before; the laſt time let it ſtand on the fire till it become red. Put a pound of this calcined copper into a glaſs body, with ſix pints of water; evaporate two pints or thereabout in a ſand heat; the water is then of a fine blue, and muſt be poured off clear; then filtrate it. Evaporate the water from the remaining ſediment of copper left in the glaſs, and with new ſulphur calcine it again and again; repeat this five or ſix times, and extract the blue tincture with water as before; filtrate all the waters, and put them together. Evaporate all to a fifth part or thereabouts, and ſet it in a cool place, and fine pointed cryſtals will be formed, reſembling emeralds; ſeparate theſe cryſtals, and evaporate the water again, till all the cryſtals be procured. Then put a pound of them into a glaſs retort, well luted and fitted to a capacious receiver; let the joints be well cloſed, and make a moderate fire for four hours; then make it violent for twenty hours, or till no more white fumes ariſe. The next day open the receiver, and ſeparate the liquor into a glaſs, where it muſt be kept carefully ſealed up. *Neri*'s Art of Glaſs, p. 50.

Very great things are to be done in the glaſs art by means of this liquor; the remainder in the retort expoſed to the air for a few days, will acquire a blue colour, and this, mixed with zaffer, will give glaſs a fine ſea-green.

White VITRIOL. It has been diſputed whether *white Vitriol* is any thing elſe than green *Vitriol* calcined. But it ſeems that *white Vitriol* is of a quite different ſpecies from either the green or the blue *Vitriols*. See *Geoffroy*. Mat. Med. Tom. 1. p. 124.

In the condition in which *white Vitriol* is uſually bought, it contains ſomewhat both of copper and iron; but, being purified by ſolution, filtration and cryſtallization, it is freed from both theſe metals, and appears to be a native *Vitriol ſui generis*. See *Cramer*, Elem. Art. Docim. vol. 1. p. 302. ed. 2. Med. Eſſ. Edinb. Abr. vol. 2. p. 472.

If four ounces of alum be put in concoction with two parts of *cadmia foſſilis* pulverized, the earth of the alum precipitates, and its acid takes hold of the earth of zinc, ſo that a true *white Vitriol* is the reſult.

This *Vitriol* being precipitated by an alkaline lye, and dried, after its ſalts are ſeparated in water, and then mixed with charcoal-duſt, it will give zinc, in the manner mentioned under the article ZINC.

The ſame thing happens in mixing *Vitriol* of iron with two or three parts of lapis calaminaris; but the operation is eaſier with alum and *Vitriol* of copper. *Marggraf.* in Mem. de l'Acad. de Berlin, 1746.

Blue VITRIOL is made by evaporating ziment-water to a proper ſtandard; after which it is let out into coolers, where it ſhoots into regular and beautiful cryſtals of a rhomboidal form, and compoſed of ten planes. Theſe have the ſame qualities with the water; and being diſſolved in common water, they make a ziment liquor, undiſtinguiſhable from the native kind. See the article ZIMENT-*Water*.

Blue Vitriol is alſo contained in ſory or ruſma, and many of the pyritæ and marcaſites or mundics, but ſeldom pure. There are alſo ſome earths which contain it, but they principally owe it to ziment-waters paſſing through them.

Blue Vitriol has copper for its baſis, and is never uſed internally, but only in external applications. There are ſeveral preparations of it recommended in diſpenſatories, the moſt valuable of which ſeems to be the *aqua Vitriolica cerulea*. See the article AQUA.

VITRIOL *of Quickſilver*, the name of a chemical preparation of quickſilver, with acid ſpirits, the proceſs of which is this: Let ſo rich a ſolution of quickſilver be made in ſpirit of nitre, or aqua-fortis, that no more can be contained; let this ſolution be made by the aſſiſtance of heat, and the liquor immediately afterwards poured off into a clean and cold glaſs. There will, on this, ſpontaneouſly ſhoot on the bottom of the glaſs a ſaline white tranſparent matter, from which the liquor being poured, it is found to be a ſharp moiſt ſaline ſubſtance, or true *Vitriol* of mercury, ſoluble in water, and not ſafe to be touched: If the liquor, poured off from this, be evaporated half away, and the remainder ſet in a cool place, more cryſtals of the ſame nature with the firſt will ſhoot.

Another method of making the *Vitriol* of mercury, is this: Reduce to powder ſome deſcrepitated ſea-ſalt, and with two parts of this mix one part of crude mercury; diſtil the whole in a glaſs body, with a ſtrong fire, continued for five or ſix hours; when the veſſels are cold, break them, and there will be found a ſolid dry mercury, ſublimed to the top and ſides of the body, in form of *Vitriol*: Nay, Boerhaave affirms, that the common mercury ſublimate is a true *Vitriol* of mercury, though ſemi-volatile. *Boerh.* Chem. part 2. p. 301.

Preparations of VITRIOL are, 1. The acid ſpirit, or oil of *Vitriol*. 2. Colcothar, or calcined *Vitriol*. 3 *Tartarum Vitriolatum*. 4. *Spiritus Vitrioli dulcis*. 5. The compound

triolatum.

ſpirit of *Vitriol*. See the articles SPIRIT, COLCOTHAR, *&c. Cycl.* and *Suppl.*

Oil of VITRIOL. Mr. Boyle informs us, that if the caput mortuum, after the diſtillation of the *oil of Vitriol*, be ſuffered to lie a conſiderable time in the air, it will be ſo impregnated with new ſaline particles, as to be worth a ſecond diſtillation. Works abr. vol. 1. p. 142.

This ſtrong acid, when expoſed to the air, attracts the moiſture from it in very great quantity, increaſing in weight gradually to more than three times what it was when firſt expoſed, and gradually diminiſhing in ſtrength. The quantity of water it attracts from the air, in any given time, is not, however, in proportion to its own quantity, but to its ſurface; and Mr. Boyle has found by experiment, that if the ſame quantities be expoſed to the ſame air in glaſſes, in the one of which the ſurface is nine times greater than the other, that with the larger ſurface will gain eighteen grains addition in weight, while the other gains only two grains; and ſo in proportion for any longer time.

When the oil of *Vitriol* is fully ſatiated in the moiſteſt air, or wetteſt weather, it afterwards retains or loſes its acquired weight, as the air proves more or leſs moiſt. It may therefore be very practicable to make it a means to eſtimate the moiſture and dryneſs of the air. A very eaſy machine may be contrived to anſwer this purpoſe; for even a common pair of ſcales will do very well; and by a ſcale, on which the tongue of the balance ſhould move, would mark out the ſmalleſt changes in the moſt nice and accurate manner.

If a quantity of *oil of Vitriol* be expoſed in a wide-mouthed glaſs, till thoroughly ſated with the moiſture of the air, and then put into a ſcale, and in the moiſteſt weather exactly poiſed with a weight in the oppoſite ſcale, it will only continue exactly poiſed ſo long as the weather continues in that moiſt ſtate; but as the air becomes gradually more and more dry, it will weigh leſs and leſs, and mount, while the ſcale with the weights preponderates and ſinks.

The tongue of a ballance of but an inch and half long, thus deſcribes an arch of the third of an inch, by the different riſing and falling of the ſcale in which the *oil of Vitriol* is; and conſequently if the tongue were a foot long, it would deſcribe an arch of near three inches, which would be a ſufficient ſpace to mark a ſcale of degrees very nicely upon; and, as the tongue is pointed to theſe, it would be an excellent hygrometer.

This ballance may be contrived two ways, either ſuch whoſe pin ſhould be in the middle of the beam, with a very ſlender tapering tongue, of a foot or a foot and half long, pointed to the diviſions on a broad arched place fixed above; or elſe the ſcale with the liquor may be hung to a point of the beam, very near the pin, and the other extreme made ſo long as to mark a large arch on a board, placed conveniently for that purpoſe; and the ſcale, in either caſe, may very conveniently be a concave glaſs of four or five inches in diameter. On the diviſion of the arches ſhould be inſcribed the different temperature of the air ſhewn by the liquor. Phil. Tranſ. N°. 157.

The oil of *Vitriol*, being a cauſtic of an oppoſite nature to *lapis infernalis*, has been known to remove the pain occaſioned by the application of the latter. See the article OPPOSITE *Cauſtics*.

VITRIOLIC (*Cycl.*) —VITRIOLIC *Minerals* are compound foſſile ſubſtances, formed of various ſtony and earthy particles, mixed with others of iron and copper, and that either ſeparately or conjunctly; ſo that, in effect, they are ores of *Vitriols*.

The different kinds of theſe minerals are, 1. The chalcites. 2. The miſy. 3 Sory or ruſma. 4. Melanteria. 5. Pyrites, or fire-ſtone. 6. Marcaſites. See the articles CHALCITIS, MISY, *&c. Cycl.* and *Suppl.*

In Europe the only uſe made of chalcitis is as an ingredient of Venice-treacle, and even here its place is generally ſupplied with common green *Vitriol* calcined to a redneſs. The antient Greeks uſed it externally in hæmorrhages and collyriums for the eyes; alſo for the herpes and eryſipelas; but never ventured to give it internally.

The antients uſed *miſy* for the ſame purpoſes as *chalcitis*, being eſteemed milder than this laſt.

At preſent it is no where put to any uſe, nor indeed does it merit it, as containing no other virtues than thoſe of green *Vitriol*, though we are not ſure what pernicious ſubſtance it may be mixed with.

VITRIOLIC *Waters*. The countries which abound with mines of copper and iron uſually afford a great many *vitriolic* waters.

One of the moſt remarkable ſprings of this kind, of which we have an account, is that near Padderborn in Germany: This is a ſort of treble ſpring, having three openings, and all three yielding very different waters. Two of theſe openings are not more than a foot and half diſtant from one another, and yet of ſo different qualities, that the one is limpid, bluiſh, milk-warm, and bubbling, and contains ſal armoniac, ochre, iron, vitriol, alum, ſulphur, nitre and orpiment; all theſe ſubſtances having been ſeparated in its analyſis. The other is cold as ice, and is turbid, whitiſh, and much heavier, and ſtronger to the taſte than the other. This holds much orpiment, with ſome ſalt, alum, nitre, ſal armoniac, and vitriol. The firſt of theſe waters is taken by the people in the neighbourhood, againſt worms, and diſorders of the ſpleen, as alſo againſt epilepſies; the other is poiſonous to birds, all that drink of it dying in a very little time. The experiment has been tried on common hens, with the water brought from the ſprings into other places, and given them to drink.

Thoſe to which ſalt is given, after the ſwallowing this poiſonous water, ſtruggle longer before they die by it; and vinegar is found to ſave them very often from death, after drinking largely of it; but in this caſe they are ſickly for ſeven or eight days after it, and have the pip, as the good women expreſs it.

In the diſſecting thoſe birds which have died by drinking this water, the lungs are always found quite ſhrivelled up.

The people of the country have not been deterred by this bad effect of the water, from uſing it in medicine; they take ſmall quantities of it diluted in water, to deſtroy the worms, and it performs this very well; but gives them a grievous ſickneſs while it operates.

The third ſtream, or opening of this remarkable ſpring, is about twenty paces diſtant from the others; the water is here very clear, of a greeniſh colour, and of a ſour, but not very diſagreeable taſte. It is of a middle weight, and of middle qualities between the other two, and is evidently formed of the joining of thoſe two ſprings with ſome other freſh water in the way; for a liquor exactly reſembling this third kind may be prepared, by mixing equal quantities of the other two with a ſufficient quantity of commom well-water. Phil. Tranſ. N°. 8.

There is a ſpring in Baſil diſcharging its water through the tanners-ſtreet, or gerber-gaſſe, which is of a bluiſh colour, and ſomewhat turbid. This holds blue vitriol, that is, copper, in the form of a ſalt, and with it bitumen and antimony; but a much larger proportion of the firſt ingredient, than of either of the others. The analyſis of it ſhews, that it contains three parts copper to one of bitumen, and two of antimony. It ſerves the tanners of the place to good purpoſe, their ſkins receiving one of their preparations from this native water.

The ſame town affords ſeveral other ſprings of peculiar qualities, all owing to the veins of metalline ores, with which the earth of the place abounds. The one of theſe is called *Bandulph's-well*, and affords a water of great uſe in medicine, ſeveral being regularly and perfectly cured of hydropical diſtempers by it. And another very remarkable one contains, as is found by its analyſis, ſulphur, nitre, and ſome gold. Theſe, however, are in ſuch ſmall quantity in it, as not to prevent its being fit for the common uſes of life. It is very ageeable to the taſte, and is much eſteemed for drinking, and ſent for all over the town.

Another *vitriolic* water runs out of a cavern near Gelſbach in Alſace. It is a fattiſh and oily liquor, and is uſed by the country-people for greaſing their wheels; but it is fit for much better purpoſes. If it be boiled to the evaporation of a third part, there will remain very little water, but a fatty bituminous ſubſtance, like tar, will ſubſide to the bottom, and there will ſwim at the top a yellow, thin, and limpid liquor, very much reſembling linſeed oil; and this, diſtilled in a ſand heat, yields an oily and watry liquor; the firſt very good for external uſes, for burns and ſcalds; and the other a good internal medicine, in conſumptions, and other diſeaſes of the lungs. Id. Ibid.

Some time ago there was a water diſcovered in England, that gave, on many experiments, an appearance of containing natural and perfect vitriol. This water was found near Egling-ham in Cumberland; and being examined, by adding galls to it, it became abſolute ink, much deeper than any of the atramentous waters ever do: When one half the quantity was ſlowly evaporated, the remainder retained this quality to a higher degree than before; and, on evaporating it yet farther, there concreted in it fair cryſtals of pure and genuine vitriol.

This was an appearance wholly new in England, and not eaſily accounted for, as we have no mineral, except the common pyrites, which contains vitriol; and it is very well known, that there requires a fermentation in the air, before the vitriol, contained in that ſtone, will be diſintangled from its other principles, ſo as to be capable of appearing in its own form; and as this ſtone, lying under water, can never impregnate that water with its vitriol, it did not ſeem eaſy to conceive in what manner a genuine vitriol ſhould be communicated to water, where there was no other ſubſtance which could give it. The ſuſpicions that theſe thoughts gave the gentleman who examined this water, occaſioned his making a viſit to the place where it was produced, when he found that the ſuppoſed *vitriolic* ſpring was no other than an old drift made for the draining the water from ſome old wrought coal-pits; the people who had worked in theſe, remembered to have ſeen great quantity of pyrites there. This drift was ſometimes dry for a conſiderable time together, and ſometimes run in a plentiful ſtream; and there is no doubt but that, in theſe dry ſeaſons, the air acted upon the pyrites, and cauſed it to ſhoot its vitriol, which the next tide of water waſhed away, and it came off diſſolved in it, and highly impregnating it.

This proved therefore no better a medicinal ſpring than ſome of a like kind, deſcribed by Mr. Leigh in his natural hiſtory

of Lancaſhire; and all theſe are very little better than the diſcovery of a medicated water in Oldſtreet, from the remains of an old colour-ſhop, or Kircher's reckoning the common ſhores of Rome among the medicated ſprings of Italy.

The *vitriolic* ſpring which has been ſo much talked of near Haigh in Lancaſhire, is no other than an accidental impregnation of common water, in the ſame manner, it being only the runnings of an old drift, or drain, made to carry off the water from ſome pits of cannel-coal; and this, like the other, as it ſometimes has water, and at other times is dry, gives time for the pyrites to let go its vitriol while dry, and then imparts it to the waters that paſs that way afterwards. Theſe are not to be accounted medicated ſprings, ſince neither natural nor continual, and ſuch may be any day made at home, by laying the common pyritæ of our clay, or coal-pits, out to moulder in the air, and then pouring water upon it, and after a ſhort time ſtanding, taking it off again. Phil. Tranſ. N°. 245. p. 380.

VITRUM, in botany, a name given by ſome of the old writers to the plant we now call *glaſtum* or *woad*.

This plant has always been a native of England, and was in uſe among the ſavage inhabitants of this iſland, for painting their bodies. Thoſe who have not underſtood this to be the name of that plant, have been ſtrangely perplexed to account for theſe people's painting their bodies with *Vitrum*, glaſs, as they underſtood it: But the whole meaning of this plant obtaining the name of *Vitrum*, ſeems to have been its ſtaining the ſkin to a pale blue colour, or, as it was called by many, a glaſs-colour.

VITRUM, *Glaſs*. As impenetrable as glaſs is to the common menſtruums, we find it eaten by the air in length of time, when expoſed in old windows; but the effects of its being kept in a ſubterraneous place are much more ſtrange. Borrichius tells us, that at the time when he was at Rome, there was dug up a whole houſe from under the kitchen-garden of a citizen. The houſe had been buried there ten ages, and there were found in it ſeveral glaſs urns, or lachrymatories. The glaſs of theſe had no holes made in it, as our old glaſs in chamber-windows has, but ſtill retained its ſmooth ſurface and tranſparence; but it was ſplit into a vaſt number of thin laminæ, which were as pellucid and fine as Muſcovy glaſs; and in ſome places were tinged with all the beautiful colours that art could have given. We are not acquainted perfectly with the antient way of working their glaſs; but it is not probable there could be any thing particular in the formation of the veſſel, to determine it to ſplit thus into flakes; but that glaſs of the ſame kind, in any form, would have done the ſame. *Borrich.* de Ortu Chemiæ.

VITRUM *Antimonii Ceratum*, in pharmacy, is thus prepared: Take glaſs of antimony in powder, one ounce, bees wax one dram; melt the wax in an iron ladle, then add the powder; ſet them on a ſlow fire without flame, for the ſpace of half an hour, continually ſtirring them with a ſpatula; then take it from the fire; pour it upon a piece of clean white paper, powder it, and keep it for uſe.

The glaſs melts in the wax with a very ſlow fire. After the materials have been about twenty minutes on the fire, they begin to change colour, and in ten more come to the colour of ſnuff; which is a mark of the medicine's being ſufficiently prepared.

The ordinary doſe for adults is ten or twelve grains; but it is ſafeſt to begin with ſix grains. The quantity of a ſcruple has been given to a ſtrong man, which wrought gently.

This medicine has for ſome time been held a ſpecific in dyſenteries; but the preparation and manner of giving it have been kept a ſecret, till Dr. Young generouſly made it public. Dr. John Pringle ſays, he tried it in a dyſentery of four years ſtanding, with ſurprizing ſucceſs. See Med. Eſſ. Edinb. vol. 5. art. 15.

It has been given in dyſenteries, with or without a fever, whether epidemic or otherwiſe, and whether bleeding and vomits have been premiſed, or not. In its operation, it ſometimes makes the patient ſick, and vomits him; it purges almoſt every perſon; but it has been known to cure without any evacuation or ſickneſs. It is to be given with an empty ſtomach, for then it operates moſt mildly. Nothing is to be drank after it for three hours, unleſs the patient is very ſick, and diſpoſed to vomit; in which caſe warm water may be given, as in other vomits.

This medicine ſhould not be given for diarrhœas in the end of conſumptions. Other diarrhœas have been cured with large doſes of it; but in ſuch caſes it fails oftner than in dyſenteries. During the uſe of this powder, fermented liquors ſhould be abſtained from, and a milk diet is proper. See Medic. Eſſ. Edinb. ibid.

This preparation has alſo been found ſucceſsful in uterine hæmorrhages, both in young and old.

It has alſo been tried in colic pains, from viſcidities in the inteſtines, and found a ſafe and eaſy purgative, and ſometimes a gentle emetic.

The method of giving it is in a bolus, with conſerve of roſes, diaſcordium, or theriaca Edinenſis. An opiate, after the operation, is proper. See Medic. Eſſ. or the Abridgment, vol. 1. p. 193. ſeq.

VITRUM *Morrhinum*, *Morrhine*, or *Myrrhine Glaſs*, a name given by Pliny, and ſome of the antients, to a ſort of manufacture made in Egypt, which though truly no other than a kind of glaſs diveſted of its tranſparency, yet was made ſo nicely to imitate the *myrra* or *morra* of the Indies, ſo famous among the Romans, under the form of cups and veſſels, called *murrhina vaſa*, that it was called by ſome, *murrha altera*, another ſort of *murrha*, and the cups made of it honoured with the name of *murrhine veſſels*. This ſerves to ſhew, that the *myrrhina vaſa*, properly ſo called, were not of any precious ſtone, as vulgarly ſuppoſed, but of a ſort of porcelain. See the article MORRINA.

VITTA, among the Romans, a fillet with which the women in Rome bound their hair. The matrons wore a double one, to diſtinguiſh them from the virgins, whoſe *Vittæ* were ſingle.

Vittæ were alſo worn by prieſts and poets, in which caſe they were made of branches of olive or laurel; the ſtatues of the gods were likewiſe adorned with *Vittæ*, as were altars, the doors of temples, victims and ſupplicants. *Pitiſc.* in voc.

VITTA *Cærulea*, in conchyliology, a ſpecies of *dolium*. See the article DOLIUM.

VITTA, in ichthyology, a name given by Gaza, and ſome others, to the fiſh called by others, *tænia*, and by the Italians, *cepole*. See the articles TÆNIA and CEPOLE.

VITULUS *Marinus*, the *ſea-calf*, in zoology. See the article PHOCA.

VITULUS, *Calf*, in zoology. See the article CALF.

VITULI *Aquatici*, in the hiſtory of inſects, a name given by the German writers to thoſe ſlender and long worms found in waters, and reſembling horſe-hairs, and which are ſuppoſed by the vulgar to be no other than real hairs, animated by lying in the water. We are not yet perfectly informed of all parts of their hiſtory; but Dr. Liſter has found them in the bodies of ſeveral of the common beetles.

VITUS's *Dance*, or ST. VITUS's *Dance*, in medicine, the name of a peculiar ſort of convulſion, to which young women are principally ſubject, toward the time of the firſt eruption of the menſes.

It ſeems to have had its name from the account which Horſtius gives of ſome women who once every year paid a viſit to the chapel of *St. Vitus* near Ulm, and there exerciſed themſelves day and night in dancing, being diſordered in mind, till they fell down like people in an extaſy: By this means they were always reſtored to health for a whole year, till the return of May, at which time they were again ſeized with a reſtleſsneſs, and diſorderly motions of their limbs, ſo as to be obliged, at the anniverſary of *St. Vitus*, to repair again to the ſaid chapel, for the ſake of dancing. *Horſtius*, Ep. Med. S. 7.

It is the moſt frequent with girls, yet not peculiar to them, attacking boys alſo, from the age of ten to fourteen. It firſt ſhews itſelf by a ſort of lameneſs, or rather unſteadineſs of one of the legs, which the patient draws after him like an idiot, and afterwards affects the hand on the ſame ſide; which being brought to the breaſt, or any other part, can by no means be held in the ſame poſture for a moment, but is diſtorted or ſtretched by a ſort of convulſion to a different poſture and place, notwithſtanding all poſſible efforts to the contrary.

If a glaſs of liquor be put into the patient's hand to drink, before he can get it to his mouth, he makes a hundred odd grimaces and geſtures, for not being able to carry it ſtrait, becauſe his hand is drawn different ways by the convulſion, as ſoon as it has reached his lips, he throws it ſuddenly into his mouth, and drinks it very haſtily, as if he meant only to divert the ſpectators.

As this diſorder appears to proceed from ſome ſharp humours thrown upon the nerves, which, by their irritation, excite preternatural motions, it ſeems that the curative indications are to be directed firſt to leſſen thoſe humours by bleeding and purging, and ſecondly, to ſtrengthen the nervous ſyſtem. Dr. Sydenham therefore propoſes the following method: Firſt to take from the arm ſeven or eight ounces of blood, more or leſs, according to the ſtrength of the patient. The next day let him take a gentle purge of rhubarb, ſena, manna, *&c.* In the evening of this day, let him take a draught, with a ſcruple of Venice-treacle, and eight drops of liquid laudanum mixed in honey and milk-water. This purging and opiate draught is to be repeated at ſome days diſtance, and the bleeding is alſo to be repeated to the fourth time; and in the intermediate days, a cordial and nervous electuary is to be given, compoſed of the conſerves of roſemary, orange-peel, and Roman wormwood, with Venice-treacle, candied nutmeg and candied ginger; of this the bigneſs of a nutmeg may be given every morning and afternoon, drinking after it a decoction of piony, maſter-wort, and elecampane, and angelica-roots, the leaves of rue, ſage, betony, and other cephalic plants, with orange-peel, and juniper-berries.

Spirit of harts-horn may alſo be given every night in ſmall doſes, in a nervous julep, and plaſters of gum caranna may be applied to the ſoles of the feet. According as the cure advances, the patient recovers the uſe of his hand and foot, and his amendment may always be diſcovered by letting him attempt to bring a glaſs of any liquor to his mouth in a ſtrait line; though the bleeding ſhould not be repeated beyond the fourth time,

time, yet the alterative and purging medicines ſhould be continued till the patient is quite well; and as people are ſubject to relapſes in this diſorder, it is proper to give the ſame medicines, and to bleed at the return of that ſeaſon of the year.

The firſt ſymptoms in this diſeaſe are often perceived to come on at the hips and os ſacrum, or extremity of the back-bone; from thence a pain extends itſelf acroſs the navel, and thence the pain runs up to the top of the head: as ſoon as this happens the convulſions uſually begin; theſe often firſt appear in the belly, and are ſo violent, that two or three perſons can ſcarce hold the patient, and are forced to lie upon the bed to prevent him from raiſing up his belly in a ſtrange manner.

After this, in ſome caſes, the nerves of the lungs become affected, and the patient will imitate the barking of a dog, or the ſnarling and howling of that animal when hurt: after this, the nerves of the jaws generally ſuffer, and the teeth are ſnapped violently together, and the mouth foams; perſons have ſometimes beaten out their teeth with the violence of ſnapping them together in theſe agonies.

There is, in the Philoſophical Tranſactions, an account of a caſe of this kind following a fever, in which the patient attempted to bite every body about him, and would have even gnawed his own fleſh, if he had not been prevented; but, though the people about him thought, from all theſe ſymptoms, that he had been bitten by a mad dog, and that this was madneſs, yet, on offering him water, he drank, or rather lapped it greedily; which proved it could be no effect of that bite, becauſe the great ſymptom of ſuch diſorders, the dread of liquids, did not ſhew itſelf in him. Theſe were merely the effect of this *Chorea Sancti Viti*, and were attended with twitching of the arms and legs, which conſtitute that diſtemper; his noiſes alſo were not confined to thoſe of a dog, but in different fits, he repreſented the ſounds of different animals, as the roaring of a bull, the grunting of a hog, and the noiſe of a gooſe.

Theſe were not premeditated, or meant by the patient, as imitably of ſuch ſounds, but merely proceeded from the forcing out the air from the lungs in different manners, according to the different power of the convulſion, which affected their nerves. The patient in this caſe was ſpeechleſs, not only in the time of the fits, but for a week together; and the country people fell into the common error of ſuppoſing that he was bewitched, but the phyſician cured them of that belief, by the curing the patient of his diſtemper by the common means, as they were convinced, that a diabolical ſpirit could not be caſt out by a regular courſe of phyſick. Phil. Tranſ. N°. 287. p. 1480.

VIVACE, VIVACEMENTE, or VIVAMENTE, in the Italian muſic, ſignifies to play with life and ſpirit. It requires a degree of movement between *largo* and *allegro*, but neareſt *allegro*. See the articles LARGO and ALLEGRO.

VIVACISSIMO, in the Italian muſic, denotes a degree or two quicker than *Vivace*, and is much the ſame with *allegro*. See the article ALLEGRO.

VIVERRA, in zoology, the name by which authors call the *Ferret*; called by ſome alſo *muſtela ſylveſtris*, *furo*, and *furunculus*.

The uſe we make of this creature, is the ſending it into rabbet holes to drive them out; but we are obliged to faſten up their mouths, that they may not tear the rabbets to pieces; but it ſtill is able to annoy them with its claws, and ſoon drives them out. It feeds on milk, ſmall birds, and the fleſh of animals, and is a creature eaſily kept tame, and will breed and bring up its young in that ſtate; and theſe will naturally hunt the rabbet, in the ſame manner as their parents.

It is of a middle ſize, between the weaſel and polecat; its head is ſmall and flattiſh; its ears ſhort, erect, and very wide; its noſe, or ſnout, long, like that of a hog; and its eyes ſmall and red; its colour is a pale, yellowiſh white; the back and ſides a little darker than the belly; and its feet have all five claws each: it breeds very well with us, but is ſaid not to be a native here, but brought from Africa. *Ray*'s Syn. Quad. p. 198.

VIVERRA *Indica*, the Indian *Ferret*, a name by which ſome have called the animal known in America by the name of *quirpele* and *quil*. See the article QUIRPELE.

VIVES, a name given by our farriers to a diſeaſe of horſes, which conſiſts in the growth of certain flattiſh kernels in cluſters, like bunches of grapes, beginning from the ears, and creeping downwards, between the chap and the neck of the horſe toward the throat.

When they are inflamed they ſwell, and become not only painful to the creature, but are even mortal, ſtopping his wind unleſs a ſpeedy courſe be taken for their cure. The difficulty of breathing, which they occaſion in their progreſs toward this higheſt degree, occaſions many ſymptoms, which being miſunderſtood by the farriers not being well acquainted with the nature of this diſeaſe, are often treated as peculiar diſtempers themſelves, and the creature periſhes by the treatment of them in an improper manner.

The horſe will often lie down, and ſtart up again, and tumble about in a ſtrange manner, and be ſuppoſed to have convulſions, when he has really no other complaint but the difficulty of taking his breath.

The common cauſe of this diſtemper, is the drinking cold water after any violent heat: It is alſo ſometimes ſaid to ariſe from the eating too much bad corn. The method of cure is to be varied according to the progreſs and ſtate of the diſeaſe, and the immediate danger.

If the tumors be not grown ſo large as to put the horſe in abſolute danger of ſuffocation, the farrier uſually attempts to rot them away, by taking hold of each gently with a pair of pincers, and beating them gently with the handle of a ſhoeing-hammer, or bruiſing them with the hand alone, till they grow ſoft; this will often make them diſappear; but this method is only to be uſed when they are nearly ripe; for otherwiſe they will return after a time; their being in a proper ſtate for this, is known by the ſeparation of the hair, which eaſily comes off on the taking hold of it between the fingers. If the caſe be more deſperate, and the horſe likely to be immediately ſuffocated, it is beſt to open them with an inſtrument. Whether this, or the other method be taken, the horſe ſhould immediately after be blooded under the tongue, and afterwards in the flanks, and his mouth waſhed with ſalt and vinegar, and ſome of the ſame mixture ſhould be put into his ears, rubbing and ſqueezing them hard to make it penetrate: this will wonderfully aſſwage the pain. After this, the horſe is to take a quart of white wine, with two handfuls of hempſeed bruiſed, two nutmegs ſcraped, and the yolks of ſix eggs, all thoroughly mixed in it. About an hour after this draught, he is to have the following glyſter: Boil an ounce and half of ſal polycreſtum, finely powdered, in five pints of beer; when this is taken off the fire, two ounces of oil of bays is to be put to it; and the whole is to be thrown up blood-warm. This is a regular method, and ſeldom fails of a cure; but ſome, who are not willing to have ſo much trouble and expence, only cut holes where the kernels are, and pick them out at theſe with a wire; they then fill the hole with ſalt, and at the end of three days it will run; after this they waſh the wound ſome days with the juice of ſage, and heal it with the common green ointment, or with a mixture of honey, butter, and tar.

VIVIPAROUS (*Cycl.*) — The females of all the quadruped claſs are *viviparous*, and thoſe of the bird claſs are all *oviparous*.

The laws of nature in the larger animals, are therefore, in a great meaſure, fixed and certain; but it is not ſo in the inſect tribes, nor in the fiſhes; for of theſe ſome are *viviparous*, and others *oviparous*; and thoſe of genera nearly allied to one another.

Among inſects, the much greater number are *oviparous*; but there are many which are not ſo, as the pucerons, progallinſects, cochineal, &c. The millepedes and ſcorpions are alſo well known to be ſo; all the females of the butterfly, and of ſome other claſſes, lay only eggs; but the moſt ſingular and remarkable inconſtancy in nature, if we may be allowed the expreſſion, is that in the fly kingdom; the ſame claſs of inſects, and even the ſame genus, will furniſh us with ſome which are *viviparous*, and others which are *oviparous*; the two-winged flies give us inſtances of this; but theſe are not ſingle in that reſpect; for among the reptile world, there are other creatures which are ſubject to the ſame varieties; and Swammerdam has obſerved a viviparous ſnail. The two-winged *viviparous* flies bring forth worms, in all reſpects the ſame with thoſe hatched from their eggs in the other ſpecies.

Many authors having obſerved the flies in general to lay eggs, have too haſtily declared flies to be oviparous; and, on the contrary, ſome having ſeen them produce living worms, were of opinion, that they were all *viviparous*. Redi very juſtly blames both ſides for making general inferences from particular facts, and then propoſes a queſtion, whether the ſame fly, in different circumſtances, may not depoſit eggs, or living animals, and whether external cauſes, as the heat of the air, &c. may not make thoſe eggs, naturally ordained to have been laid in that form, hatch in the creature's body, and thence appear in form of a living offſpring: but as there is no probability of a chicken being in the body of the hen, though it may eaſily happen that an egg may be detained there, ſo neither is there any probability of that which nature ordained to be produced in the egg ſtate by the fly, ſhould by any accident be made to hatch into a young one, in the body of the mother.

The ſpecies of *viviparous* two-winged flies, are much more rare than the oviparous; and among the four-winged claſs, they are yet more uncommon. It is not certain, that any of the latter, beſide the winged pucerons, are of this kind; but among the former, there are ſix or ſeven ſpecies which are known always to produce living worms, and probably many more will be diſcovered, by a more cloſe attention than has hitherto been given them, to be ſo too. When we ſee the eggs of a fly depoſited in great numbers on food, excrements, or other ſubſtances, it is eaſy to follow the changes of the creature produced from thoſe eggs; and when one has it in the fly ſtate, there is a ſufficient proof that this ſpecies of fly is oviparous: but it is much otherwiſe in reſpect to the *vivipa-*

rous kinds; ſince when we ſee the multitudes of ſmall fly-worms already living on any of theſe ſubſtances, it is not to be known from all their ſucceeding changes, whether they were produced from the body of the parent-fly in that ſtate, or as eggs.

To diſtinguiſh with certainty, whether a fly be oviparous or *viviparous*, the beſt means is certainly to obſerve it in the inſtant of its producing its eggs, or young ones, which ever they are; but as that is a moment not eaſily ſeized, its place may be ſupplied either by opening the body of a female fly, diſtended and full of eggs or young, and the arrangement and form of the bodies contained, will eaſily determine the obſerver, whether he is to look on them as eggs, or embryo-animals: But a yet more certain way is to take a fly which appears ready to depoſit its future progeny, and ſqueezing its body, force out a part of what would naturally have been thrown out in a little time, and it will be eaſy to ſee whether theſe are eggs or worms.

It is eaſy to find about our houſes one of theſe ſpecies of *viviparous* flies; the creature is always buzzing about the places where meat is kept, and loves to depoſit her young as the common blue fleſh-fly does its eggs, on meat. Its way of carrying its wings is the ſame with that of the blue fly, and its antennæ are of the ſame form. It at leaſt equals the blue fly in length, but its body is leſs thick, and is a little bent at the hinder part; its colour is grey. On the corcelet this colour ariſes from a ſeries of long but irregular aſh-coloured lines ranged on a brown ground: A ſimilar colour is alſo ſeen on the upper part of the rings of the body; but the grey ſpots here are much ſhorter than on the corcelet, and almoſt ſquare, and the colour between theſe is a ſhining brown, which, in ſome lights, has a caſt of blue. Its legs are black; its petty wings whitiſh; and its reticular eyes reddiſh.

When a female of this ſpecies is taken on meat, and has not too flat a body, one may always expect the ſucceſs of an attempt to find that ſhe is big with living young. Taking a fly of this kind, and in this ſtate, between ones fingers, and obſerving its hinder part, one ſhall uſually ſee a ſmall and ſomewhat cylindric oblong body thruſt itſelf out, and move from ſide to ſide, and ſometimes make many ſinuoſities; this will be found to become more and more long, as it is more and more diſengaged from the body of the fly, and is indeed no other than a worm now firſt appearing, and endeavouring to diſengage itſelf from the body of its parent; a few moments now ſets it at liberty; and it is no ſooner fallen off, than the end of another like worm appears at the ſame apperture, and in a few moments gets its liberty, as the former did; this is ſucceeded by another, and ſo on for ten, twenty, or ſometimes many more; and when the creature ſeems to have done producing them, the ſlighteſt preſſure on the belly will ſend out numbers more, and ſometimes two or three are, by this means, forced out at the paſſage together. The aperture is naturally large, through which they are to paſs, and is, beſide this, capable of great extenſion.

It is uſually the head of the worm that firſt makes its appearance; but this is not always the caſe; and eſpecially where external preſſure has been uſed, 'tis not uncommon for the hinder part of the worm to appear firſt; and when many of them have, by this means, been forced out together, and the paſſage by this means is become enlarged, 'tis no uncommon thing for a number of them coming out together, to bring with them a part of the membrane in which they had been encloſed, while in the body of the parent-fly.

The conſideration, however, of the many animals of the inſect claſs, which are often found to breed and nouriſh in their bodies worms, not their own offspring, but that of the eggs of other inſects lodged in their fleſh, and eating them up alive, might lead one to doubt whether theſe worms, inſtead of being the genuine offspring of the fly, were not a ſet of cruel enemies which had been long devouring and preying on its entrails; and what might ſomething favour this opinion, is, that the fly uſually dies ſoon after it has finiſhed its depoſiting them. But there needs no more to refute this error, than to give theſe new-born worms ſome meat; the eagerneſs with which they bury themſelves in it, is a proof of their being in a condition to eat, and that greedily; whereas the worms bred in the bodies of inſects, from the eggs of other creatures, when they leave the body of the creature, have no farther occaſion for food, but have nothing to do but to prepare for their transformation. On the other hand, if one continues to obſerve theſe worms produced from the fly, one ſhall find that they behave in all reſpects like thoſe produced from the eggs of the blue fleſh-flies; they eat the meat to a certain time; then having obtained their full growth, they leave the ſubſtance they had fed on, and run into the earth, where they are afterwards found in form of nymphs, encloſed in a ſhell made of their own ſkin; and, at proper diſtances of time, there are produced from theſe, flies male and female; the latter, in all reſpects perfectly like the parent-fly, from whoſe body the worms had been ſeen to come.

There are, beſide this ſpecies, two other of the *viviparous* flies, which are not uncommon. Both theſe, in a great meaſure, reſemble the former; but their bodies are ſhorter; and, in the whole, they much more than the other approach to the form of the blue fleſh-fly. They are alſo ſmaller than the former ſpecies; the one of them, however, on the whole, is not much ſo, and, though ſhorter, yet is much thicker both in the corcelet and body. They are both, though ſmaller than that kind, yet tolerably large flies, and are bigger than the common horſe-fly.

On the leaves of ivy alſo there are often ſeen, about autumn, two other ſpecies of *viviparous* flies, which are eaſily diſtinguiſhed from all the others. Thoſe of one of theſe ſpecies are larger than the great blue fleſh-fly, and have a ſhorter and thicker body than that kind. The manner of carrying the wings is alſo the ſame in both; but though both have antennæ of the battledore kind, yet they are evidently diſtinguiſhed by this, that the extremities of the one are lenticular, and thoſe of the others priſmatic. Near the origin of each wing theſe have a browniſh ſpot, as have thoſe oviparous flies which uſually have in their body only two large eggs at a time, and which are produced of the yellow worms, ſo common in cow-dung. But theſe *viviparous* ones differ from thoſe flies, in that they are larger, and of a deep, but dead brown; whereas the others are black, or nearly ſo.

The other ſpecies is not much unlike this in form, but is ſmaller, being not more than of the bigneſs of the blue fleſh-fly, and of a bluiſh black; ſo that it might eaſily be miſtaken for one of the common fleſh-flies, were it not for the two brown ſpots at the inſertion of the wings; and both this and the former ſpecies are plainly diſtinguiſhed from the cow-dung-fly before deſcribed, by their wanting the gold-coloured down which that has on the fore-part of its head. *Reaumur*, Hiſt. Inſect. vol. 4. p. 405. ſeq.

ULCER (*Cycl.*)—*Callous* ULCERS. The cure of callous *Ulcers* is attended with very great difficulties, and indeed no cure is to be expected, till the callus is perfectly extirpated. This is to be done three ways; the mildeſt of theſe, which is ſuited to recent calluſes, and ſuch as are not yet become very hard, is by means of corroſive medicines, and of theſe the milder kinds are often ſufficient; burnt alum either rubbed on the parts alone, or applied with an equal part either of the common digeſtive or baſilicon, will ſometimes anſwer this purpoſe in theſe caſes, as will alſo the Ægyptian ointment, to which a ſmall quantity of red precipitate may be added occaſionally. If the callus will not yield to theſe remedies, it muſt be attacked with the common cauſtic, or with butter of antimony, or with a ſolution of quickſilver in ſpirit of nitre.

Another mild method of extirpating calloſities we are alſo taught by Le Dran. This author adviſes to apply, for four or five days, a plaſter made of the diachylon with the gums, and the mercurial plaſter, with a quadruple proportion of mercury, mixed in equal quantities; this is to be renewed morning and night, in order to ſoften the callous lips as much as poſſible; after this he makes numerous inciſions, ſo deep as to paſs quite through the ſubſtance of the callus, and ſtops the blood which flows from theſe with dry lint; then the ſame plaſter is again applied, and ſo laid on, that it may touch the naked inciſed lips. After about four days of this treatment, the ſcarifications are again repeated, and this to a third or fourth time, if the calloſity be not before deſtroyed.

If callous *Ulcers* are attended with fiſtulous ſinuſes, theſe muſt always be laid open, before we can attempt to deſtroy the callus, with any probability of ſucceſs; after this they may be cured as before directed; or, if the uſe of the knife be not ſafe, or the patient dreads it too much, it will be proper to form tents, and thruſt them up the ſinus, firſt anointing them with the Ægyptian, or with Wurtz's brown ointment. By theſe methods a callus, that is not of long ſtanding, may be extirpated; if the ends of the tents, laſt mentioned, be touched with butter of antimony, red precipitate, or the infernal ſtone, the buſineſs, in that method, will be the more eaſily effected; and, in caſes of this kind, where the callus cannot be reached by the corroſive end of the tent, it is a very good method to inject into the ſinus either the phagedenic-water, or a ſolution of the Ægyptian or brown ointment in ſpirit of wine. The opening of the ſinus ſhould be then cloſed, to keep in the injection as long as may be, and the operation frequently repeated.

Sometimes, however, it is found abſolutely neceſſary to uſe the knife, as in callous *Ulcers*, or fiſtulæ, that are of very long ſtanding, and that have formed variety of ſinuſes, and when either nothing can be done by corroſive medicines, or elſe that they tear and corrode the nerves, and bring on convulſions, and other bad ſymptoms, before they affect the callus. In theſe caſes the beſt and ſafeſt way is to lay open the ſinus, taking care not to wound the nerves, tendons, and arteries; and, after that, all the calluſes may be eaſily deſtroyed by the common methods. Finally, if even this method ſhould not have the deſired effect; and if the patient has a conſiderable ſhare both of ſtrength and courage, and the ſituation of the nerves and arteries is favourable, the callus parts muſt be all either entirely cut out with the knife, or burned away by the actual cautery. This operation, though a very painful one, is attended with this great good conſequence, that it will reduce the moſt inveterate callous *Ulcer* to the ſtate of a freſh wound; and unleſs a caries, or bad habit of body, or the pox, ſcurvy,

ſcurvy, or dropſy, or ſome other conſtitutional complaint, be in the way, it may be cured as eaſily as a freſh wound. *Heiſter*'s Surgery, p. 251.

Cutaneous Ulcers. Such of theſe as attack the ſkin of the face, both in infants and adults, approach very much to the nature of the truly phagedenic *Ulcers*; for they, like thoſe, ariſe from an acrimony of the blood, and are very apt to ſpread abroad.

In both theſe caſes therefore purging medicines, with ſuch as ſweeten the blood, will always prove of ſervice. Decoctions of the woods, or of the ſharp-pointed dock root, or the herb fumitory, ſhould be drank on theſe occaſions, half a pint at a draught, as hot as can well be borne, three or four times a day. And ſome of theſe draughts ſhould be taken in bed, and a gentle ſweating be promoted for ſome time afterwards. And abſorbent and ſweetening powders; as thoſe prepared from antimony and flower of brimſtone, ſhould be taken at the ſame time. When this caſe happens to infants at the breaſt, they can only take ſome ſlight doſes of medicines to open the bowels; but the mothers or nurſes ought to be enjoined the regimen juſt mentioned.

In regard to the external applications, oil of tartar per deliquium will be found of great ſervice; a pencil or feather is to be dipped in this, and rubbed over the parts three or four times a day. This may either be thus uſed alone, or elſe mixed with oil of eggs and wax, and a plaſter laid over it, of the de minio, or any other of the lead plaſters, or one of ſperma ceti and camphor.

If the whole face be affected, which in infants is not unfrequently the caſe, a plaſter would prove highly troubleſome; but, in this caſe, the proper ingredients may be ſpread in a ſofter form over a linnen maſk. Lime-water is a medicine of great power and value alſo in theſe caſes, as is likewiſe the water uſed in the waſhing diaphoretic antimony. The *Ulcers* may very properly be waſhed with either of theſe, and the litharge or pompholyx ointment afterwards applied; to which, in very ſtubborn caſes, a little crude mercury may be added; and ſometimes a ſmall admixture of red precipitate is found neceſſary; and finally, if theſe *Ulcers* are attended with a large and foul diſcharge, it will be proper to ſprinkle them with ſome of the abſorbent powders, as tutty, lapis calaminaris, cerus, chalk, or the like, mixed up occaſionally with a little native cinnabar, or red precipitate; or, if it be found more convenient, theſe powders may conveniently enough be made into an ointment with cream. *Heiſter*'s Surgery, p. 247.

Fiſtulous Ulcers. When it is diſcovered, either by the eye or probe, that *Ulcers* are become fiſtulous, though the fiſtulæ or ſinuſes are not yet become callous, the readieſt way of curing them is by laying them open, if that can be conveniently done, down to the bottom with the knife, and after this they may be cleanſed and healed. As patients, however, are always averſe to the knife, the cure of theſe may be attempted by injecting them with the decoctions of vulnerary herbs, ſuch as agrimony, birth-wort, or ladies mantle, and dreſſing them with digeſtive ointments or lint. Many ſurgeons are, in theſe caſes, fond of thruſting their dreſſings to the bottom of the ſinus with tents; but they are very apt to do miſchief by their hardneſs, and too great length, often bringing on a callus, inflammation, or too great flux of humours on the part. They ought therefore either wholly to be laid aſide, in theſe caſes, or elſe to be made as ſoft and as ſhort as the nature of the caſe will admit. The next particular, in the cure of theſe fiſtulous ſinuſes, is to preſs the fundus as near to the mouth or opening as poſſible; and when the wound is cleanſed, and the proper dreſſings applied, a ſmall compreſs, or a ſlip of plaſter, doubled up in the form of a ſmall compreſs, muſt be laid on the part where the fundus, or bottom of the fiſtula, is judged to be ſeated, ſecuring all on by a larger compreſs, and the proper bandages. In rolling up, in theſe caſes, the proper method is always to place the beginning of the roller upon the fundus of the fiſtula, or at leaſt to make the preſſure tight upon that part; the continuation of this will urge the contained matter up toward the opening, and the fundus, or bottom of the ſinus, will naturally be the firſt part that heals. When theſe ſinuſes penetrate ſo deep, that there is no coming at their bottoms with the dreſſings, vulnerary injections muſt be frequently uſed; and, of theſe, none are more ſerviceable in theſe caſes, than the following: Take of the common digeſtive, prepared with turpentine, diſſolved in the yolk of an egg, an ounce and half; honey, either ſimple, or the honey of roſes, or of celandine, an ounce; common-proof ſpirit, nine ounces; mix theſe together for an injection. Or take of a decoction of ſcordium, or elſe of ſouthern-wood or agrimony, eight ounces; common-proof ſpirit, three ounces; elixir proprietatis, or eſſence of myrrh and aloes, one ounce; honey of roſes, two ounces; mix all together. Theſe are to be injected at every dreſſing, and the opening of the fiſtula muſt afterwards be kept cloſed, to keep them in its cavity for ſome time, which will much haſten the agglutination of the part. If this method of cure does not ſucceed, recourſe muſt at laſt be had to the knife; and, indeed, in very many of theſe caſes, there is no great probability of relief from any other means, particularly where the fundus lies directly downward, or where the fiſtula takes ſuch an irregular courſe, that the fundus of it cannot, with any ſucceſs, be preſſed toward the opening. In this caſe there is no relief to be had, but by laying it open to the bottom. To do this, a grooved probe, or director, ſhould be gently paſſed down the fiſtula, and then directing the knife along the groove, the fleſh, and common integuments, are to be laid open, as far as is ſafe and neceſſary; a free paſſage is, by this means, given to the corrupted matter, and the part may be come at with the proper dreſſings. If the opening is attended with a large diſcharge of blood, as is frequently the caſe, the wound muſt be, at the firſt dreſſing, filled with dry lint, and afterwards it is to be dreſſed with the common digeſtive, with a ſmall mixture of the Ægyptian ointment, or with a little red precipitate, till the wound is perfectly cleanſed, and it may then be eaſily healed in the common way. *Heiſter*'s Surgery, p. 244.

Putrid Ulcers. When *Ulcers* become putrid or fetid, this accident ariſes either from a very bad habit of body in the patient, or elſe from the negligence and unſkilfulneſs of the ſurgeon.

The acrimony of the blood is by all poſſible means to be taken off in theſe caſes, and the *Ulcer* to be frequently dreſſed, and every time thoroughly cleanſed. When wounds are dreſſed but ſeldom, as will be the caſe after the ſharp engagements in an army, where great numbers have been wounded, it cannot happen, but that the injured parts, in many patients, will be annoyed with heat, putrefaction, and worms.

To prevent and remedy theſe, the wounds muſt be dreſſed with the Ægyptian ointment, mixed with Wurtz's brown ointment, or the phagedenic water may be uſed with great ſucceſs, as alſo red precipitate, either alone, or mixed with burnt alum, or with the common digeſtive. Theſe applications are to be continued till the fungous fleſh ſeparates from the bottom of the *Ulcer*; and while this is doing, it will be very proper to cover the part with lint, dipped in ſpirit of wine, which is a very powerful remedy againſt putrefaction.

When the putrid parts are caſt off, the cure will be perfected by the common means uſed in *Ulcers*; and where there are worms bred in the *Ulcer*, no particular cautions need be given againſt them, ſince the ſame applications anſwer the purpoſe, whatever reſiſts putrefaction, will alſo be found to deſtroy worms. *Ulcers* ſometimes prove, however, ſo very malign and obſtinate, that they will give way to none of theſe remedies; and in theſe caſes, though there be nothing venereal at the bottom, yet the only relief ſeems from a ſalivation. *Heiſter*'s Surgery, p. 248.

Running Ulcers. When ſtubborn *Ulcers* are attended with a large diſcharge, there is reaſon to apprehend that the blood abounds with too large a quantity of a thin acrimonious ſerum. This cannot be drawn off any way more properly than by cathartic medicines; theſe and diuretics are to be repeated as often as the ſtrength of the patient will conveniently permit, and he muſt be particularly cautioned againſt drinking too freely.

Millepedes, in any form, are very properly preſcribed to be taken internally in theſe caſes, as are alſo the eſſence of amber, myrrh, balſam of Peru, tincture of ſalt of tartar, tartarized tincture of antimony, and the like; large and frequent draughts of ſmall liquors are frequently the cauſe of theſe diſorders, and are therefore moſt carefully to be avoided; ſtrong ale, or old wine, ſhould be drank ſparingly at meals, and nothing between them.

Such meats are beſt, on theſe occaſions, as have feweſt juices in them, and are very well roaſted, and the external medicines muſt be thoſe which have the greateſt reputation as dryers.

The principal of theſe are lime-water, lapis calaminaris, tutty, chalk, maſtic, frankinſence, colophony, and native cinnabar; when any of theſe have been ſprinkled in fine powder upon the *Ulcer*, a plaſter of diapompholygos, or the like, is to be laid over it. *Heiſter*'s Surgery, p. 246.

Venereal Ulcers. Theſe are almoſt always ſituated either in the groins, after the ſuppuration of venereal bubo's, or elſe in the prepuce, frænum, or glans penis, which is uſually termed a *chancre*. In females they are frequently ſituated in the vagina, or labia pudendi, and in either ſex ſometimes in the noſe, palate, lips, fauces, tongue, and uvula; and ſometimes the os frontis, and other bones both of the head, and other parts of the body, are ſubject to them.

The great intention, in theſe caſes, is to expel the venereal poiſon by proper remedies; for one *Ulcer* of this kind, if neglected or ill-treated, will produce an univerſal pox. The internal medicines are principally calomel, mixed with purging medicines; and in the intermediate times, decoctions of the woods, with tincture of antimony, and the like; theſe laſt are to be taken before riſing in the morning, to bring on a gentle ſweat, and may be repeated afterwards many times in the day. A ſtrict regimen of diet ought alſo to be obſerved; wine, and all vinous or ſpirituous liquors, are to be forbidden, and all aromatics, ſpices, ſalt, and acrimonious or acid things, are poiſon to perſons in theſe caſes: If ſuch a regimen, and a courſe of theſe medicines, will not effect a cure, ſuch quantities of mercury muſt be ſent into the blood, as will raiſe a ſalivation, by which both the *Ulcers* and the pox, which was the cauſe of them, will be cured at the ſame time. When the

Ulcers are ſituated in the mouth, uvula, fauces, or tongue, the patient ſhould frequently uſe a gargle, made of decoctions of the woods, and ſweetened with honey of roſes, and the *ulcerated* part ſhould be frequently touched with honey of roſes, acidulated with ſpirit of vitriol, and, after this, they may be healed with eſſence of myrrh, amber, or with oil of myrrh made per deliquium.

When the *Ulcers* are on the external parts, they muſt be dreſſed either with the common digeſtive, or with baſilicon, with red precipitate mixed in them; and theſe dreſſings are to be covered, and kept on by a mercurial plaſter; and when they are thoroughly cleanſed, they may be healed in the ordinary way.

Another excellent medicine for cleanſing theſe *Ulcers*, is the phagedenic-water, or, in its place, lime-water, impregnated with calomel; either of theſe may be applied every day many times, and the parts may be, when neceſſary, touched with the cauſtic; and when they are thoroughly cleanſed, they may very ſucceſsfully be healed, either with an ointment made only of crude mercury mixed with turpentine, or with the following: Take of the diapompholygos ointment, and crude mercury, killed with a ſmall quantity of Venice-turpentine, of each equal quantities; mix them in a glaſs mortar into an ointment, or take of the amalgama of lead and tin an ounce, of bole armenic two ounces; mix theſe, and make them into an ointment, by mixing with them a ſufficient quantity of ointment of roſes, or any other ſimple ointment, in a glaſs mortar. If there be at the ſame time a caries of the bone, which is indeed too frequently the caſe, that is to be dreſſed with euphorbium, oil of cloves, phagedenic-water, or ſpirit of nitre with quickſilver diſſolved in it; or, if it can conveniently and ſafely be done, the actual cautery is of ſignal ſervice.

Sometimes, when theſe *Ulcers* fall on a ſoft part of the body, as the groin, they throw out continually ſo large a quantity of lymph, that all the medicines that can be invented or applied, are of no conſequence to ſtop it. This accident is occaſioned either by the rupture or eroſion of ſome of the lymphatic veſſels. In this caſe the ſurgeon ought to try what can be done by proper compreſſes, and a tight bandage; but when theſe, and the other milder applications are of no ſervice, the actual cautery muſt be employed, but with great care and caution to the vitiated parts.

If venereal *Ulcers* of the penis and glans are negligently or unſkilfully treated, an univerſal pox is very frequently the conſequence; the urethra will, in theſe caſes, be often perforated in various places, and the urine will be diſcharged through it, as through a ſieve; and ſometimes the whole glans, or penis itſelf, will be either totally eaten off, or ſo miſerably affected with ſchirruſes and cancers, that the ſurgeon is obliged to extirpate them with a knife. When the noſe is affected by theſe *Ulcers*, it is very frequently entirely demoliſhed by them; ſometimes the palate, with its bones, are ſo eroded and perforated, that an open communication is made between the mouth and noſtrils, and the fluid part of the aliment, in eating, is thrown out by the noſtrils. Theſe paſſages can ſcarce ever be perfectly covered again by fleſh; but when the extremities and edges of them are healed, they may be cloſed with a ſmall plate of ſilver or gold. The tonſils alſo, the external coat of the uvula, and frequently the whole uvula itſelf, are alſo deſtroyed by the virulence of theſe ulcers: And laſtly, the cranium itſelf, particularly the frontal bone, is frequently ſo eroded and perforated by a caries, that the brain lies bare, and the motion of the pulſation of the arteries may plainly be ſeen. 'Tis no wonder if the worſt of ſymptoms, and even death itſelf, follow this, if neglected, or improperly treated. *Heiſter*'s Surgery, p. 249.

ULCERS *in the Leg.* See the article LEG.

ULEX, in botany, the name by which Linnæus calls the plants named by Tournefort and other botaniſts, *geniſta ſpartium. Linnæi* Gen. Plant. p. 348. See the article GENISTA *Spartium.*

ULMARIA, *Meadow-Sweet*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the roſaceous kind, conſiſting of ſeveral petals, diſpoſed in a circular form. From the cup there ariſes a piſtil, which finally becomes a fruit, compoſed of ſeveral ſmall capſules arranged together in form of a head, each of a crooked ſhape, and each containing one ſmall ſeed.

Mr. Tournefort allows no other ſpecies of this genus, beſide the common *Ulmaria. Tourn.* Inſt. p. 265.

ULMUS, the *Elm*, in botany, the name of a genus of trees, the characters of which are theſe: The flower is of the campaniform kind, conſiſting of one leaf, and containing a great number of ſtamina. The piſtil ariſes from the bottom of the flower, and finally becomes a membranaceous or foliaceous fruit, of a heart-like ſhape, in the center of which there is placed a pear-faſhioned capſule, which is alſo of a membranaceous ſtructure, and contains a pear-faſhioned ſeed.

The ſpecies of *Elm*, enumerated by Mr. Tournefort, are theſe: 1. The common *Elm.* 2. The broad and rough-leaved *Elm.* 3. The leſſer *Elm*, with narrow and rough leaves. And 4. The ſmooth-leaved *Elm. Tourn.* Inſt. p. 601. See the article ELM.

ULNA (*Cycl.*)—*Cartilages of the* ULNA. The two ſigmoide cavities, in the upper extremity of the *Ulna*, are covered by a cartilage common to both, which is a little interrupted about the middle of the edges of the cavities, by the tranſverſe notches in this part of this bone. The inferior extremity, or ſmaller head of the *Ulna*, is cruſted over by a cartilage round its cylindric border, in the notch near the ſtyloide apophyſis, and for ſome ſpace on the apophyſis itſelf. The cartilage which covers the head of the radius, is alſo ſtretched over the cylindric border thereof, and the lateral portion of the muſcular tuberoſity immediately below the neck, is alſo covered by a thin ſhining cartilage. The lateral half-grooves or channels, at the baſis of this bone, appear likewiſe to be cruſted over with a cartilaginous matter: But this may poſſibly be only from portions of the annular ligaments. *Winſlow*'s Anatomy, p. 140.

ULNARIS *Externus*, (*Cycl.*) a long muſcle, lying on the outſide of the fore-arm, fleſhy toward the os humeri, and tendinous toward the carpus.

It is fixed above to the external condyle of the os humeri, being there united to the anconæus minor, to the annular ligament of the head of the radius, and to the upper half of the external angle of the *Ulna*; from thence it advances and forms a tendon, which paſſes through the external notch, at the lower extremity of this bone, on one ſide of the ſtyloide apophyſis. The tendon, after having paſſed under a particular ligament, ſituated near the os cunieforme of the carpus, is inſerted in the outſide of the baſis of the fourth metacarpal bone; ſending ſome tendinous filaments to the baſis of the little finger; it is likewiſe often fixed in the baſis of the third metacarpal bone. *Winſlow*'s Anatomy, p. 192.

This muſcle is alſo called *cubitalis externus*, and it is named by Cowper, *extenſor carpi ulnaris.*

ULNARIS *Graciiis*, a muſcle called by ſome, *palmaris longus.* It is a ſmall muſcle, lying between the os humeri and the carpus, on the inſide of the fore-arm.

Its body is ſmall and ſlender, and its tendon very long and flat. It is fixed by its fleſhy portion in the ſmall cryſta of the inner condyle of the os humeri, ſometimes cloſely united to the *ulnaris internus*; from thence it runs down fleſhy for ſome ſpace, turning a little obliquely toward the middle of the fore-arm, and ends in a long narrow thin tendon. This tendon paſſes down the middle of the fore-arm, over all the other muſcles, to which it ſlightly adheres, and advancing over the large internal annular or tranſverſe ligament of the carpus, is inſerted in the ſurface thereof, ſending off ſome radiated filaments to the aponeuroſis palmaris. This muſcle is ſometimes fixed to the condyle of the os humeri, by a tendon about a finger's breadth in length, to which the fleſhy body joins toward the middle of the fore-arm. The inferior tendon is alſo ſometimes inſerted in the os ſcaphoides of the carpus, without communicating with the large annular ligament; and ſometimes the aponeuroſis palmaris ariſes from this ligament. From all which variations it may reaſonably be concluded, that that aponeuroſis has no eſſential dependance on this muſcle; and ſometimes this muſcle appears to be only a production from the *ulnaris internus. Winſlow*'s Anatomy, p. 193.

ULNARIS *Internus*, a long muſcle, fleſhy at its upper extremity, and tendinous at the other, ſituated on the outer part of the *Ulna.* It is fixed in its upper part, in the backſide of the long or internal condyle of the os humeri, in that part of the olecranium which is next the condyle, along the upper half of the *Ulna* very nearly, and to the middle common tendon of the neighbouring muſcle, commonly termed the *profundus.* It runs in the direction of the external angle of the *Ulna*, and ends by a long tendon in the os piſiforme, or orbiculare of the carpus, reaching likewiſe to the os unciforme, being united to the ligament common to theſe two bones. *Winſlow*'s Anatomy, p. 191.

This muſcle is alſo called *cubitalis internus*, and is named *flexor cubiti ulnaris* by Cowper.

ULOPHONUS, in botany, a name given by the antients to a poiſonous plant, ſince called the *chamæleon thiſtle*, and even at that time known to Dioſcorides, Galen, and others, under the name of the *black chamæleon thiſtle.* The white plant of the ſame name, or the *ixias chamæleon*, ſo called from its yielding a gum like maſtic, but of a viſcous texture while moiſt and freſh, was an eſculent plant.

The antients have taken great care, in all their writings, to expreſs which of the two chamæleon thiſtles they mean, when they uſe the word; but the giving it an abſolutely diſtinct name, or preſerving to it the name chamæleon, and giving to the black kind an appellation wholly different, ſuch as this of *Ulophonus*, mentioned by Pliny, ſeems much better than the diſtinguiſhing them by epithets, which we find, however well underſtood at the time when they were uſed, never proved ſufficient to prevent errors and confuſion in after-writers. See the article IXIAS.

ULPHA, a term uſed by ſome authors to expreſs the muddy ſubſtance which falls off from whetſtones, grindſtones, and the like, which is ſometimes ordered in medicines among the chemical

chemical writers, and is only the communicated particles of the ſtone, with a very ſmall portion of iron abraded from the things ground on them.

ULPICUM, in botany, a name by which Columella, and ſome other authors have called the *allium*, or garlick. *Ger.* Emac. Ind. 2.

ULRACH, a name given by ſome writers to the *ſanguis draconis*, or dragon's blood.

ULVA, a name given by ſome botanical authors to a genus of imperfect plants, conſiſting of the common oyſter-green, the ſea-chitterling, and the like, which have been ſince called by Dillenius, *tremellæ*. See the article TREMELLÆ.

The word *Ulva* is frequent in Latin authors; but its ſignification has been much controverted. Some have been of opinion that it expreſſed the Cyprus graſſes, others the cat's-tail, and others other particular plants; but it rather ſeems that the antients uſed it as a word expreſſive of all plants that grew by river or water-ſides; Pliny, having called the ſagitta, or water-arrow-head, one of the *Ulvæ*; and others, having expreſſed the bur-reed, ruſhes, and many of the common water-plants, very different from one another, by the ſame name. Bauhine makes the *Ulva* a purple ſea-moſs allied to the alga. *Dillen.* Hiſt. Muſc. p. 4.

It is ſuppoſed by ſome, that *Ulva* is a name uſed by the antients for the hop; but it happens only in one author, that is, Cato[a], and there is certainly owing to an error of the preſs, not to any intention of the author. He mentions the hop as a plant climbing upon the willows, and by its branches affording a good ſort of litter for cattle; and this by the name of *Ulva*; but as the word appears in no other author, it is reaſonable to ſuppoſe, that it is an error of the copiſts for *upulus*, which was the old name for the hop, the adding of the initial L being only of later times. Pliny, in the ſame manner, calls the hop *lupus*, by a like error of the tranſcriber.—[a *Cato* de Re Ruſt. c. 38.]

ULULA, in zoology, the name of the grey owl, called alſo *ſtrix cinerea*. It is a very light bird for its ſize, being very thick covered with feathers, and has a ridged circle of feathers, compoſed of two rows, round its face. And there is, within this, another greyiſh circle, compoſed of ſlenderer and more diſtant plumes, which ſurround the eyes. It is of a mottled colour, mixed of a grey and brown, and is feathered nearly to the feet. It has alſo ſeveral long black ſtreaks on the breaſt, and the inner circle of the face is variegated with no other colours than brown and white. *Ray*'s Ornithol. p. 66.

UMBER (*Cycl.*)—UMBER, or OMBER, in zoology, an Engliſh name for a fiſh of the truttaceous kind, more commonly called the *greyling*, and by the authors in ichthyography, *thymallus*, a freſh-water fiſh of a very fine taſte. *Willughby*'s Hiſt. Piſc. p. 187. See the article THYMALLUS.

UMBER, in natural hiſtory, an earth of the ochre kind, uſed in painting. It is found in Ægypt, Italy, Spain, and Germany; but what we have brought into England is principally from different parts of the Turkiſh dominions. But it might be found in conſiderable plenty alſo in England and Ireland, if properly looked after, ſeveral large maſſes of it having been thrown up in digging on Mendip-hills in Somerſetſhire, and in the county of Wexford in Ireland.

The characters by which it is known from other earths, are theſe: It never conſtitutes a ſtratum of itſelf, as the generality of other earths do, but is found ſometimes in ſmall lumps among gravel, and other looſe matter, and ſometimes in the perpendicular fiſſures of the ſolid ſtrata. It is of a cloſe compact texture, yet very light, of a ſmooth ſurface, and of an elegant pale brown, in different degrees. It is ſmooth and ſoft to the touch, and adheres firmly to the tongue, breaks eaſily between the fingers, and ſcarce at all ſtains the hands, and makes no fermentation with acids. *Hill*'s Hiſt. of Foſſils, p. 63.

UMBILICAL (*Cycl.*)—UMBILICAL *Vein*. Dr. Trew aſſerts contrary to Caſſerius, that the *umbilical* vein enters the liver towards the left part of it; and that there is but one *umbilical* vein, which empties itſelf into the left extremity of the *ſinus venæ portarum*, and ſends no branches to the liver. See Phil. Tranſ. N°. 457. Sect. 7.

Dr. Trew endeavours to ſhew how, after birth, the *umbilical* veins and arteries, ſeparating from the navel, gradually retract within their ſheaths, which they have from the peritoneum; and leave the ſides of the ſheath to grow together, as the ſides of the remains of the veſſels alſo do. Hence he infers, that the hæmorrhages, which ſometimes happen at the navels of adults, muſt not be from the *umbilical* veſſels, but from ſome other. Commerc. Norimb. 1737. Hebd. 13 §. 1.

UMBILICUS *Marinus*, a name given to a ſmall oval body of a ſhelly matter, from its reſemblance to the human navel. It is properly the operculum of a ſhell-fiſh, ſerving to cloſe up the aperture of the ſhell in the buccinum, and other turbinated ſhells; and to that purpoſe it is fixed to the anterior extremity of the body of the animal; ſo that when it retracts its body into the ſhell, this naturally fills up the mouth of it: it is convex on one ſide, and flat on the other; the convex ſide is plain and white; the flat ſide is yelloviſh or reddiſh, and marked with a ſpiral line.

It is ſaid by authors to have great virtues as an abſorbent and aſtringent; but is not uſed at preſent in the ſhops, though it holds a place in the catalogues of the materia medica, as well of our own as other nations. *Pitiſc.*

UMBINUS, among the antients, a kind of coin current in Gallia Narbonenſis.

UMBLA, or, as ſome write it, UMBRA, in zoology, the name of a fiſh of the truttaceous kind, and nearly allied to the ſalmon. There are four ſpecies of this fiſh mentioned among naturaliſts; but the *Umbla prior* and *Umbla altera* of Rondeletius, which are two of them, ſeem only to be the different ſexes of the ſame fiſh. Theſe are conſiderably large, very like the common ſalmon, but have blue backs and yellow bellies. The third is the fiſh commonly called the *ſalvelin*. See the article SALVELIN. And the fourth is the red charre. *Willughby*'s Hiſt. Piſc. p. 198. See the article CHARRE.

UMBO, in antiquity, the round protuberant part of a ſhield. See the article SHIELD, *Cycl.*

UMBRA (*Cycl.*)—UMBRA, in ichthyography, the name of a ſea-fiſh caught in the Mediterranean, and brought to the markets in Italy and other places; called by ſome *chromis*, and by the Venetians *corvo*.

Its uſual ſize at market is about twelve or fourteen inches in length; but it grows to ſixty pound weight, and to the length of five or ſix feet. It is of a ſomewhat flatted figure, and its back is ridged, and riſes up from the head. It ſomething reſembles the carp in its general figure, but is broader. It is very elegantly coloured, for there are a number of long oblique lines covering its whole ſides, which are alternately of a fine pale blue, and a beautiful yellow. Its ſcales are moderately large, and its coverings of the gills, and great part of its very head, as well as its body, are covered with theſe. Its head is moderately large, but its mouth ſmall, and it has a ſingle beard hanging down from its chin. *Rondelet.* de Piſc. p. 182.

UMBRATILIS *Pugna*, the fighting with ones own ſhadow. This was one of the kinds of exerciſe much recommended by the antient phyſicians; they ordered the perſons who uſed it, not only to box, but wreſtle, with his ſhadow; that is, not only to uſe his arms, but his legs alſo; and often to put themſelves into a leaping poſture, and throw their bodies violently forward, and often to retreat haſtily backwards. The cuſtom ſeems to have been of antient date; Plato expreſsly mentions it; and St. Paul ſeems to allude to it in that paſſage where, glorying in the reality of his conflicts, he ſays, he does not fight as one who beats the air. The phyſicians greatly recommended this exerciſe to people of ſedentary lives, and to thoſe who had weak nerves, and were afflicted with tremors. They eſteemed it uſeful alſo in diſeaſes of the kidneys, and of the thorax.

UMBRINO, in zoology, a name uſed by ſome authors for the *coracinus*, or *umbra*, as ſome call it. The *Umbrino* has by ſome been eſteemed a diſtinct ſpecies of fiſh from the coracinus; but they ſeem to differ no other way than as the one is the older, the other the younger fiſh. *Willughby*'s Hiſt. Piſc. p. 330.

UMBUNCULUS, in natural hiſtory, a name given by antient authors to the ſmall prominences in the ſurface of certain ſtones. It was originally derived from the word *umbo*, which expreſſes the prominent knob, or round lump in the center of a ſhield; and its firſt uſe that we find in the naturaliſts, is, in expreſſing a very ſimilar thing; that is, the prominent part of the zmilampis. This was a ſtone of the nature of what we call *oculus beli*, or *bellocchio*, and was of a white ground, and roundiſh figure, ſomewhat reſembling an eye. It was found in the Euphrates, and other rivers, and had always an *Umbunculus* of a glaucous or bluiſh colour. This *Umbunculus* was a prominent round ſpot, ſuch as we ſee in our *oculi beli*, and and call the *pupil*. It was afterwards uſed to expreſs the inequalities on the ſurfaces of flints and agates, which frequently are roundiſh and obtuſe, and repreſent a kind of umbones.

UMPLE, in our ſtatutes, ſignifies fine linnen. 3 Ed. 4. c. 5. *Blount.*

UNANNEALED *Bottles*, or BOLOGNA *Bottles*, a kind of *unannealed* glaſs bottles made at Bologna, and many other places, in the year 1742, which, though appearing very ſtrong, yet are to be broken by a fragment of flint, ſcarce larger than a grain of ſand, thrown into them. Acta Eruditor. 1745. p. 81. See the article *Unannealed* GLASS.

UNAROTA, among the antients, a carriage with only one wheel. *Pitiſc.* in voc.

UNCATA, in botany, a name given by ſome authors to the ſtramonium or thorn-apple. *Ger.* Emac. Ind. 2.

UNCEASESATH, in our old writers, an obſolete word, uſed where one killed a thief, and made oath that he did it as he was flying for the fact, and thereupon *parentibus ipſius occiſi juret* unceaſath, *viz.* that his kindred would not revenge his death; or they ſwore, that there ſhould be no contention about it. Leg. Ino. c. 37. *Blount.*

Du Cange derives the word from the negative particle *un*, and the Saxon *ceath*; which laſt ſignifies the ſame with *aſſithment* in the law of Scotland. See the article ASSITHMENT.

UNCERTAIN, in the manege. We call a horſe *uncertain*, that is naturally reſtleſs and turbulent; and is confounded in the manege he is put to; ſo that he works with trouble and uncertainty.

UNCIFORME *Os*, in the carpus, is the fourth bone in the ſecond row; it has its name from the Latin *uncus*, a hook, and is compoſed of a body, and a hooked or uniform apophyſis. This apophyſis, which is one of the four eminences on the concave or inner ſurface of the carpus, is flat, and the hollow ſide of its curvature is turned toward the os magnum. The outer ſurface of its body is rough, and in ſome meaſure triangular; it compleats the convex ſide of the carpus, and, toward the ulna, terminates in a ſmall tuberoſity, which is all the cubical ſide of this bone.

It has three articular or cartilaginous ſides, one radial, one brachial, and one digital. The radial ſide is double, anſwering to the cubital ſide of the os magnum. The brachial ſide is very oblique, ſome part of it being gently concave, the reſt gently convex, anſwering to the digital ſide of the os cuneiforme. The digital ſide is double, or diſtinguiſhed into two halves, by a ſigmoide angular line, for its articulation with the two laſt bones of the metacarpus. *Winſlow*'s Anatomy, p. 84.

UNCINUS, in ſurgery, the name of a ſmall hooked inſtrument ſerving to many purpoſes.

UNCTUARIUM, a room in the antient baths, where people were anointed before they went away.

UNCTORES, among the Romans, ſervants whoſe employment it was to anoint their maſter when he bathed. *Pitiſc.* Lex. Antiq. in voc.

UNCUS, among the Romans, an inſtrument uſed in torturing criminals. It was a kind of club bent and inclined to one ſide. *Pitiſc.* Lex. Antiq. in voc.

UNDE *Nihil Habet*, a writ of dower. *Blount*, *Cowel.* See the article DOTE *Unde nihil habet.*

UNDERWOOD, (*Cycl.*)—In the cutting the *Underwood* of coppices, when the ſtubs are great, they ſhould be ſtubbed up, for they only take up a great deal of room, and ſend up few ſhoots, their cracks and holes letting in water, and uſually half killing them. The taking up theſe ſhould be performed in winter, and the ſpaces they leave will be ſoon occupied by young trees, if not, a long branch of ſome neighbouring tree may be laid down, and will ſoon ſend up a ſufficient ſupply of ſuckers for the place.

In felling the *Underwood*, it is always proper to leave young trees enough. The worſt of theſe may be taken down the next fall, eſpecially if any of them grow near a great tree that will be fit to fell the next ſeaſon, becauſe they may be ſpoiled by its fall. When trees are at their full growth, there are ſeveral ſigns of their decay, as the withering or drying of their top branches; their taking in water at ſome of their knots, their being hollow or diſcoloured, and their making but ſmall ſhoots. If wood-peckers make holes in the body, it is a bad ſign, and according to the appearance of one or more of theſe ſymptoms, it is very proper to cut down the tree before it decays farther. Large and ſpreading trees in coppices are often of more miſchief than advantage, as they ſpoil a great deal of the *Underwood* by their droppings.

The owner of a coppice muſt be very careful when he ſells the wood ſtanding, by the acre, to mark beforehand what ſtandards are to be left, elſe the purchaſer ſeldom fails to cheat him, by felling ſome of them. *Mortimer*'s Huſbandry, vol. 2. p. 69.

UNDETERMINED, in mathematics, is ſometimes uſed for indeterminate. *Maclaur.* Algeb. p. 298. See the article INDETERMINATE, *Cycl.*

UNDIMIA, in ſurgery, the name of a kind of an œdematous tumour, the matter contained in which is glutinous and ropy, like the white of an egg.

UNDULAGO, in natural hiſtory, a name given by Mr. Lhuyd to a ſpecies of fungites found foſſile, and uſually of a ſort of undulated figure. See the article FUNGITES.

UNDULATED *Leaf*, among botaniſts. See the article LEAF.

UNDULATION, (*Cycl.*) in medicine, the term uſed by ſome to expreſs an uneaſy ſenſation in the heart, of an undulatory motion, which may ſometimes be perceived externally.

UNDULATION is alſo a word uſed by ſome authors to expreſs the riſing of the water of the ſurface of the ſea into waves. See the article WAVE.

UNDY, in heraldry. See the article WAVED, *Cycl.* and *Suppl.*

UNEDO, in natural hiſtory, a name uſed by the antients for a fruit which they recommend as cooling and ſub-aſtringent. The generality of the world are lead into a common error of believing this to be the fruit of the arbutus or ſtrawberry-tree. Pliny has given occaſion to this error, by ſaying expreſsly that the *Unedo* is the fruit of the arbutus; but we find this to be contrary to the practice of all the antient Latin writers, who have always called the fruit by the ſame name with the tree, not by a different one. Varro de re Ruſtica, ſpeaking of gathering the autumn fruits, calls them all by the name of the trees; and among them, mentioning the fruit of the arbutus, he expreſſes it in the ſame manner, not by the word *Unedo*, *decerpendo arbutum mora pomaque*: And both Galen and Paulus Ægineta deny the *Unedo* to be the name of the fruit of the arbutus or ſtrawberry-tree, and make it the fruit of the epimelis. Servius explains the word *Unedo* by the fruit of the ſtrawberry-tree; but in this he too raſhly follows Pliny's opinion, and plainly errs from the truth. See the article EPIMELIS.

UNGUENT (*Cycl.*)—UNGUENTUM *Album*, the white ointment, a medicinal preparation, well known by name, and much uſed in families.

The late London diſpenſatory has made very great alterations in it, and indeed given a new ointment under this name; it is there ordered to be made thus: Take oil-olive a pint, white wax four ounces, ſperma ceti three ounces, melt all together with a gentle heat, and ſtir them very briſkly without ceaſing, till they are fully cold.

The ointment, formerly known by this name, had ceruſs, or white lead, for its principal ingredient; but as this is principally intended for frettings of the ſkin, that ingredient was judged dangerous. *Pemberton*'s Lond. Diſp. p. 363.

UNGUENTUM *Baſilicum Viride*, a form of medicine preſcribed in the late London pharmacopœia. It is ordered to be made thus: Take of yellow baſilicon eight ounces, oil of olives three ounces, verdegreaſe in fine powder one ounce, mix the whole into an ointment. *Pemberton*'s London Diſp. p. 366.

UNGUENTUM *Nardinum*. See the article NARDINUM *Unguentum.*

UNGUENTUM *e Pice*, *Tar Ointment*, a form of medicine preſcribed in the late London Pharmacopœia, and ordered to be made in the following manner: Take of tar, and of tried mutton-ſewet, each equal quantities, melt them together, and and ſtrain the whole while it is hot. *Pemberton*'s Lond. Diſp. p. 368.

UNGUENTUM *Saturninum*, a form of medicine preſcribed in the late London Pharmacopœia, and ordered to be made in this manner: Take of oil-olive half a pint, white wax an ounce and half, ſugar of lead, firſt brought to a very ſubtile powder, with ſome part of the oil; then add this to the reſt of the oil, with the wax melted in it, and ſtir the whole till it is cold. *Pemberton*'s Lond. Diſp. p. 369.

UNGUENTUM *Simplex*, a name given in the London Diſpenſatory, to the compoſition commonly called *pomatum*; the manner of making which, is according to the method now univerſally practiſed, delivered there in the following manner: Take of tried hogs-lard two pounds, of roſe-water three ounces; pound the lard with the roſe-water, till they are well mixed; then melt the lard with a very gentle fire, and ſet it by awhile, that the water may ſubſide, afterwards pour out the lard, and leave the water; then ſtir and beat the lard without ceaſing, while it is growing cold, that it may be broke into as light and yielding a maſs as may be; and then add as much eſſence of lemons as will give it an agreeable ſcent. *Pemberton*'s London Diſp. p. 362.

UNGUENTUM *e Sulphure*, *Sulphur-Ointment*. Take of ſimple ointment half a pound, of flower of ſulphur unwaſhed two ounces, eſſence of lemons a ſcruple. This is the preparation ordered in the late London Diſpenſatory, and expected to be kept ready mixed in the ſhops. *Pemberton*'s London Diſp. p. 370.

UNGUENTUM *Veſicatorium*, *Bliſtering Ointment*, a form of medicine preſcribed in the late London Pharmacopœia, and no other than bliſtering plaſter in a ſofter form. It is made by equal quantities of hogs-lard and bliſter-plaſter, with a very gentle heat, ſtirring them till they are cold. *Pemberton*'s Lond. Diſp. p. 371.

UNGUENTUM *Viride*, the *Green Ointment*, a form of medicine preſcribed in the late London Pharmacopœia, and ordered to be made by melting ten ounces of yellow wax in three pounds of the *oleum viride*, or green-oil, of the ſame pharmacopœia. *Pemberton*'s Lond. Diſp. p. 371.

UNGUICULI, in botany, is uſed for the ends of the petals of roſes, or other flowers, where they adhere to the plant.

UNGUIN, in botany, a name given by the people of Guinea to a plant, of which they are very fond, for its medicinal virtues: They boil it in water, and give the decoction in large draughts for pains in the back. The leaves of this plant grow alternately on pedicles of an inch long, and have the exact ſhape and ſize of thoſe of the common bay-tree; but they have neither its taſte nor ſmell, nor any thing approaching to either. Phil. Tranſ. N°. 232.

UNGUIS (*Cycl.*)—The nails both of the fingers and toes are ſubject to very great diſtemperatures in their growth. We have, in the Philoſophical Tranſactions, an account of a young fellow, whoſe finger ends were, as it were, armed with horns inſtead of nails; they grew to a very amazing length, but then would wear away, or drop off at the ends. The horny excreſcence on the thumb was the longeſt on each hand, and next to it was that of the middle finger, the reſt being gradually ſhorter; his feet were well armed with the ſame ſort of weapons, only that the two little toes had none of them.

Theſe horns ſeemed to owe their origin to a thickening of the body of the nails, which, inſtead of growing out in length in the common way, elevated themſelves in height from the back; and when they had riſen to a certain height in this direction, they turned downward, and became crooked, ſo as to repreſent a bird's claw, only that it was not taper and ſharp, but all of the ſame thickneſs, and blunt at the end. The upper or convex part of each was marked with a great many chaps, but the concave or under part was ſmooth.

The lad had no ſenſe in thoſe parts of the horns which were at a diſtance from his fingers; but they might be cut or pulled any way, without giving him pain; when they were moved near the roots, where they joined the finger, the pain was very great. The back of his hand was full of horny ſubſtances, of a like texture with theſe, but not elevated above the ſkin; they had the appearance of broad and flat warts, but were much larger and harder. The diſeaſe ſeized the lad after the ſmall-pox. The common length of theſe horns on his fingers was between three and five inches. Phil. Tranſ. N°. 229.

UNGUIS *Odoratus*, in the materia medica, a thin flat teſtaceous ſubſtance, of an oval or oblong figure, rounded at both ends, and marked on the ſurface with three or four concentric circles, or oval lines. Its colour is a duſky brown, with ſome admixture of the orange, ſometimes of a purpliſh tinge. Its uſual ſize is that of a full grown nail of a man's thumb; and its thickneſs rather leſs than that of the nail. It is tough, flexile, and elaſtic; and has no peculiar ſmell or taſte.

The want of ſmell might ſeem to argue this to be a different ſubſtance from the *Unguis odoratus* of the antients; but the truth is, that theirs owed all its ſweet flavour to its being brought over among aromatic drugs.

There were two kinds of it, the largeſt of which they had from the red-ſea, and the other from Babylon; and both were the opercula of two ſpecies of murex-ſhells. See the article MUREX.

Dioſcorides tells us that this *Unguis* was the operculum or poma of the ſhell, which ſtopped the mouth at pleaſure, and from under which the creature thruſt out its tongue to feed; and he adds, that the ſhell-fiſh to which it belonged was taken in the marſhes of India, when the waters were dried away; and that the Indian ſpikenard growing in great abundance in theſe marſhes, the creature became ſweet-ſcented in every part, by feeding on it. But in the latter part of his account he ſeems to forget the beginning; for he concludes with telling us, that there were only two kinds brought into Greece in his time, the one from the Red Sea, the other from Babylon.

The truth is, that ſpikenard grows neither in the Red Sea, nor any where about Babylon, but only in India beyond the Ganges, or about its banks. The ſpikenard alſo does not grow in the water, but only in marſhy places, and therefore can never be in the way of feeding ſhell-fiſh. Nay, this very author, in his deſcription of the ſpikenard, tells us, that it grows on mountains, and that the ſpikenard which grows in wet places, is another kind, and not the fine aromatic ſpikenard ſo valued in the ſhops; even the laſt kind, however, could not ſerve for the feeding the fiſh neither; for he ſays, that it grows in wet or moiſt grounds, but not in the water.

From this, and ſome other ſuch paſſages, it appears that Dioſcorides was an author too much of Pliny's ſtamp, and collected his accounts of things from different authors, and that without a ſufficient knowledge of the ſubject; ſo that he often contradicts himſelf. As to the Indian ſpikenard, Garcias tells us, that it is not produced wild, but is a cultivated plant, raiſed by ſowing the ſeeds in gardens, not under water. Aviſenna ſeems to have ſeen this abſurdity in Dioſcorides, about the ſhell-fiſh feeding under water on the ſpikenard, and though he tranſlates the account of his *Unguis odoratus*, or *adſer althaib*, *verbatim* from Dioſcorides in other parts, yet he here alters the ſenſe, and ſays, that the ſhell-fiſh was found in an iſland in the Indies, on which iſland the ſpikenard alſo grew in great abundance.

This, however, is but avoiding one error by another; for though, by this, he gets over the abſurdity of the ſpikenard's growing under water; yet he falls into a much worſe, which is, of the ſhell-fiſh to which the *Unguis odoratus* belongs, being found on dry land.

It is very certain that no ſhell-fiſh, living in the water, can ſubſiſt, without ſome means of cloſing up its cavity, ſo as to keep out the water at pleaſure; this is done in the bivalve kinds, by cloſing the two valves; but in the ſtromboide ones, by drawing down this operculum, which is the *Unguis odoratus*, to the mouth of the ſhell. A land-ſhell therefore can have no occaſion for ſuch a part as the poma or operculum, and no ſuch drug as the *Unguis odoratus* can be found about it. But it is to be obſerved, that Aviſenna did not know that the *Unguis odoratus* was a covering or operculum of the mouth of a ſhell, but thought that it was only a fragment cut or broken indeterminately from any part of the ſhell. This therefore might appear no abſurdity to him, and the thin and flat *Ungues* he ſaw might appear fragments artificially cut from ſome of the thin-ſhelled kind of land ſnails.

UNGUIS *Oſſa*, in anatomy, are two bones which help to compleat the internal ſides of the orbit of the eye, to cover the fore-part of the labyrinth of the noſe, and form the lachrymal duct.

They have their name from the Latin *Unguis*, a nail of the hand, and are alſo, by ſome authors, from their office in forming the lachrymal duct, called *oſſa lachrymalia*.

They are each ſituated in the orbit of the lower part of the internal angle; they are the leaſt bones of the face, and are very thin and tranſparent. They are in ſhape ſomewhat longer than broad, and not unaptly reſemble the figure of the finger nails, eſpecially while in their natural places; for, being taken out of the ſhell, their figure becomes ſomewhat more irregular. Each of them is divided, by anatomiſts, into two ſides, the one external, the greateſt part of which appears in the orbit in an entire ſkull; the other internal, which is hid; two extremities, the one upper, the other lower; and two edges, one anterior, the other poſterior. The outſide is ſmooth, and a little concave; toward the anterior edge is a groove full of ſmall holes like a ſieve, called the lachrymal groove. It begins at the upper extremity, and runs down lower on this ſide than any other part of the bone, the lower extremity of it being hid by the os maxillare. It is diſtinguiſhed from the reſt of the outſide by a very ſharp prominent edge. The inſide is rough and unequally convex, with a perpendicular depreſſion anſwering to the ſharp prominence on the outſide. On the upper part of this inſide, ſmall portions of cellulous laminæ are ſometimes obſervable, which communicate with the entry of the frontal ſinus; and there are likewiſe ſome about the middle, which compleat the anterior ethmoidal cells; and others toward the lower end, which communicate with the rugged portions of the upper border of the ſinus maxillaris: theſe, however, often vary, and are ſometimes wanting. Theſe bones are altogether without diploe; they are connected with the os frontis, and with the os ethmoides, covering a part of the cells in that bone, with the naſal apophyſes of the os maxillare, and with the groove of that bone in ſuch a manner, that the two grooves, joined together, form an entire tube, called the lachrymal duct; they alſo cover a little the opening of the maxillary ſinuſes, and join the inferior conchæ of the nares, of which they appear to be only a continuation in advanced age. *Winſlow*'s Anatomy, p. 36.

UNGUIS *of a Flower*, among botaniſts. See the article PETAL.

UNGUIS, in natural hiſtory, a name given by authors to a genus of ſhells, called more uſually *ſolenes*. See the article SOLEN.

UNGULA *Oculi*, the name given by ſome to a diſeaſe of the eye, called by others *pterygion*.

UNGULUS, in antiquity, a remarkable kind of bracelet. *Hofm.* in voc. See the article BRACELET.

UNHALTER, in the manege. A horſe is ſaid to *unhalter* himſelf, that turns off his halter. See the article HALTER.

UNICORN (*Cycl.*)—*Sea* UNICORN, in natural hiſtory, the name of a fiſh of the whale kind, remarkable for having a horn growing out at its noſe, in the manner of the ſuppoſed *Unicorn*'s horn, as deſcribed by many too credulous authors.

This fiſh feeds on fleſh, or other fiſh, and is not only found in the main ſea, but ſometimes gets up into large rivers. In the year 1636 there was a large one caught in the river Oſte, near its diſcharging itſelf into the Elbe, in the duchy of Bremen; this place is four German miles from the ſea. The ſkin of this fiſh was ſpotted with dark brown ſpots upon a white ground, the epidermis was tranſparent, and under it was another ſkin very thin and ſpotted; but the true ſkin was brown, and near an inch in thickneſs. On the top of the head there is only a ſemilunar hole, as in the porpoiſes; this hole opens into the two channels, which run through the ſkull to the palate, and are called the ductus hydrogogi. The people who examined this creature, were not able to find any aperture in the body for the diſcharge of the excrements; whence it has been generally believed, that the creature voids them through this paſſage in the head.

Authors have differed in the name of the proceſs iſſuing from the head, ſome calling it a horn, others a tooth; ſome are of opinion that it ſerves it to break the ice with for air; but others pretend that it is an offenſive weapon, with which it wounds the common whale, and other large fiſh; and that when it has plunged it up to the head in the whale's body, it ſucks the juices of that animal. See Tab. of Fiſhes, N. 1.

The fiſh was near twenty foot long, and about four foot in diameter. The horn ſtood on the fore-part of the head, juſt above the mouth, and was ſix foot long, white like ivory, and curiouſly wreathed or twiſted. The body was ſmooth and ſlippery, like that of an eel; the head, in proportion to the body, was ſmall, not exceeding ſixteen inches in length; the eyes not larger than a ſix-pence. It had, on each ſide of the neck, two black fins, one above, another at a ſmall diſtance; theſe were two foot long, of the breadth of a hand, and about half an inch in thickneſs. Phil. Tranſ. N°. 447. p. 149.

Unicorn's horn has been ſo common in the Daniſh and neighbouring ſeas, that there was a magnificent throne built only of them in that kingdom; the horns are from ten to fifteen foot in length, and are all white, and furrowed with a ſpiral line. They are the horns of that kind of whale called *narwal*, or the ſea-*Unicorn*. *Brown*'s Travels.

Unicorn's horn has the ſame medicinal virtues with hart's-horn and ivory; but at preſent is only kept as an ornament to druggiſt's ſhops.

Sea-UNICORN is alſo a name given to two ſorts of ſmall fiſhes caught in the American ſeas, and known among authors under the name of *monoceros piſcis*. See the article MONOCEROS.

UNICORNU *Foſſile*, *Foſſile Unicorn's Horn*, the name of a ſubſtance much uſed in medicine in ſome parts of the world, but which ſeems to have been very little underſtood by many who have written of it. Dr. Hill, from the examination of the

ſeveral varieties of ſhapes it is found in, and trying it by the ſeveral teſts which fix the criterions of foſſils, has determined it to be no other than a terrene cruſtaceous ſpar, not very different from the oſteocolla, and other bodies of that genus, which he has called the *cibdeloplacia*; and has diſtinguiſhed this peculiar ſpecies by the name *cibdeloplacium albido-ſubcinereum, friabile ſuperficie lævi*, or the whitiſh-grey friable cruſtaceous ſpar, with a ſmooth ſurface.

It differs principally from the oſteocolla in its ſoftneſs and the ſmoothneſs of its ſurface; but from its having, like many other of the cruſtaceous terrene ſpars, the property of encruſting, and ſometimes even permeating the pores of bodies, and in a manner petrifying them, it has obtained the names of the things it thus lodges itſelf in and about, which being uſually bone, and ſome of them bones of an extraordinary ſize and figure, have been taken for the bones and horns of *Unicorns*; and the name and nature of the body itſelf wholly loſt and neglected, and that of the horn, with that of its imaginary animal, only preſerved.

They are, however, now ſenſible in Germany, that it is not the horn, but this ſubſtance which is lodged about it, which is the medicine; for they never uſe the foſſile bones, which are petrified in the common way, but only ſuch as are impregnated with this ſparry ſubſtance; and even uſe all ſubſtances whatever, which are impregnated with this, whether bones or wood, under the ſame name, calling the natural tubular pieces of it, which are very common, and alſo the pieces of branches of tree impregnated with it, by the common name of *Unicorn's horn*, while they allow plain bones, petrified in the common way, no ſuch name. So that the word is now become a mere technical term, and ſignifies either this ſpar in its pure ſtate, or any ſubſtance whatever which is impregnated with it.

It is a lax and ſpongy terrene ſpar, and is naturally of a regular form, in ſome degree like that of the oſteocolla, being always found, where it has concreted pure and not been in the way of any extraneous ſubſtance, an oblong and moderately thick cylindric tubular body, frequently narrower at one end than the other, and approaching to a conic form. Uſually its hollow is empty, but ſometimes it is found filled up with a ſubſtance of the ſame nature with itſelf, only compoſed of a larger proportion of earth with leſs ſpar, and therefore more crumbly and ſoft. Theſe are found of various ſizes, from an inch to three feet long. The larger ſpecimens are moſt frequent. And it is very probable, that the ignorance of the firſt ages, which brought it into uſe in medicine, might take theſe natural concretions for *Unicorns horns*.

It is found in other parts of the world beſide Germany, and is in great eſteem in many places as a ſudorific and aſtringent; and is given in fevers, attended with diarrhœas, with great ſucceſs. *Hill*'s Hiſt. of Foſſ. p. 361.

UNIFORM (*Cycl.*)—UNIFORM *Matter*, in natural philoſophy, that which is all of the ſame kind and texture.

UNILOCULAR *Capſule*, among botaniſts. See the article CAPSULE.

UNISETA, in natural hiſtory, the name of a ſpecies of fly, found frequently ſitting on the ammi or biſhops-weed, and inguiſhed by having one long hair or briſtle growing out at its tail. See the article HENOTHRIX.

UNITE, in the manege. A horſe is ſaid to *unite*, or walk in union, when, in galloping, the hind quarters follow and keep time with the fore. See the article SINEW.

UNITY (*Cycl.*)—It is to be obſerved in algebra, that *Unity* itſelf has three different expreſſions of its cube root, one real, and the other two impoſſible or imaginary. Thus the three cube roots of 1, are 1, $\frac{-1+\sqrt{-3}}{2}$ and $\frac{-1-\sqrt{-3}}{2}$.

This is ſometimes of uſe in finding the cube roots of quantities, appearing under impoſſible expreſſions. See *Maclaurin*'s Algebra, p. 128. ſeq.

The two impoſſible expreſſions of $\sqrt[3]{1}$ may be thus found: Let $x = 1$ then $x^3 = 1$ or $x^3 - 1 = 0$ and $x - 1 = 0$. Divide $x^3 - 1$ by $x - 1$ the quotient is $xx + x + 1 = 0$. Or $xx + x = -1$ reſolve this quadratic equation, by adding $\frac{1}{4}$ to both ſides. Then $xx + x + \frac{1}{4} = -\frac{3}{4}$, and extracting the ſquare root, $x + \frac{1}{2} = \sqrt{-\frac{3}{4}} = \frac{\sqrt{-3}}{2}$. Therefore $x = -\frac{1}{2} \pm \sqrt{-\frac{3}{4}} = \frac{-1 \pm \sqrt{-3}}{2}$. That is, $x = \frac{-1+\sqrt{-3}}{2}$ and $x = \frac{-1-\sqrt{-3}}{2}$. See *Maclaurin*, lib. cit. p. 226.

UNIVALVE *Shells*, in natural hiſtory, a term uſed to expreſs one of the three general claſſes of ſhell-fiſh; the other two are the bivalves and multivalves. The *univalve* ſhells are thoſe which conſiſt only of one piece, not of two or more joined together. Of theſe *univalve* ſhells, nature affords a very great variety; ſo that they are aptly diſtributed by a late French author into fifteen diſtinct genera. Theſe are, 1. The *patellæ*, or limpets. 2. The *patellæ planæ*, called alſo *auris marina*, the ear-ſhell. 3. The *canales*, or *tubuli marini*, the ſea-tubes. 4. The lunar cochleæ, or round-mouthed ſnails. 5. The *cochleæ ſemilunares*, or ſnails with ſemicircular mouths. 6. The *cochleæ ore depreſſo*, or flat-mouthed ſnails. 7. The *naviculæ* or boat-ſhells, commonly called *nautili* or *nautilus*. 8. The *buccina*, or trumpet-ſhells. 9. The *turbines*. 10. The *volutæ*. 11. The *rhombi*. 12. The *murices*. 13. The *purpuræ*. 14. The *conchæ globoſæ*. And 15. The *porcellanæ*, each of which ſee under its proper head, PATELLA, AURIS *Marina*, &c. Hiſt. Nat. Eclairc. part 2. p. 235.

UNIVERSAL (*Cycl.*)—UNIVERSAL *Equinoctial Dial*. See the article RING-*Dial*, *Cycl.*

UNIVERSAL *Problem*. See the article INDETERMINED *Problem*, *Cycl.*

UN POCO, in the Italian muſic, is often put before the terms *allegro*, *adagio*, *preſto*, *piano*, &c. Where it ſhews that the movement, with their direction, is ſomething leſs than it would otherwiſe have been, had this word been omitted. Thus *allegro* ſhews that the movement is to be made in a briſk and gay manner; and *Un poco allegro* the ſame, only in an inferior degree, and ſo of the reſt.

But if *piu* is put between *Un poco*, and the above-mentioned terms, then their uſual ſignification is a little increaſed, as *Un poco piu allegro* ſignifies a little more briſkly than *allegro* alone requires. The contrary of this happens if, inſtead of *piu*, the word *men*, or *meno*, be uſed, as *Un poco meno allegro*, i. e. a little leſs gayly than if *allegro* were alone. See the articles ALLEGRO, ADAGIO, PRESTO, &c.

VOARCHADUMIA, a kind of cabala, or ænigmatic art, relative to metals, which propoſes the exultation of gold by cementations, and other methods; among which charms made of the Hebrew letters have their place.

VOCA, in ichthyology, a name given by Gaza, and ſome other writers, to the fiſh called *boops* by the generality of writers. It is a ſpecies of the ſpari, and is diſtinguiſhed from the reſt by having four longitudinal parallel lines, of a bright yellow and white colour, reſembling gold and ſilver on its ſides. See the article SPARUS.

VOCATORES, among the Romans, were ſervants whoſe buſineſs it was to call the gueſts, receive them, and aſſign every one a place according to his dignity. *Pitiſc.* in voc.

VOCE *Sola*, in the Italian muſic, denotes a piece compoſed for a ſingle voice, generally accompanied with a thorough baſs on the harpſichord or organ, without other inſtruments. But if beſides that it is to be accompanied by other inſtruments, they add, *con violini*, with violins; *due violini, e violoncello, e baſſo per l'organo*, i. e. with two violins, a baſs violin, and a thorough baſs on the organ; *con violini o ſtromenti*, i. e. with violins, or inſtruments; *parti, con parti ſenza violini*, i. e. part with, part without violins, &c.

VIOLATICA, in medicine, a name given by authors to a ſort of wandering pain, attended with a tumor, and affecting, at different times, different parts of the body; it is by ſome accounted a ſpecies of the ſcurvy; by others, of the leproſy.

VOLATILE *Salts*. It is the opinion of many of the greateſt chemiſts, that our diſtinction of ſalts into fixed and *volatile*, is far from juſt, for that there are in nature no ſuch thing as fixed ſalts.

Tartar is generally allowed to contain as much fixed ſalt as any thing, yet this ſubſtance, treated by fermentation, in Langelot's method, yields all in *volatile* ſalt that it would otherwiſe have yielded in fixed, and leaves ſcarce any fixt at all. The ſame proceſs will have the ſame effect on the ſuppoſed fixed ſalts of moſt other ſubſtances; and upon this, and many other conſiderations, it appears highly probable, that our diviſion of ſalts into fixed and *volatile* is unknown to nature; there not being to be formally found in any body, before calcination, any fixed ſalt; but ſalts are in themſelves all *volatile*, though by the action of the fire they are apt to be colliquated among themſelves, and blended with the earthy parts, and by that means rendered fixed.

The diviſion of ſalts into acids and alkalis has much more reaſon for its foundation: Theſe are differences which really exiſt in them, and by means of theſe all fermentations, and all motions in natural things begin. Both theſe ſalts appear to be in their own nature volatile, and therefore eaſily reſoluble by the ſupervening ſalt of the air.

It appears that all vegetables, eſpecially the aromatic claſs, if they are any conſiderable time expoſed to the air, loſe their ſalts. The ſoundeſt wood, loſing its ſalts in proceſs of time, in the ſame manner moulders away.

Theſe are proofs that the ſalts of theſe bodies are in themſelves volatile, though they are all liable to be rendered fixed by the action of fire, by which means the acid and the alkali are blended together, and the mixture becomes fixed.

There is an old axiom among the chemiſts, that things volatile are rendered fixed by ſuch things as are fixed; and thoſe fixed are rendered volatile by ſuch as are volatile; but it appears from theſe proceſſes, when rightly underſtood, that this is an erroneous maxim, that two volatile things may fix one another; and two fixed things may become volatile together, according to the nature of the proceſſes by which they are treated. The common traders in timber are well acquainted with theſe properties of the ſalts of wood, though they know not the reaſons of them; and as the air or fire may alter or drive off the ſalts of timber, and ſo render it leſs firm and ſtrong, they ſink ſuch pieces under water as they would

preſerve a long time. When they are to place the ends of poſts in the ground, they, on the ſame principle, burn them a little, that the volatile ſalts, which would eaſily be conſumed by the moiſture of the earth, may be, in ſome degree, liquated and blended together by the heat, and be rendered ſo much the more fixed, as to be leſs eaſily affected by external accidents. Ship-builders, in ſome places, for the ſame reaſon, burn ſlightly all the timber that is to make the bottom of the veſſel, or ſuch part of it as is to be under water.

Another very familiar inſtance of the blending the two *volatile* ſalts, naturally given to all vegetables, is in the formation of ſoot. When wood is burning, there aſcends from it a ſmoak; in this ſmoak the two *volatile* ſalts of the wood are contained, and they coagulate one another into that body which we call ſoot, and from which they may be again ſeparated by art, and rendered viſible diſtinctly. Theſe ſalts continue aſcending, and forming ſoot, till the wood is reduced to aſhes; and what remain of them toward this concluſion of the operation of the fire, are blended together by it, and make what we call the common fixed alkali, a ſalt eaſily waſhed out by water.

The formation of the fixed ſalt being thus owing to the mixing together of the two *volatile* ones found in the plant, it is eaſy to conceive why we obtain more of it from ſound wood, than from ſuch as is rotten, and more from freſh plants, than from ſuch as have been dried. If the fixed ſalt exiſted as a fixed body in the vegetable, it could not be affected by the evaporation of the water in drying, or by the evaporating of whatever elſe evaporates in the decaying of wood. But as the ſalt itſelf, or its two conſtituent parts, though called fixed by us, and rendered ſo by fire, are really *volatile* while in the plants, it is no wonder that, being reſoluble by the ſalt of the air, they are carried off in the drying, and much more ſo in the decaying of wood; for the air, in this caſe, evidently penetrates all its parts; and hence it is, that as dry plants yield leſs fixed ſalt than freſh ones, ſo the ſame wood, which, while ſound, would have yielded a very large quantity of ſalt, yet being rotten, yields ſcarce any at all, though the ſame proceſs is obſerved in burning it.

We are indebted to the pains of Dr. Cox for a method of procuring a *volatile* ſalt from plants, a thing of conſiderable uſe in medicine, though ſo much out of the common road of the chemical analyſiſes that it was not diſcovered till about eighty years ago, and ſoon after reduced to practice, in a regular manner, by that phyſician.

The method is this: A quantity of the leaves of any plant are to be carefully ſtripped from the ſtalks in ſummer, in dry weather; lay them in a heap, preſſed hard together, and they will ſoon ferment and heat, and will be reduced to a pulpy ſubſtance. This is to be rolled into little balls, and put into a retort, and diſtilled; it will yield a thick liquor, of a ſtrong ſmell, and a large quantity of a black oil, of a balſamic conſiſtence. The liquor is to be ſeparated from the oil, and diſtilled over again in a tall glaſs cucurbit; a *volatile* ſpirit ariſes; this is to be rectified two or three times more, and then is not to be diſtinguiſhed from the ſpirit of harts-horn, urine, or other animal ſubſtances, by any trials. Philoſ. Tranſ. N°. 101. p. 4.

All plants that have ever been tried in this manner, yield this *volatile* ſalt diſſolved into the form of a ſpirit; and the very loweſt claſs of plants, the moſſes, and common graſs, yield it as well as any other. And it is remarkable, that the veſſels in which theſe operations are performed, have afterwards a ſmell like muſk, which all the cleanſing in the world, and even the expoſing them to the air, does not well clear them of. The caput mortuum left in the veſſels is much leſs in quantity than in the common diſtillations of a like quantity of the ſame plant; and if the plants have not been ſufficiently fermented before the diſtillation, there remains, after the firſt rectification of the ſpirituous liquor, a ſour water.

The *volatile* ſalt, thus obtained, is conſiderably more in quantity than the eſſential or the incinerated ſalt would have been in the common ways of preparing them; but thoſe plants which yield moſt fixed ſalt, always yield moſt *volatile* ſalt this way. And theſe volatile ſalts, when well rectified, do not differ from one another, though made from ever ſo different plants; but this is not wonderful, ſince the fixed ſalts alſo, and the vinous ſpirits of all plants are alike, when reduced to the ſame degree of perfection and purity. The herb, as it ferments, affords its natural ſmell at firſt very ſtrongly; after that it yields a mixed ſmell, between its own natural ſcent and an urinous one; and at the end, when it is nearly ready for diſtillation, the ſmell becomes urinous. In this operation, the urinous ſpirit and ſalt come over chiefly toward the end of the diſtillation, and are ſeen in form of white clouds, iſſuing very faſt out of the neck of the retort, and condenſing on the ſides of the receiver into little rivulets, or winding ſtreams of water.

Sage, winter ſavory, and ſome other of the aromatic plants, yield thin *volatile* ſalt, on the firſt diſtillation, in a dry form, coating over the inſide of the receiver on the upper part, and clogging the neck of the retort; and ſaffron, in digeſtion with ſpirit of wine, has been found to yield its ſalt in the ſame dry form.

The oils procured in this manner from fermented plants partake nothing of the nature of the peculiar plant, but are alike from all; they are thick as tar, and fœtid. If the plant be not well fermented, indeed, the oil will be clear, and leave the ſmell and virtues of the plants: But this is an error in the proceſs, and this oil comes at firſt; whereas the proper oil of this proceſs comes not till the laſt, with the ſalt. Thoſe plants which, in the common way of diſtillation, yield moſt eſſential oil, yield alſo moſt of this black thick oil in this proceſs.

The fatty, moiſt, and inſipid herbs, ferment much quicker than the other kinds: They become extremely hot in this fermentation, and loſe their peculiar qualities in it; the ſpurge loſes its milkyneſs, and the celandine its tinging quality; and the juices of thoſe which are naturally the moſt acrid and ſharp, become little more ſo than thoſe of others. The ſtinking plants, ſuch as the atriplex olida, are as ſweet in this proceſs as any other; and it is particular, that the monk's rhubard, and ſome others, which are as inodorous as any plant can be, in their natural ſtate, are as fœtid as human excrements, under this treatment: And it is remarkable, that the very greateſt heat of the fermentation of theſe plants, does not prevent their being ſtored with a ſort of maggots, which ſwarm in great numbers in thoſe parts of the fermented maſs, where the heat is ſo great, that a perſon cannot bear his hand in it.

It is to be conſidered, whether theſe animals may not afford the *volatile* ſalt attributed to the plants. The doctor does not ſeem to have conſidered this; but as they are ſaid to be very numerous in the maſs, it will be very neceſſary to try the effect of a diſtillation of ſome of this fermented matter, without theſe inſects; which might be done by covering the whole from the acceſs of flies: For though the Doctor ſeems to think they are equivocally generated there, it is certain that they owe their origin entirely and only to the eggs of flies. The Doctor ſeems to think they will of themſelves yield no *volatile* ſalt or ſpirit; but this is ſo different from the nature of animal bodies in general, that it may be this opinion was founded on too ſlight a trial. If the external air be excluded from plants, they will not ferment, and if they are put into a long-necked glaſs, and left open, they will, in a few weeks, become of a mucilaginous nature; and after ſtanding a year in this manner, they will yield a large quantity of urinous ſalt or ſpirit, but not a drop of oil.

Some moſſes, and other of the plants uſually called imperfect, yield a *volatile* ſalt on diſtillation, without previous putrefaction; and ſome ſeeds, though in themſelves inſipid to the taſte, have the ſame quality.

All theſe ſpirits and ſalts have the ſame properties and effects with the ſpirits of harts-horn and urine. They change ſyrup of violets, and many other vegetable tinctures green. They are diaphoretic, diuretic, and deobſtruent, and contrary in their nature to acids. They precipitate all metals diſſolved in acids, by breaking the force of thoſe acids, and when highly rectified, and mixed with ſpirit of wine as highly rectified, they make the offa alba of Helmont like all other *volatile* alkali ſpirits; they unite with acids, and thereby become armoniac or neutral ſalts. Phil. Tranſ. N°. 101. p. 7.

Chemical experiments abundantly prove that *volatile* ſalts are obtainable from all kinds of land animals, the amamphibious and ſubterraneous tribes, birds, fiſh, and reptiles, from alkaline vegetables alſo without putrefaction, and from all other vegetables, after putrefaction, as alſo from ſoot, horns, hoofs, and all refuſe animal and vegetable matters, ſuch as the pith of horns, urine, the blood of ſlaughter-houſes, *&c.* and theſe as pure and perfect as from harts-horn; and this affords a hint for the making *volatile* alkalies and ſal armoniac cheap in England. *Shaw*'s Lectures, p. 168.

The ſhootings of *volatile* ſalts are not limited like thoſe of the fixed and common ſalts, to any determinate figures, but, by various accidents are thrown into a great variety of pleaſing forms. Fanciful people have ſuppoſed the ſhootings of ſalt of hartſhorn, in the tops of the veſſels uſed in ſubliming it, to reſemble the horns of the deers; and that of vipers, to aſſume the figure of little crawling ſerpents; but all this is imaginary, and the things from which the ſalts are obtained have no power to determine their forms, which are governed by more vague principles; ſuch as the peculiar degree of heat, the temperature of the external air, and many other the like uncertain principles.

We have, in the Philoſophical Tranſactions, an account of a whole foreſt of moſt elegant trees painted in perſpective, in the head of a veſſel, by theſe bodies. The ſubſtances employed were ſal armoniac and pot-aſhes; theſe were mixed in equal quantities, and put into a tall glaſs body, which being placed in ſand, immediately on the approach of the heat, a large quantity of the ſalt was ſublimed in flowers in the common way; this was a proceſs from which nothing particular could be expected; but after ſome time the ſublimed ſalt began to aſſume a regular form, and the head of the cucurbit, which was very large, was filled with the repreſentations of trees ſo perfect and elegant, that a foreſt, delineated by the ableſt hand, could ſcarce come up to it.

The figures, though externally numerous, yet were very regular, and all reducible to three kinds; the pine, the fir, and one

one other tree. Theſe, though very exact and beautiful, could have no analogy with the ſubſtances out of which the ſalts were formed, the fir and pine kind yielding ſo little fixed ſalt, that they are never employed for this purpoſe, and the ſal armoniac belonging to no vegetable production at all. The ſame proceſs repeated ſeveral times afterward, both with the ſame ſalts, and with others of the ſame nature, never arrived at this perfection; and the whole beauty of this was loſt while the ſpectators were gazing on it, by the ſublimation of more of the ſalt, which filled up all the interſtices, and deſtroyed the figure. Phil. Tranſ. N°. 105.

The curious in theſe reſearches, who would extend the uſe of theſe ſalts to the compoſing ſal armoniac, and many other purpoſes, for the uſe of dyers, braziers, apothecaries, chemiſts, &c. may conſult Boerhaave's hiſtory of vegetable putrefaction, and his account of ſal armoniac, and compare with them the papers of Lemery and Geoffroy, in the memoirs of the Paris academy, on the ſubject of the preparation of ſal armoniac in the Levant, and the imitation of it in other countries.

VOLCANO (*Cycl.*)—Dr. Liſter is of opinion, that all the *Volcanoes* in the world are owing to that inflammable mineral called *pyrites*, or *mundic*, a ſubſtance conſiſting of ſulphur and iron, and found in great plenty in all thoſe mountains where the *Volcanoes* are found to break out.

The quantities of ſulphur continually ſublimed in theſe mountains, in the ſame manner as the common ſulphur is ſeparated by artificial fire from the pyrites in Germany, ſeems to prove this; and what farther evinces it, is, that the black or purple cinders thrown out of theſe *Volcanoes* in their moſt violent eruptions, and wholly differing from the calcined ſtones or pumice, will be attracted by the magnet, and ſhew that the whole is very much the ſame with that caput mortuum of the common pyrites, out of which we have extracted or burnt away the ſulphur.

That theſe *Volcanoes* were all kindled of themſelves, at or near the time of the creation, is probable; becauſe there is at preſent but a certain number of them known, and theſe have all continued burning at all times, from the earlieſt hiſtory, and none of them have ever been extinguiſhed wholly, or probably ever can be, any other way than by the ſubmerſion of the whole into the ſea. That they originally kindled of themſelves, by means of the pyrites they contain, is very probable, becauſe we find that the pyrites will kindle of itſelf, and there is no other apparent cauſe for their kindling; for if we ſuppoſe the ſun to have done it, the mountain Hecla ſhould have been excuſed, as ſtanding in a northerly and colder climate; yet this, by all hiſtory, ſeems to have burnt as long as the others.

That they were at firſt fired my man, is not probable, becauſe it would not be eaſy to conceive how that ſhould be effected, if attempted; and they are in places the leaſt likely ever to have been the habitations of man, being in the tops of the higheſt mountains. If we attribute the kindling them to lightnings, or earthquakes, we favour the Doctor's ſyſtem as much as in his own way; for all theſe he deduces alſo from the breath or exhalations of the ſame mineral, the pyrites, which when fired under ground make earthquakes, when in the air lightnings.

No ſubject in the whole mineral kingdom is ſo proper for the keeping up a fire for the many ages theſe mountains have been burning, as the pyrites. Nothing is ſo laſting a fuel, and, in general, other fuels become more or leſs laſting, as they partake more or leſs of its nature. Scotch coals have more of the bitumen in them, and leſs of the pyrites than others, and therefore they burn away quickly, and leave only white aſhes, without any remains of the pyrites. The common Newcaſtle coal burns more ſlowly away, becauſe it contains a far larger portion of the pyrites mixed with its bitumen, as is found by the ſulphureous ſmell it yields in burning; and the Sunderland coal, which contains moſt of all of this mineral, burns with a more ſulphureous ſmell indeed, but ſo ſlowly, that it is ſaid proverbially to make three fires. This burns to a heavy reddiſh cinder, much reſembling the caput mortuum of the pyrites, or the ſlags caſt out of the burning mountains, and contains ſo much iron, that it is freely attracted by the magnet.

There is, in Ireland, a ſort of coal more rich in the pyrites than all theſe, and ſeeming indeed to conſiſt in great part of it. This, conſequently, keeps up a greatly more durable fire than any of the others, and will remain twenty-four hours red-hot in the fire, without changing its ſhape. The riſe of the breath or effluvia of theſe pyrites into the air, and their taking fire there, may very naturally cauſe lightning and thunder there; and it is remarkable, that even the ſeemingly miraculous accounts of ſtorms of throwing down iron-duſt or iron-ſtones, inſtead of hail or rain, does not wholly diſcredit this ſyſtem; for iron being one part of the conſtituent matter of the pyrites, it is poſſible it may have been raiſed in a vapour with it, and when the ſulphureous part was fired and burnt away, it may have again concreted into a ſolid form, and in that form have falllen to the earth again. Phil. Tranſ. N°. 157.

The neceſſity of a ſubterranean fire is argued from various inſtances, and from various phænomena.

The places to which this fire is brought up to our view, are generally the tops of mountains; where it may have its free courſe through their cavities, and burn a length of time, without doing injury to any body.

The ſubterranean fire could not exiſt without a communication with the external air; and theſe *Volcanoes* in the mountains are the ſpiracles or air holes at which it receives the neceſſary ſupplies of it, and by which it communicates with it as much as is neceſſary for its ſupport. By theſe the neceſſary magazines of fire are kept in a due ſtate, and by theſe they diſcharge the ſmoak and foulneſſes with which they would otherwiſe be choaked up and extinguiſhed.

Europe affords five principal openings of this kind. Of theſe, the chief is Ætna, in the iſland of Sicily, a *Volcano* famous in all hiſtories. The next to this is Veſuvius, near Naples; then the Strongylus, and ſome others of leſs note in the Liparine iſlands; Hecla in the frozen region of Iceland, and the Chimæra in Greece. The *Volcanoes* of Aſia are not leſs numerous; there are ſeveral in the mountains of Perſia, and in the iſland of Ormuz. The pic of Adam, in the iſland of Ceylon, alſo burns at certain times: But the principal *Volcanoes* of this part of the world are in the Philippine and Molucca iſlands. Java and Sumatra alſo furniſh ſome in the center of their largeſt mountains. The iſland of Ternate affords alſo a *Volcano* on the top of a mountain very difficult of acceſs, but opening with a vaſt mouth, and very terrible when it burns.

The ſeveral violent eruptions of this mountain have given it, within the mouth or Crater, the appearance of an amphitheatre, formed for holding people at the time of ſome public ſhew, ſeveral circles appearing in it one above another, found with a ſort of regularity that is ſurpriſing. In Japan there are very numerous inſtances of the uſe that mountains ſerve to on this occaſion, many of the higher mountains of that iſland burning almoſt continually; and the little iſlands which lie ſcattered about in the ſame ſea have alſo many of them ſpiracles of the ſame kind in the tops of the mountains, ſeen principally in the night, when the abſence of the ſun's rays gives their faint fire leave to appear.

Whatever may be the number of theſe *Volcanoes* in Aſia, there is no part of the word that yields ſo many as America. In the kingdom of Chili alone there are fourteen very conſiderable *Volcanoes*, all placed in a regular order one by the other; and not a leſs number in Peru; theſe all burſt forth from the ſummits of thoſe vaſt mountains the Andes. In New Spain there are three very formidable for the fierceneſs of their burning.

The moſt extreme parts of the northern world are not free from theſe ſtore-houſes of fire. Authors tell us of no leſs than four of them in the moſt northern parts of Tartary; and we know that Greenland, and all the neighbouring country, has them. The *Volcanoes* of the Terra del Fuego are very well known, and it is indeed the general opinion, that farther north than we have yet penetrated there may be very many undiſcovered ones; and ſome authors have gone ſo far as to declare, that, were the cold no prevention, we ſhould not be able to come much nearer than we do to the ſouthern pole, for the number and fierceneſs of the burning mountains.

People who ſee but a little way into the œconomy of the univerſe, are apt to blame the author of nature for placing ſo many of theſe *Volcanoes* in the habitable parts of the world, and expoſing ſo many of the human ſpecies to periſh by them; but when the ſyſtem of nature is more clearly ſeen into, we find all the reaſon in the world to admire and adore the goodneſs of providence in the diſpoſition of theſe very things.

When it proved neceſſary to the ends of the creation of the world, that a fire ſhould be kept up within it, where could that be ſo well kept from doing us injury, as deep in the central parts; and when it was neceſſary that this fire ſhould have ſpiracles, or air-vents; where could they be placed more out of our way, than in the tops of the higheſt mountains, as we conſtantly and regularly find they are. The ſmoak, cinders, and other recrements of the fuel that ſupports the ſubterranean fire, are by this means diſcharged far above the heads of the inhabitants, and out of the way of doing them any harm; whereas, had theſe openings been on plain ground, the whole air the neighbouring nations breathed would have been infected with the ſtench, and ſickneſs bred with it, beſide the danger of firing their houſes and towns, and ſpoiling their cultivated lands with the vaſt quantities of cinders, aſhes, and other matters thrown up, which, as it is, falling on the barren ſides of the mountains, do no harm to any thing. The provident placing of theſe mountains near the ſea, either in iſlands, or on the coaſts of continents, is alſo a great benefit to mankind, as the redundant matter diſcharged is thrown into the ſea, and as there are, in general, higher winds nearer the ſea than farther from it, by which the ſmoak, and with it the malignant vapours of the burnt minerals, are diſperſed in the upper region of the air, and never deſcend in ſuch quantities as to do harm to the neighbouring inhabitants.

This giving vent to the ſubterranean pyrophylacia, ſeems one of the great ends of the origin of mountains, and the

other is their ſerving, as hydrophylacia or magazines of water. This is ſeen throughout the world, the rivers that water all the countries inhabited or habitable ariſing from chains of mountains placed in their middle, ſeemingly with this ſole intent; the Rhine, the Rhone, and the Danube, all ariſe from the Alps, the great reſervoirs of waters in Europe. The mountains of the moon, placed in the burning ſands of Africa, give riſe to the Nile and Niger, and other rivers large enough to ſupply that vaſt and ſcorched country; and in the ſame manner the river of the Amazons, and the other immenſe beds of water neceſſary to ſupply the vaſt continent of South America, take their origin from the mountains called the Andes. *Kircher*'s Mund. Subter. p. 75. ſeq. See the article MOUNTAIN.

We have an account of mount Veſuvius, and of the eruption from it in 1737, by the prince of Caſſano, in the Philoſophical Tranſactions, N°. 455. Sect. 1.

The matter thrown out flowed like melted lead, and moved about half a mile in an hour, which was an unuſual velocity. The trees, touched by this matter, immediately took fire, and fell. Glaſs in houſes was melted into a paſte.

The academy of ſciences of Naples made an analyſis of the matter thrown out in this eruption. From which it appears, that this matter contains iron; that it is ſpongy at top, and denſe toward the bottom; and, after growing hard, it retained part of its heat above a month. Damps were afterwards ſeen to ariſe in divers parts of the mountains. An ammoniacal ſalt, which gave an extraordinary coldneſs to water in diſſolving, was alſo found here. Ibid. See alſo Sect. 2. of the ſaid Number.

VOLKAMERIA, in botany, the name of a genus of plants, called by Houſton, *duglaſſia*, and *paliuro affinis* by Sloane. The characters are theſe: The cup is a one-leaved perianthium, of a turbinated form, very ſmall, and lightly indented in four or five places at the end. The flower is one-leaved, and of the gaping kind. The tube is cylindric, and of double the length of the cup. The limb is plain, and divided into five ſegments, which are turned toward each ſide, but gape principally one way. The ſtamina are four very long capillary filaments; the antheræ are ſimple. The germen of the piſtil is quadrangular. The ſtyle is capillary, and of the length of the ſtamina, or nearly ſo; and the ſtigma is bifid. The fruit is a roundiſh bilocular capſule, and in this is incloſed a ſingle bilocular nut. *Linnæi* Gen. Plant. p. 305. *Houſton*, A. A. *Sloan*, Hiſt. vol. 2. f. 23.

VOLONES, among the Romans, the antient name of thoſe afterwards called *evocati*. See the article EVOCATI.

VOLT (*Cycl.*)—VOLT, in the manege. See the article VAULT, or VOLTE, *Cycl.*

VOLTA, in the Italian muſic, ſhews that the part is to be repeated one, two, or more times, according to the numeral adjective joined with it; thus *ſi replica una Volta* intimates to play that part once over again.

VOLTA is alſo a ſort of dance of Italian origin, in which the man turns the woman ſeveral times, and then aſſiſts her to make a leap or jump; it is a ſpecies of *galliard*. *Broſſard*.

VOLTURNALIA, among the Romans, a feſtival kept in honour of the god Volturnus, on the ſixth of the calends of September, or twenty-ſixth of Auguſt. *Pitiſc.* in voc.

VOLVA, among botaniſts, a membranous matter ſurrounding the baſes of many of the fungi; and in many of them, of very ſingular figure and ſtructure.

VOLVA is alſo a word uſed by Scribonius Largus, and ſome other authors, to expreſs the central part, or, as we call it, the core of the apple, in which the ſeeds are placed. He preſcribes this in weakneſſes of the ſtomach, and reachings to vomit.

VOLUBLE *Stalk*. See the article STALK.

VOLVENS *Oculi*, in anatomy, a name given by Spigelius, and ſome others, to one of the muſcles of the eye, called by Cowper and Albinus, *obliquus inferior*.

VOLUNTARY (*Cycl.*)—VOLUNTARY, in muſic, a piece played by a muſician extempore, according to his fancy. This is often uſed before he begins to ſet himſelf to play any particular compoſition, to try the inſtrument, and to lead him into the key of the piece he intends to perform.

In the Philoſophical Tranſactions, N°. 483. Sect. 2. we have a method of writing down extempore *Voluntaries*, or other pieces of muſic, as faſt as any maſter can play them on the organ, or harpſichord; and that in a manner expreſſive of all the varieties thoſe inſtruments are capable of. This is performed by a cylinder, turning equally upon its axis, under the keys of an organ, and by having points under the heads of the keys. Hence, when they are preſſed down, they will make a ſcratch or mark on the cylinder, which may ſhew the duration of the note, and the ſituation of this mark on the cylinder will ſhew what note was touched. For farther particulars we refer the curious to the tranſaction itſelf.

VOLUNTEERS, in the military art, perſons who of their own accord ſerve in the army, and at their own expence.

VOLUTA, the *Volute*, in natural hiſtory, the name of a genus of ſhells, the characters of which are theſe: They are univalve ſhells, and have an oblong mouth, with a clavicle ſometimes erect, ſometimes depreſſed; and they are ſometimes coronated at the top. See Tab. of Shells, N°. 10. This genus of ſhells is generally confounded by authors with that of the cylindri. There is indeed a general external reſemblance between theſe two kinds of ſhells at firſt ſight; but when they are a little examined, they will be found very different. The *Volutæ* are of a conic figure. One of their extremities is of a pyramidal figure, and the other formed into high ribs, which conſtitute a depreſſed clavicle, or a dentated crown; on the contrary, the cylinder is nearly of an equal ſize at both ends. And it is not neceſſary to have recourſe to the form of the mouth of this ſhell, in order to fix its generical character. Its figure, which is lengthened out into a point in the lower end, ſufficiently characteriſes this genus; and to this may be added another very remarkable character, which is, that the head is ſeparated from the body of the ſhell by a high rib.

The *Volutæ* are called by many authors, *rhombi*, which is a very ill choſen name, as the word expreſſes the figure of a lozenge, a figure very different from that of the ſhell. It has been called *Voluta* from the *volute* in architecture, the *volutes* of a capital diminiſhing in diameter all the way to the center, which is called the head or eye of the *volute*. See the article VOLUTE, *Cycl.*

The moſt remarkable ſpecific character in this genus is in the ſhape of the clavicle, ſome ſpecies having it very much elevated, and others very flat or depreſſed. The corona imperialis, which is a ſhell of this genus, is ſingular in the dentated crown, which terminates its head.

The *Volutæ* make the moſt rich and beautiful ſhells of the whole body of ſea productions. Rumphius calls them *eximiæ*; and the admiral and vice-admiral ſhells, ſo famous among the curious, and held at ſo great a price, are both of this genus. The brightneſs of the colours, the perfect white of the enamel, and the elegant ſhape of theſe ſhells, would make them the firſt in eſteem among this claſs of bodies, even were they common; but it happens that their ſcarcity adds immenſely to their value. There is one of theſe ſhells now in Holland, which coſt the poſſeſſor five hundred florins. It is from the bands and faſciæ of theſe ſhells, which reſemble the colours of ſhips, that they have obtained the names of admiral and vice-admiral.

Some of the Hollanders give to another ſhell of this kind the name of extra-admiral; this reſembles the admiral, but has its colours arranged without diviſions of the white enamel. It is a very ſcarce ſhell, but is leſs beautiful than either of the two others.

The family of the *Volutæ* being numerous, the ſpecies may be aptly ranged under three general heads. 1. Thoſe with an exerted clavicle. 2. Thoſe with a depreſſed clavicle. And 3. Thoſe with a coronated clavicle.

Of the firſt kind we have the following ſpecies: 1. The grand *admiral*, or *archithalaſſus primus*. 2. The *archithalaſſus ſecundus*, or the *vice-admiral*. 3. The *archithalaſſus araujicanus*, or the *orange-admiral*. 4. The navel or baſtard *admiral*. 5. The ſpectre-ſhell, or *concha ſpectrorum*. 6. The brown lineated *Volute*. 7. The flame-coloured *Volute*. 8. The Guinea-ſhell, or ſpeculation *Volute*. 9. The reddiſh ſtriated and faſciated *Volute*. 10. The punctulated *Volute*. 11. The Hebrew *Volute*. 12. The brown *Volute*, with two elegant white zones. 13. The Iſabella *Volute*. 14. The *vexillum*. 15. The *Volute*, variegated with two reticulated zones. 16. The bat *Volute*. 17. The white *Volute*, with yellow ſpots and lines.

Of the ſecond kind, or thoſe with depreſſed clavicles, we have the following ſpecies: 1. The black leopard *Volute*. 2. The yellow leopard *Volute*. 3. The reddiſh leopard *Volute*. 4. The chequered *Volute*. 5. The blue ſpotted *Volute*. 6. The faſciated *Volute*, with yellow and white ſpots. 7. The butter-tub *Volute*. 8. The agate-coloured ſtriped *Volute*. 9. The yellow *Volute*, with a white circle. 10. The onyx *volute*. This, when its outer coat is taken off, is of a true onyx colour, and it is in this ſtate that it is uſually met with in the cabinets of collectors. 11. The butterfly-wing *Volute*. 12. The green ſpotted *Volute*, with two variegated faſciæ.

Of the third kind of *Volutæ*, the head of which is coronated, we have the following ſpecies: 1. The *crown imperial*. 2. The leſs faſciated *crown imperial*. 3. The *crown imperial*, variegated with brown. 4. The black marbled *crown imperial*. And 5. The *crown imperial*, called in French the *moire*; this ſeems of the texture of the web of a ſilkworm, only more cloſely woven together. Hiſt. Nat. Eclair. p. 279.

VOLVULA, in natural hiſtory, the name of an extraneous foſſile body, nearly allied to the entrochus, being compoſed of the ſame ſubſtance, and being like that of a cylindric column, made up of ſeveral joints; the commiſſures of the joints are, however, much leſs viſible in the *Volvulæ* than in the entrochi, and they are not ſtriated, as in the entrochus, from the center to the circumference.

The *Volvulæ* are of various figures, ſome reſemble in ſhape a little bottle, and are called *Volvulæ utriculatæ*, and of theſe ſome have, and others have not, a ſtar marked on their bottom; others of them ſwell out in the middle, and taper a little toward each end; and theſe, from their reſemblance in ſhape

to a little barrel, are called *dolioli*, or *Volvulæ doliatæ*. There is great reaſon, from the analogy theſe bear to the entrochi, and other foſſils which owe their form to animal remains, to ſuppoſe theſe of the ſame origin; but we yet know not to what animal it is that they have belonged. *Hill*'s Hiſt. Foſſ. p. 653.

VOLVULUS, in botany, a name given by Daleſchamp, and ſome others, to the upright narrow leaved or toad-flax-leaved bind-weed. See the article CONVOLVULUS.

VOMER (*Cycl.*)—The ſituation of this bone is perpendicular between the two naſal foſſæ backward. It is in figure nearly of an oblique ſquare. Anatomiſts divide it into the right and left ſide, both of which are unequally flat; and four edges, the ſuperior, inferior, anterior, and poſterior; the upper edge is an horizontal groove, which receives the ſharp proceſs or roſtrum of the os ſphenoides. The anterior edge is oblique, and very unequal; its poſterior part is ſmall and thin, and ſupports the perpendicular lamina of the os ethmoides; the anterior is larger, with a pretty deep groove, continued from the canal in the upper edge, which ſuſtains the cartilaginous ſeptum of the nares. The lower edge is likewiſe unequal; and near its anterior extremity is an angle, which divides it into two parts; one anterior, very ſhort, which is ſet in the criſta narium; the other poſterior, and much longer, ſet in the common groove of the oſſa maxillaria and palate. The angle by which this edge is divided, lies in the notch formed by the criſta narium, and the groove of the maxillary bones. The poſterior edge is oblique and ſharp, becoming inſenſibly more obtuſe as it approaches to the larger groove in the edge. This bone has but very little diploe; it is connected with the os ſphenoides, os ethmoides, oſſa maxillaria, and oſſa palati; its uſe is to form the poſterior part of the ſeptum narium. *Winſlow*'s Anatomy, p. 38.

VOMICA (*Cycl.*)—VOMICA, in natural hiſtory, a word uſed by the antients to expreſs one of the blemiſhes to which cryſtals and the precious ſtones are ſubject. This is a duſky foulneſs lying deep in the ſtone, and giving a duſky colour and tinge to the whole. Both the luſtre and tranſparence of the ſtone is much hurt by this accident. When the *Vomica* was of a bluiſh or blackiſh colour, the Romans expreſſed it by the word *plumbago*. See the article PLUMBAGO.

VOMICA *Pulmonum*, in medicine, the name of a diſeaſe which is a ſanious collection of matter, or an apoſtem formed in the lungs, and included in its own proper membrane; this ſometimes ſeizes one lobe, ſometimes the other; and ſometimes lies deep in the ſubſtance, ſometimes near the ſurface. It finally breaks, and then diſcovers itſelf by a diſcharge of purulent matter from the lungs.

The ſigns of this diſeaſe are at firſt very diſtinct; it generally begins from a hard node, which, by ſlow degrees, ripens into a collection of matter. A hectic fever is a conſtant attendant on it, and there is always a dry cough attending it; but this is not very violent. Toward the ripening of the matter, there is a difficulty of breathing, and often the patient complains of a dull heavy pain, ſometimes of a very acute one, in ſome particular part of the breaſt. The face is irregularly red, and a languor grows upon the whole body. The appetite is irregular, and finally a fever comes on; and during this the ſwelling breaks, and the matter is thrown up in ſuch large quantities, as to endanger ſuffocation.

The moſt fatal diſeaſes are uſually the moſt rare, and this is of that number, ſeldom being met with, and when it is, too often fatal. The cauſes of it, are ſtagnation of the blood in plethoric habits, in the veſicles of the lungs; and theſe are uſually owing to the ſuppreſſion of natural habitual evacuations, or the omiſſion of artificial ones, as habitual bleedings and the like; to theſe are to be added, external injuries from falls, blows, or wounds of the breaſt; violent running till out of breath, and a ſudden cooling of the breaſt while the body is hot.

The uſual cauſes of the breaking of a *Vomica*, when formed, are violent ſuccuſſions of the body, loud ſpeaking or calling, violent coughing or ſneezing, and the falling of any ſubſtance in eating into the windpipe.

Prognoſtics in it. The more ſlowly this diſeaſe advances to its height, the more difficultly it is diſcovered; and the deeper it lies in the ſubſtance of the lungs, the greater is the danger of it; though, when moſt ſuperficial, it is of no ſmall danger; for, breaking externally on the lungs, it diſcharges its matter into the cavity of the thorax, and thus makes an empyema, a diſtemper little leſs fatal than the other, unleſs the matter be immediately let out by the paracenteſis. When the matter has lain deep, there is great danger of the perſon's being ſuffocated either at the firſt diſcharge of it, or at the ſucceeding ones, if they are large, and he be already wore down by a hectic, as is uſually the caſe; and even if he eſcapes this, the apoſtem degenerates into an ulcer, and ſo brings on a phthiſis.

In general, the ſmaller the quantity of matter thrown up, the leſs is the danger.

Method of Cure. The ſame general medicines are to be uſed as in a phthiſis. The apoſtem is to be cleanſed and abſterged, which is done by pectorals mixed with diſcutients; ſuch are liquorice, hyſſop, and the ſeeds of carduus mariæ. Then the ſolution of continuity is, if poſſible, to be repaired. This is to be attempted by balſamics, ſuch as comfrey, plantain, ground ivy, and the like. The febrile heat is to be allayed by mixtures of nitre and diaphoretic antimony; and the violence of the cough abated by the uſe of gentle opiates, ſuch as ſtorax pill, and the like, in ſmall doſes.

The bowels are to be kept open by clyſters and gentle purges; revulſion is to be made by bleeding in the foot, and after this, the pectorals, &c. are to be relied on. And during the whole courſe a light diet, and tranquillity of body and mind are to be preſcribed. *Junker*'s Conſp. Med. p. 173. ſeq.

VOMIT. The effects of *Vomits*, on the motion of the blood, appear by the following experiments: By obſerving the pulſe of ſeveral men, after taking a *Vomit*, it has been found, that ſo ſoon as a man begins to grow ſick, his pulſe becomes low, quick, and irregular, and, in the action of *Vomiting*, is often ſo low as not to be felt; that in the intervals, between the *Vomits*, the pulſe is ſtill low and quick, but not near ſo low and quick as in the action of *vomiting*; and that, after the operation is over, the pulſe riſes gradually, and in the ſpace of half an hour, or an hour, becomes fuller than it was before the *Vomit* was taken. Hence we ſee the effects of *Vomits* on the motion of the blood, they leſſen that motion during the whole time of their operation, and almoſt quite ſtop it in the very act of *vomiting*; and after the whole operation is over, they increaſe the motion of the blood, ſo as to make it greater than it was before.

From theſe effects of *Vomits* on the motion of the blood, we diſcover their great uſefulneſs in the cure of many diſeaſes. For inſtance, *Vomits* ſtop hæmorrhages from ſmall veſſels. For when a blood-veſſel is opened, the blood flows faſter thro' that veſſel, and ſlower through all the reſt of the veſſels, than it did before. And therefore, all that is neceſſary to ſtop a hæmorrhage from a ſmall veſſel, is to ſtop the motion of the blood in that veſſel, and increaſe its motion in all the other veſſels; and both theſe are done by *Vomits*, as appears by the foregoing experiments.

The increaſing the motion of the blood in all the other veſſels, will leſſen the motion in the veſſel ſupplying the hæmorrhage, and thereby effectually prevent a return of the diſcharge. For the ſame reaſon, *Vomits* leſſen immoderate diſcharges of the glands, and ulcers; for they leſſen the motion of the blood and humours in the parts affected, by increaſing their motion in all the other parts. By increaſing the blood's motion, repeated *Vomits*, with a proper diet, has been found to be of great ſervice in diſperſing ſcrophulous tumours; which may be allowed, when it is conſidered that theſe tumours are moſt incident to children and young bodies, the motion of whoſe blood is ſlow; and that they often diſappear of themſelves, when bodies are grown up, and their blood has acquired a ſtronger motion.

When obſtructions ariſe from too languid a motion of the blood, *Vomits* are generally of uſe in removing them. And when the motion of the blood is too great, and the obſtructions are formed by cold, *Vomits*, after large bleeding, will be of great ſervice in removing them. In ſhort, *Vomits*, repeated according to the nature and obſtinacy of the diſorder, are generally of ſervice in all irregularities, and diſproportions of the motions of the blood, and other fluids, in different parts of the body. The ſafety, as well as uſefulneſs of frequently repeated *Vomits*, is evidently ſeen in perſons at ſea, and in women with child. Perſons at ſea, who are ſick, and *vomit* much, are commonly the better for it; and frequent *vomiting* in women with child, is of ſervice, and prevents abortion. As all muſcles grow ſtronger by exerciſe, ſo the muſcular coat of the ſtomach grows ſtronger by *vomiting*. Dr. *Br. Robinſon*, of the Food and Diſcharge of Human Bodies. See the article VOMITING, *Cycl.* and *Suppl.*

Some have pretended to give rules for aſcertaining the doſes of *Vomits*. See the article PURGATIVE.

Muſtard VOMIT. See the article MUSTARD.

VOMITING (*Cycl.*)—The cauſes of *Vomiting* are very different, and the treatment of it as a diſeaſe, muſt therefore be alſo various, according to thoſe differences.

Critical *Vomitings*, by which humours of various kinds are diſcharged by the operation of nature alone, are ſalutary, and ſcarce require any care as to their cure; but are, in many caſes, to be promoted: whereas ſymptomatical *Vomitings*, which are leſs ſufficient, or leſs accommodated to the removing the cauſe, are more carefully to be treated, in order to their cure.

The two principal curative indications to be obſerved are, firſt, to quiet and compoſe the convulſive and unruly motion of the ſtomach; and ſecondly, to oppoſe and ſubdue the material cauſes of the diſorder.

The firſt intention is anſwered by corroborating and antiſpaſmodic medicines, ſuch as ſaffron and caſtor, with the teſtaceous powders, as coral, crabs-claws, and oiſter-ſhells; powders compoſed of cinnamon, the leaves of mint, nutmeg, orange-peel, calamus aromaticus, and other ſuch ſimples, are alſo of great ſervice. And if anodynes are found neceſſary, the ſtorax pill, or Sydenham's laudanum, are to be given.

While theſe medicines are taken internally, there may alſo be applied outwardly to the region of the ſtomach, ſuch things as

as have power to repreſs its diſorderly motions; of this kind are the oil of mint, nutmeg, and the like, with balſam of Peru: theſe oils may be reduced to a proper conſiſtence, with this balſam, for the ſpreading on leather, and lying on for ſome time. Hungary-water, and other the like ſpirits, are of great uſe alſo, rubbed on with the hand; and to theſe may be added yeaſt, and the ſtrongeſt wine-vinegar applied hot to the part. Finally, an excellent application is balſam of Peru alone, reduced to the conſiſtence of a cataplaſm, with crumb of bread.

The methods to be uſed to remove the material cauſes of the *Vomiting*, are next to be conſidered: If it be of the pituitous kind, and owing to crudities in the primæ viæ, and a viſcid mucus ſticking to them, it is beſt cured by an emetic: if the *vomiting* of itſelf be found not ſufficient to carry off the ſordes which occaſioned it, and the patient continues, after the fits of *vomiting*, afflicted with a nauſea and heart-burn; in this caſe, a large quantity of warm water, with a little butter, may ſerve the purpoſe; or if this be found inſufficient, a doſe of ipecacuanha is to be given. *Hoffm.* Oper. T. 3.

When infants are afflicted with *vomiting*, from milk coagulated upon their tender ſtomachs, which is a very frequent caſe, the beſt medicine is a mixture of oxymel of ſquills, and ſyrup of rhubarb. See the article INFANT.

In caſes of bilious *Vomitings*, which ariſe from a weakened digeſtion, and have their ſomes in the duodenum, the cure is to be begun with the abſorbent and teſtaceous powders; after theſe, gentle purges of rhubarb and manna are to be given; and finally, the cure is to be perfected by reſtoring the ſtrength of the ſtomach and inteſtines.

In *Vomitings* which ariſe from an acrid matter adhering to the nerves of the ſtomach, from the retropulſion of the gout, an eriſipelas, or other ſuch diſorder, the mild ſedatives are to be given, and with them ſuch medicines as promote the expulſion of the matter; and all means are to be uſed to remove it to the ſurface of the ſkin, or to the extremities again. All ſweating medicines are good in this intention, as they carry the matter to the ſurface. Camphor, taken internally in moderate doſes, is alſo of great ſervice; and warm baths for the feet often prove highly uſeful. In *Vomitings* excited by poiſonous ſubſtances, nothing gives ſuch immediate relief as the taking large quantities of warm milk, and pinguious liquors; for by means of theſe the ſpicula of the poiſon are blunted, and afterwards *vomited* up with the liquors. And hence in contagious and peſtilential caſes, where there is no inflammation of the ſtomach, many phyſicians have very ſucceſsfully given *vomits* of ipecacuanha, and after theſe acid liquors with diaphoretics.

Acrid, acid, and bilious ſordes falling upon the inteſtines, often occaſion a *vomiting*, attended with colic pains; in this caſe, ſmall doſes of oil of ſweet almonds and manna, with large draughts of barley-water between the doſes, are found of great ſervice; and ſmall doſes of laudanum, at proper times, ſerve to compleat the cure. In perſons of hot habits, ſpirit of vitriol, and mild laxatives, are found of moſt certain relief.

The too frequent method of attempting to ſtop a *Vomiting* by aſtringents and anodynes, before the peccant matter is removed, is highly blameable; for when the ſpaſmodic motions are allayed, which nature uſed to free herſelf from this matter, and that yet remains behind, there muſt follow worſe ſymptoms. Theſe remedies which affect the motion only, and not the matter, are only to be uſed when the motion ſubſiſts, after the matter is diſcharged, or when the motion is very violent, and the matter to be thrown off but very ſmall in quantity.

Hence in *Vomitings* exited by the chin-cough in children, ſedatives and anodynes are very proper, ſuch as the ſyrup of red poppies, or diacodium, and a little oil of ſweet almonds.

The *Vomitings* of pregnant women, ariſing from a regurgitation of the blood to the ſtomach, which is alſo obſerved in women afflicted with a retention of the menſes, and in men who have a ſtoppage of habitual hæmorrhoidal diſcharges, are beſt removed by temperating medicines, mild laxatives, emollient clyſters; and beſt of all, by bleeding, or recalling the natural ſecretions of blood, in the two latter caſes. On ſuch occaſions it is highly improper to give emetics, for they ſometimes bring on a *Vomiting* of blood, and ſometimes an inflammation of the ſtomach.

In caſes of efforts to *vomit*, or actual *Vomitings*, in the morning, which frequently happen to thoſe who uſe too much ſtrong liquors over night, the teſtaceous powders are to be given, and all other things which will abſorb acidities; and after theſe the grateful ſtomachics, ſuch as candied orange-peel, and the like.

Chronical *Vomitings* ſometimes affect perſons who have been in a long continued ſtate of grief; in this caſe the beſt relief is found in analeptics, and the uſe of cinnamon-water, impregnated with quinces, and of the generous wines.

In *Vomitings*, which are a ſymptom of fevers coming on, the uſe of a gentle emetic, ſuch as the ipecacuanha is very proper. In the ſmall pox, the *Vomiting* uſually ceaſes ſpontaneouſly after the eruption of the puſtules, and in theſe and many other caſes, great relief is to be obtained in *Vomitings*, by a mixture of ſalt of wormwood and juice of lemons.

In *Vomitings* ariſing from fits of the ſtone, the ſpiritus nitri dulcis often proves of great ſervice; and oily glyſters, and oil of ſweet-almonds, taken internally, are alſo of great ſervice.

The *Vomiting* of perſons in hernias, or the iliaca-paſſio, rarely remits till the cauſe ceaſes. Reſt, and lying in bed, contribute greatly to the ſtopping immoderate *Vomitings*, for all motion of the body excites in theſe caſes a freſh tendency to *vomiting*. In the beginnings of eryſipelas's, and the like diſorders, *Vomitings* often happen, and theſe are by no means to be checked; but the appearance of the diſeaſe externally is to be forwarded by diaphoretics; for as ſoon as the eruptions appear, the *Vomiting* ſtops of itſelf.

The obſtinate *Vomitings* of hyſterical patients are not to be ſtopped by opiates or aſtringents; for the conſequence of this is uſually violent convulſions in the limbs, and anxieties and pain in the præcordia; all which ſymptoms diſappear again, as ſoon as the *Vomiting* returns.

The immoderate and long-continued *Vomitings* of pregnant women, which principally happen in the firſt months of the time, eſpecially in thoſe who indulge themſelves too much in venery, and are plethoric, are by no means to be cured by aſtringents, opiates, or ſpirituous medicines; but are to be removed by repeated bleeding in the ankle, reſt of the body, and tranquillity of the mind. And when *Vomiting* of this kind is ſo violent as to threaten abortion, it is often ſtopped more effectually by the drinking cold water, than by any medicine whatſoever. When an analeptic is neceſſary, one ſpoonful of cinnamon-water, taken after meals, is ſufficient. *Hoffman*, Op. T. 3.

VOMITINGS *in Infants*. See the article INFANT.

VOMITING *of Blood*, *Vomitus Cruentus*, a very dangerous kind of hæmorrhage, conſiſting in a bringing up by *Vomit* of pure and unmixed blood from the ſtomach, and being a method, uſed by nature to throw off a portion of the blood, which moleſts the whole in the vena porta, and by that means to facilitate the circulation of the reſt of the maſs.

This diſtemper ſometimes ariſes from internal cauſes, and is regularly periodical, obſerving the ſtated times of the eruptions of the menſes, or other natural diſcharges; ſometimes it ariſes from accidents, ſuch as the giving of violent purging or emetic medicines, or corroſive ones.

Preceding Signs of it. Among theſe are to be reckoned a ſenſation of ſtraitneſs and anxiety in the præcordia, with tenſion, and involuntary ſighs; with a nauſea or ſickneſs of the ſtomach, and a ſtraining to vomit; which is more violent than in vomiting on any other occaſion; after this the blood is thrown up pure, and the *Vomiting* then ceaſes, till, after a plain ſenſation of more blood being collected in the ſtomach, the efforts to diſcharge it in the ſame manner are again renewed. The quicker the blood is thrown up, after its being diſcharged into the ſtomach, the more fluid and more florid it appears; the longer it is detained there, the blacker and thicker it appears.

Perſons moſt ſubject to it. A *vomiting* of blood is but an uncommon diſorder. It more frequently attacks women than men; among the female ſex it is principally ſeen in thoſe whom the menſes have left too early in life, or who have had violent ſuppreſſions of them for a long time. In men, this diſtemper ſeldom ſeizes any but thoſe who have been uſed to periodical diſcharges from the hæmorrhoidal veſſels, and who have had them ſuddenly ſtopped; and they are then uſually firſt attacked with violent pains in the left hypochondrium. People of ſcorbutic habits, and ſuch as have had quartan agues of long ſtanding, have been ſometimes thus affected. And, beſide theſe natural cauſes, people of all ages and ſexes may vomit blood, from external injuries.

Prognoſtics from it. A *Vomiting* of blood is ever a dangerous diſorder; for tho' the quantity of blood thrown up is ſeldom ſo great as to occaſion immediate death, yet it generally degenerates into a tabes in men, and into a cachectic habit in women. It is leſs dangerous to young women, than to any other perſons; and when it is periodical, eſpecially when it obſerves the times of the menſtrual diſcharges, is much leſs dangerous than under any other circumſtances.

Method of Cure. During the paroxyſm, the proper medicines are powders of nitre, cinnabar, and the abſorbent ſubſtances, ſuch as crab's-eyes, or the like, and afterwards bleeding, cupping, and gentle purges, and diaphoretics are to be given for ſome time. *Junker*'s Conſp. Med. 35.

VORTEX (*Cycl.*)—We have, in the Philoſophical Tranſactions, a phyſico-mathematical demonſtration[a] of the impoſſibility and inſufficiency of *Vortices* to account for the cœleſtial phænomena.—[[a] By Monſ. de *Sigorne*. See N°. 457. Sect. 6. p. 409. ſeq.]

This author endeavours to ſhew, that the mechanical generation of a *Vortex* is impoſſible; that it has only an axifugal, and not a centrifugal and centripetal force; that it is not ſufficient for explaining gravity and its properties; that it deſtroys Kepler's aſtronomical laws; and therefore concludes with Sir

Iſaac Newton, that the hypotheſis of *Vortices* is fitter to diſturb than explain the cœleſtial motions. We muſt refer to the diſſertation itſelf for the proof of theſe aſſertions.

VOTE (*Cycl.*)—In elections of members of the houſe of commons, ſuch *Votes* ſhall be deemed legal, which have been ſo declared by the laſt determination in the houſe of commons; which laſt determination concerning any county, ſhire, city, borough, cinque port, or place, ſhall be final to all intents and purpoſes. Stat. 2. Geo. 2. c. 24.

UPLAND (*Cycl.*)—The *Uplands* lie either on the tops of hills, or on their ſides, or on the ſlopes of riſing grounds. They ſometimes have a ſandy ſoil, ſometimes a rocky, gravelly, or loamy one, and ſometimes they conſiſt of tough clay, or a black mould. They are uſed by the farmers either for grazing or corn, as they happen to be more moiſt or more dry; and this difference depends upon their ſituation and nature.

Thoſe lands which lie flat upon the tops of hills, are uſually the drieſt, and thoſe which form the ſlopes or ſides, are uſually the moiſteſt, becauſe of the wet that is continually ouzing through them. The chalky, and eſpecially the clayey ſoils in theſe places, are moſt of all ſubject to be wet, eſpecially in winter, becauſe they retain the moiſture a long time; though they have alſo the inconveniencies of the ſandy and rocky lands in the ſame ſituations, chapping in ſummer. The black mould, and the hazely loams in theſe places, are the beſt for corn, as well as for paſture, eſpecially if the latter eſcapes the common misfortune of being full of worms. Theſe lands neither are waſhy in winter, nor parched up in ſummer.

The *Upland* meadows have ſome diſadvantages, as they often need mending or feeding, which thoſe that lie lower do not; but then they make amends for this in their hay, which is always much finer and ſweeter than that of the low-lands.

UPLOPER, a name given to one particular ſpecies of pigeon, called by Moore, *columba gutturoſa ſaliens*.

It was firſt brought to England from Holland, and much reſembles that kind of pigeon called the Engliſh Powter, but that it is ſmaller. Its crop is very round, and in this it buries its bill. Its legs are very ſmall and ſlender, and its toes are ſhort, and cloſe together, on which it treads ſo nicely, that, when moving, any ſmall thing might be put under the ball of its foot. The pigeons of this ſpecies are generally all blue, all black, or all white; ſeldom or never pyed. They are very ſcarce in England, and in Holland have been valued at five and twenty guineas a pair.

They have their name from the Dutch word *Oplopen*, which ſignifies to leap up, and it was thus named from its manner of approaching the hen, which is always by leaping upon her. *Moore*'s Columbarium, p. 37.

UPRIGHT (*Cycl.*)—Upright *South Dial.* See the article Prime *Vertical*, *Cycl.*

UPULUS, in botany, the old Latin name for the *lupulus*, or hop. This word *lupulus* is not old Latin, but a more modern name, formed on the word *Upulus*.

The original word *Upulus* alſo was formerly written *opulus*, being a climbing plant. The word was alſo applied to other climbing plants, ſuch as the white and black bryony. Some of the antients called the hop *upulus ſalictarius*, becauſe of its twining about willow-trees. Pliny mentions it under this name. The words indeed ſtand *lupus ſalictarius*; but this is a very plain error, ſince the *ſalictarius* is joined to the word *Upulus* by Cato, Varro, and moſt of the other writers of antiquity; but by no body to the word *lupus*. Cato in one place calls it *ulva*; but this is evidently an error of the copy. The word *ulva* is the name of a ſea-plant growing without ſtalks, compoſed only of tender leaves; and it is here called a tall plant, climbing upon the willows. There is no doubt from this, and from the ſame author's ordering it to be ſtrewed under cattle, by way of litter, that it was the *Upulus* or *lupulus*. See the article Lupulus.

UPUPA, the *Hoopoe*, in the Linnæan ſyſtem of zoology, makes a diſtinct genus of birds, the characteriſtic of which is, the having a double crown of feathers on the head. *Linnæi* Syſtem. Nat. p. 45.

Theſe birds are common in Germany, and ſometimes ſeen in England, though but rarely. Its general weight is about three ounces. The beak is black, ſlender, ſharp, and a little hooked; its head is adorned with an extremely beautiful and elegant creſt, riſing two fingers high, and compoſed of two ſeries of feathers, reaching from the inſertion of the beak to the back part of the head; and theſe can be raiſed or depreſſed by the bird at pleaſure. The tips of theſe feathers are ornamented with black and white, the reſt is of a cheſnut colour. Its neck is of a pale reddiſh brown; its breaſt white, variegated with longitudinal ſtreaks, which diſappear in the middle as the bird grows older; the tail is four fingers breadth long; it is compoſed of ten feathers, and is black; but has a large white ſpot in it, of a lunated figure, the points ſtanding towards the extremity of the tail. Its wings, when folded, do not reach to the end of the tail; and are ſtreaked acroſs with white; it feeds on beetles, worms, ants, &c. and is ſaid alſo to eat berries, and other vegetables. *Ray*'s Ornith. p. 100.

Æſchylus, Ariſtotle, and many of the other old Greek writers tell us, that the cuckow, when it has ſung all the ſummer, acquires a plume of feathers on its head, and loſes its voice for the winter ſeaſon, and is in this ſtate called the *Upupa* or *Hoopoe*; but there is no truth in this ſtory, though the general opinion of thoſe times.

In the ſame manner they ſuppoſed the *ficedula* and *melancoryphos*, or black cap, to change into one another; becauſe the one appeared at that time of the year when the other went away. We have in this bird alſo another proof of the ignorance of thoſe times in natural knowledge: they tell us, that the callais or turquoiſe, which we call the *Turkey-ſtone*, was found in the melancoryphus only, becauſe the eggs of that bird are of the ſame beautiful pale blue colour with that gem.

URACHUS (*Cycl.*—The uſe of the *Urachus* is not yet diſcovered, according to Dr. Trew. Phil. Tranſ. N°. 457. Sect. 7. See the articles Allantois and Foetus.

URANOSCOPUS, in zoology, the name of a fiſh of the cuculus kind, called in Engliſh the *ſtar-gazer*; and by ſome authors, *callyonymus*.

It is uſually caught of about ſeven or eight inches in length, but ſometimes it grows to a foot; its head is very large, bony, and rough, and of a ſort of ſquare figure; its body is long and rounded; its upper part is all of an aſh-colour; its belly white; its ſcales are very ſmall and thin, inſomuch that many have ſuppoſed it had none. Theſe are diſpoſed in oblique ranges acroſs the body of the fiſh, running toward the tail. The ſide-lines are arched, and riſe to the back fin, which is a great ſingularity. Its face is flat, and ſeems turned upwards, and its eyes are ſmall and prominent, and are ſo placed in the upper part of its head, as naturally to look up to the heavens, whence it has its name. Many of the flat fiſh have their eyes placed as thoſe of this fiſh; but the pupils in all theſe look ſideways; in this only they are turned ſtrait upward. Its mouth is very large, and opens perpendicularly downward, being placed in the ſame direction with the eyes in the upper part of the head. It has a beard under its chin, like that of a man, and its jaws are furniſhed with very ſharp teeth, as are alſo the inner parts of its mouth. Its whole head is covered with rough tubercles, and it has two fins on the back, and two on its breaſt. It is frequently caught in the Mediterranean, and is by ſome ſaid to be a well-taſted fiſh. *Geſner*, de Aquat. p. 159.

The reaſon of the ſituation of the eyes of the *Uranoſcopus*, is the providence of nature for a fiſh which, always keeping at the bottom, has no where to look for prey but in the water above it. But if other fiſh had been well examined, this peculiar name would never have been given to this. The eyes of the *rana piſcatrix* are placed in the ſame manner, and thoſe of a great number of other fiſh, whoſe cuſtom it is to keep at the bottom, are more or leſs alſo thus ſituated.

According to the new ſyſtem of Artedi, this is a ſpecies of the *trachinus*, and is diſtinguiſhed from the others of that genus, by the name of the *trachinus* with many beards on the lower jaw. The fiſh deſcribed by Willughby and others under the names of the *ſea-dragon* and *ſea-ſpider*, the *draco-marinus* and *araneus-marinus*, are of this genus. They are properly indeed only the ſame ſpecies in different ſtates, and are diſtinguiſhed from the *ſtar-gazer* by the name of the *trachinus* with the lower jaw longer than the upper, and with no beards hanging from it. *Artedi* Gen. Piſc. 73. See Tab. of Fiſhes, N°. 48. and the article Trachinus.

URCEOLUS, in eccleſiaſtical writers. See the article Aqua *Manilis*.

URCEUS, in antiquity, the name of a meaſure of liquids, which in different places was of different capacity; its moſt uſual ſtandard ſeems to have been between twelve and ſixteen ounces.

URCHIN, a common name given to the hedge-hog. See the article Erinaceus.

Sea-Urchin, in ichthyology. The *echinus marinus* of authors is, in ſome parts of England, called the *ſea-egg*, and in others the *ſea-urchin*, or *hedge-hog*. It is a genus of fiſh, of which there are a great number of ſpecies.

The manner of theſe creatures moving at the bottom of the ſea, has been diſputed among naturaliſts; the general opinion of the world has been, that they did it by means of their ſpines or prickles, which ſerved them by way of legs; but ſome of late, particularly Mr. Gandolphe, pretend that the ſpines of the *Urchins* are of no uſe to them on this occaſion, but that they move by means of certain legs, like the legs of the ſtar-fiſh, which they occaſionally put out when they walk, and at other times retract them into their body. The world was readily falling into this ſyſtem, particularly as Mr. Gandolphe affirmed, that he had been often an eye-witneſs to it; but the indefatigable Mr. Reaumur tried the experiment himſelf, and often made himſelf an eye-witneſs of the contrary fact, having frequently ſeen them walk at the bottom of a ſhallow baſon of ſea-water, with no other aſſiſtance than that of their ſpines, and even having made them perform the ſame motion, by the ſame means, upon his hand.

This curious enquirer into nature did not, however, ſtop here; but took occaſion from hence to enquire accurately into every circumſtance of their progreſſion, which is performed by ſo uncommon means.

It is certain that the *ſea-Urchin* does throw out at the lower

aperture of its ſhell, when it pleaſes, certain bodies which reſemble not a little the legs of ſtar-fiſh; but theſe ſerve not at all to its motion; but, on the contrary, their real uſe is to keep the creature ſtill, and fixed in the ſame poſition; and, to deſcribe them more exactly, they very aptly reſemble the horns of ſnails; whence Mr. Reaumur has choſen rather to call them horns than legs. The uſe the *Urchin* makes of theſe horns, while it is in motion, is to feel about, and try the ground on which it marches; and they ſerve the creature as a ſtaff does a blind man in his walking, to touch and try every thing that lies in the way; and to make them ſerve to this purpoſe, it is continually extending or retracting them during the time it is moving. Theſe horns are not only placed about the orifice of the ſhell, but they are every where diſperſed among the ſpines, all over the ſurface of the ſhell.

To underſtand properly the poſition of theſe horns, it will be neceſſary to conſider the figure of the *ſea-Urchin* ſhell, as we uſually ſee it, that is, ſtripped both of its ſpines and its horns. In this ſtate it appears a very beautiful piece of workmanſhip. It is a hard body, the figure of which approaches to that of a ſegment of a ſphere, or a mould of a button hollowed within; it has an aperture at the very ſummit of the ſhell, and another at the baſe, juſt oppoſite to it; this is the caſe in the common kind; for there are great varieties in the place of theſe holes, in the different ſpecies: at this lower aperture is placed the mouth of the animal; the upper is ſuppoſed to ſerve it to diſcharge the excrements by. The whole external ſurface is covered with protuberances of different ſizes, but all diſpoſed in a beautiful and regular order; they divide the whole ſurface, as it were, into ten ſpheric iſoſceles triangles, all which have their ſummit at the upper aperture, and their baſe at the lower. Of theſe there are five large and five ſmall; but all the large ones, and all the ſmall ones, are regularly of the ſame ſize one with another. There is a ſmall band, which is leſs rough than the other parts, which ſeparates every larger from every ſmaller triangle; theſe bands are alſo in themſelves ſo many triangles; but the calling them by this name, will better ſerve to diſtinguiſh them from the others. As the triangles, both large and ſmall, are all covered with eminences or protuberances, theſe bands are, on the contrary, all pierced with ſmall holes; theſe run quite through the ſhell, and their apertures are more ſenſible on the inſide than on the out. Theſe holes are beautifully diſtinguiſhed, on holding the ſhell againſt the light, and are arranged in a very beautiful order, and in regular ſeries on every band. There are two ſorts of ranges of theſe upon every band, one ſort containing two holes all the way, and the other four; theſe are placed in a regular alternate order; firſt, a range of two, then a range of four, then another of two again, and ſo on to the extreme edge of the band.

The ſpace contained in every triangle is alſo in the ſame manner divided into ſeveral parts by a number of lines, which begin at the upper aperture of the ſhell, and terminate at the lower; but as theſe lines in the bands are marked by little perforations, they are, in the triangles, made of thoſe eminences which render the ſurface of the ſhell rough and uneven; thoſe eminences which are in the middle of every line, are larger than thoſe which come towards one or the other end; and the ſeveral different lines are made up of theſe eminences of different ſizes one from another, ſo that, on the whole, there is every where a great variety of them. Every one of theſe eminences reſembles a ſort of teat or nipple, with a portion of the breaſt; or, to give a more determinate idea of them, each is a portion of a ſphere, the ſummit of the convexity of which is crowned with another portion of a much ſmaller ſphere. Theſe are the parts on which the baſe of every ſpine of the *Urchin* is fixed; and as this baſe is hollow, it naturally envelopes the ſmall portion of a ſphere at the ſummit of each eminence, and is able to move and turn any way upon it, in the manner of the ball and ſocket articulations. The ſmaller eminences ſuſtain the ſmaller ſpines, and the larger the great ones; the number of theſe eminences, or, in other words, the number of the ſpines on one fiſh, is ſurprizing; many of them are ſo ſmall, that it is not eaſy to count them regularly; but Mr. Reaumur found, in general, that there were conſiderably more than two thouſand on every fiſh; nor is the number of the perforations before-mentioned leſs to be wondered at; they take up but a very ſmall ſpace on the ſhell, in proportion to the ſpines, yet Mr. Reaumur obſerves, that their general number in every ſhell cannot be leſs than thirteen hundred. From knowing the number of theſe perforations, we are able to determine that of the horns; for every horn has its origin from one of theſe. The horns are never ſeen all together, they are only viſible when the creature is in the water, and even then it only exerts ſome of them at a time, ſo that it is not to be expected that they ſhould all be ſeen together. When it is in motion, it only ſhews thoſe which are placed on that ſide of the ſhell which is to move forwards in the journey; and when it is at reſt, we only can ſee thoſe which it thruſts out, and faſtens to ſtones or other bodies, to fix itſelf by. Theſe ſerve by way of anchors to the creature, it glews them faſt down to the ſtones, *&c.* and if the creature be forcibly removed, they are generally, in part, if not entirely, broken and deſtroyed by it. When the creature is taken out of the water, they are no more to be diſcerned, they are bent and folded together, and are in a flaccid ſtate, ſo that nothing but their ends can be at all perceived, and theſe no body can tell what to make of, who has not before ſeen them in their exerted ſtate in the water.

The ſpines are all capable of aſſiſting the creature in its motions, but thoſe it principally employs are ſuch as are placed near its mouth, as theſe can turn upon their balls every way with equal facility, the creature finds it equally eaſy to move on any ſide; and when it has determined which way it will move, thoſe ſpines which ſtand directly toward that point, and thoſe which are directly oppoſite, are of equal ſervice to it; it draws itſelf forward by means of the firſt, and puſhes itſelf on with the others; to do this, it firſt thruſts out the foremoſt ones as far as poſſible, and preſſing them againſt the bottom, it draws on its body by them; and this is ſucceeded by its drawing up the hinder ones cloſe to its ſhell, and then fixing them againſt the bottom, it puſhes itſelf forward by them. This is the manner of this little creature's marching in the common way with its mouth downward; but it has this ſtrange ſingularity, that it is not confined to this poſture alone in marching, but can, with equal eaſe, walk with its mouth upwards, or run along ſideways in the manner of a wheel; or in any direction between theſe. The legs and the horns cover all parts of it, and are in every part of it equally able to move it every way. What a prodigious number of muſcles muſt this little creature have to be able to move ſeparately thirteen hundred horns, and more than two thouſand ſpines, which ſerve for legs. Mem. Acad. Par. 1712.

URED0, a word uſed by ſome of the chemical writers to expreſs the virtues of metals communicated to them from the ſun. Pliny uſes the ſame word to expreſs the ſmut affecting fruits; and ſome medical writers have expreſſed by it a very violent and excruciating pain in the head. See the articles SMUT and BLASTS.

URENA, in botany, a name given by Dillenius to a genus of plants, the characters of which, according to Linnæus, are theſe: The cup is a double perianthium; the external one is compoſed only of one leaf, divided ſlightly into five broad ſegments; the inner one is compoſed of five narrow and angular leaves. The flower is compoſed of five oblong petals, which are broadeſt at the apex, and end in an obtuſe point, and at their baſes are narrow and grow together. The ſtamina are numerous filaments, which at their baſes grow together into a cylinder, but ſtand free at the tops. The apices are roundiſh. The germen of the piſtil is roundiſh; but it is formed into five angular prominences. The ſtyle is ſimple, and of the length of the ſtamina, and is crowned with ten ſtigmata, which are headed, reflex, and hairy. The fruit is a roundiſh pentangular echinated capſule, being compoſed of five valves, and containing five cells. The ſeeds are ſingle and roundiſh, and at their ends ſomewhat compreſſed. *Linnæi* Gen. Plant. p. 329. *Dillen.* Hort. Eltham. p. 319.

URETHRA (*Cycl.*)—The hard knots which are ſometimes formed in the corpus cavernoſum *Urethræ*, after venereal virulency, are very difficult to cure. Till the pocky matter is all extirpated, it is in vain to attempt the cure of theſe knots, and even then they do not yield to mercury in any ſhape, but are reſolved by embrocations of the waters of Bareges. See Mem. de l'Acad. de Chirurg. Tom. 1.

Mr. le Cat has given us the figure of the canal of the *Urethra*, determined by ſolid injections. See Phil. Tranſ. N°. 460. Sect. 5. p. 684.

URETHRÆ *Depreſſor*, in anatomy, a name given by Santorini to a muſcle of the pudenda in women, the ſame with that which he calls in men the *elevator Urethræ* and *ejaculator*. Winſlow, and the generality of the French anatomiſts, call it the *proſtatique inferieur*. And Albinus, who has given to the *tranſverſalis penis* the name of the *tranſverſus perinæi*, calls this alſo the *tranſverſus alter perinæi*.

URETHRÆ *Elevator*, in anatomy, a name given by Santorini to a muſcle of the penis, which he calls alſo the *ejaculator*; it is called by Albinus the *tranſverſalis alter perinæi*, to diſtinguiſh it from the muſcle commonly called the *tranſverſus penis*; but which he calls the *tranſverſus perinæi*. The ſame muſcle in women is called the *depreſſor Urethræ* by the ſame Santorini.

URETHRAM *Dilatans*, in anatomy, a name given by De Graef to a muſcle of the penis called the *Urethram trahens* by Spigelius, and by the later writers, the *accelerator penis*. See the article ACCELERATOR.

URETHRAM *Trahens*, in anatomy, a name given by Spigelius and others to a muſcle now generally called the *accelerator*. See the article ACCELERATOR.

URETHRÆ *Triangularis*, in anatomy, the name of a ſuppoſed muſcle of the penis, called alſo *dilatator penis*, and *dilatator Urethræ*; it is properly only a proceſs of the ſphincter ani continued into the perinæum.

URIBACO, in zoology, the name of a Braſilian ſea-fiſh, eſteemed a very well taſted and wholſome one. It is ſomewhat of the figure of the pearch; its back is ridged, and its belly ſomewhat protuberant. It grows to ten or twelve inches long. Its teeth are ſmall and ſharp, and the ends of its gills terminate in a triangular point. Its gill-fins end in a triangular

triangular point; its belly-fins are ſuſtained by a very rigid and ſtrong ſpine. Its long fin, behind the anus, is all the way ſupported by flexile and ſhort ſpines, and has one very ſtrong and rigid one before it; and it has only one fin on the back, which reaches nearly to the tail, and is all the way of an equal breadth, and ſupported by rigid and prickly rays. Its tail is very deeply forked. Its ſcales are all of a fine ſilvery white, with ſome faint caſt of a pale but bright red; its belly-fins are white, and its back-fin and tail are reddiſh. Its ſide-lines are broad, and of a fine red; and over theſe, and under them, near the tail, there is on each ſide a large black ſpot. *Marggrave*'s Hiſt. Braſil. *Ray*'s Ichthyogr. p. 338.

URINARIA, in botany, a name given by ſome authors to the common dandelion. *Ger.* Emac. Ind. 2.

URINE (*Cycl.*)—The ſecretion of *Urine*, as alſo that of perſpiration, is conſiderably influenced by the paſſions. See the article PERSPIRATION.

Dr. Rega mentions the opinion of ſome modern authors, who imagine that our drink paſſes through the coats of the ſtomach and bladder, *&c.* when it is ſo quickly evacuated by *Urine*, as it is obſerved to be after drinking ſeveral mineral waters and other liquors. He endeavours to prove, by an eaſy calculation of the quantity of *Urine* ſecreted in the kidneys, that they are capable of furniſhing all the quantity obſerved at any time. And laſtly, he mentions the fullneſs and great frequency of the pulſe, after drinking theſe liquors, as a proof of their being mixed with the blood. Med. Eſſ. Edinb.

The ſpecific gravity of the human *Urine*, made in the night-time, has been found greater than that made in the day. Hence Dr. Bryan Robinſon [b] infers, that *Urine* draws off more contents from the blood in ſleep, than when bodies are awake; and conſequently that natural ſleep is a very good ſign in fevers, in which the blood abounds more with contents than it does in health.—[[b] Of the Food and diſcharges of Human Bodies, p. 85.]

The *Urine* of phthiſical people is ſaid to be always ſpecifically heavier than that of people in health, or in any other diſeaſe.

We have frequent inſtances of peoples voiding by *Urine* much greater quantities of liquids than they take into the ſtomach in the time; but this, though a ſeeming paradox, is eaſily explained, by conſidering how very ſmall a part only of what we call ſolids, is really ſolid. Chemiſtry ſhews us that the far greater part of our food may be procured in a fluid form by diſtillation; and on this principle alone, ſo long as the quantity of *Urine* voided is not more than that of the meat and drink together, the miracle ceaſes. There are, however, inſtances of the quantity of *Urine* greatly exceeding that of both. Dr. Wittie, in this caſe, ſuppoſes the converting of air into water to make up the over-proportion; but it is more rationally accounted for by the decreaſe of the patient's fleſh all the time. Our own bodies, as well as the foods we take in for their ſupport, are compoſed of a greater proportion of fluids; and the real ſolid matter is ſo very little, that when, by the courſe of a diſeaſe, thoſe fluids, which ſhould remain locked up in the texture of the ſolids, and increaſe their bulk, are drained and ſeparated from them, it is no wonder that the diſcharge be vaſtly diſproportioned to the ſupplies, when the body itſelf goes off with them. We have indeed accounts not eaſily ſoluble on theſe principles, nor any way but by the ſcheme of converting air into water before-mentioned; but till we are certain that the quantities and proportions are accurately noted in them, it will be raſh to conclude any thing from them.

Among accounts of this kind, we have theſe recorded in the Philoſophical Tranſactions from Dr. Wittie and others. A perſon at Hull, in a diabetes, voided twenty-four pints of *Urine* every eight and forty hours, for many weeks together, during which time his muſcular parts were all in a manner diſſolved into *Urine*; and the weight of the *Urine*, voided in theſe weeks, according to the Doctor's computation, greatly exceeded the whole weight of his body, and of all that he had eaten or drank in the time. Sir Kenelm Digby tells us a thing, which, if we may credit it, calls for a ſupply greater than any thing but the converting a great part of the air taken in in reſpiration could give: This is of a nun, who voided two hundred pints of water as from her bladder every twenty-four hours, for ſome weeks together. There is another relation of a ſick maid in Italy, who voided thirty-ſix pints of *Urine* every twenty-four hours, for the ſpace of ſixty days, till at the length the whole quantity voided amounted to one thouſand ſeven hundred and forty pounds; a weight greatly ſuperior to that of her own body, and all that had been received into it in the time. The whole credit of theſe relations lies on the character of their authors; and we are to remember, that the ſtrongeſt of them comes from an author who, in another part of his works, has given a receipt for creation; a method, as he expreſſes it, of making live crawfiſh. Philoſ. Tranſ. N°. 52. See the articles SOLID and FLUID.

In order to the preparing the phoſphorus, and indeed moſt of the other preparations of *Urine*, the firſt ſtep is to reduce that liquor to the conſiſtence of a rob or thick extract; thoſe who have worked on this ſubject ſufficiently know, how abominably naſeous and diſagreeable a taſk this is. The operator alone is not the perſon who is almoſt poiſoned by it, but the whole neighbourhood is affected; and it is well known, that our Godfrey, who uſed to prepare large quantities of this ſubſtance, was always obliged to keep a houſe in the fields to perform this part of the proceſs in.

There is an eaſy and excellent method propoſed by Stahl for the performing this troubleſome buſineſs, by means of condenſation by cold or freezing. There needs no more than to expoſe the proper quantity of *Urine* to ſome froſty nights in winter; or at any time of the year to our Ice-houſes, or other places where ice is preſerved all the year round. The froſt will, in this caſe, affect a large part of the *Urine*, but not the whole; and the liquid part being ſeparated from the ſolid ice, it will be found that the watery parts alone have ſuffered the freezing, and that all the unctuous and ſaline ones are left behind in the unfrozen part, which is, by repeated freezings of its yet remaining aqueous part, at length reduced to that ſort of rob which is required for all the purpoſes of diſtillation, and that without any trouble or offenſiveneſs, either to the operator or any body elſe. The power of condenſation by freezing in this manner, extends to wine, vinegar, and all fermented liquors; but it operates differently on the ſeveral different ones, and is to be regulated according to their natures. The natural cold of our climate is ſeldom too great for any of the liquors we deſire to condenſe; that is, it is never ſo great as to condenſe the whole into ice. It often is not ſufficiently great to condenſe the aqueous part, even after ever ſo many repetitions. In this caſe, it may be proper to bring in the uſe of the common freezing mixtures, made with ice, or ſnow and ſalt. To ſuit the artificial degree of cold, in theſe caſes, requires care and experience, and is almoſt as nice a point as the ſuiting the degrees of heat in the operations of chemiſtry. *Stahl* de Concentr. Vin. *Shaw*'s Chemical Eſſays.

When *Urine* has been reduced to a rob by condenſation by freezing, it is found to vary very remarkably, according as it was taken, either freſh, or half putrified, to make the operation. That which was made freſh remains in this ſtate tolerably clear, and of a dull yellow colour, and almoſt without ſmell; but that which was taken half putrified, remains of a colour between brown and red, or ſomewhat deeper, like the brown ſtrong beer, and becomes intolerably fœtid, if ſet for any time in a warm place; but that which was condenſed freſh, is not liable to this accident, but may be kept two or three years in the ſtate of rob, and will never grow fœtid, nor ſmell much like *Urine*. *Stahl* de Concentration.

Glauber has taught the world to believe, that there is nothing ſo deſtructive to vegetables of all kinds as *Urine*, which, he ſays, by means of the ſal armoniac that it contains, burns up all the roots. This is certainly true of *Urine*, and of dung too, when laid on in too great quantities; but it is certain that *Urine* is as ſafe as dung, and as profitable, when laid on in a ſparing and proper manner. Dung is of no uſe to land, but by its fermentation; but the beſt of all things to haſten and perfect that fermentation is *Urine*. The Dutch are perfectly ſenſible of this, and are as careful to preſerve the *Urine* of their cattle as the dung. *Mortimer*'s Huſbandry.

Bloody URINE, *Mictus Cruentus*, in medicine, the name of a very troubleſome and often dangerous diſeaſe; it is a voiding of pure blood by the urinary paſſages, and takes its origin from a congeſtion of blood in the emulgents, and is the method (tho' an unhappy one) taken by nature to diſcharge the load of a plethora, and give the maſs of blood freer room to circulate. This is the natural or ſimple *Mictus Cruentus*; but, beſide this, there is another accidental one, ariſing from an injury of the veſſels from a rough ſtone in the kidney. This, however, is a much leſs frequent caſe than is vulgarly imagined; for there are great numbers of nephritic patients who have very large ſtones in the kidneys, yet void no blood, and in many caſes, where this is a ſymptom, it will be more juſt to attribute it to the effect of the ſharp nephritic medicines, than to the action of the ſtone.

Signs of it. When a *Mictus Cruentus* is natural, it uſually comes on tacitly, and without any previous ſymptoms, or if there be any, they are only ſome ſenſations of a weight and preſſure upon the loins: but when this is brought on by accidents, as by the rubbing of a ſtone, or the like, it is always preceded by violent pains. The blood voided with the *Urine* is florid, and, after a time, ſubſides perfectly from among it; but when there is an exulceration of the kidneys, the blood is altered in its texture and appearance, and ſhews itſelf like worms.

Perſons moſt ſubject to it. Theſe are old men of plethoric habits; but even with theſe it is a rare diſtemper. When young men, or even middle-aged ones, are affected with it, we are to ſeek for its origin in violent and preternatural cauſes. Men are alſo, in general, more ſubject to it than women; but theſe are not wholly free from it.

Cauſes of it. Theſe are uſually a plethora, and an unnatural derivation of the hæmorrhoidal blood to the kidneys, where the veſſels burſt; for it is very rarely, and never but from ſome preternatural cauſes, that they burſt in the bladder. The common violent and preternatural cauſes of this diſeaſe, are the uſe of the hot diuretics, of balſam of ſulphur, of oil of amber, and, above all, of cantharides. Long riding on horſe-

horſeback, or blows on the region of the loins. In old men, an over uſe of venery may alſo bring it on, as alſo violent paſſions of the mind, a ſpirituous diet, an exulceration of, or a ſtone in, the kidneys; and finally, an omiſſion of habitual diſcharges of blood, whether they have been artificial by bleeding, or natural by the hæmorrhoids, or the like.

Prognoſtics from it. It is a diſtemperature that never can prove of benefit in any caſe, but is often very dangerous. Old men who are afflicted with it, rarely live long after it, eſpecially if the diſcharges are not regularly made; and if it be raſhly ſuppreſſed by the uſe of aſtringents, in any caſe, it brings on inflammations, fevers, and often dropſies. Ulcers in the kidneys are another very frequent effect of this; and under theſe, blood and purulent matter are voided together, and appear like clouds in the *Urine*.

Method of Cure. In the time of the fit, the violent emotion of the blood is to be reſtrained by nitre, cinnabar, and ſome of the abſorbent powders, and if theſe are found inſufficient, the milder aſtringents are to be joined with them; coral, crocus martis, and vitriol of iron; and if theſe fail, the aſtringent tinctures of ſteel, and the terra Japonica, are to be given. Some alſo recommend as ſpecifics, the juice of nettles, a decoction of the equiſetum or horſe-tail, and a tea made of aſparagus-roots. The bowels muſt be kept gently open by clyſters, or the milder purgatives; and after the fit the ſame methods are to be continued, to prevent a return. After this, bleeding in the foot is of great ſervice, and old perſons are not to be excuſed from it on account of their age. It is finally to be conſidered, whether an obſtruction of the menſes, or of the hæmorrhoidal diſcharges, have occaſioned the diſeaſe; and if ſo, they are to be regulated with all due care for the future; and for the firſt the proper medicines are to be given; for the latter, leeches are to be applied to the hæmorrhoidal veſſels. *Junker's* Conſp. Med. p. 39—44.

In caſes of *bloody Urine*, ſpirit of vitriol, mixed with the patients drink, has been found ſerviceable. See Medic. Eſſ. Edinb. abrig. vol. 1. p. 68.

Incontinence of URINE. This is a term uſed by medical writers to expreſs an involuntary excretion of this liquor, whether it be inceſſantly, or in larger quantities at different intervals.

This is of two kinds; in the one it is only in the night, in the time of ſleep; and this ariſes merely from careleſsneſs, and a bad habit; in the other, it depends on a paralytic affection of the ſphincter of the bladder; and in this caſe it drops away continually from the patient; and this is therefore called by ſome a *ſtillicidium*.

Authors alſo divide an *incontinence of Urine* into the idiopathic and ſymptomatic: The idiopathic is a diſeaſe in itſelf, and depends upon the preceding cauſes; the ſymptomatic happens to different perſons on different occaſions, as a ſymptom of other complaints. It is common to dying perſons; it is alſo very frequent to women who are very big with child, and ſometimes happens from violent ſneezing, coughing, or laughing.

Perſons ſubject to it. The voiding of the *Urine* involuntarily, and in the ſleep, in infants, is not to be accounted a diſeaſe; but when this cuſtom continues with them as they grow up, from idleneſs, or ill habit, it is at length to be conſidered as a diſeaſe, as they are by no means able to help it. Women who have ſuffered much in child-birth are often ſubject to an *incontinence of Urine* afterwards, eſpecially perſons who have had their firſt child at an advanced age. People in years, who are ſubject to paralytic complaints, are alſo often afflicted with this troubleſome complaint; and many who have been cut for the ſtone by perſons not ſufficiently ſkilled in the operation. Perſons ſubject to the piles alſo ſometimes fall into it, from the ſuppreſſions of their uſual diſcharges, and ſometimes from the tumors becoming fiſtulous, and reaching to the neck of the bladder. Impoſthumes of the bladder will alſo occaſion it, and violent external injuries.

Prognoſtics in it. An *incontinence of Urine*, which happens only in the night, and is merely cauſed by a bad habit, and not of long ſtanding, uſually admits of a cure; but the ſtillicidiums of *Urine*, from paralytic diſorders of the ſphincter of the bladder, are very rarely cured, eſpecially when they have been fixed ſome time upon the perſon.

Method of Cure. The involuntary voiding the *Urine* in the night, in children, is to be cured, in a great meaſure, with puniſhment for the neglect, and by denying them much liquids after dinner-time; by a proper diet; the avoiding all diuretics, and the making water immediately before going to bed; and when it has gone ſo far, that the tone of the parts is injured, the uſual ſtrengthening medicines are to be given, as in the following caſes.

When the *incontinence of Urine* is occaſioned by a paralytic weakneſs of the ſphincter, nervous and ſtrengthening medicines are the proper method of curing; in this caſe, maſtic, amber, nutmeg, and cinnabar, are found to be of great ſervice, and pills or powders compounded of them, are an excellent general remedy to be given in ſmall doſes, two or three times a day. Externally, it is very proper to uſe by way of fomentation, decoctions of roſemary, ſage, ſerpyllum, marjoram, and the like warm herbs in red wine.

When the diſeaſe is occaſioned by an impoſthume or ulcer in the neck of the bladder, balſamics are to be given, as maſtic, gum juniper, and boiled turpentine; but when it is owing to injuries received in child-birth, the manual operation of the ſurgeon is uſually to be preferred to all internal medicines. *Junker's* Conſp. Med. p. 538.

Suppreſſion of URINE. See the article SUPPRESSION *of Urine*.

URINE *of a Cow.* This diſagreeable potion having been much recommended as a medicine both in England and France, Mr. Lemery was at the pains of inquiring how far it might reaſonably be ſuppoſed to poſſeſs the virtues aſcribed to it.

He obſerves, that *Urine* in general is a ſerous liquor, impregnated with a volatile ſalt and oil, both which it has taken up from the blood, in the courſe of its circulation with it. It is eaſy to conceive, that principles ſo active as theſe may give it virtues, and thoſe very great ones. We find that recent human *Urine* purges, when taken in a proper quantity; but for all medicinal purpoſes, it muſt be much more proper to take the *Urine* of ſome animal which feeds only on vegetables, that being a ſort of extract of the more ſubtle ſaline parts of the herbs on which the creature feeds.

Tho' the *Urine* of any of theſe animals ſeems equally to be recommended; yet that of the cow has, in all times, been preferred to others, from the quantities of it eaſily obtained, and the tame and pacific nature of the animal, which has been ſuppoſed ſo far to influence it, as to occaſion its *Urine* to be leſs acrid than in other beaſts.

The ſpring ſeaſon is the propereſt for the uſe of this remedy, and the method of taking it is to drink two or three large glaſſes in a morning faſting, a quarter of an hour after one another: Thus taken, it purges both by ſtool and *Urine*; the perſon is to walk about, after taking it; and it has been found, in this manner, to do great ſervice in jaundices, dropſies, rheumatiſms, and aſthmas, as alſo in ſciaticas, and vapours.

Mr. Lemery gives ſeveral inſtances of cures performed by it, under his own direction, and afterwards proceeds to give its analyſis.

This *Urine* is uſually ſomewhat turbid, and when it has been ſuffered to ſtand by a little, depoſits a ſediment; it is of a pale yellow colour, and of a faint ſmell, greatly different from the *Urine* of the generality of other animals, and reſembling the ſmell of the dung of the ſame creature, only leſs ſtrong, and with ſome mixture of the ſmell of new milk.

The taſte is ſaline, acrid, and bitter; cows kept in cities often have their *Urine* very acrid; but thoſe in the fields frequently have it with only a ſlight bitterneſs at firſt, and not ſhewing its ſaline or acrid properties till after it has been made ſome hours. It always readily ferments with acids.

Mr. Lemery put into a cucurbit ſixteen pounds of *Urine of a cow*, kept in the country, and which had been made two days; This being diſtilled in a cucurbit, purged with leſs violence than before. The purging virtue plainly conſiſts in a volatile ſalt, which the *Urine* carries up with it in vapour; for it taſtes ſomewhat acrid and ſaline after diſtillation.

The diſtillation being continued in the ordinary way, there ariſes a large quantity of volatile ſalt and oil, in nothing differing from thoſe of the human *Urine*; and the remainder, in the bottom of the veſſel is a black, light, and ſpongy coal, weighing four ounces: this, being calcined in an unglazed earthen veſſel, over an open fire, and treated in the common way of elixiviation, affords three ounces two drams and a half of a fixed acrid and highly alkaline ſalt, white, and without ſmell. Mem. Acad. Par. 1707.

URN (*Cycl.*)—*Roman* URNS. Theſe veſſels are frequent in many parts of this kingdom, where there have been Roman ſtations, and are of very various kinds and manner of workmanſhip.

Dr. Liſter, who was very fortunate in his reſearches into the ſtructure and differences of theſe remains of antiquity, obſerved, that in Yorkſhire, where there are great numbers found, there were met with three very different kinds, as to their matter and tempers.

1. A bluiſh-grey ſort, which had a great quantity of coarſe ſand wrought in among the clay. 2. A ſort of the ſame bluiſh colour, but containing a ſand of a much finer kind, and full of mica, and probably made of a clay naturally ſandy, or a fine ſmooth and ſtiff loam. And 3. A red ſort, made of a fine pure clay, with little or no mixture of ſand. Theſe are throughout of a fine red colour like bole, and many of them are elegantly adorned with figures in *baſſo relievo*; and uſually theſe have on the bottom, or elſe on the cover, the name of the workman, which ſome have miſtaken for the name of the perſon whoſe aſhes they incloſe; but this muſt be an error, ſince great number of pots and urns are found with the ſame name. Theſe are varniſhed all over, both inſide and out, with a varniſh of a bright red colour.

The ſeveral matters of theſe *Urns* informed this ingenious inquirer of the place where they were made; which he found

to be in the ſame county on ſand-hills, now never uſed as potteries; but, as he well obſerves, the difference is very great between the potteries of thoſe days and of ours, ſince we, who uſe great quantities of clay, and but little ſand, erect theſe works where there is much clay, and bring the ſmall quantity of ſand we uſe to it; whereas the Romans, on the other hand, who uſed much ſand and but little clay, naturally eſtabliſhed their works where there was plenty of ſand, and brought their clay to it.

The *Roman Urns* differ from the earthen-ware made at this time in ſeveral particulars: 1. They have no lead-glazing, which ſeems a modern invention, and is, in many reſpects a very bad one. See the article GLAZING. 2. They are compoſed of a far larger quantity of ſand than clay. And 3. they are baked not in an open fire, as our common earthen-ware, but have been incloſed in large earthen veſſels, to defend them from the immediate contact of the flames; and hence it is, that the natural colour of the clay they are made of is not altered in them.

The red *Urns* ſeem to have been the maſter-piece of the workmen, and to have employed their greateſt art; the emboſſed work upon them is often very beautiful, and their coral-like glazing is more beautiful than any thing of the modern times, and ſeems to have been done by dipping them all over in ſome appropriated liquor, and afterwards baking them in the cloſe manner before deſcribed. This has certainly been the method they uſed, ſince the fragments of theſe large coffins, or caſes, are found near all the Roman potteries. *Hook*'s Philoſophical Collections, p. 87.

The Romans, and moſt other nations, contented themſelves to make their funeral *Urns* of potters ware, or baked earth; but we find there have been ſome people who have made them of gold, on particular occaſions. In the year 1685, as a peaſant of the iſland of Funen was ploughing a piece of land, which had before lain barren, he turned up no leſs than ſix golden ſepulchral *Urns*. They were all full of a greyiſh ſubſtance, which ſome took to be a grey earth; but it was much more probably aſhes.

Theſe are all preſerved at this time in the muſæum of the king of Denmark at Copenhagen; the largeſt of them weighs two ounces and a half, and the others about two ounces and one dram each. Wormius, and ſome others, give accounts, that it was an antient cuſtom among the northern nations to burn their dead, and when they were great perſons, to collect their aſhes and bury them in golden *Urns*; and the finding theſe ſeems an evident proof of the truth of that account.

Theſe *Urns* were very thin, and each had three rings of gold about their necks, and ſeveral circles, one within another, with one common center carved on the outſide round the body of the *Urn*. They held about five ounces of liquids apiece, or a little more than that; one near ſix ounces.

Sepulchral *Urns* of cryſtal were alſo not uncommon; the ſame muſæum has ſome of theſe: they are of a conic figure, and have uſually a gold wire wound round them. *Urns* of this kind have been found buried in ſome parts of Norway. Another kind of *Urns* were thoſe which they called *lachrymales*, or the *tear-Urns*: Theſe were contrived to receive the tears of the friends of the deceaſed, which were afterwards mingled with the aſhes of the burnt corpſe: Theſe were made of various materials, and of various ſhapes and ſizes, according to the fancy of particular people. Phil. Tranſ. N°. 285.

UROGALLUS, in zoology, the name of a bird of the gallinaceous kind, called alſo *tetrao*, and in Engliſh the *cock of the wood* or *mountain*. See Tab. of Birds, N°. 25.

In ſhape it reſembles the turkey, and approaches to it in ſize. Its legs are feathered down to the toes before, and naked behind. Its breaſt is of a pale reddiſh brown; the ends of the feathers white; and the whole variegated with tranſverſe black ſtreaks. Its belly is greyiſh, and its back elegantly variegated with black, reddiſh-brown, and grey. The ends of the feathers are all ſpotted with ſmall ſpecks, unleſs on the head, where they are of a fine plain black; but with a glow of purple intermixed. The tail is of a reddiſh brown, variegated with tranſverſe black ſtreaks, and is white at the tip or end. It is common on the Alps, and in ſome parts of Italy, and is ſaid to be found alſo in the mountainous parts of Ireland. Its fleſh is very delicate.

UROGALLUS *Minor*, in zoology, the name of a large bird common in ſome counties of England, and called the *black game*, or *grouſe*, and by ſome authors, *tetrao minor*. *Ray*'s Ornithology, p. 123. See Tab. of Birds, N°. 26. and the article GROUSE.

UROMASTIX, in zoology, a name uſed by ſome authors for that ſort of lizzard called *cordylus*. *Grew*'s Muſ. p. 45. See the article CORDYLUS.

VROW-*Fiſh*, in zoology, the name of a freſh-water fiſh of the malacoſtomous kind, or, as we call it, the leather-mouthed kind, caught in the lakes and rivers of Germany, and eſteemed a very delicate fiſh.

It is ſomething like the Engliſh rudd or finſcale, but its body is ſomewhat longer, in proportion to its breadth; its back is brown, and its belly yellow; the belly-fins near the anus are a little reddiſh, but all the reſt are brown; the ſcales are large and ſilvery, and the iriſes of the eyes have each, in their lower part, a blood-coloured ſpot; the tail is forked; and its uſual ſize is about ſeven or eight inches, though it is ſometimes caught conſiderably larger. *Willughby*'s Hiſt. Piſc. p. 253.

URRY, in natural hiſtory, a name given by the people of Cheſhire, and ſome other counties of England, to a black fat earth found in coal pits, lying immediately over the ſtratum of coal. It is found to be an excellent manure for land, particularly in cold clayey ſoils. *Mortimer*'s Huſbandry.

URSUB, a name by which ſome of the chemical writers have called lead.

URTICA, *Nettle*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the apetalous kind, being compoſed only of a number of ſtamina placed in a cup. Theſe are barren, and the ſeeds grow on other plants of the ſame ſpecies, which have no flowers, and are contained either in round globules, or bivalve capſules, or in long tufts.

The ſpecies of *Nettle*, enumerated by Mr. Tournefort, are theſe: 1. The great ſtinging *Nettle*. 2. The great ſtinging *Nettle*, with red ſtalks. 3. The common leſs ſharp *Nettle*. 4. The common ſmall *Nettle*. 5. The ſtinging *Nettle*, with round balls, and ſeeds ſhaped like linſeed. 6. The pellitory-leaved *Nettle*, with round balls. 7. The great Canada racemoſe *Nettle*. 8. The Canada *Nettle*, with leaves like the myrrhis. And 9. The racemoſe American *Nettle*, with large hazel-like leaves. *Tourn.* Inſt. p. 334.

The roots of the common *Nettle* are much recommended in medicine; they are powerful diuretics, and are ſaid to have great virtues againſt the ſtone and gravel. They cleanſe the blood, and are ſaid to be of great ſervice in hæmorrhages of all kinds, particularly in ſpittings of blood, and overflowings of the menſes. Authors add to this, that they are ſpecifics, by way of antidote againſt the poiſon of henbane and hemlock; but this we are not ſo well aſſured of. The young ſhoots of the plant are eaten in the ſpring, as good againſt ſcorbutic complaints. *Dale*, Pharm.

The antients ſeem to have deſpiſed this plant, from its being common, and, though poſſeſſed of great virtues in medicine, neither the Greeks nor Latins have ſaid much about it; nor have the Arabians, who abound in the imaginary virtues of plants, thought the real ones of this herb worth their conſideration.

It has, however, been more honoured lately, and notwithſtanding its being now the moſt vile and abject plant among us, as well as the leaſt regarded by the antients, Johannes Francus, an author of conſiderable fame, has publiſhed a treatiſe ſolely upon it; in this he has treated at large on its hiſtory and virtues. He deſcribes its ſtings in a very judicious manner, according to the preſent doctrine of the microſcope, and gives the hiſtory of certain worms of ſingular kinds which feed upon it; and adds its uſe in our own foods as a wholeſome and agreeable pot-herb; in our drink as a ſubſtitute for hops, being as well capable of preſerving it as thoſe, and its great ſervice to the farmer in fattening hens.

John Melchiore Dreſchler, in the year 1717, ſuſtained alſo a theſis on the virtues and uſes of this plant, which has been ſince printed, ornamented with ſeveral cuts. In theſe two authors we find the whole account of the ſeveral uſes this common plant has been put to, and may be put to in our manufactures, our domeſtick and medicinal uſes; and, if what they ſay be true, we muſt wonder to ſee ſo much value overlooked in an herb, only becauſe it is common.

URTICA *Errans*, in zoology, the name of a ſea-animal, of the nature of the common *Urtica marina* in many particulars; but as that is always fixed down to the rocks, this ſpecies is always found looſe.

It has been ſuppoſed that theſe creatures affected the ſkin with a pain like that of the ſtinging of nettles on touching them, and even the eyes of thoſe who only look attentively on them; but Mr. Reaumur, who ſaw prodigious numbers of them on the coaſts of Poictou, declares that he found no ſuch property in any of them, any more than in thoſe fixed to the rocks.

Theſe in ſubſtance ſo much reſemble a ſtiff jelly, that if they were called ſea-jellies, there would want but a ſhort additional deſcription to make them underſtood. Their fleſh, if it may be ſo called, appears of the colour as well as the conſiſtence of a common jelly; and if a piece of one of them be taken up, the mere heat of the hand is ſufficient to make it melt away into plain water. Theſe are notwithſtanding true and perfect animals; and thoſe who have been of a contrary opinion, have not examined them with ſufficient attention. There are very different figures among them; but this is owing to their being of different ſpecies, for all thoſe of the ſame ſpecies are ever exactly of the ſame figure. One great reaſon of people's ſuppoſing them unorganized bodies, is, that what is ſeen of them about the ſhores is very often a fragment of a dead animal, not the whole of a living one; and no wonder if all the

neceſſary

neceſſary parts of an animal could not be found in ſuch a piece of one.

Though the generality of theſe animals are of the ſimple colour of a jelly, there are ſome of a greeniſh caſt, and others which have a broad band of a beautiful purple round their extremity; and ſome are beautifully ſpotted with brown. Their figure is very well expreſſed by that of the head of a large muſhroom; their upper ſurface is convex in the ſame manner, and this convexity is greater or leſs in the different kinds, as it is in the different ſpecies of muſhrooms; all that is to be obſerved on this convex ſurface, is, that it has ſeveral little protuberances on it, ſhaped like ſo many nipples, and placed in an irregular manner: theſe are of the ſame colour with the reſt of the body; but though there is nothing more to be ſeen on this ſurface, the under, or concave one, gives proof enough of a regularly organized body. The edge is very thin, and cut in ſeveral places; and juſt within that there appears a great number of concentric circles, which cover the reſt of the ſurface. Theſe are not all complete; however, thoſe which are near the center, are divided into ſixteen arcs, and thoſe more diſtant into eight. Theſe ſeparations in the circles are made by certain tubes, which are always full of water, which they can, at pleaſure of the animal, communicate to other very ſmall and fine tubes, placed between the circumferences of ſome two of the circles. Theſe ſmall tubes are of great conſequence to the well-being of the animal, and they are known to be tubes by their figure, when full, and are eaſily proved to have communication with theſe other reſervoirs, by the preſſing the larger, which always ſends the water into theſe ſmaller ones. The large veſſels, which go from the center to the circumference, and theſe ſmall circular ones ſeem, in ſome meaſure, to reſemble in their office the veſſels of larger animal bodies; and this water contained within them, to be a liquor elaborated there, and analogous to blood, which fills out and diſtends the very fine and ſmall ſolid parts, of which this animal's body is compoſed. If one of theſe animals be dried in the ſun in hot weather, there remains nothing of it but a ſubſtance like a thin parchment; but if one of them be boiled in water, it does not diſſolve away as might have been expected, but only regularly decreaſes in ſize; and when it has become of about one fourth of its natural bigneſs, it there ſtops the decreaſe, and continues nearly of that ſize, and after that will not melt away upon the hand.

Near the end of the ſtrait tubes, all the animals of this ſpecies are divided into four parts, by four bands or columns, for they are round in ſome, and flat in others. Theſe are ſometimes raiſed almoſt perpendicularly on the baſe; ſometimes they make an acute angle, and they all join at length to a round trunk of about their own length; this trunk is of a cylindric figure, and is divided into eight branches. In the ſpace contained under the four columns, there is a large canal formed by a thick membrane, which ſeems the only ſolid ſubſtance in the animal; this membrane is folded into a ſort of purſe, and forms a ſort of canal, which becoming round near the baſe of the columns, takes the ſame figure which a ribband would have, if turned round the four arms of a large and regularly ſhaped croſs. This large canal is full of a yellowiſh glutinous liquor, and it uſually gives one or two branches to each of the columns. Theſe four colums terminate, as before obſerved, in a trunk, which then divides into eight branches, and their route may be further traced through the whole body of the animal, as they contain the ſame yellowiſh liquor with this large veſſel, which is every where diſtinctly ſeen, as being very different from the reſt of the body in colour.

All the creatures of this ſpecies, which we ſee thrown upon the ſhores, are found lifeleſs and without motion; but there is nothing wonderful in that, becauſe the violent ſhocks and blows which they muſt have received, in being daſhed againſt the rocks or ſands by the waves, are enough to kill ſo tender an animal. One proof that theſe animals once lived, is, that all thoſe which we find about the ſhores are heavier than the water, and ſink to the bottom, whereas all thoſe ſeen out at ſea, ſwim upon the ſurface; and this could not be the caſe in regard to any ſubſtance heavier than water, unleſs kept up by ſome voluntary motion. This motion Mr. Reaumur has obſerved to be a reciprocal contraction and dilatation of the whole body, in the manner of a ſyſtole and diaſtole. In the contraction it elevates the convexity of the body, and in the dilatation it makes it more flat, and by continually repeating theſe motions, it keeps above water as a man does by ſwimming. Mem. Acad. Par. 1710.

URTICA *Marina*, the *Sea-Nettle*, in botany. See the articles LAMIUM and ARCHANGEL.

URTICA *Marina*, in zoology, the name of a remarkable genus of fiſhes, ſo called from their affecting the ſkin on touching them, with a painful ſenſation like that of the ſtinging of nettles. Theſe are an animal of the loweſt claſs, and have by many been reckoned among thoſe creatures called *zoophytes*, or plant animals, as ſuppoſed to partake of the nature of vegetables and of animals. Some of the ſpecies of this fiſh are found looſe upon the ſmooth ſhores, and ſome fixed to the rocks which are always covered with water. This has given birth to a diſtinction of them into two claſſes, which is as old as Ariſtotle; thoſe of the one being ſuch as move in the open ſea, and thoſe of the others ſuch as are fixed to rocks, and were ſuppoſed always to remain immoveably in the ſame place. The accurate Mr. Reaumur has obſerved, however, that even theſe laſt have a power of a progreſſive motion, and are not doomed to an eternal reſidence on the ſame ſpot. The motion of theſe creatures is ſo ſlow, that it might eaſily paſs unobſerved by leſs accurate obſervers; this gentleman comparing it to that of the hour-hand of a clock, and adding, that a journey of an inch takes them up commonly between one and two hours. He obſerves alſo, that many of the ſpecies have no property of ſtinging, or cauſing any painful ſenſation on the fleſh. Ariſtotle and Pliny, who were both inclined to make theſe creatures of a middle nature between plants and animals, yet differ in their accounts of them; the former affirming that they have no anus or exit for their excrements, and the other allowing them an extremely fine tube or pipe for that purpoſe. What Pliny ſeems to mean by this pipe, muſt be one of the horns of the creature; but the matter it diſcharges from that, has nothing of the appearance of excrements, being mere clean water. Senſation, a power of eating and digeſting food, and locomotion, being certainly ſufficient characters of animal life, and this creature being evidently poſſeſſed of them all, there is no room to doubt its being as truly and properly an animal, as a whale or an elephant.

Theſe creatures occaſionally change their bodies into ſo many different forms, that there is no giving any deſcription of their figure. The moſt natural and general ſhape, ſeems that of a truncated cone, the baſe of which is applied to the rock; but this baſe is often round, often elliptic, and often of a perfectly irregular figure. This baſe is alſo ſometimes perpendicular to the ſummit; but very often it is oblique; and in changing the figure and extenſion of this, the animal alters its own whole ſhape at pleaſure; for the ſmaller this baſe is, the more elevated is the top; and, on the contrary, the broader it is, the flatter and lower is the whole fiſh. The ſurface of the top of the cone is not flat, but convex, and has in its center an aperture, which the creature makes larger or ſmaller at pleaſure. In ſome poſitions the whole fiſh not unaptly reſembles a purſe, only with this difference, that the body is not drawn up into any folds or wrinkles by the cloſing the aperture or mouth. In the middle of this purſe, as we call it, is placed the body of the fiſh, touching this outer covering at the bottom on every ſide, and of a conic figure, as that is. At its top, however, it is looſe, and ſtands every way free from its covering; the ſides are more or leſs diſtant from this free or looſe part of the body, as the aperture at the top of the cone is more or leſs open; when it is nearly ſhut up, very little of the body of the animal can be ſeen; but when it opens it to different widths, more or leſs of the body becomes viſible, and when it is at the wideſt, every part of it, and all the horns, are ſeen perfectly diſtinct. Theſe horns reſemble in appearance thoſe of the common ſnail; but in their uſe they ſeem much more allied to the pipes or proboſcides of the chamæ kind, the fiſh generally throwing out water at them on being touched. They are placed in three ranges on the internal ſurface of the covering, and are very numerous, their whole number not being leſs than 150.

The creature very often not only opens the outer covering or purſe to the utmoſt width it is capable of, but at the ſame time turns back its extremities; in this caſe the internal part, or body of the fiſh, becomes viſible on the ſurface, and at the ſame time all the horns being, by this bending back of the ſkin on which they grow, thrown into the poſture of ſo many rays; the whole makes a very remarkable figure, and not unaptly reſembles an anemony, or ſome other ſuch flower, when fully open. Very often alſo there is a great addition to the beauty of this appearance, by ſeveral round veſicles of water, which appear blue, or of ſome other lively colour. The general colour of the different ſpecies of this fiſh, or indeed of the ſame ſpecies in different circumſtances, is as variable as the ſhape; ſometimes they are ſeen pellucid and colourleſs, ſometimes white, often yellowiſh, ſometimes of a roſe colour; at other times they are of a beautiful green, and often of various ſhades of brown. In ſome theſe colours are equally diffuſed through every part; in others they are only ſeen in form of ſpots and clouds or variegations; ſometimes theſe are irregularly diſpoſed, ſometimes more regularly; but always with great beauty. The green ones have uſually a broad line of blue all round their baſe. The colours nor ſhapes of theſe animals can be no marks of different ſpecies; but the firmneſs of their fleſh may; in this they remarkably differ one from another, and this is a difference the more obvious, as their fleſh is always open to the touch, there being no ſhell, nor any other hard ſubſtance to cover it.

However ſlow the progreſſive motion of this fiſh is, when examined it is found to depend on a very remarkable mechaniſm, to underſtand which we muſt attentively conſider what is obvious to the eye in the ſtructure of the creature, and remember the compariſon of the whole fiſh to a purſe. We find that what reſembles the bottom of that purſe is flat, and is fixed to the rock, while the body of the fiſh is

contained

contained in the reſt of the purſe, but never fills it, unleſs when the mouth of the purſe or covering is cloſe drawn together. The whole covering is a collection of muſcles which are all tubular. The baſe of the fiſh never appears to us, becauſe always fixed down to the rock; but when the creature is raiſed from that poſition, and the baſe examined, it appears compoſed of a vaſt number of tubes placed one behind another, and running from the center to the circumference. Theſe tubes are often filled with an aqueous liquor, which may be forced out on preſſing them. Beſides theſe tubes, there are alſo to be ſeen many circular ones, which ſurround one another, and have for their common center that of the baſe. The conic part of the covering is in the ſame manner compoſed of a number of circular tubes, which are placed very cloſe to one another, and all run parallel with the round verge of the baſe, and terminate at the upper circle or rim of the cone. Under theſe there is another ſeries of ſtrait tubes, which all run from the baſe to the top of the cone. It is remarkable that the circular and ſtrait muſcles are never ſeen together in the ſame place; whether it be that the extending of the one ſet makes the others flaccid, or only that the leſs extended ones are hid by thoſe which are more ſo. Sometimes there are only the circular ones viſible, ſometimes only the ſtrait ones, and often only a few of the circular ones appear, reſembling ſo many bands, between which it is eaſy to ſee the parts of the ſtrait ones which lie under them. The creature ſeems capable of making all theſe changes at pleaſure, filling ſuch as it will with an aqueous liquor, which is the cauſe of their becoming more viſible, and which is let out, if they are pricked with the point of a pin. The inflation of different parts of theſe ranges of ſtrait and circular tubes, is what makes all the differences in the ſhape of the fiſh, and ſerves alſo to the purpoſe of its progreſſive motion; and it ſeems probable that the aqueous liquor which ſerves to diſtend them, is, at the pleaſure of the creature, conveyed to them from the horns, and from them back to the horns again. The progreſſive motion ſeems thus performed: When the creature has determined which way it will march, it diſtends all thoſe longitudinal tubes which are on that ſide of its body which is placed toward the point it would move to; this, from its round ſhape at the baſe, gives it an oblong one; that is, it throws the fore-part ſomewhat forward upon the rock; and, at the ſame time, if the longitudinal tubes on the oppoſite ſide of the body be all left empty, and the circular ones diſtended, theſe naturally draw the whole body toward the fore-part, and thus a ſmall advance is made and preſerved, and this, often repeated, is the ſlow progreſſion of this animal. All this is, however, performed ſo very ſlowly, that though there is a continual change going on in the creature, both as to ſhape and place, yet if the eye is kept continually on the object, neither is perceived; but, if taken off for ſome time, and the place and figure both kept in mind, both will be found to be altered on viewing again.

There is a ſpecies of this fiſh alſo which moves by means of its horns; this is known from the reſt by the length of the horns, and their being covered with a glutinous moiſture. This ſpecies lives in the cavities and holes of rocks; and when it has a mind to move, it turns itſelf bottom upwards, and crawls ſlowly on by means of its horns, which then touch the rock.

The food of the *Urtica-marina* is not leſs wonderful than its ſtructure and motions. It ſhould ſeem very ſtrange that an animal, ſoft like this creature, with no feet, no inſtrument of that kind to help itſelf with, ſhould be able to feed on the fleſh of muſcles, ſea-ſnails, and other ſhell-fiſh; yet theſe are its conſtant food. They find means to take in the ſhell-fiſh whole into the body, and then cloſe the aperture faſt upon it, ſo that it is not to be ſeen that they have any ſuch thing within them; they keep them here as long as they pleaſe, and afterwards throw out the empty ſhells by the ſame aperture, which they can, as before obſerved, widen and contract at pleaſure. By what means the *Urtica* is able to get out the body of theſe fiſh, is not known, as it all paſſes in the body; but it very often fails, and the creature is obliged to throw out the ſhell fiſh alive again; and ſometimes, when it has greedily gorged too large a morſel, and it is got into a wrong poſition to be thrown out the ſame way, it is obliged to let it through the baſe, where there is no natural aperture, and where its paſſage muſt be attended with a terrible wound. The manner in which the larger ſhells are thrown out by the mouth, is by opening it extremely wide, and turning it back, ſo that the inſide appears outward for a little way down; and this motion is alſo uſed on another very neceſſary occaſion, the excluding the young ones, for theſe animals are viviparous. Mem. Acad. Par. 1710.

It has been found that this creature has the remarkable property of the polype, in re-producing ſuch parts as it had loſt. Mr. Reaumur tried many experiments on the various ſpecies of this, and of the ſtar-fiſh kind, and found that whatever parts were cut off, the wound ſoon healed; and Mr. de Villars had opportunities of watching the whole progreſs of the growth of the animals afterwards, and found that they not only ſeemed alive and well after cutting, their wounds ſoon cicatriſing, but that they, in a very little time, regained what had been cut off, and became as perfect as before.

URUS, in natural hiſtory, the name of a ſpecies of wild bull, of a very remarkable ſize and ſtrength. Cæſar, in his commentaries, has deſcribed them as little inferior to elephants in ſize, and reſembling the bull in ſhape, figure, and colour. He adds, that they were very ſwift and fierce, and had horns very much larger, and very different from thoſe of the common bull. And Mentzelius tells us, that it is a vaſt and terrible ſpecies of wild bull, common in Livonia, *&c.* and that when killed, its brain is found ſcented like muſk. Mr. Ray wiſhes very much, that ſome one, who has an opportunity of ſeeing this creature, would give a more accurate and perfect account than thoſe we already have of it. *Ray*'s Syn. Quad p. 70.

USNEA, (*Cycl.*) in botany, the name of a genus of moſſes, the characters of which are theſe: They are wholly deſtitute of leaves, and are compoſed only of long ſlender filaments or ſtalks, which are uſually ſolid, rigid, and of a cylindric figure. The extremities, or other parts of theſe, are at times furniſhed with a ſort of orbicular bodies, dry and deſtitute of uſe, but ſeeming to ſupply the place of flowers. Theſe are hollow, in form of cups, but have no rim. The whole plants are fixed in the manner of miſletoe to the barks of trees. Micheli has given accounts of flowers and ſeeds in theſe plants; but Dillenius ſuſpects the accuracy of the obſervation, and adds, that if there are ſuch, they are too minute to be of any ſervice in the general diſtinctions of the plants. *Dillen.* Hiſt. Muſc. p. 68. Of this genus of plants there are nineteen known ſpecies. 1. The ſtringy-tree moſs, or common *Uſnea* of the ſhops. This conſiſts of long and variouſly implicated threads, which are branched out into ſeveral diviſions; this grows on old oaks, and other trees, in thick woods. 2. The wide-forked tree *Uſnea*, with finer points, deſcribed by Micheli, and in its ſeveral varieties, by him called of three ſpecies. It is compoſed of thicker branches than the former, and they are only dichotomouſly divided, having no ſmall branches but at the points or ends. 3. The wide forked *Uſnea*, with thicker points; this and the two former are of a grey colour, and this compoſed of rough ruſhy branches. It grows on old fir-trees. 4. The capillaceous knotty tree *Uſnea*, called the *long headed Uſnea*, or *necklace moſs*. This is of a bluiſh-grey colour, and hangs down from the branches of old trees. 5. The flat Alpine *Uſnea*. This is ſofter than the others, and has long and flatted branches, and commonly is found on the larch-tree. 6. The beard *Uſnea*. This is compoſed of thin and fibrous branches, and is uſually more or leſs knotty. It is of a pale grey colour, and grows on old beech, and other trees. 7. The black mane *Uſnea*. This grows in great plenty in the Hartz Foreſt, and in ſome parts of England. It is rigid, and of a ruſty black. 8. The black, hard, woolly *Uſnea*. This grows on rocks and ſtones, and reſembles flocks of black wool, but is more rigid. 9. The black tufted *Uſnea*. This alſo grows on ſtones; it is ſmall and ſlender, but uſually ſtands in thick tufts. 10. The hard and rigid tree *Uſnea*, with branches expanded every way. This is of a greeniſh grey, and grows on oaks, and ſometimes on rotten poſts and old boards. 11. The horſehair *Uſnea*. This is black, and compoſed of ſlender filaments, ſcarce at all branched, reſembling horſe-hairs. It is common on the barks of trees in Patagonia. 12. The common ſmall *Uſnea*, without rundles or cups. This is a very common moſs on old trees and boards; it is very much branched, and does not hang in long ſtrings, like the others, but is of a ſomewhat ſhrubby appearance. 13. The common ſmaller *Uſnea* with rundles. This is not leſs common than the former, and much reſembles it; but the lateral branches are more rigid. 14. The true *Uſnea* of the Arabian phyſicians. This is of a whitiſh colour and ſmooth ſurface, and is divided in the manner of a ſtag's horns, and of a very agreeable ſmell. The branches are partly cylindric, but a little compreſſed, and are uſually crooked, and divided into many filaments. It is not a native of England, but is very common in the Eaſt Indies, and in many other parts of the world. Bellonius ſays, that it is commonly ſold in Conſtantinople. 15. The orange-coloured forked *Uſnea*. This is of a deep yellow, and conſiſts of flatted branches, dichotomouſly divided, and terminating in fine ſlender filaments. It is often found of a foot in length, and is common in the Canaries. 16. The braſs wire *Uſnea*. This is of a fine gold yellow; its branches are cylindric and rigid, and it grows up in the form of a ſmall ſhrub. 17. The ſmaller yellowiſh tree *Uſnea*, with coronated rundles. This is ſmaller, and of a paler yellow than the other, and its branches are thicker. 18. The ſmall hairy black *Uſnea*. This grows on ſtones and rocks, and is very ſhort and rigid. 19. The ſmalleſt of all the *Uſneas*. This is of a black colour, and grows on the barks of old trees, but is ſo ſmall as to be ſcarce viſible. *Dillen.* Hiſt. Muſc. p. 70.

USNEN, in botany, a name given by Aviſenna and Serapion to the plant Kali, of which the alkali ſalt called *pot-aſhes*, and uſed in the compounding our ſoap, is made. There are alſo ſeveral other things called by this name, and, in general, all that were

were uſed in the ſcouring or cleaning of clothes. The dung of ſparrows was uſed by ſome people for this purpoſe, as the dung of hogs is at this time, and this was therefore called by ſome *Uſnen*. Hyſſop, a plant famous for its cleanſing virtue, was alſo called by the ſame name; and ſome have alſo applied it to the ſoldanella, or ſea bind-weed.

Wherever, in the Arabian writers, the word *Uſnen* is uſed in any of theſe latter ſenſes, there is ſomething added to diſtinguiſh which of the things before expreſſed is meant by it; but whenever it ſtands alone and unexplained, it is to be underſtood as meaning the *kali*.

USSAC, in the materia medica of the Arabians, a name given by Serapio to the gum ammoniacum of the Greek writers. It ſeems no other than a falſe ſpelling of the word *aſſac*, which is the common name of the gum in Aviſenna, and other of the writers of that nation; but this does not ſeem to be the ſame drug which we call gum ammoniacum at this time.

USTRINA, among the Romans, the place where they burnt the bodies of the dead. It was commonly in the Campus Martius, or ſome other place in the ſuburbs, and ſometimes in the city for perſons of quality; and for the common people on the Eſquiline mount. *Danet.* in voc. See the article BUSTUM.

USTULATION, *Uſtulatio*, a word uſed by pharmaceutic writers to expreſs the roaſting or torrefying of humid or moiſt ſubſtances over a gentle fire, ſo as to render them fit for powdering. The ſame word is alſo uſed by ſome for what we call burning of wine.

UTAMANIA, in zoology, the name of a bird of the web-footed kind, wanting the hinder toe. It is common about the iſland of Crete, and is very expert at diving. It is of the ſize of a teal, and has its head and back black, and its belly white. Its feathers are ſoft and ſlender, and rather reſemble down than plumage; but they are very firmly affixed to the ſkin. Its beak is ſharp at the edges, and is covered in a great part with down. Bellonius, who deſcribes the bird, ſuppoſes it to be the only web-footed one that wants the hinder toe; but in this he is miſtaken: his deſcription and figure comes alſo ſo near the common beak or razor-bill, that it is pretty certain the bird is nearly allied to that, if at all eſſentially different. *Bellonius* de Avib. *Aldrovand.* de Avib. T. 3. p. 240.

UTAS, *Octava*, in our ſtatutes, the eighth day following any feaſt or term; as the *Utas of St. Michael*, &c. And any day between the feaſt and the octave is ſaid to be within the *Utas*. The uſe of this is in the return of writs, as appears by Stat 51 Hen 3. *Blount*, *Cowel.*

UTERINE (*Cycl.*)—UTERINE *Hæmorrhages*. In this dangerous diſorder the ſtyptic powder of Helvetius is much recommended: and the ſtybium ceratum has alſo been tried with great ſucceſs. See the articles STYPTIC *Powders* and VITRUM *Antimonii Ceratum*.

UTERINUS *Lapis*, in natural hiſtory, a name given by ſome authors to a ſtone found in New Spain, and in ſome other parts of America; it is very hard and heavy, of a beautiful black, and capable of a very elegant poliſh. The natives cut it into various ſhapes, and apply it to the navel in diſeaſes of the womb, and pretend that it poſſeſſes very great virtues.

UTERUS (*Cycl.*)—Authors have differed as to the thickneſs of the *Uterus* of a woman with child. In an account of a diſſection of a woman dead in labour, mentioned in the Medical Eſſays, vol. 4. art. 33, it is ſaid, the *Uterus* was found at leaſt half an inch thick in the thinneſt part, and a good deal more at the fundus.

UTERUS *of Fiſhes*.—Among the fiſh kinds, all thoſe which are oviparous have no *Uterus*; but, on the contrary, all the viviparous fiſhes have this part. The whales, and all the cetaceous kinds, as alſo many of the cartilaginous ones, have the *Uterus* very fair. It is probable that the eel kind alſo have it; but this is leſs certain, the generation of thoſe fiſhes being yet ſomewhat obſcure. The *Uterus* in the cetaceous fiſhes is always divided into two proceſſes or horns; but in the cartilaginous ones it is divided into two glandulous bodies, which are pervious, and, according to the opinion of Needham, diſcharge a whitiſh liquor into the womb, and are of great uſe in gravidation.

UTFANGTHEF, in our old law-books. See the article OUTFANGTHEF, *Cycl.*

UT QUEANT LAXIS, *&c.* in antient modern muſic, a hymn to *St. John the Baptiſt*, compoſed about the year 770, in the time of Charlemagne, according to Poſſevin, by Paulus Diaconus of Aquileia. It is very famous in muſic, becauſe the ſyllables whereby the muſical ſounds are diſtinguiſhed, were taken by Guido Aretine from the firſt ſtrophe thereof.

UTRAQUISTÆ, in church hiſtory, an appellation given by way of reproach, to thoſe in Bohemia who communicate under both ſpecies, bread and wine. *Hofm.* Lex Univ. in voc.

UTRICULARIA, in botany, the name of a plant uſed by Linnæus for what other authors have called *lentibularia*, or hooded water milfoil. This, in his ſyſtem of botany, is alſo a diſtinct genus of plants, the characters of which are, that the cup is a two-leaved perianthium; its leaves being very ſmall, of an oval figure, hollow, and falling with the flower. The flower is labiated, and conſiſts of one petal; the upper lip is plain, obtuſe, and erect; the lower is large, plain, and undivided; between the two there is a heart-faſhioned palate, ſtanding a little out; the nectarium is corniculated, is ſhorter than the petal, and is produced from its baſe. The ſtamina are two ſhort and crooked filaments; the antheræ are ſmall, and cohere together; the piſtillum has a round germen, a thread-like ſtyle of the length of the cup, and a conic ſtigma. The fruit is a large conic capſule, containing only one cavity. The ſeeds are very numerous.

UTRICULI *Foliorum*, a name given by the writers on the anatomy of plants to a number of ſmall and fine veſſels, which fill up the interſtices between the ſeveral ramifications of the ſurculi, or minuteſt diviſions of the branches of the middle rib.

Theſe are to be examined by good microſcopes, in order to obtain any idea of their ſtructure. This is found to be compoſed of a reticular plexus of fine white and flat filaments, whoſe interſtices are again filled up with other ſmaller *Utriculi*; ſo that nature ſeems but forming new bodies, by making congeries of the ſame, but in a more minute ſtate. When the largeſt of theſe are opened by a fine inſtrument, they are found to conſiſt only of a white ſkin, containing a greeniſh matter, compoſed of particles ſo fine, that the beſt glaſſes are uſed in vain to diſtinguiſh their figure.

Accident ſometimes offers what all the art in the world would attempt in vain; and the leaves of trees, whoſe cuticle has been eat off on one ſide by ſmall inſects, ſometimes afford views of theſe *Utriculi*, which no art could have laid open in ſo nice a manner, or in ſuch various views. Act. Erudit. Ann. 1722. p. 28.

UVA, *Grape*. See the article GRAPE.

UVA *Gruina*, in the materia medica, the name of the fruit of the great American *vitis idæa*, or crane-berries. *Dale*, Pharm. p. 173.

UVA *Lupina*, *Wolf-Berries*, in botany, a name given by ſome authors to the common water-elder, and by others to the *herba Paris*, or herb true-love. *Ger.* Emac. Ind. 2.

UVA *Marina*, in botany, the name given by many authors to the *ephedra*, the ſea-grape, or ſhrub ſea horſe-tail. *J. Bauhin.* vol. 1. p. 406.

UVA *Quercus*, in natural hiſtory, a name given to certain accidental productions of the oak, a tree famous for producing many ſuch, beſide its common fruit: The beſt account we have of this in particular, is from Mr. Marchant. He obſerved a vaſt quantity of this production upon an oak of about twelve foot high; this tree had no acorns, but there hung from almoſt all the branches a great number of greyiſh threads, of two inches or more in length, and of a ſilky flexible matter; to ſeveral parts of theſe there were fixed certain round red berries, ſometimes two or three, ſometimes ten or twelve on a thread; theſe were of the ſize of a half-ripe red gooſeberry, but they had no umbilicus, nor any appearance of fibres; they were hard, and not hollow, but filled with a cottony matter, very cloſely compacted. The threads on which theſe berries were produced all grew out of the alæ of the leaves, in the very places where the beds for the rudiments of young branches ſhould have come; and over theſe filaments there were often a few ſmall leaves, of the regular ſhape of the oak-leaf.

It is generally aſſerted, that there are eggs of inſects lodged in all theſe extraordinary productions of the oak, which are ſuppoſed to be produced by a wrong derivation of the juices, occaſioned by the puncture of the fly which leaves thoſe eggs; but the moſt accurate ſearch could not diſcover the leaſt appearance of any animal remains in any part of theſe productions, neither in the berries, nor in the threads that ſupport them.

There is another ſpecies of this remarkable production, differing from the former, by not having the long threads on which the berries of that are ſupported; this, however, has been confounded by the generality of naturaliſts under the ſame name, and of this Mr. Marchant has given an equally accurate deſcription. In the month of October he obſerved a young oak of about ſix foot high, in a coppice-wood, in a very flouriſhing condition, very full of branches and leaves, but without fruit. The young branches of this oak were loaded with cluſters of red berries, of the ſhape and ſize of common red gooſeberries; they ſtood principally at or near the extremities of the branches, and were of a very poliſhed and ſhining ſurface, and of a ſpongy and tender ſubſtance. They ſtood in cluſters of three, four, and five together, and each grew immediately to the branch, without any pedicle; they had ſome appearance of fibres, but not the leaſt mark of an umbilicus, as in the regular fruits. On opening theſe berries, they were found full of a mucilaginous and viſcous juice, of a red colour, tolerably fluid, and having ſome fibres intermingled with it; the taſte of this juice was acrid, and its ſmell diſagreeable, and like that of rotten wood; but there appeared not in theſe, any more than in the other ſpecies,

any the leaſt appearance of any thing belonging to an animal, no egg, no worm, no fly, nor indeed any foreign body of any ſort whatever.

Theſe berries, though ſo large and ſucculent, are but of a very ſhort duration, for Mr. Marchant going three days after he had ſeen them in the greateſt perfection, to gather ſome of them, with intent to try their juice on different liquors, found they were all become flaccid and withered; and returning again three days after this, they were ſo entirely periſhed and gone, that there remained only a few veſtiges of thin ſkins on the places where they had been fixed to the tree, and ſome few fallen ones among the buſhes, that grew under the tree; and upon inquiring of the people who lived thereabout, to know whether theſe berries were a regular annual production of the tree, they told him that they never remembered to have ſeen any thing of the kind before.

It may not be eaſy perhaps to account regularly for theſe fortuitous productions; for they ſeem merely of the nature of monſters among animals, and it may be allowed no improbable conjecture in regard to them, that the root of theſe ſmall trees having taken in more nouriſhment than they could circulate, when it came to load the tender extremities of the young branches, may have made its way through their laxer texture, and being retained yet in ſome of their membranes, may have ſwelled out more and more, by the addition of freſh matter, and finally have been maturated by the ſun's heat into theſe ſeemingly regular productions. Mem. Acad. Par. 1692.

UVA *Urſi*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the globoſe bell-ſhaped kind, conſiſting only of one leaf. The piſtil ariſes from the cup, and is fixed in the manner of a nail into the hinder part of the flower. This finally becomes a round ſoft fruit or berry, containing little ſtony ſeeds, which are gibboſe on one ſide, and flat on the other.

There is only one known ſpecies of the *Uva Urſi*, which is the plant called by ſome *idæa radix*, and by others the *whortle-berry*, with thick, fleſhy, and, as it were, punctated leaves. *Tourn.* Inſt. p. 599.

UVA *Vulpis*, a name given by ſome authors to the common nightſhade. *Ger.* Emac. Ind. 2.

VUBARANA, in zoology, the name of a harengiform fiſh, caught in the American ſeas.

It reſembles in figure our river trout. Its body is very nearly of the ſame thickneſs all the way, but is elevated a little on the back, and ſomewhat ſlender juſt near the tail. It grows to a foot in length, and to ſix inches in thickneſs. Its head is ſmall, and pointed; its mouth not large, and having no teeth; and its tongue long. It has but one fin on the back, and its tail is long and forked. Its ſcales are very ſmall, and are diſpoſed ſo evenly, and laid ſo cloſely down, that it ſeems ſmooth to the touch. Its back is of a bluiſh white, and the reſt of its body appears either of an olive colour, or of a ſilvery white, according to the light in which it is viewed. The belly is ſomewhat flat, and perfectly white, and the coverings of the gills ſeem plates of ſilver, their whiteneſs and luſtre are ſo elegant. It is a very well taſted fiſh, and is generally dreſſed with the ſcales on, they being not offenſive in eating. *Marggrave*'s Hiſtory of Braſil.

UVEA (*Cycl.*) — Mr. Ferren demonſtrated to the academy of ſciences at Paris, the lymphatic veſſels of the *Uvea* of the human eye. Hiſt. de l'Acad. des Sciences, 1738.

VULCANALIA, among the Romans, a feſtival in honour of Vulcan, which was kept from the twenty-third to the twenty-ninth of Auguſt. On this occaſion the people uſed to throw animals into the fire. *Pitiſc.* in voc.

VULGAGO, a name given by ſome botanical authors to the aſarum or aſarabacca, whoſe leaves and root are uſed in medicine. *Ger.* Emac. Ind. 2.

VULNERARIA, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the papilionaceous kind, and from its cup, which is of a tubular form and turgid, there ariſes a piſtil, which finally becomes a ſhort pod, containing roundiſh ſeeds; and being contained in a membranaceous bladder, which was before the cup of the flower.

The ſpecies of *Vulneraria*, enumerated by Mr. Tournefort, are theſe: 1. The common yellow-flowered *Vulneraria*, called *kidney-vetch*, and *ladies finger*. 2. The white-flowered *Vulneraria*. 3. The purple-flowered *Vulneraria*. 4. The five-leaved *Vulneraria*, called by many the *bladder lotus*. *Tourn.* Inſt. p. 391.

VULPANSER, in zoology, a name given by ſome authors to the ſhell-drake, or burrow-duck, a very beautiful ſpecies of duck, common on ſome of our coaſts, and called by the generality of authors *tadoma*. See the article TADOMA.

VULPECULA, in ichthyology, a name given by Bellonius and Geſner to the fiſh called by the generality of authors *centrine*.

It is a ſpecies of the ſqualus, diſtinguiſhed by Artedi under the name of the *triangular-bodied ſqualus, with no pinna ani*. The Italians call this *peſce porco*. See the article SQUALUS.

VULPES, the *Fox*. This creature has been long famed for its cunning, and is plainly of the dog-kind.

It differs, however, from the common dog in the length, denſe diſpoſition, and ſoftneſs of its hairs, eſpecially thoſe about its tail, and in its ſmell, which is peculiarly rank and diſagreeable. Its uſual colour is a reddiſh tawney, though it is ſometimes found white, and ſometimes black. Its manner of digging itſelf a hole in the earth, is alſo a cuſtom wholly different from all the dog kind, and it is far from the tameneſs of that animal, being with difficulty made to loſe its fierceneſs. Its internal parts, in general, are very like thoſe of a dog. *Ray*'s Syn. Quad. p. 177.

VULPES *Marina*, or *Alopecias*, in natural hiſtory, the name given by authors to a large fiſh, called the *ſea-fox* by us.

It is ſaid by many authors to have naturally the rank ſmell of the fox, and to be one of the worſt-taſted fiſhes in the world; but this does not appear to be true, on a ſtrict inquiry; for its ſmell ſeems very little different from that of other fiſhes, and its fleſh is well-taſted; ſo that theſe things ſeem only to have been ſaid, in order to ſtrengthen the reſemblance with the fox; a name which ſeems, upon the whole, to have been given it only from the length of its tail; and even that, though very long for a fiſh of this kind, has no reſemblance with the tail of a fox. The length of this fiſh is about nine foot, and its breadth, in the broadeſt part of the belly, fourteen inches. Its tail is nearly as long as the whole body beſide, and is of the ſhape of a ſcythe, and is bent downwards. Near the origin of the tail, it has a ſingle fin below, and the ſpine is more moveable up and down in this part, than in any other; ſo that the tail is, by this means, eaſily elevated or depreſſed. It has two eminences on the back, one large one near the middle, and the other a ſmall one near the tail: And it has three fins on each ſide; the pair that ſtand near the head are large, and reſemble the wings of a bird; the others are ſmaller. The ſkin is ſmooth, and without ſcales; and the fins and eminences on the back are compoſed of a ſort of ribs, held together by a tough and ſtrong membrane. The tongue adheres inſeparably to the lower jaw, and is compoſed of a great number of bones, articulated together by a fleſhy ſubſtance of a fibroſe texture, and covered with a membrane beſet with ſeveral prominences, which make it feel very ſmooth when the hand is drawn from the point towards the root; but very rough when it is drawn the contrary way. Theſe prominences, when viewed by the microſcope, appear as pellucid as the fineſt cryſtal. Its throat and ſtomach are remarkably large; and authors ſay, that when in a fright it will ſwallow its young ones into its ſtomach, and afterwards caſt them up again when the danger is over. Others who ſpeak largely of its cunning, ſay, that when it has ſwallowed a bait at a hook, it will take in the whole line, till it comes to a weak place, where it can bite it aſunder. This is a tale very well calculated for the carrying on a reſemblance with the fox in cunning; but it is very ill adapted to this fiſh, which has no teeth with which it can bite any thing aſunder. The heart of this fiſh is remarkably ſmall, nothing larger than a hen's egg; it is alſo much of the ſame ſhape, and has no pericardium; but the aorta for a little way is covered with a membrane analogous to a pericardium. The head ſeems a mere lump of fleſh, being covered with muſcles, of which ſome are four inches thick; and though the head is ſo large, the ſkull is not bigger than a man's fiſt; it is thick, and is divided within into three cavities, each of which contains a ſmall quantity of a mucous matter mixed with blood; ſo that the fiſh ſeems ſcarce to have any brain at all, what little matter of it there is being quite ſoft, and having very few windings. The eyes are as large as thoſe of an ox, and are only hemiſpheric in figure, being flat before, ſo that they appear of a very ſingular ſhape. Mem. pour Hiſt. Anim. p. 114.

The guts of this fiſh have a very peculiar ſtructure. In the upper part of them, inſtead of the ordinary circumvolutions of the guts of animals, the cavity is diſtinguiſhed by many tranſverſe ſeparations compoſed of the membranes of the inteſtine turned inwards: Theſe ſeparations ſtand at about half an inch diſtance from one another, and turn helically like a ſnail-ſhell. The conſequence of this is, that the food is detained a long time in its paſſage, though the way it has to go be very ſhort. This creature feeds both on other fiſh, and on ſea-plants; and it is very remarkable, that the fiſh it has devoured are ſometimes found in its ſtomach without the head, ſcales, ſkin, and bowels, the muſcular fleſh remaining entire, while all theſe harder and tougher parts are diſſolved. Ouvrage adopté de l'Acad. Par. vol. 1.

VULTURIUS, among the Romans, a throw of the *tali*, otherwiſe called *canis*. *Pitiſc.* in voc. See the articles CANIS and TALARIUS *Ludus*.

VULTURIUS *Lapis*, a name given by many to the ſtone called *quandros*. See the article QUANDROS.

VULTURNALIA. See the article VOLTURNALIA.

VUNENA, a name given by the people of Guinea to a kind of catch-fly, or lychnis, common in that part of the world, and much uſed by them in a decoction to cure ſwellings of the legs. Petiver has called it *lychnis Guineenſis fructu caryophylloide foliis roris marini, hirſutis, anguſtioribus*. Phil. Tranſ. N°. 232.

UVULA, (*Cycl.*) in anatomy, is alſo called *columella*, *gargareon*, γαργαρ, *gurgulio*, *uva*, *uvigena*, *uvigera*, *epiglottis*, and *cion*. *Blancard* in voc. *Cion*.

The cutting out of the *Uvula*, when ſwelled and hanging down, is commonly practiſed in Scotland, and no other remedy applied than a piece of bread and cheeſe. The ſurgeon, who is ſome neighbouring peaſant, uſes alſo no other inſtrument than his knife; and yet all ſucceeds very well.

UVULÆ *Prolapſus*. See the article PROLAPSUS.

UVULARIA, in the materia medica, the name given by authors to the plant called *hypogloſſum*, or double-tongue. *Dale*, Pharmac. p. 169.

UXOR, in the language of the chemiſts, the mercury of metals. This is the wife they ſay, and ſulphur is the huſband. See the article MARITUS.

W.

WADD (*Cycl.*)—WADD-*Hook*, or WORM, a ſmall iron turned ſerpent-wiſe like a ſcrew, and put upon the end of a long ſtaff, to draw out the *Wad* of a gun, when it is to be unloaded.

WAGE, in the law of England, is uſed for the giving ſecurity for the performance of any thing. Terms de Ley. in voc.

Thus we ſay, to *wage law*, to *wage deliverance*. See the article GAGE.

None *wages* law againſt the king. *Brook*, Abr. Tit. choſe en Action. 6.

WAGGEL, in zoology, a name given by the people of Cornwall to a ſpecies of the *larus*, or ſea-gull, known among authors by the name of *martinozzo*. See the article MARTINOZZO.

WAGGON (*Cycl.*)—WAGGON-*Maſter-General*, in the military art, is he who has the ordering and marching of the baggage of the army. On a day of march he meets the baggage at the place appointed in the orders, and marſhals it according to the rank of the brigade or regiment each *Waggon* belongs to, which is ſometimes in one column, ſometimes in two; ſometimes after the artillery; and ſometimes the baggage of each column follows their reſpective column.

WAIN, a vehicle or carriage drawn by oxen. See the article CART.

WAKE-*Robin*, *Arum*, a medicinal plant. See the article ARUM.

WALDRAPP, in zoology, a name given by ſome to the wood-raven, or *corvus ſylvaticus* of Geſner, a bird of the ſize of a hen, of a gloſſy black, and adorned with a creſt on its head. See the article CORVUS.

WALE, or WAIL, in a ſhip, thoſe outermoſt timbers in a ſhip's ſide, on which men ſet their feet when they clamber up a ſhip's ſide. They are reckoned from the water, and called her *firſt*, *ſecond*, or *third Wale*, or *berd*.

WALE-*Knot*, aboard a ſhip, a round knot or knob made with three ſtrands of a rope, ſo that it cannot ſlip, by which the *tacks*, *top-ſail-ſheets*, and *ſtoppers*, are made faſt, as alſo ſome other ropes.

WALE-*reared*, on board a ſhip, a name the ſeamen give to a ſhip, which, after ſhe comes to her bearing, is not narrow in her upper work, nor *houſed in*, as their word is, but is built ſtrait up; which way of building, though it does not look well, nor is, as they ſay, *ſhip-ſhapen*, yet it hath this advantage, that a ſhip is thereby more roomy within board, that is, ſhe is larger within, and alſo becomes thereby a wholſome ſhip in the ſea, eſpecially if her bearing be well laid out.

WALINGHURU, in botany, a name by which ſome authors have called the plant, of which the medicinal zerumbeth is the root. *Herm.* Muſ. Zeylon, p. 51.

WALK (*Cycl.*)—WALK, in the manege, is the ſloweſt and leaſt raiſed of all a horſe's goings. The Duke of Newcaſtle ſays, that this motion is performed with two legs, diametrically oppoſite in the air, and two upon the ground at the ſame time, in form of a ſaint Andrew's croſs: but this, in reality, is the motion of a trot; and accordingly all the later writers agree, that this author is miſtaken, and that the *Walk* is performed, as any one may obſerve, by the horſe's lifting up its two legs on a ſide, the one after the other, beginning with the hind-leg firſt. Thus, if he leads with the legs of the right ſide, then the firſt foot he lifts is the far hind-foot, and in the time he is ſetting it down (which in a ſtep is always ſhort of the tread of his fore-foot on the ſame ſide) he lifts his far fore-foot, and ſets it down before his near fore-foot. Again, juſt as he is ſetting down his far fore-foot, he lifts up his near hind-foot, and ſets it down again juſt ſhort of his near fore-foot, and juſt as he is ſetting it down, he lifts his near fore-foot, and ſets it down beyond his far fore-foot.

This is the true motion of a horſe's legs in a *Walk*; and this is the pace in which many things are beſt taught. For inſtance, when the horſe is to be taught to turn to the right and left, or from one hand to another, he is firſt to be taught it on the *Walk*, then on the trot, and finally on the gallop.

Graſs WALKS. See the article GRASS.

Gravel WALKS. See the article GRAVEL.

WALKÆPETHIGA, in botany, a name by which ſome authors have called the tree, on which the gum lacca of the ſhops is uſually found. *Herm.* Muſ. Zeyl. p. 34.

WALL (*Cycl.*)—Of all the materials for building *Walls* for ripening fruit, brick is generally the beſt, as it reflects a great deal of heat, retains its warmth a great while, and affords, by the ſmallneſs of the joints, the convenience of faſtening up the trees with ſmall nails. If theſe *Walls* are coped with free-ſtone, and have ſtone pillaſters at proper diſtances, to break the force of the winds, and ſhelter the fruit-trees, they make the moſt advantageous, as well as the moſt beautiful of all *Walls*.

It is ſometimes an advantageous thing to build theſe *Walls* upon arches, that the roots of the trees may have room to ſpread under, and to the other ſide of them. This is neceſſary when the ſoil is a hard gravel; for without this, when the roots of peaches, &c. have reached the gravel, they find not ſufficient nouriſhment, and the trees canker and die. But though Mr. Fairchild had found great advantages from this way of building *Walls*, Mr. Miller diſapproves it. Some alſo have propoſed the building ſlanting *Walls*; but the ſame author gives many reaſons why the perpendicular are preferable, and ſeems to think that if *Walls* could be eaſily contrived to ſlope a little forward, they would be even preferable to theſe. *Miller*'s Gardener's Dict.

WALL *of Severus*. See the article AGGER.

WALL-*Flower*, in botany. See the article LEUCOIUM.

WALL-*Moſs*, *Bryum*, in botany, the name of a genus of moſſes, the characters of which are theſe: They produce membranaceous capſules, covered with a calyptra or hood, and ſtanding on pedicles more or leſs long. In all this they agree with the hypnums; but they differ from them in that this pedicle has no covering round its baſe, but in the place of it has a node or tubercle. Theſe pedicles alſo uſually ariſe from the tops of the branches, or from thoſe of the laſt years, which were then the talleſt, though now nearer the roots. To this it is to be added, that the ſtalks are uſually erect, leſs branched than in the hypnums, and not creeping. The calyptræ in ſome ſpecies ſtand ſtrait, in others obliquely on the capſules; and the opercula, when the duſty matter within the head has arrived at its maturity, fall off tranſverſely, ſometimes with a ſmooth, ſometimes with a jagged eye.

The family of the *bryums* being very numerous, they are divided into ſeveral orders and ſeries. The firſt order comprehends thoſe which have erect heads, and of theſe thoſe of the firſt ſeries have rounded, bellied, and turbinated heads.

Of this ſeries the following are the know ſpecies: 1. The hair-leaved globe *Bryum*. This is called by ſome the *apple-headed moſs*; it is a very beautiful ſpecies; the ſtalks are about an inch long, and ſtand in tufts, and the heads are round and placed on long pedicles; the leaves are of a dark green. It is common on ditch-banks. 2. The ſlender ſtar-topped marſh *Bryum*, with round heads. This is another very beautiful kind. The leaves compoſing the ſtarry tops of the branches are more rigid and ſtiff than the reſt. It is common in wet places. 3. The narrow-leaved *Bryum*, with tranſparent thyme-like leaves, and heads ſhaped like cruets. This alſo is a beautiful ſpecies. It grows in wet moſſy places, but is not very common. 4. the wide-necked cruet *Bryum*, with tranſparent mother-of-thyme leaves. This is found in boggy places in the weſt of England. 5. The narrow-leaved ſlender cruet *Bryum*. This is a beautiful plant, it grows to four inches in height, and is uſually found on heaths about cow-dung. 6. The pear-headed *Bryum*, with tranſparent mother-of-thyme leaves. This is very common in February about hedges, and in ſhady places. *Dillen.* Hiſt. Muſc. p. 336.

The ſecond ſeries of this order of *Bryums* contains thoſe which have oblong, oval, and rounded heads. Of theſe the firſt diviſion comprehends thoſe which have broad leaves. Of theſe the following are the known ſpecies: 1. The ſmall thyme-leaved *Bryum*, with thick-ſet ruſty heads. This is very common on ditch-banks, and by way-ſides, and produces a great number of heads. 2. The leſſer extinguiſher *Bryum*. The calyptra of this ſpecies exactly reſembles an extinguiſher. It grows in thick tufts, and its leaves are pellucid, and ſomewhat like thoſe of the ſerpyllum. 3. The larger extinguiſher *Bryum*. This is larger than the former, and ſomewhat branched; it grows alſo in thick tufts. 4. The awl-headed *Bryum*. The leaves of this are of a pale green, oblong, and hollowed in the middle; the pedicles of the heads are long, and moderately thick. It is common on ditch-banks in January and February. 5. The tranſparent *Bryum*, with leaves leaning all one way. The leaves are obtuſe and pellucid;

lucid; the pedicles of the heads about an inch long, and the heads themſelves ſlender. It grows in ſandy places in Virginia. 6. The hoary branched country *Bryum*, with coloured heads. This grows in thick tufts, and is very common in country villages on the trunks of trees, walls, and houſes. 7. The ſmooth *Bryum*, reſembling the former kind. The leaves of theſe are ſmaller than thoſe of the other, and ſmooth, and the whole plant leſs. It grows in Patagonia. 8. The common dwarf hoary wall *Bryum*. This is a very ſmall ſpecies, extremely common on old walls, and the tiles of houſes. 9. The common dwarf tranſparent *Bryum*, with green, not hoary leaves. This reſembles the former in figure, but its leaves are broader, thinner, and more pellucid. It grows in many places on ditch-banks. *Dillen.* Hiſt. Muſc. p. 354.

The ſecond diviſion of this order of the *Bryums*, comprehends thoſe with narrower leaves, of which ſome are remarkably longer than others: Of theſe the following are the known ſpecies: 1. The ſickle-leaved bending beſom *Bryum*. This is a large and erect ſpecies, very common in thick tufts about hedges. 2. The red-ſtalked, tranſparent, graſſy-leaved *Bryum*. The ſtalks are ſlender; the leaves of a pale green; it grows in many parts of Germany, but has not yet been obſerved in England. 3. The tranſparent, hart's-tongue-leaved curled *Bryum*, with crooked heads. This is a very common ſpecies. It grows to two or three inches high, and its leaves are long, narrow, and alated. 4. The juniper-leaved curled *Bryum*, with ſtraiter heads. The leaves of this are narrower than thoſe of the former, and leſs curled; it is very common in Virginia. 5. The larger brittle whitiſh *Bryum*, with ſtrait leaves, and ſhort pedicles. This is a very common ſpecies in wet places on heaths. It grows in very thick tufts, and imbibes and retains a great quantity of water. 6. The dwarf white larix-leaved *Bryum*. This grows in ſmall and ſhort tufts, and is a native of North America. *Dillen.* Hiſt. Muſc. p. 360.

The ſecond ſubdiviſion of the narrow-leaved *Bryums* contains thoſe of the ſhort-leaved kind; of theſe the following are the known ſpecies: 1. The white brittle *Bryum*, with crooked leaves. This is much like the common white heath *Bryum*; but the leaves are bent, and the pedicles of the capſules grow out of the ſame parts of the ſtalks, whereas in that they grow from the tops. 2. The tranſparent bog *Bryum*, with crooked ſhort leaves and heads. This is common in marſhy places; it grows to two or three inches high, and uſually in very thick tufts. 3. The ſhort-headed *Bryum*, with drooping leaves. This is of a yellowiſh-green, and grows on wet places in the Welch mountains. 4. The ſharp-headed *Bryum*, with leaves leaning one way. This grows to two inches high, and is not uncommon in the northern parts of England. The hypnum-like water *Bryum*, with pointed black calyptræ. 5. This is a very ſingular ſpecies; it grows in water, and lies upon ſtones; but does not properly creep or root itſelf on them. It is found in rivulets in mountainous places. *Dillen.* Hiſt. Muſc. p. 366.

The third diviſion of the firſt order of *Bryums* comprehends thoſe with extremely narrow, or capillaceous leaves. Of theſe ſome reſemble the hypnums, and many of theſe have their leaves terminated by long hairs. Of theſe the following are the known ſpecies: 1. The common hoary hypnum-like *Bryum*. This is of a yellowiſh green, and when dry becomes whitiſh. It is conſiderably branched, and is found on Hampſtead-Heath, and in the like places. 2. The green cluſtery Alpine *Bryum*. This is of a greeniſh yellow colour, but wants the hairs which terminate the leaves of the former kind. It is common in the mountainous parts of Wales and Yorkſhire. 3. The ſmall-headed hypnum-like Alpine *Bryum*. This is a ſmall moſs, but much branched; the leaves are very narrow. It grows in the mountains of Wales and Yorkſhire, and is ſometimes found quite black, both in leaves and ſtalks. 4. The hypnum-like Alpine *Bryum*, with obtuſe calyptræ. The branches of this are hairy, the leaves very numerous and very ſmall, and of an obſcure browniſh green. It grows on the hills in Wales and Yorkſhire. 5. The heath-like Alpine *Bryum*, with bearded heads. The ſtalks of this are leſs branched than in the former, and the leaves ſhorter; it grows in mountainous places in Yorkſhire. 6. The many-headed, hoary, hypnum-like mountain *Bryum*. The ſtalks of this are rigid, and are four or five inches long, ſometimes ſingle, ſometimes branched. The leaves are narrow, and end in fine ſmall hairs. It is found in the mountainous parts of Yorkſhire. *Dillen.* Hiſt. Muſc. p. 370.

The ſecond ſubdiviſion of theſe *Bryums* contains ſuch as are hairy, and have capillaceous leaves; but differ from the hypnums in their proper figure, and general appearance. Of theſe the following are the known ſpecies: 1. The ſoft-hair pencil *Bryum*, with crooked ſhanks. This is a very minute moſs, but very beautiful; its leaves terminate in fine hairs, and its heads are ſmall. It is not unfrequent in the woods of Germany, but is not common in England. 2. The bright green, pointed ſphagnum-like *Bryum*. This grows an inch or two high, and its branches are uſually divided into two or three at the ends. It grows on the mountains of Yorkſhire. 3. The whorled-hair *Bryum*. This grows in very thick tufts. The ſtalks are ſlender, and about an inch long. The leaves are capillaceous, and the heads ſmall and roundiſh. It is found on the trunks of trees, and on the ground in the northern parts of England not unfrequently. 4. The conferva-like bog *Bryum*. This is very ſmall, and compoſed of extremely ſlender branches, which entangle with one another, and are furniſhed with ſmall leaves placed alternately, and not ſet very cloſe; it grows in wet places. 5. The bending hair-pencil *Bryum*. This is a very elegant little moſs. It grows in thick tufts on ditch-banks, and is not above half an inch in height. The leaves are long and capillaceous; the heads very ſmall and reddiſh. 6. The cluſtery crooked-leaved hair *Bryum*. This is a ſmall moſs, the ſtalks ſometimes ſimple, ſometimes branched; the capſules are very ſlender, and their pedicles reddiſh. This grows on the mountains of Wales. 7. The black-headed bog *Bryum*, with ſhort leaves. The ſtalks of this are ſlender, and ſeldom branched; the heads are ſmall and of a blackiſh brown, and the pedicles ſhort. It is common in Yorkſhire. *Dillen.* Hiſt. Muſc. p. 376.

The third ſubdiviſion comprehends ſuch of theſe *Bryums* as have curled leaves, or leaves that become variouſly undulated as they dry. Of theſe the following are the known ſpecies: 1. The long-ſhanked frizzled *Bryum*. The ſtalks of this grow to near two inches high; the leaves ſtand very thick, and always curl up in the drying. It is found in mountainous places. 2. The ſhort-ſhanked, many-headed frizzled *Bryum*. This has ſhorter ſtalks than the former, and the leaves ſtand in cluſters on the tops; it is found on the mountains of Wales and Yorkſhire. 3. The fine ſtar-topped *Bryum*, which curls up its leaves in drying. This grows in thick tufts, and its leaves are of a beautiful green; it is common on heaths, and under hedges. 4. The ſhort pale green hair *Bryum*, with oval heads. This is a very ſmall moſs, but it grows in thick tufts; the leaves, while freſh and vigorous, are expanded, and form ſtellar tops to the branches; but, in drying, they curl up and wither. It is very common on ditch-banks. 5. The neat pale green *Bryum*, with ſtarry tops, and ſlender heads. This is a very ſmall ſpecies; but its ſtalks are divided into ſome branches. Its leaves form ſtarry tops to the branches, while freſh; but they curl up and loſe their figure in drying. 7. The ſmall red ſtar-topped bog *Bryum*. The ſtalks of this are moderately long and branched; the leaves alſo are long. It is found in the mountains of Wales. 8. The ſmooth and ſlender pale-ſhanked *Bryum*, with thick-ſet leaves. This is frequent at the bottoms of old walls. *Dillen.* Hiſt. Muſc. p. 379.

The fourth ſubdiviſion of theſe *Bryums* comprehends thoſe which have roſtrated calyptræ and pointed capſules, afterwards becoming of the ſhape of bottles, from the rim of which there grow up ſeveral oblong bodies, in form of a beard. Of this kind are the following ſpecies: 1. The thick-topped bearded birds-claw *Bryum*. The ſtalks of this are ſhort, ſometimes branched, ſometimes not; the leaves ſmall, ſtrait, carinated, and of a lively green. It is common on old walls. 2. The ſmall ſtar-topped *Bryum*, with clawed and bearded heads. The ſtalks of this are ſhort; the leaves ſtellate at the tops; the pedicles of the heads grow not from the ſummits, but from the laſt year's top of the ſtalk. It grows on the ground, and is found in Germany, and in ſome parts of England. 3. The ſlender-bearded *Bryum*, with narrow and thin-ſet leaves. The ſtalks of this are very ſlender, and ſend up their pedicles from the ſummit. It is common on the earth in dry places, and ſometimes on old *Walls*. *Dillen.* Hiſt. Muſc. p. 381.

The fifth ſubdiviſion of theſe *Bryums* comprehends thoſe which have a ſhorter operculum, and whoſe capſules appear ſtriated when fully ripe. Of this kind are the following ſpecies: 1. The ſmall forked *Bryum* with twin heads. The ſtalks of this are ſhort, and uſually ſend up two pedicles from each ſummit, each carrying its capſule. The leaves are ſmall, and of a dark green. 2. The ſtarry-topped red-ſhanked *Bryum*. This grows in cluſters or tufts; the ſtalks are divided ſometimes into two, ſometimes into three branches. It is very common by way-ſides, and is eaſily known by the redneſs of the pedicles. 3. The fine-leaved bog-*Bryum*, with long and ſhining-red pedicles. This grows in the manner of the former; but the leaves are longer, and more pointed, and the pedicles are long, and grow ſeveral together from one ſtalk. It is common in Wales. *Dillen.* Hiſt. Muſc. p. 387.

The ſixth ſubdiviſion of theſe *Bryums* takes in thoſe which have either no ſtalks, or at the utmoſt only very ſhort ones. Of this kind are the following ſpecies: 1. The leaſt dwarf hair *Bryum*, with ſhort heads and pedicles. This has extremely narrow leaves, of a deep green; it grows in marſhy places. 2. The ſmall black, hair *Bryum*, with longiſh heads and pedicles. The heads of this are large, and their pedicles are conſiderably long. 3. The dwarf fine-leaved heath-like *Bryum*. The leaves of this ſpecies are very rigid, and greatly reſemble thoſe of the fine-leaved heath. It grows on rocks and ſtones in the weſtern parts of England. 4. The dwarf tufted *Bryum*, with fine ſoft leaves, and conic heads. The leaves of this are very narrow and carinated, and of a deep green. It grows by the ſides of rivers in Virginia, Penſylvania, and other parts of America. 5. The dwarf long-ſhanked *Bryum*, with hairy leaves, all leaning one way.

This alſo is common in Virginia. 6. The golden long-ſhanked hair *Bryum*, with upright crooked heads. The ſtalks of this are very ſhort, and ſometimes a little branched. It is a ſummer-moſs, and is frequent in Germany.

The ſecond order of the *Bryums* comprehends thoſe which have capſules, hanging downward from the bending of the pedicles. The calyptræ in theſe ſpecies quickly fall off; and the opercula are uſually obtuſe.

The firſt ſeries of theſe comprehends thoſe which have extremely narrow leaves. Of this ſeries the following are the known ſpecies. 1. The ſhort-ſhanked hair *Bryum*, with red ſtooping heads. The capſules of this ſeem in a middle ſtate between the erect and pendent ones. It grows in moiſt graſſy places, but is not very common. 2. The golden-hair *Bryum*, with pear-like bowing heads. The ſtalks of this are low, and rather may be called creeping fibres; the leaves of a pleaſant green, and very narrow; the pedicles are an inch high, and the heads yellow when ripe. It is found in many parts of England in moiſt places. 3. The lovely green hair *Bryum*, with pendulous heads. The capſules of this are oblong and drooping, the leaves are extremely narrow. It grows in wet places on Woolwich-Heath. *Dillen.* Hiſt. Muſc. p. 386.

The ſecond ſeries of theſe *Bryums* contains thoſe which have leaves a little broader, and though narrow, not capillaceous. The firſt diviſion of theſe contains thoſe which have equal and cylindric branches. Of theſe the following are the known ſpecies: 1. The catkin-ſtemmed ſilver *Bryum*. This is a very ſmall moſs; but it grows in extremely large tufts, and is very common on the tiles of houſes; its ſilvery look diſtinguiſhes it from all the others at firſt ſight. 2. The round-ſtemmed green *Bryum*, with pendulous heads. The capſules of this are of an oval figure; it grows on walls. 3. The hypnum-like *Bryum*, with elegant blackiſh-red heads. This is found on the Welch mountains. *Dillen.* Hiſt. Muſc. p. 393.

The ſecond diviſion of theſe comprehends thoſe which have unequal and irregularly-ſhaped branches. Of theſe the following are the known ſpecies: 1. The hoary round-tufted tile *Bryum*, with pendulous heads. This is an extremely ſmall moſs, and grows uſually on little round tufts; the heads are not ſeen till the plant is cloſely examined; they ſtand on very ſhort ſtalks. This is one of the moſt frequent of all the moſſes on old *Walls* and the tiles of houſes. 2. The tufted red and yellow-ſhanked *Bryum*. The leaves of this are broader, membranaceous, and of a pleaſant green. It is common on old walls. 3. The tranſparent and larger tufted *Bryum*, with long pendulous heads. This is common on heaths; it is of a pleaſant green, and grows to two inches high. 4. The tranſparent-leaved *Bryum*, with long pendulous heads. This is common in moiſt ſhady places. 5. The lancet-leaved *Bryum*, with round fleſh-coloured pendulous heads. This is found in the ſummer months on Black-Heath, and in many other places about London. 6. The tender, lancet, and graſs-leaved pendulous *Bryum*. The ſtalks of this are red; they do not exceed half an inch in height, and are not branched; the pedicles are of a pale red, and grow from the ſummits of the ſtalks. It grows in tufts in Wales. 7. The ſwans-neck *Bryum*. This is a very elegant ſpecies, it grows in woods, in ſomewhat moiſt places, and is an inch or two, ſometimes more, in height. The leaves are large, and of a beautiful green, and the pedicle bends with the capſule, ſo as to repreſent the head and neck of a ſwan. It is common in our woods. 8. The pendulous and ſwoln-headed bog *Bryum*. This grows to three or four inches high; the leaves are like thoſe of ſerpyllum, and are pellucid, and of a lively green. It grows in boggy places on heaths, *&c.* 9. The long-ſhanked bog *Bryum*, with long pendulous heads. This is not unfrequent with us in damp places, in woods, and under ſhady hedges. 10. The red bog *Bryum*, with plated leaves, and pear-ſhaped pendulous heads. This is found in many parts of England on mountainous boggy grounds. *Dillen.* Hiſt. Muſc. p. 397.

The third ſeries of theſe *Bryums* comprehends ſuch as have broad leaves. Of this kind the following are the known ſpecies: 1. The golden bulbed *Bryum*, with pear-faſhioned bowing heads. This is called by ſome *little goldilocks*, or *golden maidenhair*. It is a very common moſs, and grows on the ground. 2. The many-headed pendulous ſhrub *Bryum*, with pellucid leaves, reſembling thoſe of the hart's-tongue. This is a very common moſs; it creeps at the root, and ſpreads very faſt; it grows in woods, and under hedges. 3. The larger ſtarry roſe *Bryum*, with pendulous oval heads. The ſtalks of this are naked near the ground; but on their upper part they have many ſmall leaves. It grows in moiſt and ſhady places. 4. The leſſer ſtarry roſe *Bryum*, with long pedicles, and long heads. The leaves of this are very ſhort. It is not uncommon under ſhady hedges. 5. The pendulous oval headed *Bryum*, with various tranſparent leaves. The ſtalks of this are about half an inch high, and the leaves obtuſe, and ſhort toward the bottom, and longer and narrower at the top. It is very common in wet places on heaths and woods. 6. The long tranſparent ſerpyllum-leaved *Bryum*, with ſharp ſtooping heads. This grows in marſhy places. 7. The round tranſparent mother-of-thyme-leaved *Bryum*, with pendulous oval heads. This has but ſmall leaves, and grows always in boggy places; the heads are of a pale green while young, and of a pale yellow when ripe. *Dillen.* Hiſt. Muſc. p. 415.

WALLA, the name of an officer in the eaſtern nations. The Arabs have the care of the country round about the city of Cairo in Egypt, and a *Walla* is obliged to patrole continually about there, eſpecially in the night.

His buſineſs is to take up all perſons who are committing any diſorders, or who cannot give an account of themſelves, or are found abroad at irregular hours; and he often has their heads cut off upon the ſpot. As this officer is naturally the terror of rogues, ſo for preſents made to him he often becomes their protector. Without this they are ſure, one time or other, to fall a ſacrifice to his reſentment; and to him the great people ſend for any villains who have rendered themſelves obnoxious to them, and are ſure to have them delivered up. *Pōcock's* Egypt. p. 165.

WALLING *of Brick*. See the article BRICK.

WALNUT, in botany. See the article NUX.

The effluvia of *Walnut-trees* are ſaid to be hurtful to the head. Mr. Boyle aſſures us they cauſed the head-ach in himſelf. Works abr. vol. 1. p. 436.

WALRUS, in zoology, the name by which ſome authors call the morſe, or ſea-horſe, called alſo by others, *roſmarus*, a creature very different from the *hippopotamus*, or river-horſe. See the article MORSE.

WALT, at ſea, is applied to a ſhip, when ſhe hath not her due ballaſt, *i. e.* not enough to enable her to bear her ſails.

WALTHERIA, in botany, the name of a genus of plants, the characters of which are theſe: The perianthium conſiſts of one leaf, and is of the ſhape of a cup, lightly divided into five ſegments, and remains after the flower is fallen. The flower conſiſts of five petals, which are cordated at the top, and ſtand expanded. The ſtamina are five filaments, growing together into a cylinder. The antheræ are ſimple, and ſtand free. The germen of the piſtil is oval. The ſtyle is ſimple, ſomewhat longer than the ſtamina; and the ſtigma is bifid. The fruit is a capſule of an oval figure at the top, compoſed of two valves, but containing only one cell. The ſeed is ſingle, obtuſe, and broad. *Linnæi* Gen. Plant. p. 327.

WAMPUM, a ſort of ſhells, ſeveral of which being ſtrung upon threads, are uſed as money among the Indians.

It is made of a ſhell, formed into ſmall cylinders, of about one quarter of an inch long, and a fifth of an inch over, and being bored as beads, is ſtrung in great numbers upon long ſtrings. In this ſtate it paſſes among the Indians in their uſual commerce, as ſilver and gold among us; but being looſe, it is not ſo current.

It is both white and black; and the meaneſt is in ſingle ſtrings, of which the white goes at five ſhillings a fathom, and the black at ten; or by number, the white at ſix a penny, the black at three. The next in value to the ſingle ſtrings, is that which is wove into bracelets of about three quarters of a yard long, black and white, in ſtripes, and ſix pieces in a row, the warp conſiſting of leather thongs, and the woof of thread; theſe the gentlewomen among them wear, wound twice or oftener about their wriſts.

The moſt valuable of all is that woven into girdles. Theſe are compoſed of many rows, and the black and white pieces woven into ſquares or other figures. Theſe girdles are ſometimes worn as their richeſt ornaments; but they are oftener uſed in their great payments, and make their nobleſt preſents, and are laid up as their treaſure. *Grew's* Muſæum, p. 370.

WANDSU, in zoology, the name of a ſpecies of monkey found in the iſland of Ceylon. It is all over of a fine deep black; but has a long white beard hanging from its chin.

WANHOM, in the materia medica, a name by which Kæmpfer has called the plant, of which the great galangal of the ſhops is the root. *Kæmpf.* Amæn. Exot. p. 901.

WANT, in zoology, a name given by many to the mole. See the article TALPA.

WANTI. See the article GLOVE.

WAPP, in a ſhip, that rope wherewith the ſhrowds are ſet taught with wale-knots, one end is made faſt to the ſhrowds, and to the other are brought the lanniards.

WAPPER, in zoology, a name given by ſome to the ſmaller ſpecies of the river-gudgeon. *Ray's* Ichthyogr. p. 264. See the article GOBIO *Fluviatilis*.

WAR (*Cycl.*)—WAR-*Horſe*. The proper rules for the chooſing a horſe for ſervice in *War*, are theſe: He ſhould be tall in ſtature, with a comely head, and out-ſwelling forehead. His eye ſhould be bright and ſparkling, and the white part of it covered by the eye-brow. The ears ſhould be ſmall, thin, ſhort, and pricking; or, if long, they ſhould be moveable with eaſe, and well carried. The neck ſhould be deep, and the breaſt large and ſwelling. The ribs bending, the chine broad and ſtrait, and the buttocks round and full. The tail ſhould be high and broad, neither too thick, nor too thin; the thigh ſwelling; the leg broad and flat, and the paſtern ſhort. When ſuch a horſe is choſen, he muſt be kept high during the time of his teaching, that he may be full of vigour. His food muſt be ſweet hay, and good clean oats, or two parts of oats, and one part of beans or peas, well dried and hardened. The quantity ſhould be half a peck in the morning,

ing, and the ſame quantity at noon, and in the evening. Upon his reſting-days he is to be dreſſed between five and ſix in the morning, and watered at ſeven or eight. In the evening he is to be dreſſed at four, and watered about five, and he muſt always have provender given him after watering; he muſt be littered about eight, and then muſt have food given him for all night.

The night before he is ridden, all his hay is to be taken away about nine o'clock, and he muſt have a handful or two of oats about four in the morning, when he has eaten theſe, he is to be turned upon the ſnaffle, and rubbed very well with dry cloths; then ſaddled, and made fit for his exerciſe. When he has performed this, he is to be brought ſweating into the ſtable, and rubbed down with dry wiſps. When this has been done, the ſaddle is to be taken off, and he is to be rubbed down with dry cloths; the houſing cloth is then to be laid on, and the ſaddle being again laid on, he is to be walked gently about till thoroughly cool. After this, he muſt ſtand without meat two or three hours, then he muſt be fed; and in the afternoon he is to be rubbed and dreſſed as before, and watered in the uſual manner.

WARD's *Pill.* Some have conjectured that this medicine, which had ſo great a run, and to which a diminution of the numbers in the bills of Mortality, one year after it happened to come in vogue, was ſaid in a public advertiſement to be owing; it has been conjectured, I ſay, that this medicine was made of butter of antimony; others think it the glaſs of antimony, and cinnabar of Antimony amaſſed with gum tragacanth. See *Ward's Pill* diſſected, and Med. Eſſ. Edinb. abr. vol. 2. p. 434 and 470.

Mr. Clutton mentions ſome caſes where they did ſervice; but relates the hiſtories of fifty caſes where they did great miſchief.

To diſcover the compoſition of theſe pills, he diſſolved the ſeveral ſorts of them, and then viewing with a microſcope the powder which precipitated, he ſaw three different coloured powders remaining of the blue pill; to wit, a yellow, red, and white powder; the yellow and red agreed exactly with the glaſs of antimony, and the white one appeared to be common arſenic. *Ward's Pill* being incloſed in copper, and expoſed to a ſtrong heat, made the copper white, and as hard as iron, which arſenic always does. He alſo obſerved in this blue pill another powder, which he judged to be zaffre, that is, calcined cobalt, incorporated with flints. He thinks the proportion of the ingredients in this blue pill to be, one third glaſs of antimony, near two thirds of arſenic, and a very ſmall part of cobalt, or zaffre, with ſome powder of blue.

The red pill appeared to be much the ſame compoſition as the blue, only red arſenic was made uſe of inſtead of the white, and that the colouring of blue powder was left out.

The purple pills tinged glaſs blue, which cobalt or zaffre does, and therefore Mr. Clutton thinks them principally compoſed of cobalt, with a little glaſs of antimony, which left a yellowiſh border upon the glaſs. See *True and candid Relation of the good and bad Effects of* Ward's *Pill and Drop*, and Med. Eſſ. Edinb. abr. vol. 2. p. 470, 471.

WARNAS, a name by which ſome of the chemical writers expreſs what others of them call the *acetum philoſophorum*, or vinegar of the philoſophers.

WARNING (*Cycl.*)—WARNING-*Piece*, in the military art, is the gun which is fired every night about ſun-ſet, to give notice to the drums and trumpets of the army to beat and ſound a retreat or tattou, which is likewiſe called, ſetting the watch. See the article RETREAT.

WARNOTH, in our old writers, an antient cuſtom by which if a tenant, holding of the caſtle of Dover, failed in paying his rent at the day, he was to forfeit double; and for the ſecond failure, treble: and the lands ſo held were called *terris cultis*, and *terris de Warnoth. Blount.*

WARPS (*Cycl.*)—WARP, in a ſhip, a rope uſed to hale a ſhip into, or out of a harbour.

WARRANT, (*Cycl.*) in the manege. A jocky that ſells a horſe is, by cuſtom, in ſome countries, obliged to *warrant* him, that is, to refund the money that was given for him, and re-deliver the horſe in nine days after the firſt delivery, in caſe he ſold him when under ſuch infirmities as may eſcape the view of the buyer, and as are not obviouſly diſcovered. Theſe infirmities are purſiveneſs, the glanders, and unſoundneſs, hot and cold: But he does not *warrant* him clear of ſuch infirmities as may be diſcerned. Not only jockeys or horſe-merchants, but alſo perſons of what quality or condition ſoever, are obliged to take back the horſe, and repay the money, if he is affected with the ſaid diſorders. But the rule of the law of England is, *caveat emptor*, unleſs the ſeller expreſsly *warrants*.

Dividend WARRANTS. See the article DIVIDEND.

WARREN (*Cycl.*)—The word *Warren* is now generally applied to a piece of ground ſet apart for the breeding and preſerving of rabbets.

In the ſetting up a *Warren*, great caution is to be uſed for the fixing upon a proper place, and a right ſituation. It ſhould always be upon a ſmall aſcent, and expoſed to the eaſt or the ſouth. The ſoil that is moſt ſuitable, is that which is ſandy; for when the ſoil is clayey or tough, the rabbets find vaſtly more difficulty in making their burrows, and never do it ſo well; and if the ſoil be boggy or mooriſh, there would be very little advantage from the *Warren*, for wet is very deſtructive of theſe animals.

All due precautions muſt be taken, that the *Warren* be ſo contrived, that the rabbets may habituate themſelves to it with eaſe. Many would have it that *Warrens* ſhould be encloſed with walls; but this is a very expenſive method, and ſeems not neceſſary nor adviſeable; for we find but very few that are ſo, and thoſe do not ſucceed at all the better for it.

Mr. Chomel's opinion is, that it ought to be ſurrounded with a ditch. This indeed is no fence to prevent the rabbets from going out, unleſs there be water in it; but it marks the intended bounds of the *Warren*, and the rabbets generally confine themſelves within its circumference, though not neceſſarily compelled to do ſo. The ſpace proper for a *Warren* has no limits but the owner's pleaſure; but, in general, the larger it is, the more profitable it alſo proves: and the rabbets, when once accuſtomed to the place, will keep within its bounds, though they are neither hemmed in with walls nor ditches, nor any other fence whatever.

Some have preſcribed the making deep ditches, and conſtantly keeping them ſupplied with water in the ſummer as well as winter ſeaſon, that they may ſerve as fences to the rabbets; but as it is not found neceſſary to fence them in at all, it is extremely injudicious to do it, by means of a thing known to be ſo very prejudicial to theſe creatures, as water is. If the perſon who has ſet up a *Warren* has but few rabbets to ſtock it with, the more patience he muſt have as to the profit of it; but the beſt method of getting quickly into the ſcheme of profit in it, is the buying at firſt a large number of doe-rabbets, all big with young. Theſe being unweildy and heavy, will naturally ſtay in the place, and the young ones will be habituated to it as their native place, and will never run from it. Theſe young ones will ſoon breed again, and the *Warren* will begin quickly to be ſtocked with inhabitants, almoſt all natives of the place. They ſhould not he hunted at all the two firſt years, and but very moderately the third. After this they will increaſe ſo faſt, that ſcarce any body can conceive the numbers that may be taken, and the profit that may be annually made without hurting it.

The *Warren* is the next franchiſe in degree to the park, and when ſpoken of in law, the terms uſed are, the liberty and franchiſe of a free *Warren*.

The beaſts and fowls of a *Warren* are underſtood to be four, the rabbet, the hare, the partridge, and the pheaſant, and no other. Theſe were eſteemed the proper game to be taken by the long-winged hawk.

A foreſt, which is in dignity the higheſt and greateſt franchiſe, comprehends in it a chace, a park, and a free *Warren*; for which reaſon the beaſts of the park, and the beaſts and fowls of the free *Warren*, are as much privileged within the foreſt, as the beaſts of the foreſt itſelf are.

WARTS (*Cycl.*)—There are a thouſand ſuperſtitious remedies for *Warts*, but none of them are of the leaſt conſequence. The ſurgeon's aſſiſtance is the only true method of getting rid of them. There are ſeveral ways of deſtroying them in his hands, as by ligature, extirpation, evulſion, the cauſtic, and the actual cautery. The cure by ligature, is by means of a looſe hair, or a piece of fine and ſtrong ſilk, tied very tight about the root of the *Wart*; and by this means the nutricious veſſels being compreſſed, the excreſcence withers and decays.

The method by extirpation, is to take them up with a pair of plyers, and cut them cloſe off with ſciſſars, dreſſing the wound with the common cauſtic, to remove the roots, if there be any, which would give riſe to a new tubercle.

The cure by cauſtics is beſt performed by cutting off the hard upper part of the *Wart* with a razor or ſciſſars, and then ſurrounding its bottom with a circle of wax, to prevent the ſpreading of the remedies, to touch it daily with oil of tartar, ſpirit of ſalt, aqua-fortis, or butter of antimony.

The cure by cautery is performed by chooſing a cautery of a proper ſize, and with that burning down to the root of the *Wart*. This is the moſt painful of all the methods of extirpating theſe excreſcences; but the pain is but for a moment, and the *Warts* extirpated this way never return again.

The cure by evulſion is performed by anointing them with ſoftening ointment, and then ſeizing them artfully between the thumb and the fore-finger, and forcibly wrenching them out. This is a mountebank method, and a bad one; for it is not only very painful, but the *Warts* commonly grow up again.

Cancerous WARTS. It is no uncommon thing to find on the face, lips, and about the eyes, *Warts* which look blue and livid; theſe are always to be let alone entirely; for when irritated, they frequently degenerate into a cancer, and miſerably torment the parts where they are ſituated. *Heiſter*'s Surgery, p. 32.

WART, in the manege, is an excreſcence, or ſuperfluity of ſpongy fleſh, that riſes in the hinder paſterns of coach-horſes, almoſt as big as a walnut. It ſuppurates, and voids red ſtinking matter, and does not cure but for a time, for it returns again.

WARTH, in our old writers, ſeems to be the ſame with *ward-peny*, being a cuſtomary payment for ſome caſtle-guard. *Blount*'s Tenur. 60. *Blount*.

WASH, the diſtillers name for the fermentable liquor, made by diſſolving the proper ſubject for fermentation and diſtillation in common water.

With reſpect to the proper workings of this liquor, great regard is to be had to the containing veſſel. Its purity, and the proviſion for its occaſional cloſeneſs, are the things to be principally conſidered. Though it is neceſſary that the veſſel be perfectly clean, yet in the cleanſing it great care muſt be taken that no ſoap, or other unctuous body, be uſed, for this would check the fermentation in it; and for the ſame reaſon all ſtrong alkaline lixiviums are to be avoided. Lime-water, or even the turbid ſolution of quick lime, however, may be ſafely uſed for this purpoſe; and this is indeed particularly proper to deſtroy a prevailing acid, which is very apt to be generated about the ſides and bottoms of theſe veſſels, if the warm air has acceſs to them, and thus prevents the order of the fermentation. All ſtrong alkaline lixiviums have as bad an effect on the contrary, and a ſpecial care muſt be had that no corrupt or putrified yeaſt, nor any remains of former fermented matters, hang about the ſides of the veſſels, for this would infect whatever ſhould be afterwards put into them. Foulneſſes of this kind, when of long ſtanding, are of all others the moſt difficult to be cured, and often are of great damage to the diſtiller.

The occaſional cloſeneſs of the veſſel may be provided for by having covers very well adapted to it, in the large way of buſineſs, and by the uſe of valves in the ſmaller, where common light caſks will ſerve the purpoſe, while the valve occaſionally gives the neceſſary vent to preſerve the veſſel, and otherwiſe it remains perfectly cloſe, and impervious to the air but at diſcretion.

It is a very prejudicial miſtake, in the buſineſs of fermenting the *Waſh*, to ſuppoſe that the free concourſe or admiſſion of the external air is neceſſary to the operation. The expreſs contrary is the truth, and a great advantage will be found in practiſing upon this ſuppoſition. A conſtant influx of the open air, if it does not carry off ſome part of the already formed ſpirit; yet it certainly catches up and diſſipates the fine ſubtle oleaginous and ſaline particles, of which the ſpirit is formed, and thus conſiderably leſſens the quantity to be procured. This inconvenience is wholly avoided by the way of cloſe fermentation, by which all air, except that which is contained in the veſſel, is kept out. The great ſecret, in this proceſs, is to have a proper ſpace for the reception of this air, at the top of the veſſel, over the ſurface of the liquor; and when ſuch a ſpace is left, as ſoon as the fermentation is fairly ſet on foot, the veſſel is to be cloſe bunged down, and left to itſelf, no more freſh air being left in but what is admitted by the valve. No new air is neceſſary, when the ſpace unoccupied by the liquor is more than one tenth part of the gage, the artificial air generated in the operation being very ſeldom of force, to endanger the burſting of the caſk, or any other miſchief.

This method of cloſe fermentation is practicable to good advantage in the ſmall way of buſineſs; but it requires ſuch a conſiderable time, that it will never be liked by the large dealers, who are in a manner forced to admit the free air, and thus ſuſtain a very conſiderable loſs in the ſpirit, only to get the operation over in a proper time. Excepting for the neceſſity of expedition of this kind among the large dealers, it is certain that this ſlow and imperceptible vinous fermentation is greatly preferable, on all accounts, to the other. During the whole courſe of this operation, the veſſel is to be kept from all external cold and external heat that is conſiderable, it being neceſſary that it ſhould be kept in an equable uniform and temperate ſtate, ſo as not to be cognizable to the ſenſes, either as heat or cold. In the winter a ſtove-room, ſuch as are common in Germany, would be fitteſt for this purpoſe, the veſſel being placed at a proper diſtance from the ſtove; but at other ſeaſons no particlar cautions are neceſſary with us, provided that the place be well ſheltered from the violent heat of the ſun, and from the bleak northerly winds.

The operation is known to be over in this cloſe way of fermentation, as ſoon as the hiſſing noiſe ceaſes, and can no longer be heard on applying the ear to the veſſel; and when, on opening it, the liquor is found to be clear, and of a vinous pungent taſte; when it is arrived at this ſtate, it ſhould be ſet by for a time in a cooler place than that in which it was fermented; in this manner it will thoroughly purge itſelf of its lees, and will become perfectly clear, vinous, and pungent; in this ſtate it ſhould be drawn clear off from the lee, and immediately committed to the ſtill; and by this method a perfectly pure vinous ſpirit will be procured, greatly better than that which can be obtained by the common way, which thoſe who work large quantities fall into for the ſake of expedition.

The action of fermentation works ſuch a change in the body of the tincture or ſolution, called the *Waſh*, as to render it ſeparable by the action of fire, into parcels of matter that are ſpecifically different, and of a nature entirely foreign to what the ſame liquor would have yielded without the fermentation. The ſtill being charged and luted, and brought to work with a ſoft boiling heat, there firſt comes over a quantity of intenſely pungent aromatic and nidorous liquor, which, if received into a large quantity of cold water, throws off a copious eſſential acrid or aromatic oil, though the original ſubject, before the fermentation, were ever ſo cooling, mild, or contrary to a ſpicy nature. This eſſential oil is found to be the principal thing that gives the predominant or peculiar taſte to the ſpirits, according to the ſeveral ſubſtances from which they are made; and the ſpirits are, from the flavour they receive from this, diſtinguiſhed into malt ſpirit, melaſſes ſpirit, cyder ſpirit, wine ſpirit, arrac, and the like. The fineſt, moſt ſubtle, and moſt efficacious part of this eſſential oil is what comes firſt, the portions that come after being gradually more and more viſcous and nauſeous, and the ſpirit running in a continued thread from the end of the worm, will be found to change its nature oftener than could be imagined, if taſted at different intervals. Beſide this eſſential oil, the ſpirit of the firſt running contains only an acid, more or leſs in quantity, and more or leſs pungent and volatile, or ſenſible to the noſe, in proportion as the fermentation has been more or leſs continued; or according to the degree of acidity acquired in the operation. This acid, and the aqueous part that riſes with it, may be kept back by a proper rectification; though where the acid is very volatile, ſome part of it is apt always to riſe along with the totally inflammable ſpirit, ſo as to give it a flavour like that of a very much diluted ſpiritus nitri dulcis. *Shaw*'s Eſſay on Diſtillery.

The *Waſh* of the malt diſtiller ought to be about the ſtrength of the ten-ſhilling ſmall-beer; and if the ſpirit be expected fine, it had better be too thin than too thick. It is only made by mixing the water hot with the malt ground into meal. If the water be too hot, the mixture will become gluey; and if too cool, a part of the virtue of the malt will be loſt. Under the right application of the water is to be conſidered the proper manner of agitating the maſs, ſo that all the parts of the aqueous fluid may come fully and freely in contact with the ſoluble particles of the ſubject. When once the water is well ſaturated by ſtanding on the malt a proper time, it muſt be drawn off, and freſh poured on, till at length the whole virtue, or all the ſugary ſweetneſs of the malt is extracted, and nothing but a fixed huſky matter remains behind, uncapable of being farther diſſolved by the action of hot or boiling water, or of being advantageouſly waſhed or rinſed out by the bare affuſion of cold. This artificial and external agitation or ſtirring about of the maſs, is neceſſary not only in the common way of brewing for the malt diſtillery, but alſo in that more expeditious way, now in uſe with ſome, of reducing the operations of brewing and fermenting to one, and grinding the malt to a fine meal, which is to be kept in the *Waſh* during the whole time, and even put into the ſtill with it, and worked together. The ſtirring may be repeated to great advantage more than once in each operation, as at the affuſion of every parcel of freſh water, in the common way, and at any ſhortly diſtant times in the ſhort way, in which it is of greater ſervice. *Shaw*'s Eſſay on Diſtillery.

The difference of ſeaſons is found to require ſome alteration in the direction and management of the buſineſs of brewing for the malt-diſtillery. The water muſt always be uſed colder in ſummer than in winter, and the tincture muſt be cooled ſuddenly in cloſe ſultry weather, to prevent it from becoming eager or ſour. The ſummer ſeaſon alſo gives malt an over-forward diſpoſition to ferment, and this impairs the quantity of ſpirit, and is to be checked by the addition of a quantity of unmalted meal, which being much leſs diſpoſed to ferment than the malted meal, will reſtrain and moderate its impetuoſity, ſo as to render the operation ſuitable and effectual to the production of ſpirit, a great quantity of which would be otherwiſe diſſipated, and thrown off by a too haſty fermentation, and that eſpecially when the warm air is ſuffered freely to come at the fermenting liquor. Some of our malt-diſtillers have a cuſtom of uſing rye-meal for this purpoſe; but though this anſwers the end in moderating the fermentation, as well as the other, yet it gives the ſpirit a nauſeous flavour, which is not eaſy to be got off or altered to advantage by any known method of rectification. Some of the malt-diſtillers, the better to prepare their malt, ſprinkle it before the grinding with a ſolution of nitre, or common ſalt, in fair water, and ſome, inſtead of theſe ſolutions, uſe lime-water; but this is not ſo well adapted to the deſign of the thing, which, beſide the preventing the flying away of the finer part of the flowers in the grinding, is to promote the fermentation, and to increaſe the quantity of ſpirit, or add to its pungent acid vinoſity.

It has alſo been judged by ſome to be of ſervice either in general, or eſpecially at ſome particular ſeaſons, to acidulate the water employed in brewing, with a ſmall proportion of ſome vegetable or light mineral, and which is ſuppoſed to curb and regulate the fermentation of the tincture, improve the acid vinoſity of the ſpirit, and occaſion ſome ſmall increaſe of its quantity; and with the ſame view, tartar, as well as common ſalt and nitre, have been uſed in the ſame manner.

The particular intention of the operator may render alſo various other additions neceſſary; thus ſome, to diſpoſe the *Waſh* to yield more ſpirit, or to give the ſpirit a greater degree of pungency, and a better flavour, add to it the ſtrong

and pungent aromatics: the cheapeſt choſen for this purpoſe, and the moſt uſed, are, the cortex winteranus, ginger, and grains of paradiſe. *Shaw*'s Eſſay on Diſtilling.

In the common way, theſe additions, however, do very little, though by a proper artifice in the management they may be made of conſiderable uſe. Upon this foundation, ſtands a very inſtructive method uſed abroad, of making geneva *ab origine*, by mixing the bruiſed juniper berries among the malt, and brewing the whole together; by this means a compound tincture, or *Waſh*, is prepared, which, by fermentation and diſtillation, affords a ſpirit much more intimately and homogeneouſly impregnated with the eſſence of the berry, than that prepared by our diſtillers, in the common way of adding the berry to the malt ſpirit, and diſtilling it from them again. The inconveniencies that attend the brewing directly with malt, are very conſiderable, the malt being of a very large bulk, in proportion to the ſaccharine part, which it can alone impart to the water, and in which its virtues, as yielding a ſpirit, wholly conſiſt. On this account numerous large veſſels, much labour, and great expence, are required to conduct and manage ſuch a buſineſs in the large way. The remedy in this, as in many other caſes, may be much more eaſily ſtarted, than effectually applied; however the foundation for it ſeems to conſiſt in the practically reducing the perplexed buſineſs of the malt diſtiller, to the ſimple buſineſs of the fine ſtiller, or, in other words, in the reducing malt to treacle.

It is very certain, that the thing here propoſed, may be effected to perfection by the common proceſſes of infuſion and evaporation: but the people concerned in this branch of trade are the only proper perſons to try it in the large way, and calculate that advantage and expence, and by that means regularly find whether or not it will be worth while to introduce it as a common method of buſineſs.

The experiment may be tried in this manner: When a parcel of wort is brewed in the common manner, and is become fine by ſtanding, let it be decanted clear off, and immediately boiled away in a common copper, till it begins to inſpiſſate, and acquires a duſky brown colour: at this time it muſt be taken out of the copper, and poured into a balneum mariæ, where the remainder of the evaporation may be made without any danger of burning, and the whole may be reduced to the conſiſtence of treacle; in which form it will keep a long time, and be always ready for uſe, when occaſion requires it. The continuing the evaporation to the end, in the copper over a naked fire, would not only be liable to give it an empyreumatic taſte, from the burning, which would remain ſo ſtrongly in the ſpirit, as to ſpoil it; but the violence of the heat acting immediately upon it, would diſſipate much of its active part, and there would be a much ſmaller quantity of ſpirit procured from it; but if the operation be dexterouſly and carefully performed, as here directed, the extract, or ſaccharine matter, though of as full a body, will be abundantly paler than treacle, a little more glutinous, very ſweet, and pleaſant to the taſte, and will have a fine agreeable bitterneſs, as the flavour goes off, though no hops are uſed in the preparation. In this manner it may be kept, or tranſported to other countries, and will always be reducible to the ſtate of wort again, only by mixing common water with it; and this wort will ferment as freely and as fully as that made in the common way, and will yield its ſpirit in the manner of treacle. *Shaw*'s Eſſay on Diſtilling.

Glauber and Becher were both convinced of the utility of this ſcheme, and both laboured hard at the bringing it to bear: Glauber ſeems to have ſucceeded tolerably in it; but Becher, who had it in his thoughts to extend the practice to the wines as well as the malt liquors, after a whole year ſpent in the attempt, declares, that he can ſcarce believe what Glauber ſays of it, and ſo candidly owns himſelf not poſſeſſed of the ſecret of doing it, that he offers a handſome reward to any body that will inform him of it. What theſe chemiſts ſeem not to have hit on, the way or the beſt way of doing, ſeems however, from experiments in ſmall quantities, perfectly practicable; and if it may be brought to bear in the large way, plentiful years, convenient ſituations, and other helps may be pitched upon, for ſetting up a new trade of treacle, making at leaſt enough for the diſtillers uſe, if it ſhall not be found practicable to convert this new ſort of treacle into potable liquors, or into ſugars.

It is poſſible, that on this plan ſomething may be ſet on foot at home of the nature of the ſugar-worts in our American plantations, which may turn to as good account, and yet be managed with much leſs labour and expence than we find it poſſible to do that. When malting in particular caſes could not be practiſed, ſubſtitutes of various kinds might be invented to ſupply its place on this plan: thus, ſuch grain or pulſe as cannot be made into malt in the common way, may be boiled in water, inſtead of being brewed, and an extract made of their clear decoctions, evaporated into a treacle in the ſame way as the other. The Indians in this manner diſſolve their rice into a thin pap, or jelly, by boiling it in water; and afterwards they ferment this into a potable liquor, or a ſort of wine, which they preſerve under-ground for many years ſucceſſively. And it may be tried whether this method of malting the Indian corn or maize, or that by putting it in the ground till it ſprouts, will be the moſt ſerviceable in the article of diſtillery. Moſt of the Engliſh grains may be eaſily malted in the common way, and their extract thus made into a ſort of treacle, with little trouble, and to very great advantage. It remains to try whether the buck-wheat may be malted in the common way, and put to this uſe? and whether, by ſome variation introduced in the way of malting, the nauſeous flavour of our rye may not be taken off? All the other vegetable ſubſtances intended for brewing, ſhould as much as poſſible have their fermentable parts reduced to the ſtate of a treacle, ſugar, or inſpiſſated juice, not only for the ſake of preſerving them perfect, but for the greater eaſe and convenience of working them. Thus the juices of the birch, the ſycamore, and many other trees, which bleed freely on being tapped in ſpring, are readily boiled up to this ſort of conſiſtence; and in the ſame manner, wherever it is worth while, the juices of canes, fruits, and ſweet roots may be thickened and preſerved.

When once the fermentable parts of vegetables are thus concentrated, and brought together into a ſmall compaſs, the buſineſs of brewing, whether, for the diſtillers uſe, or for the making potable liquors, will be very eaſy and ſhort, the whole being no more than mixing or diſſolving the inſpiſſated juice in a ſufficient quantity of warm water; and this ſolution, either alone, or with ſome trifling additions, will be perfectly fitted for fermentation. *Shaw*'s Eſſay on Diſtillery.

Waſh being of a mucilaginous, or ſomewhat glutinous nature, requires a particular management to prevent its ſcorching, and make it work kindly in the ſtill: If it ſhould happen to be burnt in the operation, the ſpirit will have a moſt diſagreeable flavour, and ſuch as can never be got off again, without very great labour, and a particular treatment, not known to every body. To prevent this ill effect, there muſt be three things obſerved; the liquor, or *Waſh*, muſt be made dilute, the fire muſt be well regulated, and the whole kept in a conſtant agitation. The manner of making the *Waſh* dilute, has been long known among the more judicious diſtillers in this branch, and they have always found their ſpirit the purer for it. The fire is eaſily kept regular, by a conſtant attendance, and avoiding haſty ſtirring it, or throwing on new fuel; and the ſtirring the liquor in the ſtill is to be effected by means of a paddle, or bar kept in the liquor, till it juſt begins to boil, which is the time for luting on the head; and after which there is no great danger, but from the improper management of the fire: this is the common way, but it is hard to hit the exact time, when to lute down the head; and the doing it either too ſoon, or too late, is attended with great inconvenience, ſo that many have found out the other methods, of either putting ſome moveable ſolid bodies into the ſtill with the *Waſh*, or placing ſome proper matter at the bottom and ſides of the ſtill, which are the places where the fire acts ſtrongeſt.

The uſe of the paddle would be better than either of theſe ways, could it be continued while the ſtill is working; and this it may be by the following method: Let a ſhort tube of iron or copper be ſoldered in the center of the ſtill-head, and let a croſs-bar be placed below in the ſame head, with a hole in the middle, correſponding to that at the top; through both theſe let an iron pipe be carried deep down into the ſtill, and let an iron rod be paſſed through this with wooden ſweeps at its end; this rod may be continually worked by a winch at the ſtill-head, and the ſweeps will continually keep the bottom and ſides ſcraped clean, the interſtices of the tubes being all the time well crammed with tow, to prevent any evaporation of the ſpirit at them. *Shaw*'s Eſſay on Chemiſtry.

The ſame effect, may, in a great meaſure, be produced a leſs laborious way, that is, by placing a parcel of cylindrical ſticks lengthwiſe, ſo as to cover the whole bottom of the ſtill, or elſe by throwing in a parcel of looſe faggot ſticks at a venture; for thus the action of the fire below moving the liquor, at the ſame time gives motion to the ſticks, and makes them act continually like a parcel of ſtirrers upon the bottom and ſides of the ſtill, which might, if neceſſary, be furniſhed with buttons, or loops, to prevent them from ſtarting. Some alſo uſe a parcel of fine hay laid upon the looſe ſticks, and ſecured down by two croſs poles, laid from ſide to ſide, and in the ſame manner faſtened down with loops. Care is to be taken in this caſe not to preſs the hay againſt the ſides of the ſtill; for that would ſcorch almoſt as ſoon as the *Waſh* itſelf; but the ſticks never will: theſe are ſimple but effectual contrivances, and, in point of elegance, they may be improved at pleaſure.

There is another inconvenience attending the diſtilling of malt ſpirit, which is, when all the bottoms, or groſs mealy fæculence is put into the ſtill along with the liquor, the thinner part of the *Waſh* going off in form of ſpirit, the mealy maſs grows by degrees more and more ſtiff, ſo as to ſcorch toward the latter part of the operation. The method to remedy this, is to have a pipe with a ſtop-cock, leading from the upper part of the worm-tub into the ſtill; ſo that, upon a half, or quarter turn, it may continually ſupply a little ſtream of hot water, in the ſame proportion as the ſpirit runs off, by which means the fear of ſcorching is taken away, and the operation at the ſame time not at all retarded. In Holland, the malt diſtillers work all their *Waſh* thick, with the whole body of the meal among it; yet they are ſo careful in the keeping their ſtills clean, and ſo regular and nice in the management of their fires, that, tho' they uſe no artifice at all on this head, only to charge the ſtill

while it is hot and moiſt, they very rarely have the misfortune to ſcorch, except now and then in the depth of winter. When ſuch an accident has once happened in a ſtill, they are extremely ſolicitous and careful to ſcrape, ſcrub, and ſcour off the remains of the burnt matter, otherwiſe they find the ſame accident very liable to happen again in the ſame place. But beyond all the other methods in uſe on this occaſion, would be the working the ſtills not by a dry heat, but in a balneum mariæ, which might poſſibly be ſo contrived by the baſon being large, and capable of working a great many ſtills at once, as to be extremely worth the proprietor's while in all reſpects. *Shaw*'s Eſſay on Diſtillery. See the article MALT-*Diſtillery*.

WASH is alſo uſed for the ſhallow part of a river, or arm of the ſea, as the *Waſhes* in Lincolnſhire. *Blount*.

WASHING (*Cycl.*) WASHING *of Ores*, the purifying an ore of any metal by means of water, from earths and ſtones, which would otherwiſe render it difficult of fuſion.

The method of doing it is this: Break the ore to a coarſe powder in an iron mortar, weigh twenty or thirty docimaſtical centners of it, put them into the *Waſhing*-trough, and pour ſome water upon them, that the ore may be thoroughly moiſt; then have a veſſel full of water, the diameter of which muſt be a little larger than the length of the trough; take the trough with the left-hand by the top of the hinder part, and dipping it horizontally into the water, move it gently with the right-hand from the fore part of the trough, which is always to be made the ſhallower part of it, toward the hinder part, which is deeper, then take out the trough, and incline it a little on the fore-part that the water may run out, and the heavier metallic part remain at the bottom; repeat this ſeveral times till the remains at the bottom of the trough are quite pure. If the ſtone in which ore is lodged be too hard for powdering in its natural ſtate, as the flinty and debaſed cryſtalline ones commonly are; the whole muſt be calcined, and quenched in cold water ſeveral times over, and afterwards powdered and waſhed in this manner: when it is thus waſhed, aſſay a centner of it, and from the bead of metal this yields, it will be eaſy to eſtimate the value of the ore. *Cramer*'s Art of Aſſaying, p. 244.

WASP. The *Waſp* has four wings and ſix feet; his body is yellow, with black triangular ſpots: the common *Waſp* breeds in the ground. There is another kind much more fierce, but very rare: theſe breed in woods and mountains; they are larger, and have broader bodies, and much more black about them; their ſting is ſo large, that it ſeems diſproportioned to the ſize of their bodies.

To theſe are to be added the *Ichneumon-waſps*, which are ſmaller than the others, and have very ſlender bodies, but of the ſame colours with the common kind: theſe uſually live in the holes of mud-walls, and make a ſort of porch of mud before the doors of their habitations.

There is alſo another *Waſp* common about Vienna; this is three times as large as the common kind, and ſeems of two different ſpecies, the one having rough antennæ, and the other ſmooth: they are both variegated with black and a bright yellow. *Mouffet*'s Hiſt. Inſect. p. 6.

The *Waſps* conſtruct regular combs, and rear their young in the cells of theſe combs in the manner of bees: wherever there is a young worm in a cell, the old *Waſps* frequently thruſt their heads into it, and caſt up the food for the young one out of their mouths: their cells are hexagonal; and when they have a mind to enlarge their habitation, and make more or bigger combs in them, they are ſeen very buſily coming out of the mouth of the hole, every one loaded with a parcel of earth, till they have carried out as much as is neceſſary for the intended enlargement.

They ſupport their combs one over another by croſs pieces of about an inch long, ſo that there is ample room for the *Waſps* to paſs in their ſeveral buſineſſes. Thoſe cells which ſtand in the center of a comb, are always perpendicular; the others all ſtand more or leſs obliquely; and in the center, the comb is ſomewhat hollowed and depreſſed on the face, and convex on the back; and in this part is inſerted the principal croſs piece that ſerves for a ſupport. *Ray*'s Hiſt. of Inſects, p. 250.

The eggs of the *Waſp* are of an oblong form, and reſemble thoſe of the common fly, but they are larger; they are always faſtened to the angles of a cell, never to the ſides of it. They are uſually placed ſingle; it is very rare to find two in one cell; and if they are laid ſo, it ſeems that one only ſucceeds; for there is never found more than one worm in a cell. The egg is always fixed to that angle of the cell which is neareſt the center of the comb, and always near the bottom, not in the middle of the cell; and when there are two eggs in one cell, they are never fixed to the ſame angle, but ſtand at the ſame height from the bottom, in the two neareſt angles to the center of the comb. The heads of the nymphs are at firſt round and pellucid; but ſoon afterwards the ſkull and the forcipes become reddiſh. The heads of all the nymphs are turned toward the center of the comb, and their tails go obliquely downward towards the baſe of the cell. They are continually ſeen opening their mouths, and moving their forcipes, ſeeming ever hungry, and impatiently waiting for food from their parents. The cells are left open, till the nymph is at its full growth; then the *Waſps* cover it over with a thin lid, under which the worm undergoes its transformation; and as ſoon as it is arrived at the *Waſp* ſtate, it eats its way through this thin cover, and comes to work with the reſt. Mr. Ray mentions a peculiar ſpecies of *Waſp*, which builds a much ſmaller neſt. This is uſually fixed to a beam of ſome old building, and has only one aperture, which is about half an inch wide, and ſerves for the *Waſps* to go in and out at. This aperture is always exactly oppoſite to that part of the hive, where it adheres to the beam. The hive or neſt is covered with a thin membranaceous ſubſtance reſembling paper, of a brown colour, with ſtreaks of white, diſpoſed in regular circles. The whole neſt is about three inches in diameter, and is uſually compoſed of about nine cruſts; when theſe are cut away, there appears a round comb in the center, and a ſmaller above it, fixed up by a pedicle ariſing from the center of each. In every one of theſe cells, which are hexagonal as thoſe of the common *Waſp*, is reared one worm, which, in fine, becomes a *Waſp*.

The ſpecies of *Waſp* which builds in this manner, differs from the common *Waſp*, in that it is ſomewhat larger; it is ſmoother alſo, and has rings of a deeper yellow on the back: the black ſpots are not ſo regular in this, as in the common *Waſp*; and the forehead in this is of a perfect yellow, without any ſpots. Theſe marks, with the difference of hanging a ſmall neſt againſt a beam, and building a large one in the ground, are ſufficient to diſtinguiſh this as an abſolutely different ſpecies. Beſide theſe two, Mr. Ray mentions four other ſpecies of *Waſps*: 1. The long and narrow-winged *Waſp*, with long antennæ, and a broad line of black in the middle of the belly. 2. The long and ſlender black *Waſp*, with three yelloviſh-white ſtreaks on the belly. 3. The broad and ſhort-bodied *Waſp*, with rings of yellow and red. This much reſembles the common *Waſp* in ſhape. 4. The ſharp-tailed *Waſp*, with a black body, variegated with yellow rings. This ſpecies is found about old walls, and is furniſhed with but a very weak ſting. All the others are found wild in our fields. *Ray*'s Hiſt. Inſect. p. 251.

We have an account in the Philoſophical Tranſactions, N°. 476, of ſome *Waſp*-neſts made of clay in Penſilvania. Theſe are of two kinds, one plain, fabricated by a ſmall black *Waſp*, the figure of which is delineated in tab. 3, of that number. The other is a wreathed tubulated clay neſt; and theſe are built by a purpliſh black *Waſp*, of the figure there repreſented. When theſe *Waſps* have laid their eggs, it is ſaid they go and catch ſpiders, and cram the cells full of them; and what is remarkable, they do not kill the ſpiders, but only diſable them, as if they intended to prevent their crawling away, and yet keep them alive.

Mr. Reaumur, in his hiſtory of inſects, vol. 6. mentions clay neſts from St. Domingo, ſomewhat different from theſe.

Ichneumon-WASP. See the article ICHNEUMON.

WASP-*Fly*, in natural hiſtory, a ſpecies of fly having very much the external figure of a *Waſp*, but harmleſs, without a ſting, and with only two wings.

It is black and yellow on the body, and marked exactly as the *Waſp*, and is produced from a ſpecies of the rat-tailed fly-worms. See the article DRONE-*Fly*.

But beſide theſe there is another ſmall fly produced of the puceron-eaters, which has extremely the appearance of a ſmall *Waſp*; but it is perfectly harmleſs, and has only two wings. *Reaumur*, Hiſt. Inſ. vol. 4. p. 486.

WASP-*Tipula*, in natural hiſtory, the name of an inſect deſcribed by Mr. Reaumur, and being properly a tipula, or long-legs, though greatly reſembling a *Waſp*.

This is produced of a worm found in the earth, lodged in the cavities of old trees; the worm has no legs, but has a regularly figured ſcaly head. The fly produced from it has the long legs and the mouth of the tipula, with the remarkable double beard which covers it, and which makes the great character of this claſs of inſects; but then the body is ſhort and thick, whereas the bodies of the common kinds are very bony and thin. This, as alſo the breaſt, is variegated with ſtreaks of black and yellow, in the manner of the *Waſp*; and its antennæ are very beautifully feathered, and bearded like thoſe of the males of many of the gnat-kind. The head is black, and the legs are yelloviſh. The wings have a yelloviſh caſt, and near their end have each a large ſpot of brown. The body of the female of this ſpecies is always much thicker than that of the male; and the ſexes are eaſily diſtinguiſhed by this. *Reaumur*'s Hiſt. Inſ. vol. 9. p. 19.

WASTE-*Cloths*, in a ſhip of war, the cloths hung up on the uppermoſt work of a ſhip's hull, to ſhade the men from an enemy in the fight; and therefore by ſome are called *fights*.

WASTE-*Trees*, in a ſhip, are thoſe timbers which lie in her *Waſte*.

WASTORS, in our ſtatutes, a kind of thieves ſo called, and mentioned among robbers, draw-latches, &c. Stat. 4. c. 27. *Blount*, *Cowel*.

WATCH (*Cycl.*)—The movement of theſe machines will be ſtopped with great cold; and therefore in very cold climates, it is proper to keep them in one's fob by day, and in the bed by night. See Phil. Tranſ. N°. 465. Sect. 2.

WATCH-*Glaſs*. Mr. Boyle informs us, that to faſhion glaſſes for *Watches*, or the like purpoſe, into a convex or concave figure,

figure, there is no neceſſity for grinding: For, a ſmooth and flat piece of glaſs, of a competent thickneſs, being carefully laid upon a ſhallow concave cylinder of iron, ſo that the edges of both touch, the heat of a fire, warily applied, will ſoften the glaſs, and ſuffer it to ſink into the form required. See Works abr. vol. 1. p. 135.

WATCH-*Glaſs*, aboard a ſhip, runs four hours, and is uſed to ſhift or change their *Watches* by. There are alſo *half-watches*, *hour-glaſſes*, *minute*, and *half-minute-glaſſes*; by which laſt they count the knots when they heave the log, in order to find the ſhip's way.

WATER, (*Cycl.*) in natural hiſtory. See the Appendix.

WATER-*Bomb*, a name given by our chemiſt Godfrey to a machine he invented on the plan of Greyl's diſcovery, for the extinguiſhing accidental fires in houſes. He conſidered firſt, that the unmanageable ſize of Greyl's engine was a very great objection; and on this plan contrived a medicated liquor, which was ſuch an enemy to fire, that a very ſmall quantity would extinguiſh as much as a greatly larger of common water; and this liquor had the farther advantage, that it might be kept ever ſo long without corrupting, and by that means the veſſels containing it would remain always fit for uſe; whereas in Greyl's method they muſt have been rotted by the corrupting and fermenting of the water, after a few years.

The author of this invention tried it twice in public with us, and both times with all the ſucceſs that could be wiſhed: but the ſtructure of the veſſel was ſo much the ſame with that of Greyl's, that Godfrey cannot be allowed any farther merit, as an inventor, than that of contriving the medicated liquor inſtead of common water. The machine is a wooden veſſel, made very firm and ſtrong, that the liquor, when once put in, cannot leak out any where; in the center of this is an oblong cylindric veſſel, which is filled with gun-powder; a tube is brought from this to the head of the barrel, and this being filled with combuſtible matter, and the inner caſe with powder, and both made of plate-iron, that no water may get in, the veſſel is then filled with the medicated liquor. The top of the tube is then covered, and the thing ſet by for uſe.

When there is occaſion for it, it is only neceſſary to uncover the tube, and ſetting fire to the matter in it, it is conveyed to the veſſel containing the powder, and the whole machine being thrown into the place where the fire is, is torn to pieces by the exploſion, and the extinguiſhing liquor ſcattered every way about, on which the fire is quenched in an inſtant.

The contriver of theſe things propoſed the making three kinds of them, the one containing five gallons of the liquor; this was the largeſt ſize, and contrived for the largeſt rooms, and moſt urgent neceſſities. The ſecond kind contained three gallons; and the ſmalleſt, which was meant for a cloſet, or other little room, contained only two gallons. The ſmaller kind alſo had ſometimes a peculiar difference in their ſtructure, the powder-veſſel being placed not in the center, but at the bottom: the intent of this was to fit them for chimneys, when on fire, as by this means the liquor, not being wanted to be ſcattered on all ſides, was carried moſtly upwards. Theſe were fixed on the end of a long pole, and by this means thruſt to a proper height up the chimney; and the tube that communicated the fire was placed downward.

The manner of uſing the machines for rooms on fire, is this: the perſon who has the care of them is to throw them as nearly as may be into the middle of the room, and then to retire to a little diſtance: As ſoon as he hears the exploſion, he may ſafely enter the room, and with a cloth, or any thing of that kind, put out any remaining ſparks of fire that there may be in particular places. If the room be ſo large that one of the machines cannot diſperſe the liquor to every part of it, two are to be uſed, one being laid at each end; and if ſeveral rooms are on fire at once, as many of the machines are to be uſed, one being thrown into each room. If a whole houſe is on fire, the lower rooms are firſt to be taken care of, and after theſe the upper, as they aſcend.

Our Godfrey had ſcarce better ſucceſs than his predeceſſor Greyl; for while he was making his public experiments, one Povey, collecting ſome of the fragments of his broken veſſels, found out the ingredient uſed in the medicated liquor, and made and ſold the things in the ſame place where he had proved his right to them. It is probable that the medicated liquor was no other than common water, with a large quantity of ſal armoniac, that ſalt having this virtue of extinguiſhing fire in a very remarkable degree: But it is greatly to be wondered at, that while all the world were convinced by experiments of the uſe of the machine, the author made but little advantage of it, and it is now diſuſed. Act. Erudit. Ann. 1724. p. 183.

WATER-*Dog*. The ſportſmen generally eſteem the black *Water*-ſpaniels above thoſe of any other colour, they being generally the moſt hardy. If there be any farther judgment to be made from the colour, it is, that the ſpotted or pied are generally the quickeſt at ſcent, and the ſimple liver-coloured the quickeſt at ſwimming. Theſe, however, are but very uncertain rules to judge by, and the things principally to be regarded are the dogs being of a good breed, and well taught. As to the ſhape, the head of a good *Water*-dog is generally round, and the hair curling, the ears large and broad, and hanging down; the eyes full and lively, the noſe ſhort, and the lips like a hound's. The neck ſhould be thick and ſhort, the ſhoulders broad, the legs ſtrait, and the chine ſquare. The buttocks ſhould be round, and the thighs brawney. The paſterns ſtrong, and the fore-feet round. The hair in general ſhould be long and curled, not looſe and ſhaggy.

As to the training up a dog for ſporting, the maſter of him cannot begin when he is too young, the principal thing to be taught being obedience, and that being beſt taught while the creature is young. As ſoon as he can lap, he ſhould be taught to couch and lie cloſe at command, and not to dare to ſtir from that poſture till he is ordered; he will ſoon be brought to this by beating when he diſobeys, and encouraging him when he does right. He ſhould always be taught before the times of his eating, and never have his food given him, but when he has done ſomething to deſerve it. This will teach him always to do well, for the ſake of the expected victuals. No perſon ſhould ever interfere in the teaching, for two maſters breed a confuſion, and the creature never will learn well from them.

The teacher muſt be careful always to uſe the ſame words in his leſſons; thoſe words are to be choſen which are the moſt plain in their ſounds, and the moſt diſtinct from one another; and when theſe are once fixed upon, they muſt never be altered; for the dog, being guided wholly by the ſound, not at all by the ſenſe, any alteration of them, though the change be into words of the ſame ſenſe, quite confounds the creature. The word *down* is ſhort and expreſſive, and no other need be uſed when he is ordered to couch; but this being once given him, is never to be varied afterwards. The next ſound he ſhould be taught after this, is the word of correction, for no leſſon can be given but faults will be committed, and no fault ſhould paſs without correction or blame; in this caſe the word *ſirrah*, ſpoke angrily, will always be underſtood: This, at firſt, ſhould be uſed with a laſh or a blow, and after a time he will know it as a word of diſpleaſure, and it will do for ſmall faults without the blow. Certain words of cheriſhing and encouragement muſt alſo be taught him at the ſame time, as *good boy*, or the like, uſing always with them actions and looks of chearfulneſs and pleaſure, as clapping him on the back, and the like. After theſe, he muſt be taught the meaning of ſome words of advice, to put him in mind of his buſineſs, when he is out upon the ſport, ſuch as *take heed*, or the like. Theſe will not only ſet him upon the watch, and make him diligent; but he will alſo be careful and cunning, and at the ſame time chearful and pleaſed in himſelf, at knowing that he is doing his maſter a pleaſure.

When the young dog is thus far inſtructed, and knows the meaning of the words of inſtruction, correction, encouragement, and advice, and will couch and lie down at his maſter's feet, how and when he pleaſes, and that with the ſignal of a word, or a look only; he is then to be taught to follow cloſe at his maſter's heels, by leading him by a line tied to his collar; he is to be carefully taught this, ſo that when taken out to the ſport, he muſt neither run under the legs, nor hang too far back; this alſo will tend to the making him the more obedient. When he has been thus taught to follow with a line, he muſt be taught to follow in the ſame manner, looſe, and without a line, and always to be at his maſter's heels.

The next leſſon he is to be taught, is to fetch and carry any thing he is commanded; this muſt be taught him by way of ſport, as a diverſion, by ſhaking a glove at his head, and teaching him to ſnatch it, and afterwards to catch it when thrown from the hand, and bring it back again; this he is to be encouraged in with cheriſhing words, and all other means.

The beſt method of perfecting the creature in this, is by letting him have no food, but what he earns by doing well, always feeding him when he does as he ſhould do. If he carry the glove away, or play wantonly with it, and refuſe to bring it back, his maſter is to uſe the word of inſtruction, as *take heed*: If this does not bring him to, he is to uſe the word of correction; and if he does not bring it back at this, he muſt proceed to blows; and on many other trials he muſt have nothing given him to eat, till he has done as he ought, and has it by way of reward. When by this means he is taught ſo well, that he will bring back the glove, wherever it is thrown, and carry it only to his maſter, though he is in company with other perſons, who all call him, he is then to be cheriſhed and encouraged, and taught to bring back any thing elſe that is thrown, whether ſticks, ſtones, or any thing whatever. After this, he is to be taught to carry dead fowl, and finally live ones, and this with ſo tender a mouth, as not to hurt them: thus he will be taught at length to bring the fowl that his maſter ſhoots, without tearing them or hurting a feather.

The next leſſon is to be taught by taking him out in the field, and dropping ſomething unknown to him; after he is come to ſome diſtance from the place, he is to be ſent back to ſeek for it, and if he bring it back, he is to be encouraged. If he bring back a wrong thing, he is to be encouraged for the attempt, and ſent back again: By repeating this at different diſtances

diſtances, he will be taught to go back ever ſo far in ſearch of any thing; and if he fails in the leſſons, he is to be chid, beaten, or kept faſting, for it, according to the offence.

When he has been perfected in all theſe leſſons, he muſt be taught his buſineſs of hunting; he is to be firſt taught with tame fowl, which his maſter is to aſſiſt him in taking, and reward and encourage him when he has done. After this, he is to be ſent in without aſſiſtance to take the fowl alone, and if he ſucceeds, he is to be encouraged and rewarded, and corrected if he fails. By this practice he will ſoon become maſter of his game; but great care is to be taken in the teaching him, when he has caught it, to bring it back to the ſhore, without biting or hurting it.

The next thing to this, is the training him to the gun; to this purpoſe he muſt be taught to follow ſtep by ſtep behind his maſter, and under covert of his ſhadow, till he has ſhot, or, when there is occaſion, to couch and lie cloſe, never daring to ſtir till the gun has gone off; and then, upon the leaſt notice or beckoning, to come and do what he is commanded.

Many of theſe dogs are ſo expert, that they will have their eye upon the game as ſoon as their maſter, and the moment the gun is gone off, they will, without bidding, go and fetch it; but this is being too forward, and if he is uſed afterwards with nets or lime-twigs, he will do great miſchief, by ruſhing on the birds as ſoon as they are taken, and tearing the nets, or ſpoiling the twigs. Obedience is the beſt quality in this ſort of dog, and it is better he ſhould wait for command, than know his buſineſs without it.

The ſportſmen, who know the time of birds moulting, make a very great uſe of this ſort of dog, taking him with them without gun, net, or any other aſſiſtance. The common moulting-time of *Water*-fowl is from June to Auguſt; in this time they are not able to fly well, and in ſome part of it, when their old wing-feathers are off, and the new ones are grown ſcarce at all, the dog is then to be taken to the ſides of rivers, and other waters, and ſet to hunt about the cloſe places, among which they hide themſelves at this time; the dog, being ſet to hunt, will eaſily find them in theſe retreats, and will take them either by leaping ſuddenly upon them, or fairly purſuing ſuch of them as have not the uſe of their wings.

There is alſo another great uſe of the dog in driving them without catching them. This is practiſed only in mooriſh and fenny countries, where they are very numerous. In theſe countries a proper place is to be ſought for, where the birds retire to, and theſe are planted with nets; then the dog is ſent into the *Waters* and places of covert, where they are ſuppoſed to be, and this at the moulting-time, when they cannot fly away from him. The alarm he puts them into which he firſt attacks, ſoon calls many others together, and there is a large body of them formed, which the dog drives before him like a flock of ſheep, and being directed by the ſportſmen, frightens directly into the places of their retreat, where the nets are placed before-hand to receive them.

WATER-*Fowl*. We are apt to ſuppoſe that theſe birds have ſomething more peculiar in their ſtructure than they really have, to enable them to live without the benefit of reſpiration a conſiderable time. It was ſuppoſed that they could ſubſiſt without air a long time, till Mr. Boyle found by his experiments with the air pump, that they could not bear the exhauſted receiver any longer than other birds, a full grown duck being killed in two minutes in it. But what is more obſervable is, that their power of remaining under *Water* is for a much more limited time than is imagined. On tying a weight to the legs of a duck, and ſinking her in a tub of water, it was found that two minutes immerſion proved very troubleſome to her, and occaſioned great efforts for riſing; that after this the air-bubbles were diſcharged in plenty from the mouth and noſtrils, and finally the beak was wide opened, the *Water* admitted, and the creature abſolutely drowned, ſo as to be irrecoverably dead in ſix minutes. A young duckling put into the *Water* in the ſame manner, died at the end of the fourth minute, after diſcharging many air-bubbles both from the noſtrils and mouth, and yet more from the upper part of the head, a little behind the eyes. Phil. Tranſ. N°. 62.

Water-fowl may be taken in great abundance by nets properly managed. The net for this purpoſe ſhould be always made of the ſmalleſt and ſtrongeſt packthread that can be got. The meſhes may be large, but the nets ſhould be lined on both ſides with other ſmaller nets, every meſh of which is to be about an inch and half ſquare each way, that as the fowl ſtrike either through them or againſt them, the ſmaller may paſs through the great meſhes, and ſo ſtreighten and entangle the fowl.

Theſe nets are to be pitched for every evening flight of fowl, about an hour before ſun-ſet, ſtaking them on each ſide of the river, about half a foot within the water, the lower ſide of the net being ſo plummed, that it may ſink ſo far and no farther; place the upper ſide of the net ſlantwiſe, ſhoaling againſt the *Water*, but not touching it by near two foot; and let the ſtrings which ſupport this upper ſide of the net be faſtened to ſmall yielding ſticks ſet in the bank; theſe, as the fowl ſtrikes, will give the net liberty to play, and to entangle them. Several of theſe nets ſhould be placed at once over different parts of the river, at about twelve-ſcore fathom diſtance one from another; and if any fowl come that way, the ſportſman will have a ſhare of them. It is a good method, when the nets are ſet to go to places ſufficiently diſtant from them with a gun, to fright them toward the places where the nets are; and wherever any of the fowl are ſtarted from, it may not be amiſs to plant ſome nets alſo there to take them as they return. The nets are to be left thus placed all night, and in the morning the ſportſman is to go and ſee what is caught; he ſhould viſit the river firſt, and take up what are caught there, and, frightening the reſt away to the other places where his nets are, he is next to viſit them, and take what are there ſecured.

WATER-*Gavel*, in our old writers, a rent paid for fiſhing in, or other benefits received from, ſome river. *Blount*.

WATER-*Horehound*. See the article LYCOPUS.

WATER-*Salamander*. See the article SALAMANDRA.

High WATER is when the tide is at the higheſt. See the article TIDE, *Cycl*.

Low WATER is when the tide is at the loweſt.

WATERING, (*Cycl*.)—WATERING *of Horſes*. All the while that a perſon is on a journey, the horſe ſhould always be ſuffered to drink of the firſt good water he comes to after ſeven o' clock in the morning in ſummer, and after nine or ten in the winter. Moderately pure water is to be preferred, that being beſt of all which is neither too clear and penetrating, nor muddy and ſtinking.

Though it is the cuſtom in England to run and gallop horſes after drinking, which we call *Watering*-courſes, and which we ſuppoſe brings them into wind, yet Sollyſel, and many other of the beſt judges of horſes, tell us, that it is one of the worſt and moſt pernicious practices that we can be guilty of; there can no good accrue from it, and many horſes are rendered purſy by it.

While a horſe is drinking, the rider ſhould draw up his head five or ſix times, making him move a little between every draught. The rider need not be afraid of giving him water, with proper moderation, even in almoſt any circumſtances. If he be warm and ſweat very much, yet if he is not quite out of breath, and there are four or five miles to ride, he will be better after drinking a little, than if he had drank none at all; only obſerving, that if the horſe were very warm at his going into the water, his pace muſt not be leſs than a moderate trot when he comes out, that he may not be chilled.
