In the time of a journey the horſe ought to be ſuffered to drink in this manner, of the waters that come in the way, as often as may be; for if the rider happens to bait when he is hot and ſweaty, he muſt not be ſuffered to drink of a long time, as it would endanger his life; and if he has not been *watered* in this manner on the road, his exceſſive thirſt will often prevent his eating, and he will not be able to touch any ſort of food of an hour or two, which is uſually more time than the rider can ſtay, and yet without eating at baiting-times he will not have ſtrength to go on. The giving him water on the road will, on the contrary, keep him ready for food whenever it is offered him, and the rider need ſtay no longer than his own refreſhment requires, the horſe eating immediately, and being readily qualified to go on again.

If there be any ſhallow water in the way, a little before the coming to the inn where the horſe is to reſt all night, it is always proper to ride him in, and not only give him a little drink, but ride him about ſeveral times, not quite up to the belly; this will clean his legs, and prevent humours from falling down into them. If the horſe be very warm, and there has been no convenience of *Watering* him upon the road, the oats that are given him ſhould be firſt ſteeped a while in ale; this will induce him to eat, though he could not have touched any that were wholly dry.

Many are of opinion, that horſes are ſometimes ſpoiled by giving them oats before their water; but Mr. Sollyſel affirms, that though it be not the cuſtom to give oats till afterwards, yet it never does any harm to feed the horſe with them both before and after drinking; and that it is often proper and neceſſary, eſpecially when the horſe has been hard rid, and is warm.

WATRY *Sores*, in the manege, called in French *mauvaiſes eaux*, are a ſuppuration of ſtinking and malignant humours, which iſſue from the paſtern and fetlock joints of a horſe, and that from the hinder rather than the fore-legs.

WAVE (*Cycl*.)—This motion of the ſea-water depends greatly on the winds, and on the ſituation of mountains, in regard to the ſea; for the winds are driven back from theſe with great impetuoſity; and in ſome places this occaſions a great and very irregular undulation, beſide that which is produced by the immediate action of the winds on the ſurface of the water, in their own direct courſe.

Waves are to be conſidered as of two kinds, and theſe may be diſtinguiſhed from one another by the names of natural and accidental *Waves*.

The natural *Waves* are thoſe which are regularly proportioned in ſize to the ſtrength of the wind, whoſe blowing gives origin to them. The accidental *Waves* are thoſe occaſioned by the wind's reacting upon itſelf by repercuſſion from hills and mountains, or high ſhores, and by the waſhing of the *Waves* themſelves, otherwiſe of the natural kind, againſt rocks and ſhoals;

ſhoals; all theſe caſes give the *Waves* an elevation, which they can never have in their natural ſtate.

The great Mr. Boyle has proved by numerous experiments, that the moſt violent wind never penetrates deeper than ſix foot into the water; and it ſhould ſeem a natural conſequence of this, that the water moved by it can only be elevated to the ſame height of ſix foot from the level of the ſurface in a calm; and this ſix feet of elevation being added to the ſix of excavation, in the part whence that water ſo elevated was raiſed, ſhould give twelve foot for the utmoſt elevation of a *Wave*. This is a calculation that does great honour to its author; for Count Marſigli meaſured carefully the elevations of the *Waves* near Provence, and found that, in a very violent tempeſt, they aroſe only to ſeven foot above the natural level of the ſea, and this additional foot in height he eaſily reſolved into the accidental ſhocks of the water againſt the bottom, which was, in the place he meaſured them in, not ſo deep as to be out of the way of affecting the *Waves*; and he allows that the addition of one ſixth of the height of a *Wave*, from ſuch a diſturbance from the bottom, is a very moderate alteration from what would have been its height in a deep ſea, and concludes, that Mr. Boyle's calculation holds perfectly right in deep ſeas, where the *Waves* are purely natural, and have no accidental cauſes to render them larger than their juſt proportion

In deep water, under the high ſhores of the ſame part of France, this author found the natural elevation of the *Waves* to be only five foot; but he found alſo that their breaking againſt rocks, and other accidents to which they were liable in this place, often raiſed them to eight foot high.

We are not to ſuppoſe, from this calculation, that no *Wave* of the ſea can riſe more than ſix foot above its natural level in open and deep water, for *Waves* immenſely higher than theſe are formed in violent tempeſts in the great ſeas. Theſe, however, are not to be accounted *Waves* in their natural ſtate, but they are ſingle *Waves* formed of many others; for in theſe wide plains of water, when one *Wave* is raiſed by the wind, and would elevate itſelf up to the exact height of ſix foot, and no more, the motion of the water is ſo great, and the ſucceſſion of *Waves* ſo quick, that, during the time this is riſing, it receives into it ſeveral other *Waves*, each of which would have been at the ſame height with itſelf; theſe run into the firſt *Wave* one after another, as it is riſing; by this means its riſe is continued much longer than it naturally would have been, and it becomes terribly great. A number of theſe complex *Waves* ariſing together, and being continued in a long ſucceſſion by the continuation of the ſtorm, make the *Waves* ſo dangerous to ſhips, which the ſailors in their phraſe call mountains high. *Marſigli*, Hiſt. Phyſ. de la Mer.

WAVE-*Offering*, among the Jews, a ſacrifice offered by agitation or *waving* towards the four cardinal points. See the article AGITATION.

WAVED, or WAVEY, (*Cycl.*) in heraldry, denotes that the firſt of the family in whoſe arms it ſtands, acquired his honours for ſea ſervices, and has this peculiar commemoration of it ordered in his arms. *Niſbet*'s Heraldry.

WAX (*Cycl.*)—Before it is poſſible to underſtand the accounts authors give of the manner in which the bee collects its *Wax* and honey, and forms the cells to depoſit the laſt fluid in, it is neceſſary to underſtand the true ſtructure, and know the ſeveral parts of this little creature.

The anterior part of the head of a bee is triangular, and ſomewhat flat; it goes tapering from the baſe to the extremity, and the reticular eyes are placed at the ſides; theſe are of an oval figure, one point or end being much larger than the other. The narrower end of each eye is on the lower part of the head, and reaches almoſt to the origin of the teeth; there is a large ſpace between the eyes, and this is full of little irregularities. The antennæ are placed at the two ſides of an eminence in this part, coming near the eyes; they are of no very ſingular ſtructure, but are compoſed of ſeveral joints, and ſeem of the nature of horn; they are ſo made that they may be eaſily folded in two, and they are always found to be ſo in dead bees. The head is not very thick, but appears ſomewhat broad; and at the upper part there are placed three ſmall ſhining eyes in a triangular ſituation, as is the caſe in many other of the winged inſects.

The bee has a trunk and teeth, and the ſituation of theſe, at the extremity of the head, has a great ſhare in giving that part a triangular figure. The teeth, when they are not in action, meet in a point at their extremities, and form an angle which projects out from the cruſtaceous lips. Theſe teeth are a very eſſential part of the creature, and are not only intended for the common purpoſes of eating, but ſerve alſo to the great purpoſes of erecting the works within the hive. Theſe teeth are properly a ſort of grinders, one of which has its origin on one ſide of the head, and the other at the ſame height on the other; they are ſmaller near their origin than in any other part, and thence grow larger to the extremity, where they are cut off obliquely in ſuch a manner, that when their two ends are applied one againſt the other, they make a ſort of angular pair of pincers, which are able to lay very faſt hold of any thing; they are not only capable of meeting in this manner, but they can, upon occaſion, croſs one over the other; and this is the poſition they are uſually found in when the bee is dead. The truncated ends of the teeth have each a ſemicircular cavity, ſurrounded with hairs; theſe meeting, when the teeth are cloſed, form a regular cavity, capable of receiving whatever is ground to pieces by the ſides of the teeth. *Reaumur*'s Hiſt. Inſ. vol. 9. p. 357.

The head of the bee is faſtened by a ſhort, flexile, and fleſhy neck to the breaſt; the hinder part of the head receives the end of the neck, and near the inſertion of this is placed the origin of the trunk; this goes ſtrait forward from this place as far as the angle made by the teeth, and thence returns in a curved form to fall over the breaſt. On the ſides and upper part of the breaſt are the origin of the four wings, and on its under part the four legs are inſerted. There are alſo on the breaſt the four principal ſtigmata, which are ſituated as in other flies. In the ordinary poſition of the parts, the poſterior end of the corcelet is placed cloſely upon the firſt ring of the body, ſo that they ſeem joined together by their whole ſurfaces. But the true ſtate of theſe parts is, that they are only joined by a ligament; this ligament is placed on the lower part of the corcelet and body, and, being very ſhort, is often not at all ſeen. The poſterior part of the corcelet alſo has a convexity, and the anterior part of the firſt ring of the body a cavity that receives it; whence theſe parts, in their common ſtate, appear joined together in a great extent, in which they really only touch. The body is compoſed of ſix rings, which are covered with very ſtrong ſcales; theſe are very neceſſary to them, for they often fight, and were it not that there was ſuch a defence againſt one anothers ſtings, they would unqueſtionably often periſh.

The body of the bee appears in ſeveral places ſpotted with a reddiſh colour; all theſe parts are ſo many hairy ſpots, and owe their colour to the reddiſh hue of the hair. The body, breaſt, and head of the bee, are alſo covered in many places with longer and more diſtinguiſhable hairs. In examining the creature in this view, it is proper to uſe a microſcope, for tho' the naked eye ſhews many hairs, this inſtrument ſhews vaſt numbers more, and thoſe in places where they could not have been ſuſpected to grow; the very eyes are not exempt from them, the large reticulated ones being as thick ſet with ſhort and fine hairs, as almoſt any other part of the body.

Theſe hairs, when ſeen through the microſcope, do not appear in form of ſingle filaments, but they repreſent ſo many buſhes or beds of moſs, every filament, or as it appears to the naked eye, ſingle hair, being thus ſeen to be branched and beſet with ſhort prominences reſembling leaves of a plant. *Reaumur*'s Hiſt. Inſ. vol. 9. p. 361.

Many have ſuſpected what are called the reticulated eyes of flies not to be real eyes, and theſe growing hairs upon them has ſeemed a convincing proof of their not being ſo, ſince it has been ſuppoſed that they could ſerve to no other purpoſe than to impede viſion. Mr. Hook and others have ſaid a great many things in favour of the opinion of their being eyes; but Mr. Reaumur has proved it beyond all doubt; he choſe to this purpoſe the eyes of the bee for his experiment, as they were the moſt hairy of thoſe of any known inſect, and therefore the leaſt qualified to act as eyes, according to the common opinion. The bee is known to ſee very well; and this author determined to try whether ſhe would do ſo without the aſſiſtance of theſe reticulated ſubſtances; he to this purpoſe covered over the reticulated parts of the head of three or four bees of the common kind, and then incloſed them with twenty others in a wooden box. When they had been there ſome time, he opened the lid of the box; thoſe which were not varniſhed immediately flew out, and went directly to their hive; the others, whoſe eyes were thus cloſed up, continued in the box a long time, and when diſturbed, in order to ſend them out, flew in various directions againſt the ſides of the box; and in fine, when in the air, ſeemed to know nothing of their way to the hive, but flew up into the air till out of ſight.

This experiment ſeems to have wholly determined the point, ſince if the creature be rendered blind by the covering the reticulated ſubſtances on the head, it muſt be allowed that thoſe reticulated ſubſtances are the eyes. The hairs which grow on them do not take their origin from the pupils or lenſes, of which they are compoſed, but from the ſubſtance which ſeparates or makes cells for them; and though theſe hairs appear to ſome to be greatly injurious to viſion, it may very poſſibly be, that they ſerve only as our eye-laſhes, to break the too violent light to which the eyes are ſometimes expoſed. It is to be obſerved, that the hairs which grow upon the reticular eyes of the bee are not branched or foliated in the manner of thoſe of the body, but are only ſingle, ſhort, and ſtrait filaments, perfectly reſembling the hairs of large animals. When Mr. Reaumur had thus proved the uſe of the reticulated eyes of the bee, he was determined to try the uſe alſo of the three ſmall and ſhining eyes, which ſtand on a triangle on the back part of the head; to this purpoſe he covered theſe eyes with the ſame varniſh with which he had before covered the reticulated ones, but leaving theſe bare: he did this with ſeveral bees, and afterwards placing them at a few yards diſtance from the hive, he left them at liberty. Not one of them found the way to the hive, or even ſeemed able to direct its flight towards it; but they all flew directly to the flowers that were

nearest them, to which they perfectly saw the way. These did not fly upwards, as all the others did.

The hairs of the bee are of different use from that of the hairs of other animals, and therefore all this varied structure was necessary. See the article HONEY.

The legs of the bee are six; the two anterior pairs are of the same length; but the two hinder legs, or posterior pair, are considerably longer than the others. Each leg is composed of five principal pieces; of these, that next the origin is thicker and shorter than any of the others. This is a sort of conic button, to the end of which the second piece is articulated; this is much longer and thicker in the middle, and thinner at each end; the third piece of the leg in the hinder pair is different from that of the others; it is flat and of a triangular figure, and is called by Reaumur and other French authors, *palette triangulaire*. This is articulated with the second piece by its point, and with the fourth by its broad part. This third piece in the second pair of legs is much less flat and triangular than in the hinder pair; and in the first pair it is scarce at all so. The fourth piece in the two hinder pairs of legs is also broad and flat; but it is not triangular, but of a square figure. The French writers call this the *brosse*. This is much larger and broader on the hinder pair of legs than on the second, and in the first it is not at all of this flatted or square figure, but is cylindric and slender. The fifth piece of each leg is what may be called the foot. It is an extremely fine part, and is composed of fine joints, placed close to one another. The four anterior pieces are a sort of truncated cones, a little flatted, and are joined by the base of the first to the head of the second, and so on. The last piece is long, slender, and cylindric, and is terminated by two hooks resembling the claws of a bird. One of these is twice as long as the other, and between these two claws there is placed a fleshy protuberance covered with hairs, of the nature of that of the feet of the flies; by means of which they are able to climb upon glass, or other smooth bodies. *Reaumur*'s Hist. Inf. vol. 9. p. 368.

The first joint of all the legs of the bee is covered with the foliated hairs before-mentioned; the second piece has strait hairs, and the third piece, or palette on the hinder pair, is so beset with large and stiff hairs all round its edges, and so hollowed in its anterior part near the bottom, that it resembles a sort of basket, and it is made for that very purpose, serving the creature as a sort of basket to carry home its *Wax* in.

The third joint of the first and second pair of legs has no structure like this; and we find that it is not in those legs used to the same purposes, it being only on the last pair of legs that the lumps of *Wax* are seen, when the bee is loaded with them. The fourth piece of the two hinder pair of legs, which the French call the *brosse*, or the brush, and which is of a square figure, serves the creature in the place of a brush, and is in reality formed somewhat like one. The outer surface of this is convex and smooth, the inner is concave and hairy, and the hairs on this part do not stand singly, but are placed in little tufts, wider at the extremity than at their origin, and exactly resembling the tufts of hair in our clothes-brushes. *Reaumur*, Hist. Inf. vol. 9. p. 369.

The several authors who have treated ever so largely on the arts and industry of bees, and described the manner of forming their waxen structures or combs for the reception of their honey, have yet omitted to clear up the material point of what that *Wax* is, what it is originally composed of, and by what artifice the bee works it out of its rough state, in the plant in which it is found, into the substance which we call *Wax*.

It is very certain that the farina fœcundans of the flowers of plants, contained in their apices, is the matter of which the bees form their *Wax*; they either dislodge this from its cells with their teeth, or else merely by rubbing their bodies among the stamina and apices, load themselves with the globules of it, which their hairs keep sticking upon their body, and which they afterwards brush off with their legs, and, by degrees, collect into balls or lumps, which they deposit upon the flat and triangular piece, which makes the third joint of the hinder pair of their legs.

The lumps of *Wax* with which we see them loaded in this part, and carrying to their hives, is only the farina of flowers worked up and compressed into a mass or sort of cake. The stamina of the flowers therefore sustain certain cases, containing a powder, which is the matter of bees *Wax*. This powder, thus collected into lumps on the legs of the bees, is called rough *Wax*, and is probably *Wax* to all intents and purposes, only wanting a little beating together. *Wax*, therefore, so long esteemed an animal substance, will appear to be a native vegetable production. We know very well, that different species of trees yield us the several gums and resins used in medicine and mechanics, in the same perfect form in which we see and use them; and there is a species of shrub, very well known in America, and called the *candle-berry-tree*, the berries of which yield a *Wax* perfect in all respects, and fit for the making candles, &c. without having passed through the manufacture of the bee at all.

In the same manner it seems that all our common plants produce *Wax* in their flowers, but that this is in such very small quantities, that these little animals alone are able to collect and work it into a state fit for our use: but this does not absolutely hold good; for if we examine what we call rough *Wax*, that is, the balls of *waxey* matter on the legs of the bees, we shall find that it is not yet bees *Wax*. It is an easy matter to catch a few bees as they return in a morning loaded to the hive, and on separating the *waxey* matter from their legs, and pressing it between the thumb and a finger, it will be found to differ greatly from perfect *Wax*. This would, in a like case, soften of itself, and form a regular and uniform flat cake; whereas, on the contrary, the matter from the bees legs is friable, not ductile, will not soften itself between the fingers; and when pressed a little to a flatness, it is seen to be still composed of regular globules, which all retain their pristine form, not mixing or blending among one another, and hanging together only by means of some humidity which hangs about their surfaces. If it be tried by a greater warmth, it will be found in the same manner to differ from *Wax*, in the want of some of its essential qualities. If a piece of it be put into a silver spoon, and held over lighted charcoal, it will not melt as *Wax* would do, but will take fire and burn regularly into a cinder: and finally, if it be carefully worked into a long thread, and the end of it put to the flame of a candle, it will take fire as readily as *Wax* would do, but it will not run or melt like it, but burn like a piece of dry wood. Water also gives as evident a proof of the difference between the rough *Wax* and the perfect, as fire. If a piece of this rough *Wax*, as taken from the legs of the bee, be thrown into water, it sinks to the bottom; whereas perfect *Wax* will always swim upon the top: This might seem owing to the great humidity of the rough *Wax*, while loaded with the juices of the plant; but it is proved by experiment that this is not the case; for if the rough *Wax* be kept till ever so perfectly dry, it still preserves its own nature, and will sink in water as readily as at first. *Reaumur*'s Hist. Inf. vol. 10. p. 39.

From the whole then it is evident, that the bee does something to the matter of which *Wax* is made, in order to the reducing it into perfect *Wax*. It might be supposed that the several globules of this matter were so many sacks containing the true *Wax*; and that the bee need only break or open those sacks, to get at the true and genuine *Wax* within; but this does not appear to be the case upon experiment, since if this matter be ever so nicely and carefully pounded and broke to pieces, it does not become any more *Wax* for this treatment, nor is any more fusible or ductile than before. The opinion of Swammerdam and Maraldi was, that the bee added some other matter to the rough *Wax*, in order to reduce it to this proper state. And as there is no substance so ready for the bee as honey, they supposed that she mixed honey with this matter, and so made *Wax* of the compound; but experiment is also wholly against this, since if honey, and this matter collected from the bees, be mixed in any proportions, the compound has no more the properties of *Wax* than it had before, but still remains a quite different substance. Swammerdam afterwards fell into another opinion, in regard to the matter mixed with the rough *Wax*, in order to render it perfect; this was, that the bee mixed with it the venomous liquor, of which she has a bag full near the tail, in order to poison the wounds made by her sting. He made some experiments on this plan, which he thought favoured his system, and endeavours to strengthen the probability, by observing, that as the sting of a bee comes but very little into use, it would not have been necessary that the creature should have been thus constantly supplied with a large bag of this matter, if nature had not allotted to it some other use beside that regarding the sting. This opinion prevailed among the learned, till Mr. Reaumur of late proved by experiments, that this liquor had no effect on the matter found on the thighs of the bee, as to the turning it into *Wax*; and also, that several creatures which make no true genuine *Wax*, such as the humble bee, the wasp, and the hornet, whose combs are made of a sort of paper, yet have all this bag of liquor near their sting.

It is most probable, that the method in which the bees turn the farina of flowers into *Wax*, is a very simple one; and most likely it consists only in a sort of beating the quantities of them, which they collect, till they are very thoroughly united. We have never been able yet to discover their manner of doing it; but this appears most like the course of nature, in the operations of other insects; if this be the case, it would be possible, perhaps, for us to imitate their method, and procure for ourselves *Wax* out of the stamina of flowers; this would be a discovery of the utmost importance: For though at present the bees which work it for us cost us nothing in keeping, yet it is to be observed, that they are too few in number to collect so much as we might wish. Doubtless it is not one thousandth part of the waxey matter, produced only by a few plants, that the bees of a whole province collect, while the rest all falls to the ground, and is lost. If we could arrive at the way of converting the farina of flowers into *Wax*, without the assistance of the bee, we might have it in infinitely larger quantities; since children might be taught to beat off, or shake down, the farina from numbers of plants, which, when in full flower, would yield a much greater quantity than could be expected by those who are not conversant in these studies.

The

The probability of ſucceſs in an attempt of this kind, has engaged the French naturaliſts in the following trials.

Mr. Geoffroy, in his account of the farina of plants, obſerves, that they preſerve their figure a long time when immerſed in ſeveral liquors, but that they impart a tincture to thoſe liquors. This induced Mr. Reaumur, to try the experiment of what different fluids were able to extract from them. For this purpoſe he collected a conſiderable quantity of the rough matter from the legs of the bees of one of his hives, and dividing it into three parts, he poured upon one ſome common water, upon the other ſpirit of wine, and upon the third oil of turpentine.

When theſe had all ſtood three months, often renewing the liquors, he evaporated the water, which was coloured of a deep and duſky brown, to a perfect dryneſs. When this was done, there remained at the bottom of the ſpoon in which the evaporation was made, a ſmall quantity of a perfect gum, which had all the properties of the common vegetable gums, and was as eaſily ſoluble in water as any other of them.

The impregnated ſpirit of turpentine was next evaporated; but the reſiduum was not great in quantity, and was in ſo much owing to the liquor itſelf, that little could be judged from it. In trials made after this, by boiling the rough *Wax* in freſh oil of turpentine, this appeared to be but a very poor menſtruum for it, the *Wax* rather hardening than ſoftening in it.

The ſpirit of wine impregnated with the tincture of the farina was next evaporated; as the liquor grew thick toward the end of the evaporation, it ſent out a ſtrong ſmell of *Wax*, and, when wholly evaporated, it left on the ſpoon a cake of yelloviſh matter, having perfectly the ſmell and external appearance of *Wax*. We may learn from this, that the ſubſtance of *Wax* is in the farina of flowers, and that this menſtruum is capable of extracting its finer parts. The quantity of extract remaining from this operation was a ſcruple. This carried all the external appearances of *Wax*, and ſome of its properties. It was of the ſame colour and conſiſtence with the common yellow *Wax*; its ſmell was wholly the ſame, and it would fuſe or run into a liquid matter at the fire, and might be moulded between the fingers, being as ductile as common *Wax*.

With all theſe properties there was great reaſon to ſuppoſe it to be perfect *Wax*; but this appeared not to be the caſe when it was held a little time in the mouth, for it there broke to pieces, and diſſolved in the manner of the common lozenges, which have ſugar for their baſis. The evident reſult of this experiment was, that the matter of *Wax* was contained in this ſubſtance, collected on the legs of the bees, and owing its origin to the farina of flowers; but that it was as yet mixed with ſome other ſubſtance, and the ſpirit of wine had extracted them both together.

The moſt likely extraneous matter to be mixed with the *waxey* ſubſtance, was ſome ſalt; this was eaſily proved to be the caſe by another operation; for if this reſiduum was dried to a perfect hardneſs over the fire, it would become ſo moiſt again, on being expoſed to the air, that in an hour's time the fingers would ſtick to it; this imbibing humidity from the air is ſo known a property of ſalts, and ſo uncommon in other things, that there is little room to doubt but that this was the caſe in this reſiduum.

It is evident, however, from this experiment, that a part, at leaſt, of the matter of which *Wax* is made, is contained in the ſtamineous powder, or farina of plants, and that the ſpirit of wine extracts this, and with it ſome portion of heterogene matters. It is probable, that if we knew the proper diſſolvent of *Wax* in its perfect ſtate, which is a thing not yet known, we ſhould be able, by means of that, to extract the *Wax* pure and alone, either from the ſtamina of flowers, or from the matter lodged on the legs of the bees; but that till we are acquainted with ſuch a diſſolvent, we are not to wonder that we cannot extract pure and perfect *Wax*, either from the farina in its natural ſtate on the plant, or when lodged on the legs of the bee.

Laſtly, ſpirit of wine digeſted upon real *Wax*, and the tincture evaporated, does not diſſolve the whole ſubſtance of the *Wax*, but the reſiduum of the evaporation is the ſame with that from the farina itſelf; a ſubſtance of the conſiſtence of butter, of a yellow colour, having the ſmell of *Wax*, and ſome of its properties, but being ſoluble in water. *Reaumur*, Hiſt. Inſ. vol. 10. p. 48.

The ſalt which is extracted from perfect *Wax*, as well as from the farina of plants, by digeſtion in ſpirits of wine, is of the nature of ſugar or honey, being the eſſential ſalt of ſome peculiar juices of the plant. This is contained in much larger quantity in the virgin *Wax*, of which the firſt combs of bees are made, than in ſuch common *Wax* as has been melted and run into cakes; this is proved by extracting a tincture from ſuch virgin *Wax*, which always has a plainly ſaccharine or honey-like taſte.

The difficulty in the way of the making *Wax* from the ſubſtance from which the bees make it, is the poſſibility of its being converted into *Wax* within the body of the animal: If this is the caſe, notwithſtanding that we perfectly know the matter of which *Wax* is made, we are not to wonder that we are not able to make it, any more than that we are not able to make chyle or blood out of the ſeveral ſubſtances uſed by us as food, and out of which we well know that it is made within our bodies.

Crude or rough WAX, called by the French *cire brute*, in natural hiſtory, a name given to a ſubſtance called by the antients *erithace*, *ſandarac*, and *ambroſia*.

We ſeem to have no name for it in Engliſh, but may call it after the name of the French, *rough-Wax*.

The Dutch call it the food of the bees, and that perhaps very properly, there appearing many reaſons to think that the bees eat it.

It is the yellow ſubſtance found on the hinder legs of bees in ſmall lumps, and is the ſubſtance of which *Wax* is made by this inſect. See the article WAX, *ſupra*.

Manner of collecting the crude WAX. If we examine a bee juſt entering a flower, which is well opened, and in its perfect ſtate, we ſhall uſually ſee her body very clean and neat; but if we examine her when ſhe comes out, ſhe is uſually found covered over with a fine duſt: It is very eaſy to determine that the creature has got this duſt from ſome part of the flower; and obſervations equally eaſy will alſo prove, that this powder is the matter of which the bee makes its *Wax*.

People who have not examined flowers as botaniſts have, yet often obſerve, that in a tulip or a lilly there are certain filaments which duſt over the fingers in touching them. Theſe filaments are by authors called the ſtamina or threads of flowers, and they always contain a large quantity of this duſt. Tournefort, and many other great writers, have ſuppoſed this duſt to be only a ſort of excrement ſecreted from the abundant juices of the plant by theſe filaments, which they have ſuppoſed to be organs deſtined only for that purpoſe; but later obſervers have allotted a more noble uſe to this duſt; they have called it the *farina fæcundans*, and have proved that all the fæcundity of plants is owing to it, the ſeeds never growing if they are not properly impregnated with the particles of this duſt, any more than the eggs of animals will be hatched into young ones, if not impregnated by the male ſemen. This farina is not to be ſuppoſed an irregular duſt, in the manner of our common powders; but the farina of the ſame plant is always compoſed of particles of the ſame ſhape, and that different from the ſhape of the globules of the farina of other plants. *Reaumur*, Hiſt. Inſ. vol. 9. p. 371.

It is of this powder or farina that the bees prepare their *Wax*. When one of theſe inſects goes into a flower, ſhe always ſhakes theſe ſtamina, and diſcharges all their globules or duſt upon her body, while ſhe is ſucking the honey with her trunk. It is on this occaſion that the hairs, with which the bee is covered, are of ſervice to her. Theſe round globules would all roll off from her ſmooth body and legs; but they are entangled in great numbers among this foreſt of branched and foliated hairs, and the creature carries them off for her ſervice. Thus when the bee comes out of a flower, ſhe is always ſeen to be duſted over with a yellow, a red, or a white powder, according to the colour of the farina of that ſpecies of plant. In ſome places the bees return to their hives, at certain ſeaſons, ſo covered with theſe powders, that the owners have thought they were, at certain times of the year, poſſeſſed of yellow or white bees.

Some bees carry their duſt thus on their body to the hive; others take the pains to clean themſelves firſt, by bruſhing their bodies, and collecting the whole together into a body, or ſmall lump: This is done by means of the ſquare bruſhes, which make the fourth pieces of the four hinder legs; theſe are beſet with tufts of hairs, in the manner of a common bruſh uſed for cloaths, and theſe they are able to move to every part of the body. The hairy parts of the anterior pair of legs ſerve to bruſh the head, and parts about it, as clean as the bruſhes on the other legs do the body; and the duſt, which is to them a very precious matter, is by this means collected into two parcels or lumps, one of which they place in the triangular baſket, with which nature has furniſhed them on the third joint of the hinder legs. See the article BEE. *Reaumur*, Hiſt. Inſ. vol. 9. p. 374.

This lump on each leg is formed into a ſort of round figure, and they fix it down in the cavity of this triangular piece, and the ſtrong and large hairs with which all the edges of this piece are furniſhed, very well keep it in till the creature gets to the hive.

The quantity of powder received from a ſingle flower, when thus collected into two lumps, ſeldom forms them ſo large as a ſmall pin's head; but as the creature inceſſantly flies into freſh flowers, the new matter collected from each, and added to the reſt, ſtill increaſes the heap, till, when the bee is ready to return to the hive, each ball often is as large as a pepper-corn, and reſembles it in ſhape, only that it is ſomewhat flatted. Many perſons have obſerved the bees thus buſying themſelves, and forming the powder with which they are covered into balls; but the motion of their limbs, on this occaſion, is ſo ſwift, that we can only ſee the bruſhing, and the effect of it in the balls; but our eye can never trace the manner of the operation. There are ſome circumſtances alſo in which the bee may be ſeen to make an immediate collection of *Wax* from the flowers, to the place on the hinder legs, where it is

received

received in a lump, without ever going on the body at all. This is very happily obſerved in the flowers of the apple and pear-tree in the ſpring-ſeaſon.

It is but of a very late time that men have found out that the little buttons on the ſummits of the filaments of the flowers of plants contained this powder or farina fæcundans; but the bees ſeem to have known it from all time; and before theſe little buttons or caſes of the farina burſt open, is the time when the bee can furniſh herſelf the moſt completely with the farina from them. If the bloſſoms of an apple-tree be obſerved when juſt opened, and the apices or buttons of the ſtamina ripe, but not yet burſt, a bee that comes into ſuch a flower, tries one of theſe apices with her teeth; if ſhe finds it is not ripe, ſhe goes to another; but if it be, ſhe burſts it open with her teeth, and wiping all the duſt clean out of it with her fore-leg on this ſide, ſhe paſſes the powder, thus received, to the ſecond leg, and thence to the third, where it is immediately lodged in a lump in the proper receptacle on the triangular piece, which makes the third joint of that leg. This being at a ſeaſon of the year when the weather is cold, and the bees not very briſk, their operations are ſeen better than at other times; but even here it is but imperfectly that they are traced, the motion of the legs, in delivering the treaſure from one to another, is too quick to be ſeen.

There is, however, another occaſion in which theſe motions are to be ſeen much more diſtinctly than in any other of theſe operations; this is when the bees are employed, as they ſometimes are, in collecting a reddiſh glutinous matter inſtead of *Wax*: This matter is of the conſiſtence of a reſin while ſoft; it is pliable, and ſticks to whatever it touches, ſo that the creature is troubled enough to deliver it from part to part, and the motions by which it performs this are conſequently much ſlower than thoſe by which it manages its *Wax*. The method of this proceſs is thus: the bee bites off a ſmall piece of the reſinous matter from the vegetable, with its teeth; it then holds this piece between the teeth, till it has faſhiond it into a ſmall round globule; as ſoon as this is done, the laſt joint of the anterior leg, which may be called the foot, receives it from the teeth; this foot is compoſed of five joints, and has a power of bending and cloſing in the manner of our fingers; this ſeizes upon the little globule while it is held between the teeth, and with ſome difficulty diſengages it. It then delivers it to the foot of the ſecond leg of the ſame ſide, which ſeizes it, and ſlowly delivers it from its adherences to the foot of the firſt leg; when perfectly freed, this places it on the triangular joint of the third leg, and then beats it down into the cavity by repeated ſtrokes, at once working it into a proper conſiſtence, and driving it into the mould, as the labourers uſe the ſoft clay of which they make bricks. This is doubtleſs the proceſs in the depoſiting and working the common *Wax* into form; but that being a leſs viſcid and tenacious ſubſtance, the whole motion is performed too quick to be obſerved diſtinctly; whereas in this, the tenacity of the ſubſtance making the parts ſtick to it, the motions are ſlower, and conſequently are more eaſily ſeen. *Reaumur*'s Hiſt. Inſ. vol. 9. p. 378.

All the bees do not return loaded in the ſame degree with *Wax* to the hive; ſome perhaps are better workers than others, and probably ſome have the happineſs to meet with flowers that yield more honey than others. When the lump is ſmall, it is contained within the verge of the palette, or flat part of the leg; but when it is larger, it hangs over the ſides, and entangling among the hairs, forces them outward; but theſe hairs are at the ſame time greatly aſſiſtant in retaining it in its place. When the bee meets with a flower whoſe apices are not ſo ripe as to burſt open on the touch, ſhe is obliged to bite every one of them with her teeth, and then collects the matter of the *Wax*, as in the inſtance of the apple-bloſſoms; but when the apices are ſo perfectly ripe as to burſt of themſelves on being touched, ſhe has nothing to do but to introduce herſelf among them, and then ſhaking them thoroughly about, their powder is diſcharged all over her body, and is to be bruſhed off, and collected into lumps by a more tedious proceſs, every particle of it being probably obliged to come into the reach of the feet of the anterior legs, and when worked into lumps in them, to be delivered to the feet of the next pair, and by them depoſited on and preſſed down into the palette or third joint of the laſt pair of legs.

If the bees are obſerved when returning to the hive loaded with their lumps of *Wax* on their thighs, theſe lumps on ſome will be found to be white, on others yellow, on others red, and on ſome greeniſh: This is owing to the different colours of the farina, yielded by the different plants they have been at work upon. The manufacture of the bee in moulding this into a lump, has not yet been able to alter the colour of the farina, nor even its figure; for if the lumps be examined by the microſcope, they will all be found to conſiſt of globules of a rounded or oval figure, or of whatever other ſhape they had when on the plant. The bees returning to their hives after their morning excurſions in the ſpring, are always found to contain in the cells of their palettes large lumps of *Wax*; but thoſe which go out in the heat of the day, return with little or none; the reaſon of this is, that the humidity of the farina, by means of the dew, makes it eaſily formed into a lump or maſs, its particles naturally ſticking together; whereas in the heat of the day this powder is too dry to be formed thus into a compact maſs, and therefore cannot be carried home by the bee. *Reaumur*, Hiſt. Inſ. vol. 9. p. 382.

Chemical Analyſis of WAX. Tho' bees-*Wax* be of ſo firm and ſolid a ſubſtance as we ſee, yet it is very remarkable that it contains no earth, but riſes wholly in the fire in the common way of diſtillation by the retort, without leaving a reſiduum. Another ſingular obſervation in this proceſs, is, that the more fluid matter there comes over into the receiver, the thinner the remaining matter in the retort becomes, not as might naturally be expected the thicker.

When the ſpirit of *Wax* (which is a phlegm with ſome acid particles ſuſpended in it) is all driven over by the fire, the reſiduum is a ſoft fatty ſubſtance, commonly called the butter of *Wax*; and if this butter be rectified, that is, if more acid and more phlegm be driven from it by the force of fire, the reſiduum of this proceſs is yet thinner than before, remaining in form of a clear liquor like oil, It appears therefore, on this analyſis, that *Wax* is compoſed of two parts, an aqueous ſubſtance, with ſome acid particles blended in it, and an oil; theſe two liquors have, by their union, formed this concrete, and acquired a hardneſs; but in the ſeparating them from one another, they become fluid again.

The proportion of the ingredients in this ſubſtance is alſo a very ſingular thing, for all the care in the world cannot ſeparate quite one fourth part of the weight of the *Wax* in form of oil, the remainder then is all phlegm and acid. Mr. Homberg advanced, that oils only became inflammable by means of the acid they contained, and this ſeems a proof of it; but when we conſider that *Wax* all burns away, it is an odd obſervation, though a very certain one, that three fourths of what is burning is water. Mem. Acad. Par. 1708.

To imitate Fruit in WAX. Take the fruit, and bury it half-way in clay; oil its edges, and the extant half of the fruit, then nimbly throw on it tempered alabaſter, or plaſter of Paris, to a conſiderable thickneſs. When this is concreted, it makes the half mould, the ſecond half of which may be obtained in the ſame way. The two parts of the mould being joined together, a little coloured *Wax*, melted, and brought to a due heat, being poured through a hole made in any convenient part of the mould, and preſently ſhook every way therein, will repreſent the original fruit. *Boyle*'s Works abr. vol. 1. p. 136.

WAY (*Cycl.*)—WAY *aftward on*, or *foreward on*, in a ſhip, is the ſame with her run or rake. See the article RAKE and RUN.

WAYED *Horſe*, in the manege, is one that is already backed, ſuppled and broken, and ſhews a diſpoſition to the manege.

WEACHIN, in botany, the name given by the Indians of America to the maiz, or Indian corn, which they cultivated for bread before we knew them.

WEAK (*Cycl.*)—WEAK, or *eaſy branch*, in the manege. See the articles BANQUET and BANQUET-*Line*.

WEALD (*Cycl.*)—WEALD, or WALD, in the beginning of names of places, ſignifies a ſituation near woods; and the woody parts of the counties of Kent and Suſſex are called the *Wealds*, though miſprinted *wildes*, in the ſtatute 14 Car. 2. c. 6.

The word *Weald* in Saxon ſignifying a wood.

WEALREAF, in our old writers, ſignifies the robbing of a dead man in his grave. *Leg. Ethelred.* c. 21. *Blount.*

The word comes from the Saxon *Weal*, ſtrages, and *reaf*, ſpoliatio.

WEASEL, in zoology. See the article MUSTELA.

WEATHER (*Cycl.*)—We have ſeveral ſchemes for keeping journals or diaries of the weather, extant in the Philoſophical Tranſactions, the medical Eſſays of Edinburgh, and in other books. The *Ephemerides Ultrajectinæ* may alſo be conſulted.

The inſtruments requiſite for ſuch a journal, are a barometer, thermometer, hygrometer, anemoſcope, and ombrometer, which ſee in their proper places in the Cyclopædia or Supplement.

WEATHER-*Cord*, is an hygrometer of a very antient invention, and, if properly conſtrued, may be uſed with good ſucceſs, to ſhew the alterations of the atmoſphere, with reſpect to moiſture and drineſs; but as commonly made, [a] it never riſes or falls ſufficiently to point out ſuch changes as the curious would be deſirous to know. But theſe riſings and fallings may be made very ſenſible, by means of a long index, moveable round a center, and pointing to a divided arch. We have a conſtruction and figure of an improved *Weather-cord* in the Philoſophical Tranſactions. N°. 479. p. 170. fig. 5.

WEATHER-*Quoil*, or *Coile*, in the ſea language, is the turning the ſhip's head about, ſo as to lie that way which her ſtern did before, without looſing any ſail, but only by bearing up the helm.

WEAVER's *Alarm*. This contrivance is only a weight faſtened to a packthread, which is placed horizontally, ſo that in a certain time a candle may burn down to it. Then the flame of the candle ſetting fire to the thread, the weight falls, and awakens the ſleeping perſon. See Phil. Tranſ. N°. 477. Sect. 14. where we have a figure to explain the invention, which got its name from being in frequent uſe among the *Weavers*.

WEEDS (*Cycl.*)—This term is uſed by our huſbandmen to expreſs ſuch plants as come up in their lands, and are different from the crop ſown there.

No plants are uſeleſs in themſelves; but in reſpect to the farmer they are both uſeleſs and hurtful, when they come in this manner, and devour the nouriſhment deſtined for the crop of what was ſown.

All *Weeds* are pernicious; but ſome much more ſo than others: Some are very miſchievous, but eaſily killed; ſome leſs hurtful, but more difficultly rooted out; and ſome have both qualities together. The hardeſt to kill are thoſe which grow readily from ſeed, and have roots, every part of which is qualified for the becoming a ſtout plant in a ſmall time; the worſt are couch-graſs, colts-foot, melilot, fern, and ſome others of the like kind.

Some of theſe pernicious plants only affect the crop by ſtarving, and leſſening its increaſe; but there are others which add to this miſchief, that of ſpoiling what they leave; theſe infect the crop with their own nauſeous ſmell, ſuch as melilot, garlic, and ſome others. It is ſuppoſed by ſome, that *Weeds* ſtarve the ſown plants, by taking up the room they ſhould poſſeſs; hut this is an error, and the real way in which they prejudice them, is, the devouring the nouriſhment that they ſhould imbibe.

This is eaſily proved by the following experiment. Let three beds of the ſame ſoil, equal in ſize, and equally prepared, be ſown with the ſame corn; let the firſt of theſe be kept clear from *Weeds*; in the ſecond, let the *Weeds* be ſuffered to grow up among the corn; and in the third, ſtick up a quantity of dead ſticks, greater in bulk than the *Weeds*. It will be found that the produce in the third bed will be equal to that of the firſt, though as much and even more room is taken up by the ſticks, than by the *Weeds* in the ſecond; but the quantity in the ſecond bed will be leſs, in proportion to the *Weeds*, than in any other. The quantity of nouriſhment loſt, is not proportioned to the quantity of the *Weeds* that exhauſt it; for theſe being of different ſpecies, ſome are greatly more miſchievous and devouring than others.

The farmer finds it impoſſible ever wholly to deſtroy the *Weeds* in his lands; and the reaſon ſeems to be, that in many kinds the ſeeds will lie many years in the ground, and ſucceſſively grow, ſome one year, ſome another; ſo that the deſtroying the crop entirely for one year, does not kill them for ſucceeding ones. The ſeed of red poppy will lie twenty years in the ground, in a land all that time occupied by ſaintfoin; and if it be, after that, ploughed for corn, they will all grow, and fill the field.

The ſeeds of theſe plants will never all come up in one year, becauſe they muſt have their exact degrees of depth, moiſture, and covering; the ſeeds which want any of theſe one year, lie to grow up another. The beſt defence the farmer has hitherto found againſt theſe enemies, is to endeavour their deſtruction by a ſummer fallow. This, if the weather be propitious, does make ſome havock among them, but it never deſtroys them entirely. If the ſeeds lie ſo high that the ſummer's heat parches them up, or ſo deep that it cannot reach them, they do not germinate, and are by that means ſaved for another year. And another thing, which ſaves a very great number of them, is their being able to bear the heat and moiſture of a whole year without growing. Wild oats, and many other ſeeds of *Weeds* are of this kind. If you gather theſe when ripe, and ſow them in the moſt careful manner, watering them at times, and taking all the care of them that is neceſſary to the moſt tender plants, they will not grow till the ſpring come twelve-month after they were ſowed, and ſometimes not till the ſpring after that; that is, two years and a half after the time of putting them into the ground. It is plain from this, that no art can deſtroy theſe by fallowing, or other means, in one year.

The common way of *weeding* among the young corn, turns out to very little good; if this is done while the *Weeds* are young, the greateſt part of them are only cut or broken off near the ground; this, inſtead of deſtroying them, gives them new vigour, and they ſhoot up with many heads in the place of one, and draw more nouriſhment than at firſt: if, on the other hand, it is done when they are grown up, the relief comes after the diſeaſe; for by that time they have robbed the corn of all the nouriſhment, or nearly all, they could. Hand-*weeders* alſo frequently do more harm in the corn, by treading it down, than they do good by taking out the *Weeds*. This operation ſometimes coſts the farmer twelve ſhillings an acre, beſide the miſchief done, and yet there remain *Weeds* enough for a crop the next year from ſeeds.

The method of horſe-hoeing is a very excellent way of curing lands of this diſeaſe, ſo long as it is carefully practiſed; one of the greateſt advantages it will bring the farmer, is, that no *Weeds* will grow up but thoſe whoſe ſeeds are brought in the air, and theſe are but very few in compariſon of the other kinds.

WEEDS, in mining, a term uſed by our Engliſh diggers to expreſs any ſort of unprofitable ſubſtance found among the ores of metals. They ſeem to have borrowed the phraſe from the gardeners; and as every thing with them is a *Weed*, except what they have planted, and expect to gather, ſo every thing is a *Weed* with the miners, except the thing they are ſinking for. See the articles DIGGING and MINING.

The principal ſubſtances known in our mines under the names of *Weeds*, are mundic or marcaſite; this is of three ſorts, white, yellow, and green; daze, a kind of glittering talcy ſtone, of the telaugium kind, which endures the fire, and is of various colours and hardneſſes; iron-moulds, or pyritæ; caul, which is browniſh and ſpongy; and gliſter, which is a ſort of talc. Phil. Tranſ. N°. 69.

Hair-WEED. See the article HAIR.

WEEK (*Cycl.*)—WEEK-*Fiſh*, in zoology, a name given by ſome to a very delicate fiſh, caught on the Eaſt Indian ſhores, and called by the Dutch there the *wit viſch*. *Ray*'s Ichthyography, append. p. 6. See the article WIT-*Fiſh*.

WEEVER, in ichthyology, the Engliſh name for the fiſh called by Willughby and other authors, the *draco-marinus*, or ſea-dragon, and the *araneus-marinus*, or ſea-ſpider. Some alſo have called it *trachurus*.

It is properly, according to the Artedian ſyſtem, a ſpecies of the *trachinus*, and is diſtinguiſhed by that author by the name of the *trachinus* without beards, and with the lower jaw longeſt. See the articles DRACO-*Marinus* and TRACHINUS.

It is to be obſerved that Willughby and Geſner have deſcribed what they call two other ſpecies of this fiſh; but theſe are all found, on a cloſe obſervation, to be the ſame fiſh, differing only in reſpect of age and ſize, or other accidental variations, owing to the like natural cauſes.

WEEVIL, in natural hiſtory, the name of a ſmall inſect which does great damage in magazines of corn, by eating into the ſeveral grains, and deſtroying their whole ſubſtance.

This creature is ſomewhat bigger than a large louſe, and is of the ſcarab kind, having two pretty, jointed, tufted horns, and a trunk or piercer, projecting from the forepart of its head: at the end of this trunk, which is very long in proportion to its body, there are a ſort of forceps, or ſharp teeth, with which it gnaws its way into the heart of the grain, either to ſeek its food, or to depoſit its eggs there.

By keeping theſe creatures alive in glaſs tubes, with a few grains of wheat, their copulation and manner of generation have been diſcovered. The female perforates a grain of wheat, and therein depoſits a ſingle egg, or, at the utmoſt, two eggs; and this ſhe does to five or ſix grains every day for ſeveral days together. Theſe eggs, which are not larger than a grain of ſand, in about a week produce as odd a ſort of white maggot, which wriggles its body very much about, but is very little able to move from place to place: this, in about a fortnight, turns to an aurelia, from which is produced the perfect *Weevil*. This deſtructive creature is itſelf very ſubject to be deſtroyed, and when in the egg or aurelia ſtate, is very ſubject to be eaten by mites. *Baker*'s Microſ. p. 221. *Lewenhoeck*.

WEIGHT (*Cycl.*)—In the Philoſophical Tranſactions [a] we have an account of the analogy betwixt Engliſh *Weights* and meaſures by Mr. Barlow. He advances that antiently a cubic foot of water was aſſumed as a general ſtandard for liquids, and weighed 62 pounds and a half. And, in effect, we find [b] the *Weight* of a foot of pump-water to be 62 pounds 8 oz. —[[a] N°. 458. Sect. 1. [b] Phil. Tranſ. N°. 169.]

This cubic foot multiplied by 32, gives two thouſand, the *Weight* of a ton. And hence 8 cubic feet of water made a hogſhead, and four hogſheads a ton, in capacity and denomination, as well as *Weight*.

Dry meaſures were raiſed on the ſame model. A buſhel of wheat, aſſumed as a general ſtandard for all ſorts of grain, alſo weighed 62 pounds and a half. Eight of theſe buſhels made a quarter, and 4 quarters a ton weight. See the article BUSHEL.

Coals were ſold by the chaldron, ſuppoſed to weigh a ton, or 2000 pounds. See the article CHALDRON, *Cycl.*

Hence a ton in *Weight* is the common ſtandard for liquids, wheat, and coals. Had this analogy been kept up, it would have prevented the confuſion now complained of.

It may be reaſonably ſuppoſed that corn and other commodities, both dry and liquid, were firſt ſold by *Weight*, and that meaſures, for convenience, were afterwards introduced, bearing ſome analogy to the weight before uſed.

Mr. Barlow's ſcheme ſhews the reaſon why the word *ton* is applied both to *Weight* and liquid meaſure, *viz.* becauſe the ſame quantity of liquor is a ton both in *Weight* and meaſure. Hence the word *quarter* may alſo be explained. Biſhop Fleetwood [a] gueſſed that it ſignified the fourth part of ſome *Weight*, and not of any meaſure. And it ſeems plainly to ſignify the fourth part of a ton, or 2000 pounds [b].—[[a] Chron. Pret. p. 72. [b] Phil. Tranſ. ibid.]

WEIGHT *of the Human Body*. It is to be obſerved, that the heat and dryneſs of the air both leſſen the *Weight* of the body, and the cold and moiſtneſs of the air both increaſe this *Weight*. See the article MOISTURE *of the Air*.

Much ſleep, much food, and little exerciſe, are the principal things which increaſe the *Weight* of the body, and make animals grow fat. Conſequently, if the weight of the body be too great for good and uninterrupted health, it may be leſſened by diminiſhing ſleep and food, and by increaſing exerciſe.

ciſe. On the contrary, if the *Weight* of the body be too little for good health, it may be increaſed by adding to food and ſleep, and by leſſening exerciſe; and the food muſt be increaſed chiefly by increaſing drink and liquid nouriſhment. For the diſcharges are commonly leſs from drink and liquid nouriſhment, than from dry and ſolid food. Dr. *Bryan Robinſon* of the Food and Diſcharge of Hum. Bod. p. 89, 90.

There is but one *Weight* under which a body can enjoy the beſt and uninterrupted health, and that *Weight* muſt be ſuch, that perſpiration and urine may be nearly equal at all ſeaſons of the year; for by this means the body will be uniformly drained of its moiſture: the inward parts by urine, and the more ſuperficial parts by perſpiration, without any irregular and unnatural diſcharges, and its moving *Weight* will continue nearly the ſame at all ſeaſons of the year. Dr. Bryan Robinſon thinks this *Weight* may be ſettled, by his obſervations in his treatiſe on the food and diſcharges of human bodies.

A quick increaſe of *Weight* in human bodies often produces diſtempers; the beſt way to prevent this increaſe is either by faſting or exerciſe. But amidſt a variety of diſturbing cauſes, nothing ſo effectually prevents ſuch an increaſe of *Weight* as a very exact and regular diet, which may prevent the diſcharges from running into irregularities and diſproportions to one another. See Dr. *Bryan Robinſon* of the Food and Diſcharges of Human Bodies, p. 82. ſeq.

Men and other animals of extraordinary *Weight*, are often recorded in the writings of the learned. We have lately had two inſtances of uncommon bulk and *Weight* in men near Halifax in Yorkſhire. One weighed 35 ſtone and ſome odd pounds, which is about 500 lb. And his brother weighed 34 ſtone odd pounds; between them they make 70 ſtone, or 980 pounds. Phil. Tranſ. N°. 479. p. 102.

Athletic WEIGHT, in the animal œconomy, that *Weight* of the body under which an animal has the greateſt ſtrength and activity. Dr. Robinſon thinks this happens when the *Weight* of the heart, and the proportion of the *Weight* of the heart to the *Weight* of the body, are greateſt. For the ſtrength of an animal is meaſured by the ſtrength of its muſcles, and the ſtrength of the muſcles is meaſured by the ſtrength of the heart. Alſo the activity of an animal is meaſured by the *Weight* of the heart, in proportion to the *Weight* of the body. See Diſſert. on the Food and Diſcharges of Human Bodies. p. 117, 118.

If the *Weight* of the body of an animal be greater than its athletic *Weight*, it may be reduced to that *Weight* by evacuations, dry food, and exerciſe. Theſe leſſen the *Weight* of the body by waſting its fat, and leſſening its liver, and they increaſe the *Weight* of the heart, by increaſing the quantity and motion of the blood; ſo that by leſſening the *Weight* of the body, and by increaſing that of the heart, they will ſoon reduce the animal to its *athletic Weight*. Thus a game cock, in ten days, is reduced to its *athletic Weight*, and prepared for fighting. If the food which, with the evacuations and exerciſe, reduced the cock to his *athletic Weight* in ten days, be continued any longer, the cock will loſe his ſtrength and activity.

It is known by experience, that a cock cannot ſtand above 24 hours at his *athletic Weight*, and that he has even changed for the worſe in 12 hours. When he is at the top of his condition, his head is of a glowing red colour, his neck thick, and his thigh thick and firm; the day after, his complexion is leſs glowing, his neck thinner, and his thigh ſofter; and the third day his thigh will be very ſoft and flaccid. Four game cocks, reduced to their *athletic Weight*, were killed, and found to be very full of blood, with large hearts, large muſcles, and no fat.

It is to be obſerved, that the *athletic Weight* of an animal is a very dangerous *Weight*. Fevers and apoplexies are the diſorders which commonly happen to animals under or near their *athletic Weights*. Hence, horſes fed upon dry food are much more ſubject to fevers and apoplexies, than horſes fed upon graſs. Dr. *Robinſon*, ibid.

WELD, (*Cycl.*) the name by which our farmers commonly call the *luteola*, or dyers weed.

This is a very rich commodity among the dyers, and is the more advantageous to the farmer, as it may be raiſed on very poor land, and at a very ſmall expence. Moderately fertile land does beſt for it; but it will grow upon the moſt barren; and if this be but dry and warm, it will require no tillage. The ſeed may be ſown with barley or oats, and only harrowed in with bruſh or furze, or rolled down with a wooden roller. It is a very ſmall ſeed, and the greateſt difficulty about it is the ſowing it even. It is a ſlow grower; a gallon of ſeed is ſufficient for an acre; and though it makes but little progreſs the firſt ſummer, it begins to grow after the corn is cut, and the next year yields a good crop.

There is a great nicety required in the time for gathering it; for this ſhould be when the ſtalk is full ripe, and the ſeeds not ſo ripe as to fall out; it is to be pulled up by the hand, and made up into little bundles to dry. The ſeed may be either thraſhed out as ſoon as it is houſed, or in the ſpring following; but the plant muſt be carefully kept dry.

The ſeed ſells at about ten ſhillings the buſhel, and the dyers uſe it for deep lemon colour, and bright yellows. It is more cultivated in Kent than in any other part of England, and it there yields the farmer from forty ſhillings to ten pound an acre. *Mortimer*'s Huſbandry, p. 165.

WELL (*Cycl.*)—In Scotland they have a *Well*, which Sibbald has mentioned as foretelling ſtorms. It is a deep and large *Well* near Edinburgh, and from the noiſes heard in it at certain times, is called by the people the *routing Well*. They go to this to liſten after the preſages of weather, and it is ſaid that ſtorms are particularly foretold by it; and that noiſes are not only heard in it before ſtorms happen, but that they are always heard determinately and diſtinctly on that ſide whence the ſtorm will come. *Sibbald*'s Prod. Hiſt. Scot.

In the Philoſophical Tranſactions we have an account of a boiling *Well*. See the article SPRING.

WELLE *Coronde*, *ſandy cinnamon*, a name given by the Ceyloneſe to a ſpecies of cinnamon which feels hard and gritty between the teeth, as if it were full of particles of ſand, tho' in reality there is no ſand among it.

The bark of this tree comes off very eaſily; but it is not ſo fit to roll up into quills as the right cinnamon, for it is more rigid and ſtubborn, and apt to burſt open. It is of a ſharp but bitteriſh taſte. The roots of all the cinnamon-trees yield more or leſs camphor, but this as ſmall a quantity as any of them. Philoſ. Tranſ. N°. 409.

WENDING, at ſea, a term for bringing a ſhip's head about, and ſeems only to be a corruption from *winding*. They ſay, *how wends the ſhip?*

WEPOLON, in zoology, the Ceyloneſe name of an Eaſt Indian ſerpent, of a very long and ſlender body, and in ſome degree reſembling a piece of cane.

WERST, or WURST, a Ruſſian meaſure equal to 3500 Engliſh feet. A degree of a great circle of the earth contains about 104 *Werſts* and a half. Phil. Tranſ. N°. 445. Sect. 7.

WEST-ASHTON *Water* is a chalybeat water, reſembling that of Holt. See Phil. Tranſ. N°. 461. Sect. 20.

WESTERWALD *Earth*, a kind of earth mentioned by Agricola, of a whitiſh yellow colour, of a like nature to the terra Sileſiaca, but preferable to it, as yielding more ſalt. He tells us that it diſſolves ſilver ſo much better than other menſtrua, as to render it potable, and parable into a uſeful medicine in cephalic caſes. *Boyle*'s Works, vol. 1. p. 501.

WESTING, in navigation, the ſame with departure. See the article DEPARTURE, *Cycl.*

WET (*Cycl.*)—WET *Air*. See the article MOISTURE *of the Air*.

WET *Couch*, a term uſed by the maltſters for one of the principal articles of malt-making.

In the making malt, the uſual way is to ſoak the grain in water two or three days, till it becomes plump and ſwelled, and the water is brown; the water is then drained away, and the barley is removed to a floor, where it is thrown into a *wet couch*, that is, an even heap of about two foot thick.

In this heap the barley ſpontaneouſly heats, and begins to grow, ſhooting out firſt the radicle, and, if ſuffered to continue growing, ſoon after the blade; but at the eruption of the radicle, the proceſs is to be ſtopped ſhort, by ſpreading the *wet couch* thin over the floor, and turning it once every four or five hours for two days, laying it thicker each time; after this it is thrown into a large heap, and there ſuffered to grow hot of itſelf, and afterwards ſpread abroad again and cooled, and then thrown upon the kiln to be dried criſp without ſcorching. *Shaw*'s Lectures, p. 186.

WHALE (*Cycl.*)—The *Whale*-fiſhery of the Caroline iſlands is the moſt eaſy and agreeable of that of all other places, and, beſide the great profit, affords a pleaſant ſpectacle to multitudes of people on the ſhores.

There are ten or twelve of theſe iſles diſpoſed in form of a circle, ſo that they make a ſort of port, in which the ſea is perpetually calm and pleaſant.

When a *Whale* appears in this gulf, the people all get into their canoes, and rowing toward the ſea, keep between the creature and its retreat, and drive him forwards towards the iſles at the bottom of the port. They drive him in this manner before them into the ſhallows, where they plunge into the water themſelves, and ſome get ropes and chains about him, while others dart him with their ſpears. Their agility and addreſs is wonderful in this. The creature can never get away when they have once got him faſtened, but is ſoon killed, and got to the ſhore.

The anatomy of the bones of the *Whale* has been ſo little underſtood, that there have been many very great errors in regard to ſuch of them as have been at times found foſſile, or buried in the earth among the teeth of elephants, and the remains of teſtaceous and other animals. The moſt frequent and moſt ridiculous of all the wrong opinions about theſe, is their having originally belonged to creatures of the human ſpecies; yet many, even among the more intelligent part of the world, have taken them for the remains of giants. The vertebræ of a *Whale* have been miſtaken for thoſe of a giant, and a part of its fins for a hand, and ſo of the reſt. While the world, more ready to ſpread the marvel, than to inquire into the truth, have made computations of the height of the man to whom bones of that ſize muſt have belonged, and from their proportion

tion in regard to those of the common human size, have found the giant who possessed them must have been ninety or an hundred foot high; while much less pains in comparative anatomy would have taught them, that they never could have belonged to any human body at all. Mem. Acad. Par. 1727.

Toothed WHALE, *Cetus Dentatus*, a name given to a peculiar kind of *Whale*, called by Johnston, and many other writers, by the too general name of *balæna*.

This is distinguished from the common *Whale* which yields the *Whale*-bone, by having white and strong teeth in the lower jaw, which that fish has not. This is the species of *Whale* from which the sperma ceti was originally taken. It was first of all discovered on the coast of New England, being thrown on the shore there, and sperma ceti formed by the sun and air out of the oil of its head; but it is far from being peculiar to that place; the northern seas afford it, and it is not unfrequently taken on the western coasts of Ireland. One caught there about fifty years since, measured seventy-one foot in length, which is nineteen foot more than the length Clusius allows to this fish.

The sperma ceti originally used in medicine was only a part of the oil or liquid fat of this species of *Whale*. This, in its first confused appearance, as drawn from the animal, appears of a whitish colour like milk, and in this state is put into large vessels, in which a clear yellowish oil separates itself to the bottom; the sperma ceti, as it is called, swims at top in white flakes or scales; these soon after precipitatate themselves to the bottom of the vessel, where they candy together, and form large lumps of sperma ceti; there requires some care and trouble to separate and purify this thoroughly from the stinking oil that is apt to stick to it, but the price of the drug very well allows it.

The fat of the body affords the same substance, but it is obtained in larger quantities from that about the head. Several hundred weight of this may be got from one *Whale*: But our common practice at present is to make it from the lees and settlements of common train oil. Philos. Trans. N°. 227. p. 508.

WHAME; in natural history, the name given by the people of some parts of England to the burrel-fly or wringle-tail, a species of bee-fly very troublesome to horses. See the article WRINGLE-*Tail*.

WHEAT (*Cycl.*)—It has been very justly observed by the antients, as well as moderns, that *Wheat* will grow in almost any part of the world, and that, as it is the plant most necessary to mankind, so it is the most general and the most fruitful. It grows well not only in the temperate climates, but in the very hot and very cold ones; and when sown in places where it never grew spontaneously, succeeds as well as where it has been always common.

The success of our crops of *Wheat* in America plainly prove this: And in Peru and Chili in particular, where those countries were very well inhabited, it never was known till the Europeans brought it in, it produces as large crops as in any part of England. *Deslandes*, Trait. Phys.

When *Wheat* is planted early, less seed is required to an acre than when it is planted late, because less of it will die; and poor land should always be allowed more seed than rich, because a greater number of the plants will perish on this land than on the other. The least quantity of all of seed is necessary for rich land, that is planted early, for in this case very few of the seeds will fail to produce a plant that will live and flourish. The use of the hoe causes every plant to send out a great number of stalks from the same root, and in these, more than in the number of plants, consists the richness of a crop, as the ears on these are always largest and fullest.

Another thing to be considered, in order to find the proper quantity of seed to plant, is, that some *Wheat* of the same species has its grains twice as large as others: in this case a bushel, containing but half the number of grains that it does in the small-grained *Wheat*, one bushel of the small-grained will plant just as much as two bushels of this; not the measure of the seeds, but the number of the grains being the thing to be considered in regard to the sowing. *Tull*'s Horsehoeing Husbandry.

It is a very natural thing to suppose that a large-grained *Wheat* will produce larger and finer plants, and larger grain than a small-grained one; but experiments have proved, that there is nothing in this; for the smallest-grained *Wheat* produces fully as large plants as the largest, and those with as great ears, and as big seeds; but the young plants appear smaller and poorer.

Six gallons of middle-sized seed is the usual quantity drilled upon an acre; but on rich lands, planted early, four gallons will suffice; because then the *Wheat* will have roots at the top of the ground before winter, and tiller very much, without danger of the worms, and many other accidents, which the late planted *Wheat* is liable to.

If it be drilled too thin, it will be in danger of falling, and if too thick, it may happen to tiller so late in the spring, that some of the ears may be blighted; a medium therefore is best.

The depth to plant it at is from half an inch to three inches; for if planted too deep, there is more danger of its being eaten off by worms between the grain and the blade. A *Wheat*-plant that was not sown early, sends out no root above the grain, before the spring, and is nourished all the winter by a single thread, proceeding from the grain up to the surface of the ground: this is the thread of life to the plant during the winter, and the longer that is, the greater danger there is of the worm, that creature much more easily finding a thread that extends by its length to five or six inches deep, than one which reaches but one inch; beside, the worms in winter do not inhabit very near the surface of the ground, and therefore they never naturally come in the way of the short threads, though the long ones are always in their reach.

It is very necessary to take care against the rooks, just at the time when the *Wheat* is shooting up. These mischievous birds perceive it beginning to sprout, before the farmer can see any thing of it, and are led by the shoot to pick it up; they must be carefully kept off the ground for a week or ten days at this season; for at the end of that time the blade will be grown up, and the grain so exhausted of its flour, that it will be of no value to them, nor will they give themselves any trouble about stealing it.

The rooks never molest such *Wheat* as is sown about Michaelmas time; for at this season there is so much grain of the late harvest scattered about the fields where it has grown, that they find it much more worth their while to pick it up there, than to search under ground for it in the sown crops, which therefore escape till too far grown for this animal. *Tull*'s Horsehoeing Husbandry.

Many experiments have been tried to the great purpose of multiplying grain, some of which are commemorated, with an account of their different success, in the Philosophical Transactions. Digby mentions a plant of barley, all rising from one corn, which, by steeping in water in which was a small quantity of salt-petre, and afterwards being watered every day with the same water, brought forth two hundred and forty-six stalks, and above eighteen thousand grains: And the last edition of Cambden mentions a thing very observable of this kind, though from another cause; which is, that the corn sown in a field in Cornwall, where a battle had a little time before been fought in the civil wars, brought forth four or five ears upon every stalk.

Mr. de da Primce has fairly tried the common and many other methods, which though they have not had such immense products for their success as these related above, yet may set the world right as to what they have to expect from the different ingredients generally used, and which of them promise most fairly for success.

The experiments are these: On the 22d of March there were laid to steep a pea, a barley-corn, a *Wheat*-corn, and an oat-corn, in brimstone-water. These were also steeped in alum-water, in a solution of salt of tartar, in the solution of the caput mortuum of sal armoniac, in common urine, in a solution of the common nitrum murale or salt of old walls, in a solution of salt-petre in water; and, finally, in the nostoc or star-jelly.

When these had all stood steeping in this manner in their several liquors five days and five nights, they were set in a good soil, in a garden, under a wall, directly facing the sun. They were set in the morning after a rainy night, and there were set with them a pea, a *Wheat*-corn, a barley-corn, and an oat-corn, unsteeped, and in the common way. This was on the twenty-seventh of March, and on the tenth of April following, some of them were come up, others did not appear. Those which had been steeped in the brimstone-water, all came up together. Of those steeped in alum-water, the three grains were sprouted; but the pea, though very much swelled, had made no attempt to shoot. Of those made in the solution of salt of tartar, the barley and oat were above-ground, and the pea had sprouted a little, and the barley scarce at all. Those steeped in the solution of the caput mortuum of sal armoniac, in urine, as also those in the solution of the salt of walls, were all come up. Of those steeped in the solution of salt-petre, the oat and barley were quite up, the others had sprouted a little. Those which were steeped in the nostoc or star-jelly, were none of them come up, and scarce had made any attempt to sprout. The barley and oat steeped in urine had just come up; but the *Wheat* and pea had scarce so much as sprouted; and finally, those which had not been steeped at all, were all come up as soon, and appeared as vigorous as these, except the *Wheat*, which appeared a little less forward than the rest.

All these shoots or young plants were set about a finger deep in the ground, and they had a fine favourable season to grow in.

It appears from the whole, that alum-water is particularly bad for peas, tho' it agrees well enough with *Wheat* and barley, and with oats. That salt of tartar does very well with oats and barley, but is hurtful to peas, and to *Wheat*. That salt-petre does not appear to have that virtue which has been so long given it, of promoting the growth of plants; and in fine, that all these steepings did no visible service to the grain; but that many of them evidently hurt the several kinds.

All these young plants were digged up, except three of the shoots of barley; and these increased so very much, on stand-

ing in a good ſoil and aſpect, and at the diſtance of two foot aſunder, that they had ſixty, ſixty-four, and ſixty-ſeven ſtalks, from their ſingle grain and root. Each of theſe ſtalks had an ear, and, one with another, there were about forty corns in each ear. New ſhoots were continually iſſuing from the roots; and as the Eaſt Indian trees afford leaves, bloſſoms, and ripe fruit at the ſame time, ſo if the ſun's heat had continued, there would have been young ſhoots, young ears, and ripe ears on the ſame plant, at the ſame time, all the year round.

It ſeems very plain, from the whole of theſe experiments, that the multiplying of *Wheat* and other grain is rather to be expected from the ſowing it on a good ſoil, and at a proper diſtance, than from any of theſe liquors contrived to ſteep the ſeed-grain in. As moſt of the liquors contrived for this purpoſe are, however, harmleſs, it will be worth the farmers while to try them at times, and in a regular manner, ſowing the different parts of the ſame field with ſteeped and unſteeped grain, in the ſame proportion.

The experiment of the ſteeping the grain in the offals of animal ſubſtances, carries with it evident ſucceſs; but we are to remember, that only a third part of the quantity of ſeed is to be uſed to the ſame quantity of ground in that method, as is in the common way; and it is more than poſſible that the increaſe which attends this method, may be owing to this diſtance of the plants, rather than to the good done by the water. Philoſ. Tranſ. N°. 281. p. 1212.

It is evident from experience, that the multiplication of *Wheat*, that is, the quantity of *Wheat* produced from every grain, is very different in different places, and according to various accidents. It has been often attempted to arrive at the art of cauſing every grain of *Wheat* to yield its utmoſt poſſible increaſe; and if this could be brought about on eaſy terms in the large way, ſo as to affect whole fields, it is evident that the advantage would be very conſiderable. This has been attempted by Vallemont in ſeveral different ways, but with moſt ſucceſs in theſe following: Let there be collected together as large a quantity as may be of the bones, ſkins, feathers, and other parts of animals, which are thrown away as refuſe, together with the refuſe of foods and wearing apparel, ſuch as old ſhoes, gloves, or whatever elſe of this kind comes in the way, though horns and hoofs of all animals are excellent; and, in ſhort, let every thing be collected that abounds with ſalts: when a large parcel of theſe things is got together, let them be ſeparated into two or three heaps, according to their different natures; the hardeſt kinds into one heap, the ſofteſt into another, and ſo on. Let each of theſe parcels be put into a large wooden veſſel, and a ſufficient quantity of rain or river-water be poured on them, that they may ſwim at liberty in it. When the water has ſtood ſo long, that it ſtinks very much; ſtrain it off, and keep it in veſſels for uſe. The ſofteſt bodies will give the water this ſtink in five days; the moderately hard ones in ſeven days; and the hardeſt of all in nine days. Theſe laſt are to be broken to pieces before they are put into the water. The liquor prepared from theſe is called the *prepared water*.

Let a quantity of plants of any kind, no matter what, be burnt with their flowers and ſeeds, and let a lixivial ſalt be made from the aſhes in the common way. Then take as many pounds of ſalt-petre as there are acres of land to be employed, and let each pound be diſſolved in twelve quarts of water, and to this ſolution add a ſmall quantity of the lixivial ſalt of the plant. This liquor the author calls the *univerſal matter of vegetation*. When both the liquors are thus made, mix together an equal quantity of each of them; that is, of the prepared water, and of the univerſal matter; and let the whole quantity be ſo much as will ſerve thoroughly to wet and ſoak the quantity of corn that is to be ſown; this is to be ſo much, that it ſtands two fingers breadth above the grain. When the grain and the liquor are thus mixed, the light grains, which will not grow, will ſwim at the top, and may be ſkimmed off and ſeparated from the reſt. The grain at the bottom of the veſſel is to be ſtirred up and turned every two hours: in this manner, the grain is to be ſoaked twelve hours, and after this the water is to be poured off, and the grain dried, by laying on a ſieve, or thin ſpread on the floor; and after two or three hours it is to be ſown in the common way.

The quantity of ſeed neceſſary for an acre of ground, when thus ſteeped, is only one third of the quantity commonly uſed, and this will produce infinitely more grain, and is as much as the land can bear. The liquor poured off from the ſoaking of this quantity of grain, is not to be thrown away, but muſt be ſaved, for it will ſerve as well for ſeveral more parcels as it did for this.

This was tried in the year 1706, which was the year after the book came out, in ſeveral parts of France, and that with ſo much ſucceſs, that the author got great reputation, and his book was tranſlated into the German, and ſome other languages. Whether the method was found afterwards not to ſucceed ſo well, or whether it was dropped through mere inadvertence, the thing has not been regarded ſince that time; but the proceſs is at once ſo cheap and ſo eaſy, that it ſhould ſeem extremely worth while to bring it into trial again. *Vallemont*. Curioſ. de Vegetat.

There are four ways of augmenting the crops of *Wheat*, not in the number of the plants, but in the ſtalks, ears, and grains.

The firſt is by increaſing the number of ſtalks from one, two, or three, to thirty or forty in each plant, in ordinary field land; and the crop is augmented by bringing up all theſe ſtalks into ear, which is the ſecond way; for if it be diligently obſerved, it will be found that not one half of the ſtalks of *Wheat* ſown in the common way, ever come to ear at all: Nay, if a ſquare yard of ſown *Wheat* be marked out, and the ſtalks thereon numbered in the ſpring, it will be found that no leſs than nine parts in ten of them are wanting at the harveſt-time.

An experiment of the advantage of this augmentation was made by Mr. Tull in rows of *Wheat* that were equally poor; one of theſe rows was increaſed ſo much, as to produce more grains than ten of the other, by bringing up more of its ſtalks into ears, and alſo by augmenting the ears to a much greater bigneſs, which is the third way; for it is very certain that the ears will be much larger or much ſmaller, according to the quantity of nouriſhment that is given them.

The fourth and laſt way of increaſing the crops of *Wheat*, is by cauſing the grain to be much larger in the ears. This can no way be done ſo effectually as by late hoeing, eſpecially if it be done juſt after the *Wheat* is gone out of the bloſſom; by this means the grains will weigh twice as much as thoſe produced in the ſame ſort of *Wheat*, when this late hoeing has been omitted; their number, at the ſame time, is the ſame in the ear; and as the *Wheat* is ſold not by tale, but by meaſure, the farmers gain is double in this caſe, the *Wheat* meaſuring juſt twice as much as it would otherwiſe have done.

Thus by increaſing the number of the ſtalks, bringing more of them up into the ear, making the ears larger, and the grains larger, plumper, and fuller in every ear; the method of horſe-hoeing, by which alone this can be effected, makes a larger crop out of the tenth part of the number of plants, than in the common way: but all theſe advantages will be loſt by thoſe who, though they give into the horſe-hoeing way, yet will not allow the ſix foot intervals between the rows; for it is owing to this great ſpace of ground alone, that as much nouriſhment may be given to the *Wheat* as the farmer pleaſes.

In the method by theſe wide intervals, we can raiſe a larger crop of *Wheat* with leſs labour, leſs ſeed, no dung, and no fallowing; but not without a competent quantity of earth, which is the cheapeſt thing given to corn. The earth of a whole good acre being but about the tenth part of the expence, and of indifferent land but about a twentieth.

The crop enjoys all the earth, for between the laſt hoeing and the harveſt, there remains nothing but a ſpace of empty mould in the middle of the intervals. Farmers do not grudge the price of three or four pounds in the buying and carriage of dung for an acre; but they think themſelves undone if they afford an extraordinary eighteen-pennyworth of earth to the wide intervals of an acre, not conſidering that earth is at once the beſt and the cheapeſt entertainment that can be given to plants; for at five and ſixpence rent, which is common to ſome land in many parts of the kingdom, the whole earth belonging to each of the rows coſts only ſixpence; that is, a penny for a foot broad and ſix hundred and ſixty foot long, that being the ſixty-ſixth part of an acre. But the vulgar count this expence of a foot breadth of ground not as they ought, only as part of the rent, but as an eleventh part of their own uſual charges added to the rent.

If the intervals are narrower in deep land, there might be earth enough in them; but there would not be room enough to pulverize it.

The horſe-hoe, well applied, ſupplies the uſe of dung and fallow; but it cannot ſupply the uſe of the earth, though it can infinitely increaſe the virtue of it, where there is any reaſonable quantity.

The mean price of *Wheat*, between dear and cheap, is reckoned five ſhillings a buſhel; and therefore an acre of land that ſhould produce every year eight buſhels, without any expence, would be accounted a very profitable one. Now an acre of land drilled with *Wheat*, and horſe-hoed, will produce ſixteen buſhels of *Wheat* eaſily, with the expence only of ten or fifteen ſhillings, and this is a third part more profitable.

It is commonly computed that the farmer cannot live, if the *Wheat* he ſold under five ſhillings a buſhel; he muſt therefore keep his *Wheat* when it is ſold cheaper than that in the markets; and the common method is to keep it in the ſtraw, taking care to keep away the mice. The ſecureſt method of all is to dry the *Wheat* in the grain; but this many are afraid to practiſe.

Some people, who have known this ſecret, have made great profit by buying up the *Wheat*, when under three ſhillings a buſhel in the markets, and then preſerving it in this manner till a dearer time. The method is to dry it in a malt-kiln, but with no other fuel than *Wheat*-ſtraw, never ſuffering it to have any ſtronger heat than that of the ſun. The longeſt time the *Wheat* need lie in this heat, is twelve hours; but ſometimes four hours is ſufficient; according to its dampneſs when bought, and the time it is intended to be kept, it requires a longer or ſhorter drying. The only thing that cauſes

the decay of *Wheat*, and gives way to that devouring animal the weevil in it, is its too great dampneſs; this is carried off in this manner, by a heat no greater than that which the ſun might have given to the grain. The vegetating power therefore is not deſtroyed by this; and the bakers have acknowledged that the flour of this *Wheat* does rather better for the working into bread, than that of freſh *Wheat*.

Though all ſorts of vegetables may have great benefit from the hoe, becauſe it ſupplies them with plenty of food at the time of their greateſt need; yet they do not all equally require hoeing; but the plant that lives longeſt ſhould always have the greateſt ſtock of nouriſhment provided for it, and ſhould therefore be moſt frequently hoed of any plant. *Wheat* generally lives, or ought to live, longer than any other corn; for if it be not ſown before ſpring, its grain will be thin, and will have but little flour in it; and when it is ſown late in the winter, it is in great danger of being killed by the froſts, while weak and tender.

To prevent theſe inconveniencies, *Wheat* is generally ſown in autumn; and by this means, having thrice the time to be maintained that ſpring corn hath, it requires a larger ſupply of nouriſhment, in proportion to that longer time; not that the *Wheat* in its infancy conſumes the ſtock of food that it afterwards does, but becauſe, during that long interval between winter and the ſpring ſeed-times, moſt of the artificial paſture or benefit from former tillage, is loſt both in light and ſtrong lands.

This is the reaſon why all that extraordinary pains in fallowing and dunging of the ſoil is neceſſary for *Wheat*; and yet all this trouble and expence is ſo far loſt, that if a part of the ſame field unfallowed and undunged be ſown in April, after good plowing, it will raiſe as fair a crop in all reſpects as the other, only that the flour will be in leſs quantity, by wanting time in the ground for filling the grains.

Poor light land, in the common way of huſbandry, muſt be extremely well manured, in order to the maintaining *Wheat* a year, which is the uſual time that it is in it; and if it be ſown late, the greater part of it uſually periſhes, not being able to ſurvive the winter while ſo poor, and on ſuch land; and if it be ſown very early on ſtrong land, though rich, well tilled, and dunged, the crop will be worſe than on poor light land ſown early. The new method of horſe hoeing gives both to ſtrong and to light land all the advantages neceſſary, and takes off all the diſadvantages of both. By this method the ſtrong land may be planted with *Wheat* as early as the light, if plowed dry; and the hoe-plough, if rightly applied, will be able to give it nouriſhment equal to that of dung in both ſorts of land.

The tops of the ridges for the drilling of *Wheat* muſt not be left quite ſo narrow and ſharp as they are for drilling of turneps, *Wheat* being generally to be ſowed in treble rows, and the turnep only in ſingle ones. In reaping the *Wheat* thus ſown, it is to be cut as near to the ground as poſſible, and this is eaſier done in this than in *Wheat* ſown in the common way, becauſe in this drilled method the ſtalks all ſtand cloſe together. When the *Wheat* is cut thus low in the reaping, the ſtubble is no great impediment to the preparing the land for the ſucceeding crops.

As ſoon as conveniently may be, after the carrying off a crop of *Wheat*, if the trench in the middle of each wide interval be left deep enough by the laſt hoeing, the farmer is to go as near as he can to the ſtubble with a common plough, and turn two large furrows into the middle of the intervals, which will make a ridge over the place where the trench was; but if the trench be not deep enough, it is beſt to go firſt in the middle of it with one furrow, this, with two more taken from the ridges, will be three furrows in each interval; this plowing is to be continued as long as the dry weather laſts, and then the whole is to be finiſhed by turning the partitions on which the laſt *Wheat* grew up to new ridges, which is uſually done at two great furrows; theſe laſt furrows, which complete the ridges, may be plowed in wet weather. By this ſort of management, the *Wheat* being planted in rows, at ſix foot intervals, the ſame piece of ground will produce every year a new crop of *Wheat* in the intervals, without any fallowing or manure, only by means of the ſufficiently breaking the ſurface with plowing and horſe-hoeing.

It is a general rule, that all ſorts of grain proſper beſt where they are ſown at a time when the ground is ſo dry that it is broken to a ſort of powder by the plough. *Wheat* alone is an exception to this rule; and the reaſon of this is, that as *Wheat* is to endure the ſeverities of a whole winter, after it is ſown, it therefore ſucceeds beſt by being ſown in wetter weather, when the ground is not to be broken ſo very ſmall, and is preſſed down cloſe upon the ſeeds, and covers them better. If *Wheat* were as hardy as rye, and its roots were as hardy and patient of the cold, it might be ſown in as dry a ſeaſon as the rye, and would profit as much by it; but, on the contrary, it requires ſo much covering, that it is a very good practice of ſome farmers to turn on their ſheep over very light land, as ſoon as it is ſown with *Wheat*, in order to tread the ſurface of it hard, and then the cold of winter cannot ſo eaſily kill or penetrate the roots. And as *Wheat* requires to have the earth lie harder on and about it in the winter, ſo it alſo requires more dung, or ſomewhat elſe, to diſſolve the earth about its roots, after the cold weather is paſt, than the rye does, whoſe roots were not ſo confined by the preſſing of the earth about them.

It is another general rule, that all vegetables thrive beſt when ſown on freſh tilled ground, immediately after it is plowed; but *Wheat* is alſo an exception to this rule, for the beſt way for it is to plow the ground when very dry, and then to let it lie even, though it be many weeks till ſome rain come to moiſten it, and then drill the *Wheat*. The harrows and the drill, in this caſe, will move a ſufficient part of the ground, which will ſtick together for the defence of the ſmall roots during the winter, the reſt of the mould lying open, and divided underneath until ſpring, to moiſten them and nouriſh them.

There is a ſort of binding ſand, which requires not only to be plowed dry, but to be ſowed dry alſo, or elſe the *Wheat* will dwindle in the ſpring, and fail of being a good crop. What is meant here by dry plowing, is not, however, that the ground ſhould be ſo dry that the duſt ſhould fly; but it muſt not be ſo wet as to ſtick together in lumps; neither ſhould the ground be drilled when it is as wet as pap: it ſuffices that it is moiſt; only the lighter lands ought to be more moiſt than the ſtrong.

Strong land plowed wet in November, will be harder in the ſpring than if plowed dry in Auguſt, though it would then have three months longer to lie. *Tull*'s Horſe-hoeing Huſbandry.

Buck-WHEAT. This is a plant very advantageous to the farmers of England, who have barren lands in poſſeſſion. It is to be ſown in May. One buſhel of ſeed will ſow an acre, and it will grow on any ſoil. It ripens late in autumn, and, when mowed, it muſt lie upon the ground till the ſtalks, which are naturally hard, grow ſoft; it will not ſhed the ſeed in lying, nor will it get any damage by the rain. It yields a very conſiderable increaſe, and if the land be tolerable, ſometimes no leſs than fifty or ſixty buſhels from an acre.

It is excellent food for hogs, poultry, and other animals. The flour of it is very white, and, mixed with *Wheat*-flour, is uſed for food by the country people in ſome places. The ſtraw is good fodder for cattle, and the grain is good to give to horſes among their oats; but it muſt be broken in a mill, otherwiſe it will paſs through them whole.

Buck-Wheat makes a very good lay for *Wheat* or rye, eſpecially if not mowed, but plowed in; but the beſt way is, juſt before it bloſſoms, to feed it with cattle, eſpecially with milch cows, which it cauſes to yield a great deal of milk, aud that ſuch as yields very good cheeſe and butter. It is food for the cattle in the very dryeſt time, when all the common graſs in paſtures is burnt up; and proves a very great improvement for the land. For this purpoſe they ſow it thicker than for others, ſometimes three or four buſhels on an acre. *Mortimer*'s Huſbandry, p. 137.

White-Cone-WHEAT, a term uſed by our huſbandmen to expreſs a peculiar kind of *Wheat*, which is very ſtrong, and has a large ear.

It is the beſt kind for ſowing in fields ſubject to the blight; for the ſtalks of it being, for the moſt part, ſolid or full of pith like a ruſh, not hollow like thoſe of common *Wheat*; the inſects that cauſe the blight ſiezing on the ſtalks of other *Wheat*, does this no injury, even though they ſhould attack it; the ſtalks of this kind being often found full of the black ſpecks, which are always the marks of that inſect having been there, and yet the ear full, and the grain good.

This *Wheat* makes very good bread, if the miller does not grind it too ſmall, or the baker make his dough too hard, it requiring to be ſomewhat larger than other *Wheat*-flour, and ſomewhat ſofter in the dough. A buſhel of *white-cone-Wheat* will make conſiderably more bread than a buſhel of Lammas *Wheat*; but it gives it a ſomewhat yelloviſh caſt. *Tull*'s Horſe-hoeing Huſhandry.

Smyrna WHEAT, a peculiar kind of *Wheat* that has an extremely large ear, with many leſſer or collateral ears coming all round the bottom of the great one.

As this is the largeſt of all ſorts of *Wheat*, ſo it will diſpenſe with the nouriſhment of a garden, without being overfed, and requires more nouriſhment than common huſbandry in the large way can give it. In the common way its ears grow not much larger than thoſe of our common *Wheat*.

This ſort of *Wheat* ſeems, of all others, the moſt proper for the new method of horſe-hoeing huſbandry, as that method ſeems capable of giving as much nouriſhment as the farmer pleaſes, by often repeating the hoieng. Next to this, the *white-cone-Wheat* is beſt for this ſort of huſbandry; then the grey-cone-*Wheat*..

WHEAT-*Bird*, a name given by the people of Virginia to a ſpecies of bird, which, after the time of the ſowing the *Wheat* in that country, made its appearance annually at the ſeaſon of its beginning to ripen, and was never ſeen there before. See the article *Birds of* PASSAGE.

WHEAT-*Ear*, in zoology, the Engliſh name of the common œnanthe, called alſo the *white-tail*, and the *fallow-finch*. See Tab. of Birds, N°. 33.

It is ſomething larger than the common ſparrow; its head and back are of a greyiſh colour, with ſome admixture of red-

redneſs; and the female has ſometimes a conſiderable caſt of green; the rump is white, whence the bird has its name of the *white-tail*; tho' this is ſometimes not the caſe, the rump being of the ſame colour with the reſt of the back. The belly is whitiſh, with a glow of red; the breaſt and throat are redder than the belly: And in the male birds the belly is ſometimes yellowiſh. There is on each ſide of the head a long white line running above the eyes, and under them a ſhorter of black, which laſt is wanting alſo in the female. The wing-feathers are black, except their extremities, which are edged with a reddiſh brown, with a caſt of whitiſh; the tail is very beautifully variegated with black and white. Its beak is black, ſlender, and ſtrait. Its mouth black within, and opening very wide. It feeds on beetles, and other inſects, and builds in the deſerted burrows of rabbits, *&c.* They are extremely plentiful in Suſſex, and ſome other counties of England, after harveſt-time, when they are extremely fat, and very much eſteemed at table. *Ray*'s Ornithol. p. 168.

WHEEL (*Cycl.*)—WHEEL-*Animal*, a name given by the writers on microſcopical diſcoveries, to a ſpecies of minute animalcule, which appears in a ſort of ſheath or caſe, the end of which it faſtens to the roots of water-plants, or whatever elſe is in its way. See Tab. of Microſcopical Objects, Claſs 1.

This little creature has two ſeeming *Wheels*, with a great many teeth or notches coming from its head, and turning round, as it were, upon an axis. This little creature, on the leaſt touch, draws in its *Wheel* into its body, and its body into the ſheath; but as ſoon as all is quiet, it throws them out, and works them again.

In order to find theſe animalcules, chooſe ſuch roots of duck-weed as are long, and proceed from ſtrong old plants, for the young roots ſeldom afford any; they ſhould not be covered with that rough matter which is frequently found about them, nor any way tending to decay, as they will often be.

In the water found remaining in the leaden pipes, or gutters, on the tops of houſes, there are alſo found great numbers of theſe *Wheel-Animals*. Theſe are of a different ſpecies from the former; and when the water dries away they contract their bodies into a globular or oval figure, and are then of a reddiſh colour, and remain mixed with the dirt, growing together into a lump as hard as clay. This, whenever it is put in water, in half an hour's time diſcovers the animals living again, and as briſk as ever; and they have been found to be living in this manner, after the matter had been kept dry twenty months.

It ſhould ſeem from this, that as the water dries up, their pores become ſhut in the manner of thoſe of ſuch animals as remain torpid for the winter; and that when they find water come on again from rain, they then unfold themſelves, and live and feed as long as it laſts. *Baker*'s Microſcope, p. 91.

WHEELER, among brick-makers. See the article BRICK.

WHEEZING, a name given by our farriers to a diſtemperature in horſes, in which they draw their breath with difficulty and noiſe.

The generality of people make this and purſineſs, in horſes, the ſame diſtemper; but the more judicious always diſtinguiſh it, as wholly different from that. Purſineſs proceeds always from a ſtuffing or oppreſſion of the lungs; but this *Wheezing* is only owing to the narrowneſs of the paſſages between the bones and griſtles of the noſe.

The horſes that are moſt of all afflicted with this diſtemper, do not want wind; for notwithſtanding that they *wheeze* exceſſively when they are exerciſed, yet all the time their flanks are not moved, but keep in the ſame condition that they were while the creature ſtood ſtill. The dealers call theſe ſort of horſes *blowers*, and though there is no real harm in the thing, it is a diſagreeable quality, and few people will chooſe them, that have much ſervice for them.

There are ſome horſes that have a natural defect in their breathing, which makes it at all times attended with ſome difficulty, but not with the *Wheezing* before-mentioned; theſe are called thick-winded horſes.

People who are careful in the buying horſes, will purchaſe neither of theſe kinds; but there is this caution to be obſerved in regard to this defect, that it often ſeems to be in horſes where it really is not. When a horſe has been kept a long time in the ſtable without exerciſe, he will at the firſt riding be out of breath, and fetch it in a difficult and painful manner, though he be neither a blower nor thick-winded; but all this will go off with a little exerciſe.

There are ſome temporary *Wheezers* and *blowers* among horſes: theſe at times rattle, and make a great noiſe through their noſes in taking breath; but the complaint goes off and returns. This is only occaſioned by a great quantity of phlegm, for their flanks do not redouble with it at the worſt of times, nor have they any cough with it; ſo that there is no danger of their being purſy.

WHELPS. Nothing is more eſſential to the having a good pack of hounds, than a proper care of the *Whelps*, and of the parents from which they are to be bred.

The bitches, in particular, ſhould be careſully choſen, and ſhould be ſuch as are the ſtrongeſt and beſt proportioned; they muſt alſo have large ribs and flanks.

The beſt ſeaſon for the coupling of hounds is in January, February, or March, for then they will litter in a good time of the year, that is, in ſpring; ſo that they will be fit to enter in due courſe, without loſs of time, or of the ſeaſon; for if bitches litter in winter, it is very difficult to bring up the *Whelps*, the cold killing them if there is not great care taken of them.

The dogs that line the bitches muſt not be above five years old; for if they are older than this, the young ones will be dull and heavy. Care ſhould be taken to have a proper dog ready the firſt time of the bitches going proud; for it is affirmed by many, who ſay they have experience for it, that whatever kind of dog lines a bitch the firſt time, there will be one puppy at leaſt in all her ſucceeding litters that will have ſome reſemblance of him.

The firſt litter of puppies that a bitch brings, are never eſteemed ſo good as the ſecond or third. When a bitch has been lined, and grows big with *Whelps*, ſhe is not to be ſuffered to hunt among the pack, nor to take any other violent exerciſe; for that would endanger her caſting her *Whelps*; ſhe ſhould be kept up, and fed well, and a good place ſhould be provided for her to litter in.

As ſoon as ſhe has littered, thoſe which are intended to be kept ſhould be ſelected out, and the reſt immediately drowned. There is great difficulty in chooſing the beſt at this early time; but the general opinion gives it for thoſe which are the lighteſt, that they will be the ſwifteſt and beſt as they grow up.

Others take all the *Whelps* away, and having determined what number they will keep, they ſettle the choice on thoſe which the bitch carries back firſt to the place where ſhe littered; but all this ſeems very uncertain.

The *Whelps* muſt have good freſh ſtraw to lie in, and it muſt be often changed. They are to be kept in a place where neither the rain nor ſun-ſhine can be troubleſome to them, and once a week it will be proper to anoint them all over with a little nut-oil, with ſome ſaffron infuſed in it. This will prevent the flies from annoying them ſo much as they otherwiſe would, and will kill worms of all kinds. When they are fifteen days old, it is the cuſtom to worm them, and a week after one joint of their ſtern ſhould be twiſted off. As ſoon as they can ſee, they ſhould have milk given them to lap, and at two months old they muſt be weaned, keeping them wholly from the bitch. They muſt at this time be well kept, but not too high fed: And it is proper to put ſome cummin ſeed into their food, to keep the wind out of their bellies.

Many let the *Whelps* of their hounds ſuck three months, and then ſend them away to villages to be bred up till they are ten months old, cautioning thoſe people who have the care of them, not to let them eat carrion, nor frequent warrens.

Rye bread is a very common food for young hounds, and is particularly recommended by many, but wrongly, for it ſoon paſſes through them, and gives them very little nouriſhment. When they are fed conſtantly with this, in the time of their growing up, they always become narrow backed; and this is a great fault in this ſort of dog, a broad back being one of the greateſt recommendations in a hound. *Wheat* bread is greatly preferable on all accounts for the food of the young hound, giving him ſtrength and firmneſs.

At ten months old they are to be taken home, and put into the company of the others, to live as they do: and after a few weeks keeping company with the reſt, they are to be coupled, and to go out to hunt. Five or ſix days practice will, at this time, do a great deal toward the inſtructing them; and, if they are apt to run aſtray, or to open unſeaſonably, they muſt be made to feel the ſmart of the whip: This, and the example of the reſt, will ſoon learn them to run and open in a proper and regular manner.

WHELPS, in a ſhip, the ſeamens term for thoſe brackets which are ſet up on the capſtan, cloſe under the bars; they give the ſweep to it; and are ſo contrived, that the cable, winding about them, may not ſurge ſo much as it might otherwiſe do, if the body of the capſtan were quite round and ſmooth.

WHERN, in natural hiſtory, a name given by ſome of our miners to a kind of ſtone found in ſtrata; but of the hardneſs and fineneſs of flint. It is called alſo *chert* and *nicomia*.

WHEWER, a name uſed in ſome parts of England for the common wigeon. See the article PENELOPE.

WHEY (*Cycl.*)—In many diſorders of the human body, where the ſtomach will not bear milk; or when it is not proper, for other reaſons, *Whey* may be given with great ſucceſs.

We have a diſſertation of Fred. Hoffman on this ſubject. *De ſaluberrima ſeri lactis virtute.* Oper. Tom. 6. p. 9. This author recommends a particular kind of ſerum or *Whey*, made by evaporating milk to a dryneſs, and mixing the reſiduum with water. See the article MILK.

There are various methods of making *Whey* vulgarly known. That with oranges is very agreeable, and much recommended by Dr. Cheyne in his *Nat. Meth. of curing Diſeaſes.*

Alum WHEY, *Serum Aluminoſum*, a *Whey* made with alum. Two drams of alum to one pint of cow's milk boiled. See Lond. Diſp. It is a good aſtringent.

WHINCHAT, in zoology, the Engliſh name of a ſpecies of *œnanthe*, or fallow-finch, called by Aldrovand and ſome other authors, *anthus* and *florus*.

It is of the ſize of the common water-wagtail. Its head, neck and back, are of a reddiſh brown, with regular rows of black ſpots. Each feather has a black ſtreak along its middle, and a browniſh one on each ſide. The belly is whitiſh, with a ſlight tinge of a reddiſh brown. The upper part of the breaſt and the ſides are of a browniſh yellow. Its wing-feathers are brown, with yellowiſh edges. The tail is part black and part white. The beak is ſtrait, ſlender, and black. The male has much of a white variegation on his wings, which the female has not. It lives about ditch banks, and the like places, and feeds on beetles and other inſects.

The colours are very uncertain in this bird, and it often much reſembles the ſtone-chatter; but may always, by an accurate obſerver, be diſtinguiſhed from that bird by the white ſpots in its wings, by the whiteneſs of the under part of its tail, and the white lines on its head. *Ray*'s Ornithol. p. 169.

WHIPLADE, in huſbandry, a term uſed by the farmers in ſome places for a particular ſort of cart, whoſe hinder part is made up of boards, after the manner of a dung-cart, having alſo a head of boards, and ſhambles over the thills; this head being made ſo as either to be taken out or left in. The cart may be indifferently uſed to carry dung or other things; dung when the head is in, and corn, *&c.* when it is taken out. *Plot*'s Oxfordſhire, p. 262.

WHIRL-*Pool* (*Cycl.*)—Theſe in rivers are very common, from various accidents, and are uſually very trivial, and of little conſequence. In the ſea they are more rare, but more dangerous. Sibbald has related the effects of a very remarkable marine *Whirlpool* among the Orcades, which would prove very dangerous to ſtrangers, though it is of no conſequence to the people who are uſed to it. This is not fixed to any particular place, but appears in various parts of the limits of the ſea among thoſe iſlands. Wherever it appears it is very furious, and boats, *&c.* would inevitably be drawn in and periſh with it; but the people who navigate them are prepared for it, and always carry an empty veſſel, a log of wood, or large bundle of ſtraw, or ſome ſuch thing, in the boat with them; as ſoon as they perceive the *Whirlpool*, they toſs this within its vortex, keeping themſelves out; this ſubſtance, whatever it be, is immediately received into the center, and carried under water; and as ſoon as this is done, the ſurface of the place where the *Whirlpool* was, becomes ſmooth, and they row over it with ſafety; and in about an hour they ſee the vortex begin again in ſome other place, uſually at about a mile diſtance from the firſt. *Sibbald*'s Prodr. Hiſt. Scot.

WHISTLE *Fiſh*, a name given by the people of Cornwall to a ſpecies of gadus, with only two fins on the back, otherwiſe called *muſtela fluviatilis*. See the articles GADUS and MUSTELA.

WHITE (*Cycl.*)—WHITE-*Face*, or BLAZE, in the manege, is a *white* mark upon a horſe, deſcending from the forehead almoſt to the noſe. It is called in French *chanfrin blanc*. See the article CHANFRIN.

WHITE-*Foot*, in the manege, called in French *Balzane*, is a *white* mark that happens in the feet of a great many horſes, both before and behind, from the fetlock to the coffin. The horſes thus marked are either tramelled, croſs-tramelled, or *white* all four. Some horſemen place an unlucky fatality in the white of the far foot behind. See the articles CHAUSSE *trop haut*, and TRAMELLED.

WHITE-*Hart-Silver*, in our old cuſtoms, a mulct on certain lands in or near the foreſt of *White-hart*, paid yearly into the exchequer, impoſed by King Hen. 3. upon Thomas de la Linde for killing a beautiful *White-hart*, which the King before had ſpared in hunting. *Cambd. Brit.* 150. *Blount*, *Cowel.*

WHITE-*Horſe-Fiſh*, a common Engliſh name for a thorn-back, called by Willughby the *raia aſpera noſtras*, and ſuppoſed by moſt authors to be the *fullonica* of Rondeletius.

It has a long and pointed noſe, and is covered with prickles upon the back. When it is of a yellowiſh colour, its belly is perfectly white, without ſpot or ſtain, whence it has its name. *Willughby*'s Hiſt. Piſc. p. 78.

WHITE *Land*, in agriculture, a tough clayey ſoil, naturally of a ſomewhat whitiſh hue when dry, eſpecially when it has lain ſome time untilled, but becoming blackiſh after rain; this appears of a light greyiſh colour, when turned up by the plough, and ſlides off from the plough-ſhare with eaſe, and with a ſmooth gloſſy ſurface.

It has often a yellowiſh hue with the grey, and is often veined with large parcels of a blue marly earth. *Moreton*'s North. p. 43.

WHITE *Swelling*. We have ſeveral examples of ſucceſsful cures of *White Swellings* of the joints, or tumors from inſpiſſated lymph, by a ſmall ſtream of warm water falling from a height on them.

When the water is impregnated with penetrating medicines, or natural minerals, its virtues are greater. The application of bladders, containing warm water, to the parts affected, is alſo recommended. See *Le Dran*, Obſ. Chirurg. Tom. 2. Obſ. 93, 94.

WHITE-*Tail*, in zoology, an Engliſh name for the common œnanthe, more frequently called the *fallow-finch*, or wheat-ear. See the article WHEAT-*Ear*.

WHITE-*Throat*, in zoology, the name of a ſmall bird, very common in our gardens and hedges, and ſeeming to have been deſcribed under the name of *ſpipola* by Aldrovandus and ſome others, though moſt approaching to the *ficedula* claſs.

Its beak is black above, and whitiſh below; its feet of a yellowiſh brown; its neck and back are of a browniſh-grey; its head more grey than either, and upper part of the throat *white*, the reſt reddiſh; its breaſt and belly are alſo a little reddiſh; but in the female the breaſt is perfectly white. The edges of the long-wing feathers are ſome whitiſh and others browniſh, and the tail is variegated with black and white, and ſome grey or aſh-colour intermixed. It is extremely common in our gardens and orchards, and feeds on flies, ſpiders, and other inſects. It builds in buſhes, at a ſmall height from the ground, with ſtubble and horſe-hair, and lays five browniſh-green eggs, with black ſpots. *Ray*'s Ornithology, p. 171.

WHITE *upon White*, in the porcelain manufactory, a name given by the Engliſh merchants to a particular China-ware, which is formed of three different *white* ſubſtances, the body being of one, the flowers of another, and the varniſh which covers theſe of a third.

The principal art in the making this ſort of China, is the finding the proper degree of dryneſs in the veſſels for receiving the pencilling or upper coats. It is a fine art, and the principal colour is made of an earth called *hoache*, which is much of the nature of our *ſteatites*. See the articles HOACHE and STEATITES.

WHITES, the popular name of a diſorder incident to women. See the article FLUOR-*Albus*.

WHITENING *of Bones*, for a ſkeleton. See the article BONE.

WHITING, in zoology, the Engliſh name of a common fiſh of the aſellus kind, commonly diſtinguiſhed by the writers in ichthyography by the name of *aſellus mollis*, though by ſome called *aſellus albus* and *merlangus*.

The *Whiting* is diſtinguiſhed from the other ſpecies of the cod kind by theſe characters: It is of a ſmall ſize, ſeldom much exceeding a foot in length, and is thin and ſlender in proportion to its length, particularly about the tail. Its ſcales are very ſmall, and its colour much more pale and whitiſh than in any other fiſh of the cod kind, whence it has its Engliſh name. The belly is white, and the belly-fins behind the tail are ſpotted with ſmall black dots. It has no beard. Its eyes are large, and its upper jaw longer than its under; ſo that its teeth, which are large and crooked, fall over, and are uncovered when the mouth is ſhut; and the inner part of this jaw is armed alſo with very ſmall teeth. Its belly, or rather its breaſt-fins, are nearer the head than in any other ſpecies. It is common in the Engliſh ſeas and elſewhere. *Willughby*'s Hiſt. Piſc. p. 170.

According to the Artedian ſyſtem of ichthyology, the *Whiting* is one of the *gadi*, diſtinguiſhed by that author by the name of the *gadus* with three fins on the back, without beards, with a white body, and with the upper jaw longer than the under. See its deſcription and hiſtory under the article ASELLUS. See alſo the articles GADUS and MERLANGUS.

WHITING-*Pollack*, a fiſh of the cod kind. See the article HUITINGO *Pollachius*.

WHITLOW-*Graſs*, in botany, the Engliſh name of a genus of plants. See the article PARONYCHIA.

WHOLSOME *Ship*, in the ſea language, one that will try, hull, and ride well, without rolling, or labouring in the ſea. A long ſhip that draws much water, may try, hull, and ride well; but if ſhe draws little water, ſhe may try and ride well, but never hull well; and a ſhort ſhip, that draws much water, may hull well, but neither ride nor try well; and ſuch is called an *unwholſome* ſhip.

WICKER *Tree*, a name given by the Engliſh to a tree common in China, and deſcribed by Kircher and others. It is, as it were, a rope twiſted by nature, about an inch thick, and creeps along the earth often for above a hundred paces together, much embarraſſing the way, but ſerving for cables of ſhips, ſeats, hurdles, beds, mats, and various other neceſſary uſes. It endures no vermin, and is much valued for being cool and refreſhing in the hot ſeaſons. *Kircher*'s China illuſt.

WICRANGLE, in zoology, an Engliſh name for the mattageſs, or greater butcher-bird, the *lanius cinereus major* of authors. *Ray*'s Ornithol. p. 53. See the articles LANIUS and MATTAGESS.

WICRANTUM, in natural hiſtory, a name given by the people of the Eaſt-Indies to certain foſſile bodies, of the nature of the pyrites, of the ſize of peas, and formed into variouſly angular figures.

They look black and gloſſy, and much of the nature of blende, or mock lead; but when put into the fire, they ſhew us by their ſmell that they contain ſulphur. They are found in the diamond mines.

The natives firſt powder them; and then mixing them with the juices of certain plants, they dry them, and then calcine them again. Theſe proceſſes they repeat at leaſt ſixty times; but the firſt calcinations are made with a mixture of divers urines, as that of the horſe, the camel, the cow, and the like.

After

After this tedious preparation, they are given in coughs and colds, and are ſaid to be a remedy even in conſumptions.

WIDE-*eared* in the manege, is applied to a horſe, when the root, or lower part of his ear is placed too low, and the ear itſelf is too large. The French uſe the term *Oreillard* for ſuch a horſe.

WIDOW (*Cycl.*)—Mr. Kerſeboom has given us a table, ſhewing how long 432 *Widows* lived, and finds, that, at a medium, each lived fourteen years. Phil. Tranſ. N°. 468. ſect. 3.

Among the antient Greeks, *Widows* had the Care of the eternal fire of *Veſta* committed to them; which charge, among the Romans, could be performed by virgins only, who from their office were called veſtals. *Hofm.* Lex. Univ. in voc. *Vidua*. See the article VESTAL, *Cycl.*

King's WIDOW. See the article DOTE.

WIDURIS, in natural hiſtory, the name of a ſtone found in Java, Malabar, and ſome other places, and deſcribed by Rumphius. Some ſpecies of this are all over of a fine white; others are of a duſky colour, with ſtreaks of white; the ſimply white ones are ſemi-pellucid, and look very like the white of an egg. Some alſo have called this the *Hyalops*, or *Achates vitreæ perſpicuitatis*.

WILD *Oat*. See the article OAT.

WILD-*Gooſe Chace*. See the article CHACE.

WILDERNESS, (*Cycl.*) in gardening. There is nothing ſo great an ornament to a large garden as a *Wilderneſs*, when properly contrived, and judiciouſly planted.

The *Wilderneſs* ſhould always be proportioned to the ſize of the garden, and ſhould never be ſituated too near the houſe; becauſe the trees perſpire ſo large a quantity of watery vapours, as make the air very unwholſome. The *Wilderneſs* ſhould never be ſo placed as to block up a good proſpect; but where the view naturally ends with the verge of the garden, or little more, nothing terminates it ſo well as a fine plantation of trees. The ſize of the trees ſhould be conſidered, and tall growing ones ſhould be planted in larger places; ſmaller, in leſs extenſive; ever-greens alſo ſhould be kept by themſelves, and placed moſt in ſight, not mingled confuſedly among the trees which caſt their leaves. The walks ſhould be large and not numerous; the large walk is beſt made ſerpentine, and this ſhould not be entered upon the grand walks of the garden, but by ſome private walk.

It is too common a method to diſpoſe the trees in *Wilderneſſes* in form of regular ſquares, triangles, *&c.* but this is faulty; for as nature ſhould be ſtudied in theſe works of fancy, the moſt irregular is the moſt pleaſing plantation. The walks for the ſame reaſon are much more pleaſing when they run in wild meanders, than when they interſect one another in ſtudied and regular angles. The winding walks ſhould be made to lead to an open circular piece of graſs, with a ſtatue, an obeliſk, or a fountain; or, if an opening large enough for a banquetting-houſe be contrived in the middle, it will afford a very pleaſing ſcene. The trees ſhould gradually riſe from the ſides of the walks and openings, one above another to the middle of the quarters, where the largeſt trees ſhould ſtand, by which means the heads of all the trees will appear in view, but their ſtems will not appear in ſight.

Not only the growth of trees is to be conſidered in the planting of a *Wilderneſs*, but their nakedneſſes are to be conſidered and hid. The larger growing trees are allowed a proportionable diſtance, and their ſtems hid by honeyſuckles, roſes, ſpireas, and other low flowering ſhrubs. Theſe may alſo be planted next all the walks and openings; and at the foot of theſe, near the walks, may be ſet rows of primroſes, violets, and daffodils, with other the like flowers; behind the firſt rank of lower flowering ſhrubs ſhould be planted thoſe of a ſomewhat higher ſtature, as the *althæa frutices*, the cytiſuſes and gelder-roſes; and behind theſe may be rows of the talleſt flowering ſhrubs, as the lilacs, laburnums, and the like; and behind theſe, the heads only of the lower growing trees will appear, which ſhould be backed gradually with thoſe of higher growth, to the center of the quarter; from whence the heads of the trees ſhoold deſcend every way to the walks, or openings. The grand walks and openings ſhould always be laid with turff, and kept well mowed; but, beſide theſe, there ought to be ſmaller ſerpentine walks through the ſeveral quarters, where perſons may retire for privacy: theſe ſhould be left with the bare earth, only kept clear of weeds, and laid ſmooth.

Theſe walks ſhould be made as winding as poſſible, and a few wood-flowers planted along their ſides will have a very good effect. The ever-greens ſhould be allotted a peculiar part of the *Wilderneſs*, and ſuch as fronts the houſe; and, in the planting theſe, the ſame regard is to be had to their growth, that the talleſt trees be planted hindmoſt, and their ſtems hid by ſhorter ones, and ſo on, down to the verge: as in the firſt row may be planted lauruſtines, boxes, ſpurge laurels, junipers, and ſavins; behind theſe, laurels, hollies, and arbutuſſes; next behind theſe, yews, alaternuſſes, phillereys, cypreſſes, and Virginian cedars; behind theſe, Norway and ſilver firs, and the true pine; and finally, behind theſe, the Scotch pine and pinaſter. Theſe will have a very beautiful appearance, as their tops will only be ſeen, and make a ſheet of green, which may alſo be very beautifully varied, from the artful admixtures of the ſeveral ſhades of green which the various plants have.

In all theſe plantations, the trees, however, ſhould not be ſet in formal ſtiff rows, but in a looſe variety, proportioned to their manner of growth. *Miller*'s Gardener's Dict.

WILDS, a term uſed by our farmers to expreſs that part of a plough by which the whole is drawn forwards.

The *Wilds* are of iron, and are of the form of a gallows, whence they are by ſome called the *Gallows* of the plough, but improperly, the gallows of the plough being properly that part formed by the crow-ſtaves, and the tranſverſe piece into which they are mortiſed at the top.

The *Wilds* conſiſt of two legs, and a tranſverſe top-piece: one of the legs, and the top-piece, are all of one piece of iron, and the other leg, which is looſe, has a hole in the top, into which the end of the tranſverſe piece is received; both theſe legs paſs through the box of the plough, which is that tranſverſe timber through which the ſpindles of the wheels run: theſe legs are pinned in behind the box with iron pins: the holes through the box at which theſe legs paſs, are not made at right angles, but ſlanting upwards, ſo that the fore-part of the *Wilds* is higher than the hinder part; were it not for this, the upper part of the crow-ſtaves would lean quite back when the plough is drawn.

The uſe of the notches in the *Wilds* is to give the plough a broader or narrower furrow; if the links are moved to the notches on the right-hand, it brings the wheels toward the left, which gives a greater furrow; and, on the contrary, a ſmaller furrow is made when the links are moved to the notches on the left. The legs of the *Wilds* ſhould be nineteen inches, and their diſtance eight inches and a half; they muſt be made ſtrong, and the links muſt be placed in different notches, that the front of the plough may be kept ſteady, and the wheels not be drawn one before the other. Theſe links are of iron alſo, and are each ſix inches and a half long, and to theſe are faſtened the chains of the harneſs, by which the whole plough is drawn along. *Tull*'s Huſbandry. See the articles PLOUGH and GALLOWS.

WILLOW, in botany. See the article SALIX.

Our common *Willows*, in the ſpring ſeaſon, when they are in flower, produce a quantity of cottony matter, which might be put to ſome uſe.

The Chineſe are induſtrious enough to collect this cotton as it falls from their *Willows*; and the women and children, among the poorer people, card it, and pick out the ſeeds, and render it fit for many uſes in the place of cotton.

The poor people, in ſome parts of the Indies, make a ſort of liquor of the flowers of the *Willow* before they are opened, which intoxicates them very ſuddenly; and the dry huſks of the ſame tree, remaining after the flowers and ſeeds are fallen, are wholſome as food, people in times of famine having lived upon them, boiled in water.

The ignorance of the Chineſe in natural hiſtory, has occaſioned two very ſtrange ſtories, about the downy or cottony matter of the *Willow*, to be recorded in their books, and firmly believed among them.

The one is, that if this down fall upon the water, it is in one night's time converted into the plant called duck-weed, and if it falls upon any of their fur garments, it becomes a ſort of moth, or worm, that eats them to pieces. The common people are ſo fully perſuaded of this, that they will never let any garment of this kind he expoſed to the air at this time of the year. There is ſome probability, that the down of this tree may contain the eggs of certain inſects, but then it does not change into them; and theſe can only be the eggs of thoſe butterflies which frequent that tree; the conſequence of which muſt be, that they will produce caterpillars whoſe food is the *Willow* leaves, not any other ſubſtance.

The other error may probably be owing to the water-plant uſually making its firſt appearance at the ſame ſeaſon when the *Willows* are in flower, ſo that it ſeems produced of them.

A like error we have among the common people of England, in regard to the yellow *rattle*, or *criſta galli lutea*. This plant appears in our meadows juſt at the time when the cowſlips have done flowering, and is thence vulgarly ſuppoſed to be the ſame plant in a different ſtate, or that the cowſlip at a certain time changes into this plant.

The wood of the *Willow*, though in itſelf very light and ſpongy, is yet of a nature to bear the injuries of wet better than almoſt any other kind. It is uſed by the Chineſe on this occaſion, in the making their wells, and on all other occaſions where wood is to ſtand under water, and ſucceeds perfectly well. Obſerv. ſur les Coutumes de l'Aſie.

WILLOW-*Galls*, in natural hiſtory, the name given by authors to certain protuberances found very frequently on the leaves of the ſeveral ſpecies of *Willow*, which are properly galls, each containing the worm of a fly, and owing its exiſtence to that inſect.

The galls are uſually of a roundiſh or oblong figure, and are equally protuberant on each ſide of the leaf: They are of a pale green at firſt; but they afterwards become yellowiſh, and finally reddiſh. The ſurface of theſe is ſeldom perfectly even, but uſually has ſeveral little prominences and cavities in it. When this gall is opened, there is found in it a worm much reſembling a caterpillar in figure, having a ſmooth annulated

nulated body, and a hard brown head. This, however, is not a caterpillar, the utmoſt number of legs in that genus of animals being found to be ſixteen, and this worm having twenty.

It is one of thoſe creatures which Reaumur, from their reſemblance to the caterpillar kinds, has called falſe or baſtard-caterpillars. This creature, when the gall is young, is blue; it afterwards becomes greeniſh; and finally, when the gall becomes red, it is white. It is in this ſtate that Redi has figured and deſcribed the gall, and he therefore naturally deſcribes the worm as white. This inſect ſeems to eat in its priſon more voraciouſly than any other gall-inſect whatever; for while the gall grows in ſize, it becomes alſo thinner in every part; ſo that the creature, at the proper time, has but little difficulty to get out. *Reaumur*'s Hiſt. Inſect. vol. 6. p. 211.

Theſe galls ſometimes ſtand ſingly on the leaves; but more frequently there are three or four on a leaf; not unfrequently there are great numbers, and particularly on the leaves of the ozier: theſe being very narrow, the galls are beautifully arranged on them, ſtanding uſually in two rows, one on each ſide the middle rib; and theſe ſo cloſely ſet together, that they reſemble the beads of a lady's necklace. The inner ſurface of moſt other galls is ſmooth, and the animal lodged in a poliſhed cavern; but that is not the caſe in theſe galls, the animal eats too faſt to eat with ſo much regularity; and, in fine, before it arrives at its full growth, it uſually eats its way through the ſides of it, and feeds on the ſubſtance of the leaf in other parts, retiring at pleaſure again into its cell. This is a very ſingular thing, no other inſect of this kind being known to do it. Vallinſieri is the perſon who affirms it of this, and ſays, that he has ſeen the fact.

When the time of the laſt change of this inſect draws nigh, it leaves the tree, and deſcending to the earth, makes its way into it in a proper place, and then becomes a nymph, out of which, at a proper time, iſſues a four-winged fly. This is alſo the laſt ſtate of all the baſtard-caterpillars that have yet been traced through their ſeveral changes.

The obſervation of this change, however, is not ſo eaſy as that of ſeveral other ſpecies, ſince the creature does not undergo it in the gall, but under the earth, and there can be no certainty in expecting the inſect out of the ground.

Redi, who was very curious in theſe particulars, could never arrive at the ſight of the winged animal. His method of attempting it was by putting a great number of the galls into boxes, and expecting their changes there; but theſe creatures all died for want of the proper nidus for the chryſalis. Vallinſieri ſucceeded better, by means of putting a large quantity of a moiſt friable earth, of the ſandy kind, into the boxes with the galls. The conſequence of this was, that he ſoon ſaw ſuch of the inſects as were arrived at a ſtate proper for their change, creep out of the galls, and bury themſelves in the earth at the bottom of the boxes. On tracing them farther, he found that each of them ſpun itſelf a caſe of ſilk, like the ſilk-worm's web, under the cover of which it lay in the earth all the winter, and in the ſpring following, about the middle of April, it came up in the form of a ſmall four-winged fly, of no very ſingular beauty. This is alſo obſerved of all the other baſtard-caterpillars, none of them producing flies of any beauty, though ſome of very ſingular figures. *Reaumur*, Hiſt. Inſ. vol. 6. p. 213.

The flies which are thus produced in April, copulate almoſt as ſoon as freed from their exuviæ of the chryſalis ſtate, and the females ſoon after lodge their eggs in the leaves of the *Willows*. This is all done before the end of April, and the young ones hatched of theſe eggs, live but a ſhort time before they paſs into the chryſalis ſtate, and living flies are hatched from theſe in June. It is this brood whoſe young ones paſs their chryſalis ſtate in the earth, and appear not during the whole winter, till the ſpring ſun enlivens them again. There are, beſide theſe, another kind of galls of the *Willow* leaves, which are of the claſs of thoſe, each of which contains ſeveral cells; in each cell of theſe there is found a ſmall white maggot, the offſpring of the egg of a two-winged fly, which, after paſſing the chryſalis ſtate in the earth, alſo comes out in the form of its winged parent. The cells in the galls are different in number in the ſeveral galls, and are from four or five to twenty: They have no communication with one another, but each worm lives in its own cell.

Beſide theſe there is alſo ſometimes found in theſe galls a worm of a browniſh white colour, having two hooks in its head, and no legs at all. This has all the appearance of a carnivorous animal, and probably was depoſited there in the egg-ſtate by its parent, not to feed on the gall, but on its defenceleſs inhabitant. This worm finally becomes a ſmall bluiſh beetle, and is often found alone in the cavity of the gall, often in company with its proper inhabitant, ſucking its juices as it feeds on thoſe of the plant. There ſeem to be ſeveral ſpecies of theſe devourers common to theſe galls; ſince Vallinſieri obſerved, in the boxes where he kept theſe galls to produce the animals from thence, many ſpecies of ſmall beetles, and ſeveral diſtinct kinds of flies, which were probably the laſt ſtate of ſeveral kinds of carnivorous worms, which had preyed upon the proper inhabitant of the galls. *Vallinſieri*, Dialog. des Inſect.

WILLOW *Herb*, in botany, the Engliſh name of the *lyſimachia*. See the article LYSIMACHIA.

WIMBREL, in zoology, the Engliſh name of a bird of the curlew-kind, and known among authors by the name of *arquata minor*, or the leſſer curlew, and called in the Venetian markets *taraniola*.

It is very much of the ſhape of the common curlew, but is not more than half its ſize. Its beak is about three fingers breadth long. Its feet are greeniſh, and its wings ſpotted with large ſemicircular ſpots; and its general colour is a duſky brown.

WINCRANTUM, in natural hiſtory, a name given by the people of the Eaſt Indies to a foſſile ſubſtance reſembling, in ſome degree, the plated lead ores of Europe, but containing very little of that metal; it is properly a ſpecies of blende, or mock lead, of a talcy appearance; it is conſiderably hard, and is uſualy found in other ſtones. It is given in medicine in the Indies as a provocative to venery, being firſt calcined and beat to powder.

WIND (*Cycl.*)—*Wind* has been, by many authors, made the baſis of many different diſeaſes: among others, Dr. Reyn has given it as his opinion, in a treatiſe on the gout, that flatuſes, or *Wind* incloſed between the perioſteum and the bone, are the true cauſe of that diſeaſe; and accordingly, that all the method of cure ought to tend to the expelling that *Wind*. He ſuppoſes this *Wind* to be of a dry, cold, and malignant nature, conveyed by the arteries to the place affected, where forcibly ſeparating that ſenſible membrane the perioſteum, and diſtending it, the pain muſt needs be very great.

He is alſo of opinion, that head-achs, palpitations of the heart, tooth-ach, pleuriſy, convulſions, colics, and many other diſeaſes, are originally owing to the ſame cauſe, and only differ in regard to the place affected, and to the various motions and determinations of the *Wind*. The moveableneſs of the pain in gouty perſons from one part to another, he looks on as a proof of this, and thinks that the curing the gout by burning moxa, or the cotton of the mugwort leaves, upon it, is owing to its giving way to the *Wind* in the part to evaporate itſelf.

That theſe *Winds* are cold, appears from the ſhivering fits which generally precede a paroxyſm of the gout, and the ſhiverings in the beginnings of fevers, and before all fits of agues, are owing to the ſame cauſe, is ſuppoſed by this author a natural concluſion from the former obſervations.

The *Winds*, according to this author and Fienus, are a ſort of halituous ſpirits, raiſed by the improper degree of our native heat, or out of our meat and drink; or, finally, out of an abundance of black choler.

Their differences, he ſays, principally proceed from the various ferments producing in us a variety of humours; which acting upon one another, do in their efferveſcences create *Winds* of various effects, and denominate diſeaſes from the places which are the ſcenes of their action. It is on this account that the acupunctura, or pricking with long needles, among the Chineſe, is of uſe. The Japoneſe, and other neighbouring nations, having no other cure for moſt diſeaſes than the pricking with the needle, and the burning the moxa on the part. *Reyn* de Arthritid.

The huſbandman often ſuffers extremely by high *Winds*, in many different reſpects. Plantations of trees at a ſmall diſtance from the barns and houſes, are the beſt ſafeguard againſt their ſuffering by *Winds*; but they muſt not be planted ſo near as that their fall, if it ſhould happen, would endanger them. Yews grow very ſlowly, otherwiſe they are the beſt of all trees for this defenſive plantation. Trees ſuffer by *Winds*, being either broken or blown down by them; but this may be in a great meaſure prevented by cutting off great part of the heads and branches of them, in places where they ſtand moſt expoſed.

Hops are the moſt ſubject to be injured by *Winds* of any crop; but this may be in a great meaſure prevented by a high pale, or very thick thorn hedge; this will both keep off the ſpring *Wind*, which nips the young buds, and be a great ſafeguard againſt other *Winds* that would tear the plants from their poles. The poles ſhould always be very firm in the ground; and the beſt ſecurity to be added to this, is a row of tall trees all round the ground.

Winds, attended with rain, do vaſt injury to the corn, by laying it flat to the ground. The beſt method of preventing this, is to keep up good incloſures; and if the accident happens, the corn ſhould be cut immediately, for it never grows at all afterwards. It ſhould be left on the ground, in this caſe, ſome time after the cutting, to harden the grain in the ear. *Mortimer*'s Huſbandry, p. 302.

Large WIND, in the ſea-language; to ſail with a *large Wind*, is the ſame as with a *fair Wind*.

Quarter WIND, at ſea. See the article QUARTER.

Tropic WINDS. See the article TROPIC.

Side WIND, at ſea, that which blows on the ſide of the ſhip.

WIND, in the manege. A horſe that carries in the *Wind*, is one that toſſes his noſe as high as his ears, and does not carry handſomely.

The difference between carrying in the *Wind*, and beating upon the hand, is, that a horſe who beats upon the hand, ſhakes his head, and reſiſts the bridle; but he who carries in the *Wind*, puts up his head without ſhaking, and only ſometimes beats upon the hand. The oppoſite to carrying in the *Wind*, is arming and carrying low.

WIND-*Flower*, in botany, the Engliſh name of the *anemone*. See the article ANEMONE.

The proper ſoil and culture of the many varieties of this beautiful flower are theſe: For the ſoil, take a quantity of freſh light ſandy loam, or hazel earth from a common, or dry paſture, not dug above eight or ten inches deep; mix this with a third part its quantity of rotton cow-dung, and lay it up in a heap; turn this over at leaſt once a month, and every time pick out the ſtones, and break the clods. After this mixture has been twelve months made, it will be fit for uſe.

The beds of this earth muſt be prepared in September, and ſhould be made eight inches deep, if it be in a wet ſoil; but if in a dry one, three or four inches will be ſufficient; three weeks after this has been laid in, ſtir it for ſix inches deep with a ſpade, and then with a ſtick draw lines each way of the bed, at four inches diſtance, ſo that the whole may be in ſquares; then make a hole three inches deep in the center of each ſquare, and plant a root in each; and when all are planted, rake the earth of the whole bed ſmooth, ſo as to cover the roots two inches thick. The ſeaſon of planting theſe roots for forward flowers, is the middle of September, and for the later in October: this is beſt done at a time when there are gentle rains. Some roots ſhould alſo be ſaved to be planted after Chriſtmas, for fear of accidents to the former from very hard weather.

Theſe uſually flower three weeks after thoſe planted in autumn. In the beginning of April the early planted roots will begin to flower, and they will keep in flower near a month, if the weather prove favourable, and they are properly ſhaded with matts, laid over hoops in the greateſt heat of the day: the ſecond, and laſt planted ones, will follow theſe; and, in the whole, there will be at leaſt two months fine flowering.

Toward the latter end of May the firſt planted roots will loſe all their leaves, and they muſt be then taken up and waſhed clean, and laid to dry on mats in the ſhade; after which they are to be put up in paper bags, and hung up till the time of planting them comes on again. The later planted ones are to be taken up alſo as ſoon as their leaves are decayed, and not ſuffered to remain to make new ſhoots; for then it is too late to remove them.

They are propagated two ways, either by dividing the roots, or by ſowing. The roots are to be divided as ſoon as they are taken up out of the ground: they will ſucceed if broken into as many parts as there are eyes or buds in them; but they flower moſt ſtrongly, if not parted too ſmall.

The way, by ſowing, is this: Chooſe firſt ſome good kinds of *Anemones*, plant theſe early, and they will produce ripe ſeed three weeks after the flower firſt blows. This muſt be carefully gathered, and in Auguſt it ſhould be ſowed in pots or tubs, or a very well prepared bed of light earth, rubbing it between the hands with a little dry ſand, to prevent ſeveral of the ſeeds from clinging together, and ſpreading them as even as poſſible all over the bed; after this a light hair bruſh ſhould be drawn many times over the ſurface of the bed, to pull aſunder any lumps of ſeed that may yet have fallen together; obſerving not to bruſh off the ſeed, and as much as poſſible not to bruſh it into heaps. When this is done, ſome light earth, about a quarter of an inch deep, ſhould be ſifted over the bed. If the weather be hot, the bed muſt be at times covered with mats laid hollow, and gently watered.

In about two months after ſowing, the plants will appear, if the ſeaſon has been favourable, and they are to be carefully defended from the hard froſts by proper covering, and from the heat of the ſun afterwards by a moveable reed fence. As the ſpring advances, if the weather be dry, they muſt be gently watered, and when their green leaves decay, there muſt be a quarter of an inch more earth ſifted over them, and the like again at Michaelmas; and the bed muſt be kept clear from weeds, and the following ſpring they will flower. *Miller*'s Gardener's Dict.

WIND-*Gall*, a name given by our farriers to a diſtemperature of horſes. In this caſe there are bladders full of a corrupt jelly, which, when let out, is thick, and of the colour of the yolk of an egg.

They vary in ſize, but are more uſually ſmall than large. Their place is about the fetloc-joint, and they grow indifferently on all four legs, and are often ſo painful, eſpecially in the ſummer-ſeaſon, when the weather is hot, and the ground dry and hard, that they make the creature frequently ſtumble, or fall abſolutely down.

The general method of cure is to open the ſwelling about the length of a bean, and to preſs out the jelly: when this is done, they apply a mixture of the oil of bays, and the white of an egg, covering it with tow.

Another method is, after the jelly is all ſqueezed out, to wrap round the part a wet woollen cloath, and then applying a taylor's hot iron, this is to be rubbed over till all the moiſture is carried away; it is then to be daubed all over with pitch, maſtic, and reſin, boiled together, laying tow in plenty over all.

The *Wind-galls* that are ſituated near the ſinews, are much the moſt painful of all, and ſooneſt make the horſe lame.

The general cauſe of *Wind-galls* is ſuppoſed to be extreme work or exerciſe in very hot weather; but it is to be obſerved, that thoſe horſes, which have long joints, will be *Wind-galled* if they work never ſo little. The worſt *Wind-galls* are thoſe of the hinder legs; all the above-mentioned will frequently miſs of ſucceſs in theſe, and nothing but fire will cure them.

WIND-*Hatch*, in mining, a term uſed to expreſs the place at which the ore is taken out of the mines.

The word *hatch* is the general term uſed by the miners to expreſs an opening from the ſurface into the mine, or in the attempting to find a mine.

Thus the word *eſſay-hatches* ſignifies the openings made in ſearch of the trains of ſhoad-ſtones; and the *tin-hatch* in Cornwall is the name of the opening by which they deſcend into a tin-mine.

The word *Wind-hatch* ſeems to be a corruption of *winder-hatch*; for at theſe places they have a *winder* conveying two buckets, the one conſtantly up, the other conſtantly down; the man below fills the bucket that deſcends; and when that which aſcends full is emptied at the mouth of the hatch, the perſon who has the care of that part of the work, delivers it empty to go down again. Phil. Tranſ. N°. 69.

WIND-*Sails*, in a ſhip, are made of the common ſail-cloth, and are uſually between twenty-five and thirty foot long, according to the ſize of the ſhip, and are of the form of a cone ending obtuſely: when they are made uſe of, they are hoiſed by ropes to about two thirds or more of their height, with their baſis diſtended circularly by hoops, and their apex hanging downwards in the hatch-ways of the ſhip; above each of theſe, one of the common ſails is ſo diſpoſed, that the greateſt part of the air, ruſhing againſt it, is directed into the *Wind-ſail*, and conveyed, as through a funnel, into the upper parts of the body of the ſhip. Phil. Tranſ. N°. 463. p. 65.

WIND-*Shock*, a name given by our farmers to a diſtemperature to which fruit-trees, and ſometimes timber-trees, are ſubject.

It is a ſort of bruiſe and ſhiver throughout the whole ſubſtance of the tree; but the bark being often not affected by it, it is not ſeen on the outſide, while the inſide is twiſted round, and greatly injured.

It is by ſome ſuppoſed to be occaſioned by high *Winds*; but others attribute it to lightening. Thoſe trees are moſt uſually affected by it, whoſe boughs grow more out on one ſide than on the other.

The beſt way of preventing this in valuable trees, is to take care, in the plantation, that they are ſheltered well, and to cut them frequently in a regular manner, while young.

The *Winds* not only twiſt trees in this manner; but they often throw them wholly down: in this caſe, the common method is to cut up the tree for firing, or other uſes; but if it be a tree that is worth preſerving, and it be not broken, but only torn up by the roots, it may be proper to raiſe it again by the following method: Let a hole be dug deep enough to receive its roots, in the place where they before were; let the ſtraggling roots be cut off, and ſome of the branches, and part of the head of the tree; then let it be raiſed; and when the torn-up roots are replaced in the earth in their natural ſituation, let them be well covered, and the hole filled up with rammed earth; the tree will, in this caſe, grow as well, and perhaps better, than before. If nature be left to herſelf, and the tree be not very large, the pulling off the roots will raiſe it. *Mortimer*'s Huſbandry, vol. 2. p. 79.

WIND-*Thruſh*, in zoology, a name given by ſome to the redwing, and ſuppoſed to be given from their generally firſt appearing with us in windy ſeaſons; but it appears more probably to be derived from the German name *wint-troſſel*, or vine-thruſh, from its doing great miſchief there in the vineyards, by eating and deſtroying the grapes. *Ray*'s Ornithology, p. 139. See the article RED-*Wing*.

WIND-*Hover*, in zoology, the name of a ſpecies of hawk, called alſo by ſome the *ſtannel*, but more uſually the *keſtrel*, and known among authors by the names of the *tinnunculus* and *cenchris*. *Ray*'s Ornithol. p. 50. See the article TINNUNCULUS.

WIND-*Ward*, (*Cycl.*) in the ſea language, denotes any thing towards that point from whence the wind blows, in reſpect of a ſhip.

WINDAGE *of a Gun* is the difference between the diameter of the bore, and the diameter of the ball.

WINDER-*Meb*, in zoology, the name of a bird of the larus or gull-kind, moderately large, and deſcribed by Aldrovand under the name of *larus major*.

Its head is remarkably large and thick, and is of a mottled colour of white and grey; its breaſt and belly are alſo variegated with the ſame colour, but they are ſomewhat paler. Its beak is thick and ſtrong, of a yellow colour, and very ſharp; and the opening of its mouth very wide. Its wings are variegated with white, grey, and cheſnut-colour; and both theſe

and the tail have much black in them. The feet are webbed and yellow, the claws are ſharp, and the hinder toe larger than in moſt birds of this kind. *Ray*'s Zoology, p. 267.

WINDING-*Tackle*, in a ſhip. See the article TACKLE.

WINDOW (*Cycl.*)—Before glaſs *Windows* came into uſe, the *Window* caſements were commonly made of a tranſparent ſtone called *ſpecularis lapis*, and thence called *ſpecularia*; and before the *ſpecularia*, veils were the only defence they had againſt the weather. *Pitiſc.* Lex. Antiq. in voc. *Specularia*.

WINDY *Tumors*. See the article *Windy* TUMORS.

WINE (*Cycl.*)—The method of converting white *Wines* into red, ſo much practiſed by the modern *Wine*-coopers, is this: Put four ounces of turneſole rags into an earthen veſſel, and pour upon them a pint of boiling water; cover the veſſel cloſe, and leave it to cool; ſtrain off the liquor, which will be of a fine deep red, inclining to purple. A ſmall proportion of this colours a large quantity of *Wine*. This tincture might be either made in brandy, or mixed with it, or elſe made into a ſyrup with ſugar for keeping. A common way with the *Wine*-coopers is to infuſe the rags cold in *Wine* for a night or more, and then wring them out with their hands; but the inconveniency of this method is, that it gives the *Wine* a diſagreeable taſte; or, what is commonly called the taſte of the rag; whence the *Wines*, thus coloured, uſually paſs among judges, for preſſed *Wines*, which have all this taſte from the canvas rags in which the lees are preſſed.

The way of extracting the tincture, as here directed, is not attended with this inconvenience; but it loads the *Wine* with water; and if made into a ſyrup, or mixed in brandy, it would load the *Wine* with things not wanted, ſince the colour alone is required. Hence the colouring of *Wines* has always its inconveniencies. In thoſe countries which do not afford the tinging grape, which affords a blood-red juice, wherewith the *Wines* of France are often ſtained, in defect of this, the juice of elder-berries is uſed, and ſometimes log-wood is uſed at Oporto.

The colour afforded by the method here propoſed, gives *Wine* the tinge of the Bourdeaux red, not the Port; whence the foreign coopers are often diſtreſſed for want of a proper colouring for red *Wines* in bad years. This might perhaps be ſupplied by an extract made by boiling ſtick-lack in water. The ſkins of tinging grapes might alſo be uſed, and the matter of the turneſole procured in a ſolid form, not imbibed in rags. *Shaw*'s Lectures, p. 211.

Any conſiderable heat, or even a degree of ſimmering, or tepidity, will, by its inteſtine and ſubtile agitation, that barely diſturbs the fine ſaline and ſpirituous parts, which are very ſuſceptible of heat, thereby disjoin them from the reſt, and occaſion an alteration in the taſte, tranſparency and durability of the *Wine*, as much as if the ſpirit had been drawn off by diſtillation, and afterwards poured in again, in which caſe the whole ceaſes to be *Wine*, though it is poſſible to bring it to *Wine* again, by bringing on a new fermentation.

It is a common accident, and a diſeaſe in *Wines*, to be kept too hot, and is not eaſy to cure when it has been of any long continuance, otherwiſe it may be cured by introducing a ſmall artificial fermentation, that new ranges the parts of the *Wine*, or rather recovers their former texture: but the actual expoſing of *Wine* to the fire, or the ſun, preſently diſpoſes it to turn eager; and the making it boiling hot, is one of the quickeſt ways of expediting the proceſs of making of vinegar.

On the other hand, *Wine* kept in a cool vault, and well ſecured from the external air, will preſerve its texture entire in all the conſtituent parts, and ſufficiently ſtrong for many years, as appears not only from old *Wines*, but other foreign fermented liquors, particularly thoſe of China, prepared from a decoction of rice, which being well cloſed down in the veſſel, and buried deep under ground, will continue, for a long ſeries of years, rich, generous, and good, as the hiſtories of that country univerſally agree in aſſuring us.

The ſame is to be underſtood of vinegar which has once thrown off the ſuper-abundant earthy parts, and many of the oily ones which preſided in it while it was *Wine*; whence the ſaline ones now get the aſcendant, and as it were ſubdue and preſide over the ſpirituous ones. In this ſtate it will continue perfect a long time; good and ſtrong vinegar, well ſtopped down, and placed in a cool place, preſerving itſelf unaltered for a long ſeries of years: but if it be left open, ſo that its fine vapour exhales, or its ſubtile part be drawn from it, and again poured back; in either caſe it loſes its uniform conſiſtence, and particularly its durability, and immediately hurries into vapidity and corruption.

If either by fraud or accident a larger portion of water is mixed with *Wine* than is proper for its conſiſtence, and no way neceſſary or eſſential, this ſuperfluous water does not only deprave the taſte, and ſpoil the excellence of the *Wine*, but alſo renders it leſs durable; for humidity in general, and much more a ſuperfluous aqueous humidity, is the primary and reſtleſs inſtrument of all the changes that are brought on by fermentation. It may doubtleſs therefore be uſeful, and ſometimes abſolutely neceſſary, to take away this ſuperfluous water from the other part which ſtrictly and properly conſtitutes the *Wine*. This has been agreed upon on all hands as a thing proper; but the manner of doing it has not been well agreed on; ſome have propoſed the effecting it by means of heat and evaporation, others by percolation, and others by various other methods, all found unſucceſsful when brought to the trial; but the way propoſed by Dr. Shaw from Stahl, is the moſt certain and commodious; this is done by a concentration of the *Wine*, not by means of heat, but of cold. *Stahl*'s Schediaſm. de Concentratione Vini. See the next article.

Condenſing of WINES; a phraſe uſed by Stahl, and ſome other writers, to expreſs what is more uſually called the concentrating them, that is, the freeing them from what ſuperfluous humidity they contain, and by that means rendering them more rich and noble, freeing them from their taſteleſs part, reducing them to a ſmaller bulk, and by that means making them fitter for tranſportation, and finally rendering them more durable in their perfect ſtate, and much leſs ſubject to the various accidents that make them decay.

Various methods have been attempted for the effecting of this, and great objections found in the way of all of them, except the lateſt, brought into uſe by *Stahl*, and ſince recommended greatly to the world by Dr. Shaw in his chemical eſſays.

If any kind of *Wine*, but particularly ſuch as has never been adulterated, be in a ſufficient quantity, as that of a gallon or more, expoſed to a ſufficient degree of cold in froſty weather, or be put into any place where ice continues all the year, as in our ice-houſes, and there ſuffered to freeze, the ſuperfluous water that was originally contained in the *Wine*, will be frozen into ice, and will leave the proper and truly eſſential part of the *Wine* unfrozen, unleſs the degree of cold ſhould be very intenſe, or the *Wine* but weak and poor. This is the principle on which Stahl founds his whole ſyſtem of condenſing *Wines* by cold.

When the froſt is moderate, the experiment has no difficulty, becauſe not above a third or a fourth part of the ſuperfluous water will be froze in a whole night; but if the cold be very intenſe, the beſt way is, at the end of a few hours, when a tolerable quantity of ice is formed, to pour out the remaining fluid liquor, and ſet it in another veſſel to freeze again by itſelf: this is proper, for two reaſons; firſt, becauſe the quantity of ice growing large, more of the concentrated *Wine* will be apt to lodge in it than ſhould, and it will require a longer time to drain and clear away from the ice. The making the experiment will ſufficiently explain this to any body; for, without breaking the ice, the unfrozen part will, barely by inclining the veſſel, find its own way out, and drain clear from the watery part, which is now converted into ice; ſo that if the draining be perfect, the ice of the moſt perfectly red Bourdeaux claret will become nearly as clear and pale as water, and will reſolve by heat into an almoſt entirely colourleſs phlegm. This is no ſmall curioſity attending this experiment, and at the ſame time affords a criterion of its exact performance.

If the veſſel, that thus by degrees receives the ſeveral parcels of the condenſed *Wine* be ſuffered to ſtand in the cold freezing place where the operation is performed, the quantity lying thin in the pouring out, or otherwiſe, will be very apt to freeze anew; and if it be ſet in a warm place, ſome of this aqueous part thaws again, and ſo weakens the reſt. The condenſed *Wine* therefore ſhould be emptied in ſome place of a moderate degree as to cold or heat, where neither the ice may diſſolve, nor the vinous ſubſtance mixed among it be congealed. But the beſt expedient of all is to perform the operation with a large quantity of *Wine*, or that of ſeveral gallons, where the utmoſt exactneſs, or the danger of a trifling waſte, needs not be regarded.

By this method, when properly performed, there firſt freezes about one third part of the whole liquor, and this is properly the more purely aqueous part of it, inſomuch that when all the vinous fluid is poured off, to be again expoſed to a concentration, the ice remaining behind, from this firſt freezing, being ſet to thaw in a warm place, diſſolves into a pure and taſteleſs water.

If the *Wine*, now once concentrated, ſhould, by a long continuance in the freezing cold, be again congealed to the utmoſt (unleſs the cold were very ſevere indeed) and then again be drained from its ice, there, ſoon after this, falls to the bottom of the veſſel, a pure white powder or tartar, and even the icy part afterwards depoſits alſo a little of the ſame ſubſtance after thawing; and after the ſtanding two or three days, there is always more and more of this tartar precipitated, and that conſtantly the more in proportion as the *Wine* was more auſtere, or leſs adulterated with ſugar brandy, or the like, for theſe things contain no tartar.

The ice of the ſecond operation on a quantity of *Wine*, differs in nothing from that of the firſt, provided only that the *Wine* was poured clear off from it, before the ice is ſet to melt, by which means it diſſolves into a clear phlegm. This ſhews the excellency of the operation, as it loſes not its efficacy upon repetition, but brings away mere water as well at laſt as at firſt, without robbing the *Wine* of any of its genuine or truly valuable parts. The remaining liquor, which has eſcaped being

ing frozen in these two operations, is a real concentrated *Wine*, as appears by its colour, consistence, taste, and smell; for it now has all these properties in a much larger degree, than while it contained so much superfluous moisture of a merely aqueous kind. It therefore becomes a nobler and richer *Wine*, than could any way be procured without such a contrivance. For as, by this means, two thirds of the quantity are taken away in the better sorts of *Wine*, and three fourths in the weaker, what remains must needs possess three or four times the strength and virtues of the same quantity of the crude *Wine*.

This operation, though it be perfect in regard to *Wines*, yet does not succeed so well in regard to the malt liquors. The experiment has been fairly tried by Stahl on a gallon of strong malt drink, and the success was as follows: The ice separated in the first operation, when thawed by heat, resolved into a liquor of the colour and taste of small beer; and the second concentration afforded an ice of much the same kind, which might have passed for ordinary small beer, but for a flashy watery taste that manifestly predominated in it. The liquor unfrozen was but a pint and half by measure, but it was extremely rich and thick, and seemed very strong and spirituous, and perfectly aromatic, or highly flavoured. The consistence was somewhat like that of a thin syrup, and it had a pleasing softness that sheathed the acrimony of the spirit, and covered the bitter taste of the hop.

The mucilaginous nature which is predominant in all malt liquors, occasions a great inaccuracy in this experiment, as not suffering the water to run clear, or be separated from the richer tincture of the malt, nor letting the condensed liquor be obtained clean from the ice; but as the loss occasioned by this is not great, and the liquor is much cheaper than *Wine*, if this should ever come into use in the large way, the thawed liquor of the ice might be used again in a new brewing, and so the loss of that part of the strength which was carried away by the freezing be recovered.

The phlegm of *Wine*, separated by this operation, when it has not succeeded perfectly well, carries off something also of the flavour and taste of the *Wine*; and this need not be supposed all lost, for this liquor alone will, if strong enough, serve excellently to make vinegar, or if not so much impregnated as to do for that purpose, it will serve the vinegar-makers instead of other water, and be of so much advantage in the process, as fully to make up for the quantity of *Wine* lost.

The frozen part, or ice, consists only of the watery part of the *Wine*, and may be thrown away, and the liquid part retains all the strength, and is to be preserved. This will never grow sour, musty, or mouldy afterwards, and may at any time be reduced to *Wine* of the common kind again, by adding to it as much water as will make it up to the quantity that it was before.

Wines in general may by this method be reduced to any degree of vinosity or perfection. Thus, for example, if a *Wine* of a moderate strength have a third part of its water taken away, in form of ice by congelation, the remaining part will thereby be doubled in strength and goodness: for if we allow, in the better sorts of *Wine*, that one third part, which is near the truth, is truly good or vinous, and two third parts are nothing but water, one third part of the good *Wine* being blended among the two third parts of water, of no strength nor value; it follows, that if one of these third parts of water be taken away, and all the *Wine* left, that which was before but one third *Wine*, is now one half *Wine*, no way reduced in its strength, and therefore the whole must be stronger in that proportion.

But if this operation of congelation be carried to the utmost, and be practised on a large quantity of *Wine*, and with a very intense cold, and the ice taken away several times, and the *Wine*, thus freed from a part of its water, again and again exposed, it will be found that good *Wines* will be reduced to one sixth part of their original quantity; and the vintner will easily find out the use of this remaining sixth part, which is a true quintessence of *Wine*, and will be of the utmost benefit, by mixing in small quantities with poor and low-flavoured *Wines*, to meliorate and improve them; and even to convert the low-flavoured and least valuable ones into those very *Wines* from which this condensed part was procured.

Glauber laboured hard at bringing this sort of thing to bear, and attempted it with what he called the quintessence or essential oil of *Wine*; but this, though prepared ever so curiously from the very finest *Wines*, was never found to answer well on the trial, but retained a nidorous and disagreeable flavour, different from that of the *Wine*. Glauber's method, therefore, which was excellent in theory, is by this method of congelation reduced to practice, and that with little trouble, and the greatest advantage.

The benefit and advantage of this method of congelation, if reduced to practice in the large way, in the *Wine* countries, must be evident to every body. Concentrated *Wines*, in this manner, might be sent into foreign countries, instead of *Wine* and water, which is what is usually now sent, the *Wines* they export being loaded, and in danger of being spoiled by three or four times their own quantity of unnecessary, superfluous, and prejudicial water.

The business is, how to perform the operation, for *Wine*-countries being in general hot countries, the business of freezing will not be so easily carried on there as in the cold ones: but this is an objection easily solved by observing, that in most of the *Wine* countries that we are acquainted with, there are hills and mountains, the tops of which are covered with snow all the year round; and all who are acquainted with natural philosophy, very well know, that where there is snow to be had, there will be no difficulty about freezing.

The difficulty rests therefore not in the matter of freezing, but in the reducing the *Wines*, when thus concentrated, to their due and natural state again; for though the addition of water alone does this in a tolerable manner, yet better means may certainly be found on farther trials. The way of using poor *Wines*, and such as in themselves are of little use or value, is always a good one, and is sufficiently advantageous; because what there is in the price of these above water, is made up to the proprietor in the quantity of the final produce; water could only give the same quantity of the *Wine* that there was originally, and before the condensation; but these *Wines* will bear to be mixed in so much larger a quantity, that the produce will warrant the gaining by the practice.

This method is not practicable to advantage in the *Wine* countries alone. Dr. Shaw assures us, that he has himself experimented it here, and with the use of proper freezing mixtures, has reduced *Wines* in England to a much smaller quantity, in proportion to the whole, than in the strongest of Stahl's experiments. It is evident that, by how much the quantity is smaller, by so much it is richer and stronger, provided that the operation has been properly performed. The Doctor assures us, the noble essence or rob, thus prepared, is capable of working almost miracles, by turning water into *Wine*, and the like; but that, in order to its succeeding well, there requires great care in the operator, when the congelation is repeated the last times. *Shaw*'s Chemical Essays. *Stahl*'s Concentrat. Vin.

Diseases of WINES. All *Wines*, malt liquors, and vinegars, which are well made, and perfect in their kind, will grow fine of themselves, barely by standing; so that if they do not thus grow fine in a reasonable time, it is a sign that they labour under some disease; that is, they are too aqueous, too acid, too alkaline, or they tend to putrefaction, or the like. In all these cases, which may properly enough be called the *diseases of Wines*, suitable remedies are required before the *Wines* will grow fine. The most general remedy hitherto known for all the diseases of *Wines*, is a prudent use of tartarized spirit of *Wine*, which not only enriches, but disposes all ordinary *Wines* to grow fine. *Shaw*'s Lectures, p. 209.

Extemporaneous WINE. A hundred weight of good treacle will produce, according to the art of the distiller, from four to seven gallons of pure alcohol; that is, from eight to fourteen gallons of the common-proof melasses spirit. The still-bottoms have many uses. The distillers scald and recover their musty casks with them, and they may be used for all those purposes of cleansing where argol is required. Mr. Boyle's acid spirit of *Wine*, or a spirit very like it, may also be procured from them, and a matter analogous to what Beccher calls the *media substantia vini*. This liquor gives a durable *extemporaneous Wine*.

Fining of WINES. See the article FINING.

Low WINES, in the distillery, the term for the spirituous liquor distilled immediately from the fermented matter, and continued running so long, that the last of it was not at all inflammable. This liquor is afterwards rectified to a proof-spirit of the strength of brandy, and thence to a rectified spirit, called *alcohol*, or spirit of *Wine*. *Shaw*'s Lectures, p. 216.

WINE *Lees*. The distillation of *Wine lees* into spirit is conducted very much in the same manner with that of the malt-wash, when distilled with the mealy part in it: The principal difference is on this account, that the oil of the malt being very nauseous and disagreeable, the utmost care is to be used to keep it back in all the processes of primary distillation, and of rectification; whereas, on the other hand, the oil of the *Wine* lees being a very agreeable and pleasant one, as much care as possible is to be taken to bring it over with the spirit. Glauber has written a peculiar treatise on this subject, in which, without touching upon the most advantageous production of all, he has proved the work to be so very profitable, that the whole usually passes for one of his wild flights, rather than a solid business.

The method of distilling a liquid lee for its spirit, is a thing very universally known; but the advantageous thing, on this basis, is the distilling a dry lee pressed and preserved, and the managing the business in such a manner as at first or last to procure and separate all its valuable parts. The solid lee, here mentioned, is that usually sold to the hatters in England, and is the same thing that in France and other *Wine* countries the vinegar-makers dispose of in cakes, after they have pressed out all the *Wine*, and which is afterwards burnt, and makes what Lemery and others call *cineres clavellati*; and the English, *gravelled ashes*, a fixed alkali salt-like pot-ash.

This lee, when to be used for distilling, should be that of the French *Wines*, and either such as is newly pressed, or has been well secured by packing in a close manner in tight casks, with some proper contrivance of dry sand, or the like, to keep its

its external ſurface from the contact of the air, which is very apt to corrupt or putrify it.

If this lee is intended to be kept many months, it will be very proper to ſecure it by ſprinkling the layers as they are packed up with a little brandy. The expence of this is nothing, for the brandy is recovered again in the operation.

The eſſential oil of any fermented ſubſtance is always found preſerved in great quantity in the lee or ſediment of the fermented liquor, and in regard to the diſtilling of theſe dry *Wine* lees, the great article is the ſeparating this oil to advantage.

In order to this, the ſolid lee muſt be ſet to ſteep in ſix or eight times its own weight of water, ſtirring the whole well together at times; in this manner the liquor will take up all the lighter and better part of the lee, and will become thick and muddy, the coarſer part of the cakes, which is of leſs value, ſubſiding to the bottom. The thick liquor, without theſe lumps, is to be put into the common ſtill, and the liquor worked off, as in the common way, by the chemiſts, to obtain the eſſential oils of plants. The ſtill muſt be made hot and dewy before the liquor is put in, and the fire afterwards kept well regulated, otherwiſe there will be danger of burning; but the better way to ſecure it is to put ſome looſe ſticks at the bottom of the ſtill.

The oil is thus brought over with the liquor, and is to be ſeparated in the common way, by means of a ſeparating pot placed under the noſe of the worm; but if this oil is deſired to be obtained fine, the pot muſt be ſhifted ſoon, for, after a time, a groſs, reſinous, and much leſs agreeable oil, will mix itſelf with it, and cannot be ſeparated again without great trouble, and a ſecond diſtillation, and that will not ſucceed without great care. *Shaw*'s Eſſay on Diſtillery.

Philoſophic Spirit of WINE, in the writings of ſome chemiſts and phyſicians, a phraſe that often occurs as the name of a liquid prepared from *Wine*, and endued with very remarkable properties.

It is generally ſuppoſed that this was the ſame ſort of liquor which we at this time call by the name of *Spirit of Wine*; but this is a very erroneous opinion, and has led many into errors, about the operations in which it was concerned. It was truly no diſtilled liquor, but the ſpirituous parts of *Wine* condenſed and concentrated by the freezing of the more aqueous part. See the article *Concentrating of* WINE, ſupra.

Pricked WINES. An eaſy method of recovering *pricked Wines* may be learned from the following experiment: Take a bottle of red port that is pricked, add to it half an ounce of tartarized ſpirit of *Wine*, ſhake the liquor well together, and ſet it by for a few days, and it will be found very remarkably altered for the better.

This experiment depends upon the uſeful doctrine of acids and alkalies. All perfect *Wines* have naturally ſome acidity, and when this acidity prevails too much, the *Wine* is ſaid to be pricked, which is truly a ſtate of the *Wine*, tending to vinegar: But the introduction of a fine alkaline ſalt, ſuch as that of tartar, imbibed by ſpirit of *Wine*, has a direct power of taking off the acidity, and the ſpirit of *Wine* alſo contributes to this, as a great preſervative in general of *Wines*. If this operation be dexterouſly performed, pricked *Wines* may be abſolutely recovered by it, and remain ſaleable for ſome time: And the ſame method may be uſed to malt liquors juſt turned ſour. *Shaw*'s Lectures, p. 214.

Saffron WINE, *Vinum Crocatum*. See the article SAFFRON.

WINE-*Spirit*, a term uſed by our diſtillers, and which may ſeem to mean the ſame thing with the phraſe *ſpirit of Wine*; but they are taken in very different ſenſes in the trade.

Spirit of Wine is the name given to the common malt ſpirit, when reduced to an alcohol, or totally inflammable ſtate; but the phraſe *Wine-ſpirit* is uſed to expreſs a very clean and fine ſpirit, of the ordinary proof ſtrength, and made in England from *Wines* of foreign growth.

The way of producing it is by ſimple diſtillation, and it is never rectified any higher than common bubble proof. The ſeveral *Wines* of different natures, yield very different proportions of ſpirit; but, in general, the ſtrongeſt yield one fourth, the weakeſt in ſpirits one eighth part of proof-ſpirit; that is, they contain from a ſixteenth to an eighth part of their quantity of pure alcohol.

Wines that are a little ſour, ſerve not at all the worſe for the purpoſes of the diſtiller, they rather give a greater vinoſity to the produce. This vinoſity is a thing of great uſe in the *Wine-ſpirit*, whoſe principal uſe is to mix with another that is tartarized, or with a malt-ſpirit, rendered alkaline by the common method of rectification. All the *Wine-ſpirits* made in England, even thoſe from the French *Wines*, appear very greatly different from the common French brandy; and this has given our diſtillers a notion that there is ſome ſecret art practiſed in France, for the giving the agreeable flavour to that ſpirit; but this is without foundation. See the article SPIRIT.

When we diſtil Sicilian or Spaniſh *Wines*, we do not produce Sicilian or Spaniſh brandies; and the true reaſon of this is, that the *Wines* which they diſtil on the ſpot into brandy, are very different from thoſe which they export as *Wines*.

Thoſe they diſtil are ſo poor and thin, that they will not keep many months, nor can poſſibly bear exportation. If we had in England thoſe poor *Wines* they diſtil into brandy near Bourdeaux, Cognac, or up the Loire, there is no doubt but the ſpirit we made from them would be univerſally allowed to be French brandy. We have proof of this from ſome of the Scotch diſtilleries, where they, with no peculiar art, or ſecret method, procure from ſome of the poor pricked and damaged *Wines* received there, brandy ſo nearly reſembling that of France, that a good judge will ſcarce be able to make the diſtinction. *Wine-ſpirits* and brandies therefore are the ſame thing, only with this difference, that the former is the product of a rich *Wine*, and the latter of a poor one; or, at the utmoſt, they differ only as our two home products, the cyder-ſpirit and the crab-ſpirit do.

The *Wine-ſpirit*, diſtilled in England, is not eaſy to be had pure and unmixed at our diſtillers, nor under a price almoſt equal to that of French brandy; ſo that if it ever be required out of the trade, it is as well to uſe the French brandy, which will, in all caſes, ſerve the ſame purpoſes, unleſs where a high flavour or a copious eſſential oil are required. All other ſpirits are carefully diveſted of their oil in the rectifications; but the *Wine-ſpirit* is coveted only for its oil, and all that can be obtained is preſerved in this, its principal uſe being to give a flavour to a worſe ſpirit, and to cover the taſte of a diſagreeable oil in it.

When a caſk of *Wine* chances to turn ſour in private hands, it is worth while to diſtil it for the ſpirit. The lees alſo, if in any conſiderable quantity, will yield ſuch a proportion of the ſame ſort of ſpirit, as to render it worth while; and as the high flavour is not required in this intent, it will be beſt to draw off the ſpirit very gently, either by the cold or hot ſtill, and afterwards it may be rectified without any addition, and reduced to the ſtandard ſtrength of proof. It thus makes a very clean and pleaſant ſpirit, though very different from the brandy from the ſame country whence the *Wine* came. *Shaw*'s Eſſay on Diſtillery. See the article SPIRIT.

WINE-*Fly*, in natural hiſtory, the name of a ſmall black fly, found in empty *Wine*-caſks, and about *Wine*-lees, and called by the Latins, *bibio*.

It is produced of a ſmall red worm, very common in the ſediment of *Wine*. See the article BIBIO.

The drippings of *Wine* or beer-veſſels, the preſſings of the *Wine* or cyder-preſs, the pots in which honey has been kept, and in which a little remains ſticking to the ſides, and turning ſour, all afford vaſt numbers of a ſmall ſpecies of worm or maggot. This is of a white colour, and has two hooks placed near the head; in ſhort, it reſembles, in all the parts, the maggot of the common fleſh-fly. Multitudes of theſe ſmall creatures live and move very briſky about in theſe ſubſtances for ſeveral weeks together; but at the end of that time, when they have arrived at their full growth, they enter into the nymph ſtate under a covering or caſe made of their own ſkin, which dries, and becomes of a brown colour. After eight or nine days in this ſtate, the caſe is opened by the falling off of a ſmall piece at the end, and the fly makes its way out. The fly is extremely ſmall when its wings are not extended.

It does not exceed the ſize of the head of a middling pin; it is however very beautiful; the breaſt and body are yellow, the reticulated eyes are red, and the wings have all the rainbow-colours. The beſt way of procuring theſe little flies, which make a very beautiful microſcopic object, is to keep the matter, in which the worms are placed, in a glaſs, covered down with a paper; as ſoon as the cover is taken off, at the time of their being in the fly-ſtate, they riſe up at once in the form of a cloud; enough of them for obſervation will however remain about the ſides of the veſſel. When examined, they are found to have all the regular parts of the larger flies; their antennæ are oval and flatted, and their legs, and every other part, are as elegantly perfect, as they are ſeen to be in the moſt elegant large fly.

It is not known whether they are oviparous or viviparous; but this is to be obſerved, that they give us great light into the origin of animalcules in different fluids. Theſe are a ſpecies of winged inſect, ſo ſmall as ſcarce to be viſible as they fly, and to theſe we owe the worms in the four ſubſtances before-deſcribed, though we know not how or when they depoſit them there. Theſe maggots or worms are of the number of thoſe animals, ſuppoſed by the vulgar to be produced of corruption. Snce we ſee in theſe the evident courſe of nature in their origin, what prevents but that there may be numbers of flies yet ſmaller than theſe, whoſe eggs may be depoſited in the fluids in which we find our microſcopic animalcules. *Reaumur*'s Hiſt. Inſ. vol. 9. p. 81.

WING, (*Cycl.*)—*Wings*, among the fly-claſs, afford ſeveral ſubordinate diſtinctions of the genera of thoſe animals, under the antient general claſſes.

Several ſpecies of flies, while they are in a ſtate of reſt, or only walking, ſhew ſeveral regularly diſtinct manners of carrying their *Wings*. The much greater number, however, carry them in a parallel or plain poſition. Among thoſe who carry them thus, ſome have them in form of a ſort of oars, their direction being perpendicular to the length of the body, which is not at all covered by them. This is the caſe in many of the libellæ, and of the tipulæ.

Others carry their *Wings* in this manner, ſo as that they cover a part of the body, without at all covering one another.

Among the two-winged flies, the great blue fleſh-fly, and the common fly about houſes, give us inſtances of this.

The *Wings* of others croſs one another on the body of the creature, and the degrees in which they cover one another, give occaſion to ſeveral other ſub-diſtinctions; for ſome of them over-hang on each ſide the body of the animal, while others croſs one another, in ſuch a manner as not to cover the body of the fly entirely, but leave a rim of it viſible and uncovered on each ſide of them. Some of the flies bred of water-worms have their *Wings* in this manner.

Others have their *Wings* thus diſpoſed, but croſſing one another only in a part of their ſurface, and that at their extremities; ſo that though they there cover the body of the fly, they leave a portion of the anterior part of the body naked.

The *Wings* of other flies not only croſs one another on the body of the animal, but they round themſelves there; theſe are not exactly parallel in their ſituation, but the upper *Wing* is more elevated on the middle of the body than on the ſides.

Some flies have their *Wings* placed upon their backs, and applied againſt one another. Theſe are in a perpendicular poſition; and ſeveral of the ſmaller ſpecies of libellæ, and winged pucerons, are of this ſort; as are alſo the ephemerous, or day-flies.

The *Wings* of other flies are applied obliquely againſt their ſides, and meet above the body by their inner edges; theſe form, by their junction above, a kind of hollow roof, under which the body is placed. The flies produced from the puceron-eater, and the formica-leo, are of this kind. *Reaumur*'s Hiſt. Inſ. Tom. 4. p. 136.

Other flies have their *Wings* thus applied to their ſides, and, inſtead of riſing erect, bending themſelves at their meeting upon the creature's back, and forming a flat depreſſed roof over the body. Of this kind are the *Wings* of many of the flies produced from water-worms. Ibid. p. 137.

And finally, there are ſome of the flies which carry their *Wings* in an oblique direction, but have them meeting under their bellies. Theſe are placed exactly contrary to thoſe which form a kind of high roof over the creature's back; and of this kind are the *Wings* of that elegant fly which is produced from the cherry-worm.

The ſtructure of the *Wings* of different flies might alſo furniſh matter of farther diſtinctions. The greater part of them are of a fine ſtructure, and repreſent the fineſt gauſe, and are equally tranſparent, or nearly ſo in all parts. Some flies, however, have *Wings* of a leſs degree of tranſparence, and ſome even opake ones [a]. Others of the four-winged flies have obſcure ſpots alſo diſtributed near their very tranſparent texture; ſuch are the wings of the ſcorpion-fly; and ſome of the two-winged flies have *Wings* partly opake, partly pellucid, the opake ſpots being ſeparated by tranſparent lines [b].—[[a] Ibid. p. 137. [b] Ibid. p. 138.]

WINGS *of Butterflies*. The beautiful *Wings* of this genus of inſects, are diſtinguiſhed from thoſe of the fly-kind, by their not being thin and tranſparent, like them, but thicker and opake. This opacity in them is owing only to the duſt which comes off of them, and ſticks to the fingers in handling them, and it is alſo to this duſt that they owe all their beautiful variety of colours. The earlier naturaliſts, for this reaſon, diſtinguiſhed theſe inſects by the appellation of ſuch as had farinaceous *Wings*. *Reaumur*'s Hiſt. Inſ. vol. 1. P. 1. p. 282.

The uſe of the microſcope has taught us, that this duſt is not the reſult of ſome other ſubſtance broken into fragments; but every particle of it is a regularly figured body, made for the place and order it has in the covering of the *Wing*.

The ſeveral ſpecies of butterflies, and even the different parts of the ſame *Wing*, afford theſe bodies of different ſhapes and figures. Moſt of the authors who have written of microſcopic objects, have given the figures of the principal varieties of theſe; but no one has given ſo many as Bonani in his Micrographia, in which work the figures of the various kinds take up four quarto plates.

It has been the general cuſtom of authors to call theſe feathers; but they are by Mr. Reaumur, with much greater juſtice, called ſcales. Their ſtructure has no reſemblance to that of feathers, for they are little flat and thin bodies, of more or leſs length, and always having a ſhort pedicle which enters into the ſubſtance of the *Wing*. That part of the ſcale from which this pedicle is propagated, is rounded in moſt caſes, and very frequently the other end is rounded alſo. The whole ſcale therefore in theſe becomes of an oval figure. Others have a little dent in the middle of the end, oppoſite to the pedicle, by which they are made to reſemble the ſhape of a heart at cards, and many of them are not abſolutely flat, but are more or leſs hollowed on the under ſide: And the ends, which are in ſome plain and ſtrait at the edges, are in others indented or jagged, and in ſome cut into ſmall and elegant ſegments.

The indentings of ſome are but few in number, and theſe reſemble the fingers of a hand ſpread open, the body of the ſcale repreſenting the palm; in ſome, theſe fingers terminate in ſharp points, in others they are more obtuſe, and in ſome there are only three of theſe to each ſcale; in others there are as far as eight; ſome are regular triangular blades, and have their baſe very ſhort, in compariſon to the length of the ſides; but this is variouſly cut and indented in all the manners before ſpoken of. In ſome theſe jags at the end ſeem propagated all along the ſcale, and form in it ſo many ridges, elevated above the reſt of the ſurface on the upper ſide, and hollowed on the under. Thoſe which have theſe elongated ridges, have uſually alſo a rib running down the middle through their whole length, as the leaves of plants have, and the pedicle is in theſe ſcales as in the leaves of vegetables, only an elongation of this middle rib.

Beſide theſe, which are the more uſual figures of the feathers or ſcales of the *Wings* of butterflies, there are ſome others extremely different, and which neither Bonani, nor any other author has given the figures of till Reaumur. Theſe have leſs title to the appellation of ſcales than any of the others, and at firſt ſight might ſeem indeed to have none at all. Their pedicle is ſo long and ſlender, that they might be miſtaken for hairs; but that each of them is terminated by a ſmall flat plate, which is ſplit a little way down the middle, and in all reſpects reſembles the ſcales before deſcribed, which adhere to their ſhort pedicles. There are, however, ſome of this laſt kind, which can by no means be called ſcales. What, in thoſe deſcribed above, is a flat plate placed at the end of a very long and ſlender pedicle, is, in theſe, only a diviſion of the extremity of the long capillary pedicle, into four or five parts, which have not breadth enough to entitle them to the name of ſcales. *Reaumur*'s Hiſt. Inſ. vol. 1. P. 1. p. 255.

The diſtinction in names in theſe matters, is abſolutely neceſſary, and the calling theſe bodies, uſually termed feathers, ſcales, cannot well be avoided by an accurate obſerver, becauſe there are, in ſome of the butterflies, ſome parts which are covered with real feathers, ſome other parts have only hairs, and ſome others ſcales; all theſe have been called feathers by ſome; but they are ſo different in themſelves, that they well deſerve different denominations. Beſide all theſe, ſome parts of ſome of theſe creatures are beſet with real prickles, and ſometimes even the ſame part, in the ſame animal, is jointly covered with all theſe ſeveral ſorts of inveſtures. When the *Wing* of a butterfly is viewed by a microſcope, the arrangement of theſe ſeveral bodies in it is ſeen to be extremely beautiful and regular. The ſcales lie as regularly and evenly one over another, as the tiles on a houſe, or the ſcales on the fiſh-kind, every ſeries of them covering a ſmall part of that ſeries which runs below it. The upper and under part of the *Wing* are equally furniſhed with theſe, and there is no ſpecies of this creature, in every *Wing* of which there are not ſeveral figures of theſe ſcales in ſeveral parts: But the greater part of the ſurface, a little diſtant from the edges, has only one ſort in moſt ſpecies. But this kind is different in the ſeveral ſpecies; in ſome we only find the plain oval ones, in others the cordated, and in others thoſe which are divided at the end, in the manner of the fingers of a hand. In other ſpecies the *Wings* make a leſs elegant appearance, though more loaded with theſe ſcales; for the ſeveral ſeries of the beautiful ſorts of ſcales which have been before deſcribed, are in theſe buried under other very thick ſeries of thoſe which have long capillary ſtems, and appear only like ſo many hairs. The extremities of the *Wings* of theſe inſects appear to the naked eye as if bordered with a ſort of fringe; but, when examined by the microſcope, this fringe appears to be compoſed of a number of oblong ſcales, of the nature of thoſe triangular ones before-deſcribed, which have very narrow ends, in proportion to the length of the ſides, and theſe ends are variouſly fingered.

The ſtructure of the *Wing* itſelf, which ſupports theſe ſeveral ſcales, hairs, *&c.* is very worthy our attention. In order to examine this, it is neceſſary to rub off all the duſt or ſcales. We then find that the *Wing* itſelf is framed of ſeveral large and ſtrong ribs, which all take their origin at that part where the *Wing* is fixed to the body, and thence extend themſelves along the ſeveral ſides of the *Wing*. The largeſt and thickeſt of theſe ſurrounds the outer edge of the *Wing*, the largeſt next to this extends itſelf round the interior edge, and the others direct their courſe along the middle of the *Wing*, and then divaricate and become ramified in the manner of the ribs in the leaves of plants. The ſubſtance which connects and fills up the ſpaces between theſe ribs, is of ſo peculiar a nature, that it is not eaſy to find any name to deſign it by, at leaſt there is no ſubſtance that enters the compoſition of the bodies of the larger animals, that is at all analogous to it: It is a white ſubſtance, tranſparent and friable, and ſeems indeed to differ in nothing from that of the large and thick ribs, but in that it is extended into thin plates; but this is ſaying but little toward the determining what it really is, ſince we are as much at a loſs to know by what name to call the ſubſtance they are compoſed of. Malpighi indeed calls them bones; but though they do ſerve in the place of bones, rendering the *Wing* firm and ſtrong, without making it heavy, and are, when cut tranſverſely, found to be hollow; yet, when ſtrictly examined, they do not appear to have any thing of the ſtructure of bones, but appear rather of the ſubſtance of ſcales, or of that ſort of imperfect ſcales, of which the covering of thoſe inſects which we call cruſtaceous is compoſed. *Reaumur*'s Hiſt. Inſ. vol. 1. P. 1. p. 259.

Be this ſubſtance however what it will, it admirably ſerves the office nature ſeems to have intended it for, making the *Wings* at once very light and very firm; and the millions of ſmall

and

and flat ſcales which cover them, ſcarce at all increaſe the weight, and yet make an admirable defence for the middle part, where it is extended into thin plates between the ribs. In examining this part more narrowly, we find that it is traverſed in all parts by a number of furrows or lines running from rib to rib, each marked with a vaſt number of duſky-coloured points or ſpots. Mr. Reaumur compares theſe to the ridges and holes in the common papers on which pins are kept, and obſerves, that theſe little duſky ſpots are the holes which receive the ſtems or pedicles of the ſeveral ſeries of ſcales. This is diſtinctly ſeen by the microſcope, as the *Wing* is never wholly cleared of the ſcales; and the few which remain ſingly in their places, always fill up ſome of the holes or obſcure points in theſe ſeveral ſeries.

The *Wings* of butterflies, thus large, and thus light, are very well able to ſuſtain them a long time in the air, and thus might be expected to fly better than moſt other inſects; but many people have obſerved the irregular manner in which theſe inſects uſually fly, which is not ſtrait forward, but up and down, and to one ſide and the other: this has been ſuppoſed owing to ſome imperfection of the *Wings*; but, in reality, it is their great perfection that enables the creature to do this, and this manner of flying is abſolutely neceſſary to the preſerving their life, as birds of many kinds are continually after them while they are on the *Wing*; and it is a pleaſant ſight to obſerve, in what manner this ſort of dodging motion in the butterfly diſappoints the bird that flies ſtrait at it, and often preſerves it ſafely for a long way together.

All the beautiful variety of colours, which we ſee on the *Wings* of theſe inſects, is owing to the ſcales and feathers. The ſubſtance of the *Wing* is tranſparent, and of one uniform and duſky-whitiſh colour; this however is wholly hid by the ſcales planted on it, and is like the earth in a meadow, covered with a profuſion of flowers of various ſorts and colours. Certain parts of the *Wings* of ſome ſpecies have only blue ſcales, other parts only purple, and others only yellow, and ſo on, in the different ſpecies of different colours, a fine deep black and a pearly white being two very common colours in them, and capable of producing a fine variety in the ſhadowing: And as theſe arrangements of coloured ſcales are diſpoſed with a beautiful regularity, they give us all the appearances of clouded veins and eyes that we ſee. *Reaumur*'s Hiſt. Inſ. vol. 1. P. 1. p. 260.

WINGS *of Gnats*. Theſe are of a very curious ſtructure, and well worthy the uſe of the microſcope, to ſee them diſtinctly.

It is well known, that on touching the *Wings* of butterflies, a coloured powder is left on the fingers, which, though to the naked eye it appear a mere ſhapeleſs duſt, yet when examined by the microſcope, it is found to be very regularly figured beautiful bodies, in form of feathers and ſcales: Theſe are of various figures, and all of them very elegant. The generality of flies have nothing of this kind; but the cloſe examination of the *Wings* of the gnat will ſhew, that they are not wholly deſtitute of them; they are much more ſparingly beſtowed indeed upon the gnat than on the butterfly; but then they are arranged with great regularity. *Reaumur*'s Hiſt. Inſ. vol. 4. p. 577.

The *Wings* of the gnat, like thoſe of moſt other inſects, are of a cartilaginous ſubſtance; friable, and tranſparent as a flake of talc, and the circumference, and many parts of the inner ſtructure of the *Wing* are ſtrengthened by ſlender but firm ribs, which are divaricated into ſeveral ramifications. Theſe appear to us to be mere ſtrait fibres; but they are probably hollow, and perform the office of veſſels, for carrying the fluids or air neceſſary to the ſupport of the *Wing*, as well as to ſtrengthen it. In the *Wings* of butterflies there are ſimilar ribs, but they are there all hid by the ſcales; but it is not ſo in the gnat, for in its *Wings*, as in thoſe of the other flies, theſe ribs ſeem naked.

The aſſiſtance of the microſcope ſhews, however, that they are not abſolutely ſo in the *Wings* of gnats; but theſe nerves or ribs, with their ſeveral ramifications, look like ſo many ſtalks of a plant covered with ſmall oblong leaves. The ſeveral ſcales that are attached to theſe ribs, make acute angles with them, and are directed toward the end of the *Wing*.

The number of theſe ſcales is very ſmall in compariſon with that of the butterfly-claſs; but they make a ſlighter and more elegant ornament. There are ſome ſpecies which have the intermediate ſpaces of the *Wing* adorned alſo with theſe ſcales; but they are in theſe but thinly ſcattered. The intermediate ſpaces of the *Wings*, when they have no ſcales, are finely wrought and pointed, and the innner edge of the *Wings* is always bordered with a row of ſcales in form of a fringe, which, in ſome ſpecies, is compoſed of ſcales all of the ſame equal ſize, and in others is made up of many of very various lengths; and the exterior edge of the *Wing*, which is ſurrounded by a rib much thicker and ſtronger than the interior, is not fringed with a ſeries of ſcales, but is beſet, at certain diſtances, with a ſort of long prickles. Ibid. p. 578.

The ordinary ſhape of the ſcales of the gnats *Wings*, is that of an oblong battledoor, one end of which is broader, and the other more pointed. The narrower end is that from which goes the ſtalk by which it adheres to the rib. The other end is ſometimes more, ſometimes leſs round, and is ſometimes a little hollowed in the middle. Some of theſe ſcales are much longer in proportion to their breadth than others, and ſome of them have their extremity formed into an open creſcent. All have a number of fine lines running longitudinally through the whole ſcale. Ibid. p. 579.

Gooſe-WING, at ſea. See the article GOOSE-*Wing*.

WINTER (*Cycl.*)—WINTER-*Heyning*, in our ſtatutes, a ſeaſon between the eleventh day of November, and the three-and twentieth of April, which is excepted from the liberty of commoning in the foreſt of Dean, *&c.* Stat. 20 Car. 2. c. 3. *Blount*.

WINTERANUS *Cortex*, in botany, a name given to the wild cinnamon-tree, the characters of which are theſe: The trunk is about the thickneſs of one's thigh, riſing to about twenty or thirty foot high, having many branches and twigs hanging downwards, making a very comely top. The bark conſiſts of two parts, *viz.* outward and inward. The outward bark is thin as a milled ſhilling, of a whitiſh-aſh or grey colour, with ſome white ſpots here and there on it, and ſeveral ſhallow furrows of a darker colour, running variouſly through it, and making it rough; its taſte is aromatic. The inward bark is much thicker than cinnamon, being equal in thickneſs to a milled crown-piece, ſmooth, of a whiter colour than the outward, of a much more biting and aromatic taſte, ſomething like that of cloves, and not glutinous like cinnamon, but dry and crumbling between the teeth. The leaves come out near the ends of the twigs, without any order, ſtanding on inch-long foot-ſtalks; they are each of them two inches long, and one inch broad near the end where broadeſt, and roundiſh, being narrow at the beginning, and thence increaſing in breadth to near its end, of a yellowiſh green colour, ſhining and ſmooth, without any inciſſures about its edges, and ſomewhat reſembling the leaves of bay or *laurocerafus*. The ends of the twigs are branched into bunches of flowers, ſtanding ſomething like umbels, each of which has a foot-ſtalk, on the top of which is a calyx made up of ſome foliola, within which ſtand five ſcarlet or purple petala, and within them is a large ſtylus. To theſe follow ſo many cauliculated berries, of the bigneſs of a large pea, roundiſh, green, and containing within a mucilaginous pale green, thin pulp, four black ſhining ſeeds, or acini, of an irregular figure.

All the parts of this tree, when freſh, are very hot, aromatic, and biting to the taſte, which is ſo troubleſome as ſometimes to need a remedy from fair water. It grows in the low-land, or Savanna-woods in Jamaica, Antigua, and the other Caribbee Iſlands.

The bark of this tree is what is chiefly in uſe, both in the plantations of the Engliſh between the tropics, in the Weſt Indies, and in Europe, and is, without any difficulty, cured by only cutting off the bark, and letting it dry in the ſhade.

The people of the Weſt Indies uſe it inſtead of all other ſpices, being thought very good to conſume the immoderate humidities of the ſtomach, help digeſtion, expel wind, *&c.*

It is likewiſe, as well there as in Europe, thought a very good remedy againſt the ſcurvy, and to cleanſe and invigorate the blood, being, among the apothecaries and druggiſts of London, uſed for thoſe purpoſes under this name, though differing from the true *Cortex Winteranus*, as may appear from the deſcriptions of both; but may very well ſupply its place. Phil. Tranſ. N°. 192. See the article CORTEX, *Cycl.*

WIOCHIST, among the Indian natives of Virginia, is their prieſt, who is alſo generally their phyſician; and is the perſon in the greateſt honour amongſt them, next to their king, or great war captain. Phil. Tranſ. N°. 454. Sect. 1.

WIRE (*Cycl.*)—Iron *Wire* is made from ſmall bars of iron, which are called *oſleom iron*, which are firſt drawn out to a greater length, and to about the thickneſs of ones little finger, at a furnace, with a hammer gently moved by water. Theſe thinner pieces are bored round, and put into a furnace to aneal for twelve hours. A pretty ſtrong fire is uſed in this operation.

After this they are laid under water for three or four months, the longer the better; then they are delivered to the workmen, called *rippers*, who draw them into *Wire* through two or three holes. After this they aneal them again for ſix hours, and water them a ſecond time for about a week, and they are then delivered again to the rippers, who draw them into *Wire* of the thickneſs of a large packthread. They are then anealed a third time, and then watered for a week longer, and delivered to the ſmall *Wire*-drawers, called *overhouſe-men*.

In the mill where this work is performed, there are ſeveral barrels hooped with iron, which have two hooks on their upper ſides, on each whereof hang two links, which ſtand acroſs, and are faſtened to the two ends of the tongs, which catch hold of the *Wire*, and draw it through the hole. The axis on which the barrel moves does not run through the center, but is placed on one ſide, which is that on which the hooks are placed, and underneath there is faſtened to the barrel a ſpoke of wood, which they call a *ſwingle*, which is drawn back a good way by the cogs in the axis of the wheel, and draws back the barrel, which falls to again by its own weight. The tongs hanging on the hooks of the barrel are by the workmen faſtened to the end of the *Wire*, and by the force of the wheel,

the hooks being pulled back, draw the *Wire* through the holes.

The plate in which the holes are is iron on the outſide, and ſteel on the inſide; and the *Wire* is anointed with train oil, to make it run the eaſier. *Ray*'s Engliſh Words, p. 133.

WIRES *of Aſteriæ*, in natural hiſtory, a name given by authors to a ſort of extraneous foſſil belonging to the Aſteriæ, and being a ſort of branches from the body of that column. See the article ASTERIA.

WIRE *of Lapland*. The ſavage inhabitants of Lapland have a ſort of ſhining ſlender ſubſtance in uſe among them on ſeveral occaſions, which is much of the thickneſs and appearance of our ſilver *Wire*, and is therefore called by thoſe who do not examine its ſtructure or ſubſtance, *Lapland-wire*.

The people of this miſerable country find many uſes in every thing nature has afforded them, and, among the reſt, that ſpecies of ſtag called the rein-deer, which is the moſt frequent animal among them, is not only ſerviceable in furniſhing them with meat, cloaths, houſes, and the means of carriage and travelling; but its bones make many of their moſt neceſſary utenſils; and the ſinews, which are all carefully ſeparated in the eating, are, by the women, after ſoaking in water, and beating, ſpun into a ſort of thread, which is of admirable fineneſs and ſtrength, when wrought to the ſmalleſt filaments; but when larger, is very ſtrong, and fit for the purpoſes of ſtrength and force. Their *Wire*, as it is called, is made of the fineſt of theſe threads, covered with tin. The women do this buſineſs, and the way they take is to melt a piece of tin, and placing at the edge of it a horn with a hole through it, they draw theſe ſinewy threads, covered with the tin, through the hole, which prevents their coming out too thick covered. This drawing is performed with their teeth, and there is a ſmall piece of bone placed at the top of the hole, where the *Wire* is made flat, ſo that we always find it rounded on all ſides but one, where it is flat.

This *Wire* they uſe in embroidering their cloaths as we do with gold and ſilver; and they often ſell it to ſtrangers, under the notion of its having certain magical virtues. *Scheffer*, Hiſt. Lapland.

WIT-*Fiſh*, in zoology, a name given by the Dutch in the Eaſt Indies to a fiſh common on thoſe coaſts, and ſeeming to be of the tænia kind. It is of the ſize of our common whiting. Its back is ſtrait and even, and its belly prominent. Its ſnout is pointed ſomewhat upwards, and its tail forked. It has one ſingle ſpine or prickle on its back, and has a long belly-fin reaching from the head to near the tail. Its whole body is ſtriated, and it has two long filaments or beards hanging from its ſnout, and is a very fine and delicate fiſh. *Ray*'s Ichthyography, Append. p. 6.

WIT-*Fiſh* is alſo the name given by the Dutch to an Eaſt Indian fiſh, of the herring kind, caught in great plenty near the ſhores in many places, and called by Mr. Ray, *albula-Indica*. *Ray*'s Ichthyogr. Append. p. 3. See the article ALBULA-*Indica*.

WITCHES *Butter*, a name given by the common people of England to a ſort of tremella growing on the bark of old trees, in form of a corrugated membrane. See the article TREMELLA.

WITCH-*Craft* (*Cycl.*)—The old laws made in England and Scotland againſt conjuration and *Witch-craft* are repealed by a late ſtatute, and no perſon is to be proſecuted for any ſuch crime, 9 Geo. 2. c. 5. Sect. 1, 2, & 3.

But pretenders to *Witch-craft*, or to tell fortunes, or to any crafty or occult ſcience to diſcover ſtolen goods, may be impriſoned for a year, put in the pillory, and bound over to their good behaviour. Ibid. Sect. 4.

WITHERS, (*Cycl.*) that part of a horſe where the mane ends, being joined to and ending at the tip of the ſhoulder-blades.

Theſe parts ſhould be well raiſed and pretty ſtrong, for this is a ſign of ſtrength and goodneſs in the horſe. They keep the ſaddle from coming forward upon the horſes ſhoulders and neck, which immediately galls and ſpoils him. A hurt in this part is very difficult to cure, and, for this reaſon, they ſhould be lean rather than fleſhy, as they are then leſs ſubject to be bruiſed and hurt by the ſaddle.

When there are ſores on the *Withers*, the cauſe muſt be looked to, in order to determine a proper cure, and prevent a return.

If the hurt be cauſed by the largeneſs of the ſaddle-bands, provided that it be not too great, it may eaſily be cured by the following remedy: Take the whites of ſix eggs, beat them with a piece of alum as big as an egg for a quarter of an hour, or till the whole is reduced to a thick ſcum or froth; let the ſwelling be rubbed well with this mixture, and then covered over with more of the froth; this is to be left to dry on, and the application is to be repeated every ten or twelve hours; notwithſtanding that the heat and ſwelling remains, this, by degrees, will take place, though not at firſt.

If the hurt be great, recourſe muſt be had to bleeding; and this may be repeated after two days, if the ſwelling and inflammation continue.

If a tumour, with great inflammation, follow a bruiſe with the ſaddle-bows, the part affected is to be rubbed with lime-water, and covered with a lamb's ſkin, the woolly part next the back: after the waſhing, the ointment, well known among our farriers by the name of the *Duke's ointment*, is to be applied; and if the tumour inclines to ſuppurate, the ointment muſt be waſhed off with a mixture of vinegar and water warmed, mixed with a handful of ſalt to every quart of it: an ointment is then to be made of half a pound of populeon, and a quarter of a pound of black ſoap, and as much honey: theſe are to be thinned with a large glaſs of ſpirit of wine, and the part is to be well rubbed with ſome of this three or four times a day, covering it afterwards with a lamb's-ſkin. Some uſe, inſtead of this ointment, a pultice made of powder of cummin-ſeed, linſeed-oil, and pigeons-dung, which does as well.

WITHERS *of the Bow of a Saddle*, in the manege. See the article BOW.

WITHER-*Band*, in the manege, a band or piece of iron laid underneath a ſaddle, about four fingers above the withers of the horſe, to keep tight the two pieces of wood that form the bow.

WITHER-*Wrung*, in the manege. A horſe is ſaid to be *Wither-wrung*, when he has got a hurt in the *Withers*; which ſort of hurts are very hard to cure. See the article WITHERS, *ſupra*.

WITTENA-*Gemot* (*Cycl.*)—In the Saxon times this was the chief court of the kingdom, where all matters, both civil and criminal, and thoſe relating to the revenue, were determined. In civil and criminal matters, it was a court, in the firſt inſtance only, for facts ariſing in the county where it ſat; but it heard and determined cauſes from all other counties, by way of appeal. *Lambard*, Archaionom. 57, 239, 245. Mirror, c. 5. Sect. 1.

To this court were ſummoned the earls of each county, and the lords of each leet, as alſo the repreſentatives of towns, who were choſen by their burgeſſes. *Lambard*, Archaionom. 239.

WITWALL, a common Engliſh name for the great ſpotted wood-pecker, the *picus varius major* of authors. See the article PICUS.

WOAD, *Iſatis*, in botany. See the article ISATIS.

This uſeful plant makes a very conſiderable article in trade, and is in many parts of the kingdom propagated to very great advantage.

It requires a dry and warm ſoil, which ſhould have lain quiet for ſome time before. The land it is ſown on muſt be laid very even, and all the clods and large ſtones taken away. It is to be ſown in the latter end of July, ſoon after the ſeed is ripe. It will come up in Auguſt, and muſt then be houghed, leaving the plants about ten or twelve inches aſunder, that they may be ſtrong, and produce the larger leaves. It is never ſown more than two years upon the ſame land, becauſe it robs it greatly. It is ripe for the cutting at different ſeaſons, according to the dryneſs or moiſture of the weather; but when the leaf is full grown, and of a fine green colour, it is known to be fit for uſe, and is to be cut immediately, leſt it ſhould turn pale by ſtanding.

Good *Woad* will yield five or ſix crops in a plentiful year, and very ſeldom gives leſs than three or four. The two crops firſt cut are always the beſt, and theſe are not to be mixed among the after-cuttings.

An acre of ground uſually yields, one year with another, about a ton, which ſells, according to its goodneſs, for from ſix pounds to thirty. *Miller*'s Gardeners Dict.

According to Mortimer, the proper ſoil for this uſeful plant is a warm and rich land, and the longer it has lain unploughed the better, for the *Woad* requires a great deal of nouriſhment. It will do very well on ſandy and gravelly ſoils, if they are of a good depth, and have rich mould among them.

When land is too rank for corn, nothing can prepare it for this crop better than *Woad*, abating the too great fertility of it. The land where it is to be ſowed muſt be laid very level, and the clods all broken. The time of ſowing it is from the beginning to the middle of February. It muſt be kept conſtantly weeded; but if it come up ſtrong, it will need the leſs trouble of this kind, as it will kill the weeds of itſelf. The plant muſt be gathered when the leaves are fully grown, and have not yet loſt their colour. What grows in winter is of no uſe as *Woad* for the dyers, but it is an excellent food for ſheep. If the ground be dry, it muſt be watered for a day or two before the ſeed is ſown, otherwiſe it does not ſucceed well.

It is remarkable of *Woad*, that it requires a peculiarity of climate to bring it to its perfection, and make it fit for the dyers uſe; and that in many places where it ſeems to grow vigorouſly, it yet never ripens this juice, which is its only value, to any degree of colour.

The French cultivate this herb in as large quantities as we do in England, and have tried in many provinces; but they find it fail in ſeveral of them. In upper Languedoc it arrives at a very great degree of perfection, and its leaves are very large and ſucculent, and furniſh a blue colour, very uſeful in dying ſtuffs of all kinds; but in Normandy, where there is much land proper to cultivate it on, it has been often tried with all the advantages of manure and huſbandry; but the want of a ſufficient degree of heat will not ſuffer it to arrive at perfection. Its leaves, tho' as large as thoſe of the Languedoc *Woad*, are never ſo thick or ſucculent, and the colour they afford is

ſmall

ſmall in quantity, and of a duſky-browniſh hue, that renders it little regarded. Trait. Phyſ. de *Deſlandes*.

Though *Woad* gives a blue dye, yet it is uſed to prepare cloth for green and many other colours, when they are deſigned to be permanent, and not to fade. *Boyle*'s Works abr. vol. 1. p. 169.

Beſide the plant properly ſignified by the name *Woad*, which dyes a blue colour, we have two others known in our Engliſh herbals under this name, as alſo that of *wold* or *weld*. Theſe are both called by the common people *dyer's weed*, and are the *luteola* and the *geniſta tinctoria*.

The antients confounded all theſe three plants alſo under the ſame names. Paulus Ægineta ſeems to make them all the ſame plant; and Neophytus, ſpeaking of the *iſatis*, or our *Woad*, properly ſo called, ſays, that it was called by the Latins, *lutum*. This *lutum* has been by ſome underſtood to mean the *luteola*, and by others the *geniſta tinctoria*; but the latter opinion only is right, for it is deſcribed to us by the antients as having leaves like the *linum*, or flax, and flowers like the broom.

WOLF, *Lupus*, in zoology. See the article LUPUS.

WOLF, in the hiſtory of inſects, the name of a ſmall white worm or maggot, which infeſts granaries, and does very great damage there.

It is in this ſtate of the worm that it does the miſchief; but this is not its perfect form, for it is afterwards transformed into a ſmall moth, with white wings ſpotted with black.

This little maggot has ſix legs, and as it creeps along, there iſſues from its mouth an extremely fine thread or web, by which it faſtens itſelf to every thing it touches, ſo that it cannot fall. Its mouth is furniſhed with a pair of reddiſh forceps, or biting inſtruments, by means of which it gnaws its way not only into wheat and other grain, but perforates even beams of wood, boxes, books, and every thing it meets with.

Toward the end of ſummer this pernicious inſect may be ſeen crawling up the walls of corn-chambers, infeſted with them, in great numbers; they are then ſearching a proper place where they may abide in ſafety during their aurelia-ſtate; for when the time of their undergoing this change approaches, they forſake their food, and the little cells they had formed of hollowed grains of corn clotted together, by means of the web coming from their mouths. They now wander about till they find ſome wood, or other ſubſtance, to their mind, into which they gnaw holes with their phangs, capable of concealing them; and there enveloping themſelves in a covering of their own ſpinning, they ſoon become a dark coloured ſort of aurelia. They remain in this ſtate all the winter; but in April or May they come forth in their moth-ſhape, and are then ſeen in vaſt numbers taking ſhort flights, and creeping up the walls. In this ſtate they eat nothing; but they ſoon copulate and lay eggs, which are in the ſhape of a hen's egg, but no larger than a grain of ſand. Each female lays ſixty or ſeventy eggs, which ſhe depoſits in the little wrinkles of the grains of corn, where in about ſixteen days they hatch, and the minute maggots immediately perforate the grain, and eat out all its ſubſtance, and with the threads which come from their mouths cement other grains to it, which they, in the ſame manner, ſcoop out and deſtroy.

The watchful obſerver has two opportunities of deſtroying theſe devourers from among his corn. One is, when they forſake their food, and aſcend the walls, which they will ſometimes almoſt cover. The other, when they appear in the moth-ſtate. At both theſe times they may be cruſhed to death againſt the walls in great numbers, by clapping ſacks upon them: but they may be exterminated more effectually by cloſing up all the windows and doors, and burning brimſtone on a pan of charcoal, letting the room be full of the fumes of it for twenty-four hours. This certainly deſtroys the animals, and does no ſort of injury to the grain, not communicating the ſlighteſt ſcent to it. *Baker*'s Microſcope, p. 222.

WOLF-*Fly*. See the article LUPUS.

WOLF-*Spider*. See the article LUPUS.

WOLF-*Net*, a term uſed by the ſportſmen for a kind of net uſed in fiſhing, which takes great numbers, and has its name from the deſtruction it cauſes.

It is uſed both in rivers and ponds, and is of the nature of the rattle, excepting only the wanting the four *Wings*. The trunk or coffer conſiſts of ſeven feet, beſide the two gullets. It is ſupported by hoops, and is to be placed in ſome part where there is an abundance of ſedges, ruſhes, and water-graſs. There is to be a place made for the net here, by the uſe of a paring-knife, cutting away all the weeds and other matter, for the ſpace that will contain it; and when the net is placed, there are to be two allies cut or cleared in the ſame manner, one on each ſide of the net, that the fiſh may be invited into them, and by them into the net. There muſt be ſome ſtones or leaden weights uſed to ſink the net, and a long pole faſtened to the upper part of the mouth of it, by means of which, when it is well filled with fiſh, it may be lifted up and taken to the ſhore.

WOLF-*Tooth*, a term uſed by our dealers in horſes to expreſs an inconvenience that creature is ſubject to, in regard to its teeth.

There are uſually two of theſe *Wolves*-teeth, which are ſmall, and grow in the upper jaw, next to the great grinding teeth: theſe are ſo tender and painful, that the horſe cannot chew its meat, but is forced to let a great part of it fall out of his mouth, or to ſwallow it half chewed.

The remedy, in this caſe, is to tie up the horſe's head to ſome part of the rafter, and open his mouth with a cord, then with an inſtrument like a carpenter's gouge, and a mallet, the teeth that are thus troubleſome are to be knocked out, and the holes filled up with ſalt.

If the upper-jaw teeth hang over thoſe of the under jaw, and by that means cut the mouth, the ſame inſtrument is to be uſed, and the teeth are to be pared ſhorter by little and little. When they are ſufficiently pared down, they muſt be filed ſmooth, and the mouth waſhed with vinegar and ſalt, and the whole complaint will be thus removed.

WOLF's-*Grapes*. See the article LYCOSTAPHYLÆ.

WOLF's-*Peach*. See the article LYCOPERSICON.

WOMB (*Cycl.*)—It is the opinion of Boyle, that as in the earth, which is the fruitful *Womb* of all the ſeeds of plants, ſo in the *Wombs* of all animals, while in a fit and proper ſtate for conception, there muſt concur three things; a benign heat to cheriſh, a due fermentation to agitate and dilate, and a due proportion of moiſture, ready to enter with eaſe into the pores opened by the fermentation.

To theſe qualities is owing, in all probability, the menſtrual diſcharge of women, the blood being agitated and rarified, in a part deſtined to theſe offices, for the uſe of an included fœtus; and when that is not there, this fluid ſwells, and opens the veſſels, ſo as to burſt out into a profluvium. It is remarkable that the *Womb* in the human, and one more ſpecies of animal beſide, that is, the monkey, diſcharges this blood regularly; all other animals, at the time of the efferveſcence in that part, which is at intervals of longer periods, diſcharging only a ſmall quantity of an aqueous matter, as is ſeen in mares, cows, &c. It is obſerved by the medical writers, that there is an evident conſent of many parts of the body with the *Womb*, that is, ſeveral parts which are always affected with it, and owe their being affected to ſome diſorder in that part, which it propagates and continues to them.

The antients had an opinion of ſympathy on this occaſion; but ſuch obſcure and unmeaning ſolutions are now thrown aſide; and we find that this joint affection of the ſeveral parts to the *Womb*, is owing only to the vicinity of the parts, or the communication and ſtructure of the veſſels, by which the vitiated liquors of the body being conveyed from one part to another, may there excite the ſame or different affections: but becauſe this way of ſympathiſing by veſſels has many conſiderable and unobvious varieties, theſe muſt be examined at large, in order to a perfect underſtanding of the effects they produce. The diverſity and various uſes of the veſſels in the bodies of the perfecter animals muſt be underſtood; and the neceſſity of motion and ſenſe depending from the brain, the animal ſpirits, and the ſyſtem of the nerves, conſidered: the nature and office of theſe being well underſtood, it will appear plainly, that they, being thus diſperſed through the whole body, cannot but produce a conſent of parts through the whole; but that this will be moſt ſenſible where the connections are greateſt, and leaſt ſo where leaſt. *Boyle*'s Diſſertationes Medicæ.

The *Womb* has been generally ſuppoſed ſo extremely tender a part, that the leaſt ſcratch or injury offered it, muſt cauſe an inflammation, of which death itſelf would be the conſequence. But the Paris academy affords, in their memoirs, an inſtance ſomething very different from this. A waſher-woman, of a robuſt habit of body, and about thirty years old, who was then ſix or ſeven months gone with child, accidentally fell down upon a ſtake of an old pale, which wounded her to two or three fingers breadth, and a conſiderable depth, a little below the navel: from that time ſhe never felt the child ſtir; but eight days after, ſhe voided, by the vagina, a large quantity of putrid blood, and this continued eight or ten days.

The external wound was healed in the common way, and the woman went to her uſual work, and continued well to her nine months end; ſhe now expected delivery, but no pains came on, and ſhe thus continued to the fifteenth month without much uneaſineſs; but then ſhe perceived a tumor to ariſe in that part of the belly where ſhe had been hurt. This, in fine, opened of itſelf, and after diſcharging a laudable matter for forty days, at the end of that time it healed up.

In the twenty-ſeventh month this tumor returned again, and became then much larger than before; in three days it became vehemently enraged, and, on opening it, there was diſcharged a quart of ſtinking matter, which greatly relieved her; after three more days dreſſing, there began to appear ſome bones, and, in fine, day by day ſome were diſcharged, till, on the whole, the compleat ſkeleton of a fœtus of between ſix and ſeven months was diſcharged.

In this caſe, there is no doubt but that the *Womb* itſelf was pierced through by the point of the ſtake, at the time of the fall, and the fœtus killed by the wound, and afterwards becoming putrid in the matrix, its parts were diſcharged one by one through the wound in that organ.

This ſeems wholly contradictory to that great tenderneſs ſuppoſed

poſed in the uterus; and ſhews that, as no part is by anatomiſts allowed more delicate, ſo there is ſcarce any caſe in which nature and good conſtitution cannot make a cure.

It is to be obſerved alſo, in regard to this woman, that in the fourteenth month after her fall, ſhe found herſelf again with child; but this ended in a miſcarriage.

Several bundles of muſcular fibres enter the ſtructure of the *Womb*. Ruyſch mentions an orbicular muſcle at its fundus; which, Mr. Monro ſays, he has alſo ſeen. Vide Med. Eſſ. Edinb. vol. 2. p. 128. and *Ruyſch*, Epiſtolæ de muſcul. in fund. Uteri.

The human uterus has numerous orifices of veſſels opening into its cavities, to pour out liquors there.

Towards the fundus of the *Womb* eſpecially, theſe orifices are found to be the extremities of canals that come out from larger cavities, lodged within the ſubſtance of the *Womb*. Theſe cavities are commonly called ſinuſes. See the article SINUSES *of the Womb*.

It is a queſtion among anatomiſts and phyſiologiſts, whence the cavity in the *Womb* is formed, which in the laſt months contains the infant, the greateſt part of the waters, and all the ſecundines, except the placentia? As to which, the curious may conſult the learned Dr. *Thomas Simpſon*'s Diſſertation in the Medic. Eſſ. Edinb. vol. 4. art. 13.

WOMEN (*Cycl.*)—*Lying-in* WOMEN. See the articles LYING-*In*, DELIVERY, LOCHIA, and MOLA.

Pregnant WOMEN. See the articles PREGNANCY and GRAVIDITAS.

WOOD (*Cycl.*)—The ſtructure and organization of *Wood* is a ſubject on which many have employed their thoughts; but perhaps none with greater ſucceſs than the celebrated Monſieur Buffon, of the Royal Academy of Sciences at Paris.

This gentleman obſerves that the organization of *Wood* is yet unknown in all its parts; and that though the world is greatly indebted to the obſervations of Grew, Malpighi, and Hales, yet, when he entered on the ſubject, he found there was much more unknown than known, and determined to obſerve, from its firſt ſtate, the growth of trees, and the formation of their woody part.

The ſeed of a tree, ſuppoſe an acorn, if put into the earth in the ſpring ſeaſon, produces, after a few weeks, a tender ſhoot, of an herbaceous ſtructure, which enlarges, extends itſelf, and hardens by degrees, and in the firſt year's growth, has in it a ſlender filament of a *woody* ſubſtance. At the extremity of this young tree there is a little button formed, which opens the next year into leaves, and from which there is propagated a ſecond ſhoot, in all reſpects like that of the firſt year, except that it is more vigorous, grows faſter, and hardens much more conſiderably. This is alſo terminated by a button like that of the precedent year, and in this is contained the ſhoot of the third year; and in this manner is the growth of the tree carried on, till it has acquired its whole height.

Each of theſe buttons is a ſort of ſeed, which contains the ſhoot of the ſucceeding year, juſt as the ſeed itſelf did that of the firſt: and the growth of a tree in height is carried on therefore by a ſeries of annual productions, exactly like one another, and the full-grown tree is, though perhaps a hundred foot high, compoſed only of a number of ſhort trees, joined end to end, the longeſt of which is not above two foot in length. Theſe little trees of the ſeveral years never at all alter their height or length, or even their thickneſs; they remain even in a tree of a hundred years old, of their original length and diameter, and ſuffer no change, but in becoming harder. This then is the manner in which trees grow in height; how they grow in thickneſs is next to be inquired into.

The button, which makes the ſummit of the tree of the firſt year, draws it nouriſhment through the very ſubſtance of that little tree; but the principal tubes or veſſels which ſerve to convey the ſap, are placed between the bark and the *woody* filament.

The action of this ſap in moving, dilates and enlarges theſe veſſels, while the button, in raiſing itſelf up in growth, elongates them; the ſap alſo, in continually paſſing them, leaves behind it certain fixed parts, which augment the ſolidity. Thus the ſecond year's little tree contains in its middle a *woody* filament in form of an elongated cone, which is the production of the *Wood* of a former year, and a *woody* bed for it, which is alſo of a conic ſhape, and which ſurrounds the firſt filament, and reaches beyond it in length; and this is the production of the ſecond year. The third bed forms itſelf altogether like the ſecond, and all the ſucceeding ones are formed by the ſame law, and in the ſame order, and envelope one another in a continued ſucceſſion or ſeries, ſo that a large tree is compoſed of a number of *woody* cones, which enfold, cover, and envelop one another, as the tree increaſes in thickneſs.

When the tree comes to be cut down, one eaſily counts, in a tranſverſe ſection of the trunk, the number of theſe cones, the ſections of which make ſo many concentric circles; and the age of the tree is known by the number of theſe circles, for they are diſtinctly ſeparate from one another; in a vigorous and well-grown oak, theſe lines are each of a ſixth of an inch or more in thickneſs, and the ſubſtance of theſe lines or circles is very hard and firm, but the ſubſtance of the *Wood*, which lies between, and unites theſe to each other, is much leſs ſo. This intermediate matter is always the weak part of the *Wood*, and its ſtructure and organization is perfectly different from that of the *woody* cones, and depends entirely on the manner in which thoſe cones are united to one another. This is thus explained:

The veſſels, which are longitudinally diſpoſed in the *Wood*, and convey the nouriſhment to the button, not only are extended and hardened by the action of the ſap in motion, and by the firm particles it depoſits; but they are ever attempting alſo an extenſion of another kind; they are ramified all along as they go, and break into numberleſs extremely minute filaments, which iſſue from them like ſo many branches; theſe, on the one part, are deſtined to the production of the bark of the tree; and on the other, are connected to the *Wood* of the preceding year, and form between the two *woody* beds a ſort of ſpungy reticular work, which, when cut tranſverſely, even to a great thickneſs, ſhews numberleſs little cavities and holes, reſembling a ſort of lace-work. The *woody* beds are therefore united to one another by a ſort of net-work; this net-work, however, does not occupy nearly the ſpace of the *woody* circles which it ſeparated, and is uſually indeed but about a ſixth part of their thickneſs. This thickneſs is much the ſame in all the trees of the ſame ſpecies, whereas the *woody* beds vary in them very conſiderably in thickneſs; in the oak they are found from a ſixth to a four and twentieth part of an inch in thickneſs.

By this eaſy expoſition of the texture of *Wood*, it is eaſy to diſcover that the longitudinal coherence of the particles of it muſt needs be vaſtly greater than the tranſverſe: one ſees alſo that, in little pieces of *Wood*, as in a bar of an inch thickneſs, if there are fourteen or fifteen of theſe *woody* beds, there will alſo be thirteen or fourteen of theſe intermediate ſpaces; and conſequently it will be much weaker than if there were but five or ſix of theſe *woody* beds in it, and conſequently but four or five of theſe intermediate ſpaces.

It may alſo be obſerved, that in thoſe little bars of *Wood* there are two or three of the *woody* beds wounded, which is often the caſe; the ſtrength of the bar muſt be thence greatly impaired: but the greateſt fault theſe ſmall pieces of *Wood* are ſubject to, is the different diſpoſition of theſe beds in the different parts of the ſame tree; and this difference is ſo great, that the force or ſtrength of a large beam of any *Wood*, cannot be computed by proportion, from that of a ſmall piece of the ſame *Wood*; which, were it poſſible, would make calculations of this kind extremely eaſy. The ingenious author of this paper has from hence calculated the force and ſtrength of timber uſed in building. Memoirs Acad. Par. 1740. See the article TIMBER.

All kinds of *Wood* are to be preſerved from the worm, and from many other occaſions of decay, by oily ſubſtances, particularly the eſſential oils of vegetables. Oil of ſpike is excellent, and oil of juniper, turpentine, or any other of this kind, will ſerve the purpoſe; theſe will preſerve tables, inſtruments, *&c.* from being eaten to pieces by theſe vermin, and linſeed oil will ſerve, in many caſes, to the ſame purpoſe; probably nut-oil will do alſo, and this is a ſweeter oil, and a better varniſh for *Wood*. *Mortimer*'s Huſbandy, vol. 2. p. 105. See the article TIMBER.

Some of the Weſt-Indian trees afford a ſort of timber which, if it would anſwer in point of ſize, would have great advantages over any of the European *Wood* in ſhip-building for the merchant-ſervice, no worm ever touching this timber. The acajou, or tree which produces the caſhew-nut, is of this kind; and there is a tree of Jamaica, known by the name of the *white-wood*, which has exactly the ſame property, and ſo have many other of their trees. Phil. Tranſ. N°. 36.

To ſeaſon *Wood* expeditiouſly for ſea-ſervice, it has been uſual to bake it in ovens. *Boyle*'s Works abr. vol. 1. p. 135.

The art of moulding *Wood* is mentioned by Mr. Boyle [b] as a deſideratum in the art of carving. He ſays, he had been credibly informed of its having been practiſed at the Hague; and ſuſpects that it might have been performed by ſome menſtruum that ſoftens the *Wood*, and afterwards allows it to harden again, in the manner that tortoiſe-ſhell is moulded. Or, perhaps, by reducing the *Wood* into a powder, and then uniting it into a maſs with ſtrong but thin glue. And he adds, that, having mixed ſaw-duſt with a fine glue made of iſing-glaſs [c], ſlightly ſtraining out what was ſuperfluous through a piece of linnen, the remainder formed into a ball and dried, became ſo hard as to rebound when thrown againſt the floor.—[[b] Works abridged, vol. 1. p. 130. [c] See the article GLUE.]

The people who work much in *Wood*, and that about ſmall works, find a very ſurpriſing difference in it, according to the different ſeaſons at which the tree was cut down, and that not regularly the ſame in regard to all ſpecies, but different in regard to each. The button-mould-makers find that the *Wood* of the pear-tree, cut in ſummer, works toughеſt; holly, on the contrary, works toughеſt when cut in winter; box is melloweſt when it has been cut in ſummer, but hardeſt when cut about Eaſter; hawthorn works mellow when cut about October, and the ſervice is always tough if cut in ſummer. *Merret*'s Notes on Neri, p. 263.

It is a very well known quality of metals, to be longer and larger when

when hot, and ſhorter and ſmaller when cold: A thouſand experiments prove this, and the books of experimental philoſophy have ſufficiently expatiated upon it; on the contrary, it is found to be the property of *Wood*, that it is longeſt in cold weather and ſhorteſt in hot; this change is owing to the remains of the ſap yet in the *Wood*, which being condenſed by cold is enlarged in its ſurface, as all liquors are when frozen into ice; and ſhrinks into a leſs ſpace or bulk again, when liquated by heat.

It follows from this, that all *Wood* muſt change its ſurface more or leſs, according as it contains more or leſs ſap, and this may be made a teſt of great uſe for the determining what kinds of *Wood* have moſt, and what leaſt ſap. This would be a very valuable piece of knowledge, ſince there are many uſes for which that ſort of *Wood* muſt always ſerve beſt, which has the ſmalleſt quantity of ſap remaining in it. See the article HYGROSCOPE, *Cycl.* and *Suppl.*

Thus, in the great article of preſerving of flour, no barrels are at preſent uſed, but thoſe of ſeaſoned dry oak; the whole advantage of this *Wood* is, that it contains leſs ſap than others; for the ſap in the *Wood* makes the flour damp, and it then becomes rancid, and breeds worms. So that if any other *Wood* can by this means be found out to contain leſs ſap when dried in the common way than oak does, it will be ſo much the better for this purpoſe; or if a cheaper *Wood* ſhould be found only to contain as little ſap as the oak, it would do as well, and the price of oak would be ſaved in theſe veſſels.

A proper way of trying when the ſap was ſufficiently exhaled out of trees, might alſo be found by this experiment, and much benefit would accrue from it; for our ſhips, when made of timber not ſufficiently dried, prove injurious to the healths of the people on board; and it has been remarked both by the French and ourſelves, that many more men in general die in the firſt voyage of a new ſhip, than in the ſame time in an old one; and indeed the firſt ſix months are uſually obſerved in this caſe to be moſt fatal. The exhalation of the ſap from the *Wood* of the veſſel, is certainly the occaſion of this, and if it could be contrived to have this ſap properly exhaled before the timber was uſed, it would not only prevent this mortality among the men, but the veſſel itſelf would be the ſounder, and the better for it. *Deſlands*, Trait. de Phyſ.

Wood uſed for fuel is required of various kinds, in regard to the various works to be performed by it.

Neri every where commends oak for the *Wood* to be burnt in the glaſs-houſes, as the propereſt *Wood* for making a ſtrong and durable fire with a good flame.

Imperato, on the contrary, commends aſh on the ſame occaſion; becauſe, as he ſays, it gives a ſubſtantial, rather than a great flame: And Camerarius deſervedly commends juniper *Wood*, as affording a laſting ſtrong and ſweet fire, could plenty of it be had. Among the antients, Pliny commends light dry *Wood*; and Plutarch, the tameriſk in particular, for making the glaſs-houſe fires; but glaſs-making requires ſo great a fire, as cannot be eaſily made from ſuch *Wood*. Nor can aſh be proper, becauſe though it gives a good fire, it ſoon decays. *Merret*'s Notes on Neri, p. 275.

Foſſile WOOD. *Foſſile Wood*, or whole trees or parts of them, are very frequently found buried in the earth, and that in different ſtrata; ſometimes in ſtone, but more uſually in earth; and ſometimes in ſmall pieces looſe among gravel. Theſe, according to the time they have lain in the earth, or the matter they have lain among and in the way of, are found differently altered from their original ſtate; ſome of them having ſuffered very little change, and others being ſo highly impregnated with cryſtalline, ſparry, pyritical, or other extraneous matter, as to appear mere maſſes of ſtone or lumps of the common matter of the pyrites, *&c.* of the dimenſions, and more or leſs of the internal figure of the vegetable bodies into the pores of which they have made their way.

The *foſſile Wood*, which we find at this day, may, according to theſe differences, be arranged into three kinds: 1. The leſs altered. 2. The pyritical. And, 3. the petrified.

Of the trees or parts of them leſs altered from their original ſtate, the greateſt ſtore is found in digging to ſmall depths in bogs, and among what is called peat or turf-earth, a ſubſtance uſed in many parts of the kingdom for fuel. In digging among this, uſually very near the ſurface, they find immenſe quantities of vegetable matter buried, and that of various kinds: In ſome places there are whole trees ſcarce altered, except in colour; the oaks in particular, being uſually turned to a jetty black; the pines and firs, which are alſo very frequent, are leſs altered, and are as inflammable as ever, and often contain between the bark and wood a plain reſin. Large parts of trees have alſo been not unfrequently met with unaltered in beds of another kind, and at much greater depths, as in the ſtrata of clay and loam, among gravel, and ſometimes even in ſolid ſtone. *Hill*'s Hiſt. of Foſſ. p. 638.

Beſide theſe harder parts of trees, there are frequently found alſo in the peat-earth vaſt quantities of the leaves and fruits and catkins of the hazel, and the like trees; theſe are uſually intermixed among the ſedge and roots of graſs, and are ſcarce at all altered from their uſual texture. The moſt common of theſe are hazel nuts; but there are frequently found alſo the twigs and leaves of the white poplar; and a little deeper uſually there lies a cracked and ſhattered *Wood*, the crevices of which are full of a bituminous black matter; and among this the ſtones of plumbs and other ſtone-fruits are ſometimes found, but that more rarely.

In places where the fir and pine kinds are buried, the ſmaller twigs, and the cones or fruit are frequently met with near the ſurface, the bodies of the trees being lodged deeper. The oaks are in many places ſo found, that the *Wood* is little inferior in hardneſs to that cut out of the moſt ſolid freſh tree. The foſſile trees in our peat-earth and moors are often found entire, with their roots remaining fixed to them; but more frequently the bodies of the trees are broken off near the roots, and that and the tops of the branches with the fruit, which are often ſeparated alſo, are found at ſmall diſtances in the ſame moor: Many of the larger branches are alſo found ſevered from theſe trees, and lying at ſome diſtance; when the roots are torn up and lie in irregular directions, the extremities of theſe are alſo broken off. But very frequently the roots of trees remain in their natural poſition, and their larger roots and tap-root run ſtrait down into the clay, or other ſolid ſtratum which is the bottom of the bog; the ſtump remaining above the ſurface, and the tree lying horizontally at a ſmall diſtance, buried at a greater or ſmaller depth.

It is idle to imagine, that theſe have been thus buried either at the creation, or, as many are fond of believing, at the univerſal deluge: at the firſt of theſe times the ſtrata muſt have been formed before trees were yet in being, and the peat *Wood* is ſo far from being of antediluvian date, that much of it is well known to have been growing within theſe three hundred years, in the very places where it is now found buried.

In this ſtate, that is little altered from their original condition, it is, that the fruits, and larger parts of trees are uſually found; what we find of them more altered, are ſometimes large and long, ſometimes ſmaller and ſhorter branches of trees; ſometimes ſmall fragments of branches, and more frequently ſmall ſhapeleſs pieces of *Wood*. The larger and longer branches are uſually found bedded in the ſtrata of ſtone, and are more or leſs altered into the nature of the ſtratum they lie in: The ſhorter and ſmaller branches are found in vaſt variety in the ſtrata of blue clay, uſed for making tiles in the neighbourhood of London; theſe are prodigiouſly plentiful in all the clay-pits of this kind, and uſually carry the whole external reſemblance of what they once were, but nothing of the inner ſtructure; their pores being wholly filled, and undiſtinguiſhably cloſed by the matter of the common vitriolic pyrites, ſo as to appear mere ſimple maſſes of that matter. Theſe fall to pieces, on being long expoſed to a moiſture, and are ſo pregnant in vitriol that they are what are principally uſed for making the green vitriol or copperas, at Deptford, and other places.

The irregular maſſes or fragments of *Wood*, are principally of oak, and are moſt uſually found among gravel; though ſometimes in other ſtrata. Theſe are variouſly altered by the inſinuation of cryſtalline and ſtony particles, and make a very beautiful figure when cut and poliſhed, as they uſually keep the regular grain of the *Wood*, and ſhew exactly the ſeveral circles which mark the different years growth. Theſe, according to the different matter which has filled their pores, aſſume various colours, and the appearance of the various foſſils that have impregnated them; ſome are perfectly white, and but moderately hard; others of a brownish black, or perfectly black, and much harder; others of a reddiſh black, others yellowiſh, and others greyiſh, and ſome of a ferrugineous colour. They are of different weights alſo and hardneſſes, according to the nature and quantity of the ſtony particles they contain: Of theſe ſome pieces have been found with every pore filled with pure pellucid cryſtal; and others in large maſſes part of which is wholly petrified and ſeems mere ſtone, while the reſt is crumbly and is unaltered *Wood*.

That this alteration is made in *Wood* even at this time, is alſo abundantly proved by the inſtances of *Wood* being put into the hollows of mines, as props and ſupports to the roofs, which is found after a number of years as truly petrified as that which is dug up from the natural ſtrata of the earth. In the pieces of petrified *Wood* found in Germany, there are frequently veins of ſpar or of pure cryſtal, ſometimes of earthy ſubſtances, and often of the matter of the common pebbles: Theſe fragments of *Wood* ſometimes have the appearance of parts of branches of trees in their natural ſtate; but more frequently they reſemble pieces of broken boards; theſe are uſually capable of a high and elegant poliſh.

Many ſubſtances, it is certain, have been preſerved in the cabinets of collectors, under the title of petrified *Wood*, which have very little right to that name. But where the whole outer figure of the *Wood*, the exact lineaments of the bark, or the fibroſe and fiſtular texture of the ſtriæ, and the veſtiges

veſtiges of the utriculi and tracheæ or air-veſſels are yet remaining, and the ſeveral circles yet viſible, which denoted the ſeveral years growth of the tree, none can deny ſuch ſubſtances to be real *foſſile Wood*. *Hill*'s Hiſt. of Foſſ. p. 639. See the article *Foſſile* PLANTS.

One of the moſt ſingular inſtances we have of the matter in which *foſſile Wood* may be preſerved, is in Razynſki's hiſtory of Poland; he tells us, that when one of the kings of Poland went to viſit the great ſalt-mines in that kingdom, the ſuperintendant of the works ſhewed him by way of curioſity a vaſt maſs of the hardeſt kind of the ſalt, in which was buried a piece of an arm of a tree; the ſalt was broken with proper inſtruments, and the *Wood* taken out; it proved to be beech, with the texture ſo plainly remaining that it was eaſily known, but its pores all filled with the matter of the ſalt in which it lay. It was of the thickneſs of the bone of a man's arm, and was as perfect and entire as when growing on the tree. It is the only inſtance we have of *Wood* preſerved in this manner; and it would be well if we could by any means aſcertain the time when it was depoſited there. *Razynſki*'s Hiſt. of Poland.

Another remarkable inſtance of the change wrought on *Wood* by lying under the earth, is that of its having been found as it were converted into iron; that is, that the *Wood* has been as thoroughly impregnated with the particles of iron, as that which we uſually call petrified *Wood* is with the particles of ſtone.

Mr. Liebknecht, profeſſor of the mathematics at Giſſen, was the firſt who ever obſerved this ſingular proceſs of nature in the foſſile world: He found in a mine, where there were many iron ores, a piece of aſh-*Wood*, eaſily diſcoverable to be ſuch by the courſe of its fibres; the cortical part or bark of which was petrified or turned into ſtone, as we uſually expreſs it in the common way, and its inner ſubſtance plainly turned into abſolute iron. This part of the ſubſtance was of the colour of iron, and took a like poliſh; it gave the ſame ſound with a piece of iron when ſtruck, and bore the ſtrokes of a hammer in the ſame manner without breaking.

Its ſpecific gravity was alſo greater than that of any ore of iron. All theſe circumſtances gave great probability of its being abſolute iron, but there were others which gave abſolute certainty of that. A piece of this and a piece of a rich iron ore were beaten to pieces ſeparately, and waſhed in ſeveral waters; the iron ore was at firſt evidently lighter, and fouled the water, but the iron in the *Wood* ſunk at once without throwing off any adventitious matter. After ſeveral waſhings, however, the ore being cleared of its earth, *&c.* became heavier than the iron of the *Wood*.

After roaſting both in the fire, the iron in the *Wood* made a violent ebullition with oil of vitriol, and ſent up a thick vapour; but the ore made very little ebullition, and ſent up ſcarce any vapour. This is the more wonderful, as the finding native iron even in the richeſt pieces, is very uncommon; nor does it amount to certainty, from all theſe experiments, that this ſubſtance was really perfect iron. The author obſerves, that after melting with ſalt of tartar it was attracted by the magnet. Act. Erudit. Ann. 1710. See the article *Bog*-WOOD, *infra*.

Jamaica WOOD. See the article BRAZIL, *Cycl.*

Petrified WOOD, the opinions of the judicious part of the world have been very different in regard to the bodies preſerved in the cabinets of the curious, under the name of *petrified Wood*; ſome affirming theſe bodies to have been only pebbles, or flints accidentally formed in this ſhape, and with veins reſembling thoſe of *Wood*; and others affirming, with equal warmth, that they have been really *Wood*, into which ſtony matter has been brought by water.

Many good arguments have been produced on both ſides the queſtion, but Mr. De la Hire has attempted to bring the diſpute to a certain concluſion, by means of ſome peculiarly happy ſpecimens, which were of the palm-tree petrified, found in the deſerts of Africa: theſe on comparing them with pieces of the palm-tree cut out of the recent *Wood*, appeared to have every where the beautiful and regular veins of that *Wood*, and left no room to doubt, but that they certainly had been once the vegetating *Wood* of that tree, though now converted into hard ſtone; the petrified pieces were perfect ſtone, in all its qualities; they had its hardneſs, its ſound when ſtruck upon, and were, as many other ſtones are, opake in ſome places, and tranſparent in others; they were found on weighing them to be often of the ſpecific gravity of recent pieces of the palm *Wood*, of the ſame dimenſions. One of theſe pieces was two foot long, and four or five inches broad; this was part of the trunk of the tree ſtripped of its bark; in this all the fibres ran longitudinally, and wholly reſembled thoſe of the recent *Wood*; a certain portion of them being forked at their ends, as they are in the *Wood*; the fibres were all hollow, even in the ſtone as in the *Wood*, and the interſtitial matter which had joined them together in the tree, appeared in the ſtone to have formed a very ſtrong ſort of cement, approaching to flint. The cavities in the once woody fibres appearing very large, Mr. De la Hire gave the following account of that phænomenon: He obſerved, that long ſoft and maſſy bodies, in drying, very often had their internal parts all drawn toward the circumference, and conſequently from the center; and that the conſequence of this often was, that when the body was perfectly dried, there appeared a more or leſs regular variety in the middle, in form of an empty pipe or canal. The ſmaller branches of many trees, he obſerves, uſually dry ſo, and ſometimes their larger arms and trunks; and this eſpecially when the *Wood* has been of a ſofter nature; this he imagines to have been the caſe in the trunk of this palm-tree, and that its ſeveral fibres, being all long and ſoft, might in drying have had their ſeveral parts recede in this manner from the center to the circumference, ſo as to have at length formed every one of them a ſort of long tube or pipe; and that if this happened to them while woody, it could not but be regularly preſerved in them in their petrified ſtate.

The other ſpecimen was of the bottom of the trunk with a part of the roots: this was not only compoſed like the former of longitudinal fibres perfectly analogous to thoſe of the recent *Wood*, but from its under part there grew ſeveral roots of the thickneſs of a finger, and three inches or more in length: theſe, which were covered with a thin bark, and had within them ſeveral fibres of an inconceivable fineneſs; compoſed the body of each root, as the longitudinal fibres of larger diameters had the *Wood* of the trunk and within theſe there was contained a firm ſubſtance of the nature of the heart in the roots of trees, which had within it a yet different ſubſtance reſembling the pith of the inner part of the ſmall roots of this tree. This being all exactly the ſtate of the ſmall recent roots of the palm-tree, it does not ſeem at all to be ſuppoſed that nature, though ſhe might have imitated barely the longitudinal fibres of a plain piece of *Wood*, accidentally in ſtone, ſhould imitate all the ſeveral parts of which theſe laſt roots are compoſed, all ſo different in themſelves, and all diſpoſed in ſuch exact and nice order. The very colours of the ſeveral parts of theſe roots were different in the ſtone, ſome kind of ſtony matter having probably been fitter to enter the pores of the one part, and ſome other kind of the other. The ſeveral fine fibres which compoſe the body of each root being of a black gloſſy ſtone, of the nature of the common black flint; and the internal part or pith being ſupplied by a white and more ſoft ſtone. The pith having in drying obſerved the ſame law as was before mentioned, in regard to the fibres of the *Wood*, had become hollow like them in the drying, and conſequently this white ſtone appears hollow, and in form of a tube or pipe in many places. The compariſon of this petrifaction in this manner, with the recent *Wood* of the ſame tree, left not the leaſt room to doubt of its true origin.

Father Duchat alſo, an author of unqueſtioned credit, affirms from his own perſonal knowledge, that in the kingdom of Ava there is a river, whoſe waters petrify recent *Wood* into flint; and that he has often ſeen trees ſtanding in it, whoſe bottom part ſo far as covered with the water, has been true flint, while all above was mere dry *Wood*, and fit for firing. Mem. Acad. Par. 1692.

Shining WOOD. There are a great many things in which a piece of rotten *Wood* that ſhines in the dark, agrees with a burning coal; and there are alſo many things, in which they differ. They agree in theſe particulars: 1. They are both of them proper and true luminaries, having light reſiding in them, and are not like looking-glaſſes or white bodies, which are only luminous according to the quantity of light which falls upon them from other bodies, and which they reflect. 2. Both ſhining *Wood* and burning coals require the preſence of the air to keep them ſhining, and both require alſo an air of a conſiderable denſity; and both having been deprived of their ſhining quality by the pumping out of the air, will recover it again on the admitting freſh air to them. 3. Both of them will eaſily be quenched by putting them into water, and many other liquors. And 4. As a live coal will not be extinguiſhed by any coldneſs of the air, neither will the *ſhining Wood* be deprived of its light on any additional coldneſs in that element. Philoſ. Tranſ. N°. 32.

Theſe are the things in which they agree; thoſe they differ in are the following: 1. A burning coal is eaſily put out by compreſſion, the treading on it and ſqueezing it together readily diveſting it of its light; on the other hand, compreſſion or cruſhing of any kind ſeems not to have any effect upon the *ſhining Wood*; its bruiſed parts ſhining as brightly as its entire ones. If a piece of this *ſhining Wood* be ſqueezed between two glaſſes, this experiment will be moſt fairly tried; and in this caſe, though the contexture of the whole be evidently broken, and the parts ſeparated, the light is as ſtrong in them as while the piece was entire. 2. A burning coal extinguiſhed by the drawing out the air, will, after a few minutes be irrecoverable, on the admiſſion of air in any manner; but, on the contrary, the *ſhining Wood*, when thus extinguiſhed and kept extinct for half an hour, will be immediately re-kindled on admitting the air to it. 3. A live coal included in a ſmall glaſs, will con-

tinue ſhining but a few minutes; but a piece of *ſhining Wood*, in the ſame circumſtances, will continue bright for ſeveral days. 4. The coal, while it burns, ſends forth ſmoke and other exhalations; the rotten *Wood* ſends out none, and conſequently a coal all the while that it is ſhining waſtes itſelf at a great rate; but the rotten *Wood* does not waſte itſelf at all. And, finally, the burning coal is actually and vehemently hot; the rotten *Wood*, though it ſhines, is not ſo much as warm. Phil. Tranſ. N°. 32.

The light that is obſerved to proceed from rotten *Wood* under ſome particular circumſtances, is found by experiment to require air to feed and keep it up: on putting a piece of this *ſhining Wood* into an exhauſted receiver, the light ſoon goes wholly off, and the *Wood* remains as dark as a piece of a common ſtick; but immediately on letting in the air again the light is re-kindled, and a ſudden flaſh of lightening ſeems to illuminate the *Wood*, and it continues bright as before.

In experiments of this kind, the effect of the air-pump is often much more ſtrongly perceived a minute or two after it is worked, than during the time of the pumping; and that very degree of exhauſtion which leaves theſe luminous bodies ſome light at firſt, will by degrees deſtroy it; thus, if the pumping be ſtopped ſoon after the light begins to grow faint, and the body examined to find its changes afterwards, it will be ſeen to grow every minute more and more faint, till it wholly diſappears.

The light of ſhining fleſh and fiſh when putrified, is wholly of the ſame nature with that of rotten *Wood*, as to its dependance on the air for its ſplendor; and in the ſame manner loſes its light in the exhauſted receiver, and regains it on the admiſſion of the air into it again, in the ſame ſudden manner. Phil. Tranſ. N°. 31.

Bog-WOOD, or *Subterraneous* WOOD, a name given by the inhabitants of many parts of this kingdom to ſuch *Wood* as is found buried in the earth in boggy places, and which is found hard and ſtrong at this time. See the article *Foſſile* WOOD, *ſupra*.

We have in the Philoſophical Tranſactions an account of vaſt quantities of this ſort of *Wood* found under ground in Hatfield chace. Infinite millions of the roots and bodies of trees are found there; they are of all growths, and are moſtly ſuch trees as are the growth of our own ſoil, ſuch as oaks, firs, birch, beech, yew, holly, willow, aſh, and the like. The roots of all theſe trees ſtand in their natural poſitions as when growing, and ſtand as thick together as they could grow in a foreſt. The bodies are uſually broken off, and laid all along juſt by them.

The large trees are uſually found fallen in a north-eaſt direction, and the ſmaller ones lying always; the fir-tree or pitch-tree is more common than any other kind, and is found ſometimes of twenty, thirty, and thirty-five yards long, and ſo ſound and firm that many of them have been ſold to make maſts for ſhips. Oaks have been found of the ſame length, though wanting ſome yards of their natural tops; theſe have been ſold at ten or fifteen pounds a-piece, and are as black as ebony, and very ſound and laſting in whatever ſervice they are put to. The aſh-trees do not preſerve their firmneſs in this manner, many of them are ſo ſoft that the workman's ſpade cuts through them; and when expoſed to the air, they uſually fall to pieces; but the willows, though a much ſofter wood than the aſhes, preſerve their texture, and are found very ſtrong and firm. In ſome of the fir-trees it is very obſervable, that they have ſhot out ſide-branches after they were fallen, which have grown into large trees. Many of theſe foſſile trees appear plainly to have been burnt; the fir-trees are particularly very common in this ſtate; and of theſe ſome are burnt quite through, and others only on one ſide. Some of theſe alſo have been found with the plain marks of human work upon them; many with their branches chopt off, and their trunks cut into two or three pieces. Some ſquared, and others in part cleft, and the *wooden* wedges uſed in cleaving them are ſtill found remaining in the cracks. Stones are found in ſome of them in the place of wooden wedges, but in none iron ones. The heads of axes are alſo ſometimes found, they are of a ſtrange form, and ſomewhat repreſent the ſacrificing axes of the antients. Theſe are found at ſuch depths, that it is impoſſible they ſhould have ever been lodged there ſince the time of this place's being a foreſt; nor ever could have been found, but by means of the ground's being drained by a late invention. The general opinion as to theſe trees is, that they were buried in this manner at the time of the univerſal deluge; but they are plainly of later origin, as foſſils. The coins of ſome of the Roman emperors having been found buried under them. Phil. Tranſ. N°. 275. p. 983.

The earth of bogs is not the only ſoil that preſerves theſe trees; for in the low parts of Lincolnſhire between the towns of Burningham and Brumley, there are ſeveral large hills compoſed only of looſe ſand, and as this blows away there are continually diſcovered whole trees, or parts of trees, and particularly the roots and ſtumps of firs, and ſome other kinds, all with the marks of the ax upon them, and looking as freſh as if done but yeſterday. Under theſe hills and in the bogs before-mentioned, not only the *Wood* of the fir-tree, but its cones are found in immenſe number; many buſhels being often laid in a heap together. In cutting a drain for a river of a conſiderable depth, there were found at the very bottom ſeveral parcels of cut *Wood*, in poles, beams, and the like; the head of an ax was alſo found ſomewhat reſembling the antient battle-ax, and a coin of the Roman emperor Veſpaſian; but what was yet more remarkable, was, that what they were now ſunk to ſeemed to be the original ſurface, the ground not being looſe like all above it, but ſound and firm, and lying in ridges and furrows, with the evident marks of having formerly been ploughed. So that all the bog-earth above ſeems plainly to have been added ſince; and that the foſſile *Wood*, ſuppoſed of antediluvian origin, is but of the time of the antient Romans, or leſs than that.

All the bogs in this kingdom afford in like manner foſſile-trees; and not only thoſe, but other places, have at all times accidentally diſcovered them. Giraldus Cambrenſis tells us, that ſo long ſince as in king Henry the ſecond's time, the ſands on the ſhores of Pembrokeſhire were driven off by peculiar ſtorms and tempeſts, and that deep under thoſe ſands there were then diſcovered great numbers of the roots and bodies of trees in their natural poſtures; and many of theſe had the ſtrokes of the ax upon them, the marks at that time remaining as plain as when firſt made. Some of theſe reſembled ebony; and many other ſuch trees were diſcovered at Neugall in the ſame county, in the year 1590. Cambden tells us of ſuch *Wood* found in the bogs in Somerſetſhire, Cheſhire, Lancaſhire, Weſtmoreland, Yorkſhire, Staffordſhire, and Lincolnſhire; and ſince his time, many other counties have been found to be as fruitful in it. Dr. Plot mentions them in many parts of his hiſtory of Staffordſhire, and by their ſtanding in their natural poſtures, as to the roots at leaſt; and prudently concludes, that they certainly once grew there, and were not brought from elſewhere.

Dr. Leigh, in his hiſtory of Lancaſhire, gives an account of the ſame ſort of trees found in the draining the boggy lands at Martin-Meer; and prudently determines them not to have been of the antient date many pretend, in referring them to the deluge.

He obſerves, that they are plainly of no older date than the time of the ſavage inhabitants of England, about the time of the Roman conqueſts; for in this place, beſide the roots and bodies of trees and their fruit, there were found eight canoes, or ſmall boats, ſuch as the wild inhabitants uſed at that time. And in another moor, in the ſame county, a braſs kettle, with a ſmall mill-ſtone, and ſome beads of wrought amber. In the ſame place were alſo found ſeveral human bodies whole and entire, at leaſt to outward appearance, and the whole head of a hippopotamus or river-horſe. This is perhaps the hardeſt thing to be accounted for of the whole ſet, as to its coming there. The boggy places in Angleſea and the iſle of Man, are all full of buried trees of the ſame kind; and the bogs of Ireland abound no leſs with them.

England, and its adjacent iſlands, are not the only places where this buried *Wood* is found; for Verſtegan tells us, that the moors in the Netherlands abound with them; they all lie North-eaſt, as ours do. Helmont alſo mentions the Peel there, a moraſs of eight or nine miles broad, which is full of them. The French naturaliſts tell us of foſſile trees alſo, in their country; and in Swiſſerland and Savoy; but all in the low-grounds.

Ramazzini tells us, that in the territories of Modena, which are now a dry and fruitful country, yet in the time of the Cæſars were only a great lake, there are found at the depth of thirty, forty, and even fifty foot, the ſoil of a low marſhy country, with ſedges, water-graſs, and other marſh-weeds; and under this there lie the trunks of trees, and their roots ſtand near them in a natural poſture as when growing. Many old coins of the Roman emperors are alſo found there; as alſo ſeveral buſts, wrought marble, and ſquared ſtones, evidently ſhewing the work of ſuch tools as the Romans have been known to uſe. Some of the trees in theſe places ſtand upright. Phil. Tranſ. N°. 275. p. 986.

Gilding on WOOD. See the article GILDING *on Wood*.

WOOD-*Coppices*. In the firſt raiſing of *Coppices* two things are to be conſidered; firſt, the nature of the ſoil, that ſuch trees may be planted in it as will thrive well there; and ſecondly, the uſes that the *Wood* is intended to be ſold for, that ſuch kinds may be planted as will be moſt proper for thoſe uſes.

If the principal vent for *Wood* be for the fire, the beſt trees for *Fire-wood* muſt be planted, ſuch as the oak, beech, hornbeam or other hard woods. Theſe are the moſt profitable for ſelling as *Fire-wood*, and one or more of theſe will grow in any ſoil.

If there be a demand in the country where the *Coppice* is to be planted for hoops and hop-poles, then the aſh, the cheſnut, the oak, alder and hazel, are to be planted.

According to the profits of the *Underwood*, the thickneſs of the ſtandard-trees are to be regulated, for as they ſtand more or leſs thick, they more or leſs injure the *Underwood*. It is alſo to be conſidered at what growth the *Underwood* is to be ſold. The taller and larger the *Underwood* of a coppice in general is, the more profitable will it be for firing, and all other uſes, and the ſtandards will be the better for its being left to grow to a proper height, for their bodies will be always, unleſs very great accidents occur, carried up ſtrait as far as they are ſhaded by the coppice-*Wood*.

A deep ſoil makes the ſhrubs as well as trees grow more vigorouſly than any other, and they will be ſooner fit for cutting in ſuch places. The perſon who owns theſe *Woods* muſt contrive to cut down only a certain quantity of them every year, and regulate this ſo that he may have a conſtant ſucceſſion of a like quantity; that part of the *Wood*, which was firſt felled, may be grown up to its ſize for felling again by that time the laſt is cut. This is, in different places, to be calculated to all the various numbers between eight years and twenty or thirty.

The cutting *Wood* ſeldom yields the more and the better timber; but the cutting it oftener has greater advantages, in that it makes it grow thicker, and gives the ſeedlings time to come up. If many timber-trees grow in the coppice, and are to be cut down, they and the *Underwood* ſhould be felled together, cutting off the ſtumps as cloſe to the ground as may be, in the trees, and in the ſhrubs and *Underwood* the ſtumps ſhould be left about half a foot high, and cut ſlanting and very ſmooth.

Sawing is the beſt method of felling timber-trees; but it ſometimes kills the root; and if this is obſerved to be the caſe in the coppice, no new ſhoots ariſing from the root, then it is proper to ſtub up the root, that it may not unneceſſarily encumber the ground, that the other young plants may have the benefit of it.

In the firſt raiſing of coppices from ſeed, the ground muſt be prepared by good tillage, as much as if it were intended for corn. The ſeeds of the ſeveral trees are to he ſown in February, and if the ſoil be ſhallow, the ground ſhould be plowed into great ridges: this will make the ſoil lie the thicker upon the top of each ridge, by which means the roots will have more depth to run to for nouriſhment, and in a few years the furrows will be filled up to the level of the reſt with the dead leaves, and theſe, as they rot at the bottom, will make a kind of ſoil, through which the young roots will ſpread, and be conducted from one ridge to another, and ſo the whole ground will be occupied by them. If the coppice be to be raiſed on the ſide of a hill, plow the ridges croſs-way of the deſcent of the hill, that the water may be detained among them, and not ſuffered to run off, as it otherwiſe would, by the furrows; but if it happen that the ground be over-wet, which is more rarely the caſe, then the contrary method is to be obſerved, and the furrows plowed deep and ſtrait downards, that all the water may be carried off by them, as by ſo many trenches or drains.

Some ſow a crop of corn along with the ſeeds of the *Underwood*, for the advantage of the firſt year; but as the ſeaſon of ſowing the ſeeds of the trees, is too late for the ſowing the corn, it ſeldom turns to much advantage. It is better to ſow the trees alone, and keep them well weeded the two firſt years; after which they are ſtrong enough to take care of themſelves againſt ſuch enemies.

In very barren ground, where the young trees can hardly ſtand the heat in ſummer, it is proper, after ſowing them, to ſcatter a quantity of furze-ſeed over the land; the furze will grow quick, and over-top the trees at firſt, but it will ſerve as a guard to them at this time, defending them from injuries, and keeping the ground moiſt about their roots. In a few years the trees will grow up beyond theſe buſhes, and they will then ſoon deſtroy them by their dropping.

In the raiſing of coppices, the neareſt diſtance for the plantations ought to be five foot for the *Underwood*; but as to what number, and ſcantlings of timber are to be left on each acre, the ſtatutes in this caſe direct; but it is an ordinary coppice, which will not afford three or four firſts, fourteen ſeconds, twelve thirds, and eight wavers, according to which proportion the ſizes of young trees in coppices are to ſucceed one another. In coppice or *Underwood* felled at twenty-four years growth, there are to be left twelve ſtore-oaks upon every acre, or, in defect of them, the ſame number of elms, beech, or aſh; theſe are to be ſtrait-bodied trees, and are to be left till they are ten inches in diameter, at a yard from the ground; but it is better for the owner to have a much greater number of timber-trees, eſpecially in places where *Underwood* is cheap; and as to the felling, it is always neceſſary to begin regularly with one ſide, that the carriages, neceſſary to the taking off the *Wood*, may come on without injury to the reſt: and in large *Woods*, a cart-way ſhould always be left in the middle, quite through the *Wood*. The timber of the *Underwood* may be cut from the month of October to February; but the laſt month is greatly the beſt, in places where there is but a ſmall quantity to be felled, and it can all be got down before the ſpring is too much advanced. All the *Wood* ſhould be carried out by midſummer, and made up by April at the lateſt; for when the rows and bruſh lie longer than this unmade up, and unbound, many of the ſhoots and ſeedlings are ſpoiled by them. It is always worth the owners while to incloſe the coppice well the winter before felling, to keep out the cattle, which would elſe greatly damage the ſupply from the ſeedlings and young ſhoots.

New-weaned calves are the leaſt prejudicial to newly-cut *Woods* of any creatures, and may be put in where there is much graſs; the next in harmleſsneſs to theſe are young colts, which, at about a year old, may be put in to feed in the ſame manner; but about May they muſt all be put out.

If the *Woods* happen to be cropped by cattle, it is beſt to cut them up, and they will make new ſhoots; for that which has been bitten by the cattle, will not grow for ſeveral years in any degree.

If coppice-*Woods* are too thin, this is to be remedied by laying down the longeſt and ſmalleſt ſhoots of thoſe ſhrubs or trees which are the moſt advantageous, in the place, or of ſuch as are neareſt the bare place; theſe will each ſend forth a great number of ſuckers, and the whole *Wood* will be thickened as much as deſired in a very little time. *Mortimer*'s Huſbandry, vol. 2. p. 64.

WOOD-*Caterpillars*, in natural hiſtory, the name of a genus of caterpillars which does not live in the manner of others on leaves of trees or plants, or open to our obſervation, but is, as it were, buried alive under the bark, in the trunk and branches, and in the roots of trees, and ſometimes in the body of fruits.

Theſe are eaſily diſtinguiſhed from thoſe worms and maggots which are found in roots and fruits, and owe their origin to flies of another kind; but they are ſubject to be confounded with another ſort of animals, called by Mr. Reaumur, *falſe* or *baſtard caterpillars*, which carry a great reſemblance in their figure to the real caterpillars, but which have more legs than any of the true ones have, and are finally transformed into four-winged flies, which are not true butterflies.

The butterflies, which are the parents of thoſe caterpillars which live immured in trees or fruits, lay their eggs on the ſurface, and the young caterpillars, when hatched, eat their way in; and doubtleſs inſtinct directs the parent to depoſit its eggs only on ſuch ſubſtances as will ſupply a proper nutriment to the young. It is no wonder that we do not find, on the outſide of a fruit, the hole by which this creature has made its way in; it enters while ſo ſmall, that the orifice that admits it is ſcarce viſible, and this probably afterwards cloſes up.

What appears ſomewhat ſurpriſing, however, in this, is, that there uſually is only one caterpillar in a fruit, which is large enough to afford food to a large number; and if there are ſometimes found two creatures within, one is uſually a caterpillar, the other a worm of ſome other kind. The whole occaſion of which is, that the operation of penetrating into the fruit, is ſo difficult to the young animal, that it ſeldom ſucceeds in it; and though the butterfly depoſits many eggs on each fruit, and theſe all hatch, yet it is only here and there one on a fruit that can find the way into it.

Theſe creatures, when once lodged in their priſon, have nothing to do but to eat up the ſubſtances which incloſe them, leaving the outer hard ſhell unhurt, which ſtill ſerves as a caſe for them; this is a very frequent caſe in the grains of corn, where the farinaceous ſubſtance ſerves as aliment, and the hard outer ſkin becomes a firm hollow caſe afterwards for the animal. The farinaceous ſubſtance in this caſe uſually proves enough for the animal in its caterpillar ſtate; but if it does not, the creature has recourſe to a very ſingular expedient; it eats again its own excrements, and finds its now ſtronger ſtomach able to ſeparate nouriſhment from that very matter, which had before paſſed off from its weaker ſtomach undigeſted.

Of theſe ſpecies of caterpillars, ſome go out of their priſon in order to change into their chryſalis, and thence into their butterfly-ſtate; but the greater number remain there, and paſs through all their changes within.

The little caterpillar, which has eaten all the farinaceous ſubſtance of a grain of barley, and is to remain in the ſhell to change into a chryſalis, covers over the whole inner cavity of the ſeed with a web of her own ſilk, and then ſeparates it by a diviſion, made of the ſame matter, into two cells of different ſizes; the longeſt of theſe is for itſelf in the chryſalis-ſtate, and the ſmaller for its excrements, which it takes great care to keep out of its own habitation: when it enters into the butterfly-ſtate, it makes its way out of the priſon through a round hole, which is made through the rind of the grain, and is, till that time, ſtopped with a nice valve.

This is a precaution the caterpillar takes while it is growing, that it may not die a priſoner when it arrives at its winged-ſtate, in which it has no inſtruments for making its way out.

It is always the deſtruction of a grain of corn to have one of theſe creatures in it; and it fares not much better with the larger fruits: in theſe, though the caterpillar eats only a ſmall part of the fruit, yet it deſtroys the organization of the whole, and frequently ſo entirely ſpoils the courſe of its growth, that it falls off the tree.

Theſe caterpillars, like all the other kinds, have certain fleſh-eating worms, whoſe parents are of the fly-kind, for their terrible enemies and deſtroyers; and it is not unfrequent, on opening one of theſe ſpoiled fruits, inſtead of the expected caterpillar,

terpillar, to find a fly juſt ready to come out; this has been produced from the chryſalis of a worm, which had before found its way into the fruit, and eat up the caterpillar, which was the original poſſeſſor of the place. Memoirs Acad. Scienc. 1736.

WOOD-*Cock*, in zoology. See the article SCOLOPAX.

This is a bird of paſſage, and comes into England about the middle of October, and goes away again in March.

During their ſtay with us, they ramble about from place to place, never remaining above eight or ten days together in the ſame *Wood* or meadow. They ſeldom or never fly in the day-time, unleſs diſturbed by men, or by ſome beaſt. In whatever places they are put up, they always fly to the thickeſt *Wood* that lies near, and there hide themſelves under the ſturdieſt and thickeſt trees, where they remain all day ſearching for earthworms, and other food, under the fallen leaves.

When night comes, they go out of the *Woods*, and generally reſort to watery places, where they may waſh their bills, fouled with the taking their prey, and thruſting into the earth; here they remain all the night, and if there is tolerable ſhelter, they ſtay alſo all the day under it; but when there wants this, they fly away to the *Woods* in the morning. In their flight, they chooſe the ſhadieſt places, and will coaſt it away to a great diſtance in ſearch of the higheſt *Woods* to retire to, that they may be the better ſecured, and the more defended from the annoyance of the *Wind*. While they travel under ſhelter, they always fly low; but when they come to any glade to croſs, they mount to a conſiderable height; but as ſoon as they have paſſed this, they ſink again.

They hate flying high, and they are afraid to fly among trees, becauſe, like the hare, they ſee but very badly ſtrait before them; and it is owing to this imperfection in their ſight, that they are ſo eaſily taken in nets ſpread in their places of reſort.

The draw-net, in countries which are very *woody*, is extremely profitable in this ſport, it being no uncommon thing to take ten or a dozen *Wood-cocks* at a time in it.

The method of uſing it to advantage is this: There muſt be choſen a proper place in ſome thick *Wood*, where theſe birds are found to reſort, and a place muſt be cleared for them, and for the net. Suppoſing the *Wood* about three hundred paces long, in this caſe, toward the middle there muſt be cut a walk through it eight fathoms wide: near the end of this, two oppoſite trees are to be pitched upon, proper to ſupport the two ſides of the net; the boughs of theſe are to be all cleared away, and the nets faſtened by logs and pullies.

When the net is thus placed, the ſportſman muſt provide ſome covert in which he may ſtand concealed. This is eaſily made by half a dozen boughs of trees with their leaves on; and the ſportſman, when he has ſtuck theſe down in the ground, and interwoven their boughs together, may either ſtand behind it, or ſit down on a bundle of dry fern, or any other ſuch matter.

At three or four foot diſtance from this ſtand, toward the net, there is to be a ſtrong ſtake faſtened into the ground, and on this the lines of the net are to be faſtened when it is drawn up.

When there comes a *Woodcock*, the net is to be let down as ſoon as ever he is taken, to entangle him the more, for, otherwiſe, in the ſtruggling he may chance to make his eſcape. The ſportſman is then to run up, and break a wing, and cruſh his head. The net is then to be refitted again as quick as poſſible, for when one is caught, there is great reaſon to ſuſpect that many more are coming the ſame way, which will be all loſt if the ſportſman is ſlow at his work.

If a hare, or any other creature worth the taking, come along the walk, the net is not to be immediately let down upon it, for in that caſe it would certainly ſtart back, or run forwards, and in either caſe would probably make its eſcape: the net is to be drawn up five or ſix foot, that he may paſs quietly under it without ſuſpicion: as ſoon as he is gone by, the ſportſman is to make a great ſhout, and let go the net; the creature will, on this noiſe, ſtart back, and will thus be certainly taken in the net.

There are, in many places, great thoroughfares through ſome open piece of ground, by which *Woodcocks* paſs in great numbers from one *Wood* to another. If there be in theſe two trees, naturally planted, ſo as to ſuſtain the nets, they are by all means to be uſed; but if not, the ſportſman will find it worth his while to be at the expence of planting two trees deep in the earth, at proper diſtances, that they may ſtand all weathers. Nets ſpread between theſe, are the moſt fatal of all others to theſe birds, for all that inhabit either one or the other of the *Woods* come this way at times, without ſuſpicion of any danger or diſturbance. See the article DRAW-*Net*.

There is another method of taking theſe birds in high *Woods*, with thoſe nets called *hays*, of the nature of the rabbets-hays, only with ſmaller meſhes. The *Woodcocks* are to be driven into theſe, and there ſhould always be at leaſt two or three of them planted together. When the ſportſman has provided himſelf with nets, he is to take five or ſix perſons into the *Wood* with him. The proper *Woods* for this purpoſe are thoſe of ſeven or eight years growth; and the people are to go into ſome part of them, near the middle. The nets or hays are to be placed in the ſame manner as they are for taking of rabbets, but two or three joining together at the end, and hanging over ſlopewiſe that way which the *Wood-cocks* are intended to be driven.

The nets being thus fixed, let the company go to the end of the *Wood*, placing themſelves at about ten rods diſtance from one another; they muſt all have ſticks in their hands, and they are to move forward ſlowly toward the nets, making a noiſe by ſtriking the ſticks againſt the trees and branches, and by hollooing with their voices: in this manner they are to move up to the net; and the *Wood-cocks* in that part of the *Wood* will all be terrified before them, but will not take wing, but run along upon the ground, and thus be driven along like a drove of beaſts, ſo that when the company come up, they will find almoſt all of them in the net. When that part of the *Wood* is thus drove, the nets are to be turned the other way, and placed ſlopewiſe in the contrary direction, and the company retiring to the other end of the *Wood*, are to drive the *Wood-cocks* that are in that part with the ſame noiſe, till they have ſent them into the nets in the ſame manner.

Thus all the *Wood-cocks* in the *Wood* may be taken with very little trouble, and this may be done equally at any time of the day.

Another way of taking this bird is by means of nooſes or ſprings. See the article NOOSE.

The *Wood-cock* and the ſnipe are both eaſily taken alſo with bird-lime, when their places of reſort are known, but they are not ſo eaſily found as many other birds.

The cuſtom of the *Woodcock* is uſually to be upon the banks under hedges, and by the ſides of ditches toward the ſun; and and they will ſuffer the ſportſman to come nearer them in the day-time after a moon-ſhiny night, than after a dark one. The reaſon of which is, that having fed well by moon-light, they are only fit for reſt in the day following; but when the night has been dark, they are ſeeking food all day long.

The ſnipes naturally lie by the ſides of rivers, when the plaſhes and ponds are frozen, and they always lie with their heads up or down the ſtream, never tranſverſely.

In order to take either of theſe birds by bird-lime, the ſportſman muſt be provided with a large number of ſmall and ſmooth twigs, neatly and evenly covered with good bird-lime. Theſe muſt be placed ſloping, ſome one way, ſome another, and the whole place about where they reſort muſt be covered with them. The ſportſman then muſt conceal himſelf very carefully, that the ſight of him may not frighten away the game.

WOOD-*Cock-Shell*, a name given by the Engliſh naturaliſts to a peculiar kind of the purpura. It is called in French, *becaſſe*. See the article BECASSE.

WOOD-*Land*, in agriculture, a term uſed by the farmers of many counties of England, for a ſort of ſoil, from its conſtant humidity and dark colour, reſembling the ſoil in *Woods*, which, of whatever nature it originally is, will always be made to appear thus from the continual dropping of trees, and the want of a free air and ſun, together with the fall of leaves, deſtroyed and waſhed to pieces by the wet.

This ſoil in the open countries has a conſiderable quantity of clay in it, and holds the water a long time that once falls upon it: in wet weather it ſticks firmly to the plough-ſhare, and in dry is very apt to crack. In uncultivated places it uſually produces ruſhes and ruſh-graſs. A moiſt and dripping year is extremely detrimental to this ſort of land. *Moreton*'s North. p. 38.

WOOD-*Lark*, in ornithology. See the article ALAUDA.

This is one of the ſweeteſt of our ſinging-birds, and is indeed very little inferior to the nightingale, when in good health, for we are not to judge by ſuch as are made feeble by improper food, or want of cleanlineſs in their cages.

It is one of the tendereſt birds we have, and yet it breeds the ſooneſt of any that we know of. They principally frequent gravelly grounds, and the ſides of hills, that are expoſed full to the ſun, and if there be any ſtumps of oaks in theſe places, they always reſort to them. The females couple with the males in the beginning of February, at which time, and never before, they part with their laſt year's brood; immediately after coupling, they betake themſelves to building their neſt.

They generally build in lay, or grounds, where the graſs is rank, and is grown brown. The princpal material they uſe is dry graſs, and they always chooſe ſome place ſheltered by a good tuft for their neſt, to defend themſelves from the cold winds, which are very ſevere at that ſeaſon. They feed their young principally with a ſmall red worm; but it is very difficult to find this kind, to feed a neſt of them under our care, and they will not do well without it; ſo that they ſcarce ever come to any thing this way.

The young branchers are taken in June, July, and Auguſt. After this they may be taken in large numbers at the latter end of September, which is their general flight-ſeaſon, and then from the beginning of January to the beginning of February, at which time they get together to couple for breeding. Thoſe that are taken in the ſummer-months, are uſually taken in nets, by the help of a hawk.

The ſportſman is to go out in a dewy morning, and fixing on ſome hill, he is to go to that ſide of it which faces the riſing

riſing ſun, for this place they are ſure to frequent. He is to take out a hawk and a ſmall net at the end of a ſtick; when he eſpies a bird he is to ſhew the hawk, on which it will ſquat down, and on his approaching nearer and making the hawk flutter over the place the bird will only lie ſo much the cloſer, ſo that he may go up and lay the net over it, and thus take it without hurting it.

The beſt *Wood-larks* that are kept in cages have been caught in this manner. A better way of taking numbers of them is to prepare a net made in the ſame manner as the common net for taking partridges, only with the meſhes much ſmaller; three or four perſons are to go out with this, and one of them is to take out a hawk, which ſerves in the ſame manner for the larks as the ſetting-dog does for the partridges.

Where-ever a flock of theſe larks is ſeen together, as is very common, the whole flight keeping with the female till the next coupling ſeaſon, the hawk is to be ſhewn, and on his hovering, they will all lie ſtill, and the net may be eaſily drawn ſo compleatly over them, that not one can eſcape. The beſt time for taking this bird for the cage, is in July, or the preceding or following month; thoſe that are put into the cage at this time ſing preſently, but their ſong time is not laſting, for they ſoon fall to moulting, in which ſtate many die; but if they get over it, they commonly prove very healthful afterwards, and become very tame and familiar, and ſing ſweetly. Thoſe which are taken in the latter end of September, are generally very ſtrong and ſprightly; but they do not ſing till after Chriſtmas. Thoſe taken in January and February finally prove the beſt of all; they generally begin ſinging in two or three days, or at the utmoſt in a week after they are taken.

The method of keeping them in health in the cage, is this, there muſt be two pans of food, the one containing meat, the other oatmeal and hempſeed. A very good food is the following; boil an egg very hard to the crumb of a half-penny loaf, and as much hempſeed; let the egg be chopped very ſmall, and the hempſeed bruiſed in a mortar; when theſe are mixed, the bread is to be crumbled in among the reſt, and the whole is to be rolled together with a common rolling-pin, and kept for uſe.

There muſt be ſome fine ſmall gravel ſtrewed at the bottom of the cage, and renewed at fartheſt once in a week. This will prevent his feet from getting hurt by being clogged with the dung; and his baſking in this will keep him alſo from growing louſy, after which few come to good. There muſt be a perch in the cage, and it muſt be either lined with green bays, or made of fine matting, which the lark is very fond of.

When the bird is firſt taken, ſome meat muſt be ſtrewed upon the ſand in the bottom of the cage, for the bird will be ſometimes almoſt famiſhed before he finds the meat in the pan.

The cock-bird of this kind is known from the hen by the loudneſs and length of his call, by his tallneſs as he walks about the cage, and by his doubling his notes in the evening, as if he was going with his mate to rooſt. A better rule than all others, however, is his ſinging ſtrong; for the hen *Wood-lark* ſings but very weakly.

Both the cock and hen of this kind are tender, and ſubject to many diſorders; the principal of theſe are cramps, giddineſs of the head, and breeding lice. Cleanlineſs is the beſt cure for the firſt and the laſt of theſe complaints, but we know of no cure for the other. A good ſtrong bird however, will often laſt very well five or ſix years, and often improve all the time.

WOOD-*Louſe*. See the article MILLEPEDES.

WOOD-*Mite*, in natural hiſtory, the name of a little animal frequently made the ſubject of microſcopical obſervations, and by ſome called the *Wood-louſe*; though that leſs properly, as there is another larger animal generally known by that name.

The *Wood-mite* is in ſhape and colour very like a louſe, and is frequently found running very nimbly, but always by ſtarts and jumps, on old books and rotten wood. The eyes of this creature are of a fine gold colour, and can be thruſt out or drawn in at pleaſure; and when examined by the microſcope the periſtaltic motion of the guts is ſeen very diſtinctly, and beautifully; and what is more wonderful, there is obſerved a very diſtinct and regular motion in the brain.

This probably is the ſame animal with the pediculus pulſatorius, deſcribed by Mr. Derham, as one of the death-watches. *Baker*'s Microſcope, p. 185.

WOOD-*Pecker*, in zoology, the Engliſh name of a ſpecies of *Picus*. See the article PICUS.

WOOD-*Pucerons*, in natural hiſtory, a name given by Mr. Reaumur, to a ſmall ſpecies of inſect of the puceron kind, of a greyiſh colour, and diſtinguiſhed by its two hollow horns on the hinder part of its body.

Theſe animals very much reſemble, both in ſhape and ſize, the pucerons of the alder; but as thoſe live always on the ſurface of the ſtalk, theſe make their way deep into the wood of a tree.

Mr. Reaumur found large quantities of theſe lodged at a conſiderable depth in the wood of ſome elms, after they were cut down; the paſſages by which they had made their way in, were not to be found; but they were lodged in large and long holes, of the diameter of a gooſe-quil, and running many inches along the tree in a longitudinal direction.

All the pucerons found in theſe places, appear to be females, and none have wings; they all have vaſt numbers of young ones of different degrees of maturity within them, and theſe may be forced out by preſſing their bodies. *Reaumur*'s Hiſt. Inſ. V. 6. p. 61.

WOOD-*Ruffe*, in botany. See the article ASPERULA.

WOOD-*Sorrel*, in botany, the name of a ſmall plant, common in our woods, and having the ſame ſharp ſour taſte with ſorrel; but agreeing with that plant in no other particulars. See the articles OXYS, and SORREL.

WOOD-*Spite*, in zoology, an Engliſh name given by many to the common green *Wood-pecker*, the *picus viridis* of authors. See the article PICUS.

WOOFF, (*Cycl.*) a name given in ſome parts of England to the ſea-wolf, or *lupus piſcis*, called by Geſner *anarrhicas*. *Willughby*'s Hiſt. Piſc. p. 130. See the article LUPUS *Marinus*.

WOOL (*Cycl.*)—WOOL-*Balls*, in natural hiſtory, maſſes of *Wool* compacted into firm and hard balls, and found in the ſtomachs of ſheep, as the hair-balls are in oxen and other animals.

Theſe are doubtleſs formed in the ſame manner as thoſe hair-balls, of the outer covering of the animal, but they are much more uncommon; they are found in numbers, three, four or five in the ſtomach of the ſame animal.

Their outſide has commonly much of the appearance of a puff-ball, and is uſually either in part or wholly covered with a very thin and ſoft blackiſh ſmooth ſkin; the inner ſubſtance is entirely *Wool*, but that wrought together as cloſely as the hatter does his furs in the making them into hats.

They are uſually ſoft, ſmooth, and ſomewhat elaſtic, of a pale buff-colour, very light, and of irregular figures rather cubic than globular, and ſeldom of any great ſize, an inch in diameter being their common ſtandard. *Moreton*'s Northampt. p. 451.

WOOLLY-*Paſhnum*, in natural hiſtory, a name given by the Eaſt-Indians to a ſpecies of native red arſenic, or orpiment, found in that part of the world.

It is of a paler colour than the red orpiment of Germany. *Woodw.* Cat. Foſſ. V. 2. p. 23.

WORK (*Cycl.*)—WORK, in the manege. To *work* a horſe, is to exerciſe him at pace, trot, or gallop, and ride him at the manege.

To *work* a horſe upon volts, or head and haunches in or between two heels, is to paſſage him, or make him go ſide-ways upon two parallel lines.

WORMS (*Cycl.*) in the Linnæan ſyſtem of nature, a claſs of animals, whoſe diſtinguiſhing character is, that they have the muſcles of their body in one part affixed to a ſolid baſis. *Linnæi* Syſt. Nat. p. 33.

WORMS, in huſbandry, are very prejudicial to corn-fields, eating up the roots of the young corn, and deſtroying great quantities of the crop.

Sea-ſalt is the beſt of all things for the deſtroying them. Sea-water is proper to ſprinkle on the land where it can be had; where the ſalt-ſprings are, their water does as well; and where neither are at hand, a little common or bay ſalt melted in water does as well.

Soot will deſtroy them in ſome lands, but it is not to be depended upon, for it does not always ſucceed. Some farmers ſtrew on their lands a mixture of chalk and lime; and others truſt wholly to their winter fallowing to do it, if this is done in a wet ſeaſon, when they come up to the ſurface of the ground, and ſome nails with ſharp heads be driven into the bottom of the plough.

If they are troubleſome in gardens, the refuſe brine of ſalted meat will ſerve the purpoſe, or ſome wallnut leaves ſteeped in a ciſtern of water for a fortnight or three weeks, will give it ſuch a bitterneſs that it will be a certain poiſon to them.

A decoction of wood-aſhes, ſprinkled on the ground, will anſwer the ſame purpoſe; and any particular plant may be ſecured both from worms and ſnails by ſtrewing a mixture of lime and aſhes about its roots. It is a general caution among the farmers to ſow their corn as ſhallow as they can, where the field is very ſubject to worms. *Mortimer*'s Huſbandry, p. 328.

Generation of WORMS. See the article GENERATION.

Aquatic WORMS. Of theſe there are ſome which transform themſelves into flies, but which depart much from the manner in which the generality of the fly-worms effect this change.

Theſe are of the third claſs of fly *Worms*, and have an invariable head, and have no teeth or hooks meeting one another. They are uſually found in ponds, or in waters that have but a ſlow current. Their head is ſmall, long, and ſcaly;

ſcaly; their body long, and ſomewhat flatted, and is compoſed of eleven rings; the laſt of which is leſs flatted, and longer than any of the reſt, and in one ſpecies of theſe *Worms* is as long as five or ſix of the other rings, though it is not ſo in others. *Reaumur*'s Hiſt. Inſ. Vol. 4. pag. 310.

The firſt ring in theſe *Worms* is of a ſomewhat ſmaller diameter than the ſecond; this is of a ſmaller than the ſucceeding one; and the three laſt, or next the tail, are of a ſmaller diameter, but more length than the others. The ſkin of this *Worm* is conſiderably tough and ſtrong, though not cruſtaceous but pliable and flexile like a piece of parchment; and at the commiſſure of the rings, the anterior has a ſort of appendix which falls over that it joins to.

They ſomething differ from one another in colour, ſome are of a greeniſh brown, others of a clearer brown, and others of the greener kind are veined with brown, and of the browner with yellow; they have no legs, but have ſome cruſtaceous hooks in their places under their belly, and theſe ſo ſmall as not to be diſtinguiſhable unleſs carefully looked for, and then only at the junctions of the three laſt rings. Ibid. p. 311.

As one finds theſe *Worms* in the ſame ſtate and ſame readineſs to undergo their metamorphoſis, ſome only of ſeven or eight lines long, and others of three inches, there can be no doubt but theſe are of different ſpecies. Theſe are ſeldom extended to their full length in the water, nor have they much power of contracting themſelves, or making one ring enter into another; but they can bend their bodies upward and downward at the junctions of all the rings.

This is of the kind of *Worms* which have no teeth, properly ſo called, but many of its ſpecies have a conſiderable number of fleſhy hooks. Others have but a few, and beſide theſe they have a ſort of beards. The end of this beard is larger than any other part; and the inſect throws them out from the under part of its head, and draws them in again at pleaſure, with great ſwiftneſs; and when they are out, it moves them backward and forward with great ſwiftneſs: The ends of theſe examined by the microſcope, ſhew themſelves to be covered with cluſters of hairs. Ibid. p. 112.

There are in this ſpecies two ſpots, a little browner and more poliſhed than the reſt of the ſkin, placed one on each ſide the head, which have ſomewhat the appearance of eyes, at leaſt the creature does not appear to have any if theſe are not ſo. Ibid. p. 313.

At the extremity of the head there is a little fleſhy protuberance, which is probably either a mouth, or ſucker, by which it takes in its nouriſhment.

Notwithſtanding that this is naturally an aquatic animal, it is however neceſſary to its life, that it ſhould breathe. For this purpoſe, the laſt ring of the body of theſe *Worms* is open at the end, and ſerves them in the place of the poſterior ſtigmata, in others of the *Fly-worms*. The extremity of this ring is frequently to be ſeen on the ſurface of the water; and about it there is always ſeen a ſort of funnel made of a vaſt number of hairs that grow there, and diverge on this occaſion into this form.

Each of the hairs that forms this ſort of funnel, is itſelf a ſort of beard, furniſhed with numbers of ſhort hairs on each ſide; and the uſe of the whole is to prevent the water from getting in at the aperture made to admit the air. If any doubt could be had of the creature's reſpiring by this means, it would be extremely eaſily cleared by a ſimple and eaſy diſſection of the creature, ſeparating its belly from its back; for one then diſcovers two large veſſels running the whole length of the body, and filling up a great part of its ſpace; theſe are the two great tracheæ; they are inſerted near the head, where probably the anterior ſtigmata are placed, and running through the body join and are inſerted again at the tail. Ibid. p. 314.

It is ſtrange, that a creature like this, an inhabitant of the water, ſhould be deſtined in its ſucceeding ſtate to be an inhabitant of the air; but it is evidently ſo, this *Worm* transforming itſelf into a two-winged fly. When one knew however that this was to be the caſe, one would naturally imagine that ſome long-bodied fly of the libella kind, or ſome other ſuch ſhould be the laſt change of our long *Worm*; but, on the contrary, the production is a very ſhort-bodied fly; nor is this at all more wonderful than the caſe of thoſe libellæ, ſome of the longeſt bodied of which are immediately before their egreſs into that ſtate in the form of very ſhort *Worms*. Ibid. p. 317.

What is farther a great ſingularity in this creature, is that when it changes into the fly, and at any time before that ſtate, it undergoes no change in its exterior form, nor can the time of the change be at all foreſeen; and what is yet more ſingular, the creature when it has undergone its change, and is no more living but in the ſtate of a ſhell to the encloſed fly, is no way diſtinguiſhable by the eye from the living *Worms*, nor can be diſcovered but by the touch. The difference then indeed is eaſily perceived, as the living *Worms* are ſoft and flexile, theſe ſtiff and rigid, and incapable of moving themſelves. It is no uncommon thing for the laſt ring of the body to be turned up, and make an angle with the reſt, even in this ſtate; and often the ninth ring in the ſame ſtate makes an angle with the eighth, but in a contrary direction to the other. The *Worm* while living frequently makes alſo theſe angles, but then it changes them as it pleaſes; whereas, in this ſtate, they are become immoveable. Ibid. p. 318.

When therefore we find, among a number of theſe *Worms*, ſome that are ſtiff and rigid, we may determine that theſe have loſt their original form, and that their ſkin now only ſerves them as a ſhell for their tranſformation. When this is the caſe, there is no inſect which ſo ſoon accompliſhes its changes. Theſe *Worms* frequently within five or ſix days from the time of their firſt becoming ſtiff and rigid, are transformed into flies.

The nymphs of this fly takes up only a ſmall part of the ſhell made by the ſkin of the *Worm*, all the laſt rings, and part of the firſt remaining empty, the middle ones only being occupied by the nymph. It is not impoſſible, however, but that theſe vacant ſpaces may have their uſe, and may be neceſſary to give paſſage to the air, without which the embryo fly would periſh. Ibid. p. 319

WORMS, called *Aſcarides*. The name *Aſcarides* is given by Mr. Reaumur, to a ſort of ſmall *Worms* or maggots, bred from the eggs of winged animals; which bury themſelves between the membranes of the leaves of plants, and there eat away the parenchymatous ſubſtance.

Theſe are a very minute ſpecies of animals, and the ſmall ſpace of the inſide of a leaf allotted for the place of their reſidence, is to them a vaſt extent of country; and they eat it away at various times, and in different manners; ſome eat very ſlowly, and only burrow themſelves a way in contorted holes or cells; theſe he calls *foſſores parvi*: Others eat more variouſly, devouring all that lies before and round about them, and not burrowing in different directions; theſe laſt are called *foſſores magni*.

Theſe differ greatly one from another, and indeed are the *Worms* of different animals; ſome afterwards changing into ſmall butterflies, others into ſmall flies of the common kind; but the manner of life is the ſame in all. The butterflies whoſe eggs produce theſe, are extremely beautiful, glittering with a multitude of gaudy colours, and with ſilver and gold among the reſt; but they are too minute to ſhew their beauties to the naked eye. Thoſe of the *Aſcarides*, which do not in fine become butterflies, are two-winged flies, or ſmall beetles, in their ultimate ſtate. As ſmall as theſe *Aſcarides* in general are, they do not fail to ſhew the proper characters, by which they may be reduced to regular claſſes: Thoſe which have had their origin from the eggs of butterflies, are truly and properly caterpillars in miniature; the others are maggots, from flies; and if from beetles, they are hexapode *Worms*. Of the little caterpillars, ſome have ſixteen feet, ſome only fourteen; and ſome of them are perfectly ſmooth and equal all over the body; others have a number of rings or annular diviſions, like the larger caterpillars, their ſeveral changes for the arriving at the fly-ſtate are the ſame with thoſe of the common ſilk *Worm*, and other ſpecies of large caterpillars.

The ovula of the parent butterfly are depoſited ſingly, only one being placed on a leaf; for the little caterpillar is of the nature of the ſolitary, not the gregarious animals. Theſe eggs are ſo ſmall, as to be ſcarce viſible, except to an obſerver ſo accurate as Mr. Reaumur; but he not only diſcovered them lying upon the leaves of plants, but traced them to the time of their hatching; and obſerved this curious particular, that the caterpillar never enjoys the light or free air, but as ſoon as ever it is hatched eats its way through the integument of the leaf; and, under the cover of its ſhell, buries itſelf among the parenchymatous matter, whence it never comes out again till it arrives at the fly ſtate.

The *Worms* which are hatched of the eggs of flies, make their way as ſpeedily into the ſubſtance of the leaf; but with this difference in the manner of doing it, that as the caterpillar eats its way through with its teeth, the *Worm* ſtrikes its head forcibly againſt it ſeveral times, and by repated blows at length breaks a hole in it, large enough to admit its little body; and then feeds on the parenchyma of the leaf, in the ſame manner with the caterpillar. Theſe finally change into their chryſalis ſtate, within the covert of the membrane of the leaf.

The laſt kind of *Aſcarides* which are to become beetles, make their way into the ſubſtance of the leaf in the ſame manner; and when they have fed their deſtined time upon its parenchyma and juices, they ſometimes change in the covering of the membrane, and ſometimes come out of their holes and chooſe the ſurface of the leaf for the ſcene of this great cataſtrophe. *Reaumur*'s Hiſt. Inſ. Tom. 1..

Bee-WORM, the name given by naturaliſts to the ſmall white *Worm*, found in the cells of the honey-comb, and afterwards changing into a bee, in the manner of the white maggots, found in meat, *&c.* which, after a certain change, into a ſtate of reſt, become transformed into flies, like thoſe to which their eggs owe their origin.

To trace theſe *Worms* of the bee to their origin, we are to obſerve that the female bee lays an egg at the bottom of each cell, and that this is not ſimply dropped into this place, but that the bee fixes it to a certain part; that is, either to the baſe of the cell, or to one of the angles, by its ſmaller end. The egg is of an oblong figure, and is larger at one end than at the other; it is covered with a thin flexible membrane inſtead of a ſhell, ſo that it may be bent double, and will, on taking off the force, return to its own ſhape again. *Reaumur*, Hiſt. Inſ. vol. 10. p. 239.

Theſe eggs appear perfectly ſmooth and gloſſy to the naked eye; but when viewed with powerful glaſſes, there is a ſcaly ſtructure obſerved in them; though Mr. Reaumur ſuſpects that this is not on the outſide, but is ſeen through the tranſparent covering, and is, in reality, the ſtructure of the *Worm* within.

Though it be the regular courſe of nature, that only one egg ſhould be depoſited in each cell, yet there are ſometimes found two, three, or even four, in one place: the occaſion of this uſually is a female bee's being engaged in a ſmall ſwarm, in which the working bees cannot erect combs faſt enough, ſo that as ſhe is under a neceſſity of depoſiting her eggs from day to day, ſhe is compelled to put them two or three together: theſe, however, ſeldom come to any thing, ſuch ſmall ſwarms uſually diſperſing after a while, the female ſeeking admittance into ſome other hive, in which ſhe may lay at her leiſure. When the bees work in the common way, and the female is ſo preſſed to depoſit her eggs, that ſhe cannot ſtay the neceſſary time, ſhe often, in this caſe, places two or three eggs in a cell; but as the number of cells every day increaſes, the hive is not deſerted on this occaſion; but the ſwarm continues in it, and the female continues her laying as the workers make the cells; as it is impoſſible, however, for two or three *Worms* to live in one cell, the worm, when at full growth, and when in the nymph-ſtate, entirely filling up the whole cavity, the bees foreſee the event, and take care to remove the ſupernumerary eggs out of the cells, leaving only one in each. *Reaumur*'s Hiſt. Inſect. vol. 10. p. 244.

It has been a common opinion among authors, that after the eggs of the bees are thus depoſited in the cells, they are ſet upon, in order to be hatched in the manner of thoſe of birds. The generality of writers have given this office of ſitting to the drones or male bees; but others, who have obſerved the ſwarms more narrowly, and found that there are no drones in the hives, except for about three months of the year, and that the eggs remain in the cells at times when they are not there, have declared, that the common working-bees do this neceſſary office; nay, ſome, who have written expreſsly on this ſubject, have gone ſo far as to give directions what ſhould be done with ſuch bees as were found ſitting on the eggs, when the ſwarms were removed from one hive to another.

Mr. Maraldi, who could not give into this opinion of the bees ſitting on the eggs, yet was for giving them ſome office in regard to their hatching, and conſequently obſerves that the bees got on the tops of the cells which contains the eggs, and there fluttering their wings with great rapidity, excite a heat which occaſions the young ones to be hatched. This, however, is not leſs erroneous than the other; for a ſtrict obſervation always ſhews that the cells in which the eggs are, are wholly left and abandoned by the bees, and they never go near them, except when their road lies by them on their other neceſſary occaſions. It is very probable indeed that the heat of the hive is a great agent in the hatching of the eggs; but the ſingle bees never attempt to add to this, in regard to any particular cell, and without this the heat within is often equal to that of the eggs ſat upon by a hen, and ſometimes ſuperior to it.

The eggs are hatched about three days after the bee depoſits them, and all their changes are afterwards ſo ſwift, that it is neceſſary to watch them very attentively, in order to ſee them. In almoſt two days after the hatching, the *Worm* is found grown to ſo large a ſize, that it is ſcarce to be believed the ſame animal. The whole period of the life and changes of the *Worm* is contained in about ſeventeen days; for if a cell be obſerved in which an egg is juſt laid, and the ſame cell be examined twenty days afterwards, the young bee will be found juſt ready to appear out of the nymph of the *Worm*, and take its flight from the cell. The labouring ſeaſon of the bees, in this reſpect, is when they are newly hived, and their induſtry, and the efforts of it at that time, are ſcarce credible.

Mr. Reaumur obſerved the whole proceſs in a ſwarm which he put into a new hive on the twenty-fifth of May. They all immediately began to work upon their combs, and on the twenty-ſeventh, which was only two days after, there were a vaſt number of cells erected, in each of which the female, or queen, had depoſited an egg; and on the ſeventeenth of June, theſe cells all furniſhed the hive with a new ſwarm, each producing its bee.

From the time that the *Worm* is hatched out of the egg, to its paſſing into the nymph-ſtate, it always remains at the bottom of the cell, and lies rolled up in form of a ring, its head coming very near the tail. In this manner it lies very comfortably, there being under it a ſort of bed of a ſoft and glutinous white matter, which prevents the hard matter of the cell from preſſing againſt it. This matter has alſo another uſe yet more materially neceſſary to the animal, as it ſerves for its food.

The common working bees are deſtined to take care of the young brood, and the care they take to keep them ſupplied is ſurpriſing. The *Worm* is a feeble animal, not able to go out of its cell in ſearch of food, nor is it by any means proper that it ſhould, as the combs would be deſtroyed by the continual paſſing of a number of ſuch creatures. When the bees are obſerved by means of a glaſs-hive, it is eaſily ſeen in what manner they prevent the neceſſity of this all the time that the *Worms* are alive in the cells: their chief buſineſs is their ſupport, and there are numbers of them every moment ſeen plunging their heads into the cells, and depoſiting there a ſupply of this matter, which ſerves for the nouriſhment of the young brood. It is a pleaſing ſight to obſerve how carefully they come one after another to the ſame cell, till there is a ſufficient quantity in it, and, after this, how others that come in on the ſame ſervice, looking into that cell, and, finding it ſupplied, paſs over it to others which want their help. *Reaumur*'s Hiſt. Inſ. vol. 10. p. 246.

When we ſee the bee in this employment, after plunging its head into the cell, remain in that poſture ſome time before it draws it out again; it is eaſily conceived, that it is there diſgorging what we find afterwards left in the cell. It is to be obſerved, that ſome have ſuppoſed this white matter which ſurrounds the *Worms* to be their excrements, not their food; but there are many reaſons againſt this opinion. The *Worms* of winged inſects in this ſtate void little or no excrement; and if this matter of the bees cells was the excrement of the *Worms*, it muſt neceſſarily follow that it muſt be found in ſmalleſt quantity when the *Worm* was firſt hatched, and daily increaſing afterwards; but juſt the contrary of this is the caſe, for the quantity of it is greateſt of all while the *Worm* is very young, and there is none of it found by that time when the creature is full grown, and is ready to paſs into the nymph-ſtate.

Swammerdam, and other curious inquirers into the œconomy of bees, have wondered where the creatures produced this liquid ſubſtance, which is of a whitiſh colour, of the thickneſs of cream, and of an inſipid taſte like flour and water. Some have ſuppoſed it the extravaſated juices of trees and plants, collected by the bees for this uſe; but it is much more probable, that it is the matter of the common food of theſe animals. The honey and rough wax which, after having paſſed their digeſtion, is reduced to a ſubſtance of this kind, analogous to the milk of animals, is in this ſtate voided by the mouth by theſe animals, for the ſupport of their young, while in a condition in which they cannot help themſelves.

The bees ſeem yet farther careful of their offſpring, and take the pains to bring them up by degrees from more inſipid to leſs inſipid food; for as they are to live on honey in their fly-ſtate, they are to be by degrees brought to this diet while *Worms*. This will be found to be the caſe, on examining the cells in which they live at their different ſtages. In the firſt ſtage, or while the *Worms* are very young, the matter of their nouriſhment is found perfectly inſipid, as before obſerved; but as they advance in growth, if it be taſted at different times, it becomes more and more ſweet; and, in fine, what is brought for the nouriſhment of the *Worm*, when nearly arrived at the time of its change into the nymph-ſtate, is little different from honey.

The bees therefore ſeem able to give this matter what ſort of preparation they pleaſe, and it is evidently different at theſe different times, not only in taſte but colour. At firſt it is white, but it afterwards becomes tranſparent and colourleſs, and after this greeniſh or yellowiſh, very often reſembling in colour diluted honey. *Reaumur*'s Hiſt. Inſ. vol. 10. p. 247.

The *Worm* has no legs, as indeed it has no need of any, its whole life, in that ſtate, being deſtined to be ſpent in that cell where it is firſt hatched: it is not eaſy to get one of them out of the cell without hurting it; but when it is carefully taken out, and laid on a paper, it is found to have no power of crawling, but only gives ſigns of life by turning its head a little about. There is very little difference in the growth; its colour only changes from a ſomewhat bluiſh-white, which it is at firſt, to a purer white, and the inciſures between the rings become leſs deep, and in fine, almoſt wholly diſappear when the creature is at its full growth.

The head of this *Worm* is ſomewhat harder than the reſt of the body, and is of a regular figure, being flatted, and compoſed like the head of the caterpillar, of two lips, the under one divided into three parts, and the upper one being furniſhed with two hard ſubſtances in form of teeth, though much leſs ſolid and ſtrong than thoſe of the caterpillar, as this creature has nothing to do with ſolid food. In the full grown *Worms* there is always ſeen a yellow line or ſtreak running directly along the middle of the back. This ſeems to be a ſtreak on the ſurface of the ſkin, but it is, in reality, no other than the great canal of the inteſtines, which is eaſily ſeen through the tranſparent ſkin, as it is full of a yellowiſh matter, very much reſembling honey.

Under the belly of this creature there is an appearance of cer-

tain

tain folds more white than the reſt; theſe are diſpoſed parallel one to another, and all run in a tranſverſe direction. It is natural to ſuppoſe that theſe are the folds at which the *Worm* has a power of bending itſelf; but, when examined ſtrictly, this does not appear to be the caſe, for they are found to be in reality ſo many round veſſels of a bright ſilvery whiteneſs, placed under the ſkin, and viſible through it, on account of that ſuperior whiteneſs. They may be eaſily raiſed with the point of a needle, and taken out of the body, and they are then found to be of the ſame ſtructure with the tracheæ of all other animals of this ſmall kind; namely, they are extremely fine and ſmall cartilaginous filaments, hollow within, and rolled into a cloſe ſpiral wreath.

The ſtigmata of this *Worm* are eaſily diſtinguiſhed, though they are extremely ſmall. If one of the tranſverſe tracheæ of the belly be traced to its extremity at each end, it will be found to terminate at each in a ſtigma. Thus all the reſt of them may be found out, and they will be found to lie in a regular line along each ſide, running along the two great tracheæ, which paſs longitudinally from the head to the tail on each ſide of the *Worm*. From theſe there part ſome ſhort but thick tracheæ, which paſs toward the back, and there become divided into many branches; and on the under part of the body, near the head, there may be diſtinguiſhed ſeveral others beautifully undulated, which paſs from ſide to ſide, though not in a regular manner. The anus of the *Worm* is placed in the laſt ring of the body, and is very ſmall; it is deſtined to give paſſage but to a very ſmall quantity of excrements. *Reaumur*, Hiſt. Inſ. vol. 10. p. 257.

If the progreſs of the growth of the *Worm* be examined, it will be found that two days after the egg is laid it is hatched, and in ſix days more it arrives at its full growth. When it is firſt hatched it rolls itſelf up into a ſort of circle, which is then however ſo ſmall, that it does not reach quite round the cell, and leaves a conſiderable ſpace within its center: this, however is ſoon filled up by the growth of the creature; as it becomes longer, its head is brought to meet the tail, and is forced beyond it as far as the laſt ring but one of the body: in this time the body alſo ſwells ſo much in thickneſs, that there can no more be any ſpace left in the center of the ring, nor any room for the head to be thruſt farther forwards; as the *Worm* has much of its growth yet to come in this uncomfortable ſituation, it naturally happens that the body loſes its round ſhape, and becomes flatted, and in this manner riſes up ſo high in the cell, as almoſt to fill it up: when the cell is examined in this ſtate, it ſeems to contain two *Worms* rolled up, and laid in it, one upon another, ſince it is hard to conceive the body of one ſo faſhioned as to fill it in this manner: when the *Worm* is however taken out, its ſhape plainly ſhews how it has filled it, and in what manner it has conformed itſelf to the place of its abode: when at liberty, it ſoon recovers the natural rounded ſhape of its body.

It is very plain, that the *Worm* muſt be very little at eaſe in this ſituation, and that it will be neceſſary for it to change it, in order to its own neceſſary transformations. When therefore the time of its firſt change approaches, it ceaſes to eat, and begins to unrol the circle its body makes, and to lay itſelf at its length in the cell. When this happens, the bees become ſenſible that it has no occaſion to eat any longer, and therefore they bring it no more food; but nature only requiring for this change a ſtate of reſt, and the excluſion of the external air, they perform their laſt office to it in what might appear a very ſtrange operation, if it were not known to be neceſſary to the *Worm* in this ſtate; this is the faſtening up the top of the cell with a covering or lid of wax, ſo that the *Worm* now finds itſelf ſhut cloſe up in a ſort of box, hermetically ſealed. The manner in which the bees make this covering, is by beginning a circle within the mouth of the cell with new wax, and ſucceeding this by ſeveral others, each within the laſt, till they leave only a vacant point in the center, which they fill with a lump of the ſame wax, ſo that the cover is compoſed of a great number of concentric circles.

When this cover is finiſhed, the *Worm* compleatly extends itſelf at length within, and as it is now to paſs into the ſtate of a nymph, and the outer integument of that will be too thin and tender to bear the immediate contact of the wax of which the cell is compoſed, it begins a new work, which is the ſpinning a ſort of ſilk in the manner of the ſilk-worm; with this it forms a web, completely covering all its parts, and in this ſafe caſe it becomes a nymph. The web of ſilk which the *Worm* ſpins, on this occaſion is extremely fine, and is by degrees carried all round the cell, ſo as to line it regularly throughout in the manner of a linnen hanging. This is not only applied thus cloſely to the ſides and bottom of the cell, but in the ſame manner to the lid or top; and theſe are eaſily ſeen on breaking open a cell which encloſes a nymph; for when the wax of one ſide of the cell is broke, the *Worm* is then only ſeen through a thin and tranſparent reddiſh web, which is this lining of the cell, and is found to be very flexile, yet very tough. The time when this is beſt of all ſeen, is, however, when the combs of an old hive are broken; for, in this caſe, the webs within the cells which have been deſtined to the raiſing of young ones, are ſo thick that they will not break; but may be eaſily examined and pulled to pieces, and they are then found to be made of a great number of cruſts, one within another. *Reaumur*, Hiſt. Inſ. vol. 10. p. 261.

It is not to be ſuppoſed that one *Worm* could have formed theſe complex webs, as they are neither neceſſary to it, nor to be faſhioned in the time that animal has to work in. It is very certain that one of theſe cells deſtined to the breeding up of the young offſpring, is not only allotted to one *Worm*, but to ſeveral ſucceſſively; and each of theſe having in its turn ſpun its web, by this means the whole web is found compoſed of ſo many cruſts or doubles, or is, in reality, a collection of ſo many webs as there have been *Worms*.

As ſoon as ever one of theſe nymphs iſſues out of the cell, in the bee-ſtate, the working bees clean out the cell, and render it perfectly fit for the office of educating another young one; and as ſoon as that is done, the female bee lays another egg in it, and ſo on; ſo that almoſt as long as the comb laſts, every three weeks there is a new *Worm* to inhabit it, and a new web ſpun, and added to the former number. By ſeparating the cruſts of one of theſe complex webs one from another, it becomes eaſy to reckon how many bees have been hatched in each. The ſeveral cruſts are ſo very thin, that there may be a great number of them applied one over another, before they will ſenſibly fill up or ſtraiten the cavity within the cell, and, in other reſpects, the cell is the better for it, every coat of this matter adding a lining to it, which is at leaſt as ſtrong as the ſides of the cell.

The web that this *Worm* ſpins is remarkably fine and delicate. Its threads are of a ſmalneſs ſcarce conceivable, and its workmanſhip worthy the materials; for they are wove in ſo compact a manner, that it is not eaſy to ſee the ſtructure; inſomuch that Mr. Maraldi, a very accurate obſerver of the bees in other reſpects, ſuppoſes this lining of the cell to be formed of the ſkin of the *Worm*, thrown off at its entering into the nymph-ſtate. He is a little embarraſſed to conceive in what manner the ſkin becomes ſo regularly and nicely applied to all the angles of the cell; but a cloſer obſervation ſhews the truth; for if the cells be opened when newly covered by the bees, the *Worm* within will be found to be yet in its own form, and will be detected in the act of ſpinning its web; or if glaſſes be called in to our aſſiſtance afterwards, the web, whoſe ſtructure is imperceptible to the naked eye, will be ſeen to be compoſed of fine threads regularly woven together like thoſe of other ſpinning animals.

The female bees are treated with a peculiar diſtinction, even in this ſtate of the *Worm*, as well as afterwards. We ſee that the common cells ſerve ſucceſſively to the hatching of ſeveral of the common *Worms*, and bringing them to perfection in the bee-ſtate; but this is not the caſe in the females, each cell only ſerves to raiſe one bee of this kind, and is never found covered within with any more than one web or ſilky lining. Indeed the bees always deſtroy theſe royal cells as ſoon as ever the bee is hatched from them, or, at the moſt they only leave the bottoms of them, to ſerve as the baſe of other cells; and this indeed is wholly neceſſary, in order to their carrying on their common work, and enlarging their combs. *Reaumur*, Hiſt. Inſ. vol. 10. p. 263.

The ſucceſſive hatching of ſeveral bees in the ſame common cell, is of great uſe to it, as the web left by every one within it, greatly ſtrenghens the cell; but this is by no means neceſſary, in regard to the royal cells, or thoſe deſtined to the producing the female bees, as the ſides of thoſe are always made ſo thick, that they can require no additional ſtrengthening.

When the common *Worm* of the bee has arrived at its growth, the labouring bees bring it no more food, ſo that it eats up the whole of what remains, and the cell becomes dry and clean. It then extends itſelf at full length under the cover of the lid of the cell, and by giving itſelf ſeveral motions, it cauſes the ſkin of its back to ſplit open with a ſmall longitudinal fiſſure. The internal motion of the creature ſoon enlarges this ſlit, and at length the body of the nymph appears in the fiſſure, and by degrees makes its way compleatly out. The ſkin left behind is then only a dry membrane, and this nymph is to be looked on as the animal: this is an oblong body of a delicate ſtructure, but without any power of motion.

In this, if nicely examined, there may, however, be diſcovered all the parts of the future bee, and it ſeems indeed no other than the perfect bee, with its limbs as yet all ſoft and tender, and concealed under a thin membrane, till they acquire a due ſtrength and firmneſs. The rings of the back may be eaſily traced on the back of the nymph, and when its belly is examined, the legs and horns, or antennæ, and the trunk, are all diſtinctly ſeen extended lengthwiſe, and the wings are folded in ſmall knobs, which are afterwards to be unfolded in a wonderful manner.

The drones, or male bees, which the common working bees ſo unmercifully maſſacre and deſtroy in the month of July, or thereabouts, are not leſs taken care of in their worm-ſtate, than thoſe of the common kind. The *Worms* of theſe drones do not differ in any particular from thoſe of the common working kind, except that they are larger, and are placed in larger cells.

The bees bring food to theſe *Worms* in the ſame manner as to the others, and when the time of their change into the nymph-ſtate approaches, they as regularly and carefully cover their

cells

cells with a wax lid. It ſometimes happens, that the *Worms* of theſe drones are lodged in cells no larger than thoſe in which the *Worms* of the common bees are placed. The bees who have the care of the young brood always are able to diſtinguiſh theſe however, and when they come to make the cover of the cell they always give them room by making it of a different form; they do not extend a flat cruſt over the mouth of the cell in this caſe, but raiſe a hollowed and elevated covering. The cells of the drones are eaſily diſtinguiſhed from the reſt, by this; and a whole ſide of a comb is by this means often found to be the lodging of the drones only.

The eggs out of which the male bees are to be hatched, differ in nothing from the others, except that they are a little larger; and the bees produced of the *Worms* hatched from them, are proportionably larger, as are alſo the *Worms* themſelves when at their full growth. It ſometimes happens, however, that the male bees are no larger than the others; ſeveral hives having been found with the males of this ſmall kind. It ſometimes happens that the female bee is obliged to depoſit two, three, or even four eggs in one cell, through a ſcarcity of cells at the time when it is neceſſary for her to lay; but as theſe can never grow to their full ſize in a third or fourth part of the room they ſhould have, Mr. Reaumur is of opinion, that this is the cauſe of the ſmallneſs of theſe male bees; and that in whatever hives they are found, the eggs have been left three or four in a cell.

The love that the working bees have for the young *Worms* hatched in the combs of their own hives appears very great, and their care of them the moſt perfect in all their ſtages that could be conceived; but this love and tenderneſs does not extend to the young ones of another hive. Mr. Reaumur tried the experiment, by putting into one of his glaſs hives part of the comb from another hive, in which there were ſome eggs and ſome young *Worms*; but while the bees of this hive were perfectly careful of their own young, they were cruel in the greateſt degree to theſe, tearing them out of their cells, and carrying them out of the hive, there leaving them to periſh. *Reaumur*'s Hiſt. Inſ. V. 10. p. 267.

There are certain circumſtances alſo, under which the bees are not leſs cruel, even to their own young: If it happen that a comb break, and a piece of it fall to the bottom of the hive, the bees immediately gather about this fallen piece, and kill all the *Worms* that are in the cells of it, in the ſame manner as they did the ſtrangers, carrying them out of the hive. It ſhould ſeem, that the creatures knew, that the want of the neceſſary heat which is found in the center of the hive would be the occaſion of the death of theſe *Worms* before they could arrive at the bee ſtate, and that in mercy to the creatures themſelves they at once put a period to a life, that could only be miſerable, and prevented a great deal of unneceſſary trouble to themſelves, in feeding a number of creatures which never could come to perfection. It ſometimes happens alſo, that the bees kill and carry out of the hive the bodies of many of the *Worms*, while the combs all remain in their place, and no accident has happened to them. There are however very plain reaſons which may juſtify this cruelty, ſo very different from the general care and tenderneſs they have for them. One of theſe may be, the neceſſity of making a proviſion for themſelves againſt the winter.

If the fœcundity of the female bee continue ſo long, and be ſo great, that all the cells are filled with young ones, at a time when many of them muſt of neceſſity be filled with honey, for the ſuſtenance and ſupport of the hive in winter, it will be found abſolutely neceſſary that many of the cells muſt be cleared of the *Worms*, in order to their being filled with the honey. The preſervation of the republic being the firſt of all cares, this cruelty will be found juſtifiable, rather than by a fooliſh tenderneſs all ſhould be left to periſh with hunger. This ſlaughter is plainly very often owing to this cauſe, as it is ſeen to be made at ſuch time as the winter is coming on; and when there is preſent a ſeaſon admirably adapted to provide a ſupply for it, by affording great opportunities of collecting a great deal of honey in a little time.

There is alſo another occaſion, on which a maſſacre of this kind may be juſtified on the principles of reaſon. If a female prove very prolific, and by any accident do not lay any eggs for the producing another female, or the egg or eggs of this kind which ſhe does lay do not come to good, the young brood in this caſe cannot anſwer the general purpoſe of nature in their production, that is the forming a new ſwarm and taking care of a new offſpring; and in this caſe, as they would live to no purpoſe, it is not wrong in the bees who have the care of the young to deſtroy all theſe, and make room by that means for a new brood born with happier circumſtances.

It is very poſſible alſo, that the *Worms* may be liable to certain diſorders, which we can have no knowledge of; but in conſequence of which they could only produce very feeble and uſeleſs bees: in this caſe, which the bees who have the care of the young may eaſily perceive, it would be no improper method in them to deſtroy in the *Worm*-ſtate what they foreſaw would be of no uſe to the commonwealth in the bee-ſtate. *Reaumur*'s Hiſt. Inſ. V. 10. p. 273.

Though the common bees refuſe the care of ſuch young ones as are taken out of other hives, and put into theirs, their rules however are not ſo ſtrict as to the breeding no other young but thoſe of their own hive; for it has been found by experiments, that if all the bees of two hives be forced to make a change, and each ſwarm to enter into the hive belonging to the other, they will in this caſe take as much care of the young *Worms* they find in the combs, as they would have done of their own.

If the common bees take all this care of the *Worms* which are to become working bees like themſelves, and even of thoſe which are to become drones which after a time they are to deſtroy, there is no wonder that they take greater pains to ſecure and bring up thoſe *Worms* which are to become female bees; of which they are ſo very watchful and obſervant, that they feed theſe *Worms* with the utmoſt care; and when they have brought them up to that ſtate when they are to eat no longer but are to paſs their laſt change into the chryſalis or nymph-ſtate, they cloſe up the aperture of the cell with a lid of wax; in the making of which, they are not leſs prodigal of that choice and precious ſubſtance the wax, than they had before been in the conſtructing the cell. It takes as much wax to make one of the cells in which theſe females are to be brought up, as to make an hundred and fifty of the common cells; this may be found by weighing them againſt one another, and the cover or lid of the cell put on at the time of the transformation of the *Worm* bears the ſame proportion to the covers of the other cells. Every thing that regards theſe creatures is managed with profuſion: In the common cells there is never found a drop of that liquid matter deſtined for the food of the *Worm*, when it is arrived to the nymph ſtate, the bees never furniſhing it with a drop more than is abſolutely neceſſary; but they give ſo profuſely to the *Worm* that is to become a female bee, that when it is changed into the nymph-ſtate there is uſually found in the cell with it a quantity of this food equal to its own bulk.

This food ſeems alſo more nicely prepared, than that which is intended for the nouriſhment of the other worms; for if it be taſted, it is found very ſweet and luſcious, but attempered with a ſharpneſs like that of vinegar, and with a warmth like that of pepper, or ſome other ſpice.

It might be ſuppoſed from this food always found in the cell with the royal or female nymph, that the creature in that ſtate took in nouriſhment; but this is not the caſe, the nymph of the female bee can no more eat than any of the others; but this maſs of food is of no injury to it in that ſtate, as it does not fill up the whole cell as the others do, but has a great deal of room, and there is always a void ſpace between it and the maſs of food. *Reaumur*'s Hiſt. Inſ. V. 10. p. 278.

The progreſs of the young bee from its *Worm*-ſtate, is this: When the cover is fitted to the cell, the nymph makes its way out of the back of the ſkin of the *Worm*; it is at firſt perfectly white, but by degrees its eyes acquire a reddiſh colour, and afterwards the ſeveral parts of the body become more and more brown; by degrees they all acquire their due ſtrength and ſolidity; and when that is done, the bee appears out of its caſe, by burſting the thin membrane that covered it. The next office then, is the getting out of the cloſe cell, which is a priſon to it; in order to render this eaſy, the head of the bee is always fixed by the poſition of the nymph juſt under the center of the lid or cover of the cell.

The firſt buſineſs of the new-hatched bee is therefore with its teeth to eat a way through this covering; this it does by ſlow degrees, firſt forcing a ſmall aperture, and afterwards by degrees enlarging that to a proper ſize to let its head, and in fine its whole body, appear. This is, in favourable circumſtances, that is when the day is favourable and the young bee vigorous and ſtrong, the work of about three hours; but at other times, it is half a day's work; and in ſome caſes is never perfected at all, the creature dying by that time it has made an aperture large enough to get its head out at, and periſhing with the head out and the body within the cell.

Swammerdam ſuppoſed, that the bees which placed the covers upon the cells, took them off again at a proper time; but this is not at all conſonant to reaſon and experience, ſince, were it ſo, we could never find bees dead in the poſition juſt deſcribed. But Swammerdam living before the invention of glaſs-hives, could only gueſs at what we can now ſee diſtinctly performed under our eyes.

As ſoon as the head and the fore-pair of legs are out, the diſengaging the reſt of the body is very eaſy, as theſe legs being fixed on the outſide of the cell have ſufficient force to pull up the reſt.

When the creature is completely out, it ſtands on the ſurface of the comb near the cell out of which it is come, and its parts, which are yet very ſoft and moiſt, become hardened and dried by degrees.

While it ſtands thus, the reſt of the bees which are about the ſpot gather round it, and give evident marks of joy at its being produced; they ſtroke and make much of it, and often offer it honey out of their own mouths. While it ſtands in the midſt of theſe careſſes, its wings by degrees unfold themſelves, while ſome of the bees are thus welcoming the new inhabitant, others immediately ſet themſelves about clearing away the matters left in the cell, and fitting it for the reception of a new inhabitant.

The bee produced out of it, has neceſſarily left behind it two exuviæ; the ſkin of the *Worm* when it transformed itſelf into the nymph ſtate; and finally that of the nymph, out of which it is juſt come in form of a bee.

One of the working bees immediately enters this cell, head foremoſt, and taking up one of theſe exuviæ carries it out of the hive, and the moment ſhe has left the cell another enters it, and in the ſame manner carries out the other exuviæ; after her there enter ſeveral others, which carry out the fragments of wax that had fallen in while the *Worm* was gnawing its cover to pieces; and others, finally, put it perfectly in order, and render it fit for the reception of a new egg, which the female bee ſoon depoſits in it; inſomuch that Mr. Maraldi ſays, he has ſeen five bees produced in the ſame cell, in the ſpace of three months.

The young bees are eaſily diſtinguiſhed from the others, by their colour; they are grey, inſtead of the yelloviſh brown of the common bees. The reaſon of this is, that their body is black, and the hairs that grow upon it are white, from the mixture of which ſeen together reſults a grey; but this colour forms itſelf into a browniſh yellow by degrees, the rings of the body becoming by degrees more brown, and the hairs more and more yellow. The bee is no ſooner produced from the nymph, than it knows the whole buſineſs of its future life; it immediately goes out, and gathers wax and honey for the common ſtores. At the time that one bee hatches in this manner, as many others are alſo hatched as there were eggs depoſited by the female in the ſame day; this is often many hundreds: So that a few days of this kind render the hive too full of inhabitants, and the new-born brood are forced to go out in form of a ſwarm to find ſome other habitation, where they may employ themſelves in the ſame manner with thoſe to which they owed their origin. *Reaumur*'s Hiſt. Inſ. V. 10. p. 280. See the article SWARM.

Canker-WORM. See the article SCARABÆUS.

Churr-WORM. See the article GRYLLOTALPA.

Connough, or *Connaught*-WORM, in natural hiſtory, a name given by the common people of Ireland, to a kind of caterpillar found in many parts of that kingdom; and, from its ugly aſpect, reputed to be poiſonous.

It is ſaid to be the only poiſonous creature of that kingdom, and many miſchievous effects are attributed to its ſting, and to its poiſonous quality, when eaten by cattle.

As to the firſt of theſe opinions, it is evidently erroneous; the creature having no power to ſting at all. The other is not ſo eaſily proved falſe, but is much to be ſuſpected. The reaſons on which it is founded, are theſe: The cattle in Ireland are ſubject to a very terrible diſeaſe, which is moſt frequent in Autumn; about the time when theſe animals are in the greateſt plenty.

It is moſt frequent alſo among thoſe cattle which feed in low and marſhy grounds, where this creature lives and feeds; cows and hogs which feed in theſe places, are the only creatures ſubject to the diſtemper, and this is imputed to the cows eating by large mouthfuls, becauſe ſhe chews the cud a ſecond time; and the hogs feeding ſo foul and greedily, as to eat things which other creatures refuſe. Finally, the great cauſe of the aſſigning this diſeaſe to this creature is, that the *Worm* only appears in great numbers about once in ſeven years; and in theſe, and theſe years only it is, that the diſtemper among the cattle is common.

The ſymptoms by which this diſeaſe is diſtinguiſhed from all others, are, a great ſwelling of the head, and a falling down of the anus; the gut often hanging out to the length of ſix or ſeven inches. The common cure among the more intelligent people is a ſtrong decoction of the plant called bearsfoot, or great black hellebore, with ſome rue and garlic given with butter and beer; this is found to have great ſucceſs with the cows. The hogs are cured only by mixing reddle, or the common red ochre powdered, with buttermilk, and making them eat a large quantity of it.

The Iriſh peaſants have recourſe to many idle remedies; but theſe are found often of real ſervice. The caterpillar, ſuppoſed to occaſion this diſeaſe, feeds on the common ragwort, and is larger than moſt other creatures of this kind, being of the length and thickneſs of a man's finger; it is marked with two large ſpots behind the head, which are ſuppoſed by the vulgar to be the eyes, but are only round variegations, of the nature of thoſe common on other caterpillars; and what they take to be a ſting in the tail, is no other than a horn in that part, which is not peculiar to this caterpillar, but found on many others. That the common people are deceived in regard to the external parts of this creature, is evident; but experiments are required yet to prove, whether or not they are ſo, in regard to its poiſonous quality.

One trial is remarked by Mr. Molyneux to have been made on a dog, who eating the ſkin of only one of the creatures was found dead about three days after; another dog, which eat the juices expreſſed from that ſkin, received no hurt. The inſect is deſcribed in Liſter's edition, under the name of the elephant caterpillar. Phil. Tranſ. N°. 168. p. 880.

Flower-root-WORM. See the article FLOWER.

Fly-WORMS, in natural hiſtory, the *Worm* or maggot produced of the egg of a fly, and afterwards to be transformed into one.

Theſe *Worms* are to the fly, what the caterpillar is to the butterfly it produces. The cuſtom of the world has appropriated the term caterpillar to that one ſpecies of the flying inſects firſt ſtate; but we have unfortunately no term of diſtinction yet eſtabliſhed for any of the firſt ſtate of any of the other flying inſects, the creature produced by the egg of the fly ſcarce being indeterminately called *Worm*. Till more expreſſive names ſhall be invented for theſe, it may not be improper to diſtinguiſh thoſe of the different claſſes by the additional name of the inſect they are to be changed into, and to call that which is to become a beetle, the *Scarab-worm*, that which is to be hereafter a fly, the *Fly-worm*; and ſo of the reſt. *Reaumur*'s Hiſt. Inſ. V. 4. p. 161.

Thoſe which are to be hereafter winged creatures of the fly-claſs, are extremely different one from another in form and figure, and may very properly be arranged into ſeveral claſſes.

The moſt remarkable and ſtriking differences between the claſſes of theſe creatures, are thoſe of the form and ſhape of their heads. Many of them have heads which it is not eaſy to diſtinguiſh to be ſuch, as they carry no one mark of the head of an animal viſibly about them. We are accuſtomed to ſee in other animals a conſtant and regular form of the head, which is no way alterable during the life of the animal; but among theſe *Fly-worms* there are many, whoſe heads are variable at the pleaſure of the creature; and which at times are ſeen to be more or leſs long, more or leſs thick, more or leſs flat, more or leſs ſhortened at pleaſure by the animal, and eaſily bent and turned about in any direction.

The heads of theſe creatures are not only fleſhy, but compoſed of a very ſoft and flexible fleſh; as theſe creatures have no ſhell, it may occur to ſome to think they have no brain; but this would be a greater wonder than all the reſt. Be it as it will, the naturaliſt need make no heſitation to pronounce that the head of an animal, which is the anterior extremity of the creature, and is furniſhed with neceſſary organs for taking in the food, and conveying it into the body. Ibid. p. 162.

Though there are among the *Fly-worms* many whoſe heads are of this variable conſtruction, there are alſo others whoſe heads are hard, like thoſe of other animals; and which, like thoſe, always retain the ſame regular figure.

This grand diſtinction among theſe *Worms* may furniſh us with the firſt general arrangement of them, which may be into thoſe which have a variable, and thoſe which have an unchangeable head. Ibid. p. 163.

If we after this attend to the number, arrangement, diſpoſition, ſtructure, and form of the other parts of theſe little animals, we ſhall find ample matter for a ſufficient number of ſubordinate diſtinctions, which will alſo prove very extenſive.

Some *Worms* of this kind we ſhall find, which have not the leaſt appearance of legs; others we ſhall find, that have legs, but theſe merely membranous ones; others which have them merely ſcaly, or ſhelly; and others, which, like the caterpillars, have legs of two kinds, ſome ſhelly, and others membranous; but which have always more of the latter kind than the caterpillars have.

Other ſub-diſtinctions there will alſo be found, in the variable and unchangeable heads of divers of theſe *Worms*; and the whole form of the body in others will be found to be totally different. Some of them have a power of altering the figures of their bodies at pleaſure, being able to lengthen or ſhorten them, or to make them thicker or thinner at pleaſure. Some can alſo at the ſame time inflate, as it were, and ſwell out ſome particular parts of their body, while they make other parts thin and flat. And others have their body ſo rigid, as to be wholly incapable of theſe changes, and indeed of bending or turning otherwiſe than all together.

The external coat of ſome of them is alſo very thin, tender and membranous; whereas that of others is ſtrong, firm and ſcaly, or cruſtaceous. And finally, the different ſpecies themſelves will afford us ſufficient ultimate diſtinctions, by the poſition, number and figure of their organs of reſpiration. *Reaumur*'s Hiſt. Inſ. V. 4. p. 163.

Genera of Fly-WORMS. The diſpoſition of the ſtigmata, or air-holes, at which the tracheæ of theſe animals terminate, will help us to the occaſions of ſeveral diſtinctions of genera among the *fly-Worms* of variable heads.

The *Worm* of the common fleſh-fly has in its ſtigmata ſix apertures, three in each, of an oblong figure, and reſembling button-holes; but, inſtead of theſe, the *Worms* of many other flies have them in the ſame part of their bodies, but have, inſtead of the three button-holes, only one ſmall eminence, reſembling a little button in each: Others have them cylindric and hollow, and ſtanding out from the hinder part of their bodies in form of horns. Some genera have only two of theſe horns, and others have three: The two in ſome are placed to a conſiderable diſtance from one another, and in others they are in a manner joined together. Some alſo carry theſe pipes or horns in an elevated poſition, others having them placed flat on their bodies; and beſide theſe varieties in the number, form, and ſituations of the ſtigmata, ſome diſtinctions of genera may be drawn from the parts which ſurround them, and are deſtined by nature for their defence.

The number, diſpoſition, and figure of the hooks, which ſerve theſe creatures in the place of teeth, may alſo ſerve for matter of diſtinction, as may alſo the differences of their legs. *Reaumur*, Hiſt. Inſ. vol. 4. p. 173.

The common *Worm* of the fleſh fly has two hooks, placed at a diſtance, in a parallel direction, and a dart between them. Others have theſe hooks, but have no dart; others have theſe hooks of very different ſize one from the other, and placed one over the other; others have only one ſingle hook; and others there are, which have nothing of this kind at all, or, at leaſt, which we can never make to ſhew any. Ibid.

The figure of the body in others, will alſo give matter of diſtinction. The hinder part of ſome is, as it were, cut off, and repreſents the truncated end of a cylinder. Some there are of a much ſhorter body than others; ſome have their anterior part as thick as the poſterior: ſome are more flat, and others more round. Ibid. p. 174.

Notwithſtanding that the *fly-Worms* of the firſt claſs have, properly ſpeaking, no legs, yet ſeveral of them are able, at pleaſure, to inflate themſelves, and to ſend out from the under part of the rings of their body, in that ſtate, certain membranaceous portions analogous to, and ſupplying the place of legs, and much variety is to be obſerved in the placing of theſe. Some have them arranged orderly as legs, two and two, one on each ſide of each ring; others have a ſingle range of them all along their belly, in a row down the middle. Each of theſe is ſometimes furcated or divided into two; and others have the under part of their bodies, at or near the junction of the rings, furniſhed with a ſort of hooks, very ſhort and fine, and commonly of a red colour; theſe are of great uſe to the creature in laying hold of the ſurface on which it moves itſelf. Ibid.

The differences of ſize and colour in theſe creatures, may alſo be made the baſis of farther diſtinctions; among other things, the nature and quality of the ſkins of the different kinds may alſo be conſidered, ſome being thin and tranſparent, others thick, rigid, and opake; ſome alſo being ſmooth, others rough and wrinkled, others adorned with long hairs, and finally others, as it were, armed with prickles.

Theſe are the marks and characters of the genera of the firſt claſs. Thoſe of the ſecond, which have variable heads, and differ from the former in that they have legs like thoſe of the caterpillar-claſs, have frequently a ſort of thorns or hooks faſtened to them, and though the head of the *Worms* of this claſs is truly of a variable figure, and is fleſhy, the mouth is ever ſo viſible in all its changes, that the head is eaſily known to be ſuch.

Another very obvious character there alſo is of the generality of the *Worms* of this claſs, which is, that they have a long fleſhy tail, which they can lengthen or ſhorten as their occaſions require; the reſemblance of this to the tail of a rat may probably give this genus the name of the *rat-tailed Worms*.

This tail is the principal organ of reſpiration in theſe *Worms*; its end is always open, and ſupplies the office of the ſtigmata of the other genera. Ibid.

The *fly-Worms* of the third claſs, which have their heads of a conſtant and invariable figure, and, like thoſe of other animals, have no moveable jaws, or any thing analogous to that organization; but ſuch of them as have any teeth or hooks, have all a power of drawing them into their heads on occaſion, and only throw them out when they would uſe them.

The *Worms* of this claſs have pointed heads, or ſuch as ſeem truncated, or with the end of the rays part cut off, they have no ſhelly or ſcaly legs. Theſe are a very numerous family both in the terreſtrial and aquatic kingdom, and all, as far as is hitherto known, furniſh two-winged flies.

The firſt genus of theſe may be eſtabliſhed of the ſcaly ſpecies, which have, as it were, ſcaly rings, and are rigid, and not incapable of flexion, though wholly ſo of contraction or dilatation; theſe *Worms* can turn about nimbly enough, but cannot at all lengthen or ſhorten their bodies, and thence may be properly enough called the *ſerpentine genus*.

The former genus are naturally inhabitants of the earth; thoſe of the waters give us a ſecond genus. Theſe have a merely membranaceous ſkin, and always an oblong head, and their poſterior extremity is terminated by a ſort of pipe, open at the end for reſpiration. The bodies of theſe are round, or approaching to that figure. Ibid. p. 178.

Another genus may well be eſtabliſhed of the *Worms* with heads like the former, but with flatter bodies. There are two ſpecies of this frequently found, the one in cow-dung, the other in the agarics of the ſycamore, and other trees. Theſe have their organs of reſpiration, like the reſt, in the hinder part of their bodies, and they might in many be miſtaken for the arms of the creature, by thoſe not converſant among the creatures of this claſs.

A fourth genus may be eſtabliſhed of the *Worms* of long and rounded bodies, which are ſmaller at each end than in the middle; theſe may be called the *tipulæ-Worms*, becauſe they all are transformed into flies of that claſs. The head of theſe *Worms* is ſcaly, and ſmall in proportion to the ſize of their body, and their ſtigmata are placed in the hinder part of their bodies, and ſurrounded with a fleſhy appendix. Ibid. p. 179.

There is another genus of *Worms* which transform themſelves into tipulæ, and perhaps merit a ſeparate claſs, rather than a ſubordinate genus. Theſe are altogether red, and of a bright lively colour: they have near their head two ſhort legs, which reſemble two ſtumps of arms; but the thing that, above all others, characteriſes theſe, is, that they have, near their hinder extremity, and on the under part of their bodies, four long fleſhy ſtrings, which having ſome reſemblance to the polype-fiſh, may well enough give theſe the name of the *polype-Worm*. Theſe have alſo, at the hinder part of their bodies, two cylindric pipes, which have much of the appearance of organs of reſpiration. Ibid. p. 180.

A ſixth genus may alſo be eſtabliſhed of the *water-Worms*, which are transformed into gnats. Theſe reſpire like the reſt, by means of the hinder extremity of their body, which is an open pipe; they have alſo, beſide this, another pipe, deſtined to give paſſage to the excrements, and placed under their body. Ibid.

A ſeventh genus may be eſtabliſhed of thoſe long *Worms*, reſembling the *Worms* of the tipulæ, and having a ſmall ſcaly head: Theſe live in the earth, and in cow-dung, and are covered with hairs, which give them much the appearance of caterpillars. Theſe have two ſtigmata placed in their hinder part, ſurrounded with fleſhy appendages.

An eighth genus may be eſtabliſhed of the long, white, and ſhining, but not ſcaly *Worms*, frequently found in and among muſhrooms. Theſe have their ſtigmata not placed behind, as the reſt of the *fly-Worms* have; but, like thoſe of the caterpillars, in every ring of their body.

The *Worms* of the fifth claſs, which uſually produce four-winged flies, have heads of a conſtant and invariable figure, and have two teeth, or two moveable jaws, always open and expoſed, and which are placed near the middle of the aperture of the mouth; they have no ſcaly legs. Ibid.

The ſtigmata of theſe *Worms* are placed on their ſides, and never on the hinder parts of their bodies. The flies produced from theſe are of very numerous genera, the bees, waſps, ichneumons, gall-flies, *&c.* are all of this ſort. Ibid. p. 182.

The ſixth claſs of theſe *Worms* is that of the hexapode, or ſix-legged kind, which are transformed into ſome ſpecies of the libellæ. Theſe have no mouth, but inſtead of one, have, in a manner, two, if the openings through which their aliments paſs, may be ſo called. Theſe are at the top of their antennæ, which are placed in the fore-part of their head.

The *fly-Worms* of this ſingular claſs, are but very few in number. The formica-leo, in the ſtate in which it is known by that name, is one, and the puceron-eaters are ſo many others. Ibid. p. 183.

The ſeventh claſs is of the *Worms* which have bodies long like the caterpillar-claſs, and have ſix legs; but their ſingular character is, that they have two other ſhort legs, or properly two hooks of a particular kind, placed near their hinder part, and aſſiſting them in fixing themſelves, and moving. The water-*Worms*, which make themſelves caſes of different materials, and are afterwards transformed into papilionaceous flies, are of this claſs.

Several ſmall green and yellow *Worms*, which feed on the apricock and pear-tree, and fold up the leaves of thoſe trees, tho' they much reſemble caterpillars, are alſo truly and properly of this claſs.

The eighth claſs is of thoſe *Worms* called *falſe* or *baſtard caterpillars*, becauſe the figure of their body might make them be miſtaken for caterpillars, rather than known for fly-*Worms*, by leſs curious obſervers.

Theſe have ſix cruſtaceous legs, like the caterpillars; but they have a greater number of the membranaceous ones than thoſe inſects; they have ſcarce ever leſs than ten, and often fourteen. Theſe alſo are not edged round with hooks, as thoſe of the caterpillars are; and they differ from the true caterpillars in this alſo, that their head is more round, and has only two eyes, one on each ſide; whereas the caterpillars have on each ſide five or ſix, diſpoſed in form of an arch. Ibid. p. 185.

All this claſs of *Worms*, ſo far as is yet known, change into four-winged flies; the females of which are armed with a ſaw behind. The number of the membranaceous legs being dif-

ferent in different ſpecies of the falſe caterpillars, will very properly furniſh matter for the ſubordinate diſtinctions of the genera.

A firſt genus may be very properly eſtabliſhed of thoſe which have no more than eighteen legs in all; that is, ſix cruſtaceous, and twelve membranaceous.

A ſecond may be of thoſe which have in all twenty legs; and a third thoſe which have twenty-two legs.

The ſpecies may be ſufficiently diſtinguiſhed by their colours, and by their attitudes, which are very different in the different ſpecies, and very conſtant in the ſame: Some of them always carry the hinder part of their body elevated, others are continually rolled together; and finally, others always extended.

The greater part of the falſe caterpillars are ſmooth; but there are, however, ſome which have a very ſingular ſort of thorns, arranged with great ſymmetry.

It might perhaps not be improper to arrange the thorny ones into a diſtinct claſs, which, according to the figure and order of the thorns might be again ſubdivided into ſeveral genera. Ibid. p. 186.

Truffle-WORMS.		TRUFFLE.

Meal-WORM. There are two very different inſects found in our meal or flour; the one is ſo ſmall, that it is only to be ſeen by the microſcope; all that the naked eye can diſcover of it is, that ſomething is alive in the place, from the whole ſubſtance of the flour being in motion. See the article FLOUR.

The other *meal-Worm* is larger, and more frequently offers itſelf to our obſervation; it conſiſts of eleven rings, and has three pairs of legs. The mouth of this *Worm* is made into a kind of forceps, and from this ariſe, on each ſide, a great number of ſmall ſpinulæ; theſe ſerve inſtead of teeth, and the animal feeds by means of them. They are found ſometimes very ſoft and tender, ſometimes hard and firm, and at other ſeaſons they are very briſk and lively; at others they have ſcarce any life in them.

The moſt remarkable thing in regard to theſe *Worms*, is, that they are always exactly of the colour of the flour which they live among. Ray has obſerved, that the white flour breeds white ones; the coarſer flour breeds larger and greyer ones; and that flour which has the bran among it, breeds brown ones, of the ſame colour with itſelf. This is a proviſion of nature for the ſafety of the animal, ſince were it of a colour different from that of the flour, it muſt be eaſily diſcovered among it, and would be picked out and thrown away. The caterpillar tribe are thus preſerved, by being of the colour of the leaves they feed on; their green, uſually ſuiting itſelf exactly to that of the tree or plant. *Deſlandes*, Trait. Phyſ.

WORMS *of the Sea*. The ſea-*Worms* are of the number of thoſe animals, which with the oyſter, and ſeveral other ſhell-fiſh, furniſh us an inſtance of animals which remain all their lives fixed in the manner of plants to one ſpot, whence there is no probability of their moving themſelves.

Theſe *Worms* are included in a ſort of caſes or pipes, and may be divided into two claſſes, according to the nature of thoſe caſes. In the one ſpecies theſe are only made of grains of ſand, fragments of ſhells, and the like, faſtened together by a viſcous humour; and in the other they are compoſed of a true ſhelly matter.

Thoſe *Worms* which have ſhelly caſes, are fixed ſometimes to the ſand at the bottom of the ſea, ſometimes to ſtones, or ſea plants, and ſometimes to the ſhells of other fiſhes; their ſhells are rounded, and, in ſome degree, conic, as they always gradually grow wider from their point or apex to the mouth; as to the reſt their ſhape is different in almoſt every individual, forming divers irregular curves, and often reſembling the ſhapes into which a common earth-*Worm* curls and twiſts itſelf in its various motions.

In order to know how theſe ſhells become ſo exactly faſtened to the bodies on which we find them, it will be neceſſary to conſider the manner in which they are formed.

The creature, when juſt produced, is covered with a ſhell; but this ſhell no longer covers its whole body; as it grows, a new ſhell is formed over this, from the condenſation of its own juices, and this fixes it down as it grows to the body, be that what it will, on which it is formed; and as the *Worm*, in its growth, twiſts itſelf variouſly about, it will be fixed down in that poſture by the new-formed ſhell which covers it, and which adheres as well to the body on which the *Worm* lies, as to the old ſhell.

The marine-*Worms* of the other kind, which are not regular ſhells, but whoſe caſes are made up of fragments of different bodies, and of grains of ſand, live in the ſame manner with the others, their whole lives in the ſame hole. Theſe creatures bury themſelves in the ſand of the ſea, as the common earth-*Worms* do in the earth; and the glutinous matter which eſcapes continually from their pores, not being either ſufficient in quantity, or of a nature to harden into a perfect ſhell of itſelf, yet ſerves to faſten together the ſeveral ſmall bodies that come into contact with it all about the body of the creature; and ſerve as a ſort of mortar to cement together a multitude of little ſtones, *&c.* and of this connected maſs to form a coarſe ſort of covering for the animal, which defends it from the common injuries.

The force of this viſcous or glutinous humour flowing from the bodies of theſe *Worms*, is very evidently ſeen in places inhabited by them, when left dry by the ebbing of the tide; the ſurface of the ſands, in theſe places, appears rough and ragged in a very ſingular manner. The pipes in which theſe *Worms* are lodged, are uſually placed in great numbers near one another, and their ends all ſtand out about an eighth of an inch above the ſurface of the ſand; and the reaſon of this is, that the whole ſand-bank was, when covered with the water, of a level with the mouths of theſe pipes; the ſea, in its receſs, has carried off about an eighth of an inch of the ſurface of the ſand with it; but though it has done this every where, where the ſand was looſe and free, it has not been able to do it where it was glued together by the viſcous juices of this animal, but has left ſuch part of it ſtanding out in form of pipes or caſes to the animal.

The ſtrength of this glue is alſo ſeen in the common accident of the ſeas waſhing off a piece of a ſand-bank, in which they dwell; in this caſe the fragment is found at ſome diſtance, with the interſticial ſand every where waſhed deep away from the ſurface, but with the caſes of the *Worms* remaining prominent, and being perfect and unhurt at full length, with all their convolutions.

Sometimes alſo theſe pipes or caſes are found perfectly detached from all ſandy matter, and lying looſe on the bottom of the ſea; in this caſe the glutinous juice, cementing the outer ſurface, being much weaker than that which keeps together the more internal part, much of the ſuperficial coat is often worn away; nay, ſometimes the caſes are not thicker than a piece of writing-paper, yet ſtill preſerving their whole figure. The internal ſurface of theſe pipes is always perfectly ſmooth, even, and poliſhed, which is wonderful, as they are compoſed of ſuch rugged particles as, one would think, could not eaſily furniſh a ſmooth ſurface; but doubtleſs the mucous or viſcous humour of the animal fills up the interſtices between the particles, and, by degrees, hardens ſo far as to make one even ſurface with their prominent ends.

The *Worm* which inhabits theſe caſes is of a very ſingular figure; it is about an inch long, and of the thickneſs of a large wheat ſtraw; its head is of a very odd ſtructure; it is rounded and flat, and is much broader than any other part of the body. At certain times the extremity of the head is of this round figure, and is divided into three parts; that in the middle is of an oval figure, and hollow; the next to this is a circular zone or band which ſurrounds this oval part; and the third part is another circular zone, extended behind this laſt; on both theſe zones there are a great number of lines marked, which ſeem a ſort of rays, running from the center to the circumference.

Though this is at ſome times the figure of the head; yet at others it is of a very different form, reſembling a creſcent or a horſe-ſhoe; for there is a certain part in the middle of the head, which the creature can open when it pleaſes.

A little below the head, it has three oblong ſlender bodies, which ſerve as oars on each ſide; its body approaches to a conic figure, and is terminated by a long tail; all along the body there are placed, at different diſtances, little fleſhy protuberances ſhaped like hooks, which bend toward the tail.

Theſe are placed in three ranges, and ſeem intended to ſerve the creature in the place of legs or arms, when it has a mind to move upward or downward in the ſhell.

When we conſider the effects of this glutinous juice iſſuing from the body of this animal, in faſtening together any looſe ſubſtances it meets with, ſo as to form a caſe for it, it may be eaſily ſuppoſed that the adheſion of the *balani-marini*, and other the like ſhells, which remain all their lives fixed to ſome one ſpot, is performed in the ſame manner. Mem. Acad. Par. 1711.

Water-WORMS. There is a ſingular ſpecies of theſe creatures, which is found to be capable of reproduction or multiplication from cuttings, in the manner of the polype.

The diſcovery Mr. Trembley made of this ſtrange property in the polype, gave occaſion to the trying the experiment in regard to ſome other inſects. *Worms* were the moſt natural object of theſe experiments; and though they failed in many ſpecies, they yet ſucceeded in ſome, and proved, that nature has not given that amazing property of re-production of its moſt eſſential parts, to one only ſpecies of animals.

Mr. Bonet tried the experiment on a very nimble kind of *water-Worm*, by cutting it in two in the middle, and the ſucceſs perfectly anſwered the expectation; for the two pieces continued alive and vigorous, and in a little time became two complete *Worms*. The ſtructure of theſe *Worms*, though it appear ſimple to the naked eye, is very worthy the examination

tion of the microſcope, and when viewed with this aſſiſtance there are diſcovered in it parts extremely deſerving our attention. Phil. Tranſ. N°. 469. p. 470.

They are of a reddiſh brown colour, and of about two or three inches in length; their thickneſs is that of a common wire; they are compoſed of a ſeries of membranous rings, which continually decreaſe in thickneſs as they approach the extremities. Each of theſe rings has on its under part four, five, or ſix whitiſh ſpines, ſupplying the place of legs; and the clearneſs of the ſkin gives a happy opportunity of ſeeing the muſcular ſtructure of the body, every ring being compoſed of a great number of annular or circular muſcles, placed cloſe by one another.

The head is of no determinate figure, but the creature ſtretches or contracts it in length and breadth at pleaſure; and ſometimes it ſhews two ſmall round elevations, placed one on each ſide the head, which might be very eaſily taken for eyes; the extremity terminates in a point, that the creature may be the more eaſily able to pierce into the mud. The mouth is placed in that part where the head is largeſt, between the two elevations before-mentioned; this is terminated by two brown ſtrokes, and is of the figure of a creſcent. But when the mouth is opened, it appears an aperture of a circular figure, and is ſurrounded by a thick and ſtrong muſcle. This muſcle is of great ſervice to the animal alſo in its progreſſive motion, as it lays firmly hold of any ſmooth ſubſtance, and the animal is then able by means of its annular muſcles to draw up its whole body to that place: At the other extremity of the body, there is an oblong opening which ſerves as an anus.

There is nothing, however, more remarkable in this creature, than the great artery. This veſſel in caterpillars, and in many other inſects, runs all along the back; and is, by Malpighi, called a chain of hearts: But in this *Worm* it is folded in different degrees, in the different parts; and is in a manner only a long ſeries of folds, or doublings from one end to the other. Through theſe crooked paſſages there creeps along a liquor analogous to blood, and every moment a drop of it may be traced running up from the tail, and loſing itſelf in the brain; and it is eaſy to trace this moſt part of its way, by reaſon of the contraction and dilatation of the rings which follow one another ſucceſſively as it paſſes. Phil. Tranſ. N°. 469. p. 471.

It ſeems indeed that every portion of this artery, contained in the compaſs of one of the rings, is a true heart, which puſhes on to the next heart that drop of liquor which it had juſt before received from the preceding one; and the continual repetition of the ſyſtoles and diaſtoles in ſuch a ſucceſſive train of hearts, is an object that may be viewed a long time with pleaſure. It is beſt of all perceived in the middle of the body, where both the rings and the hearts are largeſt, and conſequently the motions moſt eaſily diſcernible. About the fifth or ſixth ring from the head this artery or chain of hearts becomes a ſmall and delicate filament, and from thence to the head diminiſhes in thickneſs, till it is wholly loſt near the mouth; but what is very obſervable, is the ſwiftneſs with which the blood is driven on in this part. Toward the tail the artery is alſo ſmall, and the alternate motion of the ſeveral portions of it confound themſelves together, ſo that the regular contractions and dilatations are not ſeen here, but only a ſort of undulatory motion of certain clouds of a fluid as it were ſucceſſively rolling one over another, but this with great regularity.

Under every junction of the rings there are to be ſeen ſmall veſſels dividing themſelves into numerous ramifications, all theſe ſeem to be branches propagated from the principal artery.

All along, and immediately under this artery, is extended the channel of the inteſtines; this would not be very viſible in itſelf, but the terreſtrial matter with which it is filled, uſually makes it eaſily diſtinguiſhable: This is furniſhed like the inteſtines of larger animals with different orders of muſcular fibres, which ſerve to protrude the remainder of the food; and this operation is alſo by means of the great tranſparency of the creature's ſkin, eaſily ſeen as it paſſes within the body.

It appears very evidently, from the contents of the ſtomach, and bowels of this animal, that it receives earth or mud into its body, and has its nouriſhment from it. Together with this earth it alſo ſometimes neceſſarily receives ſome bubbles of air; and as the air in the body of fiſhes ſerves them very greatly in raiſing and ſinking their bodies at pleaſure, ſo in the bodies of theſe *Worms* the air is not without its effect, but this is generally too powerful for the creature.

The bubbles of air are eaſily diſcerned in the body of the creature, and when they are in any great quantity they bring up the animal againſt its will, and all its ſtrength will not ſerve to carry it to the bottom; but it floats on the ſurface, till it has diſcharged a part of this troubleſome matter. This appears no eaſy thing for the creature to do, but there is often a great ſtruggle ſeen within its body, as it lies upon the ſurface of the water; the bubbles being driven toward the anus, and again forcing their way up to the head ſeveral times together.

Upon theſe *Worms* Mr. Bonet tried the experiment of cuting, in the manner of the operation on the polype, with ſucceſs. He divided one of them into two halves, and puting the ſeparated pieces into a glaſs of water; that half which had the head on it moved about, and ſeemed in all reſpects as well as before; but what was much more remarkable was, that the other half which had no head moved about and reſted occaſionally, and ſeemed to perform all its operations in the ſame manner as if it had one. It is obſerved of the pieces into which an eel is cut, or the tail of a ſerpent or lizzard, that they all move about a long time afterward; but their motion may always be ſeen to be irregular and convulſive; on the contrary, the motion of this part of the *Worm* ſeemed as regular as ever, and it made its way with tolerable ſwiftneſs, and that in a voluntary manner; the principle of life and motion ſeeming not to have been deſtroyed in it. If it met with any obſtacle in its way, it would ſtop and turn; and if ſet in the ſunſhine, it was plainly affected by the heat, and became more vigorous and moved more briſkly; and if a piece of ſtick was brought near it while it lay quiet, it would immediately ſtart and make its way as faſt as it could from it. Phil. Tranſ. N°. 469. p. 474.

On the third day ſome weeds and mud being added to the water, the half which had the head immediately plunged itſelf into the mud, but the other half only hid itſelf among the weeds; and at the cut end of this there was at this time very diſtinctly ſeen a tubercle, which looked like the knot of a branch of a tree; and at the end of a week each end was become perfect, and the two halves were two abſolutely perfect *Worms*. The new head of the one, and the new tail of the other, were perfectly the ſame with the old ones; and the ſtomach, the grand artery, and other parts had prolonged themſelves in a neceſſary manner.

After this experiment, the ſame obſerver cut other *Worms* of this ſpecies into four, eight, and as far as fourteen pieces; and moſt of theſe in a few days got new heads and tails, and became perfect animals. The ſeaſon of the year in which theſe experiments are made is of great conſequence, in regard to their ſucceſs; for in ſummer very few of the pieces fail of becoming perfect animals, even though one *Worm* be cut into near thirty pieces; but in winter many fail. Ibid. p. 475.

The ſecond or third day after the cutting produces the new heads and tails in ſummer, and in winter it is often ten or twelve days before they appear: The head always ſhews itſelf firſt, and lengthens itſelf continually for the firſt or ſecond week after its firſt appearance, and then it ceaſes to grow, having by that time arrived at a ninth part of an inch or thereabouts; this however is not, properly ſpeaking, the length of the head alone, but compriſes the rudiments of five or ſix rings which are annexed to it.

The tail does not begin to grow ſo ſoon as the head, nor does it ſtop its growth ſo ſoon, but continues increaſing in length from day to day for a long time; and in a few weeks the pieces of the middle part of a *Worm*, which were not originally above a ſixth part of an inch in length, will become perfect *Worms* of two inches.

Some of the pieces of the ſame *Worm* will grow longer and faſter than others; and, in general, the ſmalleſt or ſhorteſt pieces of the *Worm* do not grow ſo quick as the longer ones.

The ſeveral pieces cut from different parts of the ſame *Worm* alſo make a very different progreſs in their growth; but, in general it appears, that thoſe pieces which were cut off near the tail grow more ſlowly than thoſe from any other part. The laſt fragment, or that which contains the tail of the animal, grows the moſt ſlowly of all; and the head-end, which might be expected to grow as remarkably quick as this does ſlowly, does indeed exceed many of the parts in this particular, but is not always the very quickeſt of all.

There are ſeveral neceſſary circumſtances to be obſerved, in the progreſs of theſe operations; the moſt neceſſary of all is, the allowing the creatures food; as it appears plainly that they feed on mud, there ſhould always be a proper quantity of this added to the water in which the pieces are preſerved, for otherwiſe thoſe which ſeem to promiſe the faireſt for becoming perfect *Worms*, will often very ſoon periſh, merely for want of nouriſhment to ſubſiſt on, before they can grow to perfection.

Dr. Hales, in his vegetable ſtatics, relates a curious experiment, by which it is proved, that the bones of animals when they are oſſified to a certain degree, do not grow any longer, except at their extremities; and the caſe is the ſame, in regard to theſe *Worms*; for the old piece, which is the middle of the animal never lengthens itſelf, but the addition of new rings to each end make the increaſe of length in the *Worm*.

In all theſe pieces the liquor, which ſerves as blood to the animal, is found circulating from the tail-part towards the head, in the uſual way; and by this motion of the blood it

it is always eaſy to know, even in the ſmalleſt pieces, which is the head and which the tail-end, and the new head and tail are always ſeen to come regularly from the proper ends. Phil. Tranſ. N°. 469. p. 479.

Generation of WORMS. See the article GENERATION.

WORMS, in phyſiology. Many effects have been by the ignorant attributed to *Worms*, in which they have had no ſhare; and many things called *Worms*, have no right to that name.

We to this day vulgarly call the little black prominent ſpots in people's faces, *Worms*; but they are not ſo, nor any thing living. We owe the true knowledge of theſe to the ſagacious Mr. Lewenhoek, who, examining them by the microſcope after taken out of the face, found them only to be bundles of hairs or imperfect hairs in ſmall portions enveloped in thin films; in ſome, the fragments of hairs are evident, being ſtrong and rigid; but in others, they ſeem ſoft and pulpy.

Theſe *Worms*, as they are called, uſually appear as black ſpecks, ſometimes lying even with the reſt of the ſurface of the ſkin, ſometimes riſing above it; the hairs in each of theſe are from twenty to forty, in number. Their roots uſually lie irregularly, one deeper than another; but their extremities uſually are even. The deeper the *Worms* lie, the more difficult they are to be got out, and the fewer hairs they contain; ſo that they are beſt obſerved when taken from near the ſurface of the ſkin, and when taken from people who have the blackeſt hair, as they are moſt diſtinctly diſcernible in theſe, from their ſtrength and the difference of colour between them and their inveſtient membranes.

It may always be known alſo when there are hairs in one of theſe *Worms* fit to be examined, for if there are, the *Worm* is rigid, and comes out ſtrait; but if not, it comes out bent.

The make and conformation of theſe *Worms*, as they are called, is probably in this manner. When the root of a hair being deep in the ſkin ſupplies ſo much nouriſhment as to make the hair grow out and appear on the face, the upper part of the hair by rubbing, or ſome other violence, comes to be broken off, the lower part of the trunk of it ſtill remaining in the ſkin, the nouriſhment afterwards ſupplied to this part for hairs does not tend to lengthen out the broken one, the ſummit of that being ſtill liable to the ſame continual accidents; but new ones are propagated by its ſide, which being alſo broke off when they come to the ſurface, new ones are again formed and grow to the ſame length, till from the baſis of what nature intended for one hair we ſee thirty or forty; but this is probably not ſoon effected, but is the buſineſs of ſeveral years, in all which time the cluſter of hairs is ſuppoſed to be an animal, and the *Worm* is ſaid to be growing. The hairs growing on all parts of the body are ſharp-pointed at their natural ends, but thoſe ſhort ones which make up theſe *Worms* are always blunt at the end.

WORMS, in medicine. There are a great variety of medicines given for deſtroying the *Worms*, which breed in human bodies; but as they are of very different kinds, there is great caution required in ſelecting ſuch as are moſt proper for each peculiar caſe.

Acids, in general, are eſteemed good in theſe caſes; and lemon-juice, vinegar, and other vegetable acids, ſuch as pomgranate and currant-juice, and the like, are given; and ſometimes the mineral ones, as the ſpirit of vitriol, ſulphur, and the like. All theſe are properly given when there is a preternatural heat, and feveriſh diſpoſition; for they not only allay the heat, but reſiſt putrefaction.

Bitters in general are alſo reckoned among the medicines good againſt *Worms*; of this kind are wormwood, ſmall centaury, rue, and the like; and to theſe are to be added the purging bitters, ſuch as rhubarb, aloes, and coloquintida. Theſe medicines do not act merely as bitters; for it is well known, that many inſects will endure the bittereſt ſubſtances unhurt, and *Worms* will breed in the gall bladder; but they correct and alter the crude and viſcid matter in the inteſtines by which theſe animals are nouriſhed, and by ſtimulating the fibres of the inteſtines they often diſcharge the noxious matter, and *Worms* themſelves with it. They alſo correct the inactivity of the bile, which in children and perſons of moiſt habits is the general cauſe of the breeding and living of theſe inſects.

Oily medicines of all kinds are by ſome greatly extolled in caſes of *Worms*; and there ſeems this reaſon for it, that all inſects are deſtroyed by being put into oil, and that flies and many other ſmall animals, which, after ſeeming dead, on the being immerſed in other liquors, would come to life again, on being expoſed to the ſolar rays, never revived again after being drowned in oil. To this it is to be added, that very good effects always follow the giving oils, in caſes of the greateſt torment from *Worms*. It is not to be ſuppoſed however, that the oil acts by covering and drowning the *Worms*, ſince to this purpoſe there muſt be as much ſwallowed as would fill the whole inteſtinal canal; but this cannot be. Oils therefore plainly act in this caſe on the ſymptoms, not on the cauſe; and relax the ſpaſmodically contracted coats of the inteſtines, and as it were defend and line them with a ſort of mucilage, in ſuch a manner that the more acrid purging medicines neceſſary to the utter deſtruction of the animals themſelves, may be given with more ſafety. Thus it is a very good method to give a child over night half an ounce or more of oil of ſweet almonds, and in the morning following a briſk purge of the reſin of jalap, mercurius dulcis, or any thing elſe of this kind.

Saline ſubſtances in general are alſo greatly celebrated by many in caſes of *Worms*, and they are indeed capable of acting in a double capacity againſt them, at once deſtroying the tender ſtructure of many of them, and vellicating the inteſtines ſo as to promote the diſcharging them. The common bitter purging ſalts, as the glaubers ſalt, and the natural ſalt contained in the purging waters of different places, which is indeed glaubers ſalt alſo in its origin as well as qualities, are the beſt of all others for this purpoſe; if the natural waters are drank, it ſhould be in conſiderable quantities; and if the factitious ſalt be taken, it ſhould be diſſolved in large portions of water.

Many people who live on the ſea-coaſts give their children ſea-water, for the ſame purpoſe; and ſome uſe the broth of recent oyſters with pepper and other ſpices, and lemon-juice.

Salts of the vitriolic kind have alſo long been celebrated as remedies for *Worms*; and the common ſalt of ſteel, as alſo the Pyrmont waters, which are highly impregnated with particles of that metal, are found very uſeful in all caſes of this kind.

But if any diſorder admits of ſpecific remedies we might expect that this malady would; for theſe purpoſes many extol ſome of the gums, as aſſa-fœtida, galbanum, and myrrh, and the leaves of ſome plants, as wormwood and tanſey. Onions and garlick are alſo greatly commended; and bitter almonds and wormſeed, have long been famous. All theſe are found peculiarly deſtructive of *Worms*, and no method of cure ſucceeds well in which one or other of theſe has not a ſhare.

Among the minerals, we find alſo one remedy greater than all theſe, that is quickſilver; this has been given in many various forms, and found more or leſs ſucceſsful in all. Water, in which crude quickſilver had been boiled, was firſt given by Helmont, and that with great ſucceſs; after this Meiboom infuſed crude mercury in rheniſh wine, and found this more effectual than the former. But the moſt ſucceſsful method ſeems the giving proper doſes of mercurius dulcis, with ſome purging medicines, as the reſin of jalap.

Æthiops mineral, which is a mixture of quickſilver and ſulphur, is found alſo of great uſe; and quickſilver rubbed to a mixture with ſugar-candy, is preferred by Hoffman to all the other preparations. After a cure by theſe means, the patient ſhould be prevented from a relapſe, by abſtaining for a time from fleſh and fiſh; and, after this, from milk and cheeſe. Acrid purgatives, or hot remedies are never to be given, where there is any febrile heat; and when there is cauſe to ſuſpect that the duodenum is full of an acrid bile, then mercurials are to be avoided; as are all the draſtic purges; for theſe medicines, in theſe circumſtances, often bring on inflammations of the bowels.

Before the expelling the *Worms* from the ſmall inteſtines, it is proper to give glyſters of milk and honey, to allure all the worms together to that part. In caſes of the aſcarides lodged in the inteſtines, glyſters of milk with tanſey, garlick, and ſcordium boiled in it, have great effects; and glyſters of brine, or ſalt and water with aloes added to it, are alſo found of great benefit; as theſe troubleſome *Worms* are uſually lodged in the rectum, theſe glyſters take immediate effect.

It is proper alſo to give a vomit during the courſe of cure, to diſlodge ſuch *Worms* as may have got into the inteſtinum cæcum, ſince purging medicines cannot reach them while they remain there. External applications alſo of bulls gall, aloes, and coloquintida, are of ſervice laid in form of a cataplaſm to the belly. *Hoffman.* Oper. T. 4.

Tin is often recommended as a good remedy againſt *Worms*, particularly of the flat kind. Dr. Alſton, in the Med. Eſſ. Edinb. Vol. 5. Art. 7. directs an ounce and an half of the powder of pewter-metal to be mixed in half a Scotch mutchin, or about half a pint Engliſh meaſure of treacle, for children; but to grown perſons, he gives two ounces of the powder of pure tin, put through the fineſt hair-ſieve, and mixed with eight ounces of treacle. As to the adminiſtration of this midicine, the original receipt directs half of it to be taken the Friday before the change of the moon; the day after, half of the remainder; and the reſt on Sunday. On the monday a purge is to be taken. The doctor thinks there is probably nothing in the particularities of the day; but ſays, the medicine ſucceeds well in ſeveral ſpecies of *Worms*.

The Memoirs of the French Academy give a very remarkable account of an obſtinate pain cauſed by a *Worm*, in a place where few perſon, would have ſuſpected ſuch an animal for the cauſe of it.

A woman of thirty-ſix years old, who had not in any part of her life been ſubject to the head-ach in any particular de-

gree, found at this time a very violent and intolerable pain ſeize her on the lower part of her forehead toward the right ſide, and very near the top of the noſe. This held her a long time, and in the ſpace of two years extended itſelf to the temples on the ſame ſide. It now became continual alſo, whereas before it had had intermiſſions, and grew more and more violent; ſo that, in fine, it was attended with convulſions, and with a great diſordering of the patient's ſenſes during its more terrible agonies.

Many medicines were tried, but all in vain; and after four years ſpent in fruitleſs attempts for a cure, ſhe left off all medicines, and only kept to a regular courſe of life, and to the taking much ſnuff; from which ſhe uſually found eaſe. One morning, after taking ſome ſnuff, ſhe ſneezed violently, and threw out of her noſe a *Worm* wrapped up in a maſs of a pituitous matter, tinged with a little blood. She was frighted at the ſight, but ſhe found herſelf cured in a moment. The noſtril on that ſide bled a little for two or three days, and in that time her reaſon which had been much diſturbed, became perfectly calm and ſettled as before.

The ſize of this *Worm* was very extraordinary; it was thin, its utmoſt breadth or thickneſs not being ſo much as half a quarter of an inch: It uſually curled itſelf into ſeveral bendings; for it was diſcharged alive, and ſeemingly hearty, and in this ſtate was uſually about two inches long; but when it extended its body to its full length, it was not leſs than ſix inches. It was ſomething thicker in the middle than at either end, and was of a clear deep brown; its back was rounded or convex, and its belly flat; and it was covered all over, except on the head, with large and regular ſcales; theſe were evenly diſpoſed, and from between theſe there grew on each ſide fifty-ſix legs; theſe were as fine as a hair, and about one twelfth of an inch long.

The creature ſeemed therefore of the centipes kind, and in examining the head there were eaſily diſcovered the two eyes, two horns, and a pair of forceps made up of four arms; and the tail was armed with two points, longer, thicker and ſharper pointed than the legs. After examination it was put into an empty phial, where it remained alive eighteen hours; at the end of which time they poured ſome ſpirit upon it to preſerve it, and it lived and crauled about in this two hours.

The ſeat of the pain ſhews very plainly, that the *Worm* muſt have lived in the cavity of the frontal ſinus. This ſinus is about two inches long, and three quarters of an inch broad, and therefore might very well contain a *Worm* of this ſort in a bended poſture; and this ſeemed to have been accuſtomed to that poſture, by its naturally bending and folding itſelf up, when at its liberty. There is between this ſinus and the noſtril naturally a ſmall hole, by which they communicate and by which the ſinus admits the air at every inſpiration; and it is not impoſſible, but that a ſtrong ſnuffing in the air at ſome time might have carried into this ſinus with it the egg in which this little animal was incloſed.

It is poſſible indeed, that the egg might be lodged here by the round of circulation, but this ſeems much leſs probable; and it ſeems very certain that, however it got in, it was by this paſſage that it finally got out: It is true, that the cavity is naturally too ſmall to have given ſo large a creature paſſage, but it is eaſy to conceive that the creature might have gnawed it larger.

It is plain, that the egg when once received into the frontal ſinus, muſt find there every requiſite for its coming to perfection; warmth and humidity, there was very ſufficient; and when the creature was hatched, the juices excreted there might ſerve it abundantly for nouriſhment, inſomuch that it plainly grew much larger than it would have done if hatched on the earth in the common way, and lived a longer time than its fellows on earth uſually do, a life of four years free from accidents, and finely cheriſhed.

This was its ſtate; but what, alas! muſt have been that of the patient? The membrane of the ſinus being continually wounded by the forceps; the points at the tail, and no leſs than an hundred and twelve legs probably almoſt always in motion; every particular fibre of this membrane muſt have had its wound, and the complaint could not but grow worſe as the creature increaſed in ſize, and as it was irritated by the frequent uſe of the ſnuff; tobacco being a ſmell hateful to almoſt all animals.

From the ſymptoms of this patient, it will be eaſy to know any like accident that may hereafter happen, in which caſe it would be adviſeable to uſe ſnuff or tobacco in any ſhape; to take internally ſuch medicines as are known to deſtroy *Worms*, and to ſnuff ſtrongly up the noſe ſuch acrid and acid liquors as the patient could bear, and as might incommode the animal. Oil is a perfectly innocent medicine to us, yet is deſtructive of moſt animals; this therefore ſnuffed up alone, might work a cure; but if all theſe means fail, it would be very eaſy and very ſafe for a ſurgeon to make an inciſion into the part, and remove the noxious inſect. Mem. Acad. Par. 1708.

We have accounts in the Acta Leipſienſia, of *Worms* not only voided by urine, but let out of the veins in blood-letting; but there want more teſtimonies of ſuch marvellous things to procure them a general belief.

WORM, in gunnery, is a ſcrew of iron to be fixed on the end of a rammer, to pull out the wad of a firelock, carabine, or piſtol; it is the ſame with *wad-hook*, only the one is more proper for ſmall fire-arms, and the other for cannon.

WORM-*Seed-green*, a name given by authors to a ſeed of the ſantonicum kind, little known among us, but called by the generality of authors *chouan*.

WORM-*Tincture*, in chemiſtry, a name given by many to a medicine prepared by Hoffman, from earth-*Worms*; and in many parts of Germany eſteemed one of the greateſt medicines in the world, though leſs known in other places.

The preparation is this: the *Worms* are to be collected in the ſpring or ſummer months, and the larger ſort are the beſt. They are to be carefully dried, and reduced to a fine powder; this powder is to be mixed up into the conſiſtence of a pultice, with oil of tartar per deliquium, and this is to ſtand twenty-four hours; then ſpirit of wine is to be poured on it, ſo as to reach three fingers breadth above it, and a dram of ſaffron and half a dram of caſtor, are to be added, and the whole is to ſtand three days in infuſion, and after this be filtred off for uſe. Some add a ſmall quantity of opium to the tincture, but as it is often wanted in caſes where opium is not proper, it is better to keep it ſeparate thus made; and when there is occaſion to have it opiated, to add as many drops of laudanum as is judged neceſſary.

The oil of tartar in this caſe penetrates the very innermoſt ſtructure of the *Worms*, and is a means of the extracting ſuch a tincture from them, as no art could otherwiſe contrive to make; and the medicine becomes, according to Hoffman, much more an anodyne, from the admixture of the ſalt of tartar in the tincture.

When it is intended to be made with opium, it is always proper to add alſo ſome of the hound's-tongue-root, which is found as an anodyne to emulate the virtues of opium.

This tincture, which ever way prepared, is excellent in abating the pains of diſeaſes, that do not admit a cure. The fits of the gout are rendered eaſier by every doſe of it; and even in cancers, the pain is quieted in a wonderful manner by it, and life rendered much more ſupportable. *Hoffman*'s Act. Labarator. Chym.

WORM-*wood*, *Abſynthium*, in botany, the name of a genus of plants, the characters of which are theſe: The flowers are ſmall, but of the floſculous kind, being compoſed of ſeveral floſcules divided into many ſegments at the edges, and ſtanding upon the embryo-ſeeds, and contained in a ſcaly cup. The embryos ripen finally into ſeeds, not winged with down.

The ſpecies of *Wormwood*, enumerated by Mr. Tournefort, are theſe: 1. The broad-leaved tree *Wormwood*. 2. The Pontic *Wormwood*, or the Roman *Wormwood* of Dioſcorides. 3. The mountain-Pontic *Wormwood*. 4. The Cretic *Wormwood*, of a pleaſing ſmell. 5. The fine-leaved hoary Pontic *Wormwood*. 6. The Pontic *Wormwood*, with purple ſtalks, and finely divided leaves, green underneath. 7. The Auſtrian fine-leaved Pontic *Wormwood*. 8. The procumbent or creeping Pontic *Wormwood*. 9. The inſipid taſted *Wormwood*, reſembling the common kind. 10. The ſea *Wormwood*, with lavender leaves. 11. The ſea *Wormwood*, with the upper leaves divided into ſegments. 12. The German ſea *Wormwood*. 13. The Dutch ſea *Wormwood*. 14. The broad-leaved ſea *Wormwood*, of an agreeable ſmell. 15. The French ſea *Wormwood*. 16. The French wormſeed *Wormwood*. 17. The white mountain *Wormwood*. 18. The hoary Alpine *Wormwood*. 19. The dwarf white Alpine *Wormwood*. 20. The annual corymbiferous *Wormwood*. 21. The long-flowered Spaniſh white *Wormwood*. 22. The Spaniſh ſea *Wormwood*, with a rounder flower, and with the ſmell of wormſeed. 23. The ſweet-ſmelling *Wormwood*, with an elegant ſpike of flowers. 24. The African-tree *Wormwood*, with hoary vermiculated leaves. *Tournef.* Inſt. Botan. p. 457.

The common *Wormwood* is one of the fineſt medicines we know, as a ſtomachic and hepatic. It greatly ſtrengthens the ſtomach, opens obſtructions of the liver or ſpleen, promotes an appetite, and deſtroys worms.

The leaves and tops before the plant is in flower, are the parts of it moſt uſed; they are to be dried and given in powder, or in a light infuſion. Their virtues in the jaundice and dropſy, are very great. They are alſo given by ſome in putrid fevers. Many nauſeous inſects are deſtroyed, or driven away by the ſmell of this plant; and it is no uncommon practice among the good women in the country, to preſerve their cloaths from moths, by laying bundles of dried *Wormwood* among them.

The Roman and ſea *Wormwood* have much the ſame virtues with the common kind; but they are leſs nauſeous to the taſte, and therefore are generally uſed inſtead of it. The true Roman *Wormwood* is very ſcarce among us. What we buy under its name, is uſually *abſynthium ſeriphium*, or common ſea *Wormwood*.

Our brewers have ſome of them a method of uſing *Wormwood* inſtead of the hops, to give the bitter taſte to their malt-liquors, and to preſerve them: It is found to anſwer the latter purpoſe very well; but the taſte is ſo diſagreeable,

that

that it is much complained of. The reaſon of this is, that the people who uſe it do not underſtand the time of gathering it.

All plants are fulleſt of juice while in the ſhoot, but fulleſt of virtue when they have their ſeeds on them. This is the caſe with *Wormwood*, as well as a thouſand others; and though it in the ſeeding-time produces much more flavour than when younger, yet it is without that nauſeous bitter of the crude juice, which gives us the diſtaſte to the plant.

Some people have found the proper way of managing *Wormwood*, and have given a flavour with it to their malt-liquors, even preferable in the opinion of all palates to that given in the common way by hops.

The method is this: The plant is to be gathered when fully ripe and the ſeeds upon it, and in this ſtate hung up in ſmall bunches to dry. When thoroughly dried, a certain quantity of good ſtrong malt-liquor is to be impregnated with it, to the utmoſt ſtrength that it can poſſibly give it. This is to be ſet by for uſe, to add to all the reſt.

When the hops ſhould in the common way be added to the beer, this liquor is to be added in a proper quantity, making the taſte the judge when there is enough of it.

By this means juſt what degree of bitter is required may be given to the liquor, and the bitter of this common plant thus managed, is as perfectly agreeable as that of any vegetable in the world.

The *Wormwood* for this purpoſe ſhould have its ſeeds carefully preſerved in the drying, and it is beſt if not uſed till the year after it was gathered. Phil. Tranſ. N°. 124.

Many people who have been fond of the virtues of *Wormwood*, but diſguſted at its nauſeous bitter taſte, have attempted the diveſting it of its taſte, and yet preſerving its qualities; but it being as a bitter that this plant acts in many caſes, it is an evidently abſurd ſcheme to take away that quality on which its virtues depend, in order to the rendering them leſs diſagreeable to the palate.

The eſſential ſalt of *Wormwood* is afforded in great quantity, and poſſeſſes in many reſpects the virtues of the plant; this is a form in which it were to be wiſhed, that not only this, but many other medicinal plants were more often given.

Wormwood ſhares with all other bitters the virtues of an abſterſive deobſtruent, and is in ſome degree purgative as all bitters are. *Wormwood* is one of thoſe plants which the chemiſts have generally choſen for their proceſſes of the reſuſcitation of plants from their aſhes; and though the pretended principles of this art are falſe, yet there have been ſome of the artiſts ſo cunning to form repreſentations of this plant, that have deceived and puzzled the greateſt unbelievers, though they have not convinced them. Phil. Tranſ. N°. 74.

WORMS *Wood-fly*, in natural hiſtory, a very ſmall black fly, found on the ſtalks of the common *Wormwood* in June and July.

WORRALL, in zoology, an animal of the lizzard kind, of about four feet long and eight inches broad, with a forked tongue, which it puts out like a ſerpent, but without teeth.

It is a harmleſs animal, and feeds only on large flies, and the ſmaller ſpecies of lizzards. It is found in Ægypt only during the hotteſt months, and principally frequents the grottos and caverns in the mountains on the weſt of the Nile, where it ſleeps during the winter ſeaſon.

It is ſaid to be greatly affected by muſic; but experiment ſhews this to be an erroneous opinion. *Pocock*'s Ægypt. Vol. 1. p. 208.

WOUGHS, in mines, are the walls or ſides ſometimes of hard ſtone, and ſometimes ſoft; when ſoft, the miners ſay they are rotten: Theſe are the bounds of an entry. Betwixt them all ſorts of earth, ſtones, and ore lie; or, as philoſophers ſay, grow. *Houghton*'s compl. Miner, in the Explan. of the Terms.

WOUND (*Cycl.*)—There is nothing will give a truer light into the nature and conſequence of a deep *Wound*, than a due conſideration of what natural actions of the body are impeded thereby. For inſtance, in *Wounds* of the breaſt, when the patient draws his breath with ſhortneſs and difficulty, and is at the ſame time attended with an hæmoptyſis and hiccough, we may rationally conjecture that the lungs, or the diaphragm are wounded; ſo in *Wounds* of the abdomen, when chyle is voided, it is a plain indication that the ſtomach, ſmall guts, or lacteals, are wounded: When excrements paſs by the *Wound*, the great guts are wounded. In the ſame manner, bilious blood ſhews the liver or gall-bladder to be divided: If urine paſſes by the *Wound*, the urinary bladder or elſe the ureters are wounded; but bloody urine denotes a blow on the kidneys, or a *Wound* of the bladder. But when there are large profuſions of blood this way, it is a ſign that ſome of the larger blood-veſſels are wounded: Vomiting of blood, declares the ſtomach to be the injured organ: Violent pains, attended with convulſive twitches, ſhew that a nerve is wounded, or elſe that ſome foreign ſubſtance is left in the *Wound*. Whenever the ſenſes are diſordered after a *Wound* received on the head, a concuſſion of the brain is much to be feared. Difficulty of breathing, pains in the breaſt, and hiccoughing, are ſymptoms of a *Wound* in the diaphragm. It is of bad conſequence for a *Wound* to be attended with a large tumour; but it is of the laſt conſequence if it is attended with no degree of tumour at all; the firſt is an indication of great inflammation; the laſt of mortification; ſome degree of tumour is always therefore beſt in *Wounds*.

WOUNDS *naturally, and neceſſarily mortal*. We properly ſtyle thoſe *Wounds* mortal which are not to be remedied by all the art and induſtry of man. Thus *Wounds* are of this kind which are attended with ſo violent an hæmorrhage, as to produce inſtant death: of this ſort are reckoned *Wounds* that penetrate the cavities of the heart, and all thoſe *Wounds* of the viſcera, where the large blood-veſſels are opened; ſuch are large *Wounds* of the lungs, liver, ſpleen, kidneys, ſtomach, inteſtines, meſentery, pancreas, uterus; of the aorta, of the iliac, cœliac, renal, meſenteric, and carotid arteries, eſpecially if they are wounded near their origin; of the ſubclavian alſo, or vertebral; of the vena cava, the iliac vein, the internal jugular, vertebral; renal, meſenteric of the vena porta, and of the larger veins that lie deep in the body, becauſe their ſituation will not admit of proper applications to reſtrain the flux of blood. Heiſter therefore reckons, very juſtly, theſe among the *Wounds* that are abſolutely incurable, ſince they are not remediable either by aſtringents, ligature, or fire.

Thoſe *Wounds* alſo are not leſs mortal than the former, which obſtruct, or entirely cut off the paſſage of the animal ſpirits to the heart; ſuch are *Wounds* of the cerebellum, of the medulla oblongata, and ſome violent ſtrokes of the brain itſelf.

There is reaſon to apprehend very great danger, when the ſmall veins or arteries, which are contained in the cranium, are injured; for the blood flowing from them into the internal ſinuſes of the brain, either produces too great a preſſure upon thoſe very tender parts of the brain, and ſo obſtructs the courſe of the blood and ſpirits; or elſe, being corrupted, it putrifies the brain itſelf, if it cannot be evacuated by the aſſiſtance of the trepan, which is the caſe when this accident happens at the lower part of the cranium, or in the ſinuſes of the brain; nor is there leſs danger where the nerves, which tend to the heart, are wounded, or entirely divided; for, after this, it is impoſſible for the heart to continue its motion.

To this claſs are to be referred alſo all *Wounds* which entirely deprive the animal of the faculty of breathing: there is therefore great danger where the aſpera arteria is intirely divided; for where it is only divided in part, it may be healed again by the aſſiſtance of an expert ſurgeon: to this place alſo belong violent ſhocks of the bronchia, mediaſtinum, and diaphragm, eſpecially the tendinous part of it.

Thoſe *Wounds* alſo which interrupt the courſe of the chyle to the heart, are no leſs incurable than the former; ſuch are *Wounds* of the ſtomach, inteſtines, receptacle of the chyle, thoracic duct, and larger lacteals; to which may be alſo added *Wounds* of the œſophagus, if they are large; though death is not ſo ſudden an attendant on theſe *Wounds*; but, for want of nouriſhment, the perſons afflicted by them are weakened by degrees, and at length die conſumptive.

In this account thoſe *Wounds* alſo are not to be omitted, which are inflicted upon membranous parts, that are ſituated in the abdomen, and contain ſome ſecreted fluid, as on the bladder, either of the bile or urine, the ſtomach, inteſtines, receptacle of chyle, and lacteal veſſels. The fluids contained in theſe parts, when once they are let looſe into the cavity of the abdomen, cannot be properly diſcharged, and therefore eaſily corrode the internal parts of the body; and the membranes that contained them are generally ſo fine, that they will not admit of agglutination, eſpecially ſince no medicine from without can be applied. A few indeed have recovered after ſlight *Wounds* in theſe parts; but ſince the number of theſe inſtances is but few, and the cure in them has been accidental, and not performed by the ſurgeon's art, theſe may very juſtly be added to the liſt of mortal *Wounds*.

WOUNDS *mortal by Neglect*. Many *Wounds* there are which, though the experienced ſurgeon could remedy, yet prove fatal, if neglected, or left to nature: Of this number are thoſe which produce inſtant death, unleſs relieved by preſent aſſiſtance; ſuch are *Wounds* of the larger external blood-veſſels, which might be remedied by ligature, by the application of aſtringent medicines, or the actual cautery. Of this kind are *Wounds* of the brachial, or crural artery, unleſs they are too near the trunk of the body; *Wounds* in the large arteries of the cubit, or tibia; of the branches of the external carotid, or temporal artery; to theſe alſo may be added *Wounds* of the jugular and other veins, ſituated upon the external parts of the body; but in theſe caſes no help can be given, unleſs the ſurgeon be brought before there has been a vaſt profuſion of blood. *Heiſt.* Surg. p. 30.

WOUNDS *mortal by Accident*. *Wounds* are properly ſaid to become mortal by accident, where the patient's death, from them, is occaſioned either by the ill conduct of the patient himſelf, or by the neglect or ignorance of his ſurgeon, the *Wound* itſelf being of the number of thoſe deemed curable by the judicious practiſer. Under this head are to be reckoned thoſe *Wounds* which the ſurgeon has neglected to cleanſe ſufficiently, though he had it in his power to do it; as when ſome foreign body, which might eaſily have been extracted,

is

is left in the *Wound* by the careleſſneſs of the ſurgeon, and produces inflammatios, hæmorrhages, convulſions, and finally death itſelf. So in *Wounds* of the thorax and abdomen; if the ſurgeon does not uſe his utmoſt diligence to evacuate the grumous blood, it will corrupt there, and by drawing the neighbouring parts into conſent, will expoſe the patient to death: great care muſt therefore be taken that the lips of the *Wound* do not cloſe, till the blood, which is collected in the cavity of the body, be all evacuated, if poſſible, which will be perceived by the difficulty of breathing, and other bad ſymptoms going off; but if any of the larger internal veſſels are wounded, then all attempts to diſcharge the blood are vain; for the violence of the hæmorrhage takes off the patient.

Wounds are alſo to be accounted mortal by accident, which are treated or ſearched in too rough a manner by the ſurgeon; for if *Wounds* are handled roughly which are full of nervous parts, or of large blood-veſſels, there is great danger of bringing on hæmorrhages, convulſions, inflammations, gangrenes, and finally death itſelf.

The caſe is alſo the ſame in external *Wounds*, which are ſlight of themſelves, but under which the patient is loſt by the inflammation which is brought on, and increaſed by the ſurgeon's injudicious treatment; or when any one is taken off by the violence of the hæmorrhage, from a *Wound* of the hand or foot; for, in this caſe, the ſurgeon might eaſily have ſtopped the blood, by the application of proper remedies, or by ligature: Or, when the patient is guilty of any intemperance, either in eating or drinking; or of any exceſs of paſſion; of expoſing himſelf to the cold air, or of uſing violent exerciſe; for by theſe means *Wounds*, more eſpecially thoſe of the head, by being liable to freſh hæmorrhages, and other dangerous accidents, frequently become mortal, nowithſtanding that they naturally would not prove ſo, and that though the ſurgeon uſes his utmoſt care and ſkill.

Among theſe alſo are to be accounted thoſe *Wounds* of the head, where the patient is loſt by the vaſt quantity of blood, which is extravaſated in the cavity of the cranium, and is confined there; but where he might have been relieved, if the trepan had been applied in time; for though *Wounds* of this kind generally prove incurable, yet as there is, at leaſt, a poſſibility of ſaving a perſon in theſe circumſtances, by the uſe of the trepan, this may properly be reckoned among the doubtful caſes, and not deemed abſolutely mortal: And laſtly, a bad habit of body frequently prevents the cure of *Wounds*, which would admit of an eaſy cure in a healthful ſubject; ſo we frequently ſee the ſlighteſt puncture in the hand or foot of an hydropical, conſumptive, or ſcorbutic perſon, ſhall produce a gangrene, and prove mortal, though the ſurgeon ſpares no care nor application to prevent it. *Heiſter*'s Surg. p. 29, 31.

Cure of ſlight WOUNDS. This is generally performed with great eaſe, by applying to the part a ſmall portion of ſcraped lint, well ſaturated with ſpirit of wine, oil of turpentine, or St. John's wort, liniment of Arcæus, or balſam of capivi, Gilead, or Peru, and ſecuring the dreſſing with a plaſter; this dreſſing ſhould be renewed once in a day or two, and the lips of the *Wound* will preſently agglutinate. *Heiſter*, p. 34.

WOUNDS *dangerous, how to be healed.* *Wounds* of this kind are firſt to be cleanſed from the extravaſated blood, ſordes, &c. In the next place, if a bullet, the point of a ſword, or any part of the cloathing, a piece of glaſs, or any other foreign body, remains in the *Wound*, it is to be removed either with the fingers, or a pair of forceps, or other proper inſtruments. The hæmorrhage is to be ſtopped at the firſt dreſſing; the divided parts are to be brought as near to each other as poſſible, and their ſituation ſhould be ſo maintained, that the cicatrix which is left may appear even.

Where there are no extraneous bodies to be removed, the grumous blood is to be wiped away with a ſoft ſpunge, or a parcel of fine lint wrung out of hot wine or brandy; and when this is done, the next ſtep is to ſtop the hæmorrhage; but before the ſurgeon attempts the removal of extraneous bodies, it behoves him well to conſider whether it be more proper to do it inſtantly, or to wait a more convenient time; for if the patient is become extremely faint, from the loſs of blood he has already ſuſtained, it will be neceſſary, in this caſe, to ſtop the hæmorrhage, and then, in ſome meaſure, to endeavour to revive him by moderate draughts of warm broths, white-wine whey, or ſome cordial medicine; for if theſe precautions are neglected, the patient may not unlikely die in the operation: So alſo where you have reaſon to fear, that in the extracting the broken point of a ſword, or other weapon, you are in danger of wounding a large blood-veſſel or nerve, it will be better to wait a little, either till the patient is ſomewhat come to himſelf, or till the *Wound* is enlarged by ſuppuration. *Heiſter*'s Surg. p. 35.

Gun-Shot-WOUNDS. See the article GUN-*Shot*.

WOUNDS *of the Neck*. See the article NECK.

WOUNDS *of the Eyes*. See the article EYE.

Loſs of Subſtance in WOUNDS. When this happens in *Wounds*, they will not unite either by the help of plaſters, or the ſuture, or by any other method, till filled up with new fleſh. To bring on this, lint dipped in oil, or ſpread over with ſome vulnerary balſam or ointment, and applied to the bottom of the *Wound*, is very ſerviceable, covering with a plaſter compreſs, and the proper bandages; and this dreſſing is to be repeated daily. There ought to be a balſamic and emollient quality in theſe ſarcotic medicines, that they may not only reſiſt putrefaction, but may alſo ſoften the new fleſh; ſo that it may eaſily receive additions from the blood, and ſuffer itſelf to be elongated. *Heiſter*'s Surg. p. 41.

WOUNDS *in Horſes*. The moſt terrible *Wounds* theſe creatures are ſubject to, are thoſe got in the field of battle. The farriers that attend camps have a coarſe way of curing theſe; but it is a very expeditious and effectual one.

If the bullet be within reach, they take it out with a pair of forceps; but if it lie too deep to be come at, they leave it behind, and dreſs up the *Wound* in the ſame manner as if it were not there.

They firſt drop in ſome varniſh from the end of a feather, and when the bottom is thus wetted with it, they dip a pledget of tow in the ſame varniſh, which they put into the *Wound*, and then cover the whole with the following charge: Take a quarter of a pound of powder of bole armenic, half a pound of linſeed oil, and three eggs, ſhells and all; add to theſe four ounces of bean-flour, a quart of vinegar, and five ounces of turpentine; this is all to be mixed over the fire, and the *Wound* covered with it. This application is to be continued four or five days, then the tent put into the *Wound* is to be dipped in a mixture of turpentine and hogs-lard; by this means a laudable matter will be diſcharged, inſtead of the thin ſharp water that was at firſt. Then the cure is to be compleated by dreſſing it with an ointment made of turpentine, firſt well waſhed, and then diſſolved in yolks of eggs, and a little ſaffron added to it.

This is the practice in deep *Wounds* that do not go through the part; but in caſes where the bullet has gone quite through, they take a few weavers linnen thrumbs, made very knotty; theſe they make up into a kind of link, and dipping it in varniſh, they draw it through the *Wound*, leaving the ends hanging out at each ſide; by means of theſe they move the link or ſkain three or four times a day, always wetting the new part that is to be drawn into the *Wound* with freſh varniſh. They put on a charge of the bole armenic, &c. as before deſcribed, on each ſide of the wounded part, and continue this as long as the *Wound* diſcharges thin watery matter, or the ſides continue ſwelled. After this they dreſs it with the ointment of turpentine, yolks of eggs, and ſaffron, till it is perfectly cured.

The other methods are the dreſſing the *Wound* with an ointment made of wax, turpentine, and lard, and covering it with linnen rags wetted with cream; or the dreſſing, with a mixture of yolks of egg, honey, and ſaffron, and covering it up with cream and baum-leaves beaten together.

When the *Wound* is ſo dangerous as to require the aſſiſtance of internal medicines, they give the following pills: Take aſſa-fœtida, bay-berries, and native cinnabar, of each a pound; beat up the whole into a maſs with brandy, and roll it into pills of fourteen drams weight each. Theſe are to be laid in a ſhady place to dry, after which they will keep ever ſo long without any damage. The horſe is to take two of theſe every other day, or, if neceſſary, every day, till he has taken eight or ten of them, and he is to ſtand bridled two hours before and after the taking them.

When the *Wound* ſeems at a ſtand; not appearing foul, and yet not gathering new fleſh, there muſt be recourſe had to the following powder, whoſe effect in bringing new fleſh is wonderful: Take dragon's blood and bole-armenic, of each two ounces; maſtic, olibanum, and ſarcocolla, of each three drams; aloes, round birth-wort, and common iris-root, of each one dram and a half; make the whole into a fine powder. This is ſometimes uſed dry, ſprinkling it on the *Wound*; but ſometimes it is mixed with turpentine, ſometimes with juice of wormwood, and ſometimes with honey of roſes, and either way does very well.

When the *Wound* grows foul, and requires a detergent to cleanſe it, the common liquor for this purpoſe is a phagedenic water, which they make of lime-water, and ſublimate in this manner:

Take two pounds and a half of newly made and unſlacked lime, put it into a pewter veſſel, and pour on it five quarts of boiling water. When the bubbling is over, let it ſtand to reſt two or three days, ſtirring it often with a ſtick; then pour it clear off after a due time for the lime to ſettle, and filter it through ſome whited brown paper, made for the lining of funnels, on this occaſion. To a quart of the clear lime-water, thus prepared, add eight ounces of ſpirit of wine, and one ounce of ſpirit of vitriol; when theſe are well mixed, by ſhaking them together; then add an ounce of corroſive ſublimate in fine powder; mix all well together, and keep the whole in a bottle, to be uſed for the cleanſing theſe foul *Wounds*, and on any other occaſions, where there may be a detergent of this powerful kind neceſſary. It will keep good many years.

If this water will not thoroughly cleanſe the *Wound*, but there ſtill will remain a quantity of foul matter in it, and there is danger of a gangrene, they add to it as much arſenic, in fine powder, as there was of the corroſive ſublimate; that is, at the rate of an ounce to a quart and half a pint.

Theſe

Theſe are all the medicines that the farrier need carry with him on account of *Wounds*; and they are all ſuch as may be prepared at home, and will continue good ſo long as he has occaſion to keep them, or much longer; and what is left of one year will ſerve for others.

When the neceſſary applications are thus ſettled, it may not be improper to add the general rules by which they conduct themſelves in the cure.

1. The *Wound* muſt be probed at firſt, but very gently, and afterwards as gently and as ſeldom as may be, for the horſes fleſh is the moſt eaſy of all others to be contuſed in wounded parts, and to fall into a gangrene from the hurt. 2. The *Wound* muſt be kept continually as clean as poſſible, and free from proud fleſh. 3. The neceſſary revulſion muſt always be made by bleeding, as ſoon as the *Wound* is dreſſed the firſt time; this prevents inflammation, and a great many other bad accidents. 4. If the *Wound* be in ſuch a place, that the horſe can get at it with his tongue to lick it, great care muſt be taken to prevent his doing ſo, as it will greatly retard the cure. 5. The farrier is never to proceed to ſuppuration in any caſe in which the humours can be either diſſolved or repelled, and eſpecially in parts that are full of ſinews and ligaments, or that are near the bones. 6. If a *Wound* be accompanied with a great contuſion, or if it be of a round or circular figure, inciſions are often neceſſary about its edges, and ſometimes the application of cauſtics. 7. The *Wound* muſt be always carefully covered, for the acceſs of the air retards the cure. 8. The callous lips of a *Wound* muſt always be cut to the quick, before theſe can be united together. Theſe may ſerve for general rules, that hold good in all caſes; and to theſe may be added ſome that are principally applicable to peculiar circumſtances of the *Wounds*.

Wounds of the breaſt are to be cured with tents and folds of ſoft linnen laid over them, ſteeped in the following mixture: Take verdegreaſe, vitriol, and alum, of each one ounce; vinegar eight ounces, honey a pound; let all theſe be boiled together till they become red. *Wounds* in the belly can only be cured by ſowing up the peritonæum with ſtrong woollen thread, not ſilk, leaving the extremities without the ſkin. The ſkin is to be ſowed together with a ſtrong hempen thread waxed, joining the lips of the *Wound* together, by this means, in form of a buckle. This is to be covered with the common ointment for *Wounds*; and if an inflammation comes on, chalk diſſolved in vinegar is to be added.

If the *Wound* be ſuch that the guts come out at it, the horſe may ſtill be recovered, if proper caution be uſed: the guts are to be immediately returned into their place; but they muſt not in this be touched with the hand, but with a ſponge dipped in warm water. And, in order to the making them more readily get into their places, it is proper to make the creature vomit, by thruſting down his throat a feather dipped in oil. If the *Wound* through which they fell is not big enough to return them eaſily by, it muſt be enlarged by cutting; but if the guts are found to be bruiſed or wounded, it is in vain to attempt any thing, for death muſt follow.

There is alſo a certainty of death when, after a *Wound* of any kind in the belly, the horſe voids blood at the fundament.

When a horſe is wounded near the groin, he eaſily falls into convulſions; in this caſe he is to be kept from drinking as much as poſſible: he is alſo to be covered well up, and kept quiet, and to have green things given him to eat. *Wounds* on the knees are very difficult of cure, becauſe the part is in motion almoſt continually, and there is very little fleſh to work upon. When the *Wounds* are but ſlight, and in the muſcular parts of the body, a mixture of honey and tallow, boiled together, will often prove a cure; when the *Wound* is more conſiderable, turpentine melted in a little common oil, and applied hot, is the general remedy. If a wound happen between the ſhoe and the hoof, care muſt be taken that no foreign matter be left in it, and it muſt be dreſſed with any of the ointments that have verdegreaſe in them; and a charge of bruiſed elder-leaves is very proper to be applied over all. If the *Wound* be deep and narrow, it muſt be enlarged at the orifice, and turpentine and wax, melted in lard, muſt be poured into it. The ſame rule of opening the orifice holds good in all deep and narrow *Wounds*.

If a nerve happens to be cut, it muſt be cloſed, and a defenſative muſt be applied, to prevent a concourſe of humours to the part; a fomentation made of oil, wine, and honey, mixed together, is alſo very proper, wherever a nerve is hurt, and a pultice may be applied over all, made of marſhmallow-roots boiled ſoft, with bread and milk.

If the horſe happens to be wounded by a piece of wood, bone, or any other hard ſubſtance, part of which remains in the *Wound*, this muſt be carefully taken out, whatever pain it may coſt the creature to do it, and the *Wound* muſt then be dreſſed with the common *Wound*-ointments. In this, or any other caſe of a freſh *Wound*, the waſhing it with oil of turpentine, is an excellent method of preventing ill conſequences.

WRASSE, in zoology, the name of a fiſh called by authors, *turdus vulgaris*, and by ſome *tinca-marina*, the ſea-tench.

It very much reſembles the common freſh-water tench in figure, and is covered with large ſcales. Its uſual ſize is about five or ſix inches in length. Its colour is very variable; red, yellow, and browniſh, being very frequently mixed in the ſcales; and it has five or ſix longitudinal lines, alternately of a pale yellow, an olive-colour, and a duſky red. Its noſe is long, and bent upwards, and it has thick and fleſhy lips extended over the jaws. Its mouth is ſmall, and its teeth not very ſharp; its tail is not forked. The membranes of the fins and tail are variegated with red and blue ſpots, and the anterior rays of the back-fin are prickly. It is caught in plenty on the Engliſh ſhores, and is ſold among the poorer ſort of people in Wales and Cornwall; but is not eſteemed a very delicate fiſh. *Willughby*'s Hiſt. Piſc. p. 320.

WRECK (*Cycl.*)—*Wreck*, in metallurgy, a veſſel in which the third waſhing is given to the ores of metals.

In Cornwall, when the tin ore has been twice waſhed, they take the head tin, or that part of the tin ore that lies uppermoſt, out of the buddle, and throwing it into this veſſel, they pour water on it, and work it about with wooden rakes, till it is cleared from whatever other extraneous matter there may ſtill have remained mixed with it, and is, after this, fit for the blowing-houſe to be run into metal. *Ray*'s Engliſh Words, p. 122.

WREN. See the article JENNY-*Wren*.

Creſted WREN. See the article REGULUS *Criſtatus*.

WRINGLE-*Tail*, a name given by the people of ſeveral parts of England, to the *curvicauda*, a ſpecies of bee-fly, very much reſembling the bee in ſhape, but having only two wings and no ſting.

It is very troubleſome to horſes, but does not ſuck their blood, but only lays its eggs in their ſkins; it is called in other counties the *whame* and the *barrel-fly*.

WRIST (*Cycl.*)—The *carpus* or *wriſt* conſiſts of eight ſmall, unequal, and irregular bones, all of which, taken together, repreſent a ſort of grotto, of an irregular quadrangular figure, and connected principally with the baſis of the radius.

Conſidered in this manner, the whole connection of them has two ſides and four edges: One of the ſides is convex and external, the other concave and internal. The convexity of the outſide is pretty regular and even; but the concavity of the inſide has four eminencies, one at each corner. One of the four edges touches the fore-arm, and is as it were the head of the carpus; another of the edges touches the metacarpus, and may be called the baſis; the third is toward the point of the radius, and the fourth toward the point of the ulna; the firſt of theſe latter two may be called the ſmall edge, the latter the larger.

The bones of the carpus are divided into four rows, the firſt of which lies next the fore-arm, the ſecond next the metacarpus; each row conſiſts of four bones; but the fourth of the firſt row lies in a manner out of its rank. Each bone has ſeveral cartilaginous ſurfaces for their mutual articulations, and, in ſome of them, for their articulations with the radius, and bones of the metacarpus and thumb.

It is to no purpoſe to diſtinguiſh the three ordinary dimenſions in any of theſe bones, except one; but in moſt of them we may conſider ſix ſides, one external, turned towards the convex ſurface of the carpus; one internal toward the concave ſurface; one toward the fore-arm, which may properly be called the brachial ſide; one toward the fingers, to be called the digital ſide; one toward the point of the radius, or the radial ſide, and one toward the point of the ulna, or the cubical ſide.

Of theſe ſides ſome are bony, others are cartilaginous or articular; theſe laſt I call ſides, the others ſurfaces, as being portions of the carpus's ſurface in its natural ſituation: to diſtinguiſh theſe bones from each other, they have been called the firſt, ſecond, third, and fourth, bones, of the firſt or ſecond row, beginning to count from the radius or thumb. But Lycerus has been at the pains of giving a particular name to each of them.

He calls the firſt of the firſt row the *os ſcaphoides*, the ſecond the *os lunare*, the third the *os cuneiforme*, the fourth the *os piſiforme*; the firſt bone of the ſecond row the *os trapezium*, the ſecond *os trapezoides*, the third *os magnum*, and the fourth *os unciforme*; all which ſee in their proper places. *Winſlow*'s Anatomy, p. 82.

The bones of the carpus are articulated with one another by arthrodia; but the firſt row forms a ſort of ginglymus with the ſecond; becauſe the head of the os magnum may turn in the cotyloide cavity of the firſt row, while the two firſt bones of the ſecond row ſlide upon the digital ſide of the os ſcaphoides, and the os unciforme in the ſame manner on the os cuneiforme.

When all theſe bones are in their natural ſituation, a tranſverſe depreſſion is formed in the convex ſide of the carpus, by which the two rows are diſtinguiſhed. This depreſſion appears moſt between the os ſcaphoides, and the three laſt bones of the ſecond row, and looks like a fold, by which the ſecond row is thrown back upon the firſt. The four eminencies on the concave ſide of the carpus, are for the inſertion of a ſtrong tranſverſe ligament. The inner ſubſtance of all theſe bones is ſpongy, and their ſufaces are not very compact. *Winſlow*'s Anatomy, p. 85.

WRIST *Fractured.* The bones of the *Wriſt* are very ſeldom ſubject to fracture, on account of their ſmallneſs. And when they are fractured, there is but little hopes of a cure; for the ligaments and tendons are here ſo numerous, and the bones ſo very ſmall, that it is ſcarce poſſible to reduce them to their places, or to make them grow together again.

On this account the joint of the hand generally becomes ſtiff and immoveable after theſe accidents, or elſe abſceſſes, ſuppurations, fiſtulæ, and caries of the bones follow them; and theſe, on account of the ſoftneſs of the bones, and the difficulty of diſcharging the matter, are ſeldom remedied, but by amputating the hand. What can be done, however, toward the curing a fracture in this part, is this; the aſſiſtant muſt lay hold of the hand above the *Wriſt* and below it, and extend them as far as is neceſſary in oppoſite directions; the ſurgeon is, while this is doing, to replace the bones with his fingers, and when they are all replaced, to bind the hand up with a proper bandage. *Heiſter.* Surg. p. 129.

WRIST, in the manege. The bridle *Wriſt*, is that of the cavalier's left hand. A horſeman's *Wriſt* and his elbow ſhould be equally raiſed, and the *Wriſt* ſhould be two or three fingers above the pummel of the ſaddle. To ride a horſe from hand to hand, *i. e.* to change hands upon one tread, you need only to turn your *Wriſt* to that ſide you would have the horſe to turn to, without advancing your hand. But if your horſe ſtops, you muſt make uſe of both your legs. See the article HAND and LEG.

WRIT (*Cycl.*)—WRIT *of Inquiry of Damages*, a judicial *Writ* that iſſues out to the ſheriff upon a judgment by default, in action of the caſe, covenant, treſpaſs, trover, &c. commanding him to ſummon a jury to enquire what damages the plaintiff hath ſuſtained, *occaſione præmiſſorum*; and when this is returned with the inquiſition, the rule for judgment is given upon it; and if nothing be ſaid to the contrary, judgment is thereupon entered. 2 Lill. Abr. 721.

WRITING, (*Cycl.*)—To *write* without blacking the fingers: Prepare the paper with a fine powder, made of three parts of calcined copperas, two of galls, and one of gum arabic, thoſe being freſh mixed, rub them with a hare's foot into the pores of the paper; and then *write* with fair water, and the black letters will immediately appear. *Boyle*'s Works abr. Vol. 1. p. 114, 115.

To make new *Writing* appear old, moiſten it with oil of tartar per deliquium, more or leſs diluted with water, as you deſire the ink to appear more or leſs decayed. *Boyle*, ib. p. 115.

We may *write* without ink, or its materials: For this purpoſe, take a fine powder of calcined hartſhorn, of clean tobacco-pipes, or rather of mutton-bones burnt to a perfect whiteneſs, and rub it upon the paper, and then *write* with a ſilver bodkin, or the like. Ibid.

The diſcharging of ink out of parchment, paper, &c. is commonly done by aqua fortis diluted ſufficiently with water, that it may not deſtroy the paper. The like may be done with oil, or ſpirit of vitriol diluted. The juice of lemons, or ſtrong vinegar, will take ink out of linnen more ſafely, as the mineral acids are apt to deſtroy the linnen, unleſs great care be uſed in diluting them.

We may *write* on iron with corroſive ſublimate wetted with common water: For this purpoſe, the parts of metal we would preſerve untouched ſhould be covered with wax, and that taken off in the proper places to make way for the corroding ſubſtance. *Boyle*'s Works abr. Vol. 1. p. 528.

The like may be practiſed by means of aqua fortis.

Mr. Boyle mentions a method he had of copying a whole page of *Writing* at once. But we do not find his deſcription of it any where. See Works abr. Vol. 1. p. 136.

The ſame author informs us of a method of imitating *Writing*, on copper-plates. The copy to be engraved is to be wrote with a peculiar kind of ink, and the copper-plate being moderately warmed, is rubbed over with a white varniſh, and ſuffered to cool; then the paper being gently moiſtened, that it may readily communicate its ink, the *Writing* is applied to the prepared ſurface of the plate, and paſſed through a rolling-preſs; by which means the ink adhering to the varniſh, leaves the letters very conſpicuous. And hence it is eaſy with a needle to trace the ſtrokes, through the varniſh upon the plate, which being afterwards cleaned, the letters are finiſhed with the graver, and the work printed off in a rolling-preſs, as common cuts.

Mr. Boyle does not mention what the varniſh nor ink, uſed by the artificer from whom he received this method, was; but he tells us, that he himſelf uſed the purer ſort of virgin-wax, for a varniſh; and for his ink he took fine Frankfort black carefully ground, with water, till it obtained the conſiſtence of common ink; but no gum was added, leſt it ſhould hinder the ink from coming off. He alſo obſerves, that *written* characters may be taken off without the help of a preſs, by laying the moiſtened paper ſmooth upon the varniſhed copper, and rubbing it on hard with a convex piece of glaſs. Ibid.

WRONG-*Lands*, in our old writers, ſeem to denote trees that will never prove timber; ſuch as *wrong* the ground they grow in. Kitch. 169. *Cowel.*

WRY-*Necked*, a term applied to perſons affected with a diſtortion of the neck, and conſequently of the head alſo; which is pulled more to one ſide than the other.

This is a deformity uſually brought into the world with people; but ſometimes it is occaſioned by accidents afterwards. When it is from the birth, there is very little reaſon to imagine it curable, becauſe the vertebræ of the neck are rendered crooked by that poſture, while the bones are in a ſoft and pliable ſtate.

There are however, in the writings of ſurgeons, ſome inſtances of this diſorder, even in theſe circumſtances, being cured after twelve, ſixteen, or eighteen years.

When this diſorder comes on adults, it is occaſioned generally either by the contraction of the ſkin from a burn on one ſide, or from a ſtrong ſpaſmodic contraction of one of the maſtoide muſcles; which will at length become ſhorter and indurated, by continuing in that poſture; or it may proceed from a relaxation of one or more of thoſe muſcles, in conſequence of which the neck will be contracted by the ſtronger antagoniſt muſcle on the oppoſite ſide; or laſtly, it may proceed from a preternatural ligament drawing down the head. And when either of theſe is the occaſion of the diſorder, there is hopes of a cure; eſpecially if the ſubject be young, and the diſorder not of long ſtanding.

If this diſorder be recent, and cauſed by a defluxion of humours, evacuating medicines with mild ſudorifics, and heat, may be of ſervice. But when it ariſes from a contraction of the ſkin or muſcles by burning, the repeated uſe of oils, ointments, and fomentations, may relax ſo far as to make a cure. A proper firm bandage muſt be applied to pull the head toward the natural poſture, and a ſteel collar may be contrived by which the patient ſhall be ſuſpended very frequently till the neck recover its proper poſition. But when all theſe fail, the manual aſſiſtance of the ſurgeon is to be called in. If the ſkin is contracted by a burn, it muſt be carefully incided tranſverſely in ſeveral places, and the inciſions dreſſed ſo as to keep them open and dilated, and the head pulled to its proper poſition by a bandage, till the new fleſh filling up theſe inciſions gives room for the head to ſtand even. But if the *Wry-neck* proceeds from a contraction of one of the maſtoide muſcles, or from ſome ligament, they are to be divided by a tranſverſe inciſion in their lower part, near the clavicle or ſternum. *Heiſter*'s Surgery, V. 2. p. 4. *Tulpius*, V. 4. c. 58.

WRY-*Neck*, in zoology, the Engliſh name of a bird, known in Latin by the names *torquilla* and *jynx*. *Ray*'s Ornithol. p. 95. See the article JYNX.

WURST, a Ruſſian meaſure. See the article WERST.

WYCH-*Houſe* (*Cycl.*)—In the places where there are ſalt-ſprings, and ſalt-works are carried on at them, the work-houſe where the ſalt is made is always called the *Wych-houſe*; and hence we may naturally conclude, that *Wych* was an old Britiſh word for ſalt, which is the more probable in that all the towns in which ſalt is made end in *Wych*; as *Namptwych*, *Droitwych*, *Middlewych*, &c. *Ray*'s Engliſh Words, p. 175.

X.

X. We often meet with the Greek letters X and P joined in this manner ☧, on antient medals. The firſt we find are on ſome large braſs coins of the Ptolemies, kings of Ægypt, where it was placed on a civil account.

Some writers have taken it for a date, and others for the initial letters of a proper name; but as no reaſons are aſſigned for either of thoſe conjectures, Mr. Ward rather ſuppoſes it an abbreviation of the word XPHMA, *money*, impreſſed on thoſe pieces, to denote their currency as money; which might be thought proper, as they have not the heads of kings ſtamped upon them, like their ſilver and gold coins; but always that of a Jupiter on the front, and an eagle perched on a thunderbolt on the reverſe.

This character ☧ was afterwards applied to a very different purpoſe by Conſtantine the Great, who made uſe of it to denote XPICTOC, both in his coins and military enſigns; wherein he was followed not only by ſome ſucceeding emperors, but alſo by private perſons, who out of devotion put it on their lamps and other utenſils.

It afterwards came to be uſed merely as a critical note, to point out remarkable paſſages in manuſcripts; and then it ſtood for the initials of XPHCIMON, *uſeful*; as we learn from Iſidore, Orig. Lib. 1. cap. 20. See Philoſ. Tranſ. N°. 474. §. 1.

XAMDELLILAH, an Arabian term, uſed as a grace or thankſgiving after meat.

The greateſt men of that nation will often call in the meaneſt, even the beggars, to eat with them; who, as ſoon as they have done, always riſe and pronounce this word, which ſignifies God be praiſed. *Pocock*'s Egypt. p. 183.

XAMI, a name given by ſome of the old writers to the *ceration* of the Greeks, or carob-tree.

The Arabians uſe this name, and expreſs by it the ſame tree which we call by this name: They mention another kind of charnub, which is their general name for the ceration; this other kind was an aſtringent, and wholly different from any thing which we know under that name.

It is poſſible they might mean by it the acacia, which is alſo a tree that bears pods, and is of an aſtringent quality.

XANTHICA, Ξανθικα, in antiquity, a Macedonian feſtival, ſo called becauſe it was obſerved in the month Xanthus, at which time the whole royal family with the army were purified. See the article LUSTRATION.

After which the army was divided into two parts, one of which being ſet in array againſt the other, there followed a ſhort rencounter, in imitation of a fight. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 417.

XANTHIUM, in botany, the name of a genus of plants; the characters of which are theſe: The flower is of the floſculous kind, being compoſed of a number of floſcules, each having one ſtamen. The ſeeds are produced on other parts of the plant, and finally become oblong and uſually prickly fruits, divided into two cells, and containing each ſeveral oblong ſeeds.

The ſpecies of *Xanthium*, enumerated by Mr. Tournefort, are theſe: 1. The common *Xanthium*, called the ſmaller burdock. 2. The greater Canada *Xanthium*, with fruit armed with crooked prickles. 3. The jagged-leaved Portugal *Xanthium*, with fruit armed with very ſtrong prickles. *Tourn.* Inſt. p. 139.

The roots of this plant are of a bitter and acrid taſte, and are recommended as of great ſervice in ſcrophulous caſes, taken in decoction. Matthiolus gives great praiſes to the root dried and powdered, and given in mixture with rhubarb for the leproſy. *Matthiol.* in Dioſcor.

XANTHON, a name given by ſome of the antients, to a ſpecies of marble of a yelloviſh green colour, much uſed in ornamenting the inner parts of houſes; and from its equal hardneſs with the Tænarian marble, and the equal high poliſh it was capable of, ſuppoſed by the workmen to be of the ſame ſpecies.

The word *Xanthon* is of very dubious meaning, but is ſuppoſed as the name of this marble to have expreſſed a green colour, as this was otherwiſe called *marmor herboſum*. See the articles TÆNARIUM, and HERBOSUM *Marmor*.

XANTHURUS *Indicus*, in zoology, the name of a fiſh, called by the Dutch *Geel-ſtardt*.

It is of the ſize and ſhape of the bream; its jaws are armed with ſtrait and very ſharp teeth, which ſtand almoſt ſtrait out; its back is yellow, and its tail very ſtrongly tinged with that colour; its belly is of a bluiſh white; its head brown, and its fins of a fine red. It is caught with hooks among the rocks on the ſhores of the Eaſt-Indies; and is a very wholeſome and well-taſted fiſh. *Ray*'s Ichthyograph. Append. p. 2.

XANTHUS, in the natural hiſtory of the antients, the name of an iron ore of the hæmatites or blood-ſtone kind, and uſually accounted a ſpecies of it, and called by others *elatites*.

It was of a pale yelloviſh white, or the colour of the French pale yellow ochre, uſed by our painters; but like all other ferrugineous bodies it became red by burning.

Theophraſtus gives us expreſly the etymology of the name, obſerving that it was called ſo from its colour; the Dorians calling a yelloviſh white ξανθος, *Xanthus*. *Hill*'s Theoph. p. 97.

XANXUS, in zoology, a name given by ſome authors to a large ſpecies of ſea-ſhell, ſomewhat like that with which the tritons of old were painted. It is found in great abundance near Ceylon, and is uſed there in medicine as an alkali and abſorbent, in the ſame caſes in which we give the teſtaceous powders.

XATHOS, in ichthyology, a name given by Appian, to the fiſh, called by the generality of authors the *erythrinus*, or *rubellio*. See the article ERYTHRINUS.

It is of the ſparus kind, and is deſcribed by Artedi under the name of the ſilver-eyed, red-bodied *ſparus*.

XEL, in the materia medica of the antients, a name given to the fruit *ſel*. See the article SEL.

XENEXTON, a word uſed by Paracelſus, to expreſs a ſort of amulet to be worn about the neck, to preſerve people from infection in the plague.

XENINEPHIDEI, a word uſed to expreſs a ſort of imaginary ſpirits, mentioned by the adepts, as delighting to diſcover the occult qualities of bodies to men.

XENISMI, Ξενισμοι, in antiquity, ſacrifices offered at the Athenian feſtival *Anacæa*. *Potter*, T. 1. p. 366. See the article ANACÆA.

XENOPAROCHUS, among the Romans, an officer who provided embaſſadors with all kind of neceſſaries, at the public expence. *Pitiſc.* Lex. Antiq. in voc.

XERANTHEMUM, in botany, the name of a genus of plants, the characters of which are theſe: The flower is radiated; its diſk is compoſed of floſcules ſtanding upon the embryo-ſeeds; but the outer circle is compoſed of plane flat petals, which are not affixed to embryos, but are contained in the ſame cup with the floſcules which make up the diſk. The embryos finally ripen into ſeeds, which are furniſhed with a foliaceous head.

The ſpecies of *Xeranthemum*, enumerated by Mr. Tournefort, are theſe: 1. The *Xeranthemum*, with large ſingle purple flowers. 2. The *Xeranthemum*, with large double purple flowers. 3. The *Xeranthemum*, with ſingle white flowers. 4. The double white-flowered *Xeranthemum*. 5. The ſingle flowered *Xeranthemum*, with flowers mixed of white and red. 6. The double-flowered *Xeranthemum*, with flowers mixed of a duſky red and white. 7. The white-flowered hoary *Xeranthemum*. 8. The *Xeranthemum*, with ſmall ſingle purple flowers. 9. The *Xeranthemum*, with ſmall ſingle pale purple flowers. *Tourn.* Inſt. p. 499.

We have ſeveral ſpecies of this plant cultivated in our gardens, and known in Engliſh by the name of *everlaſting flowers*; a name common to all the ſpecies of this plant, and of the amaranthoides.

Theſe flowers are of ſo dry and durable a ſtructure, that if gathered juſt when they are ripe, they will laſt many years in perfection, and appear as freſh as while growing; they are alſo capable of ſeveral tinges, and hence are often ſeen of fine blues and greens, colours not natural to them.

They are all propagated by ſowing their ſeeds in Auguſt, in a warm border, obſerving to water and ſhade them till they are come up, if the weather proves very dry. When the young plants are two inches high, they ſhould be removed to another warm border under the ſhelter of a wall, and there planted at five inches diſtance from each other. They will here ſtand the winter very well, and in ſpring will be ready to grow up for flowering without any farther tranſplanting; they are only to be kept clear of weeds, and in June they will flower; the flowers ſhould be gathered in July for drying, and ſome of the fineſt ſhould be ſuffered to ſtand for ſeed; for the plants periſh as ſoon as they have perfected their ſeeds, and muſt be renewed by ſowing every year. *Miller*'s Gardener's Dict.

XERASIA, in medicine, the name of a diſeaſe, a ſpecies of alopecia, in which the hair falls off through a dryneſs of the part, and want of due nouriſhment.

XEROMYRON, a word uſed by the antients to expreſs what they do at other times call in expreſs words a dry ointment. It was a compoſition of warm and aromatic drugs, or of other things fit for external uſe, but without the fatty ingredients, by which they were uſually reduced into the form of ointments.

XEROPHAGY, Ξηροφαγια, among the antients, the feeding only on dry victuals, which was the practice of the Athletæ. *Pitiſc.* in voc. *ſaginatio.* See ATHLETA.

XEROTRIBIA, a term uſed by authors to expreſs a dry friction, a rubbing of ſome affected part with the hand or otherwiſe, to recall the warmth and circulation.

XIFINUS, a name given by ſome writers to the ſaphire.

XIMENIA, in botany, the name of a genus of plants deſcribed by Plumier, the characters of which are theſe: The cup is a ſmall three-leav'd perianthium; the leaves of it are cordated, and fall with the flower; the flower is monopetalous, of a bell ſhape, and divided into three ſegments, which ſtand erect, and are oblong, ſomewhat convoluted and obtuſe at the ends. The germen of the piſtil is ſmall, and of an oval figure. The fruit is an oval drupa containing only one cell, in which is an oval nut. *Plum.* p. 21. *Linnæi* Gen. Plant. p. 521.

XINKÆPPETHIJA, in botany, a name given by ſome authors to that ſpecies of the jujube tree, on the branches of which the gum lacca of the ſhops is uſually found. *Herm.* Muſ. Zeyl. p. 40.

XIPHIAS, (*Cycl.*) in the Linnæan ſyſtem of zoology, the name of a genus of fiſhes of the general order of the acanthopterygii or prickly-finned kind.

The characters of this genus are, that the membrane of the gills has eight bones, and the point or extremity of the noſe or ſnout of the fiſh, is ſhaped like a ſword, and that it has no belly fins. *Linnæi* Syſt. Nat. p. 54.

According to the Artedian ſyſtem of ichthyology, the characters of this genus of fiſhes are theſe: The branchioſtege membrane on each ſide contains about eight bones, the ſnout is extended into a very long and depreſſed point, imitating the figure of a ſword, and of a bony ſubſtance; the body is oblong and roundiſh, the back fin is ſmall, and is very low in the middle; there are no belly fins at all. The air bladder in this fiſh is remarkably long, and the anus very near the tail. *Artedi* Gen. Piſc. p. 24.

The *Swordfiſh* is ſo remarkable for the ſhape of its ſnout, which is extended in form of a ſword, that it has been called by all nations by a name expreſſive of that character. Its common name *Xiphias* is from the Greek ξιφός, a ſword, and it is called *gladius* in Latin, and in Engliſh the *Swordfiſh*.

It grows to a very conſiderable ſize, ſo as ſometimes to weigh an hundred pounds. It is of a long and rounded body, largeſt near the head, and tapering by degrees toward the tail; its ſkin is conſiderably rough, its back black, and its belly of a ſilvery white; its mouth is of a moderate ſize, and has no teeth; its ſnout runs out into the figure of a ſword in the upper jaw, the under is much ſhorter, and terminates in a very ſharp point; it has one only fin on the back, running almoſt the whole length of it; its tail is very remarkably forked; it has only one pair of fins at the gills, having none on the belly. It is common in the Mediterranean, and ſome other ſeas, and is eſteemed by many a very delicate fiſh for the table. The Manner of fiſhing for it is the ſame at this time, that the old writers have deſcribed it to be in theirs, by the harping-iron. *Willughby*'s Hiſt. Piſc. p. 161.

XIPHION, in botany, the name of a genus of plants, the characters of which are theſe: The flower is liliaceous, conſiſting only of one petal, and much reſembling the iris flower. The piſtil is in the manner of the iris alſo, ornamented with three petals, and the cup becomes a fruit of the ſhape of that of the iris; but the root wholly differs from that of the iris, being bulbous, and compoſed of a number of coats.

The ſpecies of *Xiphion* enumerated by Mr. Tournefort are theſe: 1. The broad-leav'd blue-flower'd ſweet-ſcented ſtalkleſs *Xiphion*. 2. The broad-leav'd ſtalkleſs *Xiphion*, with purple ſweet-ſcented flowers. 3. The broad-leav'd ſtalkleſs *Xiphion*, with ſweet-ſcented milk-white flowers. 4. The white-flower'd *Xiphion*, with blue edges. 5. The Perſian early *Xiphion*, with variegated flowers. 6. The porcelain *Xiphion*. 7. The lavender *Xiphion*. 8. The lavender *Xiphion*, with blue changeable flowers. 9. The purple-flower'd changeable lavender *Xiphion*. 10. The broad-leav'd blue-flower'd *Xiphion*, with ſtalks. 11. The cauliferous broad-leav'd *Xiphion*, with blackiſh purple flowers. 12. The cauliferous broad-leav'd *Xiphion*, with blue flowers variegated with purple, or with violet-colour'd lines. 13. The broad-leav'd cauliferous *Xiphion*, with greyiſh flowers ſtreak'd with violet colour. 14. The broad-leav'd cauliferous white-flower'd *Xiphion*. 15. The *Xiphion* with large ſpotted leaves, and purple flowers. 16. The violet-flower'd *Xiphion*, with large ſpotted leaves. 17. The broad-ſpotted leav'd *Xiphion*, with blackiſh purple flowers, white at the top. 18. The broad and ſpotted leav'd *Xiphion*, with ſnow-white flowers. 19. The narrow-leav'd *Xiphion*, with variegated flowers. 20. The narrow-leav'd *Xiphion*, with three-colour'd flowers. 21. The greater yellow *Xiphion*, with ſcentleſs flowers. 22. The great *Xiphion*, with a pale yellow flower. 23. The great yellow *Xiphion*, with mixt flowers. 24. The many-flower'd changeable colour'd *Xiphion*. 25. The leſſer *Xiphion*, with yellow-ſcented flowers. 26. The large tall *Xiphion*, with changeable yellow flowers. 27. The great but low *Xiphion*, with yellow changeable flowers. 28. The tall narrow-leav'd changeable flower'd *Xiphion*. 29. The low changeable *Xiphion*, with ſmaller flowers. 30. The middle-ſiz'd changeable flower'd yellow *Xiphion*. 31. The narrow-leav'd *Xiphion*, with blue ſweet-ſcented flowers. 32. The narrow-leav'd *Xiphion*, with variegated purpliſh blue flowers. 33. The leſſer blue-flower'd *Xiphion*. 34. The violet blue-flowered *Xiphion*. 35. The narrow-leav'd *Xiphion*, with violet-blue flowers. 36. The narrow-leav'd *Xiphion*, with flowers of a mix'd blue. 37. The white-flower'd narrow-leav'd *Xiphion*. 38. The American *Xiphion*, with blackiſh-yellow flowers. *Tourn.* Inſt. p. 362, ſeq.

We have ſeveral ſpecies of this beautiful plant cultivated in our gardens, where they are called *bulbous Iris's*; and beſides theſe, a vaſt number of varieties or new flowers, as the floriſts call them, are frequently raiſed by thoſe who propagate them from ſeeds. The culture of theſe being the ſame with that of ſeveral other plants of the ſame ſort, which are much valued for their flowers, it may not be amiſs to give it at large.

There ſhould be great care to ſave the ſeeds of the fineſt and ſtrongeſt flowers, and in September ſome ſhallow pans or boxes muſt be placed with holes at their bottom to let out the moiſture, and then filled with light and fine earth. On this the ſeeds muſt be ſown pretty thick, and as evenly as may be; half an inch of the ſame earth muſt be ſifted on theſe, and the boxes muſt then be ſet where they may have the morning ſun; and if the weather proves very dry, they muſt be gently watered at times. They muſt remain in this ſituation till October, and then muſt be removed to a place where they may have the benefit of the ſun as great a part of the day as may be; here they muſt ſtand the winter, keeping the boxes very carefully clear from weeds.

In the ſpring the young plants will appear, and they ſhould then be removed to their firſt ſituation, where they may have only the morning ſun; and if the weather be dry, they muſt be watered at times. In June their leaves will decay, and they muſt then have half an inch of freſh earth ſifted over them, and be left in their ſituation till October, when they muſt be removed to the ſame place as before for the winter.

In the ſpring the leaves will appear again, and when they are again periſhed, the earth muſt be taken out of the boxes, and ſifted to ſeparate the roots, which muſt then be planted at three inches diſtance on a bed of the ſame light earth; they muſt be buried three inches deep, and in the ſpring following muſt have about half an inch of freſh earth ſifted over them; the leaves will this year appear and decay as before; and the following year, in June, they will moſt of them flower, when the fineſt flowers ſhould be marked, that their roots may be taken particular care of. The following year the remainder, which did not flower at firſt, will produce their flowers; ſuch of theſe as are finer than the reſt, ſhould be marked in the ſame manner, and the roots of theſe choice kinds be preſerved with particular care. Whatever fine or new flower is thus raiſed from ſeed, may be afterwards propagated by off-ſets from the roots, which being planted out, will flower the ſecond year, and often produce even finer flowers than the mother root.

The roots of theſe flowers ſhould be taken out of the earth only every other year; this ſhould be done juſt when the leaves are decayed, and they ſhould not be kept out of the earth above a fortnight.

The earth in which theſe flowers thrive beſt, is a light ſandy loam; and if it be taken up with the turf and the graſs rotted among it before it is uſed, it will be ſo much the better. They do not delight in a rich dunged ſoil, nor ſhould they be placed where they are too much expoſed to the ſun; for beſides that the flowers ſoon fade in theſe places, the roots are alſo always found to decay; but in an eaſt border, where they may have the ſun till eleven o'clock, and where the ground is not too moiſt nor over dry, they will ſtand a long time in flower, and thrive extremely well. *Miller*'s Gard. Dict.

XIR, a word uſed by the chemiſts to expreſs mercury.

XISINUM, a word uſed by ſome of the chemical writers to expreſs vinegar.

XOCHIOCOTZO, in botany, a name uſed by ſome authors for the tree which produces the liquid amber, and is called the ſweet gum by the inhabitants of the Weſt-Indies. *Hernandez*, p. 96.

XOCHITENACATL, in zoology, a name given by ſome to the toucan, or American great beaked magpy. *Ray*'s Ornithology. See the article TOUCAN.

XOCHITENACATL *Alia*, in zoology, the name of a bird deſcribed by Nieremberg of the nature of the toucan or Braſilian magpy.

It is of the ſize of a pigeon, its beak is large and thick, and is black and pointed; its wings and tail are variegated with black and white; it has a large black mark reaching from its back to the breaſt; the anterior part of the wings is yellow, the

reſt of its body of a pale colour, and the legs and feet brown. It always is found among the ſweet-flowering trees, and is not uncommon in many parts of South America. *Ray*'s Ornithol. p. 298.

XOCOXOCHITL, the Indian name of the clove-berry-tree, or the *caſſia-caryophyllata*, the bark of which is uſed in medicine. *De Laet.* p. 277.

XOMOTL, in zoology, the name of an American bird, of which the Indians are very fond, making a part of their garments of its feathers.

Nieremberg has given this ſhort account of it. It is a web-footed fowl; its back and the upper part of its wings are black; and its breaſt is brown. When it is angry, it raiſes up the feathers of its head in form of a creſt. *Ray*'s Ornithol. p. 305.

XOXOUHQUITICPATLI, an American name of a ſtone of the jaſper kind, and of a beautiful green; but uſually pale, and ſometimes with a mixture of grey, and variegated in ſeveral places with ſpots of a deeper green.

It is found among the ſeveral kinds of *lapis nephriticus*, with which that country abounds, and moſt of which the Indians celebrate for their virtues againſt diſeaſes: they are not however acquainted with any medicinal virtues of this ſpecies.

XUCAHA, or XUCAAHI, in botany, the name of a plant much famed for its virtues among the antient Arabians, but unknown at this time.

It was called alſo *amgaila*, and by the Greeks, *leucacantha* and *acantha arabica*, and by many other of the names of the gum-arabic-tree. The uſe of theſe ſynonymous terms has led ſome to ſuppoſe that the gum-arabic-tree, and the *Xucaha* or *amgaila*, which is another of the Arabian names of that plant, were the ſame thing; but this is a great error.

The plant *Xucaha* had a root compoſed of ſeveral knobs, or ſeparate pieces, which when ſeparated and dried, became of a yelloviſh colour, a very light and ſpongy ſubſtance, and of an agreeable aromatic ſmell, but bitter taſte. The antients compared theſe to the cyperus-roots in ſhape, and uſed them as cordials and ſtomachics.

They called the prepared roots *bunk*, and the ſimilitude of this name in ſound with the word *buna*, the fruit of the Ægyptian tree *bon*, that is, coffee, have led ſome to ſuppoſe that it was our coffee which they called by theſe names of *bunk* and *xucaha*; but theſe are all idle conjectures, and the *bunk* being a root, and the coffee a fruit, is ſufficient alone to overthrow this opinion, were there none of the many other reaſons againſt it.

XYLAGIUM, a name given by ſome authors to the lignum ſanctum or guaiacum.

XYLOCARACTA, or XYLOCARACTE, in the materia medica, a name by which ſome authors have called the carob, or ſiliqua dulcis, the ſweet pipe-tree. *Ger.* Emac. Ind. 2.

This was called by ſome of the Greek writers *xyloceraton*, the tree bearing pods, and from a corruption of this name the other has been formed.

XYLOCARPASUM, in natural hiſtory, a name given by ſome authors to a poiſonous kind of wood.

It was the wood of that tree whoſe gum was called *carpaſum* and *apocarpaſum*. This was a much more terrible poiſon than the wood, and as it very much reſembled myrrh in colour, and came from the ſame country from whence the myrrh came, it was often found mixed with it, and many people loſt their lives by taking it.

XYLOCASIA, a term uſed by ſome modern writers on the materia medica, to expreſs what we call *caſſia lignea*, a bark ſomewhat reſembling cinnamon, but leſs aromatic, and of a mucilaginous taſte.

The antients, however, did not mean exactly what we do by this term *caſſia lignea*; they ſometimes pealed off the bark of this tree, and kept it ſeparate; and in this caſe they called it κασια Συριγξ, a term we have applied to a very different ſenſe, *caſſia fiſtula* with us ſignifying the fruit of the pudding pipe-tree; and when they cut the bark with the wood of the young branches, they then called it *hylocaſia* or *caſſia lignea*.

XYLOCOCCUM, in the materia medica, a name given by ſome of the later Greek writers to the carob-tree, or *ſiliqua-dulcis*.

This is alſo called *xyloceraton* by Ægineta, and by ſome of the latin writers of the barbarous ages, *hylocaracte*, a word plainly formed of the others.

XYLOCOLLA, a word uſed by ſome of the antient writers to expreſs what was more uſually called *taurocolla*, glue made of the ears and genitals of a bull.

XYLOCOPIA, Ξυλοκοπια, among the Greeks, a puniſhment with a cudgel. See the article FUSTIGATIO.

XYLOGLYCON, in botany, a name given to the carob, or ſiliqua dulcis, by ſome of the old Greek writers.

The word expreſſes a ſweet, or ſweet-fruited tree, and was ſufficiently expreſſive of the thing; but it was afterwards degraded into a Latin name, ſcarce intelligible, *ſililicon*; this Iſidore writes *ſilicon*, and ſuppoſes to be a falſe ſpelling of the word *ſiliqua*; but it is evidently formed of the word *Xyloglycon*.

Iſidore ſays, the acacia of the ſhops is the juice of the fruit of this tree; but this is an error formed on the expoſitions of the Arabians; they call by the common name *charnub* both the carob-tree and the acacia-tree; and what they have ſaid of the latter he has given to the former.

XYLOIDES, or HYLODES, in botany, a term uſed by many of the antient writers to diſtinguiſh thoſe plants which had woody ſtalks, though they never grew up to any conſiderable ſize; ſuch as the garden-thyme, marjoram, and the like.

XYLON, the *cotton-tree*, in botany, the name of a genus of plants, the characters of which are theſe: The flower conſiſts of one leaf, and is of the bell-ſhape, very wide at the mouth, and divided into many ſegments. From its bottom there ariſes a pyramidal tube, uſually loaded with ſtamina; and from the bottom of the cup there ariſes a piſtil, which is inſixed in the manner of a nail both to the hinder part of the flower, and to the tube. This ripens into a roundiſh fruit, divided into four or more cells, opening at the top, and containing numerous ſeeds wrapped up in a ſtringy white ſubſtance, which is called *cotton*.

The ſpecies of this genus, enumerated by Mr. Tourneſort, are theſe: 1. The tree or woody-*Cotton*, with a ſmooth ſtalk, and a blackiſh purple flower. 2. The woody *Cotton*, with yellow flowers. 3. The woody *Cotton* with prickly ſtalks. 4. The herbaceous *Cotton*. 5. The American *Cotton*, with a long pointed fruit: And 6. The fineſt American *Cotton*, with green ſeeds. *Tourn.* Inſt. p. 101.

There are ſeveral varieties, and not a few diſtinct ſpecies of this plant, propagated in the gardens of the curious with us. The moſt common ſpecies, which is the *Xylon herbaceum*, or herby *Cotton*, is cultivated very plentifully in Candia, Lemnos, Cyprus, Malta, Sicily, Naples, and alſo between Jeruſalem and Damaſcus, from whence the *Cotton* is annually brought in large quantities to us in the northern parts of Europe. It is ſown on plowed lands in ſpring, and is cut down as our corn in harveſt-time, being an annual plant.

The *Cotton* is a woolly or downy ſubſtance, which incloſes the ſeed, and which is contained in a brown huſk or ſeed-veſſel. It is from this plant that moſt of the *Cotton* we uſe is produced, the difference of the ſeveral ſorts of it being owing to the different ſoil and climates it has grown in, and the different culture it has received.

The *Cotton* in the wooll, as it is uſually called, is what we have from Cyprus. Damaſcus *Cotton* is called *Cotton* in the yarn; and the Jeruſalem *Cottons*, which are called *bazaes*, are the fineſt kinds of all.

All the kinds of *Cotton* plants are propagated with us from ſeeds, which muſt be ſown on a hot bed early in the ſpring; and when the young plants are come up, they ſhould be tranſplanted each into a ſeparate pot of light earth, which is to be plunged into a moderate hot bed of tanners bark, obſerving to water and ſhade them till they have taken root; after this they ſhould be watered at times, and have as much air as the ſeaſon will permit. As they enlarge in ſize, they muſt be ſhifted into larger pots; but they muſt be kept in the ſtove, where the herbaceous kinds will annually flower in autumn; but they will ſeldom bring their pods to any perfection. *Miller*'s Gard. Dict.

XYLON, Ξυλον, among the Athenians, a puniſhment inflicted by putting the offender into the ſtocks. See the articles PODOCACE and PUNISHMENT.

XYLOSTEON, in botany, a name by which ſome authors have called the ſmall red-berried double-fruited *chamecerafus*.

XYLOSTEUM, in botany, the name of a genus of plants, the characters of which are theſe: The flower conſiſts of one leaf, and is placed on a cup, and always diſpoſed two on each pedicle: it is tubular in ſhape, and divided into ſeveral ſegments at the edge. The cup finally becomes a fruit, compoſed of two berries, which are ſoft, and contain a roundiſh but flatted ſeed. See Tab. 1. of Botany, Claſs 20.

There is only one known ſpecies of this genus, which is the Pyreenan *Xyloſteum*. *Tourn.* Inſt. p. 609.

XYLOSTROTON, among the antients, an appellation given to moſaic or chequered work. *Pitiſc.* Lex. Ant. in voc.

XYMPATHESIS, a word uſed by ſome of the old medical writers for ſympathy.

XYNERESIS, a word uſed by Hippocrates and others of the antients, to expreſs a firm coheſion or connection of any two things: ſome uſe it to expreſs that firm ſhutting together or clenching the teeth, which happens in convulſions.

XYPHION, in botany, a name uſed by ſome authors for the gladiolus or corn-flag, a plant kept in our gardens for the beauty of its flower. *J. Bauhin.* vol. 2. p. 701.

XYRIS, in the Linnæan ſyſtem of botany, the name of a genus of plants, whoſe characters are, that the flower-cup is a ſort of roundiſh ſpike, made up of roundiſh, hollowed, imbricated ſcales, which divide the flowers; the huſk is ſmall and bivalve, each of the valves being compreſſed, arched, and in the ſhape of a little boat; they are alſo acute, and naturally incline toward one another. The flower conſiſts of three petals, which are large, flat, expanded, with notched edges, and narrow ends, of the length of the cup they are immerſed in. The ſtamina are three ſlender filaments, which are ſhorter than the flower. The antheræ are oblong and erect. The germen of the piſtil is roundiſh; the ſtyle is ſingle and thread-like, and the ſtigma divided into three parts. The fruit is a roundiſh capſule,

capſule, contained within the cup, with three cells and three valves. The ſeeds are very numerous, and extremely ſmall. *Linnæi* Gen. Plantarum. p. 11.

XYSTICI, among the antients, a deſignation given to the Athletæ, becauſe they performed their exerciſes in the *Xyſtus*. See the article XYSTUS, *Cycl.*

Y.

YARD (*Cycl.*)—YARD-*fallen*, a term uſed among our farriers to expreſs a malady to which horſes are ſometimes ſubject, which is the hanging down of the penis from its ſheath between the legs, the creature not being able to draw it up again.

This is cauſed by weakneſs of the peculiar muſcles, which ſhould act in the drawing up; and proceeds ſometimes from a violent ſlip or ſtrain; ſometimes from a blow on the back, and ſometimes from extreme wearineſs in long journeys.

The method of curing this, is firſt to waſh it with oil of roſes, after this with warm white-wine, and finally, to anoint it with a mixture of oil of roſes and honey: it is then to be returned into its place, and kept from falling down again by a little canvas bolſter. It is to be thus dreſſed once in twenty-four hours, till the cure is perfected.

There are ſome other diſtemperatures to which this part is ſubject, in a horſe, as the being foul at the end, ſo that the creature voids his urine in the ſheath; in this caſe the method of cure is to draw out the penis, and cleanſe the end of it from any foulneſs that may be found there; then it is to be waſhed with butter and white-wine vinegar melted together: ſometimes there is a diſcharge of a yellow ſtinking matter from the penis: this is peculiar to ſtone-horſes, and principally affects them after the time of their covering of mares.

This running is attended with a ſwelling of the penis, and with a pain in voiding the urine; the creature alſo finds a difficulty in drawing up the penis into the ſheath. The method of cure is, to diſſolve in a pint of white-wine an ounce of roach-alum by boiling, and four or five times a day this is to be uſed, injecting it up into the *Yard* with a ſyringe blood-warm. This will prove a certain cure.

YARIN, a word uſed by ſome of the chemical writers to expreſs the flos æris.

YARN (*Cycl.*)—*Spun* YARN, on board a ſhip. See the article SPUN, *Cycl.*

YGROPISSOS, in the materia medica, a word uſed by ſome writers to expreſs tar.

YARROW, in botany. See the article MILLEFOLIUM.

YARWHELP, or YARWIP, an Engliſh name uſed in ſome places for the *godwit*, the *ægocephalus* of authors. See the artidle ÆGOCEPHALUS.

YAWS (*Cycl.*)—This is a diſtemper epidemical, or rather endemical to Guinea, and the hotter climates in Africa, ſeldom failing to attack each individual one time or other of their lives, but moſt commonly in childhood or youth: It makes its firſt appearance in little ſpots on the cuticle, level with the ſkin, no larger than the point of a pin, which increaſe daily, and become protuberant like pimples: ſoon after the cuticle frets off, and then, inſtead of pus or ichor in this ſmall tumour, white ſloughs or ſordes are only found, under which is a ſmall fungus growing out of the cuticle, increaſing gradually to different magnitudes, ſome leſs than the ſmalleſt wood-ſtrawberry, ſome as big as a raſpberry, and others even exceeding in bigneſs the largeſt mulberries, which they very much reſemble. While they are coming to this height, the black hair, which grows out of the part now covered with the *Yaws*, changes gradually white.

It is impoſſible to calculate the exact time which this diſtemper requires, to go through theſe different ſtages. Some negroes, who were in good plight, and had full nouriſhment, in a month after diſcovering the white ſpots, have had ſeveral *Yaws* as big as a mulberry; and in other negroes, that were low in fleſh, and had but a poor ſcanty diet, in three months time none of the *Yaws* have exceeded a common ſtrawberry.

The *Yaws* appear on all the parts of the body; but the moſt and biggeſt are generally on the groins, about the privities and anus, in the arm-pits and face. When they are very large, they are few in number; and when they are many in number, they are ſmall in ſize. All this time the patient is in good health, does not loſe his appetite, and ſeems to have no other uneaſineſs than what the naſtineſs of the ſores occaſion; for they are not painful, except touched too roughly. This is the natural appearance of the diſtemper, when left to itſelf, and in this ſtate it will continue a long time without any ſenſible evacuation.

The *Yaws* do not prove often dangerous, if the cure is undertaken ſkilfully at a proper time, and the patient has not undergone any courſe of phyſic for them before; but if the patient has been once ſalivated, or taken any quantity of mercury, and the ſkin once cleared, and they appear again, they are always very difficult, and often impoſſible, to cure. Medic. Eſſ. vol. 5. art. 76.

The chief part of the cure is by gentle ſalivation with calomel, in ſmall doſes, that it may neither vomit nor purge. The patient's drink is the decoction of guaiacum and ſaſſafras, fermented with melaſſes. See Medic. Eſſ. ibid. or the Abridg. vol. 2. p. 305.

Sometimes one large *Yaw*, high-knobbed, red and moiſt, called the *maſter-Yaw*, remains after the reſt are fallen off, and the ſalivation is over. And to ſubdue this, ſome have thought new ſalivations neceſſary; but it requires only to be deſtroyed by a gentle cauſtic, or mild eſcharotic, as equal parts of red precipitate and burnt alum.

The ſalivation ſhould not be begun befor the *Yaws* are at the height, which is diſcovered by their being at a ſtand, neither increaſing in ſize or number. Their coming to the height ſhould be accelerated by proper medicines. If the patient be ſalivated before this time, the diſtemper will return ſoon after the ſalivation. Ibid. p. 304.

YAYAUHQUITOTOTL, in zoology, the name of an Indian bird, deſcribed by Nieremberg, remarkable for having two feathers of its tail much longer than the reſt, and naked for a great way; but at the end ornamented with black and blue hairs. The bird is of the ſize of the ſtarling, and is beautifully variegated with green, blue, yellow, and grey.

Mr. Ray is of opinion, that this is the bird deſcribed by Marggrave under the name *guaira guainumbi*. *Ray*'s Ornithol. app. vol. 298. See the article GUAIRA-*Guainumbi*.

YDRINUS, or HYDRINUS, a name given by ſome to the *ophites*, or ſerpent-ſtone.

YEAR (*Cycl.*)—YEAR is alſo a word uſed by ſome of the chemical writers to expreſs any product of their operations, which may ſerve as a medicine, whether internally or externally.

YEAST. Common ale-*Yeaſt* may be kept freſh and fit for uſe ſeveral months, by the following method: Put a quantity of it into a cloſe canvas bag, and gently ſqueeze out the moiſture in a ſcrew-preſs, till the remaining matter be as firm and ſtiff as clay.

In this ſtate it may be cloſe packed up in a tight caſk, for ſecuring of it from the air; and will keep freſh, ſound, and fit for uſe for a long time.

This is a ſecret that might be of great uſe to the brewers and diſtillers here, who, though they employ very large quantities of *Yeaſt*, ſeem to know no method of preſerving it, or raiſing nurſeries of it; for want of which they ſuſtain a very conſiderable loſs; whereas the brewers in Flanders make a very great advantage of ſupplying the malt-diſtillers of Holland with *Yeaſt*, which is rendered laſting, and fit for carriage, by this eaſy expedient. *Shaw*'s Lectures, p. 195.

YELION, a word uſed by ſome of the barbarous writers to expreſs glaſs.

YELLOW (*Cycl.*)—Mr. Boyle tells us a moſt beautiful *Yellow* may be procured by taking good quick-ſilver, and three or four times its weight of oil of vitriol, drawing off, in a glaſs retort, the ſaline menſtruum from the metalline liquor, till there remains a dry ſnow-white calx at the bottom: On pouring a large quantity of fair water on this, the colour changes to an excellent light *yellow*.

He ſays he fears this colour is too coſtly to be uſed by painters, and he does not know how it would agree with every pigment, eſpecially oil-colours. Works abr. vol. 2. p. 91.

The Chineſe are famous for their *Yellows* in dying, which never change with waſhing. They make this dye of the flowers of the acacia, in a manner in which we might uſe ſeveral of our own productions to great advantage.

It is thus: They gather the flowers before they are perfectly ripe, and dry them in an earthen veſſel over a gentle heat, till they criſp up in the manner of tea-leaves; they then add to them the ripe ſeeds of the ſame tree in different proportions; and then boiling them in river-water with alum, they give the *Yellow* in any degree that they pleaſe.

They have three kinds of *Yellow*, which they diſtinguiſh by the names of *Ngo-hoang*, *King-hoang*, and *hoang* alone.

The firſt of theſe is the brighteſt *Yellow*; to dye five or ſix ells of ſilk of this colour, they uſe a pound of the flowers of the acacia, about two ounces of the ſeeds, and four ounces of alum.

The *King-hoang* is a ſomewhat deeper *Yellow*; to dye this, they uſe the ſame ingredient in the ſame proportion as in the former caſe; and when the ſilk is dry from the dipping in this, they give it a ſecond dipping in a ſlight tincture of Braſil-wood, this brings it to the fine ſtrong *Yellow* we ſee.

The *hoang* or pale *Yellow*, is made of the ſame ingredients as the firſt, only inſtead of four ounces of alum they put in but three ounces: River-water is found to be greatly preferable to any other, for the extracting theſe colours; but even in that there is great difference, ſome doing the buſineſs much better than others.

The Chineſe are ſo expert in judging on this occaſion, that they can tell by the taſte of water whether it will or will not do; and if it taſte faint, they know it is faulty; but they dip the pieces twice into it inſtead of once, and then the colour ſucceeds well.

The flowers of the acacia, when they have been prepared by roaſting in this manner, may be kept all the year round, and employed in dying as occaſion requires, only there is to be longer boiling for the dryed flowers than the freſh ones; and it is always found, that the freſh flowers give the brighteſt colour. Obſerv. ſur les Coutum. de l'Aſie, p. 254.

YELLOW *Flower-de-luce*, in botany. See the article IRIS *Paluſtris*.

YELLOW-*Hammer*, in zoology, the name of a very common Engliſh bird, called by authors *emberiza lutea*; and by ſome *hortulanus*, by others *luteus*, and by others *chloreus*.

It is a little larger than the chaffinch, and is very beautifully variegated with a greeniſh or greyiſh brown and a fine bright yellow.

There is beſide this another kind, which is much ſmaller and of a browner colour on the back; this is called by ſome authors *zivolo*. *Ray*'s Ornithol. p. 196. See the article ZIVOLO.

YELLOWNESS *of Infants*. See the article INFANT.

YELLOWS, a name given by farriers to the jaundice in horſes. See the article JAUNDICE.

YERK, in the manege. See the article YERKING, *Cycl.*

YETTUS, in natural hiſtory, a name given by the writers of the middle ages, to a ſpecies of marble, of a deep red; which was uſed by ſome as a touch-ſtone.

YEVA *Charrum*, in natural hiſtory, a name given by the people of the Eaſt-Indies to a kind of litharge; which is very common in that part of the world, and is ſaid to be made partly from lead and partly from zink.

It is leſs heavy than our yellow litharge, and of a paler colour. It is uſed as a cauſtic in all the occaſions of ſurgery there.

YEW, *Taxus*, in botany, the Engliſh name of a genus of plants. See the article TAXUS.

YEW is alſo a term uſed by the ſalt-workers of Limington, and ſome other parts of England, to expreſs the firſt riſing of a ſkum upon the brine in boiling.

In the places where they uſe this term, they add no clarifying mixtures to the brine, for it ferments in the ciſterns, and all its foulneſs ſinks to the bottom, in form of a thin mud; they admit only the clear liquor into the pan, and boil this briſkly till it *yews*, that is, till a thin ſkin of ſalt appears upon its ſurface; they then damp the fire, and carefully ſkim off this film, and clear only the ſcratch or calcarious earth, which ſeparates to the bottom.

They do not collect this into ſcratch-pans, as at many of the other works, but they rake it up to one ſide of the pan, and take it out; they there add a piece of butter, and continue the fire moderately ſtrong till the ſalt is granulated. They keep a briſker fire on this occaſion at Limington, than in moſt of the other works; ſo that they will work three pans in twenty-four hours. See the article SALT.

YIELD, or SLACK *the Hand*, in the manege, is to ſlack the bridle, and give the horſe head. See the article SLACK.

YIN, a word uſed by ſome of the chemical writers, to expreſs verdigreaſe.

YOKE (*Cycl.*)—YOKE, in the ſea-language. See the article SEA-*Yoke*, *Cycl.*

YOMO, a word uſed by ſome of the chemical writers to expreſs verdigreaſe.

YOS, a word uſed by ſome of the chemical writers to expreſs verdigreaſe.

YOUNG *Animals*. It is commonly thought that the fleſh of *young* animals is ſooner digeſted, than the fleſh of the ſame kind of animals arrived at full growth; and Dr. Cheyne is alſo of this opinion. But Dr. Bryan Robinſon ſhews this to be a miſtake, in ſome inſtances; and alledges, that veal and lamb are not ſo ſoon digeſted, as beef and mutton. He mentions the caſe of a man, who took a vomit every ſecond night for ſome months, who obſerved, that when he had taken chicken for dinner, he always threw it up undigeſted; but never threw up any of his food undigeſted, when he dined on beef and mutton.

YOUTH. The renovation of *Youth* has been much ſought after by chemical adepts; and many of them pretended to various ſecrets, for this purpoſe: But unluckily, the death of the pretenders proved a ſufficient refutation of their doctrine. Paracelſus talks of the mighty things he could do with his *ens primum*; and even Mr. Boyle tells us ſome ſtrange things about the *ens primum* of balm. *Boyle*'s Works abr. Vol. 1. p. 75. but Mr. Boyle gives theſe wonderful ſtories on the credit of a French chemiſt, and not on his own. See the article ENS *Primum*, *Cycl.*

YOUTH, *Juventus*, in the Pagan theology, a goddeſs worſhipped among the Romans, who, together with the gods Mars and Terminus, kept her place in the capitol along with Jupiter, when the other deities were turned out. Whence the Romans drew a lucky omen for the durableneſs of their empire. Mem. Acad. Inſcrip. Vol. 1. p. 71. *ſeq.*

This ſtate of life was, by the antients, compared to Autumn. In which ſenſe, Horace ſpeaking of one approaching to Puberty, ſays,

Jam tibi lividos
Diſtinguet Autumnus racemos,
Purpureo varius colore.

The moderns, on the contrary, when they ſpeak of one in the autumn of his age, mean one that is upon the decline; and chooſe rather to uſe the compariſon of the ſpring, to denote *Youth*.

YS, in ichthyology, a name given by Athæneus, and ſome other of the Greek writers, to the fiſh called *Mus* and *Sus* by others. It is the capriſcus of later writers. See the article GOAT-*Fiſh*.

YSAMBRA, a word uſed by ſome as a name for hellebore, and by others to expreſs a ſpecies of poiſon prepared in Spain, of which hellebore is an ingredient.

YSOPUS, a term uſed by ſome, to expreſs the chemical art of ſeparation.

YSPAR, a name by which ſome of the chemical writers call iron.

YTIC, in natural hiſtory, the name of a ſpecies of duck, common in the Philippine-iſlands, and in China.

It is of the ſize of our tame duck, and is that ſpecies which the Chineſe hatch from the egg by heat, as the Ægyptians do chickens.

YTZAIMPATLI, in the materia medica, a name given by ſome to the cevadilla, or *hordeum cauſticum*, the cauſtic Indian barley. *Hernand.* p. 307.

YUCCA, or MANIHOT, in botany, the name of the Indian corn. See the article MANIHOT.

We have three or four ſpecies of this plant preſerved in the gardens of the curious; and the common kind, when grown ſtrong and hardy, will endure the cold of our climate in the open air, and produce its flowers with us.

All the ſpecies may be propagated either from ſeeds ſent from abroad, or from off-ſets or heads taken from the old plants, in the manner of the aloe. When they are to be raiſed from ſeeds, theſe are to be ſown in a pot of light freſh earth, which being plunged into a moderate hot bed the young plants will appear in five or ſix weeks; and when they are two or three inches high they are to be removed, each into a ſeparate pot, which is to be plunged again into the ſame hot bed, where they are to be watered and ſhaded, and to have air given them, as the ſeaſon and the heat of the bed will permit. In July they muſt be hardened by degrees to the open air, into which they muſt be removed ſoon after to harden them againſt winter. They muſt be placed in a defended ſituation, and remain abroad till October, when they are to be removed into the green-houſe, and placed among the hardier ſorts of aloes. They are here to be treated exactly as thoſe plants; and when they are grown ſufficiently ſtrong, they may be removed into common borders, where they will remain through our winters, and flower very beautifully.

When they are to be raiſed from the off-ſets, theſe muſt be laid in a dry place for a week or ten days before they are planted, that the wound where they where taken off from the old plant may heal; elſe, like the other ſucculent plants, they are apt to rot in the earth, and miſcarry. *Miller*'s Gardener's Dict.

YUCCA-*Bread*, or CASSADA-*Bread*, a ſort of bread made in many parts of the Weſt-Indies, and eaten there; and ſometimes brought over as a curioſity to us.

It is made of the root of this plant, known among the botaniſts by the name of *manihot*. This grows to five or ſix feet high, the ſtalk is woody and full of knots, and has a large pith in it; the leaves are digitated or divided into a number of ſegments, like ſo many fingers; the flowers are compoſed of one leaf, and are as large as our narciſſus, and are ſucceeded by a fruit of the ſize of a hazel-nut.

The root is very large and thick, and of a dark colour without, but very white within. It grows wild, common enough in ſome places; but it is generally cultivated for uſe, ſetting it in large furrows. Its juice is poiſonous, though the dry powder of the root is perfectly innocent and wholeſome; but there is a kind of it which may be eaten raw, and which is now getting into uſe; inſtead of the other, which is a ſpeedy poiſon, if eaten with its juice.

The manner of making the bread from theſe roots, is this; they peel them, raſp them, and putting them into bags ſqueeze out the juice; they then dry the remaining matter over the fire, and when it is ſufficiently dreſſed, they make it into cakes, which being dried either in the ſun, or by artificial heat, are the *Caſſada-bread*; which is very nouriſhing, and will keep without moulding, as well as biſcuit.

The uſe of it is apt to contract the throat, if eaten dry, and ſometimes brings on a danger of choaking; the beſt method is to moiſten it in broth, or otherwiſe. before it is eaten, or elſe to have a bottle of water at hand to waſh down every mouthful.

The juice expreſſed in preparing this root for bread, will kill any animal that drinks it crude; but it may be boiled over the fire till a great part is evaporated, and the remainder if it be far evaporated will be ſweet, and ſerve in the place of honey; if leſs evaporated, and ſet by to ferment, it will make a very good and wholeſome vinegar. The juice of the roucou is ſaid to be a counter-poiſon for the juice of *Yucca*. *Lemery*. Dict. des Drog.

The thicker cakes of *Yucca-bread* are called caſſavi, or caſſada, and are eaten by the poorer ſort. The thinner are called *ſciam*, and are eaten by the rich. *Grew*'s Muſæum, p. 371.

YXIR, a word uſed by ſome of the old chemiſts, to expreſs any thing good in medicine.

YZQUANHTH, in zoology, the Indian name for a bird deſcribed by Nieremberg, and called the creſted eagle. See the article AQUILA *Criſtata*.

YZQUIEPATL, in zoology, the name of an American animal of the fox-kind, and much reſembling a common fox when young.

It is a low animal, its body long, and its legs ſhort. Its noſe is ſharp, its ears ſmall, and its body very thick, covered with hair, particularly about the tail, which is long, and covered with the ſame ſort of hair with the reſt of the body, which is black and white. Its claws are very ſharp; it lives in the caves and in the hollows of rocks, where it breeds, and brings up its offspring. It feeds on worms, beetles, and other inſects, and ſmall animals: When purſued, it breaks wind backward with an inſupportable ſtench.

Its whole body is, indeed, of a very ill ſmell; and its urine and dung are ſo horribly ſtinking, that we have no ſtench that can compare with them. It is a mild and harmleſs animal; but when provoked, its only power of hurting is by violently diſcharging its excrements, which it will throw to ſix or eight foot diſtance, and which ſtain people's cloaths with indelible yellow ſpots, and leave a horrible ſtink which remains a long time on them.

The creature in many reſpects reſembles the rackoon, but differs in its offenſive ſmell, and in this remarkable manner of diſcharging its excrements.

Hernandez mentions two other ſpecies of it; the one variegated with numerous white ſtreaks, but this is called by no diſtinct name among the inhabitants; the other they name the *conepatl*, this has only one longitudinal ſtreak on each ſide the back, which run into the tail. *Ray*'s Syn. Quad. p. 184.

Z.

Z. This letter formerly ſtood as a mark for ſeveral ſorts of weights. Sometimes it ſignified an ounce and half, and very frequently it ſtood for half an ounce; ſometimes for the eighth part of an ounce, that is a dram Troy-weight; and it has in earlier times been uſed to expreſs the third part of an ounce, or eight ſcruples.

ZZ, theſe letters were uſed by ſome of the antient phyſicians, to expreſs myrrh. At preſent they are often uſed to ſignify *zinziber*, or ginger.

ZAARA, a word uſed by the Arabian phyſicians, to expreſs the *vigilia morboſa*, or continual watchings of perſons in many illneſſes.

ZACINTHA, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the ſemifloſcular kind, the ſemifloſcules are placed on the embryo-fruit, and are all contained in a general ſcaly cup. This cup finally becomes a ſtriated head, compoſed of ſeveral capſules, each of which contains one ſeed winged with down.

There is only one known ſpecies of this plant, which is what has uſually been called by authors *chicorium verrucoſum*, the wart gum-ſuccory. *Tourn.* Inſt. p. 476.

ZACYNTHUS, an epithet uſed by the antients to a liquid bitumen, from the iſland Zant.

ZADURA, in the materia medica of the antients, a name given to a foreign root, which was round and ſmooth, and of the colour of ginger.

It was at that time imported from the Indies, and greatly eſteemed in peſtilential caſes.

ZAFFABEN, a word uſed by ſome of the chemical writers, to expreſs putty.

ZAFFER, or ZAFFRE, in chemiſtry, the name of a blue ſubſtance, of the hardneſs and form of a ſtone; and generally ſuppoſed to be a native foſſil.

It is in reality, however, a preparation of cobalt; the calx of that mineral being mixed with powdered flints and wetted with water to bring it into this form. *Hill*'s Hiſt. of Foſſ. p. 625. See the article COBALT.

To prepare this for uſe in the glaſs-trade, put it in groſs pieces into earthen pans, and let it ſtand half a day in the furnace; then put it into an iron ladle to be heated red hot in the furnace; take it out while thus hot, and ſprinkle it with ſtrong vinegar; and when cold, grind it on a porphyry to an impalpable powder, then throw this into water in glazed earthen pans; and when it has been well ſtirred about, let it ſettle, and pour off the water: Repeat this waſhing often, and the foulneſs of the *Zaffre* will be thus wholly ſeparated: Dry the powder and keep it for uſe.

ZAFFRAMEN, a word uſed by ſome medical writers, to expreſs ſaffron.

ZAFFRAN, a word uſed often in authors to expreſs ſaffron, but ſometimes as the name of other things of a yellow colour; thus ochre was called by this name.

ZAFRANIA, in colours, a term uſed by the Greeks, to expreſs the yellow of ſaffron. The barbarous writers of the after-ages tranſlated it into the Latin *crocietas*, or ſaffron-colour.

The later Greek writers only uſe it, and they have taken it literally from the Arabians Aviſenna and Serapio. This was a term uſed by them to expreſs the colour of the fine bole-armenic of Galen, which they tell us ſtained paper to a fine and beautiful gold colour.

ZAGI. See the article ZEGI.

ZAGU, in the materia medica, the name given by ſome authors to the ſago-tree, the *todda pauna*, or *palma fructu pruniforme*. *Jonſ.* Dendr. p. 144.

ZAHIA, a word uſed by the Arabian phyſicians, to expreſs a ſort of dyſentery, in which there was a very large diſcharge of blood from the rectum, attended with an evident ſenſation of abraſion, or pain in the bowels.

ZAIBAC, one of the many names by which the antient chemiſts have called mercury.

ZAIDIR, a name by which ſome of the chemical writers have called verdigreaſe, or the ruſt of copper; and others, the metal itſelf; and ſome braſs.

ZAIN, in the manege. A horſe is called in French *Zain*, that is of a dark colour, neither grey nor white, and without any white ſpot or mark upon him.

ZAMECH, a name given by ſome writers to the lapis lazuli.

ZAMPOGNA, in the Italian muſic, is uſed to denote any inſtrument that ſounds like a flute; and particularly a bag-pipe, being an aſſemblage of divers pipes of different ſizes. It is alſo taken for a common flute.

ZANNA, the name of a medicinal earth, deſcribed by Oribaſius; he ſays, it is found in Armenia, in that part which borders on Cappadocia; and that it is very drying and of a pale colour, and eaſily diſunited by water, falling into a fine powder like lime.

It is called by the natives *Zarina*, and the mountain from which it is taken is near the city Baganona. It is of a drying and aſtringent nature.

ZANNICHELLIA, in botany, a name given by Micheli, to a genus of plants, called by others *algoides*, *aponogeton*, and *gramine folia*.

The characters are theſe: It produces diſtinct male and female flowers, which always ſtand very near one another. The male flower has neither cups nor petals, but conſiſts only of one erect ſtamen or filament, which is conſiderably

long,

leaves, and is terminated by an oval anthera. The female flower has a bellied perianthium compoſed of one leaf divided into two at the end. There are no petals. The piſtil has ſeveral corniculated germina, with as many ſimple ſtyles with plain ſtigmata of an oval figure. The ſeeds follow theſe, and are as many in number as there were horns or germina; they are oblong, pointed at each end, and gibbous on one ſide, and are covered with a ſkin or rind. *Linnæi* Gen. Pl. p. 444. *Vaillant*, A. G. 1719. *Ponteder* Anth. *Dillen.* Gen. p. 169.

ZANONIA, in botany, the name of a genus of plants, the characters of which are theſe: It produces ſeparate male and female flowers; in the male flower the cup is a perianthium, compoſed of three leaves of an oval figure, expanding every way, and ſhorter than the flower. The flower is monopetalous, but divided into five ſegments, and has an open mouth. The ſegments are jagged, and are equal in ſize, and bend backwards. The ſtamina are five filaments of the length of the cup, ſtanding open at their ends, and terminated by ſimple apices. The female flowers grow on ſeparate plants, and have the cup and flower the ſame as in the male, only that the cup ſtands upon the germen of the piſtil. This germen is oblong, and from it are propagated three reflex conic ſtyles. The ſtigmata are bifid and curled; the fruit is a long and very large berry, truncated at the end, and very ſmall at the baſe. It contains three cells, and has a curled future near the apex; the ſeeds are two; they are of an oblong figure, and flat *Linnæi* Gen. Pl. p. 477. H. Malab. vol. 8. p. 47. 49.

ZANTHENES, in natural hiſtory, a name given by the antients to a foſſile ſubſtance found in Media. Pliny quotes Democritus for ſaying, that if rubbed in palm wine and ſaffron, it became as ſoft as wax, and yielded a very ſweet ſmell.

ZARFA, in botany, a name given by Leo Africanus, and others, to the *lotus* or nettle tree.

It has been doubted by ſome what tree he meant, but his own deſcription of the *Zarfa* clears it up: he ſays, that the leaves of the tree are like the nettle, the fruit like a cherry, but ſmaller, and in taſte very much like the jujube; and that the Arabians call it *rabich*.

ZARIFU, a word by which ſome of the chemical writers have expreſſed tin.

ZARNAB, in the materia medica, a term uſed by Aviſenna and Serapion to expreſs the *carpeſia* of the antient Greeks.

This was an aromatic drug uſed as a ſubſtitute for cinnamon, and was the young ſhoots of the tree which produces the cubebs, or ſome other ſuch ſhrub. It was a fine aromatic, ſtomachic, and cordial.

Galen gives an account of two kinds of it, called *Laerticum* and *Pontiacum*, from the names of places where they grew: both theſe ſeem to have been the roots of the ſame tree, and both to have been produced in the ſame country Pamphilia, but on two different mountains there.

Some are of opinion that the *Zarnab* of the Arabians, and *carpeſia* of the Greeks, were not the ſame thing, but two drugs very like one another; but though Paulus Ægineta, and ſome others are of this opinion, it ſcarce ſeems clearly made out. See the article CARPESIA.

ZARNACH, the ſame as the word *Zarnich*; the name of the orpiment of the Arabians. See ZARNICH.

It was not confined however to this ſenſe alone, but was uſed as a name for other things uſed in painting, and particularly for the *lapis armenus*.

Aetius tells us, that the Syrians called the *lapis armenus Zarnach*, and many others have followed their example. Dioſcorides and Theophraſtus keep the words, and the things ſignified by them, wholly ſeparate. They call the *lapis armenus* by the name of *armenion*, and the *Zarnach* by that of *arrenecon*, that is orpiment. The red and yellow orpiment were both called by this name, only with the addition of an epithet that expreſſed the difference of colour. Dioſcorides indeed mentions a ſort of red arſenic, different from the red orpiment, which he ſometimes calls *ſandarach*; but the Arabians confound all theſe things under the name *Zarnach*. See the article CARNID.

ZARNICH, in natural hiſtory, the name of a genus of foſſils; the characters of which are theſe: They are inflammable ſubſtances, not compoſed of plates or flakes, but of a plain ſimple and uniform ſtructure, not flexile nor elaſtic, ſoluble in ore, and burning with a whitiſh flame, and noxious ſmell like garlick.

Of this genus there are four known ſpecies: 1. A red one, which is the true *ſandarach*. (See the article SANDARACH.) 2. A yellow one, found in great abundance in the mines of Germany, and frequently brought over to us among and under the name of orpiment. 3. A greeniſh one, very common in the mines of Germany, and ſold in our colour-ſhops under the name of a coarſe orpiment. This is alſo found in our own country among the tin mines of Cornwall. And, 4. A whitiſh one, a very remarkable ſubſtance, which has the property of turning black ink to a fine florid red. This is common in the mines of Germany, but is of little value. *Hill*'s Hiſt. of Foſſils, p. 40.

ZARUTHAN, in ſurgery, a word uſed by ſome to expreſs a hard and unequal tumor of the breaſt, attended with a burning heat, and a violent but not continual pain.

This is by ſome refer'd to the cancer, and accounted a ſpecies of that terrible diſorder: its cauſe is ſuppoſed to be a ſharp ichorous humor in the blood.

ZAUROS, in ichthyology, a name given by the antient Greeks to that fiſh which we call *ſaurus* and *lacertus*, and which is called at Rome the *tarantola*.

It is truly a ſpecies of the oſmerus, and is diſtinguiſhed by Artedi by the name of the oſmerus, with eleven rays in the pinna ani. See the articles OSMERUS and SAURUS.

ZEA. In the writings of the antient Greeks, this word ſometimes is uſed to expreſs the libanotis. Dioſcorides tells us that the libanotis was by ſome called *Zea*, and by others *cachrys*.

It is remarkable alſo, that the word *cachrys* is by ſome uſed to ſignify the libanotis, and by others for the *Zea*. There cannot well be conceived two more differant plants than the *Zea* and the libanotis, the one being a corn, and the other a tall umbelliferous plant; and it is therefore unaccountable that that the Greeks and Romans ſhould have borrowed of one another the cuſtom of calling them both by the ſame name.

The word *Zea*, when taken out of this ambiguity, and aſcertained as the name of a corn alone, is yet not certain and determinate in its ſenſe in the various writers; moſt indeed make it the name of the ſpelta, or ſpelt corn; and this certainly is keeping up to the ſenſe of Dioſcorides, whoſe *Zea* is evidently the ſpelt corn. He mentions two kinds of it, the monococcous and the dicoccous; that is, ſuch as has only one grain or two in a huſk.

The *Zea*, or *Zeia* of Theophraſtus, is alſo evidently the ſame with the *Zea* of Dioſcorides, according to his deſcription; but there is much doubt whether it can be allowed to be the *Zea* of later writers in the ſame language. Theophraſtus ſays, that the *Zea* is the lighteſt of all corn; and in this Dioſcorides agrees with him: but Mneſitheus in Athenæus ſays, that the grain *Zea* is heavy, and the bread made of it the heavieſt and hardeſt to be digeſted of that of any grain, and that it was therefore to be eat very ſparingly, or it would do miſchief; and that people who had not been uſed to it, could not bear even a little of it without harm.

The ſame author adds, that it is a grain only fit to be cultivated in the cold northern climes, where other corn will not well grow; and that people, who could cultivate no other corn, were obliged to be very careful in the making of their bread of this, and always cautious of the quantity they eat of it.

It is ſufficiently plain from this, that the *Zea* of this author is wholly different from the ſpelt corn, that is, the *Zea* of the antient Greeks. Galen deſcribes a *Zea* which he ſays he had ſomewhere ſeen, agreeing with the characters of this corn, and making a blackiſh, heavy, and unwholſome bread.

The bread made of the ſpelt corn, or *Zea* of Theophraſtus, is lighter and whiter than any other bread; and the only ſeed of the corn kind which this heavy and coarſe *Zea* ſeems to agree with, is that kind of ſecale or rye deſcribed by Pliny, which he ſays was eſteemed a very bad grain, and only eaten when no other could be had, and which he deſcribes as growing up with a thin ſtalk, but bearing a great quantity of ſeeds, and thoſe black, heavy, and of a bitteriſh, diſagreeable taſte. This agrees with the *Zea* of Mneſitheus, in growing where no other grain would, and in all its other properties.

Many authors make the ſecale and olyra to be the ſame, and many alſo make the olyra and *Zea* to be the ſame; and thence rye and *Zea* are by many brought to be the ſame corn. Herodotus tells us of the Egyptians uſing olyra, or, as it is otherwiſe called, *Zea*; ſo he expreſſes himſelf. And Heſychius ſays, that *Zea* is a kind of grain otherwiſe called *olyra*; and Nicomedes ſays, that olyra is a name given to a kind of grain otherwiſe called rye or ſecale.

This author probably means the ſecale of Pliny already deſcribed, which is not the common rye, but the ſame grain with the *Zea* of Mneſitheus. Dioſcorides mentions olyra as a grain of the ſame genus with what he calls *Zea* or ſpelta, but of a different ſpecies; therefore whatever authors meant by theſe words at other times, it is evident that the olyra in the days of Dioſcorides, was very different from rye. The antients in general are very perplexed and confuſed in their accounts of the bread corns; but thus much may be known with certainty of the meaning of the different writers on this ſubject, and this may be a very fair ſtep to the unriddling all the reſt.

ZEBET, a word uſed by ſome of the chemical writers to expreſs dung.

ZEBLICIUM *marmor*, in natural hiſtory, a name given by ſeveral authors to a ſoft green marble variegated with black and white; and though the authors who have deſcribed it have not obſerved it, yet it no way differs from the white ophites of the antients. *Hill*'s Hiſt. of Foſſils, p. 485. See the article OPHITES.

ZEBRA, in natural hiſtory, the name of an animal of the aſs kind, common in Africa and in ſome part of the Eaſt-Indies. It is of the figure and ſtature of the mule, but is very different in colour, being very beautifully variegated with ſmall broad ſtripes of black, white, and brown, drawn from the ridge of the back to the belly. It is a very ſwift creature,

and large droves of them are uſually ſeen together. *Ray*'s Syn. Quad. p. 64.

ZEFR, a word by which ſome of the chemical authors expreſs pitch. See the articles PITCH and TAR.

ZEGI, or ZAGI, a word uſed by Aviſenna and others, to expreſs all the ſeveral vitriolic minerals.

Aviſenna ſometimes writes it *alzagiat*. Some have ſuppoſed it only the name of the *calcitis*; but Aviſenna tells us, that there are ſeveral kinds of it, the one yellow, which is *colcothar*; another white, which is *calcadis*; a third green, which is *chalcanthum*, or common vitriol; and a fourth red, which is *ſory*. See the article COLCOTHAR, *&c.*

The old interpreter of Aviſenna renders the word *Zagi* by *atramenta*, inks, and this has been much cenſured as ſeeming to expreſs their being all black; but this is not a juſt cenſure. The word *atramentum* is uſed by many good authors to ſignify ink, and all the ſalts of which ink is made, that is, all the ſorts of vitriol. See the article INK.

ZEHERECH, a word uſed by ſome of the chemical writers to expreſs flowers of braſs.

ZEITRABRA, a term uſed by ſome of the chemiſts to expreſs any thing that is fluxile.

ZELEM, in the materia medica of the antients, a name given by Aviſenna and others to a fruit common in Africa in their time, and much eſteemed by the people of that country, and called there by ſome *piper nigrorum*, the black people's pepper, or negro-pepper.

We have at this time given this laſt name to the *capſicum*; but that is very different from the plant thus called by theſe writers. Aviſenna tells us, that the *Zelem* was a fattiſh ſeed, of the ſize of a cich, and of a high flavour, in colour yellow on the outſide, and white within, and that it was brought from Barbary. It has been ſuppoſed by ſome, that the *Zelem* of the Arabians was the *traſi*, or ſweet cyprus-root, dug up to be eaten in the manner of the pignut. But it is plain, from this account of Aviſenna, that this is an erroneous opinion, the *Zelem* being evidently a fruit, not a root. He adds, however, that there was another plant, properly called *fulful alſuaden*, that is, *piper nigrorum*. This, he ſays, was a ſeed contained in pods like kidney-beans, and was black, and of a pungent and acrid taſte.

This was the ſame plant with that afterwards called *piper Æthiopum*, or Æthiopian pepper, which all authors figure and deſcribe as growing in pods.

Guilandinus groſsly miſtakes Serapio, who ſpeaks alſo to this effect, and ſuppoſes that he ſays all this of the *Zelem*, which he only ſays of the Æthiopian pepper, or what was properly called *piper Nigrorum*. This author, ſpeaking of the *Zelem*, calls it *hab*, which word the Arabians never uſe for a ſeed of a plant contained in pods, but always for the round and ſingle fruit of a tree, as a berry, or the like. And Rhaſes, where he is ſpeaking of the virtues of ſeveral fruits, brings in this *Zelem* among them. From the whole, we may at leaſt clear ourſelves of a great many errors in regard to the *Zelem*, by proving what it is not, though we cannot eaſily ſay what it is.

ZELPHI. See the article ZENDA, infra.

ZEMA, a word uſed by many of the old writers for a decoction or apozem.

ZEMASARUM, a word uſed by ſome of the chemical writers, as a name for cinnabar.

ZEMECH, a word uſed by ſome writers as a name for *lapis lazuli*.

ZEMIA, Ζημια, among the Athenians, is ſometimes taken in a large and general ſenſe for any kind of puniſhment; but more frequently for a pecuniary mulct or fine laid upon the criminal, according to the degree of his offence. *Potter*, Archæol. Græc. T. 1. p. 129.

ZEMPHYRUS, in the materia medica of the antients, a name given to a precious ſtone, the fragments of which they uſed as a cordial and ſudorific.

It appears by their accounts, that this ſtone was blue; and hence many have too haſtily judged, that it was the *lapis lazuli*; but in truth it was the ſapphire.

The word *Zemphyrus* is no where uſed, but in the writings of the later Greeks, and it is plainly formed, as moſt of their names of things are, on the Arabian word, expreſſing the ſame thing. This Arabian word is *ſemphir*; and this, in Aviſenna and Serapio, is always uſed as the name of a ſapphire, never as that of any other gem. We find alſo by their accounts, that this ſapphire was not the ſapphire of the antient Greeks; but the fine blue pellucid gem we now know by that name; for the ſapphire of Theophraſtus, and the other old writers, was only a kind of lapis lazuli.

ZENDA, a general term coined by Paracelſus, by which he and his followers expreſs extraneous or equivocal generation, or the production of bodies without a ſeminal principle. The word *zerunda* is uſed to expreſs this particular ſort of generation of men, and *zelphi* in regard to other animals.

ZENECHDON, a term uſed by the Arabian phyſicians for a preparation of arſenic, for external uſe; *zeech* being their name for arſenic.

ZENEXTOR, one of the many names by which the chemiſts have called mercury.

ZENGIFUR, a word by which ſome of the chemical writers have expreſſed cinnabar.

ZENI, a word uſed by many of the chemical writers as a name for vitriol.

ZENICON, the name of a poiſon, compoſed of ſeveral ingredients, and uſed to poiſon the tips of the arrows with which the Celtic hunters ſhot at the beaſts they purſued for food. The poiſon was known to be of that quick ſpreading nature, that as ſoon as the beaſt was fallen, the huntſman ran up to it, and cut out a large piece of the fleſh about the wound, immediately to hinder the venom from ſpreading farther. The antidote to this poiſon was ſuppoſed to be the leaves of oak, beech, and other trees.

ZENITH (*Cycl.*)—*Zenith* is alſo a word uſed by ſome medical writers to expreſs the firſt appearance of the menſes in young women.

ZENUPH, in the Jewiſh antiquities, a kind of tiara worn by the kings of Juda. See the article CIDARIS.

ZEOPHILOS, a word uſed by Quercetan as the name of an antimonial medicine.

ZEOPHYRUM, in the materia medica, the name of the *triticum æſtivum*, or *hordeum nudum*, as it is called by ſome authors, the naked barley. *Dale*, Pharm. p. 260.

ZEPHYRI *Fœtus*, a term uſed by Hartman, and ſome other writers, to expreſs a mole, or falſe conception.

ZERICHUM, a name given by ſome of the chemical writers to arſenic.

ZERNA, a word uſed by ſome of the chemical writers to expreſs an ulcerated lepra or impetigo; the chemical authors uſe it alſo as a name for the foulneſſes which they call the *lepræ metallorum*, or leproſies of metals.

ZERTA, the *Zerte*, a fiſh caught in the rivers of Italy, and ſome other places, of the figure of the chubb, and called by authors, *capito anadromus*, and the *blike*.

It very much approaches to the figure of the naſus, and has by ſome been eſteemed the ſame ſpecies of fiſh. It is of a long, and not flat ſhape, of a bright ſilvery colour, and covered with ſmall ſcales. Its back is of a browniſh hue, and its belly-fins of a mixed reddiſh and bluiſh colour; the ſide-lines reaching from the gills to the tail, are ſpotted with brown dots. Its head is thick, and its eyes large and white. Its mouth is ſoft and toothleſs; but the beginning of its throat is armed with ſtrong and ſharp teeth, ſeven in number. It ſeldom grows to more than two pound weight, and, at times, lives in rivers, at times in the ſea; and is eſteemed a very well taſted fiſh, eſpecially a little before the ſeaſon of its ſpawning. *Ray*'s Ichthyogr. p. 257.

The *Zerte* is that ſpecies of cyprinus deſcribed by Geſner and others under the name of *capito anadromus*. See the articles CAPITO and CYPRINUS.

ZERUMBETH, in the materia medica, a root found both in the Eaſt and Weſt Indies. The plant producing it is called by Piſo and Marggrave, *paco-ceroca*, and by Sir Hans Sloane, *zinziber ſylveſtre*. See the article GINGER.

It is of a yelloviſh grey colour on the outſide, but whiter within; when cut, it ſhews a very ſmooth and gloſſy ſurface; its ſmell is very aromatic and agreeable, and its taſte very acrid, ſcarce leſs ſo than ginger.

It is good in nervous caſes, and on all other occaſions that zedoary is. See the article ZEDOARY, *Cycl.*

ZESTOLUSIA, a term uſed by ſome medical authors to expreſs bathing in warm water, by way of diſtinction from *pſuchroluſia*, or bathing in cold water.

ZETETÆ, Ζητηται, among the athenians, were officers appointed upon extraordinary occaſions, to enquire after the public debts, when through the neglect of the receivers, or by other means, they were run up to large ſums, and began to be in danger to be loſt, if not called in. *Potter*.

ZETUS, a word uſed by ſome of the chemical writers as a name for vitriol.

ZEUGITÆ, Ζευγιται, among the Athenians, the third claſs of the people, or thoſe who had an eſtate of two hundred medimns. *Potter*, Archæol. T. 1. p. 14.

ZEUS, in the Linnæan ſyſtem of zoology, the name of a genus of fiſhes, of the general order of the acanthopterygii, the characters of which are, that the membrane of the gills has bones not parallel, that the body is flat, and the ſcales are ſharp. Of this kind are the aper, faber, *&c.*

The characters of this genus, according to Artedi, are theſe: The branchioſtege membrane does not conſiſt of parallel bones, as in other fiſhes, but contains various bones, ſometimes laid longitudinally, ſometimes tranſverſely, and ſometimes obliquely. The ſcales are rough, and the body very broad, thin, and compreſſed; as is alſo the head. The back-fin is long, and as it were double, being cut in near the middle part, almoſt to the bottom or baſe.

The ſpecies of this genus are theſe: 1. The *Zeus* with a prickly belly, and a tail rounded at the end. This is the *faber* or *john doree*. 2. The forked-tailed *Zeus*. This is the *faber indicus*, or *piexe gallo*. 3. The red *Zeus*, with an even tail, and with the ſnout bending upwards. This is the *aper*

of Rondeletius, and the *riondo*, of the Italians. *Artedi*, Gen. Piſc. p. 35.

ZIBELLINA, or the *Muſtela* ZIBELLINA, in zoology, the name of the creature whoſe furr is the *ſable*, ſo much valued among us.

It is an animal of the weaſel-kind, of the ſize of a cat, and of a duſky yellow colour, with a mixture of a deep brown; the anterior part of the head, and the ears, are of a browniſh-grey, and the hairs about its eyes, noſe, and mouth, very long. *Ray*'s Syn. Quad. p. 201.

ZIBETHICUM *Animal*, in zoology, the name of the creature commonly, but very improperly, called the *civet cat*; for it does not at all belong to the cat kind; but wholly to that of the dog; the head and noſe are plainly of the figure of the dog's; and the figure, number, and diſpoſition of the teeth, are plainly the ſame as in the wolf, fox, and dog.

Its colour varies very much; its more uſual one, however, is that of a pale grey, variegated with long black ſtreaks, though in the females it is often yelloviſh, and ſometimes whitiſh, and the ſpots black and round, like thoſe of the leopard, or cat of mountain.

The whole ſhape of the creature approaches to that of the wolf or dog; its ſnout is long and ſmall; its ears are ſmall and roundiſh; its hairs are like thoſe of the badger, but very ſoft. It body is thick and fleſhy, and ſomething reſembles the ſhape of a hog's; its feet are ſmall, and its legs very ſhort. The bags which contain the civet are placed between the anus and pudenda, and are found equally in the males and females; but in the male they are twice as large as in the female; they have a large cavity in their internal part, and their orifice is ſmall and cartilaginous. The perfumed liquor which is found in theſe bags, ſeems to be ſecreted from a number of glands, which lie between the two ſkins, of which they are compoſed. See Tab. of Quadrupeds, N°. 16.

It is remarkable, that in this creature, as in the badger, its noſe and belly are black, whereas in almoſt all other animals theſe parts are either whitiſh, or much paler than the reſt. Theſe creatures copulate backwards. *Ray*'s Syn. Quad. p. 178.

ZIBIBIÆ, in natural hiſtory, a name given by ſome authors to a large ſort of raiſins, reſembling the ſtones of dates in ſhape; they have much pulp, but very little moiſture.

ZICCARA, a name of an Indian fruit, reſembling a pine-cone, and containing twenty, thirty, or more, kernels, of no known uſe in medicine.

ZIDRACH, in natural hiſtory, the name given by Cuba, and ſome other authors, to that ſpecies of the ſyngnathus of Artedi, commonly called the *hippocampus*.

ZIFIUS, in ichthyology, a name given by Albertus to the *xiphias*, or ſword-fiſh.

ZIGER, a word uſed by ſome of the old writers, to expreſs a very fine kind of caſſia, extremely aromatic to the taſte, and of a purpliſh black in colour.

ZIGURELLA, in zoology, the name by which ſome have called the *julis*, a ſmall but very beautiful fiſh, common about Genoa, and in ſome degree approaching to the nature of the turdus or wraſſe. *Willughby*, Hiſt. Piſc. p. 324. See the article JULIS.

It is a ſpecies of the *labrus*, according to Artedi, and is diſtinguiſhed by the name of the *palmaris labrus*, with two large teeth in the upper jaw. See the article LABRUS.

ZIMENT-*Water*, or COPPER-*Water*, in natural hiſtory, the name by which ſome have called water found in places where there are copper-mines, and lightly impregnated with particles of that metal.

The moſt famous ſpring of this kind is about a mile diſtant from Newſol in Hungary, in the great copper-mine called by the Germans, *herrn grundt*. It is not eaſy to ſay at what time theſe waters were diſcovered, ſince there is no authentic account of it. Kircher, Brown, Toll, and others, mention them as well known in their times; but it is probable that they were not diſcovered in the days of Agricola, ſince he no where makes the leaſt mention of them; and it is not probable that ſo great a curioſity, and that ſo immediately in his own way, would have eſcaped him, if known at that time, eſpecially as he has commemorated the like virtue in the Schmolnich waters, much leſs famous for it, and of much leſs power than thoſe of Newſol. The water in this mine is found at different depths, and is received into baſons, for the purpoſe of ſeparating the copper from it: in ſome of theſe it is much more highly ſated with this metal than in others, and will make the ſuppoſed change of iron into that metal much ſooner. The moſt common pieces of iron uſed in the experiments, are horſe-ſhoes, nails, and the like; and they are found very little altered in ſhape, after the operation, except that their ſurfaces are more raiſed. Philoſ. Tranſ. N°. 479. p. 355.

The water which performs this wonderful change, appears greeniſh in the baſons where it ſtands; but if a glaſs of it be taken up, it looks clear as cryſtal: it has no ſmell, but has a very ſtrong vitriolic and aſtringent taſte, inſomuch that the lips and tongue are bliſtered and ſcorched on taſting it.

The people who taſte this water do not perceive the effect upon their lips, while they are in the mine, otherwiſe than by a gentle itching; but as ſoon as they come into the open air, the places where it has touched begin to ſwell, and matter is at length found in puſtules in them.

There is great difference however in the ſtrength of the water at different times, both as to its burning the lips, and its power upon the iron; when the ſprings yield but a ſmall quantity, it is always much the ſtrongeſt; but when there flows a very large ſtream of them, they are always more languid and weak. The caverns in which the baſons are placed to receive this water, are of no offenſive ſmell; and what appears ſomewhat ſingular, are free from vitriol, which abounds ſo much in other parts of the mine. There are no cryſtals, nor filaments of it, ſeen on the walls; and the ſtones, which are in other places blue with the admixture of it in their granules, are here white, from its abſence. This is probably owing to the humidity of the air in theſe places, which waſhes away all the particles of that ſalt, and carries them to parts of the mine, where they may concrete more eaſily.

The ſides of the caverns near the floor or bottom, very often afford a yelloviſh earthy ſubſtance of a foliated texture, reſembling iſinglaſs, and of an inſipid taſte.

The miners are well acquainted with the virtues of this water, in changing the metals; but they alſo uſe it as a medicine; whatever ſickneſs they are ſeized with, they firſt attempt its cure by a large doſe of this water, which uſually both vomits and purges them very briſkly.

They alſo uſe it in diſorders of the eyes, in ſome of which it muſt be of great power; but in others, it is very improper; ſo that upon the whole, they do more harm than good with it.

The copper produced from theſe waters is valued by the people much beyond any other copper, as being much more ductile, and running eaſier in the fire, the people in the neighbourhood have many veſſels of it; but it is to be obſerved, that its ductility and hardneſs grow after it is taken out of the water; for, while immerſed in it, it is friable.

It is obſerved, that after great rains the ſprings are always fuller than at other times, and the virtues of the water conſiderably leſs.

A pound of this water when ſtrongeſt being evaporated over a gentle fire becomes firſt turbid and cloudy, and afterwards depoſits a yelloviſh ſediment, when evaporated to drineſs. This ſediment is found to weigh two ſcruples and a half, and when warm water is poured upon this and afterwards filtred, there will be left about ſix grains of yelloviſh earth in the filtre; and the greeniſh ſolution being again evaporated to a pellicle, and this repeated ſeveral times, ſomewhat more than two ſcruples of a bluiſh-green vitriol will be ſeparated in ſmall cryſtals.

A ſmall quantity of oil of tartar being added to a pound of this water, the whole becomes turbid, and on filtration, leaves a large reſiduum in the filtre; this when dried will be found to weigh about two ſcruples and a half, and to be a cupreous vitriol with a very ſmall admixture of a neutral ſalt.

Finally, if a pint of this water be put into a bottle, and a ſmall piece of iron thrown into it, ſome bubbles will be immediately found ſtanding on the iron, and it will be by degrees changed to a copper colour; the ſecond day will ſhew the water conſiderably turbid, and it will afterwards look whitiſh, and white filaments will gather about the bottom and ſides of the glaſs, and about the iron, which by that time will look throughout of a coppery colour.

From theſe experiments we may eaſily underſtand what the true nature of the water is, that it contains a large quantity of the vitriol of copper, which it probably owes to a ſolution of that metal, by means of the acid of the common pyrites and water; when this is known, the effects are not difficultly accounted for, there being no real change of one metal into another; but the true ſtate of the caſe being that the particles of one metal are diſſolved and carried away, and thoſe of another metal depoſited in their place: A water thus impregnated is a menſtruum capable of diſſolving iron, and in the ſolution of that metal becomes ſo weakned as to let go the copper it before contained, in ſmall parcels. This is ſeen to be the caſe, by examining the changed metal while it lies in the water, the copper then appearing not a ſoft malleable and even maſs, but a congeries of granules cloſely placed together, and reſembling the ſmall granules or ova in the ſpawn of fiſhes; and it is very friable and fragile while in this ſtate.

This ſolution of one metal and depoſition of the particles of another in its place, is a thing very familiar in chemiſtry, and is ſeen every day in numerous inſtances; but in none ſo familiar as in a like caſe, or ſolution of iron and of copper in the ſame menſtruum. Thus, if a piece of copper be diſſolved in aqua fortis, and when this ſolution is perfected a piece of iron be thrown into the liquor, the ſame thing will be ſeen that is in this ſpring, for the iron will be diſſolved, and the copper which was before diſſolved in the menſtruum will be ſlowly precipitated and depoſited in the place of it.

This water can only depoſit ſo much copper as it before contained, in the ſolution; and this appears upon experiment to be much leſs than might have been imagined, the quantity being no more than in every pound ſo much as can be contained in about two ſcruples of vitriol; that being the utmoſt quantity ſeparable from it, with all the art that could be uſed. Thoſe people are therefore greatly miſtaken, who ſuppoſe, that if ever ſo much iron be put into the water there will be as much copper precipitated in its place. The quantity of copper, however, annually obtained in this manner is conſiderable, as the waters are conſiderable in quantity. Phil. Tranſ. N°. 479. p. 359.

ZIMEX, a word uſed by ſome of the old chemical writers, for verdigreaſe.

ZINARIA, a word uſed by the Arabians, for a kind of vitiated bile, called æruginous bile.

ZINC. See the article ZINC, *Cycl.* and *infra*.

ZINETUS, a word uſed by Paracelſus, as a name for one of the braſs-like marcaſites.

ZINGAR, a word uſed by ſome of the chemical writers for verdigreaſe; and by others for the flos æris, or flowers of copper or braſs.

ZINGI, in the materia medica, the name of a ſeed, ſometimes alſo called the aniſum ſtellatum, or ſtarry-headed aniſe. *J. Bauhin.* V. 1. p. 586.

ZINGIBER. See the article ZINZIBER, *Cycl.* and *Suppl.*

ZINGNITES, or ZINGRITES, a ſtone deſcribed by Albertus, Ludovicus Dulcis, and other writers of that time, and ſaid to be of a cryſtalline tranſparence; they give us no farther deſcription of it, but attribute a number of imaginary virtues to it.

ZINIAR, a name given by ſome of the chemical writers, for verdigreaſe.

ZINIAT, a word uſed by the old chemical writers, to expreſs either the action of fermentation, or any thing that is capable of exciting it in bodies.

ZINK, (*Cycl.*) in natural hiſtory, the name of a very remarkable foſſile ſubſtance, reſembling biſmuth in appearance, but of a bluer colour.

It is a very remarkable mineral, and one that has never been well underſtood as to its origin, till of late; for though the world well knew of a long time both *Zink* and *lapis calaminaris*, and knew that both of them had the remarkable property of turning copper into braſs, which one would think might have given a hint to the diſcovery of a natural alliance between them; yet have they been ever treated of as two different ſubſtances, by the writers on theſe ſubjects; and Dr. Lawſon was the firſt who ever publicly declared, and proved, *lapis calaminaris* to be the ore of *Zink*. See the article CALAMINARIS *Lapis*.

Zink is generally confounded with biſmuth, though in reality a very different body; but the regulus of theſe two minerals having a very great external reſemblance, the vulgar have not diſtinguiſhed them; and hence we hear of many ores of *Zink* in the leſs accurate writers, all which are truly the ores of biſmuth.

The *lapis calaminaris* is the true and general ore of *Zink*, yet that mineral is not confined to this ore alone, but is mixed in great abundance in its diſſeminated particles among the matter of the ores of other metals, particularly of lead.

Our artificers have long been acquainted with *Zink*, under the name of *ſpelter*; but none of them till of late have ever been able to make any gueſs as to its origin. We have much *Zink* brought to us from the Eaſt-Indies, under the name of *tutenag*; yet no body ever knew from what, or how it was produced there; and all that was heretofore known of it was, that among that ſtrange mixture of ores which the great mine yields at Goſſelaer in Saxony, when they were fuſed for other metals, a large quantity of *Zink* was produced; but Dr. Lawſon obſerving, that the flowers of *Zink* and of *lapis calaminaris* were the ſame, and that their effects on copper were the ſame, never ceaſed his inquiries till he found the method of ſeparating *Zink* from it.

The pure *Zink* is a ſolid metal-like body, of a bluiſh white, and ſomewhat leſs brittle than biſmuth, eſpecially when gently heated, and moſt of all the metallic minerals approaches to malleability: It melts in a very ſmall fire, and in a ſtrong one takes fire, burning with a bluiſh-green flame, and ſubliming into white flowers, which are with difficulty reducible again into the form of *Zink*: In an open fierce fire, it wholly flies off in vapour.

There is great reaſon to believe, that all the *Zink* or *tutenag* brought from the Eaſt-Indies, is procured from calamine; and we have now on foot at home, a work eſtabliſhed by the diſcoverer of this ore, which will probably make it very ſoon unneceſſary to bring any *Zink* into England, as we have great plenty of the calamine. *Hill*'s Hiſt. of Foſſ. p. 626.

The manner of extracting *Zink* from the lapis calaminaris, is this: The lapis calaminaris muſt be finely pulverized, and well mixed with an eighth part of charcoal-duſt, and put into a cloſe retort to prevent the acceſs of the air, which would inflame the *Zink* as it riſes. The retort is to be placed on a violent fire, ſufficient to melt copper. After ſome time the *Zink* riſes, and appears in the form of metallic drops within the neck of the retort. When the veſſel is cool, it muſt be taken out, by breaking off the neck of the retort. *Marggraf.* in the Mem. de l'Acad. de Berlin, 1746.

Mr. Marggraf obſerves, that different ſorts of lapis calaminaris, ſuch as the Poliſh, Hungarian, and Engliſh, afford different quantities of *Zink*. And that a particular kind found in England, gave near half its weight of *Zink*.

This extraction of *Zink*, does not always ſucceed. Some calamine from Bohemia and Aix-la-chapelle yielded nothing. But then, as theſe kinds did not tinge copper with a yellow colour, nor produce any change in it, he thinks them not true calamine. Hence he concludes, that a ſtone which mixed with charcoal, and expoſed to the moſt vehement action of a cloſe fire, produces no *Zink*; or which, in an open fire, does not produce braſs with copper and charcoal, is not true lapis calaminaris.

Zink, produced in the manner above-mentioned, may be hammered into thin plates; which cannot be done with the common *Zink*. We muſt refer to the learned author for ſeveral other obſervations relating to *Zink*, and its flowers. See the article *White* VITRIOL.

Mr. Boyle tells us he diſſolved *Zink* in an urinous ſpirit, and then put to it a quantity of acid ſpirit; but though a manifeſt conflict aroſe, yet the *Zink* remained diſſolved in the mixture. *Boyle*'s Works abr. Vol. 1. p. 521.

Zink may be diſſolved, not only by aqua-fortis, aqua-regia, oil of vitriol, ſpirit of nitre, ſpirit of ſalt, and other mineral menſtruums; but alſo by vegetable ſpirits, as diſtilled vinegar; and by animal ones alſo, as ſpirit of ſal armoniac, and ſpirit of human blood. Ibid. Vol. 3. p. 478.

Mr. Boyle obſerves, that if the ſeveral ſolutions of this mineral be compared, it will ſhew what a variety of taſtes is producible from one inſipid body, by aſſociating it with different menſtrua. Works abr. Vol. 1. p. 541.

The ſame author tells us, that by the help of *Zink*, duly mixed after a certain manner, he has given copper as rich a golden colour as ever he ſaw in the beſt gold. Ibid. Vol. 2. p. 180.

Zink gains weight by ignition. *Boyle*, ibid. p. 391. §. 11. But quære the circumſtances of the experiment; for in the ſame book, p. 395. §. 26. the filings of *Zink* put in a bolt-glaſs with a ſlender neck, and ſet upon quick coals for four hours, loſt weight.

Flowers of ZINK. The flowers of *Zink* are a ſubſtance famous in the writings of the chemiſts, who have led their followers into a thouſand errors by the names by which they have called them.

Some have called them *talc*, and a ſolution of them in vinegar, *oil of talc*; to which they have attributed very extraordinary qualities. Some have ſet the ignorant upon a fruitleſs attempt of extracting an oil from Venetian talc, to do all the things they have commemorated of this oil. Others have called theſe flowers the *ſericum*: Others the *aqua ſicca philoſophorum*; and others the philoſophic cotton.

The moſt ſimple and eaſy way of obtaining the flowers of *Zink* pure and white, is this: Melt the *Zink* in a tall crucible inclined in the furnace in an angle of 45 degrees or thereabouts; let the fire be moderate, little ſtronger than would be neceſſary for the melting of lead. If the *Zink* is left in this ſtate without being ſtirred, it forms a grey cruſt upon its ſurface, and becomes calcined by degrees under it into a granuloſe white ſubſtance; but to have the flowers, the matter muſt be ſtirred from time to time with an iron rod, and this cruſt broken as often as it ariſes; there will then after ſome time appear a bright white flame, and about two inches above it there will be found a very thick ſmoak, and with this there will ariſe a quantity of very white flowers, which will fix themſelves to the ſides of the crucible in the form of fine cotton.

Theſe flowers are to be ſeparated at times, and by careful management there may be collected from the *Zink* a greater weight of flowers than its own weight, when put into the fire. In working four pounds of *Zink* in this manner, there will be only about an ounce of a calcined earthy matter left at the bottom of the crucible, and the quantity of flowers will be about two drams and a half in each pound, more than the quantity of *Zink*; beſide that, it is eaſy to conceive from the manner of making them, that a great quantity muſt have been carried away with the ſmoak. And this is not to be prevented, ſince if the veſſel be cloſed to keep in the fumes, the external air being denied free acceſs, the ſublimation immediately ceaſes, and no more flowers can be obtained, till the veſſel is again opened, and the air admitted.

The fumes of *Zink* have a ſtrong ſmell of garlic, and are very noxious to the lungs. The reducing *Zink* into theſe flowers, is the deſtroying it abſolutely as to its metallic form; for none of the methods uſed by chemiſts to bring back metals to their original ſtate, are able to bring theſe flowers to *Zink* again.

Mr. Hellot, of the Academy of Sciences of Paris, who has given a very accurate analyſis of *Zink*, has tried the diffe-

rent

rent acid menſtrua upon it with very great care and attention to their effects.

Diſtilled vinegar was firſt tried. Eight ounces of this diſſolved, in ten days time, over a gentle fire, an ounce all but ſix grains of *Zink*; and after this it ceaſed to act upon the metal any longer, and was ſweetened in the manner of vinegar which has diſſolved lead: This, however, is an experiment not proper to be tried by the taſte, the ſolution being very miſchievous. Six ounces and two drams of an inſipid phlegm were diſtilled from this ſolution, and after this the fire being increaſed, ſtriæ began to appear on the top of the retort; the receiver being changed, there ſucceeded to theſe ſtriæ a ſublimation of very white and beautiful flowers of *Zink*; and after this a few drops of an oil, yellow at firſt, and afterwards green, came over into the receiver. The diſtillation yielded alſo about four drams of a ſulphureous liquor, inflammable as ſpirit of wine. This liquor being poured into a phial of water, at firſt ſwam upon it, and immediately afterwards blended with it in the manner of ſpirit of wine, and left only the few drops of oil ſwimming on the ſurface. This was reddiſh in colour, and of an aromatic ſmell.

This is the famous liquor called by the chemiſts oil of talc, and ſuppoſed to have ſo many great virtues, one of which is the fixing of ſilver; that is, in other words, the concentrating it to the weight of gold, and making it indiſſoluble in aqua-fortis, rendering it like gold ſoluble only in aqua-regia; but in all probability, this oil is really nothing but the eſſential oil of the grape from which the wine was made, whence the vinegar had been obtained; and then how idle muſt appear all theſe expectations from it.

The flowers ſublimed to the neck of the retort or head of the cucurbit, during the diſtillation, burnt at the flame of a candle, emitting a fine blue flame. Three ounces of ſpirit of ſalt diſſolve perfectly three drams, except two grains, of *Zink*; a great heat is perceived while this ſolution is making, and this acid as well as diſtilled vinegar leaves untouched a ſmall blackiſh reſiduum, from this metal. Some authors have ſuppoſed, that this reſiduum contained mercury; but experiments prove the contrary, and its lightneſs alone makes ſuch a conjecture very improbable.

This ſolution being diſtilled, yielded two ounces of phlegm, two drams of a weak ſpirit of ſalt of a very agreeable ſmell; and afterwards, on changing the receiver, a few drops of a very acid and yellowiſh ſpirit, and ſome flowers, raiſed themſelves to the neck of the retort.

Six ounces of ſpirit of nitre diſſolves five drams and a half of *Zink*, without leaving any remainder; and the remainder left in the ſolutions of it by diſtilled vinegar, and by ſpirit of ſalt, is itſelf ſoluble in this menſtruum. This ſolution being diſtilled, there were ſeparated four ounces of phlegm, and afterwards ſix drams of ſpirit of nitre; this was but very weak, and no more could be raiſed; the ſtronger part of the acid remaining intimately mixed with the *Zink* at the bottom of the veſſel, in form of a viſcous tranſparent ſubſtance, of a yellow or orange colour.

Three ounces of oil of vitriol, with an equal quantity of water, diſſolved ſix drams and twenty grains of *Zink*; when the liquor was thus far ſaturated there began to be formed regular cryſtals; and after two months ſtanding the whole liquor was evaporated, and a cake of tranſparent vitriol left in the bottom of the veſſel. Memoires Acad. Scienc. Par. 1735.

ZINZIBER, *Ginger*. See the articles GINGER, *Cycl.* and ZERUMBETH, *Suppl.*

ZINZIBER *Rubrum, red Ginger*, a name by which ſome authors have called the officinal caſſumunar-root.

ZINZIBER *Caninum, Dog's-ginger*, in botany, a name given by ſome of the old writers to the *perſicaria urens*, or biting arſmart; a plant which is very hot, and pungent to the taſte, and grows in watry places. It had hence the name of *hydropiper*, water-pepper, among the Greeks; and was called *Zinziber caninum*, or dog's-ginger, by Aviſenna and others, from its heat, and from an opinion that it would poiſon dogs that eat of it.

The Arabian name is *Zinzibil alkeleb*. Aviſenna, when he gives the hiſtory of it, begins with that of ginger: he ſays that he repeats the words of Dioſcorides; which he really does, but coupling together the common ginger and this, which he calls dog's-ginger, and theſe being deſcribed in two different parts of Dioſcorides, the commentator on Garcias accuſe him of having taken the name of Dioſcorides, and the ſenſe of ſome other Greek author.

This commentator is the only perſon who has given this part of Aviſenna a Latin verſion; but when he ſays, that the fruit is ſmall and contained in pods, he errs; for the word *ania* ſignifying ſubſtance, not pod; the only meaning of the author is, that the ſeeds are ſmall, and the miſinterpreting his words into the deſcription of a podded plant carries away the idea of the arſmart; which is not a podded plant, but is yet the true *Zinziber caninum* of Aviſenna, and the *hydropiper* of Dioſcorides.

ZINZIBER *Caninum* is alſo a name given by ſome authors to the *capſicum*, or Guinea pepper. *Ger.* Emac. Ind. 2.

ZINZILLA, a name by which ſome medical writers have called that ſpecies of the herpes, which we uſually call the *ſhingles*. See the article SHINGLES, *Cycl.*

ZIRBALIS *Hernia*, a term uſed by medical writers to expreſs that kind of rupture which is cauſed by a deſcent of the omentum into the ſcrotum.

ZIRBUS, the name by which the Arabian phyſicians have called the omentum.

ZIVOLO, in zoology, a name by which ſome authors have called the ſmaller ſpecies of *yellow-hammer*, from its conſtant note, which is only *zi, zi*.

It is of the ſize of the common ſparrow; its beak is thick and ſhort, its breaſt and belly yellowiſh, ſpotted with brown; and its head, back, wing, and tail of a duſky brown, but two of the tail-feathers on each ſide have a variegation of white.

The difference between the male and female in this ſpecies is, that the male is yellower, and has ſome yellow ſpots on its neck and ſides, which are wanting in the female. It is almoſt always ſeen on the ground, and feeds on ſeeds, *&c.* It ſeems but little if at all eſſentially to differ from the common yellow-hammer; and Mr. Ray has ſome ſuſpicion, that they are the ſame ſpecies. *Ray*'s Ornithol. p. 196.

ZIZANIA, in botany, a name uſed by ſome for the *lolium*, or darnel. *Ger* Emac. Ind. 2. See the article LOLIUM.

ZIZANIA, according to Linnæus, is a genus of plants diſtinct from the *lolium*, and its characters are theſe: It produces male and female flowers on the ſame plant: The male flowers have no cup, but the flower is a bivalve glume compoſed of two equal pointed leaves without awns, which ſurround one another; the ſtamina are ſix very ſhort filaments; the antheræ are oblong and ſimple. In the female flowers alſo there is no cup, but the flower is a one-leaved glume of a convoluted figure, having ſix nerves running along it, and ending in a point terminated by a long awn or beard. The germen of the piſtil is oblong, the ſtyle is divided into two parts, and the ſtigmata are plumoſe; the fruit conſiſts of the flower itſelf, which continues rolled up, and finally parts off horizontally at the baſe: In this is contained one oblong ſeed. *Linnæi* Gen. Plant. p. 455.

ZIZERIA, a word uſed by Apicius, and ſome other authors, to expreſs the inteſtines of fowls of the gallinaceous kind, often uſed in decoctions for glyſters, *&c.*

ZIZIPHORA, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: The cup is a very long, cylindric, and tubular perianthium; it is compoſed of one leaf, and is hairy, ſtriated, and at the extremity is divided into five very ſmall ſegments, and is bearded. The flower is ringent, and compoſed of a ſingle petal; the tube is cylindric, and of the length of the cup; the limb is very ſmooth; the upper lip is ovated, erect, emarginated, and obtuſe; the lower lip is broad and patent, and is divided into three rounded, equal ſegments. The ſtamina are two ſimple, patent filaments, of the length of the flower; the ſtigma is acuminated, and inflex. There is no fruit, but the cup contains four ſeeds, which are oblong and obtuſe, gibbous on one ſide, and angular on the other. Vid. *Linnæi* Gen. Plant. p. 13.

ZIZITH, in the Jewiſh cuſtoms, a name given by the Jews to the tufts or fringes, they uſed antiently to wear at the four quarters of their upper garments[a]; but which they now only wear under their cloaths, fixed to a ſquare piece of cloth, which repreſents the garment they antiently wore in their own country before their diſperſion. The *Zizith* of the modern Jews is a tuft made of eight threads of yarn, ſpun on purpoſe for this uſe; each having five knots, which take up half the length. That which is not knotted, being furled out, makes a kind of tuft or fringe[b].— [[a]Numb. xv. 36. Deuter. xxii. 12. [b]*Leo* of Modena, Cerem. of the Jews P. 1. c. 5. *Calmet.* Dict. Bibl. in voc.

ZIZYPHUS, the *Jujube-tree*, in botany, the name of a genus of trees, the characters of which are theſe: The flower is of the roſaceous kind, being compoſed of ſeveral petals arranged in a circular form; the piſtil ariſes from the cup, and finally becomes a fruit of the ſhape of an olive, and of a fleſhy ſubſtance including a ſtone divided into two cells, each of which contains an oblong ſeed.

The ſpecies of *Jujube*, enumerated by Mr. Tournefort, are theſe: 1. The cultivated *Jujube*, with large oblong fruit. And, 2. The wild *Jujube*. *Tourn.* Inſt. p. 626. See the article JUJUBE.

The *Zizyphus*, according to Linnæus, is only a ſpecies of rhamnus, with oval leaves, and two ſtyles; the fruit, or nucleus of which, contains two cells, and its corolla has five ſegments.

It is a native of Spain and Italy; and the fruit, which is of the bigneſs of an olive, and reddiſh when ripe, was once eſteemed as a pectoral, and ſometimes preſcribed in fevers; but is diſregarded in the preſent practice. *Hill*'s Hiſt. Plant. p. 292.

ZMILACES, in natural hiſtory, a name given by Pliny to a ſtone found in the river Euphrates, reſembling marble, and of a bluiſh green colour.

ZMILAMPIS, in natural hiſtory, the name of a gem, deſcribed by Pliny and the antients, which they tell us was very like the Proconnenſian marble, except that in the center of the ſtone there was always a bluiſh ſpot, reſembling the pupil of an eye.

The Proconnenſian marble of the antients was of a fine clear and elegant white, variegated with irregular black veins. Pliny's deſcription is ſo ſhort, that it has been ſuppoſed from him that the *Zmilampis* was a ſort of marble; he only ſays of it, that it was like the Proconnenſian marble, but blue in the middle. Many had inferred from this, that he meant no more by it than that this was a ſtone, which had blue veins inſtead of the black ones in the Proconnenſian kind. But when we examine the reſt of the antients, and find that it was a ſmall ſtone, found in the river Euphrates, and worn in rings; and that its blue ſpot was like a pupil of an eye, we may eaſily determine that it was one of thoſe gems which we call *oculus beli*, or *bellocchio*; of which there are a vaſt variety found in the rivers of the Eaſt-Indies, and many have a fine opake white ground, and a bluiſh or greeniſh ſpot for the pupil.

ZMILANTHES, in natural hiſtory, a name given by Solinus, and ſome others, to a gem called by the more correct writers *Zmilampis*. See the article ZMILAMPIS, *ſupra*.

ZOCHINACAZTLIS, in botany, a name by which ſome authors have called the *flos auriculæ*, a flower of New Spain, uſed in the making of the Spaniſh chocolate. *Hernand.* p. 30.

ZODIAC (*Cycl.*) ZODIAC *of the comets*. Caſſini hath obſerved a certain tract in the heavens, within whoſe bound (by many obſervations) he hath found moſt comets, tho' not all, to keep. This he makes as broad as the other *Zodiac*, and marks it with ſigns or conſtellations like that, which are, *Antinoüs*, *Pegaſus*, *Andromeda*, *Taurus*, *Orion*, the *Leſſer Dog*, *Hydra*, the *Centaur*, *Scorpion*, and *Sagittarius*.

ZODIACAL *Light*, a brightneſs reſembling that of the milky way, and which is ſometimes perceived in the heavens, at certain times of the year, after ſun-ſet, or before its riſe. The form of this light reſembles that of a pyramid, lying lengthways in the *Zodiac*, within which its point and axis are always incloſed, its baſe being placed obliquely with reſpect to the horizon. This phænomenon was firſt diſcovered, deſcribed, and named by Mr. Caſſini the elder. See *Mairan*, ſuite des Mem. de l'Acad Royale des Sciences, 1731. p. 3.

The *zodiacal light* is nothing but the ſolar atmoſphere, a rare and ſubtile fluid, either luminous by itſelf, or made ſo by the rays of the ſun ſurrounding its globe; but in a greater quantity, and more extenſively, about its equator, than any other.

The *zodiacal light* is more or leſs viſible according to circumſtances: But the ſolar atmoſphere is not always viſible by means of this light, though it be always ſeen about the globe of the ſun in total eclipſes.

One of the moſt eſſential circumſtances for the perception of the ſolar atmoſphere by the *zodiacal light*, is its having a ſufficient length on the *Zodiac*; for, without this, its brightneſs is entirely hid from us by the twilights.

Mr. de Mairan ſays, it may be proved from many obſervations, that the ſun's atmoſphere ſometimes reaches as far as the earth's orbit, and there meeting with our atmoſphere, produces the appearance of an aurora borealis. See the article AURORA *Borealis*, *Cycl.* and *Suppl.*

The length of the *zodiacal light* varies ſometimes in reality, and ſometimes in appearance only, from various cauſes.

The oblique poſition of this light, little different from that of the plane of the ecliptic, does not permit us to ſee it diſtinctly, and ſufficiently elevated above the horizon; but ſome time after ſun-ſet, towards the end of the winter, and in ſpring, or before ſun-riſing in autumn, and towards the beginning of winter. Several cauſes hinder our ſeeing it, any more than the milky way; ſuch as moon-light and ſtrong twilights, among others.

Mr. Caſſini [a] often mentions the great reſemblance of the *zodiacal light* to the tails of comets. Mr. Fatio [b] has made the ſame obſervation; and Mr. Euler has lately endeavoured to prove them owing to ſimilar cauſes [c].—[[a] Decouverte de la lumiere celeſte que paroit dans le *Zodiaque*, art. 41. [b] Lettre à Mr. *Caſſini*, printed at Amſterd. 1686. [c] *Euler*, in Mem. de l'Acad. de Berlin, Tom. 2.] See the article TAILS *of Comets*.

The figure of this ſolar atmoſphere muſt be lenticular, or that of a flatted ſpheroid. Mr. de Mairan gives us a draught of its appearance and projection. Lib. cit. c. 4. fig. 2.

The extent of the *zodiacal light* from the ſun to its point, is ſeldom leſs than 50 or 60 degrees: It has even been known to extend to 100 and 103°. Ib. c. 6.

This light ſeems to have no other motion than that of the ſun itſelf. Ib. c. 7.

Mr. Euler obſerves, that if the ſun has an atmoſphere, the force of the impulſe of light iſſuing from that globe, muſt drive particles of that atmoſphere before it; but as gravity is very ſtrong at the ſun, this impulſe would never drive thoſe particles beyond the limits of their atmoſphere, were it not for the centrifugal force ariſing from the ſun's motion round its axis. This being oppoſite to the action of gravity, and diminiſhing its effects, the impulſe of the light may conſiderably dilate the figure of the ſolar atmoſphere, from what it would be if it aroſe from the gravity and centrifugal force of its particles only; and this dilatation will be very conſiderable near the ſun's equator, and very ſmall towards its poles. The action of light thus diminiſhing the action of gravity, Mr. Euler attempts to calculate how far this diminution of gravity may increaſe the extent of the ſun's atmoſphere about its equator. He finds a cubic equation, the roots of which expreſs the ſemi-axis, or greateſt amplitude of this atmoſphere. He adds, that this equation having three real roots, it is poſſible that the ſolar atmoſphere may become a ring ſurrounding the ſun's globe, as the ring of Saturn ſurrounds the body of that planet. Loc. cit. p. 140.

ZONA, a word uſed by ſome authors for that ſpecies of herpes which others call the *zinzilla*, and we term the *ſhingles*.

ZONITES, in the materia medica of the antients, a name given to a kind of tutty, called alſo *placitis*. It had the latter name from the Greek, πλακος, a cruſt, it being formed by way of cruſt on the ſides of the furnaces. The latter name *zonites* was given it from its being formed of ſeveral coats, which, when broken tranſverſely, had the appearance of belts or zones. See the article FURNACE.

ZONITIS *Cadmia*, a name given by ſome authors to a kind of cadmia fornacum, from its uſually ſurrounding the upper parts of the furnaces like a girdle or belt.

ZOOLATRIA, ζωολατρια, a ſpecies of idolatry, wherein divine worſhip was offered to animals. *Hofm.* Lex. in voc.

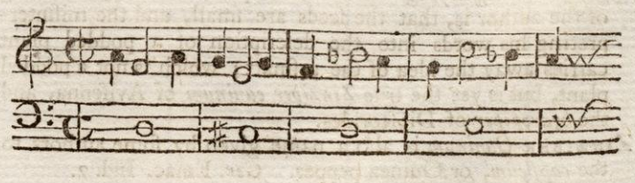
The word is compoſed of ζωον, an animal, and λατρια, worſhip.

ZOOLOGY, (*Cycl.*) the ſcience of animals. This makes one of the three kingdoms, as they are called, of natural hiſtory; the vegetable and the mineral being the two others: In theſe, however, there is this difference made by writers, that while vegetables and minerals are treated of together, as all of a piece in each, the ſubjects of *Zoology* are divided, and it is made to compoſe, as it were, ſeveral kingdoms. Whoever is to write on plants and minerals, calls his work a treatiſe of botany, or mineralogy; and we have no words to expreſs any ſubdiviſion of them into kingdoms: but, in *Zoology*, we treat, as different ſubjects, the different parts of it; and the hiſtory of birds is ſeparated by ſome from the reſt under the name of *ornithology*; that of quadrupeds under the name of *tetrapodology*; and we have for the reſt, the words *entomology*, *amphibiology*, and the like, expreſſing theſe things which are properly but the parts of *Zoology*, as ſo many diſtinct and ſeparate ſtudies.

This may eaſily be amended, by our conſidering the animal world as we do the vegetable and mineral, and dividing it, as we do the others, into its proper families; it will then be found that theſe are no better diſtinctions than thoſe of the families of theſe things, and that the authors may as well ſet up ſeparate ſtudies under the names of *bulbology*, *umbelliferology*, and the like, as thoſe.

A natural diviſion of the ſubjects of *Zoology*, on this principle, will afford ſix ſeveral families of its ſubjects. 1. The hairy quadrupeds. 2. The birds. 3. The amphibious animals, ſuch as ſerpents, lizards, frogs, and tortoiſes. 4. The fiſhes. 5. The inſects. And ſixthly, thoſe loweſt order of animated beings the *zoophytes*. *Artedi* Ichthyol. See the articles QUADRUPED, BIRD, FISH, &c.

ZOOMINERALIA, a word uſed by ſome writers to expreſs certain ſubſtances which are of animal origin, yet have ſomewhat of the nature of ſtones, as pearls.



ZOOPHTHALMUS, in botany, a name given by the antient Greeks to the *ſedum majus*, or common great houſe-leek.

It had this name from the Greek ζωὸν, an animal, and ὀφθαλμὸς, an eye, as expreſſing a reſemblance to the eyes of large animals, in the round and radiated growth of its cluſters of leaves. They alſo called it *ambroſia*.

ZOOPHYTE (*Cycl.*)—ZOOPHYTE-*Marygold*. See the article MARYGOLD.

ZOPHOCIDELUS, in botany, a word uſed ſometimes as an epithet with the word *chamæleon*, and ſometimes ſingly as the name of a plant, in both caſes expreſſing the black chamæleon-thiſtle, which the antients carefully diſtinguiſhed, in their writings, from the white kind, the former being a poiſonous plant, the other not ſo.

ZOPPO, in the Italian muſic, is applied to all thoſe counterpoints, deſcribed under the articles PERFIDIATO, OBLIGATO, &c. Thus they ſay *contra-punto alla zoppa*, a lame or hopping counter-point; becauſe, in theſe, a note is placed between two others, each of half its value in time: When this comes to be played or ſung, the voice or inſtrument ſeems to proceed by unequal leaps or ſteps, like thoſe of a lame perſon. See the example here annexed.

There

There are *contra punto alla zoppa ſopra il ſogetto*, as well as *ſotto il ſogetto*, *i. e.* above and below the ſubject. See the article SOGETTO.

ZORABA, a word uſed by ſome of the chemical writers to expreſs vitriol.

ZOSTER, a word uſed by ſome to expreſs that kind of herpes, called by others *zona* and *zingilla*, and by us uſually known under the name of the *ſhingles*.

ZOTHECA, among the antients, the place where the animals deſigned for ſacrifice were kept. *Pitiſc.* in voc.

ZOZONISIUS, in natural hiſtory, a name of one of the gems of the antients, but of which our accounts are ſo ſhort, that we can make no conjecture of what it was. Pliny only tells us, that it was found in the river Indus, and uſed by the magi.

ZUFFOLO, in the Italian muſic, a little flute or flagelet, having a very ſhrill ſound, like the whiſtling of ſmall birds. *Broſſard.*

ZURNAPA, in zoology, the Arabian name of an animal of a very ſingular kind, and ſeeming properly to belong to no known genus of animals, but to be perfectly *ſui generis*. It is alſo called *camelopardelis* by Latin authors, and *geraffa* by eaſtern nations.

It is not certainly known whether it chews the cud or not; but as its hoofs are cloven, and it has horns on its forehead, and wants the fore-teeth in its upper jaw, and feeds on vegetables, it is probable that it does.

It is a ſingular, elegant, and beautiful creature, and is very remarkably tame and tractable, even ſcarce leſs ſo than a ſheep, and ſeems intended by nature for a domeſtic, not a ſavage animal. Its head is wholly of the make of the ſtag's, but differs in ſize, and has two little obtuſe horns, which are not more than ſix fingers breadth long, and are hairy: the male and female both have theſe, and the latter is diſtinguiſhed by having them ſhorter than the former. Its ears are larger, and like thoſe of the ox-kind; its tongue is alſo like that of an ox, and it wants the fore-teeth in the upper jaw. Its neck is remarkably long, ſtrait, and ſlender, in a grown animal. The neck is uſually ſeven feet long, and the meaſure from the tail to the top of the head eighteen feet; and when it ſtands erect, its head is ſixteen foot from the ground; it has a ſmall mane; its legs are very ſlender, and the forelegs very long; the hinder ones very ſhort, ſo that the creature ſeems always to ſtand upright.

Its hoofs are cloven exactly as thoſe of the ox, its tail reaches down to its hams, and is rounded and covered with very thick hairs; the middle of its body is ſlender; it is very like the camel in all its natural properties: when it runs it holds the two forefeet together, it lies down on the belly, and claps its neck down on the thighs and breaſt in the manner of the camel. As it ſtands it can ſcarce reach to eat the graſs, unleſs its fore-legs are very far expanded, and that is a poſture of great pain to it; ſo that nature ſeems to have allotted it to feed in its wild ſtate on the leaves of trees, which its long neck will very well enable it to get at. It is very beautifully ſpotted all over its body in the manner of the leopard.

The velvety covering of its horns ſeems to make it of the ſtag kind, but its ſhape is wholly different from thoſe of that genus. *Bellon.* Obſ. l. 2. c. 49.

ZYGÆNA, in zoology, the name of a fiſh of the ſhark kind, called in Engliſh *the ballance fiſh*, or the *hammer-headed ſhark*. See Tab. of Fiſhes, No. 2.

It is an extremely ſingular and remarkable fiſh, and differs not only from all the other ſharks, but from all the fiſh in the world in the figure of its head: this is not placed, as in all other fiſhes, longitudinally, or in a line with the body, but is ſet on tranſverſely as the head of a hammer or mallet upon the handle. This is ſemicircular at the front, and runs to ſo thin and ſharp an edge, that as the fiſh ſwims forward with violence, it may cut other fiſhes, and is terminated at each end by an eye; theſe are very large, and ſo placed, that they more conveniently look down than either upward or ſideway. In the farther part of the forehead alſo, near the eyes, on each ſide there is a large oblong foramen, ſerving either for hearing or ſmelling, or perhaps for both. The mouth is very large, and placed under the head, and armed with four rows of extremely ſharp and ſtrong teeth, flat, and ſerrated at their edges. The tail is compoſed of two fins, one vaſtly larger than the other; the body is rounded and very long, and is not covered with ſcales, but a thick ſkin; the back is aſh-coloured, and the belly white. *Rondelet.* de Aquat. p. 549.

The *Zygæna* is a ſpecies of *ſqualus*, according to the Artedian ſyſtem of ichthyology. See the article SQUALUS.

It is caught in the Mediterranean, and ſometimes in different parts of the ocean. Some authors have called it *Zygena*, and others *Libella*; which laſt anſwers to the Engliſh name of the *Ballance-fiſh*.

ZYGASTICUM, Ζυγαστικον, among the antients, money paid for weighing things.

The word comes from Ζυγον, a ballance. *Pitiſc.* Lex. Antiq in voc.

ZYGITÆ, in the Roman galleys, a term uſed to expreſs thoſe rowers in the triremes, or three-rowed galleys, who ſat on the ſecond row, that is above the thalamitæ and below the thranitæ. *Meibom.* de Trirem, See the article THALAMITÆ.

ZYGOPHYLLUM, in botany, the name of a genus of plants deſcribed by Linnæus, the ſame with the *fabago* of Tournefort. See the article FABAGO.

ZYGOSTATES, among the antients, an officer who was the overſeer of weights, and was to take care that tradeſmen uſed none but what were juſt. *Pitiſc.* Lex. Antiq. in voc.

ZYMAR, a name given by ſome of the chemical writers to verdigreaſe.

ZYME, a word uſed by many authors to expreſs ferment or leaven. See the next article.

ZYMOLOGY, in chemiſtry, a term uſed by ſome writers to expreſs a treatiſe on fermentation, or the doctrine of fermentation in general.

This is a very extenſive thing, and were it well accounted for, might help us to ſolutions of many things which at preſent appear extremely difficult to us.

Dr. Sympſon has written a treatiſe on this ſubject, wherein he refers the whole to the internal conflicts of acid and ſulphur in bodies, and ſeems to think that the phænomena of hot baths, the generation of minerals, and the production of mineral waters, the grand appearances of light, heat, and fire, and the generality of the ſubterranean phænomena of damps, earthquakes, and firy eruptions, and the appearance of meteors, may be all explained by the doctrine of fermentation, eſtabliſhed on this baſis.

Fermentation, according to this author, is nothing but an inteſtine colliſion between acid and ſulphur, put together by nature or art, and ſet in a combating motion, in order to the production of concretes, or ſome other end.

The phænomena of hot baths are explained on this foundation, by obſerving, that there is nothing of this kind without ſulphur, evident even to the ſenſes; and that an acid of ſome kind is neceſſary in all mineral fermentation. Acids are well known to be common in the earth, and on the conflicts of these with the ſulphurs evident in thoſe particular places, baths are made hot, and the minerals found about them are formed. Mineral ſulphurs are of different kinds, and according to theſe it is found that the waters of theſe hot baths differ alſo, ſome of them being ſafe to take internally, and others only fit for external uſe; in this the acid alſo may have its ſhare, for in its paſſage through the earth it frequently corrodes metalline ores, and carries their particles with it; theſe, if of iron, give virtues to the water, and render it proper in ſeveral diſeaſes: but if, on the other hand, they have diſſolved copper, they become unwholſome.

The ſulphurs and acids contained in the bowels of the earth, and occupying together large ſpaces of it, are thus formed into a ſort of beds of fermenting and hot matter, through which the water of theſe baths paſſing ſlowly and leiſurely on, cannot but be heated to the degree we ſee it of; and the greater the proportion of the acid, and the more the place abounds with metalline or mineral ores, the more hot and the more impregnated with virtues of minerals the water will be. Experiments ſhew, that ſulphur may be made to ferment violently with acids, and that in this fermentation it becomes communicated, volatilized, and made capable of ſolution in water, though before it was not; and hence is capable of impregnating the baths, as we ſee.

Theſe mineral productions are not all that are referred by this, and other authors who follow his ſyſtem, to the doctrine of acid and ſulphur fermentations. The vegetable world is ſaid to be as much influenced by it, and the growth of plants, or vegetation itſelf, is ſaid to be only a natural and ſlow-paced fermentation from the peculiar acid and ſulphur of each plant. Tachenius's doctrine of acids and alkalies, is wholly diſallowed in this ſcheme, and even in a great meaſure overthrown by it; and the doctrine of ſubterraneous fires is not neceſſary to heat the hot baths. It has been ſuppoſed that the ſulphur, in order to give this heat to them, muſt be itſelf flaming and burning; but it is proved in this ſyſtem, both by reaſon and experiment, that ſulphur properly combined with an acid, may both heat, and communicate its heat to other bodies by fermentation, without being itſelf ignited or burning within the bowels of the earth; the great improbability of which, in many places where hot baths are found, has been one of the grand reaſons for believing ſulphur had no ſhare in their production.

The acid, which is the other great cauſe of fermentation under ground, may be either ſuch as is inbred in the ſame mineral concretion while in *ſucco ſoluto*, or in the ſtate of its original formation; or an extrinſic and accidentally ſupervening one, which is well known to be of ſufficient power for ſuch an effect in the reduction of minerals already formed or completed. Some of the acid juices, which the earth in almoſt all parts abounds with, are looſe in themſelves, or fluctuating about, and others embodied in various animals: where they are bedded, and naturally contained in ſulphur, they are always ready for theſe changes of fermentation; but when they are in either of the other ſtates, they can only act as brought upon the ſulphurs by their own natural fluctuating courſe, or educed by water from the other minerals, and carried by it to the beds of ſulphur.

Thus

Thus the very water may be the efficient cauſe of the fermentation which afterwards gives the heat and virtues to it. All the acids, and all the ſulphurs contained in the earth, are not equally fit for this purpoſe; but ſome of the former have evidently ſo ſtrong a power over ſome of the latter, that they are ſufficient cauſes of heat in the mineral ingredients; and heat in any body concerned, is indeed the natural and neceſſary reſult of theſe fermentations.

The fermentation that ariſes between ſpirit of nitre and butter of antimony, is not from the ſalts in this ſublimate mixing with the acid in the diſſolvent, becauſe the ſame acids poured upon the ſame ſalts while incorporated with mercury in the form of ſublimate, is the cauſe of no fermentation at all: nay, ſublimate, in which the aforeſaid ſalts which are in butter of antimony are lodged, will diſſolve in an acid without the leaſt ebullition, like a piece of ice in water.

It is water always that ſets the inbred particles of acid and ſulphur into their great inward commotions, and makes the fermentation the ſtronger, and conſequently the heat by ſo much the greater. Thus a little water put to oil of vitriol, ſets the fermental principles of acid and ſulphur connatural to that oil, into ſo violent a fermentation and heat, that it is ſcarce poſſible even to endure the hand upon the glaſs where it is mixed. *Sympſon*'s Zymolog. Chym.

ZYMOSIS, a word uſed by ſome to expreſs fermentation, and by others for a flatulent tumor of the liver, or other of the viſcera. See the arricle ZYMGLOGY, *ſupra*.

ZYTHOGALA, *Beer-poſſet*, a drink recommended by Sydenham, as good to be taken after a vomit, for allaying the acrimonious and diſagreeable taſte it has occaſioned, as well as to prevent gripes. *Syden.* Obſerv. de Morb. acut. p. 39.

The word is formed of ζυθος, *cereviſia*, and γαλα, *lac*. See the article ZYTHUM, *Cycl.*

APPENDIX.

APPENDIX.

A.

ACT

ABATE, in the manege. A horſe is ſaid to *abate*, or take down his curvets, when working upon curvets, he puts his hinder legs to the ground both at once, and obſerves the ſame exactneſs in all the times. See the article CORVET, *Cycl.*

ABBA-*comes*. See the article ABBOT, *Cycl.*

ABDELAVI, a name given by Arabian authors to the Egyptian melon. See the article MELON, *Suppl.*

ABELMOSC, or ABELMOSCH, *(Suppl.)* is uſed by ſome authors for the Egyptian *ketmia*, with perfumed ſeeds. See KETMIA, N° 21. *Suppl.*

ABIGEAT. See ABIGEATUS, *Suppl.*

ABLATIVE *abſolute*. See the article ABSOLUTE, *Cycl.*

ABRICOT, in botany. See the article APRICOCK, *Suppl.*

ABRUS, in botany, a name ſometimes given to a ſpecies of *Orobus*. See the article OROBUS, *Suppl.*

ABSINTHIUM, *wormwood*, in botany, *&c.* See the article WORMWOOD, *Suppl.*

ABSINTHIUM is alſo a name given to other plants, by different authors; as to dwarf *ptarmica*, with leaves divided after the manner of wormwood; alſo to the alpine *chamæmile*, with ſouthernwood-leaves. Vid. *Tourn.* Inſt. Bot. p. 494, 496. See alſo the articles PTARMICA and CHAMÆMELUM, *Suppl.*

ABUTILON, the name of a genus of plants, according to Dillenius, but comprehended under the *ſida* of Linnæus. See the article SIDA, *Suppl.*

ACACIA *(Suppl.)*—*Baſtard* ACACIA, in botany, the name uſed by ſome for a genus of plants, called by others *robinia*. See ROBINIA, *Suppl.*

ACADEMICIAN, the ſame with *academic*, or *academiſt*. See ACADEMIC, *Cycl.* and ACADEMY, *Cycl.* and *Suppl.*

ACANTHIS, in ornithology, a name by which ſome call the gold-finch, from its feeding among thiſtles. See the articles CARDUELIS, *Suppl.* and GOLD-FINCH, *Append.*

ACAPTARE. See ACAPITARE, *Cycl.*

ACARUS *(Suppl.)* is alſo uſed by ſome naturaliſts as the claſſical name of the lice of animals, which are indeed of as many various genera as the animals on which they breed. See the article LOUSE, *Cycl.* and *Suppl.*

ACCENTED part of a bar, in muſic. See the articles ACCENT and MEASURE, *Cycl.*

ACCOMPTANT. See ACCOUNTANT, *Cycl.*

ACEPHALITÆ. See ACEPHALUS, *Cycl.*

ACH, or ACHE. See the article ACHE, *Cycl.*

ACHETA, in zoology. See the articles HARVEST-FLY and CIGALON, *Suppl.*

ACID *(Cycl.* and *Suppl.)* —Whether the air naturally contains any *acid*, is a queſtion among philoſophers. See the article AIR, *Append.*

ACIDULÆ *(Cycl.)* — See the article WATER, *Append.*

ACINACES, in antiquity, a Perſian weapon of the ſword kind. The word is Perſian, tho' etymologiſts affect to give it a Greek origin. Some repreſent the *acinaces*, as a kind of ſpear or javelin; others, with more probability, as a ſhort crooked ſword, ſhaped like the Turkiſh ſcymitar.

The figure was altered by Darius, and accommodated to that of the Grecian ſwords. Horace calls it *medus acinaces*, in regard the Romans confounded the Medes with the Perſians. It was alſo in uſe among the Scythians, where divine honours were paid it. *Boxhorn.* Epiſt. p. 220. ſeq. V. *Voſſ.* Etym. Lat. p. 5. *Martin* Lex. Philoſ. T. 1. p. 9. *Suid.* Lex. T. 1. p. 84. *Heſych. Aquin.* Lex. Milit. T. 1. p. 14. *Potter*, Arch. Græc. l. 3. c. 4. T. 2. p. 39. *Hor.* l. 1. Od. 17. *Herodot.* l. 4.

ACTINIA, in the hiſtory of inſects, a ſmall ſea-animal of a cylindric ſhape, equally thick in all parts, and about half an inch long; its tail is divided into three parts, or terminated, as it were, by three points. It lodges itſelf in little cavities of rocks and of the larger ſea-plants of the ſtony kind, and only appears on their ſurface when all is quiet about it. Round the mouth are placed a great number of tentacula, like ſo many conic rays, and diſpoſed in two or three ſeries ſucceſſively ſhorter than each other: theſe are in a continual vibratory motion, and by that means draw ſmall animals into its mouth for food. The whole animal is of a pale fleſh colour, except theſe tentacula, which have a beautiful variety of colours, red, yellow, blue, and many others. It is found on the coaſts of the American iſlands.

There are a variety of ſpecies, differing from each other in figure, colour, *&c.* but all of them furniſhed with numerous tentacula, or rays. *Hill*'s Hiſt. of Anim. p. 94. ſeq.

AIR

ADAM'S *apple*, *Adami pomum*, in botany, a name given by ſome to the orange. See the article ORANGE and ADAMI *pomum*, *Cycl.*

ADDER *(Suppl.)*—*Sea*-ADDER, the Engliſh name of a ſpecies of *ſyngnathus*, with a round body, and no pectoral or tail fins. See SYNGNATHUS, *Suppl.*

Water-ADDER, in zoology, a name given to the *natrix*. See the article NATRIX, *Suppl.*

ADDER's *wort*, in botany, a name ſometimes given to ſnakeweed, or biſtort. See BISTORT, *Suppl.*

ADDICO, in the civil law. See ADDICTIO, *Cycl.*

ADMINICULUM, in the French law. See ADMINICLE, *Cycl.*

ADMINISTRATRIX. See ADMINISTRATOR, *Cycl.*

AERIZUSA, a name given by the antients to the ſky-coloured *jaſper*. See the article JASPER, *Cycl. Suppl.* and *Append.*

ÆS *uxorium*, in antiquity, a ſum paid as a penalty for living batchelors to old age. This anſwered to the Athenian Αγαμιε δικη, and the Spartan οψιγαμιε, and κακογαμιε δικη. *Feſt.* and *Pitiſc.* Lex. Ant.

This tax for not marrying ſeems to have been firſt impoſed in the year of Rome 350, under the cenſorſhip of M. Furius Camillus, and M. Poſtumus. V. *Scalig.* and *Dacier*, not. in *Feſt.*

The method of levying it was this; at a cenſus or review of the people, each perſon was aſked, *Et tu ex animi ſententia uxorem habes liberûm quærendorum cauſâ?* He who had no wife, was hereupon fined after a certain rate, called *æs uxorium*. Hiſt. Acad. Inſcrip. T. 1. p. 79. ſeq.

AESPING, in zoology, the name of a ſpecies of *coluber*. See the article COLUBER, *Append.*

AFTER-*pains*, in midwifry. See the article LYING-*in-women*, *Suppl.*

AGAUPE, in botany, a name uſed by ſome authors for the *nymphæa*, or common white water lilly, and other ſpecies of that plant. *Marcgrave*, p. 21.

AGRIÆ, in zoology, the name of a claſs of quadrupeds, according to Dr. Hill, the characters of which are, that they have no teeth, and that their tongues are very long and cylindric. There are only two genera belonging to this claſs, which are the *myrmecophaga* and *manis*. See the articles MYRMECOPHAGA and LACERTUS *ſquamoſus*, *Suppl.*

AGRIMONY *(Suppl.)* — *Hemp*-AGRIMONY, in botany, the Engliſh name of the plant known among authors by that of *eupatorium*. See EUPATORIUM, *Suppl.*

Water-hemp-AGRIMONY, in botany, a name given to the bidens. See the article BIDENS.

AGUE *(Suppl.)*—AGUE-*cake*, the popular name for a hard tumour on the left ſide of the belly, lower than the falſe ribs, ſaid to be the effect of intermitting fevers. Vid. *Pringle*, Obſerv. on Diſeaſ. of Army, p. 179.

AIR *(Cycl.* and *Suppl.)*—It has been a queſtion among natural philoſophers, whether the *air* contains an acid or not. Monſieur Helot gives a probability to the affirmative; and it ſeems as if this acid were of a vitriolic nature. See Mem. Acad. Sciene. 1737. p. 378 and 1740. p. 141, 142. Edit. *Paris*.

If ſalt of tartar, or oil of vitriol, be expoſed to the open *air*, theſe, tho' extremely different ſubſtances, will each receive and imbibe ſo great a quantity of matter from the *air* as vaſtly to increaſe its weight, without any other alteration in its nature than the diluting or weakening it. The ſalt becomes a fluid liquor, called *oil of tartar per deliquium*, and increaſes to ſeveral times its quantity; and a vial of oil of vitriol, nearly filled and left unſtop'd, will ſoon be found to fill up of itſelf and run over.

In both theſe caſes, the aerial particles afforded to the expoſed ſubſtances, are only water; but the *air* evidently abounds alſo with a great variety of other principles, which it may and does occaſionally afford to other expoſed ſubſtances, whoſe pores are ſo formed as to admit them eaſily. Thus the mortar expoſed in the joinings of old walls, from the particles it attracts out of the *air*, forms a peculiar ſalt; and a deal ſhelf, moiſtened with the liquor of fixed nitre, has been known to become froſted over with perfect and pellucid cryſtals of pure nitre, only from the imbibing, or regaining the neceſſary acid from the *air*, in the ſame manner as if ſpirit of nitre had been poured upon it. A viol half filled with oil of tartar per deliquium, on being expoſed to the *air*, will often form a ſet of peculiarly figured cryſtals round the veſſel, a little above the ſurface of the water. Colcothar of vitriol, which is the caput mortuum, or reſiduum of vitriol, after all the acid has been driven from it by fire,

will, on being expoſed to the *air*, attract a new acid, and on being diſtilled again, it will yield more ſpirit or oil. Philoſ. Tranſ. N°. 157.

It is remarkable, that ſo ſtrong an acid as this ſhould float in the *air* unperceived, and exert itſelf only where proper admixtures and a proper nidus call it in. In both the caſes of nitre and vitriol diveſted of their acids, the *air* gives the proper acid again; yet in the caſe of the expoſed alkali ſalt, no acid, but only pure water is received; and in ſome acids, as the oil of vitriol, pure water, only, is received from the *air*. This is evidently proved by being careful in concentrating the liquor, firſt, to a certain degree of ſtrength; and then, after expoſing it a proper time, diſtilling away what was gained from the *air*. This will be found, by the ſmell and taſte, to be no other than pure ſimple water; and the liquor remaining in the retort, when all this is driven off, will be juſt as ſtrong as before, and juſt the ſame in quantity, and as ready to receive the ſame particles again.

The ſtronger the oil of vitriol is, the more powerfully it will attract the *air*'s humidity, and the more it will increaſe in weight. Such as is perfectly dephlegmated, will increaſe to more than three times its weight; three drams of it, in an experiment of Mr. Boyle's, increaſing to nine drams and thirty grains. The increaſe is much quicker at firſt, when it is ſtrongeſt, than afterwards when it is thoroughly diluted. Oil of vitriol, in the ſmall quantity here mentioned, will receive eighteen grains addition at firſt, in the ſame ſpace of time in which it will afterwards receive but two grains. The changes of moiſt and dry in the *air* alſo affect it. Philoſ. Tranſ. l. c.

It is remarkable, that ſulphureous *air* makes an efferveſcence with pure *air*. Thus if freſh *air* be let into a glaſs veſſel filled with ſulphureous vapours, ariſing from a mixture of ſpirit of nitre, with a vitriolic mineral, an efferveſcence will ariſe, and the freſh *air* will be nearly abſorbed, and the *air* in the veſſel, which was tranſparent and clear, will become a reddiſh turbid fume. After the efferveſcence is over, the turbid *air* again becomes clear, but upon the admiſſion of freſh *air* again becomes turbid, and the *air* is abſorbed as before. But after each re-admiſſion of freſh *air*, the quantity abſorbed is leſs and leſs, 'till no more is abſorbed. See *Hales*, Hæmaſtatics, p. 280. ſeq.

Dr. Hales thinks, that the efferveſcence ariſing from the mixture of freſh *air*, with that which is ſtrongly impregnated with ſulphureous fumes, may give riſe to that irkſome heat which we feel in ſummer, and is called a cloſe, ſultry, temperature of *air*. And hence the common obſervation, that lightning cools the *air* ſeems to be well founded, as being the laſt effort of this efferveſcence. *Hales*, ib. 284, 285.

ALANA *gleba*, a name ſometimes given to the yellowiſh white tripoli. See the article TRIPOLI, *Cycl.* and *Suppl.*

ALATED *leaf*, in botany. See LEAF.

ALAUDA, *(Suppl.)* in ichthyology, a name uſed by ſome authors for ſeveral ſpecies of the fiſh called *blennius*. See the article BLENNIUS, *Suppl.*

ALAUSA, in zoology. See the article THRISSA, *Suppl.*

ALBUGO *(Suppl.)* — Dr. Mead tells us of ſeveral cures of the *albugo*, performed by means of an eye powder which he recommends. The receipt is thus, Take of common glaſs any quantity, pound it in a mortar to a very fine powder; then add an equal quantity of white ſugar-candy, and levigate the mixture 'till it becomes impalpable.

A little of this powder put into the eye with a quill, every day, gradually wears off the ſpot.

Another method of removing the ſpeck, is to have it pared by a ſurgeon every day with a knife: But this ſeems a doubtful remedy. See Monit. et Pract. Medic. Append.

ALCA, in ornithology. See the article ALKA, *Suppl.*

ALCALI, ALCALINE. } See the articles { ALKALY, *Suppl.* ALKALINE, *Suppl.*

ALDER-*tree*, *alnus*, in botany. See the article ALNUS, *Suppl.*

Berry-bearing ALDER, the name of a genus of plants, called by authors *frangula*. See the article FRANGULA, *Suppl.*

ALDERAIMIN, or ADERAIMIN, in aſtronomy, a ſtar on the left ſhoulder of the conſtellation Cepheus.

ALECTRUONURUS *gramen*, in botany, a name uſed by ſome for the *feſtuca* of Linnæus. See FESTUCA, *Suppl.*

ALECOST, in botany, a name given by ſome to a ſpecies of tanzy, more uſually called *coſtmary*. See TANACETUM, *Suppl.*

ALEHOOF, in botany, a name by which ſome call *ground-ivy*. See the article GROUND-*ivy*, *Suppl.*

ALHAGI, in botany, the name of a genus of plants, according to Tournefort; but comprehended under the *hedyſarums* by Linnæus.

The characters are theſe: the flower is papilionaceous, the germen of which finally becomes a pod compoſed of a great number of parts, articulating, as it were, with each other, and containing each a kidney-ſhaped ſeed. To theſe marks it may be added, that the leaves grow in an alternate diſpoſition.

There is only one known ſpecies of this genus, called *geniſta ſpartium*, and *geniſta ſpinoſa*, by other writers. *Tourn.* Inſt. Bot. Corol. p. 54.

ALHEAL, a name given to ſeveral plants on account of their extraordinary virtues. See PANACEA, *Cycl.* and PANAX, *Append.*

ALISANDERS, in botany, a name given by ſome to the *ſmyrnium*. See the article SMYRNIUM, *Suppl.*

ALKANET, in botany. See the article ANCHUSA, *Suppl.*

ALLIARIA, in botany, the name ſometimes given to a ſpecies of *heſperis*, called in Engliſh *jack by the hedge*. See the article HESPERIS, *Suppl.*

ALLIGATOR, in zoology, the name given to the crocodile in the cold climates of America, where it does not grow to its full dimenſions. See CROCODILE, *Cycl.* and *Suppl.*

ALLIGATOR-*pear*, in botany. See the articles PEAR and PYRUS, *Suppl.*

ALMNOD *(Suppl.)*—*Dwarf* ALMOND, a name given by ſome to ſeveral ſpecies of peaches. See the article PERSICA, *Suppl.*

Ethiopian ALMOND, the name of a genus of plants, called by Linnæus *brabejum*. See BRABEJUM, *Suppl.*

ALVI *fluxus*, in medicine. See the article DIARRHOEA, *Cycl.* and *Suppl.*

ALVI *obſtructio*, coſtiveneſs, in medicine. See the article OBSTRUCTIO *alvi*, *Suppl.*

AMARACUS, in botany, a name ſometimes uſed for the *parthenium*. See the article PARTHENIUM, *Suppl.*

AMARYLLIS, in the Linnæan ſyſtem of botany, the name of a genus of plants, called in Engliſh *daffodil-lilly*, and by other botanical writers *lilio-narciſſus*. See the article LILIO-NARCISSUS, *Suppl.*

AMBER-*tree*, in botany, the Engliſh name of a genus of plants, called by Linnæus *anthoſpermum*. See ANTHOSPERMUM, *Append.*

AMBERBEI, the name of a genus of plants, according to Vaillant, but comprehended by Linnæus under that of *centauria*. See the article CENTAURIA, *Append.*

AMBULON, in botany, the name by which J. Bauhine calls the *myrica*, or ſweet-willow. See the article MYRICA, *Append.*

AMENTUM, among botaniſts, the ſame with *catkin*. See the article CATKIN, *Suppl.*

AMGAILA. See LEUCACANTHA, *Suppl.*

AMMODYTES, in zoology, the name of a ſpecies of *coluber*. See the article COLUBER, *Append.*

AMMONIACUM *ſal*, in chemiſtry, *&c.* See the article SAL *Ammoniacum*, *Cycl.* and *Suppl.*

AMMOSCHISTA, in natural hiſtory, a genus of ſtones of a laminated ſtructure, and ſplitting only horizontally, or into flat plates.

The *ammoſchiſta* are coarſe, harſh, and rough ſtones, of a very looſe texture, and appearing ſomething porous. They are conſiderably heavy, and compoſed of a large, coarſe, and obtuſely angular gritt, ſurrounded and in part held together by a looſe earthy ſpar. They are very ſoft and friable in the maſs, but much more ſo when reduced to ſmall pieces. They make a violent efferveſcence with aqua fortis, and will not eaſily ſtrike fire with ſteel.

The ſpecies of *ammoſchiſta*, are theſe: 1. The grey, friable, dull *ammoſchiſtum*. 2. The browniſh white, glittering *ammoſchiſtum*. 3. The greeniſh grey, ſhining *ammoſchiſtum*. 4. The yellowiſh grey, glittering *ammoſchiſtum*. 5. The hard, purple, and white *ammoſchiſtum*. And 6. The bluiſh, glittering ſlate ſtone. *Hill*'s Hiſt. of Foſſ. p. 443. ſeq.

AMOMUM, a name ſometimes given to a ſpecies of *ſium*. See the article SIUM, *Suppl.*

AMPHITRITE, in ichthyology, the name of a genus of ſmall water animals, the characters of which are, that they are of an oblong figure, and have a great number of deep ſtriæ, like ſo many lamellæ; and but one tentaculum, of a ſlender and oblong form, reſembling a piece of thread. They are only a few inches long, of a tolerable firm ſubſtance, and have been ranked by ſome authors among the *urticæ marinæ*, and by others among the *epipetrons*. Vid. *Hill*, Hiſt. Anim. p. 91.

ANARTHRA, in the hiſtory of inſects, a claſſical name eſtabliſhed by Dr. Hill, comprehending ſuch inſects as have neither wings nor limbs, and whoſe bodies are covered with a ſoft ſkin.

To this claſs belong the ſeveral genera of *worms* and *leeches*. See the articles WORM and LEECH, *Suppl.*

ANASARCOUS *ſwelling*. See DROPSY, *Append.*

ANEMOSPERMOS, in botany, the name ſometimes given to the *arctotis* of Linnæus. See the article ARCTOTIS, *Suppl.*

ANGLE *(Cycl.)*—In the practice of ſurveying, no *angles* of leſs than thirty degrees ſhould be taken: nor ſhould any be aſſumed but ſuch as are actually meaſured. See Hiſt. Acad. Scienc. 1740.

ANGUIS *Æſculapii*, the name of a ſpecies of *coluber*. See the article COLUBER, *Append.*

ANIMAL *(Suppl.)*—ANIMAL *ſubſtances* comprehend all the component parts of *animals*, of what uſe or intention ſoever they may be. See SUBSTANCE, *Cycl.*

Foſſile ANIMAL *ſubſtances*, thoſe found buried in the earth, at various depths, and embodied among various ſtrata.

Theſe are principally of four kinds: 1. Sea-ſhells. 2. The teeth, bony palate, and bones of fiſhes. 3. The bones of land *animals*. And 4. Complete fiſhes. See the articles

Foſſile

Foſſile BONES, *Foſſile* SHELLS, MARINE *remains*, and *Foſſile* IVORY, *Suppl.*

Fermentative quality of ANIMAL *ſubſtances.* See FERMENT and FERMENTATION, *Append.*

ANIMALCULES *(Suppl.)*—Dr. Hill, in his hiſtory of animals, has arranged *animalcules* under three claſſes: 1. Such as have no tails, nor any viſible limbs. 2. Thoſe which have tails, but no viſible limbs. And 3. Thoſe which have viſible limbs. See the article ANIMALCULE, *Cycl.* and *Suppl.*

The firſt claſs, which he calls *gymnia*, contains ſeveral genera: 1. The *enchelides*, of a cylindric or ſubcylindric figure. 2. The *cyclidia*, of a roundiſh or elliptic figure. 3. The *paramecia*, of an irregular oblong figure. 4. The *craſſpedaria*, with an apparent mouth and a ſeries of fimbriæ round it, in manner of a fringe.

The ſecond claſs, or thoſe with tails but no viſible limbs, he calls *cercaria*; of which there are only two genuſes: 1. The *cercaria*, with tails ſhorter than their bodies, and therefore called *bracburi*. 2. The *cercaria*, with tails longer than their bodies, and hence called *macrocerci*.

The third and laſt claſs contains ſuch *animalcules* as have viſible limbs, and thence denominated *arthrodia*. There are only two genera belonging to this claſs: 1. The *ſcelaſius*, an *animalcule* with viſible legs. 2. The *brachionus*, or wheel-animal, an *animalcule* furniſhed with an apparatus of arms for taking its prey. *Hill*, Hiſt. Anim. p. 1. ſeq.

ANIMI *deliquium*, fainting or ſwooning, in medicine. See the articles LIPOTHYMIA and SWOONING, *Suppl.*

ANNULATA, in zoology, the name of a ſpecies of *coluber*. See the article COLUBER, *Append.*

ANT-*bear*, in zoology, the Engliſh name of the *myrmecophaga* of Linnæus. See the article MYRMECOPHAGA, *Suppl.*

ANTHERICUM, in the Linnæan ſyſtem of botany, the name of a genus of plants, called by Tournefort *phalangium*, and in Engliſh *ſpider-wort*. See the article PHALANGIUM, *Suppl.*

ANTHORA, in botany. See ACONITE, *Cycl.*

ANTHOSPERMUM, in botany, the name of a genus of plants, the characters of which are theſe: the cup is a one-leaved perianthium, divided into four ſegments reaching more than half way down; there is no corolla; the ſtamina are four capillary filaments, of the length of the cup; the antheræ are two in number, oblong and quadrangular; and the germen of the piſtil ſtands below the receptacle of the flower.

The male and female flowers are ſometimes ſituate on the ſame plant, but more frequently on different plants of the ſame ſpecies; in which laſt caſe, the female flowers have the piſtil and germen, but want the ſtamina. Vid. *Linnæi*, Gen. Plant. p. 496.

ANTIMONY *(Suppl.)*—The needles perceived in *antimony*, are, according to Monſieur Geoffroi, owing to the vitriolic acid united to a bitumen. See Mem. Acad. Scienc. An. 1734. p. 418.

Eſſence of ANTIMONY, an emetic wine made with glaſs of *antimony*; to which is ſometimes added a ſpicy ſtomachic.

Dr. Huxham ſays, he never found any antimonial preparation better, ſafer, and more efficacious than this ſimple infuſion of the glaſs of *antimony* in a generous white wine, with a little ſpice to render it more grateful to the ſtomach. This medicine given to twenty or thirty drops operates by gentle ſweats, and purges in larger doſes very mildly. The judicious phyſician here mentioned, recommends it in obſtinate rheumatiſms.

ANTIQUARY *(Suppl.)*—Since the printing this article, the ſociety of *antiquaries* have been incorporated, by the king's charter.

ANTISEPTIC, an appellation given to ſuch ſubſtances as reſiſt putrefaction. See PUTREFACTION, *Append.*

We have ſome curious experiments in relation to *antiſeptic* ſubſtances by Dr. Pringle, who has aſcertained their ſeveral virtues. Thus, in order to ſettle the *antiſeptic* virtue of ſalts, he compared it with that of common ſea-ſalt; which being one of the weakeſt, he ſuppoſes equal to unity, and expreſſes the proportional ſtrength of the reſt by higher numbers, as in the following table.

Salts, their antiſeptic virtue.		Salts, their antiſeptic virtue.	
Sea-ſalt —	1	Saline mixture	3
Sal gemmæ	1+	Nitre —	4+
Tartar vitriolated	2	Salt of hartſhorn	4+
Spiritus mindereri	2	Salt of wormwood	4+
Tartarus ſolubilis	2	Borax —	12+
Sal diureticus	2+	Salt of amber	20+
Crude ſal ammoniac	3	Alum —	30+

In this table the proportions are marked in integral numbers; only to ſome there is added the ſign +, to ſhew, that thoſe ſalts are poſſeſſed of a ſtronger *antiſeptic* virtue than the number in the table expreſſes, by ſome fraction; unleſs in the three laſt, where the ſame ſign imports, that the ſalt may be ſtronger by ſome units. Vid. *Pringle*'s Obſerv. on the Diſeaſes of the Army, Append. p. 322. ſeq.

Some reſinous and other ſubſtances even exceed the *antiſeptic* virtues of the neutral ſalts; thus myrrh, aſa fœtida, terra japonica and aloes, are at leaſt twelve times more *antiſeptic* than ſea-ſalt. Two grains of camphor is equivalent to ſixty grains of that ſalt. An infuſion of a few grains of Virginian ſnake-root, in powder, exceeds twelve times its weight of ſea-ſalt. Chamæmile flowers have nearly the ſame extraordinary quality. The jeſuits bark has it alſo. Beſides theſe, pepper, ginger, ſaffron, contrayerva-root, are twelve times more *antiſeptic* than ſea-ſalt. Dried ſage, rhubarb, the root of the wild valerian, mint, angelica, ground-ivy, ſena, green-tea, red-roſes, wormwood, muſtard and horſe-raddiſh, were likewiſe found more antiſeptic than the ſtandard.

To the claſe of *antiſeptic* medicines may likewiſe be added fermented liquors, acids, ſpirits, and even thoſe plants called anti-acids, and erroneouſly ſuppoſed haſteners of putrefaction, particularly horſe-raddiſh. Now vegetables, poſſeſſing this virtue, are the more valuable, in that, being uſually free of acrimony, they may be taken in much greater quantities, than either ſpirits, acids, reſins, or even the neutral ſalts.

Antiſeptics are preſcribed in all putrid, malignant, and peſtilential caſes. It is to be remarked, however, that different kinds of them are to be given in different diſeaſes, and even in different ſtages of the ſame diſeaſe. Thus, the bark is a ſpecific in a gangrene, when the veſſels are relaxed and the blood reſolved or diſpoſed to putrefaction; but will fail, if the veſſels are too full, or the blood be too thick. With the ſame caution is the bark to be uſed in wounds, *viz.* chiefly in caſes of abſorbed matter, when it infects the humours, and brings on a hectic fever.

By the great *antiſeptic* virtue of alum, the bark, and other aſtringents, it ſhould ſeem, that aſtriction had no ſmall ſhare in the cure of putrid diſorders; and, indeed, the very nature of putrefaction conſiſts in a ſeparation or diſunion of the parts. But as aſtringents are improper to be adminiſtered in many caſes, contrayerva-root, ſnake-root, camphor, *&c.* may ſupply their place; which, tho' highly *antiſeptic*, have very little, or any, of an aſtringent quality. Id. ibid. Append. paſſim.

APAGOGE, in logic. See ABDUCTION, *Cycl.*

APE, *ſimia*, in zoology. See the article SIMIA, *Suppl.*

APES. See APIS *infra.*

APHIS, in the hiſtory of inſects, the name of a genus of animals, otherwiſe called *pediculus arboreus*, and in Engliſh the *tree-louſe*.

The trunk of the *aphis* is reflex; the body is formed into two horns behind; the wings are four, and erect, or altogether wanting; and the legs are formed for walking not leaping.

Of this genus there are a great many ſpecies, denominated from the trees or buſhes on which they are found. Vid. *Hill*'s Hiſt. of Anim. p. 65.

APHRODITA, in the hiſtory of inſects, a genus of ſea-inſects about two inches in length and one in breadth, of an oval figure, and aculeated; it has alſo a perforation in the middle of the back, and is called in Engliſh the *ſea-mouſe*.

It is one of the gymnarthrodia, or inſects with naked bodies, and may be met with in great abundance on the Kentiſh coaſt, among rocks. There are ſeveral ſpecies of it. Vid. *Hill*'s Hiſt. of Anim. p. 90.

Columna calls it *Pudendum regale*; Bartholine, *vermis aureus*; others, *eruca marina griſeo-fuſca*; and ſome, *mus marinus*, or the *ſea-mouſe*.

APIS, or APES, in zoology, a large genus of four-winged inſects, the diſtinguiſhing characteriſtic of which is, that their wings are entirely membranaceous, and their tails furniſhed with a weapon, or ſting, capable of inflicting a wound.

This genus comprehends the bee, hornet, waſp, and humble-bee. See the articles BEE, HORNET, WASP, *Suppl.* For the hiſtory of the bee, in particular, ſee alſo the articles BEE-*worm*, WAX, HONEY, *&c. Suppl.*

APOSTACY, *(Cycl.)*—*Apoſtacy* is ſaid to have been antiently puniſhable, in England, by burning and tearing to pieces by horſes. Thus Fleta l. 1. c. 37. §. 2. *Apoſtatæ & ſacrilegi, & hujuſmodi, detractari debent et comburi.* And §. 4. *Si inde convincantur, detractentur, et ſuſpendantur.* Where Du Cange interprets, *detractari*, by *tirer a quatre chevaux.*

APPLE *(Suppl.)*—*Cuſtard*-APPLE, in botany, a name given by ſome to the *anona*. See the article ANONA, *Suppl.*

Sea-APPLE, in zoology, the Engliſh name of a ſpecies of *centronia*, or *ſea-hedge-hog*. See the article CENTRONIA, *Append.*

Sour APPLE, in botany, a name given by ſome authors to ſeveral ſpecies of *anona*, called by Plumier *guanabanus*. See the article ANONA, *Suppl.*

Star-APPLE, the Engliſh name of a genus of plants, called by Plumier *cainito*, and deſcribed by Linnæus under that of *chryſophyllum*. See CHRYSOPHYLLUM, *Append.*

Thorn APPLE, the Engliſh name of a genus of plants, called by authors *ſtramonium*. See the article STRAMONIUM, *Suppl.*

APTERIA, in the hiſtory of inſects, a claſſical name comprehending all thoſe inſects which have no wings. See the article INSECT, *Append.*

This ſeries is divided into two claſſes: 1. Such as have neither wings nor limbs, called *apteria anarthra*. And 2. Such as have limbs, but no wings, called *apteria podaria*. See the articles ANARTHRA and PODARIA, *Append.*

ARACHIDNA, in botany, the name uſed by ſome authors for

for a genus of plants, described by Linnæus under that of *arachis*. See the article ARACHIS, *Append.*

ARACHIDNOIDES, in botany, the name used by some for a genus of plants called by Linnæus *arachis*. See the article ARACHIS, *Append.*

ARACHIS, in the Linnæan system of botany, the name of a genus of plants, the characters of which are these: the cup is a perianthium, divided into two parts; the flower consists of three papilionaceous petals; the stamina are two subulated filaments, adhering at the base, and divided at the top; the antheræ are roundish; the germen of the pistil is oblong; the style subulated, and of the length of the germen; and the stigma simple: the fruit is a pod of an oblong oval form, narrowest in the middle, with only one cell, containing two oblong gibbous seeds.

This genus comprehends the *arachidna* and *arachidnoides* of other authors. Vid. *Linnæi* Gen. Plant. p. 361.

ARALIASTRUM, in botany, the name of a distinct genus of plants, otherwise called *panax*. See the article PANAX, *Append.*

ARBOR *vine*, a name used for some species of *convolvulus*, or *bindweed*. See the article CONVOLVULUS, *Suppl.*

ARCHANGEL, in botany, a name given to the white *lamium*, or *dead-nettle*. See the article LAMIUM, *Suppl.*

ARCTOTHECA, in botany, the name used by Vaillant for the *arctotis* of Linnæus. See the next article.

ARCTOTIS, in the Linnæan system of botany, the name of a genus of plants, the characters of which are these: the common cup is roundish and imbricated with squamæ; the composite flower is radiated; the proper hermaphrodite ones infundibuliform, with the limb divided into five segments; and the proper female ones ligulated and of a lanceolated shape; the tube is extremely short; the stamina are five very short capillary filaments; the antheræ are cylindric, of the length of the flower, and divided into five parts; the germen of the female flowers is ovato-quadragonal, villose, and coronated with very small squamæ; the style is filiform; and the stigmata, which are two in number, oval, thick, and erect. There is no pericarpium, the cup serving instead of one. The seeds are single, villose, coronated with the leaves of their proper perianthium, and placed in a circle. The receptacle is plane, and somewhat hairy. *Linnæi* Gen. Plant. p. 420.

ARENÆ, *sands*, in natural history. See the article SAND, *Cycl.* and *Suppl.*

ARGENTUM, *silver*, in natural history. See the article SILVER, *Cycl.* and *Suppl.*

ARISARUM *(Suppl.)* is also the name used by some for a species of *arum*, or *wake-robin*. See the article ARUM, *Suppl.*

ARMENIAN *bole*. See the article BOLE *armenic*, *Suppl.*

ARO-ORCHIS, in botany, a name by which some call a genus of plants, described by Linnæus under that of *kæmpferia*. See the article KÆMPFERIA, *Append.*

ARMY. For diseases incident to *armies*, see the articles DISEASE, CAMP, GARRISON, HOSPITAL, SOLDIER, *&c. Append.*

ARROW-*root*, in botany, the name of a genus of plants, called by authors *maranta*. See the article MARANTA, *Append.*

ARSON, in the law of England, a felony at common law, in maliciously and voluntarily burning the house of another by night or by day. See *Hawkins*'s, Pleas of the Crown, B. 1. chap. 39.

As to the punishment of *arson*, it seems now clearly settled, that the principal, not being in holy orders, is excluded from the benefit of clergy. See *Hawk.* lib. cit. B. 2. chap. 33. sect. 107.

In some places this crime is punished by burning the offender. And this was the old Roman law. See *Pitisc.* Lex. Antiq. in voc. *Incendiarius* and INCENDIARY, *Append.*

ARTHRODIA, in zoology, the name of a lately established class of animalcules, containing those with visible limbs. See the article ANIMALCULES, *Append.*

ASARABACCA, in botany, the name of a genus of plants, called by authors *asarum*. See the article ASARUM, *Suppl.*

ASCITES. See the articles DROPSY, *Cycl. Suppl.* and *Append.*

ASCYRUM, in the Linnæan system of botany, the name of a genus of plants, the characters of which are these: the cup is a four-leaved perianthium; the two exterior ones very small, placed opposite to each other, and linear; the two interior ones large, plane, erect, and cordated; all of them being permanent. The flower consists of four oval petals; the two exterior ones being opposite to each other, and very large; the interior ones smaller. The stamina are numerous capillary filaments, connected at their bases into four distinct parts; the antheræ are roundish; the germen of the pistil is oblong; there is no style: the stigma is simple; the fruit is an oblong acuminated capsule, formed of two valves, and included in the larger leaves of the cup; the seeds are numerous, small, and roundish.

It is extremely like the *hypericum* in appearance; but these characters sufficiently distinguish them. Vid. *Linnæi* Gen. Plant. p. 369.

ASH, in botany, the English name of a genus of trees, called by authors *fraxinus*. See FRAXINUS, *Suppl.*

Mountain-ASH, a name given by some to the *sorbus*, or *service-tree*. See the article SORBUS, *Suppl.*

Poison-ASH, a name given to the *toxicodendron* of botanists. See the article TOXICODENDRON, *Suppl.*

ASILUS, in zoology, the name of a genus of insects, called in English the *hornet-fly*, or *wasp-fly*. See the articles HORNET-*fly* and WASP-*fly*, *Suppl.*

The distinguishing characters of this genus, are these: they are of the two-winged kind, with a style or oblong body, terminated by a protuberance or head, and called a ballancer, under each wing: to this add, that the head is furnished, by way of mouth, with a snout of a subulated figure, which is simple and very sharp at the extremity. They are among the largest of the fly-kind. See the article FLY, *Suppl.*

Authors have called these insects by the names of *Muscæ crabroniformes*, *muscæ rapaces*, and *muscæ vespiformes*. *Hill*'s Hist. of Anim. p. 31.

ASINUS, the *ass*, in zoology, an animal of the horse-kind. See the article EQUUS, *Suppl.*

Though the *ass* agrees with the horse in many respects, it nevertheless has but a mean resemblance to that noble animal; being not only smaller, but wanting the symmetry and beauty, so conspicuous in the horse.

The *ass*'s ears seem much over-proportioned in length to the head. Its eyes are large, but have nothing bright or striking in them; the neck is long, but lank; and the tail is very long, but not hairy all the way, as in the horse. The fur of the *ass* is coarse and dun, only a streak of black runs down its back and across the shoulders.

So nearly allied are the horse and *ass* kind, that they will copulate together, the produce of which commixture is a mule. See the article MULE, *Suppl.*

There is a species of wild *ass*, called *zebra*, differing greatly in the colours and disposition of its streaks from the common *ass*. See ZEBRA, *Append.*

ASPEN-*tree*, in botany, the English name of the poplar with trembling leaves. See the article POPLAR, *Suppl.*

ASPHODEL, *asphodelus*, in botany. See the article ASPHODELUS, *Suppl.*

African ASPHODEL, a name used by some for the *phalangium*, or *spider-wort* of Tournefort. See PHALANGIUM, *Suppl.*

Lilly-ASPHODEL, the English name of a genus of plants. See the article LILIO-ASPHODELUS, *Suppl.*

ASS, *asinus*, in zoology. See the article ASINUS *supra.*

Wild ASS, *onager* and *zebra*. See the articles ONAGER, *Suppl.* and ZEBRA, *Append.*

ASTERIAS, in zoology, a name used by some naturalists for the star-fish, otherwise called *aster* and *stella marina*. See the article STELLA *marina*, *Suppl.*

ASTHMA *(Cycl.* and *Suppl.)*—Dr. Mead has lately given us his observations on this Distemper. Monit. & Pract. Medic. Cap. 8.

Whatever occasions the ambient air to enter the lungs with less freedom than usual, brings on this disease. Hence it may arise, 1st. From whatever is an impediment to the action of the diaphragm, the intercostal and abdominal muscles. 2dly, From whatever obstructs the free passage of the air into the aspera arteria, or its ramifications, whether the obstruction arises from a tumor, or from viscid humors. 3dly, The air itself may be a cause, if it be much heavier, or lighter than usual. 4thly, The tenderness of the lungs may sometimes occasion this distemper, as appears from those who are subject to a difficulty of breathing upon removing from the thick air of the town into the clear air of the country. 5thly, The difficult passage of the air thro' the lungs may be reckoned among the causes of difficult respiration. And this may happen either from the weakness of the heart, or the too great thickness of the blood.

The method of cure, in this distemper, must vary with its causes. Blood letting is, generally speaking, useful in every species of it. Vomits are useful, if the stomach or lungs be loaded with tough phlegm. The body must be kept open with gentle cathartics. Flatulent food and drink should be avoided; exercise used 'till weariness; and friction 'till a sweat is ready to break out.

Oxymel of squills and simple cinnamon water, or garlick, are good in case of viscid and tough humors. But if the fault lie in the nervous juice, the strong smelling gums are proper, especially the milk of gum ammoniac. Anodynes are very hurtful in the first case, but serviceable in this, if joined with volatile salts or spirits. The paregoric elixir is one of the best of this tribe.

As every kind of this disease is attended with more or less effervescence in the blood, the bark will be found useful; and the doctor assures us, that he has known instances where it has done vast services mixed with the cinnabar of antimony.

ASYLUM, in the history of insects, a name sometimes used for the gad-fly, called by zoologists *œstrum*. See the article OESTRUM, *Suppl.*

ATRACTYLIS, in the Linnæan system of botany, the name of a genus of plants, the characters of which are these: the cup is ovated, imbricated, and beset with numerous lanceolated squamæ; the flower is compound and radiated;

the ſtamina are five extremely ſhort and capillary filaments; the antheræ are cylindraceo-tubuloſe; the germen of the piſtil is very ſhort and coronated; the ſtyle is filiform, and of the length of the ſtamina; the ſtigma is bifid; and the ſeeds are of a compreſſed turbinated ſhape, and covered with a plumoſe down. Vid. *Linnæi* Gen. Plant. p. 384.

ATRACTYLIS is alſo the name uſed by Vaillant for the *carthamus*, or *baſtard-ſaffron*. See the article CARTHAMUS, *Suppl.*

AVENS, in botany, the Engliſh name of a genus of plants, called by authors *caryophyllata*. See CARYOPHYLLATA, *Suppl.*

AVOCADO, or AVOCADO-*pear*, in botany, a name given by ſome to the *perſea* of Plumier. See PERSEA, *Append.*

AVOSETTA, the Italian or modern name of a genus of birds, called in Latin *recurviroſtra*. See the article RECURVIROSTRA, *Suppl.*

AURELIA, in natural hiſtory, a ſynonymous term with *chryſalis*. See the article CHRYSALIS, *Append.*

AURELIANA, in botany, a name uſed by ſome writers for the PANAX, or *allheal*. See the article PANAX, *Append.*

AURICULA, a name ſometimes uſed for the *forficula*, or *earwig*. See the article FORFICULA, *Append.*

AURICULARIA, a name uſed by ſome for the ear-wig, a very troubleſome inſect. See the article EAR-*wig*, *Append.*

AURUM, *gold*, in natural hiſtory. See the article GOLD, *Suppl.*

AWK, or AUK. See the article AUK, *Suppl.*

AX-*vetch*, in botany, the Engliſh name of a genus of plants, called by authors *ſecuridaca*. See SECURIDACA, *Suppl.*

AXUNGIA *ſolis*, in natural hiſtory, a name uſed by ſome writers for the ſubſtance more uſually called *fileſiaca terra*. See the article *fileſiaca* TERRA, *Suppl.*

B.

BAT

BABOON, in zoology, the Engliſh name of ſuch monkeys as are uſually called by naturaliſts *papiones*. See the article PAPIO, *Suppl.*

BALANCE-*fiſh*, in zoology. See BALLANCE-*fiſh*, *Suppl.*

BALAUSTINE, a name given to the great double-flowered pomegranate. See the article PUNICA, *Suppl.*

BALISTES, in ichthyology. See the article BALLISTES, *Suppl.*

BALM, in botany, the ſame with *baum*. See BAUM.

BALSAM *of capevi*, or *capivi*, in pharmacy and natural hiſtory. See the article BALSAM *of copaiba*, *Suppl.*

Male-BALSAM, or BALSAM-*apple*, the name of a genus of plants, known among authors by that of *momordica*. See the article MOMORDICA, *Suppl.*

BALSAM-*tree*, in botany, a name uſed by ſome writers for the *terebinthus*, or turpentine-tree. See TEREBINTHUS, *Suppl.*

BALSAMINA *ſcandens*, a name by which ſome call the large fruited white bryony of Ceylon. See the article BRYONIA *alba*, *Suppl.*

BALSAMINE, in botany, the name of a genus of plants, called by authors *balſamina*. See the article BALSAMINA, *Suppl.*

BALSAMITA, in botany, the name by which ſome call coſtmary, a ſpecies of tanzy. See TANACETUM, *Suppl.*

BANE-*berry*, in botany, the Engliſh name uſed by ſome for the herb *chriſtopher*. See the article CHRISTOPHORIANA, *Suppl.*

BAR *(Suppl.)* —To BAR or STRIKE *a vein*, among farriers, an operation performed on the veins of a horſe's legs, or other parts of his body, in order to ſtop the courſe, and leſſen the quantity of malignant humors prevailing there.

It is thus performed: the farrier opens the ſkin, after diſengaging the vein, ties it above and below, and then ſtrikes between the two ligatures. Sportſm. Dict. in voc.

BARRACKS, in military affairs, buildings to lodge ſoldiers in fortified towns, or others. Thus we ſay the *barracks* of the Savoy, of Dublin, *&c.*

Barracks, when damp, are greatly prejudicial to the health of the ſoldiers lodged in them; occaſioning dyſenteries, intermitting fevers, coughs, rheumatic pains, *&c.* For which reaſon quarter-maſters ought to be careful in examining every *barrack*, offered by the magiſtrates of a place; rejecting all ground floors in houſes that have either been uninhabited, or have any ſigns of moiſture. Vid. *Pringle*, Obſerv. on the Diſeaſes of the Army, p. 13, 37, 81 and 97.

BARREN-*wort*, in botany, the Engliſh name of a genus of plants, known among authors by that of *epimedium*. See EPIMEDIUM, *Suppl.*

BARBADOES-*cherry*, in botany, the Engliſh name of a genus of plants, called by authors *malpighia*. See MALPIGHIA, *Suppl.*

BARBADOES-*tar*, a name ſometimes uſed for the thick black kind of *piſſaſphaltum*. See the article PISSASPHALTUM, *Suppl.*

BASELLA, in botany, the name uſed by ſome botaniſts for the *cuſcuta*, or dodder. See the article CUSCUTA, *Suppl.*

BATATAS, the name by which the plant producing our potatoes is ſometimes called. See the article POTATOES, *Suppl.* and *Append.*

BATCHELOR's *button*, in botany, the Engliſh name of a genus of plants, called by authors *lychnis*. See LYCHNIS, *Suppl.*

BEE

BATCHELOR's *pear*, a name uſed by ſome for ſeveral ſpecies of *ſolanum*, or night-ſhade. See SOLANUM, *Suppl.*

BATTERING-*ram*, in the military art of the antients. See ARIES, *Cycl.*

BAUM *(Suppl.)*—*Turky*-BAUM, a name given by ſome to the *dracocephalon*. See the article DRACOCEPHALON, *Suppl.*

Shrubby-BAUM, a name uſed by ſome for a genus of plants, called by authors *molucca*. See MOLUCCA, *Suppl.*

BAY *(Suppl.)* —*Alexandria*-BAY, in botany, a name given to the *ruſcus*, or butcher's broom. See RUSCUS, *Suppl.*

Cherry-BAY, or *cherry*-LAUREL, in botany, the Engliſh names of a genus of plants, called by Linnæus *padus*. See PADUS, *Append.*

Dwarf-BAY, a name ſometimes given to the *thymelæa* of authors. See the article THYMELÆA, *Suppl.*

Indian BAY, a name given by ſome to a ſpecies of myrtle. See the article MYRTUS, *Suppl.*

Roſe-BAY, a name uſed by ſome writers for the *chamærododendros*. See CHAMÆRODODENDROS, *Suppl.*

Sweet flowering BAY, the Engliſh name of a genus of plants, deſcribed by Linnæus under that of *magnolia*. See MAGNOLIA, *Suppl.*

BEAD *(Suppl.)*—BEAD-*tree*, in botany, the Engliſh name of a genus of trees, called by authors *azedarach*. See AZEDARACH, *Suppl.*

BEAM-*tree*, in botany, a name given to the *cratægus*. See the article CRATÆGUS, *Suppl.*

Hard-BEAM, or *horn*-BEAM, in botany. See the article CARPINUS, *Suppl.*

BEAN *(Suppl.)*—*Bog*-BEAN, *bug*-BEAN, or *buck*-BEAN, names given to the *menyanthes*. See the article MENYANTHES, *Suppl.*

Caper-BEAN, in botany, the Engliſh name of a genus of plants, called by authors *fabago*. See the article FABAGO, *Suppl.*

Trefoil-BEAN, in botany, the Engliſh name of a genus of plants, called by authors *cytiſus*. See CYTISUS, *Suppl.*

BEAN-*tree*, a name given to a genus of plants, called by authors *corallodendron*. See the article CORALLODENDRON, *Suppl.*

Kidney-BEAN-*tree*, a name uſed by ſome for the *glycine* of Linnæus. See the article GLYCINE, *Suppl.*

BEAR *(Suppl.)* —*Ant*-BEAR. See the article TAMANDUA, *Suppl.*

BEAR's *ear*, in botany, the name of a genus of plants, known among authors by that of *auricula*. See AURICULA, *Suppl.*

BEAR's *ear ſanicle*, in botany, a name given by ſome to the *cortuſa* of Linnæus. See the the article CORTUSA, *Suppl.*

BEAR's *foot*, in botany, a name given to ſeveral ſpecies of *hellebore*. See the article HELLEBORUS, *Suppl.* and HELLEBORE, *Cycl.*

BEARD *(Suppl.)*—*Old man's* BEARD, in botany, a name given by ſome to the *clematis* of authors. See CLEMATIS, *Append.*

BECCA-BUNGA, in botany, a name given to the *anagallis aquatica*, called in Engliſh *brook-lime*. See the article ANAGALLIS, *Suppl.*

BEDSTRAW, or *ladies* BEDSTRAW, in botany, the Engliſh name of a genus of plants, called by authors *gallium*. See GALLIUM, *Suppl.*

BEE-*flower*, in botany, the Engliſh name of a genus of plants, called by authors *orchis*. See ORCHIS, *Suppl.*

BEE-*fly (Suppl.)*—*Humble*-BEE-*fly*, a ſpecies of *culex*. See the articles HUMBLE, *Suppl.* and CULEX, *Append.*

BEER-*poſſet*. See ZYTHOGALA, *Suppl.*

BEETLE *(Suppl.)*—*Oil*-BEETLE, the Engliſh name of the *meloe* of zoologiſts. See the article MELOE, *Append.*

Water-BEETLE, the Engliſh name of a genus of *beetles*, called by Dr. Hill *dytiſcus*. See the article DYTISCUS, *Append.*

BELI *oculus*, in natural hiſtory. See OCULUS *beli*, *Suppl.*

BELL-*flower*, in botany, the Engliſh name of a genus of plants, called by authors *campanula*. See the article CAMPANULA, *Supp.l.*

BELL-*pepper*, in botany, a name uſed by ſome for the *capſicum*. See the article CAPSICUM, *Supp.l.*

BELLS, or *Canterbury* BELLS, in botany, a name given to the *campanula*. See CAMPANULA, *Suppl.*

Hair-BELLS, in botany, a name given to the *hyacinth*. See the article HYACINTH, *Suppl.*

BELLY-*ach-weed*, in botany, a name given to the *ricinoides*. See the article RICINOIDES, *Suppl.*

BELMUSK, or ABELMOSCH, in botany, names uſed for the *ketmia*. See the article KETMIA, *Suppl.*

BENJAMIN-*tree*, in botany, the name of a ſpecies of *laurus*, according to Linnæus, with deciduous leaves, without ribs, of an obverſely oval figure. See the article LAURUS, *Append.*

It is a native of the Eaſt and Weſt Indies, and is called by many late writers *arbor limonii folio*, *benzoinum fundens*, by reaſon benzoin is procured from it. See BENZOIN, *Suppl.*

BENNET-*herb*, *herba benedicta*, a name uſed by ſome for the *caryophyllata*, or avens. See CARYOPHYLLATA, *Suppl.*

BERBERRY, or BARBERRY-*buſh*, in botany. See the article BERBERIS, *Suppl.*

BERNARD *the hermit*, the Engliſh name of a ſpecies of *ſquill*. See the article SQUILLA, *Append.*

BETHLEHEM-*ſtar*, in botany, a name given to the *ornithogalum*. See the article ORNITHOGALUM, *Suppl.*

BETONY *(Suppl.)*—*Water*-BETONY, a name given to the *ſcrophularia*, or fig-wort. See the article SCROPHULARIA, *Suppl.*

BEZOAR-*goat*, a name uſed for the Indian antelope, or *gazella*, on account of the *bezoar-ſtone* found in its ſtomach. See GAZELLA, *Suppl.*

BIFOL, in botany, a name given by ſome to the *ophris*, or twyblade. See the article OPHRIS, *Suppl.*

BILBERRY, in botany, an Engliſh name given to the *vaccinium*, or *vitis idæa* of authors, called alſo the *whortle-berry*. See VITIS *idæa*, *Suppl.*

BILE *(Cycl.)*—The influence of *bile* upon the animal œconomy is allowed to be very great. By its fermentative quality, it promotes digeſtion; in which reſpect, it differs widely from vegetable bitters, which are retarders of fermentation. Vid. *Pringle*, Obſerv. on the Diſeaſes of the Army, p. 377.

However, in one thing, it agrees with them, *viz.* as a corrector of acidities. Id. ibid. p. 378.

Bile ſpeedily corrupts, but not to ſuch an high or offenſive degree as the blood or fibrous parts of the body. To this corruption of the *bile*, as one cauſe, Dr. Pringle attributes the paroxyſms in bilious fevers: nay, all bilious diſorders, as the cholera morbus, dyſentery, *&c.* are thought to be chiefly owing to a redundance or corruption of the *bile*. Hence, the reaſon why theſe diſorders are moſt frequent in hot countries, and in armies when much expoſed to the ſun, is, that the *bile*, if not more abundant, is in ſuch circumſtances more corrupted than uſual. Id. ibid. p. 184. 74.

BILIOUS *fever (Suppl.)*—Dr. Pringle, in his Obſervations on the Diſeaſes of the Army, remarks, that the *bilious* or putrid fever is epidemic in camps, eſpecially in low and marſhy countries, where the air being full of moiſt and putrid effluvia, tends to relax the fibres and promote putrefaction. As to the ſymptoms of the *bilious* fever, it always begins with chillneſs and laſſitude, pains of the head and bones, and a diſorder at the ſtomach. At night the fever runs high; the heat and thirſt are great; the tongue is parched; the head aches violently; the perſon gets no reſt, and often becomes delirious; but generally in the morning an imperfect ſweat brings on a remiſſion of all the ſymptoms. In the evening the paroxyſm returns, but without any cold fit, and is commonly worſe than the former: on the ſecond morning it remits as before. Theſe periods go on, daily, 'till the fever changes inſenſibly, either into a confirmed or into an intermitting ſhape. Sometimes looſe ſtools carry off the fit, and ſupply the place of ſweats: however, tho' it reſembles an ague in many particulars, yet it is rare to meet with a real ague in the camp, unleſs the perſon has been ill of it before he took the field. The remiſſions uſually appear from the beginning, eſpecially if the patient has been plentifully blooded: but ſometimes there are no remiſſions for the laſt two or three days. Hæmorrhages of the noſe happen frequently in the height of the paroxyſm, and always bring on the remiſſion ſooner and make it fuller. Vomiting or purging have the like effects. The fits are ſeldom preceded by ſhiverings, or any ſenſe of cold after the firſt attack; the pulſe is always full and quick during the paroxyſms, and in the remiſſions it ſtill indicates ſome degree of fever. The blood is florid, the craſſamentum is firm, in large quantity, and ſinks in the ſerum. Whilſt the weather continues warm, the *bilious* ſymptoms are moſt frequent, but as winter approaches, the inflammatory ones prevail. See INFLAMMATORY.

The doctor enumerates other ſymptoms, as crudeneſs of the urine, *bilious* ſtools, coſtiveneſs, *&c.* and farther obſerves, that the infantry are more liable to it than the cavalry.

As to the cure of the *camp-fever*, before it becomes continued, it depends upon the proper uſe of evacuations, the neutral ſalts, and the bark. Bleeding he judges indiſpenſible; which he would have repeated once or oftner, according to the urgency of the ſymptoms. After bleeding it will be neceſſary to give an emetic, the beſt time for doing which is in the remiſſion of the fever, and rather ſooner after a paroxyſm than before one. He adds, however, that vomits do harm when the ſtomach is anywiſe inflamed; in which caſe they ought never to be given. Ipecacuanha is the ſafeſt and eaſieſt, but antimonials make the moſt efficacious vomit. If the body remains coſtive, it is neceſſary to open it with ſome lenient phyſic; and eſpecially if the bowels are affected with pains, or a teneſmus. He likewiſe recommends ſalt of wormwood, lemon-juice, ſpiritus mindereri, and the bark; which laſt ought not to be given 'till the urine breaks, and the intermiſſions take place. Bleeding and purging are alſo neceſſary before the bark ought to be given: it anſwers beſt in ſubſtance adminiſtered in rheniſh wine, after ſtanding a night in infuſion.

If, after remiſſions or intermiſſions, the diſeaſe changes into a continued fever, bleeding becomes neceſſary, unleſs other ſymptoms forbid it; but whether there be room for bleeding or no, bliſters are not only uſeful, but the beſt remedy. To theſe may be joined the neutral ſalts and diaphoretic powders. But, tho' a ſweat be the proper criſis, it ought never to be promoted by theriaca, or the like hot medicines; unleſs the pulſe ſhould ſink and the petechiæ or other bad ſymptoms appear: in which caſe the warmer alexipharmics are neceſſary, as the diſeaſe has changed into a malignant fever. *Pringle*, Obſerv. on Diſeaſes of the Army, p. 165 and 202. ſeq. See *Malignant catarrhal* FEVER, *Suppl.* and MALIGNANT, *Append.*

BILOCULAR, in botany, is applied to a capſule having two cells. See CAPSULE, *Cycl.*

BIND-*weed (Suppl.)*—*Black*-BIND-*weed*, a name ſometimes for uſed the *tamnus*. See the article TAMNUS, *Cycl.*

Prickly-BIND-*weed*, a name given to the *ſmilax* of authors. See the article SMILAX, *Suppl.*

Sea-BIND-*weed*, the Engliſh name of a diſtinct genus of plants, called by botaniſts *ſoldanella*. See the article SOLDANELLA, *Suppl.*

BINN, *(Suppl.)* or BIN, the peaſe and whole oatmeal, uſed at Sea, and which are apt to ſpoil in caſks, Dr. Hales propoſes to prevent this, by putting them into large *bins*, with falſe bottoms of hair clothes laid on bars, whereby freſh air may be blown upwards thro' them, at proper times, with ſmall ventilators. See VENTILATOR, *Append.*

BINOMIAL *(Cycl.)*—*Impoſſible* BINOMIAL, in algebra, is uſed for a *binomial*, one of the terms of which is an impoſſible quantity. Thus, $a + \sqrt{} - bb$, is an *impoſſible binomial*.

BINOMIAL *ſurd* is uſed for a *binomial*, the terms of which are ſurds; as, $\sqrt{a} + \sqrt{b}$, or $a^m + b^m$, if m and n be fractions. The term *binomial ſurd*, is alſo applied to any quantity having a rational part and a ſurd part, as $25 + \sqrt{968}$. For the extraction of roots of *binomial ſurds*, ſee *Newton*'s Arithmetica Univerſalis, and *Mac Laurin*'s Algebra, p. 114---130.

BINOMIAL *curve* is uſed for a curve, the ordinate of which is expreſſed by a *binomial*. Thus if the ordinate of a curve be of this form $x \times \overbrace{e + fx^{\theta}}^{\lambda}$, the curve is called a *binomial curve*. *Stirling*, Method. differ. p. 58.

BINOMIAL *theorem* is often uſed to ſignify Sir Iſaac Newton's theorem for raiſing a *binomial* to any power, or for extracting any root of a *binomial*. See ROOT, *Suppl.*

BIOTA, in zoology, a name introduced by Dr. Hill for the *polype*. See the article POLYPE, *Suppl.*

It is of a cylindric figure, but variable; the tentacula are arranged in a ſingle ſeries round the aperture of the mouth, at the extremity of the body. There are ſeveral ſpecies of this animal.

Linnæus calls this creature *hydra*, no doubt, from the reproduction or repullulation of the parts, when cut off; and this name, *biota*, is likewiſe given it on the ſame account, being derived from βιος, life.

BIRCH *(Suppl.)* — BIRCH-*tree of America*, a name given by ſome to the *terebinthus*, or turpentine-tree. See TEREBINTHUS, *Suppl.*

BIRD *(Cycl.* and *Suppl.)*---*Admiſſive* BIRDS, *aves admiſſivæ*, in the augural ſcience of the antients, were birds of a happy omen, which denoted the approbation of the gods in an enterprize. *Danet.* Lex. in voc. *Baxt.* Gloſſ. p. 35. ſeq.

In which ſenſe *aves admiſſivæ* ſtand oppoſed to *arcivæ aves*.

BIRD's *cherry*, in botany, the Engliſh name of a genus of plants, called by Linnæus *padus*. See PADUS, *Append.*

BIRD's *eye*, in botany, the name of a genus of plants, called by authors *adonis flos*. See the article ADONIS *flos*, *Suppl.*

BIRD's *foot*, the Engliſh name of a genus of plants, called by authors *ornithopodium*. See the article ORNITHOPODIUM, *Suppl.*

BIRD's *foot trefoil*, a name given to ſome ſpecies of *lotus*. See the article LOTUS, *Suppl.*

BIRD-*lime*. See LIME-*twigs*, *Suppl.*

Water-BIRD-*lime*. See LIME-*twigs*, *Suppl.*

BIRD's *neſt*, in botany, a name uſed by ſome for the *daucus*, or carrot. See the article DAUCUS, *Suppl.*

BIRD's *pepper*, a name given to the *capſicum*, or Guinea pepper. See the article CAPSICUM, *Suppl.*

BIRD's *tongue*. See LINGUA *avis*, *Suppl.*

BIRTH *(Cycl.* and *Suppl.)*—*Difficult* BIRTH. See the article DELIVERY, *Suppl.*

BISHOP's *weed*, in botany, the Engliſh name of the *ammi*. See the article AMMI, *Suppl.*

BITTER *(Suppl.)*—*Bitters* are ſaid to reſiſt putrefaction and moderate fermentation: hence appears their uſe inputrid diſorders. *Bitters* likewiſe correct acidities, and aſſiſt digeſtion, by bracing the fibres of the ſtomach.

BITTER-*ſweet*, in botany, the Engliſh name of the *ſolanum ſcandens*, or climbing nightſhade. See the article SOLANUM, *Suppl.*

BITTER *vetch*, the Engliſh name of the *orobus*. See the article OROBUS, *Suppl.*

BITTER *wort*, the Engliſh name for the *gentiana* of authors. See the article GENTIANA, *Suppl.*

BLACK *berry*, the Engliſh name of a genus of plants called by authors *rubus*. See the article RUBUS, *Suppl.*

BLACK-*bind-weed*, or BLACK-*bryony*, a name given to the *tamnus* of authors. See the article TAMNUS, *Suppl.*

BLACK-*thorn*, a name uſed by ſome for the *prunus ſylveſtris*, or ſloe-tree. See the article PRUNUS, *Suppl.*

BLADDER-*lotus*. See the article LOTUS, *infra.*

BLADDER-*nut*, in botany, the Engliſh name of the *ſtaphylodendron*. See the article STAPHYLODENDRON, *Suppl.*

African BLADDER-*nut*, a name given to the *royena* of Linnæus. See the article ROYENA, *Suppl.*

Laurel-leaved-BLADDER-*nut*, the name uſed by ſome for the *Dodonæa* of Linnæus. See the article DODONÆA, *Suppl.*

BLADDER-*ſena*, a name given by ſome to the *colutea*. See the article COLUTEA. *Suppl.*

BLATTA *byzantia*, in the materia medica. See the article UNGUIS *odoratus*, *Suppl.*

BLEEDING, *(Suppl.)* according to Dr. Pringle, is the moſt indiſpenſible of all remedies in inflammatory diſeaſes; to the delaying of which too long, or not repeating it, are chiefly owing the bad conſequences of colds, as dangerous fevers, rheumatiſms, and conſumptions. He obſerves farther, that, in general, young practitioners are apt to be too ſparing in letting blood, by which means many lives are loſt: for a ſurgeon may be aſſured a ſoldier will never complain of a cough, or pains with inflammatory ſymptoms, wherein *bleeding* is not neceſſary; and from the ſizineſs of the blood, and continuance of the complaints, he is to judge of the neceſſity of repeating it, which, in caſe of a ſtitch, or difficult breathing, is never to be delayed. In inflammatory caſes, from twelve to fifteen ounces may be taken for the firſt *bleeding*, and ſomewhat leſs for all the reſt; and when it is neceſſary to exceed this quantity, it may be proper to follow Celſus's rule, in minding the colour of the blood whilſt it flows, and when it is of a blackiſh caſt, which is always the caſe in difficult breathing and great inflammations, to let it run till it becomes more florid. In all caſes where plentiful *bleeding* is indicated, it is beſt to do it in bed, to prevent fainting; and we may obſerve, that a perſon will bear the loſs of a much greater quantity of blood if the ſtream is ſmall, than by a large orifice, which ſome have thought neceſſary for making a more ſpeedy revulſion.

Bleeding is highly neceſſary in the phrenitis, ophthalmia, quinſey, rheumatiſm, cough, hectic fits, and, in general, in all inflammatory caſes. See *Pringle*'s Obſervations on the Diſeaſes of the Army, *paſſim.*

It is to be obſerved, however, that, in malignant and putrid diſorders *bleeding* frequently renders them more malignant, and therefore to be omitted, or at leaſt not repeated unleſs there appear evident marks of inflammation. See the articles MALIGNANT *fever*, BILIOUS *fever*, DYSENTERY, *&c.*

BLISTERS *(Suppl.)* are often neceſſary in inflammatory diſorders, as the phrenitis, ophthalmia, quinſey, pleuriſy, *&c.* as well as in chronic diſtempers, ſuch as palſies, *&c.* See PHRENITIS, OPHTHALMIA, *&c. Suppl.*

BLITE, in huſbandry. See the articles BLIGHT and RUBIGO, *Suppl.*

BLOIS, *Bole of* BLOIS, *Bolus Bleſenſis*. See the article BLESENSIS *bolus*, *Suppl.*

BLOOD *(Suppl.)*—In order to aſcertain the colour of the different parts of corrupted *blood*, Dr. Pringle made the following experiment. He took a freſh quantity without any inflammatory cruſt, and divided it into the craſſamentum, the ſerum with a few red globules in it, and the pure ſerum. The phials containing theſe ſeveral liquors were put into a furnace, where they ſtood ſome days, till they became thoroughly putrid.

The craſſamentum was changed from a deep crimſon to a dark livid colour; ſo that when any portion of it was diluted with water, it appeared of a tawney hue. Of the ſame colour was the ſerum in which the red globules remained. But the pure ſerum, after becoming turbid, dropped a white purulent ſediment, and changed into a faint olive green.

From this experiment he concludes, that the ichor of ſordes, and that of dyſentery fluxes, conſiſts of the ſerum tinged with a ſmall quantity of red blood putrified; and that when the ſerous veſſels are of a tawney caſt, we are not to refer that colour to inflammation, but to a ſudden ſolution of ſome of the red globules mixed with the ſerum.

A few drops of this putrid craſſamentum was mixed with the recent urine of a healthy perſon, which it immediately changed into a flame-coloured water, common in fevers and in the ſcurvy. After ſtanding an hour or two, the ſame gathered a cloud, reſembling what is ſeen in the crude urine of perſons in acute diſtempers.

As to a green ſerum, it is perhaps never to be ſeen in the veſſels of a living body, ſince it is not to be ſuppoſed that a perſon could ſurvive ſo great a change of the *blood*. In foul ulcers, indeed, and in other ſores, where the ſerum is left to ſtagnate long, the matter is found of a greeniſh colour, and is then always acrimonious. But the effects of a green ſerum is no where to be ſo much dreaded as in the caſe of an aſcites, where it is collected in ſo large a quantity. Of which we had, ſome time ſince, almoſt a fatal inſtance in Mr. Cox, ſurgeon at Peterborough, who, upon tapping a woman but a few hours after death, was ſo affected with the poiſonous ſteams of a green ſerum, that he was preſently ſeized with a peſtilential fever, and narrowly eſcaped with his life.

In regard to the ſediment which the ſerum dropped on becoming turbid, and which reſembled well digeſted matter, the doctor thinks it a terreſtrial ſubſtance, intended for the nouriſhment or reparation of the ſolid; in which opinion he was the more confirmed by obſerving a like ſediment in the urine of men in perfect health: and therefore concludes that the pus, or digeſted matter of ſores, is nothing but this ſubſtance ſeparated from the ſerum of the blood. And hence it is that all large ulcers are extremely weakening, from the great expence of *blood* in furniſhing this ſubſtance. Hence alſo it is, that iſſues are of more conſequence for making drains, than one would expect from the viſible evacuation: as near as the doctor could gueſs, an ounce of ſerum, after ſtanding ſome days, not furniſhing more of this matter than what might be produced in the daily diſcharge of a large pea-iſſue, or from a ſeton. *Pringle*, Obſerv. on Diſeaſes of the Army, Append. p. 386, *ſeq.* Experim. xlv.

There are frequent inſtances of the tawney colour of the ſerum, the reſolution of the craſſamentum, and even of the offenſive ſmell of *blood* recently drawn. And, indeed, if we reflect how putreſcent *blood* is in a heat equal to that of the human body, we may be convinced, that no ſooner is the perſpiration by the lungs impeded, than a corruption begins in the whole maſs; which, if not timely prevented, brings on ſome putrid diſeaſe. If the acrimony is great and ſudden, a fever or flux will enſue; but if the accumlation is ſo ſlow that the body grows habituated to the putrefaction, a ſcurvy prevails. This is the caſe in long voyages, on board unventilated ſhips; in marſhy countries; and, in a leſſer degree, in all northerly climates, in moiſt ſituations. *Id.* p. 400.

BLOOD-*flower*, in botany, the Engliſh name of the *hæmanthus*. See the article HÆMANTHUS, *Suppl.*

BLOWER, among dealers in horſes, a term uſed for ſuch horſes as wheeze much, without wanting wind. See the article WHEEZING, *Suppl.*

BOAR *(Suppl.)* The wild *boar*, among the huntſmen, has ſeveral names, according to its different ages; the firſt year it is called *a pig of the ſaunder*; the ſecond it is called *a hog*; the third, *a hog-ſteer*; and the fourth, *a boar*; when leaving the ſaunder he is called *a ſingler* or *ſangler*.

The *boar* generally lives to twenty-five or thirty years, if he eſcapes accidents. The time of going to rut is in December, and laſts about three weeks. They feed on all ſorts of fruits, and on the roots of many plants; the root of fern in particular ſeems a great favourite with them: and when they frequent places near the ſea coaſts, they will deſcend to the ſhores and demoliſh the tenderer ſhell-fiſh in very great numbers. Their general places of reſt are among the thickeſt buſhes that can be found, and they are not eaſily put up out of them, but will ſtand the bay a long time. In April and May they ſleep more ſound than at any other time of the year, and this is therefore the ſucceſsful time for the taking them in the toils. When a *boar* is rouzed out of the thicket, he always goes from it, if poſſible, the ſame way by which he came to it; and when he is once up, he will never ſtop till he comes to ſome place of more ſecurity. If it happens that a ſaunder of them are found together, when any one breaks away, the reſt all follow the ſame way. When the *boar* is hunted in the wood, where he was bred, he will ſcarce ever be brought to quit it; he will ſometimes make toward the ſides to liſten to the noiſe of the dogs, but retires into the middle again, and uſually dies or eſcapes there. When it happens that a *boar* runs a-head, he will not be ſtopt, or put out of his way by man or beaſt, ſo long as he has any ſtrength left. He makes no doubles nor groſſings when chaſed; and when killed makes no noiſe, if an old *boar*; the ſows and pigs will ſqueak when wounded.

The ſeaſon for hunting the wild *boar* begins in September and ends in December, when they go to rut. If it be a large *boar*, and

and one that has lain long at reſt, he muſt be hunted with a great number of dogs, and thoſe ſuch as will keep cloſe to him, and the huntſman, with his ſpear, ſhould always be riding in among them, and charging the *boar* as often as he can, to diſcourage him: ſuch a *boar* as this, with five or ſix couple of dogs, will run to the firſt convenient place of ſhelter, and there ſtand at bay, and make at them as they attempt to come up with him.

There ought always to be relays alſo ſet of the beſt and ſtaunchеſt hounds in the kennel; for if they are of young eager dogs, they will be apt to ſeize him, and be killed or ſpoiled before the reſt come up. The putting collars with bells about the dogs necks is a great ſecurity for them, for the *boar* will not ſo ſoon ſtrike at them when they have theſe, but will rather run before them. The huntſmen generally kill the *boar* with their ſwords or ſpears; but great caution is neceſſary in making the blows, for he is very apt to catch them upon his ſnout or tuſks, and if wounded and not killed, he will attack the huntſmen in the moſt furious manner. The places to give the wound with the ſpear is either between the eyes in the middle of the forehead or in the ſhoulder, both theſe places make the wound mortal.

When this creature makes at the hunter there is nothing for it but courage and addreſs, if he flies for it he is ſurely overtaken and killed; if the *boar* comes ſtrait up, he is to be received at the point of the ſpear; but if he makes doubles and windings, he is to be watched very cautiouſly, for he will attempt getting hold of the ſpear in his mouth, and if he does ſo nothing can ſave the huntſman but another perſon attacking him behind; he will on this attack the ſecond perſon, and the firſt muſt then attack him again; two people will thus have enough to do with him, and were it not for the forks of the boar-ſpears that make it impoſſible to preſs forward upon them, the huntſman who gives the creature his death's wound would ſeldom eſcape falling a ſacrifice to his revenge for it.

The modern way of boar-hunting is generally to diſpatch the creature by all the huntſmen ſtriking him at once; but the antient Roman way was, for a perſon on foot, armed with a ſpear, to keep the creature at bay, and in this caſe the *boar* would run of himſelf upon the ſpear to come at the huntſman, and puſh forward till the ſpear pierced him through.

The hinder claws of a *boar* are called *guards*.

In the corn he is ſaid to *feed*; in the meadows or fallow fields, to *rout*, *worm*, or *fern*; in a cloſe, to *graze*.

The *boar* is farrowed with as many teeth as he will ever have, his teeth increaſing only in bigneſs, not in number; among theſe there are four called *tuſhes* or *tuſks*, the two biggeſt of which do not hurt when he ſtrikes, but ſerve only to whet the other two loweſt, with which the beaſt defends himſelf, and frequently kills, as being greater and longer than the reſt. Gent. Recr. p. 1, 7, and 119. Trev. Dict. Univ. tom. iv. p. 1489, *voc. Sanglier.*

It is very remarkable, that theſe creatures in the Weſt Indies are ſubject to the ſtone in a very remarkable manner: few of them are abſolutely free from it, yet ſcarce any have the ſtones of any conſiderable ſize. It is common to find a great number in the ſame bladder, and they are uſually of about a ſcruple weight, and are angular, and that with great regularity, each having five angles. Phil. Tranſ. n. xxxvi.

Among the antient Romans *boar*'s fleſh was a delicacy; a *boar* ſerved up whole was a diſh of ſtate. *Pitiſc.* Lex. Ant. tom. i. p. 120. *voc.* APER.

The *boar* was ſometimes alſo the military enſign borne by the Roman armies, in lieu of the eagle. *Salmuth.* ad Pancirol. P. I. tit. liii. p. 278.

Among phyſicians a *boar*'s bladder has been reputed a ſpecific for the epilepſy. *Friend*, Hiſt. of Phyſ. tom. ii. p. 280. The tuſh of the wild *boar* ſtill paſſes with ſome as of great efficacy in quinzies and pleuriſies. *Alleyn*, Diſpenſ. p. 150.

BOAR, in the manege. A horſe is ſaid to *boar*, when he ſhoots out his noſe as high as his ears, and toſſes it in the wind. *Guill.* Gent. Dict. *in voc.*

BOLBONACH, in botany, a name given to the *lunaria* of authors. See the article LUNARIA, *Suppl.*

BOLE *(Suppl.)* — See the article BOLUS, *Suppl.* and *Append.*

BOLUS *Bleſenſis*. See the article BLESENSIS *bolus*, *Suppl.*

BOLUS *Etruſca*, the ſame with *Etruſca terra*. See the article ETRUSCA *terra*, *Suppl.*

BOLUS *Goltbergenſis*, the ſame with *terra Goltbergenſis*. See the article GOLTBERGENSIS *terra*, *Suppl.*

BOLUS *Lemnia*, the ſame with *terra Lemnia*. See the article LEMNIAN *earth*, *Suppl.*

BOLUS *Livonica*, the ſame with the *Livonica terra*. See the article LIVONICA *terra*, *Suppl.*

BOLUS *Noceriana*, the ſame ſame with *terra Noceriana*. See the article NOCERIANA *terra*, *Suppl.*

BOLUS *Veneta*. See the article VENETA *bolus*, *Suppl.*

BONANA, in botany, the name uſed for a genus of plants called by authors *muſa*. See the article MUSA, *Suppl.*

BONE *(Cycl.* and *Suppl.)*—All ſorts of *bone* may be ſtained, or dyed, any kind of colour, as directed under the article IVORY, *Append.*

BOREA, a name given by the antients to a ſpecies of jaſper, of a blueiſh green colour. See the article JASPER, *Append.*

BORECOLE, in botany, a name uſed for a ſpecies of *braſſica*. See the article BRASSICA, *Suppl.*

BOTRYS, in botany, a name ſometimes given to a ſpecies of *chenopodium*, called alſo *oak of Jeruſalem*. See the article CHENOPODIUM, *Suppl.*

BOTRYTIS, in botany, the name given by Micheli to a genus of moſſes, called by authors *byſſus*. See the article BYSSUS, *Suppl.*

BOTTLE *(Suppl.)*—*Blue* BOTTLE, a name uſed for the *cyanus* of authors. See the article CYANUS, *Suppl.*

BOWER *(Suppl.)*—*Ladies* BOWER, or *virgin's* BOWER, names given by us to a diſtinct genus of plants called by botaniſts *clematitis*. See the article VIRGIN'*s bower*. *Suppl.*

BOX-*thorn*, in botany, the Engliſh name of a genus of plants called by authors *lycium*. See the article LYCIUM, *Append.*

BRACHIONUS, in zoology, the name of a genus of animalcules of the *arthrodia* kind, containing all the wheel animals. See the articles ARTHRODIA and ANIMALCULE, *Append.* and WHEEL, *Suppl.*

BRACHURI, in zoology, a name given by Dr. Hill to a genus of animalcules of the tailed kind. See the article ANIMALCULE, *Suppl.* and *Append.*

Theſe animalcules are of a roundiſh figure, with tails ſhorter than their bodies; their ſkin is perfectly ſmooth, thin, and colourleſs. They are frequent in water-ponds, in pepper-water, and many other infuſions of vegetable ſubſtances. See *Hill*, Hiſt. Anim. p. 6, *ſeq.*

BRACHYPYRENIA, in natural hiſtory, a genus of foſſils of the claſs of *ſeptariæ*. See the article SEPTARIÆ, *Suppl.*

The *brachypyrenia* have a ſhort roundiſh nucleus, encloſed by and contained within the body of the maſs.

BRAMA *marina*, the ſea-bream, in ichthyology, a ſpecies of *ſparus*, according to Artedi. See the article SPARUS, *Sppul.*

BRAMBLE, or BRAMBLE *buſh*, in botany, the Engliſh name of a genus of plants called by authors *rubus*. See the article RUBUS, *Suppl.*

BRAMBLING, in zoology. See the article BRAMBLE, *Suppl.*

BRANCK *urſine*, a name uſed by ſome authors for the *acanthus*. See the article ACANTHUS, *Suppl.*

BRASSE, in ichythology, a name ſometimes given to the *lucioperca*, a ſpecies of pearch. See the articles PERCA and LUCIOPERCA, *Suppl.*

BREAD *(Suppl.)*—*S. John's* BREAD, in botany, the Engliſh name of the carob-tree, deſcribed by Tournefort under that of *ſiliqua*. See the article SILIQUA, *Suppl.*

BREAM *(Suppl.)*—*Sea*-BREAM, *brama marina*, in ichthyology, a ſpecies of *ſparus*. See the article SPARUS, *Suppl.*

BREAST *(Suppl.)* — *Diſeaſes of the* BREAST. See the article ASTHMA, *Append.*

BRIAR, in botany, a name given to ſeveral ſpecies of roſe. See the article ROSE, *Suppl.*

BRIMSTONE *wort*, in botany, a name given to the *pucedanum* of authors. See the article PUCEDANUM, *Suppl.*

BRIONY, in botany. See the article ERIONIA, *Suppl.*

BRISTOL *flower*, in botany, a name uſed by ſome for the *lychnis*. See the article LYCHNIS, *Suppl.*

BROCADE *(Cycl.)* — BROCADE-*ſhell*, the Engliſh name of a ſpecies of *cylindrus*. See the article CYLINDRUS, *Suppl.*

It is of a ſilvery white colour variegated with brown.

BROCATELLO, a name uſed by our lapidaries for the white and gold veined red marble. See the article MARBLE, *Suppl.*

BROCOLI, among gardeners. See BROCCOLI, *Suppl.*

BROMELIA, in the Linnæan ſyſtem of botany, the name of a genus of plants called by Tournefort *ananas*. See the article ANANAS, *Suppl.*

BROOM *(Suppl.)* — *Butcher's* BROOM, in botany, the Engliſh name of a genus of plants called by authors *ruſcus*. See the article RUSCUS, *Suppl.*

Green, and *white* BROOM, names given to the *ſpartium* of authors. See the article SPARTIUM, *Suppl.*

Spaniſh BROOM, *ſpartium*, in botany. See the article SPARTIUM, *Suppl.*

BROOM-*lime*, a name uſed for the plant known among authors by that of *veronica*. See the article VERONICA.

BROOM-*rape*, a name given to the orobanche of authors. See the article OROBANCHE, *Suppl.*

BROWN *wort*, in botany, a name given ſometimes to the *brunella*, or *prunella* of authors. See the article PRUNELLA, *Suppl.*

BROWN *wort* is alſo ſometimes uſed for the *ſcrophularia*. See the article SCROPHULARIA, *Suppl.*

BRUISE *wort*, in botany, a name given by ſome authors to the *lychnis*. See the article LYCHNIS, *Suppl.*

BRUSH *(Suppl.)* — *Silver*-BRUSH, the name by which ſome call the *barba Jovis*, a diſtinct genus of plants. See the article BARBA *Jovis*, *Suppl.*

BUBO, in ornithology. See the article OWL, *Suppl.* and *Append.*

BUCEROS, in ornithology, the name of a ſpecies of raven found in the Eaſt Indies, China, and Tartary. Its head, neck, rump, and tail are of a gloſſy black without the leaſt tinge of any other colour. It is of the bigneſs of a well grown pullet: its head is remarkably large, as is its beak, which has a conſiderable gibboſity towards the baſe, riſing above the reſt of the ſurface. See *Hill*, Hiſt. Anim. p. 383.

BUCK's *horn*, or *hart's horn plantain*, in botany, names given to the *coronopus* of authors. See the article CORONOPUS, *Suppl.*

BUCK's *horn creſs*, in botany, a name given to the *naſturtium* of authors. See the article NASTURTIUM, *Suppl.*

BUCK-*thorn*, in botany, the Engliſh name of a genus of plants called by authors *rhamnus*. See the article RHAMNUS, *Suppl.*

Sea-BUCK-*thorn*, in botany, a name given to the *rhamnoides* of authors. See the article RHAMNOIDES, *Suppl.*

BUCK-*wheat*, in botany, the Engliſh name of the *fagopyrum* of authors. See the article FAGOPYRUM, *Suppl.*

BUDDING, among gardeners, the ſame with innoculation, or innoculating. See the article INNOCULATION, *Cycl.* and *Suppl.*

BUGG, in the hiſtory of inſects, the Engliſh name of the *cimex*. See the article CIMEX, *Suppl.*

BUGG is alſo the Engliſh name of another genus of inſects found on ſeveral trees. See the article CHERMES, *Append.*

Houſe BUGG, in the hiſtory of inſects, the Engliſh name of a ſpecies of *coccus*. See the article COCCUS, *Append.*

BUGLOSS *(Suppl.)* — *Viper's* BUGLOSS, in botany, the Engliſh name of the *echium*. See the article ECHIUM, *Suppl.*

BULBINE, in botany, a name uſed by ſome for the *phalanguim* or ſpider-wort of Tournefort. See the article PHALANGIUM, *Suppl.*

BULL-*frog*, the Engliſh name of the largeſt ſpecies of the frog kind. See the articles FROG and RANA, *Suppl.*

BULLACE-*tree*, in botany, a name given to a ſpecies of the *prunus*, or plum tree. See the article PRUNUS, *Suppl.*

BULLY-*tree*, in botany, a name given to the *cainito* or *chryſophyllum* of authors. See the article CHRYSOPHYLLUM, *Append.*

BUNIUM, in the Linnæan ſyſtem of botany, the name of a genus of plants called by Tournefort *bulbocaſtanum*. See the article BULBOCASTANUM, *Suppl.*

BUNK, BUNKEN. See the article LEUCACANTHA, *Suppl.*

BUPLEURUM, hare's ear, in botany. See the article HARE'S *ear*, *Suppl.*

BURDOCK, in botany, the Engliſh name of a genus of plants called by authors *Xanthium*. See the article XANTHIUM, *Suppl.*

BURNET, in botany, the Engliſh name of a genus of plants called by authors *ſanguiſorba*. See the article SANGUISORBA, *Suppl.*

BURNET-*ſaxifrage*, in botany, a name improperly given by ſome to a ſpecies of *tragoſelinum*. See the article TRAGOSELINUM, *Suppl.*

BURNING *of diamonds*, is uſed among the jewellers for puting the diamonds into a fierce fire, in order to diveſt them of a yellow or brown colour. See DIAMOND, *Suppl.*

BURSA *paſtoris minor*, in botany, the name by which the *draba* of Linnæus is called by ſome writers. See the article DRABA, *Append.*

BUSH *(Suppl.)* — *Poiſon*-BUSH, the name by which the *tithymalus*, or ſpurge is ſometimes called. See the article TITHYMALUS, *Suppl.*

BUSTARD, the Engliſh name of a genus of birds called *otis* by authors. See the article OTIS, *Suppl.*

BUTTER-*bump*, a name uſed in ſome parts of England for the bittern, or *ardea ſtellaris*. See the article BITTERN, *Suppl.*

BUTTERFLY-*flower*, the name of a plant called by authors *orchis*. See the article ORCHIS, *Suppl.*

BUTTERFLY-*ſhell*, the Engliſh name of a ſpecies of *voluta*. See the article VOLUTA, *Suppl.*

BUTTERIS, among farriers, the ſame with *buttreſs*. See the article BUTTRESS, *Cycl.*

BUTTON-*tree*, a name given to ſome ſpecies of *platanus* and *cephalanthus*. See the articles PLANE-*tree*, *Suppl.* and CEPHALANTHUS, *Append.*

BUTTON-*tree of Jamaica*, a name given to the *conocarpus* of Linnæus. See the article CONOCARPUS, *Append.*

C.

CABBAGE *(Suppl.)* — *Sea*-CABBAGE, or ſea-cale, in botany, a name given to the *crambe* of authors. See the article CRAMBE, *Suppl.*

CABBAGE-*tree*, a name uſed by ſome for the palm-tree deſcribed by Linnæus under that of *phœnix*. See the article PHOENIX, *Suppl.*

CACALIANTHEMUM, in botany, the name by which Dillenius calls a genus of plants deſcribed by Linnæus under that of *kleinia*. See the article KLEINIA, *Append.*

CACTUS, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: the cup is a deciduous perianthium, formed of a ſingle leaf of a tubulated concave form, ſtanding on the germen, and covered with a kind of ſquamoſe leaves; the flower conſiſts of a great number of broad obtuſe petals, the exterior ones ſhort, the interior longer and connivent; the ſtamina are numerous ſubulated filaments, inſerted into the calyx, and ſhorter than the flower. The antheræ are oblong and erect; the germen ſtands under the tube of the cup: the ſtyle is cylindric, and of the length of the ſtamina: the ſtigma is capitated and multifid: the fruit is an oblong umbilicated berry, containing only one cell, and covered with little leaves, like the cup: the ſeeds are numerous, roundiſh, and ſmall.

This genus comprehends the *cereus*, *opuntia*, *melocactus*, *tuna*, and *pereſkia* of botanical authors. The *cereus* is a long cylindraceo-angulated plant; the *melocactus*, a roundiſh and angulated one; the *opuntia* is ramoſe and dichotomous; and the *pereſkia* is arboreſcent and folioſe. Vide *Linnæi* Gener. Plant. p. 210.

CADLOCK, in botany, a name uſed in ſeveral parts of England for the *rapiſtrum* of authors. See the article RAPISTRUM, *Suppl.*

CÆMENT *(Cycl.* and *Suppl.)* — We have various receipts for making *cæments* to mend broken china or glaſſes; one of the fineſt, and at the ſame time ſtrongeſt *cæments* for this purpoſe, is the juice of garlick ſtamped in a ſtone mortar; this will leave little or no mark, if done with care.

Another *cæment* for broken glaſſes, china, or earthen ware may be prepared by beating the white of an egg very clear, and mixing with it fine powdered quick lime; or iſinglaſs, powdered chalk, and a little lime may be mixed together, and diſſolved in fair water, with which the glaſſes, *&c.* are to be cæmented, and then ſet in the ſhade to dry; a precaution that ſhould be always obſerved, whichever of the above *cæments* be uſed.

CÆMENTS *for cracked chemical glaſſes*. To prepare a *cæment* for theſe glaſſes that will ſtand the fire: take wheat flour, fine powdered Venice glaſs, pulverized chalk, of each an equal quantity; fine brick duſt, one half of the quantity; and a little ſcraped lint: mix them all together with the whites of eggs: then, ſpreading this mixture upon a linnen cloth, apply it to the cracks of the glaſs, which muſt be well dried before you put it to the fire.

Old varniſh is another *cæment* which will anſwer the ſame purpoſe; for by gluing the pieces together therewith, and ſetting them to dry in the ſun, or a warm place, they will hold very well. *Smith*'s Laboratory, p. 171.

For the manner of preparing a *cæment* to bind together the various embelliſhments of grottos, ſee the article GROTTO, *Append.*

CAINITO, in botany, a name given by Plumier to a genus of plants deſcribed by Linnæus under that of *chryſophyllum*. See the article CHRYSOPHYLLUM, *Append.*

CALABASH, in botany, a name uſed by ſome for the *melopepo* of authors. See the article MELOPEPO, *Suppl.*

CALABASH-*tree*, the name of a genus of plants called by Plumier *cujete*, and deſcribed by Linnæus under that of *creſcentia*. See the article CRESCENTIA, *Suppl.*

CALAMINT *(Suppl.)* — *Water*-CALAMINT, in botany, a name given by ſome to ſeveral ſpecies of mint. See the article MENTHA, *Suppl.*

CALCITRAPA is made by Vaillant a diſtinct genus of plants, but ranked by Linnæus among the *centauria*. See the article CENTAURIA, *Append.*

CALCITAPRA is a name by which ſome call a ſpecies of *cnicus*. See the article CNICUS.

CALCITRAPA is alſo uſed as the name of ſeveral ſpecies of our common thiſtle. See the article THISTLE, *Suppl.*

CALCITRAPOIDES, a diſtinct genus of plants, according to Vaillant, but comprehended among the *centauria* by Linnæus. See the article CENTAURIA, *Append.*

CALF *(Suppl.)* — *Sea*-CALF, the Engliſh name of a genus of animals called by authors *phoca*. See the article PHOCA, *Suppl.*

CALF's *ſnout*, in botany, an Engliſh name for the *antirrhinum* of authors, otherwiſe called *ſnap-dragon*. See the article SNAP-DRAGON, *Suppl.*

CALKING, among painters, the ſame with calquing. See the article CALQUING, *Cycl.*

CALL, a name given by the miners in many parts of the kingdom to the red *telaugium*, variegated with black and white. See the article TELAUGIUM, *Append.*

CALLITRICHUM, καλλιτρίχον. See the article ADIANTUM, *Suppl.*

CAMEA, in natural hiſtory, the ſame with *camæa*, a genus of ſemipellucid gems. See the article CAMÆA, *Suppl.*

CAMEHUIA, in natural hiſtory, the ſame with what is called *camaieu* in the *Supplement*. See the article CAMAIEU, *Suppl.*

CAMPANULA *lychnidea*, the name by which J. Bauhine calls a ſpecies of the *convolvulus*, or bind-weed. See the article CONVOLVULUS, *Suppl.*

CAMMOCK, in botany, a name given by ſome to the *anonis*, or reſt harrow. See the article REST-HARROW, *Suppl.*

CAMOMILE, CHAMOMILE, or *Chamemile*, in botany, the Engliſh name of a genus of plants called by authors *chamæmelum*. See the article CHAMÆMELUM, *Suppl.*

CAMP *(Suppl.)* — Where the grounds are equally dry, thoſe *camps* are always moſt healthful which are pitched on the banks of large rivers; becauſe in the hot ſeaſon ſituations of this kind have a ſtream of freſh air from the water, ſerving to carry off the moiſt and putrid exhalations. On the other hand, next to marſhes, the worſt encampments are on low grounds cloſe beſet with trees: for then the air is not only moiſt and hurtful in itſelf, but, by ſtagnating, becomes more ſuſceptible of corruption. However, let the ſituation be ever ſo good, *camps* are frequently rendered infectious by the putrid effluvia of rotten ſtraw, and the privies of the army; more eſpecially if the bloody flux prevails, in which caſe the beſt method of preventing a general infection is to leave the ground with the privies, foul ſtraw, and other filth of the *camp* behind. This is to be frequently done, if conſiſtent with the military operations; but when theſe render it improper to change the ground often, the privies ſhould be made deeper than uſual, and once a day a thick layer of earth thrown into them till the pits are near full, and then they are to be well covered, and ſupplied by others. It may alſo be a proper caution, to order the pits to be made either in the front or rear, as the then ſtationary winds may beſt carry off their effluvia from the *camp*. Moreover, it will be neceſſary to change the ſtraw frequently, as being not only apt to rot, but to retain the infectious ſteams of the ſick. But if freſh ſtraw cannot be procured, more care muſt be taken in airing the tents as well as the old ſtraw. See *Pringle*, Obſerv. on the Diſeaſes of the army, p. 99, 103, &c.

CAMP-*diſeaſes*. See the article SOLDIER, *Append.*

CAMP-*fever*. See the article BILIOUS *fever*.

CAMP-*hoſpital*. See the article HOSPITAL.

CAMPAIGN *(Cycl.)* — The beginning of every *campaign* is conſiderably more unhealthy than if the men were to remain in quarters. After the firſt fortnight or three week's encampment, the ſickneſs decreaſes daily; the moſt infirm being by that time in the hoſpitals, the reſt more hardened, and the weather growing daily warmer. This healthy ſtate continues throughout the ſummer, unleſs the men get wet cloaths or wet beds; in which caſe a greater or leſſer degree of the dyſentery will appear, in proportion to the preceding heats. But the moſt ſickly part of the *campaign* begins about the middle or end of Auguſt, whilſt the days are ſtill hot but the nights cool and damp, with fogs and dews: then, if not ſooner, the dyſentery prevails; and though its violence is over by the beginning of October, yet the remitting fever gaining ground, continues throughout the reſt of the *campaign*, and never entirely ceaſes even in winter-quarters till the froſts begin.

At the beginning of a *campaign* the ſickneſs is ſo uniform, that the number may be nearly prædicted; but, for the reſt of the ſeaſon, as the diſeaſes are then of a contagious nature, and depend ſo much upon the heats of ſummer, it is impoſſible to foreſee how many may fall ſick from the beginning to the end of autumn. It is alſo obſerved, that the laſt fortnight of a *campaign*, if protracted till the beginning of November, is attended with more ſickneſs than the firſt two months of the encampment: ſo that it is better to take the field a fortnight ſooner, in order to return into winter-quarters ſo much the earlier.

As to winter-expeditions, though ſevere in appearance, they are attended with little ſickneſs, if the men have ſtrong ſhoes, quarters, fuel, and proviſions.

Long marches in ſummer are not without danger, unleſs made in the night, or ſo early in the morning as to be over before the heat of the day. See *Pringle*, Obſerv. on the Diſeaſes of the army, p. 118, *ſeq.*

CAMPHOR-*tree*, in botany, the name of a ſpecies of *laurus*, according to Linnæus, with oval gloſſy leaves on lax pedicles. See the article LAURUS, *Append.*

It is a native of many parts of the Eaſt: Breynius calls it *arbor camphorifera Japonica foliis laurinis, &c.*

The *camphor* of the ſhops is prepared from the wood of this tree by a coarſe kind of ſublimation. See the article CAMPHOR, *Cycl.* and *Suppl.*

CAMPION, in botany, the Engliſh name of a genus of plants called by authors *lychnis*. See the article LYCHNIS, *Suppl.*

CANARY. See *Colouring of* MARBLE.

CANARY-*graſs*, in botany. See the article GRASS, *Append.*

CANCER, the crab, in zoology, the name of a genus of *ſquillæ*. See the article SQUILLA, *infra.*

CANDLE-*berry-tree*, a name uſed by ſome for the *myrica* of authors. See the article MYRICA, *Append.*

CANDY-*carrot*, in botany, a name uſed by ſome for the *myrrhis* of Candia. See the article MYRRHIS, *Suppl.*

CANDY-*tuft-tree*, in botany, a name given to the *thlaſpi* of authors. See the article THLASPI, *Suppl.*

CANE *(Suppl.)* — *Bambo* or *bamboo* CANE. See the articles BAMBO and ARUNDO, *Suppl.*

Dumb CANE, in botany, a name given by ſome writers to the *arum*. See the article ARUM, *Suppl.*

Fiſhing-rod-CANE, the name of a ſpecies of *arundo*, or reed. See the article ARUNDO, *Suppl.*

Indian flowering CANE, in botany, the name of a genus of plants called by Linnæus and Tournefort *canna* and *cannacorus*. Se the articles CANNA and CANNACORUS, *Suppl.*

Sugar-CANE, in botany, the Engliſh name of a genus of plants called by Linnæus *ſaccharum*. See the article SACCHARUM, *Suppl.* and SUGAR, *Cycl.*

CANNABINA, baſtard-hemp, in botany, the name of a diſtinct genus of plants, the characters of which are theſe: the flower is apetalous, conſiſting of a number of ſtamina, and is barren, the ſeed being produced on diſtinct female plants of the ſame genus, which have no viſible flower. The ſeeds are triangular, oblong, and contained in membranous capſules.

The ſpecies of *cannabina* enumerated by M. Tournefort, are theſe: 1. The Cretic male *cannabina*, with flowers. 2. The Cretic fruit-bearing or female *cannabina*. Vide *Tourn.* Inſt. Bot. Coroll. p. 52.

CANTERBURY-*bell*, in botany, a name given by ſome to the *campanula* of authors. See the article CAMPANULA, *Suppl.*

CANTHARIS, the glow-worm, in the hiſtory of inſects. See the article GLOW-*worm*, *Suppl.*

CANTHARUS *unctuoſus*, a name by which ſome authors call the *meloe*, or oil-beetle. See the article MELOE, *Append.*

CANUTI *avis*, the name by which ſome call a ſpecies of *tringa*. See the article TRINGA, *Suppl.*

CAP *(Suppl.)* — *Black* CAP, the name uſed by the common people in many parts of the kingdom for the pewit, a bird of the *larus* or ſea-gull kind. See the article PEWIT. *Suppl.*

CAPER *(Suppl.)* — *Bean* CAPER, a name given by ſome to the *fabago* of authors. See the article FABAGO, *Suppl.*

CAPILLUS *veneris*. See the article ADIANTUM.

CAPILLUS *terræ*. See the article ADIANTUM.

CAPITALIS *reflexa*, in ſurgery, a kind of bandage called by the French *capeline*. See the article CAPELINE, *Suppl.*

CAPITO *anodromus*, a name by which ſome authors have called the *zerta* or *zerte*, a fiſh living partly in large rivers and partly in the ſea, and in ſome degree reſembling the common river chubb in ſhape. *Geſner*, de Piſc. p. 1269. See the article ZERTA, *Suppl.*

CAPNIAS, or *capnitis*, in natural hiſtory, names uſed by the antients for the pale bluiſh jaſper with black veins and clouds. See the article JASPER, *Append.*

CAPNORCHIS, the Indian bulbous-rooted fumitory, in botany, the name of a ſpecies of fumitory. See the article FUMARIA, *Suppl.*

CAPON's *tail graſs*, in botany, the Engliſh name of a genus of plants called by authors *feſtuca*. See the article FESTUCA, *Suppl.*

CAPRA, in ornithology, the name by which ſome call the *capella*, or lapwing. See the article CAPELLA, *Suppl.*

CAPREA, a name uſed by Pliny for the roe-deer, a creature not in the leaſt allied to the goat kind. See the article CAPREOLUS, *Suppl.*

CAPRICORNUS, in zoology, the name of a ſpecies of *mordella*, a genus of four-winged flies. See the article MORDELLA, *Append.*

CARABUS, in zoology, the name of a genus of four-winged flies, whoſe antennæ are oblong, ſlender, and ſetaceous; the thorax is ſomewhat convex, marginated, of a cordated figure, and truncated in the hinder part. Vide *Hill*, Hiſt. Animal. p. 47.

CARASSIUS, a name given by ſome to a ſpecies of *cyprinus*, with twenty bones in the back fin, and the ſide line ſtrait. See CYPRINUS, *Suppl.*

CARATAS, in botany. See the article KARATAS, *Append.*

CARAWAY, or CARRAWAY, in botany, the Engliſh name of a genus of plants called by authors *carui*. See the article CARUI, *Suppl.*

CARBO *aquaticus*, a name uſed by Geſner for the cormorant. See the article CORMORANT, *infra.*

CARDIA,

CARDIA, a name given by Dr. Hill to the heart-ſhells. See the article HEART-*ſhell*, *Suppl.*

CARDINAL's *flower*, in botany, a name uſed by ſome for the *rapuntium* of authors. See the article RAPUNTIUM, *Suppl.*

CARIQUEIBEIU, in zoology. See the article JIYA.

CARLOCK, a name uſed by ſome for the *raphaniſtrum* of authors. See the article RHAPHANISTRUM, *Suppl.*

CARNATION, in botany, a name given to ſeveral ſpecies of the *caryophyllus*, or pink, ſee the article PINK, *Suppl.*

Spaniſh CARNATION, a name given by ſome writers to the *poinciana*. See the article POINCIANA, *Suppl.*

CAROB-*tree*, the Engliſh name of the *ſiliqua* of Tournefort and the *ceratonia* of Linnæus. See the article SILIQUA, *Suppl.*

Candy-CARROT, a name given by ſome to the *myrrhis*. See the article MYRRHIS, *Suppl.*

Deadly, or *ſcorching* CARROT, in botany, a name given to the *thapſia* of authors. See the article THAPSIA, *Suppl.*

Mountain CARROT, a name ſometimes given to a ſpecies of *fennel*. See the article FOENICULUM, *Suppl.*

CASSIA, in the Linnæan ſyſtem of botany is made to comprehend both the *caſſia* and *ſena* of Tournefort. See the articles CASSIA and SENA, *Suppl.*

CASSIDA, in zoology, the name given by Dr. Hill to a genus of beetles, called in Engliſh the tortoiſe-beetles. See the article SCARABÆUS, *Suppl.*

Under this genus are comprehended all the clypeated beetles, or thoſe covered with a hard cruſt, of which there are a great many ſpecies.

CASSIDONY, in botany, a name given by ſome to the *ſtoechas* of authors. See the articles STOECHAS, *Append.*

Mountain CASSIDONY, or *Golden* CASSIDONY, names uſed for the *gnaphalium* of authors. See the article GNAPHALIUM, *Suppl.*

CASSINE, the caſſioberry-tree, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: the cup is a decompound umbel; the perianthium is very ſmall, thick at the baſe, divided into five parts, obtuſe and permanent; the flower conſiſts of a ſingle petal, divided into five ſuboval, obtuſe, patent ſegments, larger than the cup; the ſtamina are five ſubulated patent filaments, ſhorter than the flower; the antheræ are ſimple; the germen of the piſtil is conic; there is no ſtyle; the ſtigmata are three, reflex and obtuſe: the fruit is a roundiſh berry, with three cells; the ſeeds are ſingle and oval.

The *maurocenia* is nearly allied to this genus, which Dillenius makes a ſpecies of *phyllerea*. Vide *Linnæi* Gen. Plant. p. 126.

CASSIOBERRY *tree*, in botany, the name of a genus of plants called by Linnæus *Caſſine*. See the article CASSINE, *ſupra.*

CASSUMNIAR, in the materia medica, a root approaching to the nature of zeodary, though belonging to a different ſpecies of plants.

We have it from the Eaſt Indies; its ſurface is ſomewhat wrinkled, and is marked at certain diſtances with circular rings, which ſurround it and riſe prominent above the reſt of the ſurface. It is of a very compact nature, hard and heavy; not eaſily cut through with a knife, or powdered in a mortar. When cut it ſhews a very ſmooth and ſhining ſurface; and when broken, is found to be much yellower within.

It has a fragrant aromatic ſmell, and is a very famous medicine in nervous caſes, being accounted an excellent cardiac and ſudorific. It is alſo given as a ſtomachic and carminative with ſucceſs, and is moſtly preſcribed in powder, boluſſes, or infuſions. Vide *Hill*, Hiſt. Mat. Med. p. 568.

CAT, the Engliſh name of a well known domeſtic quadruped, of the *felis* kind. See the article FELIS, *Suppl.*

CAT-*mint*, in botany, the Engliſh name of the *cataria* of authors. See the article CATARIA, *Suppl.*

CATARACT *(Cycl.* and *Suppl.)* — Though it be, generally ſpeaking, true, that the cauſe of *cataracts* is the opacity of the cryſtalline humor, yet it is certain that a real membrane covering the pupil, has been ſometimes, though rarely, found. See Mem. Acad. Scienc. 1708. and Dr. *Mead*'s Monit. & Pract. Medic. cap. xi.

CATERPILLAR *(Suppl.)*—*Connaught* CATERPILLAR, a kind of caterpillar found in Ireland. See the article WORM, *Suppl.*

CATERPILLAR-*plant*, in botany, a name given to the *ſcorpioides* of Tournefort. See the article SCORPIOIDES, *Suppl.*

CATERPILLAR-*ſhell*, the Engliſh name of a ſpecies of *turbo*. See the article TURBO, *Suppl.*

CAUDA *marina*, in botany, the name uſed by Dodonæus for the *myoſurus* of botanical writers. See the article MYOSURUS, *Append.*

Dead CAVES, *Live* CAVES } See the article LIVE *caves*, *Suppl.*

CEDAR *(Suppl.)*—*Baſtard* CEDAR, a name given to the *guazuma*, or *theobroma*, of authors. See the article THEOBROMA, *Suppl.*

Bermudas CEDAR, a name given to a ſpecies of juniper. See the article JUNIPER, *Suppl.*

CEDAR *of Lycia*, or *Phœnicia*, names given to a ſpecies of juniper. See the article JUNIPER, *Suppl.*

Virginia and Carolina CEDAR, names given to a ſpecies of juniper. See the article JUNIPER, *Suppl.*

White CEDAR, a name given to a ſpecies of cypreſs. See the article CUPRESSUS, *Suppl.*

CEIBA, in botany, a name given to the *xylon* of authors. See the article XYLON, *Suppl.*

CELANDINE *(Suppl.)* *Leſſer* CELANDINE, in botany, the name of a genus of plants called by authors *ranunculus*. See the article RANUNCULUS, *Suppl.*

CELASTRUS, in botany, the name of a genus of trees, called alſo *euonymoides*, and in Engliſh, the African ſpindle-tree.

The characters are theſe: the cup is a very ſmall plane perianthium, formed of one leaf, divided into five unequal obtuſe ſegments: the flower conſiſts of five equal, oval, patent, ſeſſile petals, with their tops turned back; the ſtamina are five ſubulated filaments, of the length of the flowers; the antheræ are very ſmall, the germen of the piſtil is alſo very ſmall, and is immerſed in a large plane receptacle marked with ten ſtriæ; the ſtyle is ſubulated and ſhorter than the ſtamina; the ſtigma is obtuſe and trifid; the fruit is a coloured oval capſule, obtuſely trigonal, gibbous, formed of three valves, and containing three cells, in each of which are ſome oval coloured ſeeds, ſmooth and half covered by a calyptra, which is alſo coloured, and has an unequal rim divided into four parts. *Linnæi* Gen. Plant. p. 88.

There is a ſpecies with a triple ſtigma, and no ſtyle.

CELLS *of plants*, *Cellæ plantarum*, thoſe partitions or hollow places in the huſks or pods of plants, in which the ſeeds are lodged. *Miller*, Gard. Dict.

CENTAURIA, in the Linnæan ſyſtem of botany, the name of a large genus of plants, comprehending the *centaurium majus*, *jacea*, and *cyanus* of Tournefort and others; the *calcitrapa*, *calcitrapoides*, *rhaponticum*, *rhaponticoides*, *amberboi*, and *crocodilium* of Vaillant.

The characteriſtics of this genus are theſe: the cup is imbricated with ſquamæ; the ſtamina are five extremely ſhort capillary filaments; there is no ſtigma, nor pericarpium; the receptacle is ſetoſe.

As to the diſtinctions of the above genera, as they are called, they are theſe: the cup of the *calcitrapa* is armed with ſingle ſpines, which are large and erect; and the ſeeds either naked or coronated: the cup of the *calcitrapoides* has ſmall cluſtered ſpines: the cup of the *rhaponticum* is formed of lax undivided membranes: and in the *rhaponticoides*, of lanceolated and acuminated ſquamæ: in the *amberboi*, the ſquamæ of the cup are obtuſe and ſimple: in the *jacea* the ſquamæ are ciliated: in the *cyanus* they are likewiſe ciliated, but ſhorter; and, laſtly, the ſquamæ in the *crocodilium* are aculeated, and the ſeed downy and plumoſe. Vide *Linnæi* Gener. Plant. p. 417.

CENTAURIUM *majus*. This is made a diſtinct genus of plants by Tournefort, but comprehended along with ſeveral others under that of *centauria* by Linnæus. See the article CENTAURIA, *ſupra.*

CENTAURY, in botany. See the article CENTAURIUM, *Suppl.*

CENTIPED *worm*, a term uſed for ſuch worms as have a great many feet, tho' the number does not amount to an hundred, as the word ſeems to import. See the article SCOLOPENDRA, *Suppl.*

Mr. Maloet relates the hiſtory of a man, who for three years had a violent pain at the lower part of the forehead, near the root of the noſe; at length he felt an itching, and afterwards ſomething moving within his noſtril, which he brought away with his finger; it was a worm of the *centiped* kind, an inch and an half long, which run ſwiftly. It lived five or ſix days among tobacco. The patient was free of his pain ever after. Mr. Littre mentioned a like caſe in 1708, of a larger *centiped* voided at the noſe, after it had thrown the woman, in whoſe frontal ſinus it was, into convulſions, and had almoſt taken away her reaſon. Hiſt. Acad. Scienc. 1733.

CENTRONIA, in ichthyology, the name by which Dr. Hill calls the *echini marini*, or *echinodermata*, called in Engliſh ſea-hedge-hogs. See the article ECHINODERMA, *Suppl.*

The doctor makes them a diſtinct ſeries of animals, living under the defence of ſhelly coverings, formed of one piece, and furniſhed with a vaſt number of ſpines, moveable at the creature's pleaſure.

Of the *centronia*, or ſea-hedge-hog, we have the following ſpecies: 1. The roundiſh *centronia*, with ſmall papillæ: this is a conſiderably large ſpecies; the colour of the whole ſhell being of a duſky red, and the ſpines only a third of an inch long. 2. The roundiſh *centronia*, with very large ſquare ſpines. 3. The roundiſh *centronia*, with very large rounded ſpines. 4. The roundiſh bluiſh *centronia*, with differently ſhaped ſpines. 5. The depreſſed cordated *centronia*, with capillaceous ſpines. 6. The depreſſed flat *centronia*, with a digitated edge. 7. The depreſſed plane *centronia*, with five perforations on the diſk. 8. The depreſſed *centronia*, with two perforations near the edge. 9. The flat biperforate *centronia*, with a digitated edge. 10. The oval depreſſed *centronia*, with an undulated edge and ſix perforations. 11. The roundiſh *centronia*, with crooked and faſciculated ſpines, called in Engliſh the ſea-apple. 12. The globoſe *centronia*, with needle-like ſpines, and thence called the needle-ſhell.

The other ſpecies of *centronia* are very numerous, but may be all comprehended under the following diviſions. 1. The roundiſh

roundiſh, or ſubgloboſe kind, called by Klein *cidares*. See the article TURBAN-*ſhell*, *Suppl.*

2. The cordated kinds, called by Klein *ſpatangi* and *ſpatagoides*. See the articles SPATANGI and SPATAGOIDES, *Suppl.*

3. The flat kinds, called by Klein *placentæ*. See the article PLACENTA, *Suppl.*

Klein, who has been at much pains to arrange theſe bodies, has divided them into a number of other genera; but they may be all ranked under one or other of theſe diviſions. But beſide the known recent ſpecies, we meet with ſeveral others, foſſile, of a very ſingular figure; for which ſee the articles ECHINITES and ECHINI *foſſiles*, *Suppl.*

CEPA *Aſcalonica*, the ſame with eſchalot, vulgarly called *ſhallot*. See ONION, *Suppl.*

CEPHALANTHUS, in the Linnæan ſyſtem of botany, the name of a genus of trees, the characters of which are theſe: the cup conſiſts of a common perianthium, which contains ſeveral flowers collected into a kind of head; and of a proper perianthium, which is erect, permanent, and divided into four ſegments; the flower conſiſts of a ſingle petal; the tube is ſlender; the limb is divided into four parts, acute, reflex, and of the length of the tube; the ſtamina are four filaments, inſerted into the flower, and ſhorter than its limbs; the antheræ are ſimple; the germen of the piſtil is placed within the flower; the ſtyle and ſtigma are both ſimple; the fruit is an oblong capſule, containing only one cell, ſeveral of theſe grow together, and form a roundiſh head; the ſeeds are numerous and oblong; the flower has its limb ſometimes divided into five ſegments, inſtead of four; and then the proper perianthium has alſo five ſegments, and there are five ſtamina.

This genus comprehends the *platanocephalus* of Vaillant, and the *valerianoides* of Petiver. Vid. *Linnæi* Gen. Plant. p. 38.

CERAMBYX, a name given by ſome authors to the *capricorn-beetle*. See CAPRICORN *beetle*, *Suppl.*

CERATONIA, in botany, the name under which Linnæus deſcribes the *ſiliqua* of Tournefort. See SILIQUA, *Suppl.*

CERCARIA, in zoology, a claſs of animalcules lately eſtabliſhed by Dr. Hill, and containing all thoſe with viſible tails and no limbs. See the article ANIMALCULE, *Append.*

CERCIS, in the Linnæan ſyſtem of botany, the name of a diſtinct genus of plants, called by Tournefort *ſiliquaſtrum*. See the article SILIQUASTRUM, *Suppl.*

CERNUA, in zoology, a name uſed by Gaza for the *orpheus*, a ſpecies of *ſparus*. See the article ORPHEUS, *Suppl.*

CESSAMPELUS, a name by which many call the hoary branched ſpecies of *convolvulus*. See the article CONVOLVULUS, *Suppl.*

CESTRUM, in the Linnæan ſyſtem of botany, the name of a genus of plants, called by other botaniſts *jaſminoidis ſpecies* and *hediunda*.

The characters are theſe: the cup is a ſmall, cylindric, obtuſe, perianthium, formed of a ſingle leaf, which is divided into five ſegments at the rim, erect, and obſcure; the flower conſiſts of a ſingle infundibuliform petal; the tube is cylindric, very long and ſlender, the opening being roundiſh and the limb plicated, and formed into five equal oval ſegments; the ſtamina are five thread-like filaments, adhering longitudinally to the tube, only ſending out a little denticle in the middle, which ſtands inward; the antheræ are roundiſh, but ſomewhat tetragonal, and ſtand within the opening of the petal; the germen of the piſtil is of a cylindric, but ſomewhat oval form, of the length of the cup; the ſtyle is filiform, and of the length of the ſtamina; the ſtigma is thick, obtuſe, and ſlightly emarginated; the fruit is an oval oblong berry, containing only one cell; in which are numerous and roundiſh ſeeds. *Linnæi* Gen. Plant. p. 82.

CHACE *(Cycl.)—Wild goose* CHACE, a term uſed to expreſs a ſort of racing on horſeback, uſed formerly, which reſembled the flying of wild geeſe, thoſe birds generally going a train one after another, not in confuſed flocks as other fowls do. In this ſort of race the two horſes after running twelve ſcore yards had liberty, which horſe ſoever could get the leading, to ride what ground the jockey pleaſed, the hindmoſt horſe being bound to follow him within a certain diſtance agreed on by articles, or elſe to be whipped in by the tryers and judges who rode by; and which ever horſe could diſtance the other, won the race. This ſort of racing was not long in common uſe, for it was found inhuman and deſtructive to good horſes when two ſuch horſes were matched together. For in this caſe neither was able to diſtance the other 'till they were both ready to ſink under their riders, and often two very good horſes were both ſpoiled, and the wagers forced to be drawn at laſt. The miſchief of this ſort of racing ſoon brought in the method now in uſe, of running only a certain quantity of ground, and determining the plate or wager, by the coming in firſt at the poſt.

CHÆTIA, in zoology, the name of a genus of inſects of the *apteria* kind, without any viſible limbs. See INSECT, *Append.*

The *chætia* reſembles a hair, or a piece of fine thread; its ſurface is ſmooth, its body rounded, and very ſlender in proportion to its length. It is called in Engliſh the *hair-worm*, or *guinea-worm*. *Hill*'s Hiſt. of Anim. p. 14. See the article WORM, *Suppl.*

CHAFFER, in zoology, the Engliſh name of a ſpecies of beetle. See the article SCARABÆUS, *Suppl.*

CHAFFINCH, in ornithology, a bird of the *fringilla* kind, with a ferrugineous breaſt, and the wings black, ſpotted with white. See the article FRINGILLA, *Suppl.*

CHALICE-*ſhell*, or CUP-*ſhell*. See SHELL, *infra.*

CHALK *(Suppl.)—Silver* CHALK, *argentaria creta*, the Engliſh name of a kind of earth, not *chalk*. See the article ARGENTARIA *creta*, *Suppl.*

CHAMÆCRISTA, in botany, the name given by Rivinus to the *caſſia* of other botaniſts. See the article CASSIA, *Suppl.*

CHAMÆMILE, in botany, a name given to the *chamæmelum* of authors. See the article CHAMÆMELUM, *Suppl.*

CHAMÆMORUS, in botany, the name of a genus of plants, the characters of which are theſe: the flower conſiſts of five leaves; the fruit is compoſed of many acini, in form of the mulberry.

There is only one ſpecies of this plant known, which grows on the tops of the higheſt hills in the north part of England, but cannot be cultivated in a garden by any art. Vid. *Miller*'s Gard. Dict. in voc.

CHAMBER *(Cycl.)*—As to the proportions of *chambers*, their length ſhould be to the breadth as $1\frac{1}{2}$ to 1, or ſome ſmall matter leſs, but ought never to exceed that proportion; and as for the height, it ſhould be three fourths of the breadth. The height of the *chambers* of the ſecond ſtory, ſhould be a twelfth part leſs than the height of thoſe below: thus, if the height of the firſt ſtory be ſixteen feet, that of the ſecond will be fourteen feet eight inches. As to the height of the third ſtory, it ſhould be only three fourths of the ſecond.

In building bed-*chambers*, regard ſhould be had as well to the ſituation of the bed, as to that of the chimney. For which reaſon, the chimney ought not to be placed juſt in the middle, but diſtant from it about two feet, or two and an half, in order to make room for the bed, which prevents this inequality from being diſcerned. Build. Dict. in voc.

CHAR, in ichthyology. See the article CHARRE, *Suppl.*

CHARVIL, or CHERVIL, in botany. See the article CHERVIL, *Suppl.*

CHEESE-*runnet*, in botany, a name uſed by ſome for the *gallium* of authors. See the article GALLIUM, *Suppl.*

CHEMICAL *glaſſes*, how cæmented, when cracked: ſee the article CÆMENT, *Append.*

CHERMES, in the hiſtory of inſects, a genus of the four-winged flies, the roſtrum of which is ſituate under the breaſt, and the lateral legs formed for leaping.

This genus comprehends the alder-bug, the fir-tree-bug, the graſs-bug, and elm-tree-bug; together with thoſe of the birch, maple, willow, aſh, nettle, apple-tree, poplar, *&c.* *Hill*'s Hiſt. of Anim. p. 64.

CHERRY-*tree*, in botany, the Engliſh name of a diſtinct genus of plants, called by authors *ceraſus*. See the article CERASUS, *Suppl.*

Barbadoes-CHERRY, or *cowhedge*-CHERRY, names given by ſome to the *malpighia* of authors. See the article MALPIGHIA, *Suppl.*

Bay-CHERRY, *Bird*-CHERRY, *Laurel*-CHERRY, *&c.* names uſed by ſome for a genus of plants, called by authors *padus*. See the article PADUS, *Append.*

Cornelian-CHERRY, a name given by ſome to the *cornus*, or cornel-tree, of others. See the article CORNUS, *Suppl.*

Winter-CHERRY, a name uſed by ſome for the *alkekengi* and *ſolanum* of others. See the articles ALKEKENGI and SOLANUM, *Suppl.*

CHERVIL *(Suppl.)* — *Wild*-CHERVIL, in botany, a name given to the *myrrhis* of authors. See the article MYRRHIS, *Suppl.*

CHESNUT-*tree*, the Engliſh name of a genus of plants, called by authors *caſtanea*. See the article CASTANEA, *Suppl.*

It is pity *cheſnut*-plantations are not more common. They quickly grow up, and are not only pleaſing to the eye, but their flowers prove no leſs agreeable to the ſmell, and even the taſte will be gratified in time. Another conſiderable uſe of theſe plantations, is to defend thoſe of other trees from the injuries of cold and froſt, which they do to admiration.

Next to oak-timber, that of *cheſnuts* is moſt coveted by carpenters and joiners. It likewiſe makes the beſt ſtakes, vine-props, and hop-poles; and is extremely proper for mill-timber, and water-works, or wherever it may lie buried.

Cheſnut-timber is alſo proper for columns, tables, cheſts, chairs, ſtools, bedſteads, and wine-caſks; giving the liquor the leaſt tincture of any wood whatſoever, and is exceeding durable, if dipped in ſcalding oil, or well pitched. Build. Diction. in voc.

Horſe-CHESNUT, in botany. See HIPPOCASTANUM, *Suppl.*

Scarlet-horſe-CHESNUT, a name given by ſome to the *pavia* of authors. See the article PAVIA, *Suppl.*

CHIAN *marble*. See the article CHIUM *marmor*, *Suppl.*

CHIARO *ſcuro*, among painters. See CLAIR *obſcure*, *Cycl.*

CHICHES,

CHICHES, a name given to the *cicer*, or chich-pea. See the article CICER, *Suppl.*

CHICK-*weed (Suppl.)*—*Berry bearing* CHICK-*weed*, in botany, a name given to the *cucubalus*. See the article CUCUBALUS, *Suppl.*

CHICKLING-*pea*, a name uſed by ſome for the *lathyrus* of authors. See the article LATHYRUS, *Suppl.*

Cæments for broken CHINA-ware. See CÆMENT, *Append.*

CHIONANTHUS, the *ſnow-drop-tree*, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: the cup is a one-leaved perianthium, divided into four ſegments at the edge, erect, acuminated, and permanent; the flower conſiſts of a ſingle petal, and is divided into four parts; the tube is very ſhort and patulous; the limb is divided into four extremely long ſegments, which are erect, acute, of a linear figure, and ſomewhat uneven; the ſtamina are two very ſhort filaments, of a ſubulated figure, and are inſerted into the tube; the antheræ are cordated and erect; the germen of the piſtil is of an oval figure; the ſtyle is ſimple and of the length of the cup; the ſtigma is obtuſe and trifid; the fruit is a round berry, containing only one cell, in which is included a ſingle ſtriated oſicle. *Linnæi* Gen. Plant. p. 8.

This genus is allied to the *nyctanthes*, *ſyringa*, *olea*, *liguſtrum*, *phillyrea*, and *jaſmine*, but, moſt of all, to the flower bearing *fraxinus*. There is only one known ſpecies of it.

CHIVES, a name given to a ſpecies of onion. See the article ONION, *Suppl.*

CHIVES is alſo a name given to the ſtamina of plants. See STAMINA, *Suppl.*

CHLOREUS, a name given to a bird of the thruſh kind, otherwiſe called *galbula*. See GALBULA.

CHOCOLATE-*tree*, in botany. See the article CACAO, *Suppl.*

CHOUGH, *coracias*, a bird of the corvus kind, no where ſo frequent with us as in Cornwall, and thence called the *corniſh chough*. See the article CORACIAS, *Suppl.*

CHRENECRUDA, a term occurring in writers of the middle age, and expreſſing a cuſtom of thoſe times, but its ſignification is doubtful. It is mentioned in *Lege Salica*, Tit. 61. which ſays, he who kills a man, and hath not wherewithal to ſatisfy the law, or pay the fine, makes oath that he has delivered up every thing he was poſſeſſed of; the truth of which muſt be confirmed by the oaths of twelve other perſons. Then he invites his next relations by the father's ſide to pay off the remainder of the fine, having firſt made over to them all his effects by the following ceremony. He goes into his houſe, and taking in his hand a ſmall quantity of duſt from each of the four corners, he returns to the door, and with his face inward throws the duſt with his left hand over his ſhoulders upon his neareſt of kin. Which done, he ſtrips to his ſhirt; and coming out with a pole in his hand, jumps over the hedge. His relations, whether one or ſeveral, are upon this obliged to pay off the compoſition for the murder. And if theſe (or any one of them) are not able to pay, *iterum ſuper illum chrenecruda qui pauperior eſt, jactat, & ille totam legem componat.* Whence it appears, that *chrenecruda jactare*, is the ſame with throwing the duſt, gathered from the four corners of the houſe. Goldaſtus and Spelman tranſlate it *viridem herbam*, green graſs, from the German *gruen kraut*, or from the Dutch *groen*, green, and *gruid*, graſs. Wendelinus is of a contrary opinion, who thinks that by this word *denotari purificationis approbationem*, from *chrein*, pure, chaſte, clean; and *keuren*, to prove: ſo that it muſt refer to the oaths of the twelve jurors. Be this as it will, king Childebert reformed this law by a decree, chap. 15. both becauſe it favoured of pagan ceremonies, and by reaſon ſeveral perſons were thereby obliged to make over all their effects: *De crenecruda lex quam paganorum tempore obſervabant, deinceps nunquam valeat, quia per ipſam cecidit multorum poteſtas. Du Cange*, Gloſſ. Lat.

CHRISTMAS-*roſe*, in botany, the name uſed by ſome for a ſpecies of black *hellebore*. See the article HELLEBORUS, *Suppl.*

CHRISTOPHER-*herb*. See the article CHRISTOPHORIANA, *Suppl.*

CHROASTACES, in natural hiſtory, a genus of pellucid gems, comprehending all thoſe of variable colours, as viewed in different lights.

Of this kind are the *opal* and the *aſteria*, or *oculus cati*. See the articles OPAL and ASTERIA, *Suppl.*

CHRONOMETER, a term uſed by ſome for a kind of clock, or machine, ſo contrived as to meaſure a ſmall part of time very exactly, even to the ſixteenth part of a ſecond.

We have a deſcription of one of theſe, made by the ingenious Mr. George Graham, in *Deſaguliers*, Experim. Philoſ. vol. I. p. 375.

A *chronometer* is of great uſe for meaſuring ſmall parts of time in aſtronomical obſervations, the time of the fall of bodies, the velocity of running waters, &c. But long ſpaces of time cannot be meaſured by it with ſufficient exactneſs, unleſs its pendulum be made to vibrate in a cycloid; becauſe, otherwiſe, it is liable to err conſiderably, as all clocks are which have ſhort pendulums that ſwing large arcs of a circle. Id. ibid. p. 376.

CHROSTASIMA, in natural hiſtory, the name uſed by Dr. Hill for all pellucid gems, which have one ſimple and permanent appearance in all lights.

Of this kind are the diamond, the carbuncle, the amethyſt, the ſapphire, the beryl, the emerald, and the topaz. See the articles DIAMOND, CARBUNCLE, &c. *Suppl.*

CHRYSALIS, in natural hiſtory, the name of that ſtate otherwiſe called *aurelia*, in which butterflies and ſeveral other animals paſs the time between their caterpillar or other creeping ſtate, and their winged one.

In this ſtate no creatures afford ſo beautiful a variety as the butterfly kinds; and they all paſs thro' this middle ſtate, without one exception.

The figure of the *aurelia* or *chryſalis*, generally approaches to that of a cone, or at leaſt the hinder part of it is of this ſhape; and the creature, while in this ſtate, ſeems to have neither legs nor wings, nor has any power of walking. It ſeems, indeed, to have hardly ſo much as life, and to be reduced to a very imperfectly organized maſs of matter. It takes in no nouriſhment in this ſtate, nor has it any organs for the taking any; and indeed its poſterior part is all that ſeems animated, this having a power of giving itſelf ſome motions. The external covering of the *chryſalis* is cartilaginous and conſiderably large, and is uſually ſmooth and gloſſy; but ſome few of them have a few hairs, ſome are alſo as hairy as the caterpillars from which they are produced, and others are rough, or, as it were, chagreened all over.

In all of theſe there may be diſtinguiſhed two ſides; the one of which is the back, the other the belly of the animal; and on the anterior part of the latter, there may always be diſtinguiſhed certain little elevations running in ridges and reſembling the fillets wound about mummies. The part whence theſe have their origin, is eſteemed the head of the animal; the other ſide or back is ſmooth, and is of a rounded figure in moſt of the *chryſaliſes*; but ſome have ridges on the anterior part and ſides of this part; and theſe uſually terminate in a point, and make an angular appearance on the *chryſalis*.

From this difference is drawn the firſt general diſtinction of theſe bodies. They are by this divided into two claſſes; the round and the angular kinds. The firſt kind are by the French naturaliſts called alſo *feves*, from the common cuſtom of calling the *chryſalis* of the ſilk worm, which is round, by this name.

There is ſomething more regular in this diſtinction alſo than might be at firſt conceived; for the diviſion is continued from the fly ſtate: the rounded *chryſaliſes* being almoſt all produced by the phalenæ or moths; and the angular ones by the papilios or day-flies. There are ſeveral ſubordinate diſtinctions of theſe kinds, but in general they are leſs different from one another than the caterpillars from whence they are produced.

The head of thoſe of the firſt claſs, uſually terminates itſelf by two angular parts, which ſtand ſeparate one from the other, and reſemble a pair of horns. In ſome theſe horns are bent into the form of creſcents, and turned one towards the other. The elm caterpillar, called the *bedaude*, is one that furniſhes a *chryſalis* of this kind; other *chryſaliſes* have only one ſuch horn, inſtead of two. Theſe horns always give a remarkable figure in their extenſion along the belly of the *chryſalis*; and when the bark is examined, there is a very remarkable appearance from the lines which run there, the figure often reſembling, very exactly, a human face, or a maſque of ſome kind: there is an eminence in the middle of the back, which repreſents a noſe as well as an engraver could have faſhioned it; and there are always a number of other marks and eminences, which imagination may form into eyes, chin, and the other parts of a face; and often the reſemblance is ſo perfect as to ſurprize the obſerver.

There are a great variety, and a great deal of beauty in the figures and arrangement of the eminences and ſpots on the other parts of the body of the *chryſalis* of different kinds; ſome have an arrangement of elegant figures all along one ſide, and ſeeming to be a ſort of prickles propagated from every ring of the body; and others have a ſecond arrangement of theſe ſort of ſpines, which begin about the end of the figure of the human face, and run quite to the extremity. The *chryſaliſes* that are thus furniſhed, appear actually prickly; and there are ſome others which have only a few of theſe prickles on every part; but theſe have uſually two protuberances on their ſides, which have the appearance of the fins of fiſhes. Theſe and the like varieties in marks and figure, give very plain means of dividing the *aurelia* of the ſeveral claſſes into a number of diſtinct genera.

It is a general obſervation, that thoſe *chryſaliſes* which are terminated by a ſingle horn, afford day-butterflies of the kind of thoſe which have buttoned antennæ, and whoſe wings, in a ſtate of reſt, cover the under part of the body, and which uſe all their ſix legs in walking, thoſe of many other kinds uſing only four of them. Thoſe *chryſaliſes*, which are terminated by two angular bodies, and which are covered with a great number of ſpines, and have the figure of a human face on their back in the greateſt perfection, afford butterflies of the day kind and of that claſs, the characters of which are, their walking on four legs and uſing the other two, that is, the anterior pair, in the manner of arms or hands. The

chryſaliſes which have two angular bodies on their heads, but ſhorter than thoſe of the preceding, and whoſe back ſhews but a faint ſketch of the human face, and which have fewer ſpines, and thoſe leſs ſharp, always turn into that ſort of butterfly, the upper-wings of which are divided into ſegments, one of which is ſo long as to repreſent a tail, and whoſe under-wings are folded over the upper part of the back. A careful obſervation will eſtabliſh many more rules of this kind, which is not ſo perfect as to be free from all exceptions, yet are of great uſe, as they teach us in general what ſort of fly we are to expect from the *chryſalis*, of which we know not the caterpillar, and therefore can only judge from appearances.

Theſe are the principal differences of the angular *chryſaliſes*; the round ones alſo have their different marks not leſs regular than thoſe.

The greater number of the round *chryſaliſes* have the hinder part of their body of the figure of a cone; but the upper end, which ought to be its circular plane baſe, is uſually bent and rounded into a ſort of knee: this is uſually called the head of the *chryſalis*; but there are alſo ſome of this kind, the head of which is terminated by a nearly plane ſurface: ſome of the creeping ten-legged caterpillars give *chryſaliſes* of this kind, which have each of them two eminences that ſeem to bring them towards the angular kind. Some of theſe are of a long and ſlender conic figure, terminating in a ſharp point; others are more thick and ſhort, and blunter at the ends; and ſome are very ſhort, and have no part conic except the point: in ſome of the kinds alſo the rounded end or head is flatted on two ſides, and this flatneſs is continued a little way along the belly; and of the conic ones, ſome have a ſort of hollow on the back, reſembling engraved work. Some of this kind alſo are not conic, but are flatted on the belly, and only rounded on the back; and ſome of them have, as it were, a ſort of noſe that bends over the belly.

Among the angular *chryſaliſes* there are ſome whoſe colours ſeem as worthy our obſervation as the ſhapes of the others. Many of them appear ſuperbly clothed in gold: and this in the ſeveral ſpecies is of ſeveral colours; in ſome it is a pure yellow, in others a very pale whitiſh yellow, and in others a greeniſh; but in all, the gold is very bright, and appears like the burniſhed parts of gilding. It is theſe elegant ſpecies which have obtained the names of *chryſalis* and *aurelia*, which are derived from Greek and Latin words, ſignifying gold; and from theſe all other bodies of the ſame kind have been called by the ſame names, though leſs or not at all entitled to them. As ſome kinds are thus gilded all over, ſo others are ornamented with this gay appearance in a more ſparing manner, having only a few ſpots of it in different places on their back and belly. Some ſpecies alſo have ſilver in the place of gold, either extending itſelf all over them, or forming ſome particular ſpots upon their back and belly. Theſe obvious marks, however, are not to be depended upon as certain characters of diſtinction, for accidents in the formation of the *chryſalis* may alter them; and thoſe which naturally would have been gilded all over, may be ſometimes only ſo in part, and either theſe or the others may by accidents be ſo formed as to ſhew nothing of this kind at all, but be only of a duſky brown. Thoſe, however, which have neither ſilver nor gold to recommend them to our eyes, do not want other colours, and thoſe beautifully variegated. Some of them are all over of an elegant green, as is the *chryſalis* of the fennel caterpillar; others are of an elegant yellow, and ſome of a bright greeniſh tinge, variegated with ſpots of a ſhining black; we have a very beautiful inſtance of this laſt kind in the *chryſalis* of the elegant cabbage-caterpillar. The general colour of the *chryſalis* of the common butterflies, however, is brown: they are of a very elegant cheſnut colour, and vary from this into all the ſhades of brown, from the moſt deep and duſky to ſuch as are almoſt white. Some alſo are of a fine deep black, and of theſe many are ſo ſmooth and gloſſy, that they are equal to the fineſt Indian japan. The common caterpillar of the fig-tree gives an inſtance of one of theſe beautifully gloſſy ones; the caterpillar of the vine affords another of theſe fine black *chryſaliſes*.

The rounded *chryſaliſes* do not afford any thing of that variety of colouring ſo remarkably beautiful in the augular ones; they are uſually of a duſky yellow, in different ſhades, and are often variouſly ſpotted with black: but theſe, as well as all other *chryſaliſes*, before they arrive at their fixed colour, paſs through ſeveral other temporary ones, ſome being of a different colour when firſt produced from the caterpillar, from what they are a few days afterwards; and ſome varying ſo greatly, though only in degree, as not to be diſtinguiſhable by the moſt converſant eye for what they were when firſt produced. The green rough caterpillar of the cabbage has a *chryſalis* which is green at firſt, and from that gradually goes through all the ſhades of green to a faint yellow, which is its laſting colour; and one of the oak caterpillars yields a *chryſalis* beautifully ſpotted with red at its firſt appearance, but theſe ſpots change to brown for their fixed colour: the third day from their formation uſually fixes their laſting colours; and if they are obſerved to turn black in any part after this time, it is a ſign that they are dead or dying.

The ſeveral ſpecies of inſects, as a fly, a ſpider, and an ant, do not differ more evidently from one another, in regard to appearance, than do a caterpillar, its *chryſalis*, and a butterfly produced from it; yet it is certain that theſe are all the product of the ſame individual egg; and nothing is more certain than that the creature which was for a while a caterpillar, is, after a certain time, a *chryſalis*, and then a butterfly. Theſe great changes produced in ſo ſudden a manner, ſeem like the metamorphoſes recorded in the fables of the antients, and indeed it is very probable that thoſe fables firſt took their origin from theſe changes. It appears in theſe caſes, that an inſect is immediately transformed into another perfectly different inſect, and this was for a long time ſuppoſed to be really the caſe: better obſervation, however, and the more improved modern philoſophy informs us, that nature does not uſe any ſuch violent and ſudden changes in any of her operations. Malpighi and Swammerdam were the firſt who traced the animal through all its ſeveral forms, and they ſoon found that there was in reality no ſuch change as was here talked of, but that the creature remained the ſame in all: they diſſected the creature a little before the times of their ſeveral changes, and found that the whole ſuppoſed metamorphoſis was due to the firſt ſtate's being a ſort of caſe, under cover of which it was neceſſary that certain parts, hereafter to become neceſſary to the animal, ſhould arrive at their proper ſtate; and that theſe parts were very diſtinct in the body of the animal at the time that it threw off its outer coat, in order to appear in another form, in which they had a better opportunity of becoming as dry and hard as they ought to be, and to be prepared for their final appearance in the open ſtate of the flying inſect. They evidently ſaw and proved, that the butterfly was all the time alive and growing within the body of the caterpillar, and that this growth was effected by a developement of parts, as we ſee to be the caſe in all ſorts of organized bodies, in the vegetable as well as animal world: and while they threw off all the falſe marvels of the tranſformations and changes which the world had before believed, in regard to theſe animals, they gave matter enough of real admiration in the diſcovery of the truth itſelf.

The words tranſformation and metamorphoſis then are found to be falſe terms in theſe ſubjects; but as we have already explained the true ſyſtem of the whole, we may be allowed to uſe theſe ſtill, as the moſt received terms, for theſe ſudden changes.

Every animal of this kind, we find, undergoes two of theſe tranſformations, the one out of the caterpillar into the *chryſalis*, the other out of the *chryſalis* into the butterfly. The laſt of theſe, when properly conſidered, has nothing very wonderful in it, as we find, on an accurate inſpection, that the *chryſalis* itſelf is a butterfly, only folded over with a thin ſkin. We find in it, while yet in this ſtate, every part of a butterfly; the wings, the legs, the antennæ, and the trunk may be all traced out; but they are folded and laid together in ſuch a manner, that the creature cannot in this ſtate make any uſe of them, nor is it fit that it ſhould, as they are all of them yet too ſoft and tender for uſe, and are placed in this ſtate with no other intent, than that they may be by degrees hardened.

The back of a *chryſalis*, when nicely obſerved, ſhews us the origin of the wings; and we may count in it the number of rings of the body. It is eaſy to find that there are nine of theſe rings; there are therefore three wanting of the number that the caterpillar had: theſe are the three at the anterior end, and of theſe the third, or that moſt diſtant from the head, is in part ſeen and in part hid by a cruſt, which is not divided in an annular manner, but which takes up the place of the two firſt rings; this is uſually called the corcelet, in the *chryſalis*, becauſe it is found to lie over the corcelet of the body of the encloſed butterfly: but it is on examining the other ſide, or belly of the *chryſalis*, that we find the ſeveral parts moſt peculiar to the butterfly. This part of the *chryſalis* is always carved as it were in relief, and every figure of this work is ſome part of the animal. Two plates, larger than all the reſt, which have their origin at the corcelet, and either touch or nearly meet one another on the belly, are the elevations formed by the four wings; theſe are placed two on each ſide, and have a much ſmaller extent allowed them than they have afterwards, when the animal is at liberty to fly about. There remains a triangular ſpace between the origin of the wings and the place where they meet in a point, and this is the receptacle of the parts, of the utmoſt conſequence to the animal. In this part one may eaſily trace nine ſtreaks, running longitudinally from the top, or head part, toward the tail; theſe are the legs, antennæ, and trunk of the butterfly, which are all extended ſtrait along the belly, in this ſtate; theſe are all much ſhorter than when the animal is in its perfect ſtate; and the trunk, when the *chryſalis* belongs to a ſpecies that has one, is not rolled up into a ſpiral form, but lies at length in the middle between the antennæ and pairs of legs.

The parts being thus diſtinguiſhable in the *chryſalis*, we eaſily find the difference of the ſpecies or claſs of the fly that is to proceed from it. The naked eye ſhews whether it be one of thoſe that have, or of thoſe that have not a trunk, and the aſſiſtance of a microſcope ſhews the antennæ ſo diſtinctly, that we are able to diſcern whether it belongs to the day or night claſs; and often to what genus, if not the very ſpecies: nay,

in the plumoſe horned kinds we may ſee by the antennæ whether a male or female phalena is to be produced from the *chryſalis*, the horns of the female being in this ſtate evidently narrower and appearing leſs elevated above the common ſurface of the body, than thoſe of the male.

All theſe parts of the *chryſalis*, however, though ſeen very diſtinctly, are laid cloſe to one another, and ſeem to form only one maſs; each of them is covered with its own peculiar membrane in this ſtate, and all are ſurrounded together by a common one, and it is only through theſe that we ſee them, or rather we ſee on theſe the figures of all the parts moulded within, and therefore it requires attention to diſtinguiſh them. There is however a time at which they are very eaſily diſtinguiſhed, when the external covering is thin and tranſparent, nay when this no longer exiſts, and when the others are perfectly tranſparent; and all the exterior parts may, after this ſtate, be eaſily ſeparated from one another. This however is at a time when it might be leaſt expected that any thing worthy obſervation ſhould appear; and therefore authors have diſregarded it; it is at that time when they ſay the whole is a maſs of jelly-like matter that this is to be ſeen, that is, at the time of its being firſt produced out of the body of the caterpillar; but this is a ſeaſon of ſhort duration, and muſt be careſully attended to.

The *chryſalis* is ſoft when firſt produced, and is wetted on the front with a viſcous liquor; its ſkin, though very tender at firſt, dries and hardens by degrees; but this viſcous liquor, which ſurrounds the wings, legs, &c. hardens almoſt immediately, and in conſequence faſtens all thoſe limbs, &c. into a maſs, which were before looſe from one another; this liquor as it hardens loſes its tranſparence and becomes brown: ſo that it is only while it is yet moiſt that theſe parts are to be ſeen diſtinct.

It is evident from the whole, that the *chryſalis* is no other than a butterfly, the parts of which are hid under certain membranes, which faſten them together, and when the limbs are arrived at their due ſtrength they become able to break through theſe membranes, and then expand and arrange themſelves in their proper order.

The firſt metamorphoſis therefore differs in nothing from the ſecond, except that the butterfly comes from the body of the caterpillar in a weak ſtate, with limbs unable to perform their offices; whereas it comes from the *chryſalis* perfect. *Reaumur*, Hiſt. Inſ. vol. i. p. 2—17. See the article FEVE, *Suppl.*

Mr. Reaumur has given us many curious obſervations on the ſtructure and uſes of the ſeveral coverings that attend the varieties of the caterpillar kind in this ſtate.

The creatures in general remain wholly immoveable in this ſtate, and ſeem to have no buſineſs in it, but a patient attendance on the time when they are to become butterflies: and this is a change that can happen to them only as their parts, before extremely ſoft and weak, are capable of hardening and becoming firm by degrees, by the tranſpiration of that abundant humidity which before kept them ſoft; and this is proved by an experiment of Mr. Reaumur, who encloſing ſome *chryſaliſes* in a glaſs tube, found, after ſome time, a ſmall quantity of water at the bottom of it, which could have come there no other way but from the body of the incloſed animal. This tranſpiration depends greatly on the temperature of the air: it is augmented by heat, and diminiſhed by cold; but it has alſo its peculiarities in regard to the ſeveral ſpecies of butterfly to which the *chryſalis* belongs.

According to theſe obſervations, the time of the duration of the animal in the *chryſalis* ſtate muſt be in different ſpecies very different; and there is indeed this wide difference in the extremes, that ſome ſpecies remain only eight days in this ſtate, and others eight months. It may be eaſily conceived from this, that there may be in one year two generations of caterpillars of the ſame ſpecies; and that the eggs laid by the butterfly in the latter end of autumn, having lain the winter in that ſtate, become hatched early in the ſpring, and the caterpillars produced from theſe being come to the *chryſalis* ſtate, remain in it but a little time, becauſe they are favoured by the warmth of the ſeaſon; and hatching into butterflies, theſe ſpeedily lay their eggs, that they may have a remainder of warm weather to be hatched in the remainder of the ſummer ſeaſon, and give a race of ſtrong caterpillars before the end of autumn: but circumſtances muſt happen very favourably in all reſpects, in order to bring this about.

Mr. Reaumur has proved that heat and cold make great differences in the time of hatching of the butterfly from the *chryſalis* ſtate: and this he particularly tried with great accuracy and attention, by putting them in veſſels in warm rooms, and in ice-houſes, and it ſeemed wholly owing to the haſtening or retarding the evaporation of the abundant humidity of the animal in the *chryſalis* ſtate, that it ſooner or later appeared in the butterfly form. He varniſhed over ſome *chryſaliſes*, in order to try what would be the effect of thus wholly preventing their tranſpiration; and the conſequence was, that the butterfly came forth from theſe two months later than their natural time. Thus was the duration of the animal in this ſtate lengthened, that is its life was lengthened, but that without any advantage to the creature, ſince it was in the time of its ſtate of inaction, and probably of inſenſibility.

Though this was of no conſequence, Mr. Reaumur deduces from it a hint that ſeems to be of ſome. He obſerves that hen's eggs, of which we make ſo many uſes, and eat in ſo many forms, are properly a ſort of *chryſalis* of the animal; their germ, after they are impregnated by the cock, containing the young animal alive, and waiting only a due degree of warmth to be hatched and appear in its own form. Eggs tranſpire notwithſtanding the hardneſs of their ſhells; and when they have been long kept, there is a void found near one of their ends between the ſhell and the internal membrane; this is a mark of their being ſtale, and is the effect of an evaporation of part of their humidity: and the ſame varniſh which had been uſed to the *chryſaliſes*, being tried on eggs, was found to preſerve them for two years, as freſh as if laid but the ſame day, and ſuch as the niceſt palate could not diſtinguiſh from thoſe that were ſo.

It is not yet known how much farther this uſeful ſpeculation might be carried, and whether it might not be of great uſe even to human life, to invent ſomething that ſhould act in the manner of this varniſh, by being rubbed over the body, as the athletæ did of old, and the ſavages of the Weſt Indies do at this time, without knowing why. See the article EGGS, *Suppl.*

But to return to the inſects which are the ſubjects of this article: their third ſtate, that in which they are winged, is always very ſhort, and ſeems deſtined for no other action but the propagation of the ſpecies. See the article GENERATION, *Suppl.*

CHRYSTAL *(Suppl.)*—*Sprig* CHRYSTAL, the Engliſh name of a genus of *chryſtals*, called by authors *ellipomacroſtyla*. See the article ELLIPOMACROSTYLA, *Suppl.*

Pebble CHRYSTAL, the name of a ſpecies of *petridium*. See the article PETRIDIA, *Append.*

CHRYSOLITE *paſte*. The way of making an artifical *chryſolite* paſte is this: take of prepared *chryſtal* two ounces, ordinary red lead eight ounces; mix theſe well together, and add crocus martis made with vinegar, twelve grains: mix all together; put them into a crucible, lute it over, and bake the whole for twenty-four hours, or longer, in a potter's kiln, and it will produce a very elegant reſemblance of the true *chryſolite*.

CHRYSOMELA, in zoology, a genus of inſects frequently confounded with the beetles, the antennæ of which are made in form of bracelets, or necklaces of beads, and are thickeſt toward their extremity: the body, in figure, approaches to oval, and the thorax is oblong and rounded.

Of this genus Dr. Hill enumerates a great many ſpecies, for which ſee his Hiſt. Anim. p. 43, *ſeq.* See alſo the article SCARABÆUS, *Suppl.*

CHRYSOMITHRES, in ornithology, the name by which ſome call the gold-finch. See the articles CARDUELIS, *Suppl.* and GOLD-FINCH, *Append.*

CHRYSOPHYLLUM, the *ſtar-apple*, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: the cup is a ſmall permanent perianthium, compoſed of five roundiſh leaves; the flower is formed of a ſimple campanulated petal; the limb being divided into ten ſegments, which are alternately roundiſh and patalous, and narrow and erect; the ſtamina are five ſubulated filaments; the antheræ are ſimple; the germen of the piſtil is roundiſh; the ſtyle is ſubulated; the ſtigma is ſimple; the fruit is a large berry, containing only one cell; the ſeeds are oſſeous, and three in number.

This genus comprehends the *cainito* of Plumier, and is of kin to the *rhamnus* and *ſideroxylum*. Vide *Linnæi* Gen. Plant, p. 81. See the articles RHAMNUS, *Suppl.* and SIDEROXYLUM, *Append.*

CHURN *owl*, a name given to a beautiful bird called by authors *caprimulgus*. See the article CAPRIMULGUS, *Suppl.*

CICUTARIA *(Suppl.)* is alſo uſed for a ſpecies of *cicuta*, or hemlock, called by ſome writers fool's-parſley. See the article CICUTA, *Suppl.*

Sweet CICUTARIA, the name ſometimes given to a ſpecies of *myrrhis*. See the article MYRRHIS, *Suppl.*

CIBOULS, a name given by ſome to a ſpecies of onions. See the article ONION, *Suppl.*

CICELY, the name of a genus of plants, called by authors *myrrhis*. See the article MYRRHIS, *Suppl.*

CILERY, in architecture, a term uſed to denote the drapery, or leaveage, which is wrought upon the heads of pillars. Build. Dict. *in voc.*

CIMELIARC, in church-architecture, the room where the plate, veſtments, &c. belonging to the church, are kept; this, in Engliſh, is called a veſtry.

CINNAMON-*tree*, in botany, makes only a ſpecies of the *laurus*, according to Linnæus; diſtinguiſhed by its oblong-ovated, trinervous, plane leaves. See the article LAURUS, *Append.*

Its berries are an excellent carminative, and much uſed in medicine.

CINQUEFOIL *(Suppl.)* — *Strawberry*-CINQUEFOIL, the name by which ſome call the *pentaphylloides* of Tournefort. See the article PENTAPHYLLOIDES, *Suppl.*

CIRSIUM, in botany, the name of a genus of plants, according to Tournefort, but comprehended under the *carduus*, or thiſtle, by Linnæus. See the article THISTLE, *Suppl.*

CISTUS *(Suppl.)* — *Dwarf* CISTUS, a name given by ſome to the *helianthemum*, or ſmall ſun-flower. See the article HELIANTHEMUM, *Suppl.*

CITRINE *ſtœchas*, in botany, a name uſed by ſome for a genus of plants called goldy-locks. See the article ELYCHRYSUM, *Suppl.*

CITRON *(Cycl. and Suppl.)* — CITRON *water*, a well known ſtrong water, or cordial, which may be thus made: take of fine thin lemon-peel eighteen ounces, of orange-peel nine ounces, perfect nutmegs one quarter of a pound, alcohol perfect, that is, the fineſt and beſt rectified ſpirit of wine two gallons and an half; digeſt in balneo mariæ for one night; draw off with a ſlow fire; then add as much water as will juſt make the mixture milky (which will be about ſeven quarts or two gallons) and add alſo two pounds of fine ſugar candy.

This compoſition may be improved by freſh elder-flowers hung in a cloth in the head of the ſtill, ſprinkled with amber-greeſe in powder, or its eſſence. This article is referred to WATER, but is there omitted.

CITY *(Cycl.)* — It has been obſerved that large *cities* are more liable than other places to peſtilential and putrid diſorders, which is owing to the ſtagnation and corruption of the air. This is always the caſe in thoſe which are low and unprovided with common ſewers; where the ſtreets are narrow and foul, the houſes dirty, water ſcarce, and jails and hoſpitals crowded: alſo when in ſickly times the burials are within the walls, or when dead animals and offals are left to rot in the kennels or on dunghills; when drains are not provided to carry off any large body of ſtagnating water in the neighbourhood; when fleſh-meats make the greateſt part of the diet, without a proper mixture of greens, bread, wine, or fermented liquors; from the uſe of old mouldy grain. In proportion to the number of theſe and the like cauſes concurring, a *city* will be more or leſs ſubject to peſtilential diſeaſes, or to receive the leaven of the true plague brought into it by any merchandize. *Pringle*, Obſervat. on the Diſeaſes of the Army, p. 284, *ſeq.*

However, as great *cities* furniſh many materials for vitiating the air, they likewiſe afford two conſiderable antidotes; the firſt ariſes from the circulation of the air, by means of the conſtant motion of people and carriages, and of the draughts made by fires: the other depends on the great quantity of an acid produced by fuel, the ſtrongeſt reſiſter of putrefaction. *Id. ibid.* p. 297.

CLARY, or *garden* CLARY, a name given to the *ſclarea* of Tournefort. See the article SCLAREA, *Suppl.*

Wild CLARY, in botany, the ſame with the *horminum* of Tournefort. See the article HORMINUM, *Suppl.*

CLEAVERS, or CLIVERS, in botany, the Engliſh name of a genus of plants called by authors *aparine*. See the article APARINE, *Suppl.*

CLEDGE, a name given by the miners to the upper part of the ſtratum of fuller's earth. See the article FULLER's *earth*, *Suppl.*

CLEMATIS, in botany, the name of a genus of plants, the characters of which are theſe: there is no calyx; the flower conſiſts of four lax oblong petals, of an uncertain ſhape; the ſtamina are numerous ſubulated filaments, ſhorter than the flower; the antheræ adhere to the ſides of them; the germina are numerous, compreſſed, and terminate in ſubulated ſtyles, which are longer than the ſtamina; the ſtigmata are ſimple; there is no pericarpium; the receptacle is capitated and ſmall; the ſeeds are numerous, roundiſh, compreſſed, and have the ſtyle adhering to them.

This genus comprehends the *clematitis*, *flammula*, and *viticella* of authors. See the article CLEMATITIS, *Suppl.*

CLIMBER, in botany, a name given to the *clematitis* of authors. See the article CLEMATIS, *Append.*

CLIVERS, or CLEAVERS, in botany. See the article APARINE, *Suppl.*

CLOCK *(Cycl.)* — What is inſerted in the *Cyclopædia* on this head, is taken from *Derham*'s Artificial Clock-maker. Since that time a fuller and more complete treatiſe on this ſubject has been publiſhed by Mr. Thiout, at Paris, which is recommended in the Hiſtory of the Royal Academy of Sciences, an. 1740.

CLOUDBERRY, in botany, the Engliſh name of a genus of plants, called in Latin *chamæmorus*. See the article CHAMÆMORUS, *Append.*

CLOWN's *wound-wort*, in botany, a name uſed by ſome for the *ſideritis* of authors. See the article SIDERITIS, *Suppl.*

COASTMARY, or COSTMARY, a name given by ſome to a ſpecies of tanzy, called by others *balſamita*. See the article TANACETUM, *Suppl.*

COB-*nut*, a name given by ſome to the *corylus*, or hazle. See the article HAZLE, *Suppl.*

COBELLA, in zoology, the name of a ſpecies of *coluber*. See the article COLUBER, *Append.*

COBWEB. This ſubſtance, dried and powdered, is eſteemed by ſome as a good aſtringent and abſorbent.

COCCUS, in the hiſtory of inſects, the name of a very comprehenſive genus, the trunk of which ariſes from their breaſt; the body is cetoſe behind; the wings only two, placed erect, and to be found only on the males.

This genus contains all the progal-inſects of Reaumur. See the article PROGAL-INSECT, *Suppl.*

The principal ſpecies are: 1. The *kermes*, or *coccus* of the holm-oak. 2. The Poland ſcarlet-grain, or the purple *coccus* of the roots of plants. 3. Cochineal, or the *coccus* of the opuntia. 4. The green houſe-bug, or the *coccus* of the orange tree. 5. The water-*coccus*, found on the leaves of the water-lilly. 6. The *coccus* of the birch tree. 7. The *coccus* of other inſects. 8. The *coccus* of canary-grais. 9. The *coccus* of the *jacobæa*. 10. The *coccuſes* of the alder, peach, *&c.* See the article KERMES, *&c. Suppl.*

COCCYGRIA, in botany, the name of a genus of plants, called by Tournefort *cotinus*. See the article COTINUS, *Suppl.*

COCK, *gallus*, in ornithology, the Engliſh name of the male of the gallinæ-kind. See the articles GALLINÆ and GALLUS, *Suppl.*

The front part of the *cock*'s head is ornamented with a longitudinal fleſhy creſt, or comb; and the wattles on the throat are two, they alſo are longitudinal and fleſhy.

In the choice of a dunghill-*cock*, he ſhould be of a large body, very long from the head to the rump, thick in the girth, the neck long, looſe, and high; the comb, wattles, and throat large; the eyes round and large, and anſwerable to the colour of his plume or main, as grey with grey, yellow with yellow, and ſo of the reſt; his beak ſhould be ſtrong and hooked; and his main or neck-feathers very long and gloſſy, covering his neck and ſhoulders; the legs ſhould be ſtrait and of a long beam, with very large and long ſpurs, a little bending; the colour ſhould be black, yellow, or browniſh; the claws ſhould be long and ſtrong; the tail long, bending back and covering the whole body; the wings very ſtrong; and the general colour ſhould be reddiſh.

Game COCK. See the article GAME, *Suppl.*

Indian COCK, the Engliſh name of a diſtinct genus of birds called by zoologiſts *crax*. See the article CRAX, *Suppl.*

COCK's-*comb*, in botany, a name given to a ſpecies of *pedicularis*, or louſe-wort. See the article PEDICULARIS, *Suppl.*

COCK's-*comb* is alſo a name given to a ſpecies of amaranth. See the article AMARANTH, *Suppl.*

COCK's-*foot-graſs*, in botany, a name given to a ſpecies of graſs. See the article GRASS, *Append.*

COCK's-*head*, in botany, the Engliſh name of a genus of plants called by authors *onobrychis*. See the article ONOBRYCHIS, *Suppl.*

COCK-*throppled*, a name given by dealers in horſes to one whoſe wind-pipe is ſmall and bends like a bow when he bridles his head. See the articles HORSE and HUNTER, *Suppl.*

COCKLE, *pectunculus*, the Engliſh name of thoſe *pectens* which have no ears. See the article PECTEN, *Suppl.*

COCO-*nut*, or COCOA-*nut*, in botany, the ſame with the cacao of Tournefort. See the articles CACAO, *Suppl.* and CHOCOLATE, *Cycl.*

COCOON. See the article SILK.

COD, in ichthyology, the Engliſh name of a ſpecies of *gadus*. See the article GADUS.

CODLIN-*tree*, in botany, the name of a ſpecies of apple-tree. See the articles APPLE and MALUS, *Suppl.*

CODLINS *and cream*, the name of a genus of plants called by Tournefort *Chamænerium*. See the article CHAMÆNERIUM, *Suppl.*

CŒNOTAPH. See the article CENOTAPH, *Cycl.*

CŒRULEUM *nativum*, a name frequently uſed by the antients for the friable blue ochre, called *lapis armenus*. See the article ARMENUS *lapis*, *Suppl.*

COFFEE-*tree*, the Engliſh name of a ſpecies of jaſmine. See the articles JASMINE, *Suppl.* and COFFEE, *Cycl.*

COGGLE, a ſmall fiſhing-boat upon the coaſt of Yorkſhire: it is alſo called a little *cogge*, from the old Teutonic *kogge*, a ſhip; whence the middle aged Latin *coggo*, *cogga*, *&c. Preparatis coggionibus*, *galleis*, *& aliis navibus*, *&c.* Mat. Paris. And hence the Latin *cogcio*, a wandering and begging ſeaman; and the *cogciones*, cog-men or boat-men, who, after ſhipwreck, or loſſes by ſea, travelled about to defraud the people by begging and ſtealing, are reſtrained by many civil and good laws. *Du Freſne.*

COIX, in the Linnæan ſyſtem of botany, the name of a genus of plants, called by others *lacryma Jobi*. See the article LACRYMA, *Append.*

COLCOTHAR *(Cycl. and Suppl.)* — The Latin writers of the middle ages uſe *colcothar* as a name of vitriol in general, which was called by the Greeks *chalcanthum*.

Colcothar is originally an Arabic word, which does not ſignify the common vitriol, but the *chalcitis*. The word has been ſpelt *calchuthar*, and from this the word *chalcitis* differs not very much. The Greeks of the middle ages followed the Arabians in the uſe of the word *colcothar*, but added to it a termination proper to their language, and particularly to the cuſtom of thoſe times, which ſeemed not to expreſs exactly the ſame thing, but a diminutive of it: they wrote it *colcotharion*, or *chalcitarion*. This they alſo called the *orchis*, *orchidion*, the *ladi eladion*, and ſo in a thouſand other inſtances. Avicenna uſes the word *zagi* to expreſs this ſubſtance, but then he is by no means determinate

minate in it, but makes it include the *miſy*, *ſory*, and *melanteria*, as well as the *chalcitis*; but diſtinguiſhing in another place the ſeveral kinds of *zagi*, he tells us, that one was the *chalcand*, which was green; a ſecond the *chalcitis*, which was yellow; a third the *ſory*, which was red. *Alzagiat* is a name alſo uſed by him to expreſs all theſe kinds; and this word the interpreters generally render *atramenta*, inks. This is generally ſuppoſed to expreſs their being all black ſubſtances, which is not the caſe; but all that it does ſignify is, that they are all vitriolic foſſils: *atramentum* being a name of vitriol, as a ſubſtance uſed in the making of ink.

COLD *(Suppl.)* — The diſeaſes ariſing from *cold*, are all of the inflammatory kind, *viz.* coughs, pleuriſies, peripneumonies, rheumatic pains, and conſumptions; which, in the army, are almoſt always owing to neglected coughs. All poſſible means ought therefore to be uſed, in order to remove theſe in the beginning; for which purpoſe, ſmall and repeated bleedings are moſt efficacious, and likewiſe prove highly beneficial in coughs and the confirmed conſumption, even after a purulent ſpitting and hectic ſymptoms have appeared. The quantity drawn may be from four to ſeven or eight ounces, once in eight or ten days. It is obſervable, that the patients never find themſelves ſo much relieved on the firſt, as on the ſecond or third night after veneſection. See CONSUMPTION, *Append.*

COLD-*finch*, in zoology, the name of a bird of the *œnanthe* kind, or nearly approaching to that genus, common about the Peak in Derbyſhire. Its belly is white; its breaſt of a yelloviſh brown, and its head and back of a browniſh or greeniſh grey; the long feathers of its wings and tail are black, but with ſome variegation of white toward the end; its beak is ſlender, ſtrait, and ſomewhat ridged or triangular; it feeds on worms and other inſects. *Ray*'s Ornithology, p. 170.

COLE-*fiſh*, a name given to a ſpecies of beardleſs *gadus*. See the article GADUS, *Suppl.*

COLE-*wort*, the Engliſh name of a ſpecies of *cabbage*. See the articles CABBAGE and BRASSICA, *Suppl.*

Sea-COLE-*wort*, a name given to the *convolvulus* of authors. See the article CONVOLVULUS, *Suppl.*

COLLAR, among builders, the ſame with *cincture*. See CINCTURE, *Cycl.*

COLLAR-*beam*, among houſe-carpenters, the beam which is framed croſs betwixt two principal rafters. Build. Dict. in voc.

COLLIFLOWER, the name of a kind of *cabbage*. See the articles CABBAGE and BRASSICA, *Suppl.*

COLOCASIA, in botany, a name uſed by ſome for a ſpecies of *arum*. See the article ARUM, *Suppl.*

COLOQUINTIDA, a name often uſed for the *colocynthis* of botanical writers. See the article COLOCYNTHIS, *Suppl.*

COLT's *foot (Suppl.)* — *Alpine* COLT's *foot*, a name uſed by ſome for the *cacalia* of authors. See the article CACALIA, *Suppl.*

COLUBER, in zoology, the name of a very numerous genus of ſerpents, the abdomen of which is covered with ſcuta, and the under part of the tail with ſquamæ or ſcales.

Of this genus are the *natrix torquata*, the viper, and a great many other ſpecies. See the articles NATRIX, VIPER, *&c. Suppl.*

COLUMBINA *marga*, the name by which Pliny calls the ſtony bluiſh marle. See the article MARLE, *Suppl.*

COLUMBINE *(Suppl.)* — *Feathered* COLUMBINE, a name uſed by ſome for a plant known among authors by that of *thalictrum*. See the article THALICTRUM, *Suppl.*

COLUMNAR-*marble*, the ſame with the *baſaltes*, or *lapis lydius*. See the article BASALTES, *Cycl.* and *Suppl.*

COMB *(Suppl.)* — *Ladies*-COMB, or *Venus* COMB, the name of a diſtinct genus of plants, called by Tournefort *ſcandix*. See the article SCANDIX, *Suppl.*

COMB-*fiſh*, *pecten*, in ichthyology, a genus of fiſhes ſo called from the longitudinal ſtriæ reſembling the teeth of a *comb*, with which its ſtructure is covered. See PECTEN, *Suppl.*

COMBUSTIO *pecuniæ*, the antient way of trying mixed and corrupt money, by melting it down, upon payments into the Exchequer. In the time of king Henry II. a conſtitution was made called the trial by *combuſtion*; the practice of which differed little or nothing from the preſent method of aſſaying ſilver. But whether this examination of money by *combuſtion* was to reduce an equation of money only of ſterling, *viz.* a due proportion of alloy with copper, or to reduce it to pure fine ſilver, doth not appear. On making the conſtitution of trial it was conſidered, that tho' the money did anſwer *Numero et Pondere*, it might be deficient in value; becauſe mixed with copper or braſs, *&c.* Vide *Lownde*'s Eſſay upon Coin, p. 5.

COMET *(Suppl.)* — The *comet* which appeared in December 1743, and in January and February following was exceeding bright and diſtinct. The diameter of its nucleus being nearly equal to that of Jupiter. Its tail extended above 16 degrees from its body.

From the obſervations of Mr. Bliſs, and from ſome taken at the obſervatory of the earl of Macclesfield, Mr. Betts has determined this *comet*'s parabolic trajectory. He found the place of the aſcending node to be ☊. 15°. 45′. 20″; the logarithm of the perihelion diſtance 9.346472; the logarithm of the diurnal motion 0.940420; the place of the perihelion ♎. 17°. 12′. 55″; the diſtance of the perihelion from the node 151°. 27′. 35″; the logarithm, ſine, and coſine of the inclination of the orbit to the ecliptic 9.865138, 9.832616; and thence the time the *comet* was in the vertex of the parabola, or the time of the perihelion was Febr. 19ᵈ. 8ʰ. 12′. The motion of the *comet* in its orbit was according to the order of the ſigns.

From theſe elements, by the help of Dr. Halley's general table, he has given us the computation of the *comets* places, for the times of obſervation, and the differences between the obſerved and computed places, which ſeldom amount to above half a minute.

The nodes of this *comet* and of the planet Mercury, are within leſs than half a degree of each other, which perhaps gave riſe to a report, that the *comet* had carried Mercury from its orbit. But the *comet* was at that time diſtant from Mercury nearly $\frac{1}{3}$ of the ſemi-diameter of the *orbis magnus*, and almoſt twice as near to the ſun; hence it could have no ſenſible influence on the motions of that planet.

This *comet* is ſuppoſed at leaſt equal in magnitude to the earth. See Phil. Tranſ. N°. 474. ſect. 2.

Comet of 1743. See obſervations of this *comet* made at Vienna by father Frank, a Jeſuit, in Phil. Tranſ. N°. 470. ſect. 1.

The parabolic orbit of the *comet* of 1739, as obſerved by Signior Zanotti at Bologna, is deſcribed in Phil. Tranſ. N°. 461. ſect. 15.

The path of the *comet* which appeared from the beginning of March to the beginning of April 1742, has been computed by Mr. Hodgſon from the obſervations of the Jeſuits of Pekin in China. Vide Phil. Tranſ. N°. 481. p. 264.

COMFREY *(Suppl.)* — *Spotted* COMFREY, a name by which ſome call the *pulmonaria*. See the article PULMONARIA, *Suppl.*

COMMENDATORY *Abbot*. See ABBOT *in commendam*, *Cycl.*

COMPOSITION *(Cycl.)* — COMPOSITION *of ratios*, in arithmetic and algebra, is performed by multiplying the quantities or exponents of two or more ratios together; the produce is then ſaid to be compounded of the ratios whoſe components were multiplied. Thus if the quantities or exponents of the ratios *a* to *b*, *c* to *d*, *e* to *f*, be multiplied, we ſhall have $\frac{a}{b} \times \frac{c}{d} \times \frac{e}{f} = \frac{ace}{bdf}$. And the ratio *a c e* to *b d f*, is then ſaid to be compounded of the ſeveral ratios *a* to *b*, *c* to *d*, *e* to *f*, *&c.* Thus alſo the ratio of 10 to 12, is compounded of the ratio of 2 to 5, and of 3 to 4; for $\frac{2}{5} \times \frac{3}{4} = \frac{10}{12}$.

This operation is by ſome called *addition* of ratios.

CONCAMERATED, among builders, an appellation given to ſuch roofs as are arched in the manner of vaults.

CONCHA *anatifera*, in the hiſtory of ſhell-fiſh. See the article ANATIFERA *concha*, *Suppl.*

CONCHA *veneris*, in natural hiſtory, the name by which ſeveral ſpecies of *chama* are called. See the article CHAMA, *Suppl.*

CONCHÆ *margaritiferæ*, a name ſometimes uſed for thoſe *mytuli* which produce pearls. See the article MYTULUS, *Suppl.*

CONE *(Cycl.)* — CONE *and key*. Bracton, lib. 2. c. 37. num. 3. ſays, *Fœmina in tali ætate (i. e. 14 et 15 Annorum) poteſt diſponere domui ſuæ et habere* Cone *et* Key.

The words come from the Saxon *colne*, *i. e. calculus*, and key *clavis*; ſo that a woman was then held to be of competent years when ſhe was able to keep the accounts and keys of the houſe: and *Glan.* lib. 7. cap. 9. has ſomewhat to the ſame purpoſe.

CONE, in botany, an hard dry ſeed-veſſel of a conical figure, conſiſting of ſeveral woody parts; and is, for the moſt part, ſcaly, adhering cloſely together, and ſeparating when ripe. *Miller*'s Gardener's Dict. in voc.

CONGE *(Cycl.* and *Suppl.)* — The *conge*, originally, was a ring or ferril, fixed on the extremities of wooden pillars, to keep them from ſplitting; this, afterwards, came to be imitated in ſtone-work. Build. Dict. in voc.

CONGELATIONS. See FREEZING, *Suppl.*

CONIC-*ſection (Cycl.)* — The doctrine of the *conic-ſections* is of great uſe in phyſical and geometrical aſtronomy, and the phyſico-mathematical ſciences. This doctrine has been much cultivated by geometers antient and modern; and we have many good treatiſes on the ſubject; but that publiſhed by Mr. Simſon, profeſſor of mathematics at Glaſgow, deſerves to be particularly mentioned not only for its elegance, but for its geometrical accuracy, which as he juſtly remarks in his preface, has not always been ſo well obſerved in treatiſes of this kind, as it ought to be.

To the properties of the *conic-ſections* mentioned in the *Cyclopædia*, it may be proper to add the properties of their oſculatory circles or circles of curvature. See CURVATURE.

CONJUGATE *(Cycl.)* — CONJUGATE *hyperbolas*, in geometry. See HYPERBOLA, *Append.*

CONJURATION, *conjuratio*, *(Cycl.)* ſignifies a plot or confederacy, made by perſons combining together by oath or promiſe, to do ſome public harm.

But it was more particularly uſed, formerly, for the having a perſonal conference with the devil, or ſome evil Spirit, to know any ſecret, or to effect any purpoſe. *Anno* 5 *Eliz.* c. 16.

It is ſaid in ſome of our law books, that the difference between *conjuration* and *witchcraft* is, that the former endeavours by prayers and invocation of God's powerful name, to compel the devil to ſay or do what the offender commands him; the latter deals rather by friendly and voluntary conference or agreement with the devil or familiar, to have the offender's deſires ſerved, in lieu of blood, or other gift offered to the devil, eſpecially of the offender's ſoul. And both theſe differ from *inchantment* or *ſorceries*; becauſe thoſe are perſonal conferences with the devil, and theſe are but medicines and ceremonious forms of words (commonly called *charms*) without apparition. *Cowel.*

But all theſe nice diſtinctions are now uſeleſs, ſince the ſtatute of his preſent majeſty forbidding all proſecutions for witchcraft, *&c.*

CONOCARPODENDRON, in botany, a name given by Boerhaave to a genus of plants, deſcribed by Linnæus under that of *leucodendros*, or the ſilver pine-tree. See the article PINE-*tree*, *Suppl.*

CONOCARPUS, the *button-tree*, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: the cup is a very ſmall, erect perianthium, formed of one leaf, and divided, at the extremity, into five ſubulated ſegments; it is placed on the germen, and is permanent; there is no corolla; the ſtamina are five; the germen is large, compreſſed, obtuſe, thickeſt towards the point, and placed under the receptacle of the flower; the ſtyle is ſimple; there is no fruit, but the ſeed is naked and ſingle, and has on each ſide a prominent, membranaceous margin; a number of the germina are arranged together, in an imbricated manner, and form a ſhort and roundiſh one; they appear like ſo many reflex ſquamæ.

This genus comprehends the *rudbeckia* of Houſton, and is called *alni fructu laurifolia arbor*, by Sir Hans Sloane. Vide *Linnæi* Gen. Plant. p. 75.

CONSOLIDA, in botany, a name given by ſome authors to the plant more uſually called *bugle*. See BUGULA, *Suppl.*

CONSOUND, a name given to ſeveral different plants: thus *ſymphytum* is called the great *conſound*, *bugula* the middle *conſound*, *bellis* the leaſt *conſound*, and *ſolidago* the ſaracens *conſound*. See SYMPHYTUM, *&c. Suppl.*

CONSUMPTION *(Suppl.)* is frequently the conſequence of a neglected cold. See COLD, *Append.*

Beſides repeated ſmall bleedings, which is the beſt of all remedies for diminiſhing the hectic fits, the ſaline draughts and a cool diet are to be uſed. Colliquative ſweats may be checked by drinking about a pint of lime-water, ſoftened with a little new milk.

In the advanced ſtate of a *conſumption*, we may diſtinguiſh two kinds of coughs, one cauſed by the ulcers of the lungs, and the other by a thin rheum falling upon the fauces and trachea. For the firſt of theſe, about ten drops of balſam of Peru or Copaiba may be given twice a day in a bolus of conſerve of roſes; and for the latter, incraſſants, as conſerve of roſes and opium; which laſt ought to be given with caution, as being apt to heat the body.

CONVAL-*lily*, *lilium convallium*, or lilly of the valley. See the article LILIUM *convallium*, *Suppl.*

CONVALLARIA, in botany, the name given by Linnæus to a large genus of plants, comprehending the *lilium convallium*, *polygonatum*, and *unifolium* of other botanical writers. See LILIUM *convallium*, *&c. Suppl.*

The characters of the *convallaria*, according to Linnæus, are theſe: there is no calyx; the flower conſiſts of a ſingle ſmooth petal, of a campanulated form, divided at the extremity into ſix ſhort, obtuſe, patento-reflex ſegments; the ſtamina are ſix ſubulated filaments, inſerted into the petal of the flower, and ſhorter than it; the antheræ are oblong and erect; the germen of the piſtil is globoſe; the ſtyle is filiform and longer than the ſtamina; the ſtigma is obtuſe and trigonal; the fruit is a globoſe berry, containing three cells, and is ſpotted before it is ripe; the ſeeds are ſingle and roundiſh.

In the *lilium convallium*, the petal of the flower is globoſe, campanulated and patent; in the *polygonatum*, it is tubulato-campanulated; and in the *unifolium*, a third part of all the fructification is wanting.

Some of the ſpecies of Tournefort's *ſmilax* are likewiſe included in this genus; in which the petal of the flower is divided into ſix very acute and patent ſegments. Vide *Linnæi* Gen. Plant. p. 146.

CONYZA is alſo uſed, by C. Bauhine, for a different genus of plants from the *flea-bane*, and called *erigeron* by Linnæus. See the article ERIGERON, *Append.*

CONYZOIDES, or CONYZELLA, in botany, names by which Dillenius calls the *erigeron*, or ſweet flea-bane of Linnæus. See the article ERIGERON, *Append.*

COPAIBA, or COPAYBA, in natural hiſtory and pharmacy. See the articles COPIVI, *Cycl.* and BALSAM *of Copaiba*, *Suppl.*

COPERAS, in natural hiſtory, the ſame with *copperas*. See the article COPPERAS, *Cycl.* and *Suppl.*

COPPER *(Cycl.* and *Suppl.)*—*White* COPPER, a kind of metal frequently brought from China, and ſuppoſed, by many, to be natural. But according to Mr. Geoffroi, *white copper* is only a mixture of red *copper* with arſenic. See Hiſt. Acad. Scienc. 1739. p. 24.

CORAAGE, *coraagium*, in our old cuſtoms, a kind of impoſition extraordinary, growing upon ſome unuſual occaſion; and it ſeems to be of certain meaſures of corn: for *corus tritici* is a meaſure of wheat. *Bracton*, l. 2. c. 116. num. 6. who in the ſame chapter, num. 8. has theſe words,—— *Sunt etiam quædam communes præſtationes, quæ ſervitia non dicuntur, nec de conſuetudine veniunt, niſi cum neceſſitas intervenerit, vel cum rex venerit; ſicut ſunt hidagia, coraagia, & carvagia, et alia plura de neceſſitate et ex conſenſu communi totius regni introducta*, &c.

CORAL *(Cycl.* and *Suppl.)*—For the method of making artificial *coral* to adorn grottos, ſee GROTTO, *Append.*

CORAL-*tree*, or CORAL-*wood*, in botany, the Engliſh name of a plant, called by authors *corallodendron*. See the article CORALLODENDRON, *Suppl.*

CORCHORUS, the name of a genus of plants, by miſtake printed *corehorus*. See the article COREHORUS, *Suppl.*

CORIARIA, *myrtle-ſumach*, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: the cup is compoſed of five very ſhort leaves, which are concave and of a ſomewhat oval figure; the flower conſiſts of five petals, and is very like the cup; the ſtamina are ten filaments of the length of the flower; the antheræ are ſimple; the germina of the piſtil are five in number, compreſſed, and adhering together by their inner ſides; there are likewiſe five ſetaceous long ſtyles; the ſtigmata are ſimple; there is no pericarpium; the ſeeds, which are five in number, and kidney-ſhaped, being incloſed in the petals of the flower, which become carnous. Vid. *Linnæi* Gen. Plant. p. 204.

CORK *(Cycl.)*—Cups made of *cork*, are ſaid by ſome to be good for hectical perſons to drink out of. The Egyptians made coffins of *cork*; which being lined with a reſinous compoſition, preſerved dead bodies uncorrupted. The Spaniards line ſtone-walls with it, which not only renders them very warm, but corrects the moiſture of the air. The wood of the *cork*-tree is not only good firing, but applicable to ſeveral other uſes.

CORK-*tree*, the Engliſh name of a genus of plants, called by authors *ſuber*. See the article SUBER, *Suppl.*

CORMORANT, in ornithology, the Engliſh name of a bird of the order of *anſeres*, or gooſe kind, called alſo *pelicanus* and *corvus aquaticus*. See the articles PELICAN and CORVUS *aquaticus*, *Suppl.*

CORN-*bottle*, or *blue-bottle*, a name given to the *cyanus* of authors. See the article CYANUS, *Suppl.*

CORN-*flag*, in botany, a name given to the *gladiolus* of authors. See the article GLADIOLUS, *Suppl.*

CORN-*marygold*, a name given to the *chryſanthemum* of authors. See the article CHRYSANTHEMUM, *Suppl.*

CORN-*parſley*, in botany, a name given to a ſpecies of *ſium*. See the article SIUM, *Append.*

CORN-*ſallet*, in botany, a name given to the *valerianella* of authors. See the article VALERIANELLA, *Suppl.*

CORN-*violet*, a name uſed by ſome for the *campanula* of authors. See the article CAMPANULA, *Suppl.*

CORNEL-*tree*, in botany, the Engliſh name of a genus of plants, called by Latin writers *cornus*. See the article CORNUS, *Suppl.*

CORNELIAN, *ſarda*, in the hiſtory of gems. See the articles CORNELIAN, *Cycl.* and SARDA, *Suppl.*

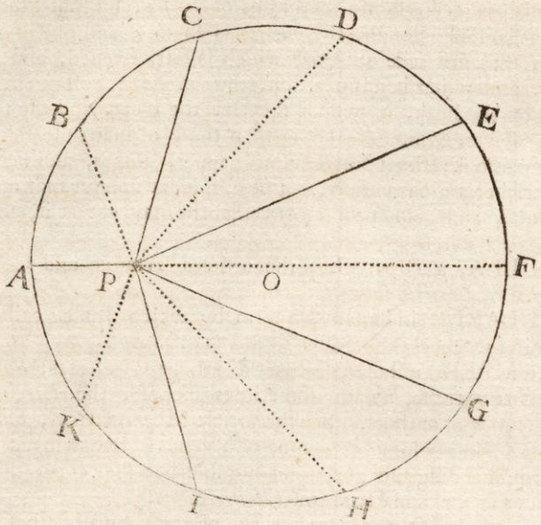
CORNELIAN-*cherry*, a name uſed by ſome for a ſpecies of the *cornus*, or cornel-tree. See the article CORNUS, *Suppl.*

CORNER-*ſtones*, among builders, the name of the two ſtones which ſtand one in each jaumb of a chimney. Their faces are hollowed in breadth, being a certain ſweep of a circle. The breadth of each ſtone is equal to that of the jaumb, and their height reaches from the hearth to the mantle-tree

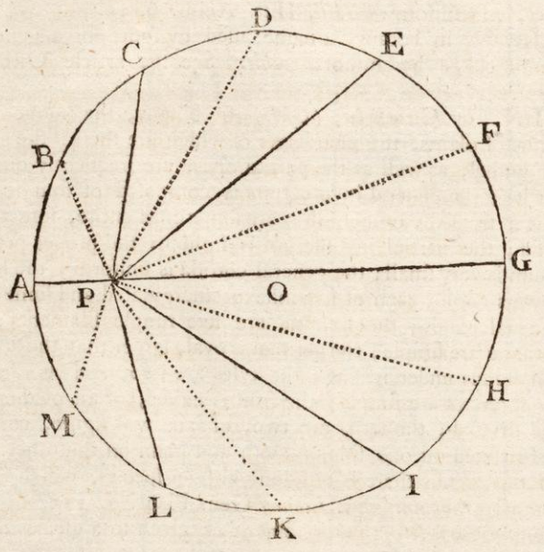
Corner-ſtones are commonly made of Rigate or fire-ſtone. Build. Dict. in voc.

CORSA, in architecture, the ſame with *plat-band*. See the article PLAT-BAND, *Cycl.*

CORTEX *aurantiorum*. The powder of *cortices aurantiorum*, ſometimes cures quartan agues. Commerc. Norimb. 1735. hebd. 11. §. 3.



COSTMARY, the Engliſh name of a ſpecies of tanzy, called by ſome writers *balſamita*. See the article TANACETUM, *Suppl.*



COSTUME *(Suppl.)*—To obſerve the *coſtume*, among painters, is to make every perſon and thing ſuſtain the proper character, by not only obſerving the ſtory, but the circumſtances, the ſcene of action, the country or place, habit, manners, *&c.*

The word is Italian, ſignifying cuſtom.

COTESIAN *theorem*, in Geometry, an appellation uſed for an elegant property of the circle diſcovered by Mr. Cotes. The theorem is,

If the factors of the binomial $a^\lambda \pm x^\lambda$ be required, the index λ being any integer: let the circumference ABCD, the center of which is O, be divided into as many equal parts as there are units in 2λ; and from all the diviſions let there be drawn to any point P in the radius OA, produced if neceſſary, the right lines AP, BP, CP, DP, EP, FP, &c. then ſuppoſing $OA = a$, $OP = x$, the product of all the lines AP, CP, EP, &c. taken from the alternate diviſions throughout the whole circumference, will be equal to $a^\lambda - x^\lambda$, or $x^\lambda - a^\lambda$, according as the point P is within or without the circle; and the product of the reſt of the lines BP, DP, FP, in the remaining alternate places will be equal to $a^\lambda + x^\lambda$.

For inſtance, if $\lambda = 5$, let the circumference be divided into 10 equal parts, and the point P be within the circle, then will $AP \times CP \times EP \times GP \times IP$ be equal to $\overline{OA}^5 - \overline{OP}^5$, and $BP \times DP \times FP \times HP \times KP = \overline{OA}^5 + \overline{OP}^5$. In like manner if λ be $= 6$, having divided the circumference into twelve equal parts, $AP \times CP \times EP \times GP \times IP \times LP$ will be equal to $\overline{OA}^6 - \overline{OP}^6$, and $BP \times DP \times FP \times HP \times KP \times MP = \overline{OA}^6 + \overline{OP}^6$.

The demonſtration of this theorem may be ſeen in Dr. *Pemberton*'s Epiſt. de Coteſii inventis.

By means of this theorem the acute and elegant author was enabled to make a farther progreſs in the inverſe method of fluxions, than had been done before. But in the application of his diſcovery there ſtill remained a limitation, which was removed by Mr. de Moivre. See Dr. *Smith*'s Theorem. logometrica & trigonometrica, added to *Cotes*'s Harmonia menſurarum, p. 114, 115. *De Moivre*, Miſcel. Analyt. p. 17, *ſeq.*

COTTON *(Cycl.)* — *Lavender*-COTTON, a name ſometimes given to a genus of plants, called by authors *ſantolina*. See the article SANTOLINA, *Suppl.*

COTTON-*tree*, in botany, the Engliſh name of a genus of plants, called by authors *goſſypium*. See the article GOSSYPIUM, *Append.*

Silk-COTTON, a name uſed by ſome for a genus of plants, called by authors *xylon*. See the article XYLON, *Append.*

COTTON-*weed*, a name uſed for the *gnaphalium* of authors. See the article GNAPHALIUM, *Suppl.*

COUCH-*graſs*, or dog's-graſs, in botany. See the article GRASS, *Append.*

COVENTRY-*bells*, a name ſometimes given to the *campanula*. See the article CAMPANULA, *Suppl.*

COUGHS *(Cycl.)* — See the articles COLD and CONSUMPTION, *Append.* and TUSSIS, *Suppl.*

COULTER *neb*, in zoology, a name given to the *anas arctica*. See the article DUCK, *Suppl.*

COW, in zoology, the female of the ox-kind. See the articles BOS and OX, *Suppl.*

Sea-COW, the Engliſh name of a genus of ſea-animals, called by zoologiſts *manati*. See the article MANATI, *Suppl.*

COW-*itch*, *phaſeolus hirſutis*, in botany. See the article PHASEOLUS, *Suppl.* Vide *Quinc.* Pharm. p. 230.

COW's-*lip of Jeruſalem*, in botany, a name ſometimes given to the *pulmonaria* of authors. See the article PULMONARIA, *Suppl.*

French COW's-*lip*, a name by which ſome call the *auricula*, or bear's ears of botanical authors. See the article AURICULA, *Suppl.*

COWL *(Cycl.)* — *Friar's*-COWL, in botany, a name ſometimes uſed for the *ariſarum* of authors. See the article ARISARUM, *Suppl.*

CRAB, in zoology, the Engliſh name of a genus of ſhell-fiſh, of the *ſquilla* kind. See the article SQUILLA, *infra.*

CRAB-*tree*, in botany, the Engliſh name of the *malus ſylveſtris* of authors. See the article MALUS, *Suppl.* and *Append.*

CRABRO, the hornet, in zoology, the name of a genus of flies of the *apis*, or bee-kind. See the articles BEE and HORNET, *Suppl.* and APIS, *Append.*

CRANE *(Cycl.)* — There are ſeveral improvements of this uſeful machine mentioned in *Deſagulier*'s Experim. Philoſ. p. 178, *ſeq.* particularly how to prevent the inconveniencies ariſing from ſudden jerks, as well as to increaſe its force by uſing a double axis in peritrochio, and two handles.

CRASPEDARIA, a genus of animalcules, without any viſible limbs or tails, but with an apparent mouth, and a ſeries of fimbriæ round it in the manner of a fringe.

Of this genus there are three ſpecies: 1. The *craſpedarium* with a roundiſh body. 2. The *craſpedarium* with an oval body. 3. The *craſpedarium* with a cylindric body. *Hill*'s Hiſt. of Anim. p. 5.

CRASSULA, in botany, the name of a diſtinct genus of plants called by ſome *baſtard-navel-wort*.

The characters of this genus are theſe: the cup is a perianthium, formed of five lanceolated, hollowed, acute, erect, and permanent leaves, which meet in ſuch a manner as to form a kind of tube; the corolla is ſomewhat of an infundibuliform ſhape, and is compoſed of five petals, the ungues of which are very long, linear, ſtrait, connivent, and joined at their baſes; and the bracteæ, which form the limb, oval and reflexo-patent; the nectaria are five very ſmall emarginated ſquamæ, annexed outwardly to the baſe of the germen; the ſtamina are five ſubulated filaments, of the length of the tube, and inſerted into the ungues of the corolla; the antheræ are ſimple; the germina are five, oblong, acuminated, and terminated by ſubulated ſtyles, of the length of the ſtamina; the ſtigmata are obtuſe; the fruit is compoſed of five oblong, acuminated, ſtrait, compreſſed capſules, opening longitudinally inwards; the ſeeds are numerous and ſmall. *Linnæi* Gen. Plant. p. 133.

Vaillant makes it only a ſpecies of *ſedum*. See the article SEDUM, *Suppl.*

CRAX, in zoology, a name given by the antients to the *ortygometra*, or daker hen, a bird larger than the quail, and common in Ireland and ſome of the northern counties of England. *Ray*'s Ornithology, p. 122. See the article ORTYGOMETRA, *Suppl.*

CRAY-*fiſh*. Theſe fiſh are comprehended among the ſpecies of *ſquillæ*. See the articles CRAY-*fiſh*, *Suppl.* and SQUILLA, *Append.*

CRAZE-*mill*, or CRAZING-*mill*, a mill in all reſpects like a griſt-mill to grind corn, and is ſo called by the tin-miners, who uſe it to grind their tin, which is yet too great, after trambling, and then it is trambled only.

CREEPER, the Engliſh name of a ſpecies of *iſpida*, which, though very unlike the common king's-fiſher both in colour and figure, yet is comprehended under that genus on account of the ſtructure of its feet. See the article ISPIDA, *Suppl.*

This ſmall bird has likewiſe been called *certhia* and *certhius*, by authors, and in Engliſh the ox-eye. See the article CERTHIA, *Suppl.*

CREODIBA, in the cuſtoms of the middle age, a robbery and murther committed in a wood, where the body of the perſon killed was burnt, in order to prevent any diſcovery of the crime. The word, ſays Wendelinus, is compounded of *gruy* and *diven*, that is, wood-robbers. Tit. 74. of the Salic Law, edit. Heroldi, relates to *creodiba*. *Du Cange*, Gloſſ. Lat.

CRESSES *(Suppl.)* — *Indian* CRESS, *Naſturtium Indicum*, in botany, the Engliſh name of a genus of plants, called by authors *cardamindum* and *tropæolum*. See the articles CARDAMINDUM, *Suppl.* and TROPÆOLUM, *Append.*

Sciatica CRESS, a name uſed by ſome for a genus of plants, called by others *iberis* and *cardamine*. See the article CARDAMINE, *Suppl.*

Sciatica CRESS, or *babylonian* CRESS, are names ſometimes alſo given to the *lepidium*, or Dittander. See the article LEPIDIUM, *Suppl.*

Water-CRESS, or *winter*-CRESS, names given by ſome writers to a genus of plants known among authors by that of *ſiſymbrium*. See the article SISYMBRIUM, *Suppl.*

CRESTED *graſs*, in botany. See the article GRASS, *Append.*

CRIMSON *graſs-vetch*, a name given to the *niſſolia*, a genus of plants. See the article NISSOLIA, *Suppl.*

CRINUM, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: the cup is a ſpathiform general involucrum, compoſed of two oblong leaves, which bend downwards, and expoſe to ſight a kind of little umbel; the flower conſiſts of a ſingle petal, which is infundibuliform; the tube is oblong, cylindric, and bent; the limb is divided into ſix lanceolato-linear, obtuſe, concave, reflex ſegments, three of which, alternately, are diſtinguiſhed by an uncinated appendage; the ſtamina are ſix ſubulated filaments ariſing from the baſe of the limb, they are of the length of the limb, and connivent; the antheræ are oblong, linear, incumbent, and aſſurgent; the germen of the piſtil is placed in the bottom of the flower; the ſtyle is ſubulated and ſhorter than the ſtamina; the ſtigma is trifid and very ſmall; the fruit is a capſule of a ſuboval figure, with three cells; the ſeeds are numerous.

This genus, of which we know only one ſpecies, is commonly, though improperly, reckoned a ſpecies of lilly-aſphodel. *Linnæi* Gen. Plant. p. 140.

CROCEUS, in natural hiſtory, is ſaid to be an amphibious animal which is neither fiſh nor bird, but both. All the ſummer it is a bird, of a ſaffron colour, and flies through the mountains; but towards the end of autumn it returns to the ſea and becomes a fiſh. It is only in the winter that they catch it, when it proves a very ſavoury bit. *Hoffm.* Lex. Univ. in voc.

CROCODILIUM, in botany, a diſtinct genus of plants, according to Vaillant; but comprehended by Linnæus under the *centauria*. See the article CENTAURIA, *Append.*

CROCODILODES, in botany, the name uſed by Vaillant for a genus of plants, called by others *atractylis*. See the article ATRACTYLIS, *Append.*

CROSS *(Cycl.)* — The adoration of the *croſs* appears to have been practiſed in the antient church, in as much as the heathens, particularly Julian, reproach the primitive chriſtians with it [a]. And we do not find that their apologiſts diſclaimed the charge. Mornay, indeed, aſſerted that this had been done by St. Cyril, but could not ſupport his allegation at the conference of Fontainbleau. St. Helena is ſaid to have reduced the adoration of the *croſs* to its juſt principle, ſince ſhe adored in the wood, not the wood itſelf, which had been direct idolatry and heatheniſm, but him who had been nailed to this wood [b]. With ſuch modifications ſome proteſtants have been induced to admit the adoration of the *croſs*: John Huſs allowed of the phraſe, provided it were expreſly added, that the adoration was relative to the perſon of Chriſt. But however Roman catholics may ſeem to triumph by virtue of ſuch diſtinctions and mitigations, it is well known they have no great place in their own practice: Imbert [c], the good prior of Gaſcony, was ſeverely proſecuted in 1683, for telling the people, that in the ceremony of adoring the *croſs*, practiſed in that church on Good-friday, they were not to adore the wood, but Chriſt who was crucified on it: the curate of the pariſh told them the contrary; it was the wood, the wood! they were to adore. Imbert replied, it was Chriſt, not the wood: for which he was cited before the archbiſhop of Bourdeaux, ſuſpended from his functions, and even threatened with chains and perpetual impriſonment. It little availed him to cite the biſhop of Meaux's diſtinction; it was anſwered, that the church allowed it not. [[a] Nouv. Rep. Lett. tom. x. p. 508. [b] *Du Pin*, Bibl. Eccleſ. tom. xvii. p. 34, *ſeq.* Id. Bibl. Ant. Separ. tom. ii. p. 310. *Tillem.* Mem. Eccleſ. tom. vii. Nouv. Rep. Lett. tom. xxi. p. 344. Jour. des Scav. tom. lix. p. 104. [c] *Wake*, Expoſ. of the Doct. of the Ch. of Eng. Pref. p. ix, *ſeq.* *ejuſdem.* Def. of Expoſ. p. 121, *ſeq.* Bibl. Univ. tom. xi. p. 459. Nouv. Rep. Let. tom. iv. p. 691.]

CROSS-*wort*, in botany, the Engliſh name of a genus of plants called by authors *cruciata*. See the article CRUCIATA, *Suppl.*

CROSS *of Jeruſalem*, a name ſometimes given to the *lychnis* of authors. See the article LYCHNIS, *Suppl.*

CROW *(Suppl.)* — *Scare*-CROW, the Engliſh name of a bird of the *larus* kind. See the articles LARUS, *Suppl.* and SCARE-*crow*, *Append.*

CROW-*flowers*, in botany, a name ſometimes give to a genus of plants, called by authors *lychnis*. See the article LYCHNIS, *Suppl.*

CROW-*garlick*, a name given by ſome writers to a ſpecies of onion. See the article ONION, *Suppl.*

CROWN-*imperial-ſhell*, the name of a ſpecies of *voluta*. See the article VOLUTA, *Suppl.*

CRYSTALLIZATION *of ſalts*. See the articles SALT and VEGETATION *of ſalts*, *Suppl.*

CTENITA, or CTENOIDES, names ſometimes given to thoſe *pectens*, which have one of their ſhells very convex. See the article PECTEN, *Suppl.*

CUBICLE, a name ſometimes uſed for a bed-chamber. See the article CHAMBER, *Cycl.* and *Suppl.*

CUCKOW-*flower*, in botany, a name uſed by ſome writers for the *cardamine*, or lady's-ſmock. See the article CARDAMINE, *Suppl.*

CUCKOW-*ſpit-inſect*, the Engliſh name of a ſpecies of *cicada*. See the articles CICADA and HARVEST-*fly*, *Suppl.*

CUCKSOO, the name of a common diſh among the Moors of Africa, made of flower, and prepared for ſeveral ways of dreſſing afterwards. They take fine wheat flower, or, when that is ſcarce, barley, millet, or *Indian* corn flower is made to ſerve: they firſt ſprinkle ſome water over the bottom of an unglazed earthen pan, and then ſhake ſome of this flower into it; they knead theſe together with their hands, and roll it backwards and forwards under their open palms; by this means they work it into grains like ſago, and then it is fit for uſe: when they have meat to ſtew, they do this in an earthen pot, and over the mouth of this they place a colander, in which is put a quantity of this granulated paſte; over this colander is fixed on a top or cover for the pot, and by this means as the meat ſtews, all the vapour that aſcends from it is received into the grains of *cuckſoo*; by that time the meat is done enough, the *cuckſoo* is ſo too; and opening the pot, they firſt take out this, which is ſoft, ſwelled, and tender, and piling it up in a diſh, they make a hollow in the top of the heap, in which they lay the meat, and then add their ſpices, which are better than thoſe of many neighbouring nations; the pooreſt uſing pepper, ginger, and ſaffron, the richer a great variety. The diſh is ſet upon a mat on the ground, and four people conveniently may eat at it, ſometimes ſix do.

CUCULLA, a cowl. See the articles ABBOT and COWL, *Cycl.*

CUCULARIA, in botany, a term by which Juſſieu calls the fumitory. See the article FUMARIA, *Suppl.*

CUCUMBER, in botany See the article CUCUMIS, *Suppl.*

Wild CUCUMBER, a name ſometimes uſed for the *elaterium* or *momordica* of authors. See the article MOMORDICA, *Suppl.*

CULEX, in zoology, the name of a genus of two-winged flies, comprehending the gnats and humble-bee-flies. See the articles GNAT and HUMBLE-*bee-fly*, *Suppl.*

The diſtinguiſhing characteriſtic of this genus is, that their head is furniſhed with a ſiphon, or ſucker, very ſlender, oblong, and filiform. *Hill*, Hiſt. Anim. p. 35.

CULLION, in botany, a name uſed by ſome for a genus of plants called by authors *orchis*. See the article ORCHIS. *Suppl.*

CUMIN, or CUMMIN, *(Cycl.)* in botany, the name of a genus of plants, the characters of which are theſe: the general umbel, as well as the partial ones, are frequently quadripartite; the general involucrum is compoſed of four leaves, longer than the umbel, they are ſometimes entire, ſometimes trifid; the partial involucrum is ſimilar; the proper perianthium is very ſmall; the general corolla is uniform; the ſingle flowers conſiſt each of five inflexo-emarginated and ſomewhat unequal petals; the ſtamina are five ſimple filaments; the antheræ are ſimple; the germen is oval, larger than the flower, and ſtands under its cup; the ſtyles are two, and very ſmall; the ſtigmata are ſimple; the fruit is naked, of an oval figure, and ſtriated; the ſeeds are two, of an oval figure, convex, and ſtriated on one ſide, ſmooth and plain on the other.

Of this genus there is only one known ſpecies, which is the common *cummin*. See *Linnæi* Gen. Plant. p. 115.

Meadow CUMMIN, a name ſometimes given to a ſpecies of *carui*. See the article CARUI, *Suppl.*

CUNEI, in natural hiſtory, a name given to thoſe *tellinæ*, which have one ſide of their ſhell much more extended in length than the other. See the article MYTULUS, *Suppl.*

CUNICULUS, in zoology, the name of a genus of animals of the *lepus*, or hare kind, called in Engliſh rabbits. See the articles RABBIT and LEPUS, *Suppl.*

CUNICULUS *Sibericus*, the name of the long-tailed Siberian rabbit, the fur of which is much valued. During the ſummer months many of them are beautifully variegated with oblique and tranſverſe ſtreaks of black and grey. *Hill*, Hiſt. Anim. p. 525.

CUNICULUS *Braſilienſis*, the name of a ſpecies of rabbit called by zoologiſts *aperea*. See the article APEREA, *Suppl.*

CUNILA, in the Linnæan ſyſtem of botany, the name of a diſtinct genus of plants called by Tournefort *marrubiaſtrum*. See the article MARRUBIASTRUM, *Suppl.*

CUP-*ſhell*, or CHALICE-*ſhell*. See the article SHELL, *infra.*

CUPRUM, *copper*, in natural hiſtory. See the article COPPER, *Cycl.* and *Suppl.*

CURATAS, a title given to the petty princes of Peru. See the article CAZIC, *Suppl.*

CURATOR, among the Romans, an officer under the emperors, who regulated the price of all kinds of merchandize and things to ſell in the cities of the empire.

They had likewiſe the ſuperintendence of the cuſtoms and tributes; whence alſo they were called *logiſtæ*. *Hoffm.* Lex. in voc.

CURCULIO, in zoology, the name of a genus of beetles diſtinguiſhed from the others by having their antennæ affixed to an elongated horny ſnout. See the article SCARABÆUS, *Suppl.*

CURRENT *(Cycl.)* — The doctrine of *currents*, their cauſes, *&c.* is ſtill very imperfect: it were to be wiſhed that it were otherwiſe, for the improvement of navigation and natural hiſtory. See *Marſigli*, Hiſt. Phyſ. de la Mer, p. 44—47.

CURRODREPANUS, in antiquity, a kind of chariot armed with ſcythes. The driver of theſe chariots was obliged to

ride on one of the horſes, as there was no other ſeat for him: the uſual place for him being all armed with knives, as was likewiſe the hinder part of the chariot. There were no ſcythes pointing down to the earth, either from the beam or axle-tree; but theſe were fixed at the head of the axle-tree in ſuch a manner as to be moveable by means of a rope, and thereby could be raiſed or let down, and drawn forward or let fall backward by relaxing the rope. *Pitiſc.* Lex. Ant. *in voc.*

CURVATURE *(Cycl.)* — The theory of the *curvature* of lines is of great uſe in geometry, and in the phyſico-mathematical ſciences. Hence mathematicians have treated this ſubject fully. We ſhall here inſert as much of this doctrine as ſeems neceſſary to enable beginners to form a juſt notion of the ſubject, and refer thoſe who deſire a farther knowledge to Mr. Mac Laurin's Treatiſe of Fluxions, whom we have in this, as in many other articles, followed; becauſe he every where endeavours to avoid that air of paradox and myſtery which has been more than once made a reproach to modern mathematicians.

Any two right lines applied to each other, perfectly coincide; and the rectitude of lines admits of no variety. Arches of equal circles applied upon each other, perfectly coincide likewiſe; and the *curvature* is uniform in all the parts of the ſame, or of equal circles. Arches of unequal circles cannot be applied upon each other ſo as to coincide; but when they touch each other, the arch of the greater circle is leſs inflected from the common tangent, and paſſes betwixt it and the arch of the leſſer circle, through the angle of contacts formed by them, and is therefore leſs curve. Any two arches of curve lines touch each other when the ſame right line is the tangent of both at the ſame point; but when they are applied upon each other in this manner, they never perfectly coincide, unleſs they be ſimilar arches of equal and ſimilar figures: and the *curvature* of lines admits of indefinite variety. As the *curvature* is uniform in a given circle, and may be varied at pleaſure in circles by increaſing or diminiſhing their diameters, their flexure or *curvature* will therefore ſerve for meaſuring that of other lines. There is but one right line that can be the tangent of a given arch of a curve at the ſame point; but an indefinite variety of circles may touch it there; and theſe have various degrees of more and leſs intimate contact with it. And as of all the right lines that can be drawn through a given point in the arch of a curve, that is the tangent which touches the arch ſo cloſely, that no right line can be drawn between them; ſo of all the circles that touch a curve in any given point, that is ſaid to have the ſame *curvature* with it, which touches it ſo cloſely that no circle can be drawn through the point of contact between them, all other circles paſſing either within or without them both.

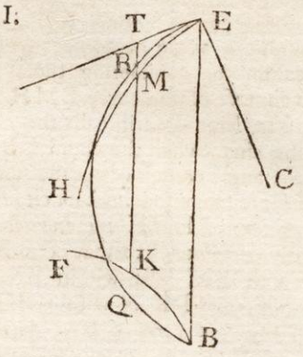
This circle is called the *circle of curvature*; its centre, the *centre of curvature*; and its ſemidiameter, the *ray* or *radius of curvature*, belonging to the point of contact. It is alſo called, eſpecially by foreign mathematicians, the *oſculatory circle*.

The arch of this circle cannot coincide with the arch of the curve, but it is ſufficient to denote it the circle of *curvature*, that no other can paſs between them; as the tangent of the arch of a curve cannot coincide with it, but is applied to it ſo that no right line can be drawn between them.

As in all figures, rectilinear ones excepted, the poſition of the tangent is continually varying; ſo the *curvature* is continually varying in all curvilinear figures, the circle only excepted.

As the curve is ſeparated from its tangent by its flexure or *curvature*, ſo it is ſeparated from the circle of *curvature* in conſequence of the increaſe or decreaſe of its *curvature*; and as its *curvature* is greater or leſs, according as it is more or leſs inflected from the tangent, ſo the variation of *curvature* is the greater or leſs according as it is more or leſs ſeparated from the circle of *curvature*.

It is manifeſt, that there is but one circle of *curvature* belonging to an arch of a curve at the ſame point. For if there were two ſuch circles, any circle deſcribed between theſe through that point, would paſs between the curve and circle of *curvature*; againſt the ſuppoſition.



When any two curves touch each other in ſuch a manner that no circle can paſs between them, they muſt have the ſame *curvature*; for the circle that touches the one ſo cloſely that no circle can paſs between them, muſt touch the other in the ſame manner.

It appears from the demonſtrations of geometricians, that circles may touch curve lines in this manner; that there may be indefinite degrees of more or leſs intimate contact between the curve and the circle of *curvature*; and that a conic ſection may be deſcribed that ſhall have the ſame *curvature* with a given line at a given point, and the ſame variation of *curvature*, or a contact of the ſame kind with the circle of *curvature*.

If we conceive the tangent of any propoſed curve to be a baſe, and that a new line be deſcribed, whoſe ordinate is a third proportional to the ordinate and baſe of the firſt; this new line will determine the chord of the circle of *curvature*, by its interſection with the ordinate at the point of contact; and by the tangent of the angle in which it cuts that circle, it will meaſure the variation of the *curvature*. The leſs this angle is, the cloſer is the contact of the curve and circle of *curvature*; and of this contact there may be indefinite degrees.

To give an example: let any curve EMH (fig. I.) and a circle ERB touch the right line ET on the ſame ſide at E; let any right line TK, parallel to the chord EB, meet the tangent in T, EMH in M, and a curve BKF that paſſes through B in K: then if the rectangle MTK be always equal to the ſquare of ET, the *curvature* of EMH at E will be the ſame as that of the circle ERB; and the contact EM and ER will always be the cloſer, the leſs the angle is that is contained at B by the curve BKF, and the circle of *curvature* BQE.

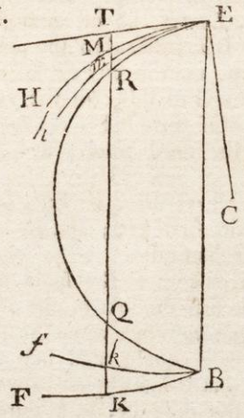


Fig. I.

For it is demonſtrable from the elements of geometry (ſee Mac *Laurin's* Fluxions, art. 366.) that all the circles that can be deſcribed through E fall without both ER and EM, or within them both, and no circle whatever can paſs between them when the rectangle MTK is always equal to the ſquare of ET, and the curve in which K is always found, paſſes thro' B, and conſequently the circle ERB, and the curve EM, have the ſame *curvature* at E.

Now let E*m* (fig. II.), any other curve touching ET in E, and *fk* B another curve paſſing through B meet TK in *m* and *k*, and let the rectangle *m*T*k* be likewiſe equal to the ſquare of ET; then will the *curvature* of E*m* at E be the ſame as that of the curve EM, as has been mentioned. But the rectangles *m*T*k*, MTK, RTQ being equal to each other, and their ſides therefore in a reciprocal proportion to each other, it is plain that if the arch B*k* paſs between BK the arch of the curve BKF, and BQ the arch of the circle BQE; the curve E*m* muſt paſs between EM the arch of the curve EMH, and ER the arch of the circle of *curvature* ERB: ſo that E*m* muſt have a cloſer contact with this circle than EM has with it; and the leſs the angle is that is formed by the curve FKB and the circle of *curvature* EQB at B, the cloſer is the contact at E of the curve EMH and the circle of *curvature* ERB. Thus the curve BKF, by its interſection with EB, determines the *curvature* of EM; and by the angle in which it cuts the circle of *curvature* it determines the degree of contact of EM and that circle, the angle BET and the right line ET being given.

Fig. II.

Hence it follows, that the contact of the curve EMH, and the circle of *curvature*, is cloſeſt when the curve BK touches the arch BQ in B, the angle BET being given; but it is farthеſt from this, or is moſt open, when BK touches the right line EB in B.

Hence, alſo, there may be indefinite degrees of more and more intimate contact between a circle and a curve.

The firſt degree is, when the ſame right line touches them both in the ſame point; and a contact of this ſort may take place betwixt any circle and any arch of a curve. The ſecond is when the curve EMH, and circle ERB have the ſame *curvature*, and the tangents of the curve BKF and circle BQE interſect each other at B in any aſſignable angle. The contact of the curve EM and circle of *curvature*, ER, at E is of the third degree, or order, and their oſculation is of the ſecond, when the curve BKF touches the circle BQE at B, but ſo as not to have the ſame *curvature* with it. The contact is of the fourth degree, or order, and their oſculation of the third, when the curve BKF has the ſame *curvature* with the circle BQE at B, but ſo as that their contact is

only of the ſecond degree: and this gradation of more and more intimate contact, or of approximation towards coincidence, may be continued indefinitely, the contact of EM and ER at E being always of an order two degrees cloſer than that of BK and BQ at B. There is alſo an indefinite variety comprehended under each order: thus, when EM and ER have the ſame *curvature*, the angle formed by the tangents of BK and BQ admits of indefinite variety, and the contact of EM and ER is the cloſer, the leſs that angle is. And when that angle is of the ſame magnitude, the contact of EM and ER is the cloſer the greater the circle of *curvature* is. When BK and BQ touch at B, they may touch on the ſame or on different ſides of their common tangent; and the angle of contact KBQ may admit of the ſame variety with the angle of contact MER; but as there is ſeldom occaſion for conſidering thoſe higher degrees of more intimate contact of the curve EMH and circle of *curvature* ERB, Mr. Mac Laurin calls the contact or oſculation of the ſame kind, when the chord EB and angle BET being given, the angle contained by the tangents of BK and BQ is of the ſame magnitude. Lib. cit. Art. 368.

When the *curvature* of EMH increaſes from E towards H, and conſequently correſponds to that of a circle gradually leſs and leſs, the arch EM falls within ER, the arch of the circle of *curvature*, and BK is within BQ. The contrary happens when the *curvature* of EM decreaſes from E towards H, and conſequently correſponds to that of a circle that is gradually greater and greater, the arch EM falls without ER, the arch of the circle of *curvature*, and BK is without BQ. And according as the *curvature* of EM varies more or leſs, it is more or leſs unlike to the uniform *curvature* of a circle; the arch of the curve EMH ſeparates more or leſs from the arch of the circle of *curvature* ERB, and the angle contained by the tangents of BKF and BQE at B, is greater or leſs. Thus the quality of *curvature*, as it is called by Sir Iſaac Newton [a], depends on the angle contained by the tangents of BK and BQ at B; and the meaſure of the inequability or variation of *curvature*, is as the tangent of this angle, the radius being given and the angle BET being right [b]. — [a Method of Flux. and Inf. Ser. Prob. vi. p. 75. b *Mac Laurin*, lib. cit. Art. 369.]

The rays of *curvature* of ſimilar arches in ſimilar figures, are in the ſame ratio as any homologous lines of theſe figures; and the variation of *curvature* is the ſame. See *Mac Laurin*, lib. cit. ſect. 370.

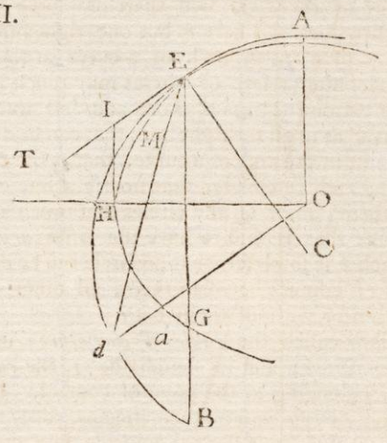
When the propoſed curve EMH, is a conic-ſection, the new line BKF is alſo a conic-ſection; and it is a right line when EMH is a parabola, to the axis of which the ordinates TK are parallel. BKF is alſo a right line when EMH is an hyperbola, to one aſymptote of which the ordinate TK is parallel. *Mac Laurin*, lib. cit. Art. 371, 372.

When the ordinate EB, at the point of contact E, inſtead of meeting the new curve BK, is an aſſymptote to it, the *curvature* of EM will be leſs than in any circle; and this is the caſe in which it is ſaid to be infinitely little, or that the radius of *curvature* is infinitely great. Of this kind is the *curvature* at the points of contrary flexure in lines of the third order. See *Mac Laurin*, lib. cit. Art. 377—379.

When the curve BK paſſes thro' the point of contact E, the *curvature* is greater than in any circle, or the radius of *curvature* vaniſhes; and in this caſe the *curvature* is ſaid to be infinitely great. Of this kind is the *curvature* at the cuſpids of the lines of the third order. See *Mac Laurin*, lib. cit. Art. 378, 379.

As to the circles of *curvature* for lines of the third or higher orders, ſee lib. cit. Art. 379; and Art. 380, when the propoſed curve is mechanical.

As lines which paſs thro' the ſame point have the ſame tangent when the firſt fluxions of the ordinates are equal, ſo they have the ſame *curvature* when the ſecond fluxions of the ordinate are likewiſe equal; and half the chord of the circle of *curvature* that is intercepted between the points wherein it interſects the ordinate, is a third proportional to the right lines that meaſure the ſecond fluxion of the ordinate and firſt fluxion of the curve, the baſe being ſuppoſed to flow uniformly. When a ray revolving about a given point, and terminated by the curve, becomes perpendicular to it, the firſt fluxion of the radius vaniſhes; and if its ſecond fluxion vaniſhes at the ſame time, that point muſt be the center of *curvature* [a]. The ſame may be ſaid, when the angular motion of the ray about that point is equal to the angular motion of the tangent of the curve; as the angular motion of the radius of a circle about its center is always equal to the angular motion of the tangent of the circle. Hence the various properties of the circle may ſuggeſt ſeveral theorems for determining the center of *curvature* [b]. — [a *Mac Laurin*, lib. cit. Art. 382, &c. b *Ibid.* Art. 389, &c.]



See alſo Art. 396, of the ſaid treatiſe, and the following, concerning the *curvature* of lines that are deſcribed by means of right lines revolving about given poles, or of angles that either revolve about ſuch poles, or are carried along fixed lines.

It is to be obſerved, that as when a right line interſects an arch of a curve in two points, if by varying the poſition of that line the two interſections unite in one point, it then becomes the tangent of the arch; ſo when a circle touches a curve in one point and interſects it in another, if, by varying the center, this interſection joins the point of contact, the circle then has the cloſeſt contact with the arch, and becomes the circle of *curvature*; but it ſtill continues to interſect the curve at the ſame point where it touches it, that is, where the ſame right line is their common tangent, unleſs another interſection join that point at the ſame time. In general, the circle of *curvature* interſects the curve at the point of oſculation, only, when the number of the ſucceſſive orders of fluxions of the radius of *curvature*, that vaniſhes at the term of time that this radius comes to the point of oſculation, is an even number. *Mac Laurin*, Flux. Art. 493.

It has been ſuppoſed by ſome, that two points of contact, or four interſections of the curve and circle of *curvature*, muſt join to form an oſculation. But Mr. James Bernoulli inſiſted juſtly, that the coalition of one point of contact and one interſection, or of three interſections, was ſufficient. In which caſe, and in general, when an odd number of interſections only join each other, the point where they coincide continues to be an interſection of the curve and circle of *curvature*, as well as a point of their mutual contact and oſculation. See *Mac Laurin*'s Fluxions, Art. 493.

From theſe principles the circle of *curvature* at any point of a conic-ſection may be determined. Suppoſe EMH (fig. III.) to be any conic-ſection, ET the tangent at E, HI a tangent parallel to EB, (a chord of the circle of *curvature*) that meets ET in I, and let EMH meet EB in G. Take EB to EG, in the ſame ratio as the ſquare of EI is to the ſquare of HI; or, when the ſection has a center as in the ellipſis and hyperbola, as the ſquare of the ſemi-diameter O*a* parallel to ET, is to the ſquare of the ſemi-diameter OA parallel to EB; and a circle deſcribed upon the chord EB that touches ET, will be the circle of *curvature*.

Fig. III.

When BET is a right angle, or EB is the diameter of the circle of *curvature*, EG will be the axis of the conic-ſection, and EB will be the parameter of this axis; and when the point G where the conic-ſection cuts EB, and B are on the ſame ſide of the point E, EMG will be an ellipſis, and EG the greater or leſſer axis, according as EG is greater or leſs than EB.

The propoſitions relating to the *curvature* of the conic-ſections, commonly given by authors, follow without much difficulty from this conſtruction.

1. When the chord of *curvature* thus found paſſes thro' the center of the conic-ſection, it will then be equal to the parameter of the diameter that paſſes thro' the point of contact.

2. The ſquare of the ſemi-diameter O*a*, is to the rectangle of half the tranverſe and half the conjugate axis, as the ray of *curvature* CE is to O*a*. And therefore the cube of the ſemi-diameter O*a*, parallel to the tangent ET, is equal to the ſolid contained by the radius of *curvature* CE, and the rectangle of the two axes. See *De Moivre*, Miſcel. Analyt. p. 235.

3. The perpendicular to either axis biſects the angle made by the chord of *curvature*, and the common tangent of the conic-ſection and circle of *curvature*.

4. The chord of the circle of *curvature* that paſſes thro' the focus, the diameter conjugate to that which paſſes thro' the point of contact, and the tranſverſe axis of the figure, are in continued proportion.

5. When the ſection is an ellipſis, if the circle of *curvature* at E meet O*a* in *d*, the ſquare of E*d* will be equal to twice the ſquare of O*a*. Hence E*d* : O*a* : : $\sqrt{2}$: 1. Which gives an eaſy method of determining the circle of *curvature* to any point E, when the ſemi-diameter O*a* is given in magnitude and poſition.

Several other properties of the circle of *curvature*, and methods of determining it when the ſection is given; or *vica verſa*, of determining the ſection when the circle of *curvature* is given, may be ſeen in Mr. *Mac Laurin*'s Fluxions, Art. 375.

Variation of CURVATURE. See VARIATION, *Suppl.*

Double

Double CURVATURE is uſed for the *curvature* of a line, all the parts of which are not ſituated in the ſame plane. See the next article.

CURVE *(Cycl.* and *Suppl.)* —The theory of *curves* is a very conſiderable branch of the mathematical ſciences. Thoſe who are curious of advancing beyond the knowledge of the circle and the conic-ſections, and to conſider geometrical *curves* of a higher nature, and in a general view, will do well to ſtudy Mr. Cramer's Introduction a *L'Analyſe des lignes Courbes Algebriques*, printed at Geneva, 4°. 1750, which the learned and ingenious author compoſed for the uſe of beginners. We have an elegant poſthumous work of Mr. Mac Laurin's, printed at the end of his Algebra, and intituled *De Linearum geometricarum proprietatibus generalibus.* The ſame author at a very early age gave a remarkable ſpecimen of his genius and knowledge in his *Geometria Organica*, and carried theſe ſpeculations farther afterwards, as may be ſeen in the theorems he has given us in the Philoſophical Tranſactions. See Dr. *Martin*'s Abridg. vol. viii. p. 62, ſeq.

Curves may be organically deſcribed by the rotation of angles, in the manner mentioned in the *Cyclopædia*, which is Sir Iſaac Newton's invention.

But there is another general method of deſcribing *curves* by the rotation of rulers or ſtrait lines, inſtead of angles.

Thus, if inſtead of angles we uſe three rulers, DQ, CN, SP, (fig. IV.) which are ſuppoſed to revolve about the poles D, C, S, and to cut one another always in three Points N, Q, and P; if any two of theſe interſections as N and Q, be carried along the given ſtrait lines AE, EB, the third interſection P will deſcribe a conic-ſection. See *Mac Laurin*'s Algebra, p. 346. ſeq.

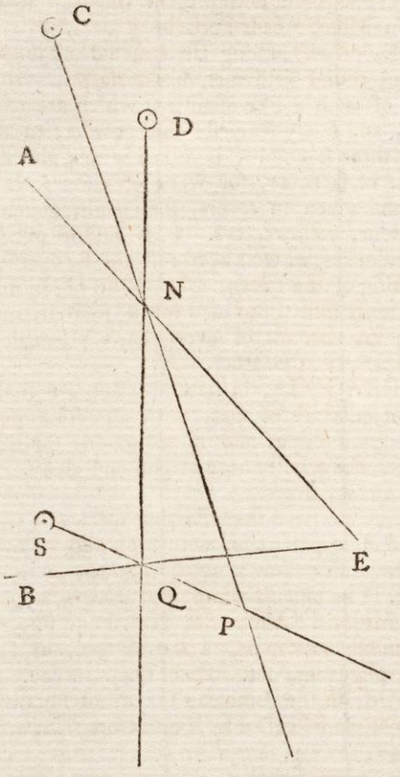


Fig. IV.

If you aſſume any number of poles whatſoever, and make rulers revolve about each of them, and all the interſections but one, be carried along given right lines, that one ſhall never deſcribe a line of a higher nature than a conic-ſection. And if inſtead of rulers you ſubſtitute given angles which move on the ſame poles, the *curve* deſcribed will ſtill be no more than a conic-ſection.

But by carrying one of the interſections neceſſary in the deſcription over a conic-ſection, lines of higher orders may be deſcribed. *Mac Laurin*, ib. p. 351.

The Rev. Mr. Brakenridge has given us a general method of deſcribing *curves* by the interſection of right lines moving about points in a given plane. See Phil. Tranſ. N°. 436. Dr. *Martin*'s Abridg. vol. viii. p. 58. ſeq. But the demonſtrations are not yet extant, excepting the particular caſes demonſtrated in his *Exercitatio Geometrica de Curvarum deſcriptione*, *Lond.* 1733, 4°.

Curves may alſo be deſcribed by the projection, or ſhadows of other *curves*. Thus the projection, or ſhadow of the circle upon different planes, will form the reſt of the lines of the ſecond order, or conic-ſections. This is evident, becauſe the rays of light proceeding from a point out of the plane of a circle, and falling upon the circumference of that circle form a cone, which being cut by the plane upon which the ſhadow of the circle is projected, the different conic-ſections will be formed according to the poſition of the interſecting plane.

In like manner the projections or ſhadows of lines of the third order, will form other lines of the third order; and projections or ſhadows of lines of the fourth order, will form lines of the fourth order, *&c.*

And as the circle, by the projection of its ſhadow, forms the conic-ſections, ſo the five diverging parabolas among the lines of the third order, will, by their ſhadows, form and exhibit all the reſt of the lines of that order. See *Newton*, enumerat. lin. tertij. ordin. publiſhed by Mr. *Jones*, 1711.

This hint of Sir Iſaac Newton has been lately purſued and illuſtrated with great elegance by Mr. Murdoch, in his treatiſe entitled, *Newtoni Geneſis curvarum per Umbras, ſeu perſpectivæ univerſalis elementa. Lond.* 1746, 8°.

By an accurate enumeration of theſe projections, Mr. Murdoch finds, that the number of ſpecies of the lines of the third order amount to ſeventy-eight in all.

CURVE *of a double curvature*, or CURVE *having a double curvature*, is uſed for a *curve*, all the parts of which do not lie in the ſame plane, that is, ſuch as cannot be deſcribed on the ſame plane.

The *curves* commonly treated of in geometry, are ſuppoſed to be deſcribed, or to have all their points placed in the ſame plane; but if a *curve* be ſuppoſed to be deſcribed on a *curve* ſurface, in ſuch a manner that all the points of that *curve* cannot lie or be ſituated in one and the ſame plane, then will the *curve* ſo deſcribed have a *double curvature*.

Monſieur Clairaut has publiſhed an ingenious treatiſe on *curves of a double curvature*. See his *Recherches ſur les Courbes, a double Courbure*, at *Paris*, 4°. 1731. Mr. Euler has alſo treated this ſubject in the Appendix to his *Analyſis infinitorum*, Vol. II. p. 323, ſeq.

CUSTARD-*apple*, a name uſed by ſome for the *guanabanus*, a ſpecies of *anona*. See the article ANONA, *Suppl.*

CUTTLE-*fiſh*, the Engliſh name of the *ſepia* of authors, called alſo the *ink-fiſh*. See the articles SEPIA and INK-*fiſh*, *Append.*

CYANEUS, in zoology, the name of a ſpecies of *coluber*. See the article COLUBER, *Append.*

CYANUS. This is made a diſtinct genus of plants by Tournefort, but comprehended under that of *centauria* by Linnæus. See the article CENTAURIA, *Append.*

CYCLIDIA, in zoology, the name uſed by Dr. Hill for a genus of animalcules of a roundiſh or elliptic figure, and without any viſible limbs or tail. See the article ANIMALCULE, *Suppl.* and *Append.*

CYMBIUM, in natural hiſtory, a name given to the *gondola*-ſhell. See GONDOLA.

CYNOCRAMBE, in botany, a name given to a ſpecies of *dog*'s mercury. See the article MERCURIALIS, *Append.*

CYNOCTONUM. See ACONITE, *Cycl.*

CYPRESS *(Cycl.* and *Suppl.)* —The timber of the *cypreſs-tree* is good for making cheſts, muſical inſtruments, and other utenſils. It never cleaves, and is extremely hard and durable; its bitter juice reſiſting worms and putrefaction. Thus, we are told, that the gates of St. Peter's church at Rome, made of *cypreſs-wood*, had laſted had ſix hundred years as freſh as new, when pope Eugenio ordered gates of braſs in their ſtead. Some will have it, that the wood, gophir, of which Noah's ark was made, was *cypreſs*; which Plato preferred to braſs itſelf, for writing his laws on. Build. Dict. in voc.

Summer-CYPRESS, a name uſed by ſome for the *chenopodium* of authors. See the article CHENOPODIUM, *Append.*

CYSTICAPNOS, in botany, a name uſed by Boerhaave for the *fumaria*, or fumitory. See FUMARIA, *Suppl.*

D.

DAFFODIL, the Engliſh name of a genus of plants known among authors by that of *narciſſus*. See the article NARCISSUS, *Suppl.*

DAFFODIL-*lilly*, in botany, a name ſometimes given to the *lilio-narciſſus* of authors. See the article LILIO-*Narciſſus*, *Suppl.*

Sea-DAFFODIL, the Engliſh name of a genus of plants called by authors *pancratium*. See the article PANCRATIUM, *Append.*

DARE. See the article LEUCISCUS, *Suppl.*

DAIRY, or DAIRY-*houſe*, in rural architecture, a building where milk, butter, cheeſe, whey, &c. are made or kept. See the articles MILK, BUTTER, &c. *Suppl.*

DAISY, in botany, the Engliſh name of a genus of plants called by authors *bellis*. See the article BELLIS, *Suppl.*

Great DAISY, a name ſometimes given to a genus of plants known among authors by that of *leucanthemum*. See the article LEUCANTHEMUM, *Suppl.*

Ox-eye DAISY, a genus of plants called by botanical writers *buphthalmum*. See the article BUPHTHALMUM, *Suppl.*

DAME's *violet*, in botany, a name uſed by ſome for the *heſperis* of authors. See the article HESPERIS, *Suppl.*

DAMP is ſometimes uſed in a ſynonymous ſenſe with moiſture. See the article MOISTURE, *Append.*

DANE-*wort*, or dwarf-elder, names ſometimes given to a genus of plants called by authors *ſambucus*. Seethe article SAMBUCUS, *Suppl.*

DARNEL, the Engliſh name given to a genus of plants called by botanical writers *lolium*. See the article LOLIUM, *Suppl.*

DARNEL-*graſs*. See the article GRASS, *Append.*

DARSINE, a kind of cinnamon. See the article CINNAMUM, *Suppl.*

DASYPUS, in zoology, the name of a genus of animals called *armadillo* and *tatu-muſtelinus*. See the articles ARMADILLO, TATU, and TATUETE, *Suppl.*

DATE *(Cycl.)* — DATE-*tree*, in botany, a name given to ſeveral ſpecies of palm-tree. See the article PALM, *Suppl.*

DATE-*plum*, the name of a genus of plants called by Linnæus *dioſpyros*, and by Tournefort *guaiacana*. See the article GUAIACANA, *Suppl.*

DAY-*lilly*, a name uſed ſometimes for the *hemerocallis* of authors. See the article HEMEROCALLIS, *Suppl.*

DEAD-*nettle*, in botany, the Engliſh name of a genus of plants called by authors *lamium*. See the article LAMIUM, *Suppl.*

DEADLY *carrot*, the Engliſh name of a genus of plants called by authors *thapſia*. See the article THAPSIA, *Suppl.*

DEADLY *nightſhade*, in botany, a name given to the *belladonna* of authors. See the article BELLADONNA, *Suppl.*

DEATH-*watch*, in zoology, the Engliſh name of the *pediculus* of old wood. It is nearly of the ſize of the common louſe, and the noiſe, reſembling the beating of a watch, is made by the male or female, when wooing each other. *Hill*, Hiſt. Anim. p. 22.

DECURSIO, in Roman antiquity, See the article CAMPICURSIO, *Suppl.*

DEER *(Suppl.)* — *Rein*-DEER, the Engliſh name of an animal of the *deer* kind, called by authors *rangifer*. See the article RANGIFER, *Suppl.*

DENTALIUM, in zoology, the ſame with *dentale*. See the article DENTALE, *Suppl.*

DERMESTES, the name given by Dr. Hill to a numerous genus of inſects commonly confounded with the *ſcarabæi*, or beetles, from which they are diſtinguiſhed by having their antennæ of a clavated figure. Vide *Hill*, Hiſt. Anim. p. 40.

DETTANDER. See the article LEPIDIUM, *Suppl.*

DEVICE, among painters, &c. the ſame with deviſe. See the article DEVISE, *Cycl.*

DEVIL *in a buſh*, a name ſometimes given to a genus of plants called by authors *nigella*. See the article NIGELLA, *Suppl.*

DEVIL's *bit*, in botany, a name uſed by ſome writers for the *ſcabioſa* of others. See the article SCABIOSA, *Suppl.*

DEW-*born*, in the management of cattle, an exceſſive ſwelling of the body, proceeding from the greedineſs of a beaſt to feed, when put into rank paſture.

This ſwelling is often ſo great that the creature runs the utmoſt hazard of burſting; in which caſe it ſhould be made to ſtir much, and purge well: but the proper cure is to bleed the creature in the tail, then putting a nutmeg into an egg, to thruſt it down the creature's throat, ſhell and all; after which by walking him up and down he will ſoon mend. Ruſt. Dict. in voc.

DIABETES *(Cycl.* and *Suppl.)* — According to Dr. Mead, the *diabetes* is a diſeaſe of the liver, and not of the kidneys, as has been generally thought. See Monit. & Pract. Medic. cap. ix. § 2. and Mechanic Account of Poiſons, Eſſay i. Ed. 4. The Doctor recommends the following medicine as efficacious in this diſtemper: take four pints of milk, boil it a little, and turn it with three drachms of alum; four ounces of this ſhould be taken three times a day at leaſt.

This diſeaſe happens moſt frequently to thoſe who, without due exerciſe, indulge themſelves with drinking vinous liquors, and then quench the thirſt ariſing from thence by too great a quantity of ſuch as are cooling.

The *diabetes* ſeem to have been rare among the antients, ſince Galen ſays he ſaw it but twice only.

DIAGONAL *ſcale*. See the article PLOTTING *ſcale*, *Cycl.*

DIALLING *(Cycl.)* — We have a treatiſe, by Mr. Deparcieux, on this ſubject, publiſhed 1740, recommended in Hiſt. Acad. Scienc. 1740.

DIAMOND *(Cycl.* and *Suppl.)* — When *diamonds* are fouled with a yellow or brown colour, it is a common practice among jewellers to put them into a fierce fire; this diveſts them of their colour, without doing them the leaſt ſenſible injury. *Du Fay*, in Mem. Acad. Paris. 1735.

DIAPENTE, *(Cycl.)* among farriers, a drink made for horſes, of gentian, round birthwort, barberries, myrrh, and ivory ſhavings, of each a like quantity, which are to be pounded ſeparately, and finely ſearced: this powder, to the quantity of two or three ſpoonfuls, is mixed with a pint and a half of muſcadine, or ſack, or, for want of either, with ſtrong ale or beer, and given in fevers, the cough, glanders, ſurfeits, inflammations, yellows, &c. It is ſaid to purify the blood from all foulneſſes, as well as to reſtrain the overflowing of the gall, working of the ſpleen, &c. Ruſt. Dict. in voc.

DIARY, a term ſometimes uſed for a journal, or day-book, containing an account of every day's proceedings. Thus we ſay *diaries* of the weather, &c.

DIAUGOPHRAGMIA, in natural hiſtory, a genus of *ſeptariæ*, whoſe ſepta are of ſpar, with an admixture of cryſtal, which being ſometimes alſo mixed among the matter of the tali, renders the whole more bright and gloſſy. See the article SEPTARIÆ, *Suppl.*

Of this genus we have the following ſpecies: 1. The ferrugineous red *diaugophragmia*, with browniſh yellow partitions. 2. The browniſh yellow *diaugophragmium*, with whitiſh partitions. 3. The blueiſh white *diaugophragmium*, with ſtraw-coloured partitions. Vide *Hill*, Hiſt. Foſſ. p. 522.

DIBBLE, among gardeners, a ſetting-tool, or forked ſtick, wherewith plants are ſet. Ruſt. Dict. in voc.

DICTAMNUS, in the Linnæan ſyſtem of botany, the name of a genus of plants called by Tournefort *fraxinella*. See the article FRAXINELLA, *Suppl.*

DIE. See the article DYE, *Cycl.*

DIER. See the article DYER, *Suppl.* and *Append.*.

DIESIS *(Suppl.)* — a wrong notation has crept into this article; for E, ♮ E, F, read E, ♯ E, F. And ſo in other places of this article, where ♮ E occurs, ſubſtitute ♯ E.

DIET. See the article FOOD, *Suppl.*

One great reaſon why leproſies, hot ſcurvies, dyſenteries, plagues, peſtilential fevers, and the like diſtempers, formerly ſo frequent in London, are now ſo rare, is the change that has been made in the *diet* of the inhabitants. Hoped beer, wine, and ſpirituous liquors coming into general uſe, have been a great means of ſuppreſſing putrid diſeaſes; greens and fruit are likewiſe more univerſally eat, and ſalted meats make a much leſs part of *diet* than formerly: to this add the more general conſumption of tea and ſugar. *Pringle*, Obſerv. on the Diſeaſes of the army, p. 294, *ſeq.*

A vegetable *diet* is moſt proper for ſcorbutic and hectical perſons, and does very well with people who have great exerciſe; but, in other circumſtances, a mixed *diet* of vegetable and animal ſubſtances, ſuch as is commonly uſed, ſeems beſt calculated to nouriſh and preſerve the body from decay. *Id. ibid.* p. 366, *ſeq.*

Irregularities in *diet* are commonly, though unjuſtly, ſuppoſed to have the greateſt ſhare in producing military diſeaſes; were this the caſe, the changes in the weather and ſeaſons would not ſo remarkably affect their health; the ſobereſt and moſt regular corps would not be ſo ſickly; different nations in the ſame camp, living variouſly, would not be afflicted with the ſame diſtempers; nor would there be ſuch an inequality in the numbers of the ſick in different years, were the greateſt part of diſeaſes owing ſolely to *diet*.

Againſt exceſs, the moſt common error in *diet*, the ſmallneſs of a ſoldier's pay is a ſufficient ſecurity: in regard to them, therefore

therefore, the danger lies on the other hand; for, when all are not obliged to eat in meſſes, ſome will be apt to lay out their pay upon ſtrong liquors, and to ſquander away in one day what is but barely a maintenance for a week; but, on the ſuppoſition that every man contributes his ſhare to a meſs, we may be aſſured there can be no errors in *diet* of any conſequence, whilſt almoſt the whole pay is ſpent upon common food. As to the abuſe of ſpirits and fruit, ſoldiers are generally blamed without any foundation; ſpirits being rather beneficial than hurtful to them, ſo often expoſed to the extremes of heat and cold, to moiſt and bad air, long marches, wet cloaths, and ſcanty proviſions; and as to fruit, a few diſorderly men may rob orchards, which is the only way they can come at fruit, but the camp-diſeaſes are incident to the moſt regular equally with them. See *Pringle*, Obſerv. on the Diſeaſes of the army, p. 86, *ſeq.*

A fundamental rule in regard to the *diet* of ſoldiers, is to oblige them to eat in meſſes, by which means their pay will be laid out upon wholeſome food. The greateſt impediment to meſſing are the wives and children, who muſt often be maintained on the ſoldier's pay; in which circumſtances it is not improper food, but the want of it, that may endanger a ſoldier's health.

The meſſing being eſtabliſhed, there remains only to ſee that the men be well ſupplied with bread, and that the markets be ſo regulated that the traders may have encouragement to come to the camp, and the meſſes have good proviſions at a moderate price; and particularly vegetables, which, during the hot weather, ought to make a great part of the *diet*. In eſtabliſhing the meſſes, ſome regulations might be made with regard to an allowance of ſpirits, either by ſtoppages on the pay or otherwiſe. This is already practiſed in the navy, and probably for the ſame reaſons that make ſpirits neceſſary for ſoldiers; ſince in ſhips men are liable to diſtempers from moiſt and corrupted air.

As to the *diet* of officers, their chief rule, in ſickly times, is to eat moderately, avoiding all ſurfeits and indigeſtion, and uſing wine in moderation. *Id. ibid.* p. 112, *ſeq.*

DIFFERENTIAL *equation* is uſed by ſome mathematicians for an equation involving infiniteſimal differences, or fluxions. Thus the equation $3x^2dx - 2axdx + aydx - 3y^2dy + axdy = 0$ in the foreign notation, or $3\dot{x}x\dot{x} - 2ax\dot{x} + ay\dot{x} - 3y^2\dot{y} + ax\dot{y} = 0$ in the Engliſh notation, is called a *differential equation*. But theſe equations ſhould conſiſtently with the Engliſh or Sir Iſaac Newton's notation, be rather called fluxional equations.

Hence ſome of our mathematicians have applied the term *differential equation* in another ſenſe, to certain equations defining the nature of ſeries's. See the article SERIES, *Append.*

DIFFERENTIAL *method*, in mathematics, an appellation given to a method of deſcribing a curve of the parabolic kind thro' any given number of points.

This method is given by Sir Iſaac Newton in the fifth lemma of the third book of his Principles. He diſtinguiſhes two caſes of this problem; the firſt, when the ordinates drawn from the given points to any line given in poſition, are at equal diſtances from each other; and the ſecond, when theſe ordinates are not at equal diſtances. He has given a ſolution of both caſes, but without demonſtration in that place, which has ſince been ſupplied by himſelf and others. See his Methodus Differentialis, publiſhed with other tracts of the ſame author, by Mr. Jones, London, 1711; and Stirling's explanation of the Newtonian *differential method* in the Philoſ. Tranſ. N°. 362. *Cotes*, de Methodo differentiali Newtoniana, in his works publiſhed by Dr. Smith; *Herman.* Phoronomia in Append. p. 389; ſee alſo *Le Seur* and *Jacquier*, in their Comment on Sir Iſaac's Principles, tom. ii. p. 42, *ſeq.*

Where it is to be obſerved, that the methods there demonſtrated by ſome of theſe authors extend to the deſcription of any algebraic curve through a given number of points, which Sir Iſaac, writing to Mr. Leibnitz, mentions as a problem of the greateſt uſe.

By this method, ſome terms of a ſeries being given, and ſuppoſed to be placed at given intervals, any intermediate term may be found nearly; and this therefore gives a method for interpolations. *Newt.* Meth. Differ. prop. v.

Any curvilinear figure may alſo be ſquared nearly, of which ſome ordinates may be found. *Newt. ibid.* prop. vi.

And this method may be extended to the conſtruction of mathematical tables by interpolation. *Ibid. in* ſchol. p. 100.

The ſucceſſive differences of the ordinates of parabolic curves, becoming ultimately equal, and the intermediate ordinate required being determined according to Sir Iſaac's rules, by theſe differences of the ordinates, is the reaſon of this method's being called the *differential method.*

To be a little more particular:

The firſt caſe of Sir Iſaac's problem amounts to this; a ſeries of numbers, placed at equal intervals being given, to find any intermediate number of that ſeries when its interval from the firſt term of the ſeries is given.

Subtract every term of the ſeries from the next following, and let the remainders be called firſt differences; then ſubtract each difference from the next following, and let theſe remainders be called ſecond differences; again, let each ſecond difference be ſubtracted from the next following, and let theſe remainders be called third differences, and ſo on: then if A be the firſt term of the ſeries, d' the firſt of the firſt differences, d'' the firſt of the ſecond differences, d''' the firſt of the third differences, *&c.* and if x be the interval between the firſt term of the ſeries and any term ſought, E, that is, let the number of terms from A to E, both incluſive, be $= x + 1$, then will the term ſought,

$$E = A + \frac{xd'}{1} + \frac{x.\overline{x-1}}{1.2}d'' + \frac{x.\overline{x-1}.\overline{x-2}}{1.2.3}d''' + \frac{x.\overline{x-1}.\overline{x-2}.\overline{x-3}}{1.2.3.4}d'''' + \&c.$$

which ſeries differs from the Newtonian in this, that the quantities $\frac{d''}{1.2}$, $\frac{d'''}{1.2.3}$, $\frac{d''''}{1.2.3.4}$ here uſed, ſignify the ſame with d'', d''', d'''', uſed by Sir Iſaac.

Hence if the differences of any order become equal, that is, if any of the quantities d'', d''', d'''' become $= 0$, we ſhall have a finite expreſſion for E, the term ſought; it being evident, that the ſeries muſt terminate when any of the differences d'', d''', *&c.* become $= 0$.

It is alſo evident that the coefficients $\frac{x}{1}$, $\frac{x.\overline{x-1}}{1.2}$, *&c.* of the differences, are the unciæ of the binomial theorem.

A method may be deduced from the foregoing expreſſion, of finding the ſums of the terms of ſuch a ſeries. For if we imagine a new ſeries, whereof the firſt term ſhall be $= 0$, the ſecond $= A$, the third $= A + B$, the fourth $= A + B + C$, the fifth $= A + B + C + D$, and ſo on, it is plain that the aſſigning one term of this ſeries is finding the ſum of all the terms A, B, C, D, *&c.* Now ſince thoſe terms are the differences of the ſums 0, A, $A + B$, $A + B + C$, $A + B + C + D$, and that, by the ſuppoſition, ſome of the differences of A, B, C, D, *&c.* are $= 0$; it follows that ſome of the differences of the ſums will alſo be $= 0$; and that whereas in the ſeries $A + xd' + \frac{x.\overline{x-1}}{1.2}d''$, *&c.* whereby a term was aſſigned, A repreſented the firſt term, d' the firſt of the firſt differences, and that x repreſented the interval between the firſt term and the laſt, we are to write 0 inſtead of A, A inſtead of d', d' inſtead of d'', d'' inſtead of d''', *&c.* and $x + 1$ inſtead of x; which being done, the ſeries expreſſing the ſums will be $0 + \overline{x+1}.A + \frac{\overline{x+1}.x}{1.2}d' + \frac{\overline{x+1}.x.\overline{x-1}}{1.2.3}d'' + \&c.$ or $\overline{x+1} \times A + \frac{x}{2}d' + \frac{x.\overline{x-1}}{2.3}d'' + \frac{x.\overline{x-1}.\overline{x-2}}{2.3.4}d''' + \&c.$ Or again, if the real number of terms of the lines be called z, that is, if $z = x + 1$, or $z - 1 = x$, we ſhall have the ſum of the ſeries $= z \times A + \frac{\overline{z-1}}{2}d' + \frac{\overline{z-1}.\overline{z-2}}{2.3}d'' + \frac{\overline{z-1}.\overline{z-2}.\overline{z-3}}{2.3.4}d''' + \&c.$ See *De Moivre*, Doctr. of Chances, p. 52, 53. Miſc. Analyt. p. 153.

For inſtance, let it be required to find the ſum of a ſeries of the ſquares of the natural numbers $1 + 4 + 9 + 16 + 25 + 36$

Then, $A = 1$ d'

4 3 d''

9 5 2 d'''

16 7 0

25 9 2 0

36 11 2

The ſum conſequently will be,

$$= z \times 1 + \frac{\overline{z-1}}{2} \times 3 + \frac{\overline{z-1}.\overline{z-2}}{2.3} \times 2$$

$$= z \times 1 + \frac{3z-3}{2} + \frac{zz-3z+2}{3}$$

$$= z \times \frac{6 + 9z - 9 + 2zz - 6z + 4}{6}$$

$$= z \times \frac{1 + 3z + 2zz}{6} = \frac{z.\overline{1+z}.\overline{1+2z}}{6} = \frac{6.7.13}{6} = 91$$

This eaſy example will be ſufficient to ſhew the applications of the rule. Thoſe who are deſirous of ſeeing its uſe in queſtions of chance, may conſult Mr. *de Moivre*'s Doctrine of chances, p. 53, *ſeq.* Various other inſtances of the uſe of this rule in finding ſums of progreſſions of figurate members, *&c.* may be ſeen in Miſc. Analyt. p. 154, *ſeq.*

As to the *differential method*, it is to be obſerved, that though Sir Iſaac and others have treated it as a method of deſcribing an algebraic curve, at leaſt of the parabolic kind, through any number of given points; yet the conſideration of curves is not at all eſſential, though it may help the imagination. The deſcription of a parabolic curve through given points, is the ſame problem as the aſſigning of quantities from their given differences, which may always be done by algebra, and by the

the resolution of simple equations. See Mr. *Stirling*'s Methodus Differentialis, p. 97. This ingenious author has treated fully of the *differential method*, and shewn its use in the solution of some very difficult problems.

DIFFERENTIAL *scale*, in algebra, is used for the scale of relation subtracted from unity. See the article *Recurring* SERIES, *Append.*

DIGESTION, how promoted by fermentation. See the article FERRMENTATION, *Append.*

DIMNESS *of sight*, in horses. Seethe article SIGHT, *Append.*

DISAFFORESTED, the same with deafforested. See the article DEAFFORESTED, *Cycl.*

DISBUDDING *of trees*, is the taking away such branches or sprigs, newly put forth, as are ill placed. Dict. Rust. in voc.

DISBURDENING *of fruit-trees*, is the taking off part of the leaves and fruit, when too numerous, that those which remain may grow the larger. Dict. Rust. in voc.

DISCLOSED, a term used for chickens or hawks newly hatched, or just peeping through the shells; also for buds or flowers just blown. Dict. Rust. in voc.

DISEASES *of soldiers*. See the article SOLDIERS, *Append.*

DISEMBARK, in the sea-language, signifies to land goods from on ship-board. Dict. Rust. in voc.

DISPLANTING, among gardeners, is the plucking up a tree or plant out of the ground. Dict. Rust. in voc.

DISPLANTING *scoop*, an instrument for taking up plants with earth about their roots. *Id. ibid.*

DISSEPIMENTUM, among botanists, the thin septum separating the cells of the fruits of plants.

DISTAFF, an instrument about which flax is tied, in order to the spinning it.

DISTAFF-*thistle*, a name sometimes given to the *atractylis* of authors. See the article ATRACTYLIS, *Append.*

DITTANDER, in botany, the English name of a genus of plants, called by authors *lepidium*. See the article LEPIDIUM, *Suppl.*

DITTANY *(Suppl.)* — *Bastard*-DITTANY, the English name of a genus of plants called by authors *Pseudo-dictamnus*. See the article PSEUDO-*dictamnus*, *Suppl.*

DOCK *(Suppl.)* in botany, the English name of a genus of plants called by authors *lapathum*. See the article LAPATHUM, *Suppl.*

DOCK, among sportsmen, denotes the fleshy part of a boar's chine, between the middle and the buttock.

DOCTOR *Tinkar's weed*, in botany, a name given to a genus of plants called by authors *triosteospermum* and *lonicera*. See the article LONICERA, *Append.*

DOE, the female of the buck-kind. See the article BUCK, *Cycl.* and *Suppl.*

DOG, *(Suppl.)* the English name of a very numerous genus of animals. See the articles DOG and CANIS, *Suppl.*

DOG's *bane*, in botany, the English name of a genus of plants called by authors *apocynum*. See the article DOG's *bane*, *Suppl.*

DOG-*berry-tree*, a name given to the *cornus*, or cornel-tree. See the article CORNUS, *Suppl.*

DOG-*days*, the same with canicular days. See the article CANICULAR, *Cycl.*

DOG's *grass*, in botany. See the article GRASS, *Append.*

DOG's *mercury*, in botany, a name given to a species of *mercurialis*. See the article MERCURIALIS, *Suppl.*

DOG's *stones*, in botany, a name by which some call the *orchis*. See the article ORCHIS, *Suppl.*

DOG's *tongue*, in botany, the English name of a genus of plants called by authors *cynoglossum*. See the article CYNOGLOSSUM, *Suppl.*

DOG's *tooth-shell*, the English name of a species of *dentalium*. See the article DENTALIUM, *supra.*

DOG-*wood*, a name sometimes given to the *cornus*, or cornel-tree. See the article CORNUS, *Suppl.*

DOG-*wood of Jamaica*, the name by which some authors call *robinia*, a genus of plants. See the article ROBINIA, *Suppl.*

DOG-*wood of Virginia*, a name sometimes given to a species of *laurus*, or bay-tree. See the article LAURUS, *Suppl.*

DOGGS, machines of iron for burning wood on; also hooks fixed in large timbers, for drawing them with horses. *Blanckley*, Nav. Expositor, p. 51.

DOOLS, a term used in several parts of the kingdom for balks, or slips of pasture, left between the furrows of ploughed lands. Dict. Rust. in voc.

DORIA, in botany, the name used by Dillenius for the *solidago*, or *virga aurea* of other botanists. See the article VIRGA *aurea*, *Suppl.*

DORMOUSE, the English name of a genus of animals called by authors *sorex*. See the article SOREX, *Suppl.*

DOTTEREL *(Suppl.)* — For MAINELLUS, referred to in this article, read MORINELLUS.

DOUBLE *(Cycl.* and *Suppl.)* — A hare is said to *double* when she keeps in plain fields, and winds about to deceive the hounds. Dict. Rust. in voc.

DOUBLE-*leaf*, or TWYBLADE, in botany, names given by some to the *ophris* of authors. See the article OPHRIS, *Suppl.*

DOUBLE-*tongue*, a name sometimes given to the *ruscus*, or butcher's broom. See the article RUSCUS, *Suppl.*

DOUCETS, or DOULCETS, among sportsmen, denote the testes of a deer or stag. Dict. Rust. in voc.

DOVE's *foot*, in botany, a name sometimes used for the *geranium*, or crane's bill of authors. See the article GERANIUM, *Suppl.*

DOWN, in natural history, denotes the finest feathers of geese, with which beds, pillows, *&c.* are stuffed: also the cottony substance growing on the tops of thistles, and other plants.

DOWNY, something partaking of the nature, or abounding with down: thus, some leaves, fruit, *&c.* are found covered with a *downy* matter.

DRABA, in the Linnæan system of botany, makes a distinct genus of plants, which have no style, and whose fruit is an oval pod of an oblong figure.

C. Bauhine calls it the *bursa pastoris minor*.

DRABA is also a name by which some species of two very distinct genuses of plants, not only from the former, but from each other, are sometimes called; those are the *lepidium* and *hesperis* of botanical writers. See the articles LEPIDIUM and HESPERIS, *Suppl.*

DRAFF, a term used in many parts of the kingdom for the wash given to hogs: also for the grains of brewers usually given to cows.

DRAGG *(Suppl.)* — *Draggs* are also a kind of basket used in clearing the aprons of ship-docks of filth. *Blanckley*, Nav. Expos. p. 51.

DRAGON *(Suppl.)* — *Sea*-DRAGON, in ichthyology, the English name of the *cottus*, with the second back-fin white. See the article COTTUS, *Suppl.*

DRAGON-*tree*, a name sometimes used for the palm-tree. See the article PALM, *Suppl.*

Wild DRAGON, a name sometimes given to *abrotanum*, or southernwood. See the article SOUTHERNWOOD, *Suppl.*

DRAW-*net*, a kind of net for taking the larger sort of wild fowl, which ought to be made of the best packthread, with wide meshes: they should be about two fathoms deep and six long, verged on each side with a very strong cord, and stretched at each end on long poles.

It should be spread smooth and flat upon the ground, and strewed over with sedge, grass, or the like, to hide it from the fowl; and the sportsman is to place himself in some shelter of grass, fern, or some such thing. Dict. Rust. in voc.

DRAW-*gear*, in husbandry, any kind of harness for drawing a waggon or other carriage.

DRAWING *of teeth*, or *Tooth*-DRAWING, in surgery. See the article TOOTH-*drawing*, *Suppl.*

DRAY, a name given by sportsmen to squirrel-nests, built in the tops of trees. See the article SQUIRREL, *Suppl.*

DRAY is also a kind of cart used by brewers for carrying barrels of beer; also a sledge drawn without wheels. Dict. Rust. in voc.

DREDGE, or DREG, a term used by the farmers for oats and barley mingled together. Dict. Rust. in voc.

DREDGERS, a term used in the admiralty-courts for the fishers for oysters. Dict. Rust. in voc.

DRIFFLAND, the same with droffland. See the next article.

DROFFLAND, or DRIFFLAND, in our old customs, a yearly payment made by some tenants to their landlords, for driving their cattle through the manor to fairs and markets. Dict. Rust. in voc.

DROP-*wort*, the English name of a genus of plants called by authors *filipendula*. See the article FILIPENDULA, *Suppl.*

Water-DROP-*wort*, the English name of a genus of plants called *œnanthe* by authors. See the article ŒNANTHE, *Suppl.*

DROPSY *(Suppl.)* — *Dropsies*, attended with anasarcous swellings, are not to be cured with purging alone, nor by soap, nor mercurials; but chiefly by the lixivial salts, either in the form of broom-ashes, salt of wormwood, or salt of tartar. The common method is this; about thirty or forty grains of salt of tartar is dissolved in an infusion of wormwood, to which is added spirit of juniper; and this mixture is to be given in three doses, and repeated daily. Besides this it may be proper to give the patient, once in four or five days, half a dram of *pilulæ ex coloquintida cum aloe*, as a purge; and toward the decline of the disease, some common chalybeate. The diuresis may also be promoted by swallowing garlick, or mustard-seed. See *Pringle*, Observ. on Diseases of the Army, p. 213.

DROSERA, in the Linnæan system of botany, the name of a genus of plants called by Tournefort *ros solis*. See the article ROS *solis*, *Suppl.*

DRUM *(Cycl.)* — *Mire*-DRUM, the name by which the bittern is called in several parts of the kingdom. See the article BITTERN. *Suppl.*

DUBBING *of a cock*, a term used by cock-masters for the cuting off a cock's comb and wattles. Dict. Rust.

DUCK's *foot*, in botany, the English name of a genus of plants known among authors by those of *podophyllum* or *anapodophyllum*. See the article ANAPODOPHYLLUM, *Suppl.*

DUCK-*weed*, or DUCK's *meat*, the English name of a genus of plants called by authors *lemna*. See the article LEMNA, *Append.*

DUMBNESS *(Cycl.)* — When this disorder arises from deafness, it sometimes admits of a cure. See the Phil. Trans. N°. 61. where Dr. Wallis gives an account of two persons deaf and dumb, who were taught to understand and speak a language. And in N°. 245. the doctor gives an account of his method for this purpose. This art is now practised successfully in London by the ingenious Mr. Baker.

DWALE, a name ſometimes given to the deadly nightſhade, or *belladonna*. See the article BELLADONNA, *Suppl.*

DYER's *broom*, in botany, the name of a ſpecies of *geniſta*. See the article GENISTA, *Suppl.*

DYNA, in commerce, a kind of Eaſt-Indian coin, worth about thirty Shillings of Engliſh money.

DYSENTERY *(Cycl.* and *Suppl.)* — The *dyſentery* is owing to cauſes little different from thoſe which produce the bilious or putrid fever. Accordingly it is agreed on all hands, that it proceeds chiefly from two cauſes, different in appearance, but in effect the ſame; one from acrimony generated within the body, and the other from foul ſteams, which being received into it, act as a ferment, and ſuddenly produces the ſame diſorder that ariſes more ſlowly from an internal cauſe.

As to the acrimony, it appears to be of the putrid kind, the *dyſentery* being moſt frequent in hot, cloſe, and moiſt ſeaſons, when bodies are moſt ſubject to putrefaction; and, beſides, prevails chiefly among thoſe of a ſcorbutic habit, or the meaneſt and pooreſt people, who, from foul air, bad diet, and naſtineſs, are moſt liable to putrid diſeaſes.

There is likewiſe an old obſervation, that ſuch ſeaſons as produce moſt flies, caterpillars, and other inſects (the increaſe whereof depends ſo much upon heat, moiſture, and conſequently upon corruption) have likewiſe been the moſt productive of *dyſenteries*.

Laſtly, it is beyond diſpute, that the infection is communicated by putrid effluvia from the bodies, but more eſpecially the fæces of thoſe who are ill of the diſtemper. See *Pringle*, Obſervations on the Diſeaſes of the Army, p. 224, *ſeq.*

This diſeaſe is the ſame in camps as in other places; its greater fatality in the former ariſing more from want of neceſſaries than from any extraordinary virulence in the *dyſentery* itſelf.

Phyſicians diſtinguiſh three ſtates of the *dyſentery*; the firſt, when recent, the ſecond, when it has continued ſome time, and has much impaired the ſtrength, weakened the tone of the inteſtines, and abraded their villous coat; and the third, when, either from the putrid fumes within the body, or the foul air of an hoſpital, a malignant fever is joined, and a mortification threatened.

In the firſt ſtage bleeding is proper, though not in the ſubſequent ones; alſo vomiting with *ipecacuhana*, in ſmall quantities, and repeated ſeveral times. *Vitrum ceratum antimonii* is alſo recommended as the moſt efficacious emetic for relieving the ſtomach and bowels, provided it be given in the beginning of the diſtemper. After vomiting, a purge of rhubarb, to which are added a few grains of ſalt of wormwood, may be given. In winter, indeed, and vernal fluxes, bleeding and rhubarb have been found ſufficient, without vomits. In regard to diet, the common practice is to confine the patient in the beginning to rice-gruel, panado, mutton-broth, and the like; and for drink rice or barley-water, or the white decoction are recommended. In the convaleſcent ſtate they may be allowed meat, but no ſmall beer, and never any milk unleſs diluted with lime-water. *Pringle*, Obſerv. on the Diſeaſes of the Army, p. 230, *ſeq.*

In the ſecond ſtage, the ſame diet, with ſmall doſes of the bark, to which has been added the extract of logwood, or the *tinctura Japonica*, is recommended.

The *dyſentery*, after a ſeeming cure, is apt to recur upon any cold, or error in diet: however, it is to be obſerved, that, for the moſt part, relapſes are not attended with ſuch acrimony as at firſt. When relapſes are apprehended, or the cure imperfect, the patient muſt ſtill uſe a ſoft mucilaginous diet, and continue to take ſome mild aſtringent; which laſt intention may be anſwered by lime-water, given to a pint a day, and ſoftened with half that quantity of boiled milk. Sometimes ſmall doſes of the bark have been no leſs effectual. *Id. ibid.*

Gripes always attend the *dyſentery*, and are relieved by opiates, by fomenting the belly, and by drinking chamemile-tea; for carminatives, in this caſe, inſtead of mitigating, increaſe the pains. The tea produces this effect not only by its antiſpaſmodic but antiſeptic virtue. The fomentations, which are made of herbs, adding ſome ſpirits, muſt be frequently repeated; and when theſe are found ineffectual, the pains may be relieved with a bliſter, or only a warm plaſter with a fourth or fifth part of the *emplaſtrum epiſpaſticum* added to it.

As to the third ſtage of this diſtemper, it coincides with the malignant or hoſpital fever. See the article HOSPITAL *fever*, *Append.*

DYTISCUS, in zoology, the name of a genus of four-winged flies, the antennæ of which are ſlender and ſetaceous. They have likewiſe feet formed for ſwimming, and their habitation is generally in the water, whence they have been called in Engliſh, water-beetles.

E.

EADISH, among farmers. See the article EDDISH, *Append.*

EAGLE *(Suppl.)* — *Sea*-EAGLE, in ichthyology, the Engliſh name of the *aquila marina*, a ſpecies of *raja*. See the articles RAJA and AQUILA *marina*, *Suppl.*

EAGLE-*bat*, the Engliſh name of an animal of the bat-kind. See the article VESPERTILIO, *Suppl.*

EAGLE-*flower*, the name by which ſome call the *balſamina*, a diſtinct genus of plants. See the article BALSAMINA, *Suppl.*

EAGRASS. See the article EDDISH, *Append.*

EAR-*wig*, *forficula*, a well known inſect, very ſwift, with two ſmall horns on its head, and ſix feet; its tail is forked; its body is about the thickneſs of a ſmall worm, and very ſmooth.

It is a very troubleſome creature, frequently introducing itſelf into the ears, and cauſing a great deal of pain by its biting: it likewiſe burrows in other parts of the body, which it bites in the ſame manner.

The dried powder of *ear-wigs* is eſteemed good for deafneſs; and the oil prepared from them, in convulſions and ſpaſms. Vide *Lemery*, Dict. des Drog. *in voc. Forficula.*

EARNING, or YEARNING, a name uſed in ſeveral parts of the kingdom for rennet.

EARSH. See the article EDDISH, *Append.*

EARTH *(Suppl.)* — *Fuller's* EARTH, *terra fullonica*, the Engliſh name of a ſpecies of marle. See the articles MARLE and FULLER'S *earth*, *Suppl.*

EARTH-*nut*, in botany, the Engliſh name of a genus of plants called by authors *bulbocaſtanum*. See the article BULBOCASTANUM, *Suppl.*

EARTH-*nut-peas*, in botany, the name of a genus of plants called by authors *lathyrus*. See the article LATHYRUS, *Suppl.*

African EARTH-*nut-peas*, in botany, a name ſometimes given to the *arachis* of authors. See the article ARACHIS, *Append.*

ECHINI *marini*. See the article CENTRONIA, *Append.*

ECLIPTIC *(Cycl.)* — The obliquity of the *ecliptic* is not conſtant. The mean obliquity is, according to Dr. Bradley, 23° 28′ 30″. Whether this obliquity be the reſult only of the nutation of the earth's axis from the cauſe mentioned in the article STAR, *Append.* or whether there be beſides ſome cauſe producing a gradual approach of the *ecliptic* to the equator, either at the rate of 1′ in 100 years, or at any other rate, is not yet aſcertained.

EDDISH, or EADISH, among farmers, denotes the latter paſture, or graſs, which comes after mowing or reaping, and is otherwiſe called eagraſs, earſh, and etch.

EEL-*backed*, a term uſe by dealers in horſes, for thoſe which have black liſts along their backs.

EFFLUVIA, *(Suppl.)* in medicine, are aſſigned as the cauſe of various diſorders, eſpecially of the contagious kind. Thus, when a conſiderable quantity of putrid *effluvia* has been admitted into the blood, beſides acting thereupon ſlowly, by way of inquinamentum, or ferment, they ſeem immediately to affect the nerves, and thereby to bring on ſome extraordinary diſorder of the whole frame. Hence ariſe ſpaſms, obſtructions, palpitations, a high degree of fever, or a languid circulation, chillneſs, or intenſe heat, and a variety of contrary ſymptoms, according to the different affection of the nerves. To putrid *effluvia* is likewiſe owing the jail diſtemper, which is the ſame with the hoſpital fever. See the article HOSPITAL-*fever*, *Append.*

Some, indeed, unacquainted with the dangerous nature of putrid *effluvia*, have aſcribed the mortality occaſioned by them, to a cold, or other the like cauſe; but, in this, they have entirely miſtaken the cauſe. Vide *Pringle*, Obſerv. on the Diſeaſes of the Army, p. 186, *ſeq.*

Effluvia iſſuing from corrupted ſubſtances chiefly conſiſt of the phlogiſton or ſulphur principle, ſince they ſo readily unite with, and volatilize acids, as appears from the increaſe and particular change of the ſmell. But it is proper to remark, that from a ſimple putrid ſubſtance the phlogiſton does not ariſe alone, but combined with the ſaline parts of the body; for this principle, when ſingle, is perhaps imperceptible to the ſmell; and, when diveſted of theſe ſalts, is never, ſo far as is known, peſtilential: ſo that the deleterious particles of rotten

ſubſtances

ſubſtances ſeem to conſiſt of a certain combination of the ſulphureous with the ſaline principle, which united, not only become the moſt irritating ſtimuli to the nerves, but act upon the humours as a putrid ferment in promoting their corruption. *Id. ibid.* p. 385. See the article MALIGNANT, *Append.*

EGG *(Suppl.)* — *Sea*-EGG, the Engliſh name of a ſpecies of *centronia*. See the article CENTRONIA, *Suppl.*

EGLANTINE, in botany, a name given to the ſweet-briar, a ſpecies of roſe. See the article ROSE, *Suppl.*

EGLECOPALA, a name ſometimes uſed for the ſtony, blueiſh marle. See the article MARLE, *Suppl.*

ELAEAGNON, or ELAEAGNON *Theophraſti*, in botany. See the article AGNUS *caſtus*.

ELATER, the name of a genus of four-winged flies with ſetaceous antennæ; which, when laid on their backs, have a power of leaping with great force and agility.

ELATERIUM, in botany, a name uſed by ſome for the *momordica* of others. See the article MOMORDICA, *Suppl.*

ELDEN, a word uſed in ſome parts of the kingdom for fuel. Dict. Ruſt.

ELDER-*tree*, *alnus*, in botany, the Engliſh name of a genus of plants. See the article ALNUS, *Suppl.*

Dwarf-ELDER, in botany, a name given ſometimes to the *ſambucus* of authors. See the article SAMBUCUS, *Suppl.*

Marſh-ELDER, or *Water*-ELDER, the name by which ſome writers call the OPULUS. See the article OPULUS, *Suppl.*

Spaniſh-ELDER, the Engliſh name of a genus of plants called by authors *Saururus*. See the article SAURURUS, *Suppl.*

ELEPHAS, the elephant, in zoology. See the article ELEPHANT, *Suppl.*

ELICHRYSUM, in botany, the name of a genus of plants, called in Engliſh *goldy-lock*. See the article ELYCHRYSUM, *Suppl.*

ELICHRYSUM, in botany, is alſo a name given by Tournefort to the *gnaphalium*, or cut-weed, of Linnæus. See the article GNAPHALIUM, *Suppl.*

EMPHEREPYRA, in natural hiſtory, a genus of *ſiderochita*, compoſed of various cruſts, or coats, ſurrounding a nucleus of the ſame matter and ſtructure with themſelves. See the article SIDEROCHITA, *Append.*

Of this genus we have the following ſpecies: 1. The very hard ſmooth *empherepyra*, with brown, yellow, and red cruſts. 2. The hard, glittering, rough *empherepyra*, with brown, purple, and deep yellow cruſts. 3. The ſoft browniſh-yellow *empherepyra*. 4. The ſoft *empherepyra*, with ſhining brown and duſky green cruſts. 5. The ſoft *empherepyra*, with lucid, whitiſh, yellowiſh, and red cruſts. *Hill*, Hiſt. Foſſ. p. 532, *ſeq.*

EMPRIMED, among ſportſmen, a term applied to a hart when he forſakes the herd. Dict. Ruſt. in voc.

ENCAMPMENT. See the article CAMP, *Append.*

ENCEPHALOS, ἐγκέφαλος, in phyſiology, is uſed for the brain. *Caſtel.* Lexic. Medic. See the article BRAIN, *Cycl.*

ENCHANTER's *nightſhade*, a name ſometimes given to a genus of plants, called by authors *circæa*. See the article CIRCÆA, *Suppl.*

ENCHELIDES, in zoology, the name of a genus of animalcules, containing the capillary eels, whether of pepper-water, vinegar, &c. See the articles ANIMALCULE, *Append.* and PEPPER, VINEGAR, and EEL, *Suppl.*

ENDEW, in falconry, is ſaid of a hawk that digeſts her meat ſo well, that ſhe not only diſcharges her gorge of it, but even cleanſes her pannel. Dict. Ruſt.

ENDIVE, *endivia*, in botany, a name given to ſeveral ſpecies of *cichorium*. See the article CICHORIUM, *Suppl.*

ENGOUTED, in falconry, is ſaid of a hawk's feathers when they have black ſpots in them. Dict. Ruſt.

ENHYDRIS, in zoology, a name given by the antient Greeks to the otter, from its living in the water. See the article LUTRA, *Suppl.*

ENHYDRI, in natural hiſtory, a genus of cruſtated ferrugineous bodies, formed into large, and in great part, empty caſes, encloſing a ſmall quantity of an aqueous fluid.

Of this genus we have only two ſpecies: 1. The thick ſhelled *enhydrus*, with black, reddiſh, brown, and yellow cruſts. 2. The thinner ſhelled *enhydrus*, with yellowiſh, brown, and purpliſh cruſts. *Hill*, Hiſt. Foſſ. p. 544.

ENSEELED, in falconry, a term uſed for a hawk which has a thread drawn through her upper eye-lid, and made faſt under her beak, to take away the ſight. Dict. Ruſt.

ENTERING *of a hawk*, among falconers, denotes her being allowed to kill for the firſt time. Dict. Ruſt.

ENTERING *of hounds*, is the inſtructing them how to hunt. Dict. Ruſt. See the article ENTRANCE, *Suppl.*

ENTERMEW, in falconry. See the article FALCON.

ENTERMEWER, among falconers, a hawk which changes the colours of her wings by degrees. Dict. Ruſt.

ENTERSELE, in architecture, a kind of ſmall ſtory, ſometimes called a *meazanine*. See the article MEZANINE, *Cycl.*

ENTRY, among ſportſmen, a term by which ſome call thoſe places or thickets, through which deer are found lately to have paſſed. Dict. Ruſt.

EPILOBIUM, in the Linnæan ſyſem of botany, the name of a diſtinct genus of plants, called by Tournefort *chamænerium*. See the article CHAMÆNERIUM, *Suppl.*

EQUATION *(Suppl.)* — Dr. Halley's method for the ſolution of *equations* is thus:

Let the root z of any *equation* be taken equal to $a \pm e$; where a is ſuppoſed to be taken near to the true value. Then from the quantity $a \pm e$ let all the powers of z found in the propoſed *equation*, be formed; and to theſe let their reſpective coefficients be prefixed. Let the power to be reſolved be ſubducted from the ſum of the parts of the firſt column where e is not found; and let the difference be $\pm b$. Then take the ſum of all the coefficients of e in the ſecond column, which call s: and having added all the coefficients of ee, the ſum of which is called t; the root ſought z, will, in a rational form, $= a + \frac{sb}{-ss \pm tb}$; and, in an irrational form, $= a \frac{\mp \frac{1}{2}s \mp \sqrt{\frac{1}{4}ss \mp bt}}{t}$

For inſtance, let it be propoſed to find a root of the *equation* $z^4 - \underset{d}{3}zz + \underset{c}{75}z = 10000$, where 10000 is the reſolvend.

For a firſt ſuppoſition let $a = 10$; we ſhall therefore have the *equation*

$$\begin{array}{l} z^4 = a^4 \pm 4a^3e + 6a^2ee \pm 4ae^3 + e^4 \\ -dzz = -da^2 \pm dae - dee \\ +cz = +ca \pm ce \\ = 10000 \pm 4000e + 600e \pm 40e^3 + e^4 \\ - \quad 300 \pm \quad 600e - \quad 3e \\ + \quad 750 \pm e \quad 75e \\ - 10000 \\ \hline \underset{s}{+450} \mp \underset{t}{40}\,15e + \underset{u}{597}ee \mp 40e^3 + e^4 = 0 \end{array}$$

The ſigns + and — with reſpect to e and e^3 are left doubtful, till it be known whether e be affirmative or negative; in which there is ſome difficulty, as in *equations* having ſeveral roots, the *homogenea comparationis*, as they are called, are often increaſed by diminiſhing a, and on the contrary diminiſhed by increaſing a. But the ſign of e is determined by the ſign of the quantity b; for the reſolvend being ſubtracted from the *homogeneum* formed from a, the ſign of se, and therefore of the parts prevailing in its compoſition, will always be contrary to the ſign of the difference b. Hence it will appear whether e be affirmative or negative, or whether a has been aſſumed greater or leſs than the true root. But e is always equal to $\frac{\frac{1}{2}s - \sqrt{\frac{1}{4}ss - bt}}{t}$, as often as b and t have the ſame ſign; but when they are connected with different ſigns, e becomes $= \frac{\sqrt{\frac{1}{4}ss + bt} - \frac{1}{2}s}{t}$. After that e has been found to be negative, e, e^3, e^5, &c. muſt be made negative in the affirmative members of the *equation*; and affirmative in the negative members, that is, they muſt be writ with a contrary ſign: but if e be affirmative, then muſt e, e^3, e^5, &c. be affirmative in the affirmative members, and negative in the negative.

In the propoſed example we have 10450 inſtead of the reſolvend 10000, or $b = +450$; from whence it appears that a was taken greater than the true root, and conſequently that e is negative. Hence the *equation* becomes $10450 - 4015e + 597ee - 4e^3 + e^4 = 10000$; that is, $450 - 4015e + 597ee = 0$. Therefore, $450 = 4015e - 597ee$, or $b = se - tee$; the root of which is $e = \frac{\frac{1}{2}s - \sqrt{\frac{1}{4}ss - bt}}{t}$, or $\frac{s}{2t} - \sqrt{\frac{ss}{4tt} - \frac{b}{t}}$, that is, in the preſent caſe, $e = \frac{2007\frac{1}{2} - \sqrt{3761406\frac{1}{4}}}{597}$, from whence the approximated root is found to be $= 9.886$. Now this root being taken for a ſecond ſuppoſition, and the operation being repeated we ſhall have $a + e = z = 9.886260336495$, which is very exact, ſcarcely exceeding the truth by above 2 the laſt figure.

This is ſufficient to give a notion of Dr. Halley's method: thoſe who deſire more examples, and farther inſtructions, may conſult the Philoſ. Tranſ. N°. 210. or Lowthorp's Abridg. vol. i. p. 85, *ſeq.*

Differential EQUATION. See the article DIFFERENTIAL, *Append.*

ERIFFS, a name given to canary birds about two years old. See the article CANARY, *Suppl.*

ERIGERON, in the Linnæan ſyſtem of botany, the name of a diſtinct genus of plants, called by other botaniſts *conyzoides*, *conyzella*, and *ſenecionis ſpecies*; and by us the great ſweet fleabane.

The characters of this genus, according to Linnæus, are theſe: the common cup is oblong, cylindric, imbricated, and beſet with ſubulated ſquamæ; the compoſite flower is radiated; the proper hermaphrodite ones are of an infundibuliform ſhape, the limb being divided into five ſegments; and the proper female ones linear, ſubulated, erect, and moſt frequently entire; the ſtamina of the hermaphrodite flowers are five very ſhort capillary filaments, the antheræ, cylindraceo-tubuloſe; the germen of the piſtil is extremely ſmall; the ſtyle is filiform; the ſtigmata are two, oblong and revolute; there is

no pericarpium; the ſeeds are ſmall, oblong, and covered with long down; the receptacle is naked and plane. See *Linnæi* Gen. Plant. p. 400.

The ſpecies of *erigeron* are theſe: 1. The ſingle lateral flowered *erigeron*, with ſquamoſe cups. 2. The toad-flax-leaved annual Canada *erigeron*, called by ſome *conyza*. 3. The coronopus-leaved *erigeron* of America. 4. The ovato-lanceolate-leaved camphorated *erigeron*. 5. The ſhort leaved *erigeron*. 6. The ramoſe, long leaved, ſmall flowered *erigeron*. 7. The larger flowered *erigeron*. *Hill*, Hiſt. Plant. p. 575.

ERINGO, in botany, the Engliſh name of the *eryngium*, a diſtinct genus of plants. See the article ERYNGIUM, *Suppl.*

ERUCA *marina griſeo-fuſca*, a name ſometimes given to the *aphrodita*, a genus of ſea-inſects. See the article APHRODITA, *Append.*

ETCH. See the article EDDISH, *Append.*

ETCH-*crop*, among farmers, the third crop of corn upon land newly broken up. Ruſt. Dict. in voc.

ETERNAL *flower*, the Engliſh name of two different genuſes of plants, the *gnaphalium* and *xeranthemum*. See the articles GNAPHALIUM and XERANTHEMUM, *Suppl.*

EVERLASTING-*pea*, the name of a genus of plants, called by authors *lathyrus*. See the article LATHYRUS, *Suppl.*

EUONYMOIDES, in botany, a name uſed by ſome for the *celaſtrus* of Linnæus. See the article CELASTRUS, *Append.*

EUPHONIC *accent*. See the article ACCENT, *Cycl.*

EWE, the Engliſh name of the female of the ſheep-kind. See the articles SHEEP and OVIS, *Suppl.*

EXAGON, the ſame with hexagon. See the article HEXAGON. *Suppl.*

EXERCISE *(Cycl.)* — Proper *exerciſe* conduces much to the health of ſoldiers in camp.

The *exerciſe* of a ſoldier may be conſidered under three heads; the firſt relating to his duty, the ſecond to his living more commodiouſly, and the third to his diverſions.

The firſt, conſiſting chiefly in the *exerciſe* of his arms, will be no leſs the means of preſerving health, than of making him expert in his duty; and frequent returns of this, early and before the ſun grows hot, will be made more advantageous than repeating it ſeldom, and ſtaying too long out at a time; for a camp affording little convenience for refreſhment, all unneceſſary fatigue is to be avoided.

As to the ſecond article, cutting boughs for ſhading the tents, making trenches round them for carrying off the water, airing the ſtraw, cleaning their cloaths and accoutrements, and aſſiſting in the buſineſs of the meſs, ought to be no diſagreeable *exerciſe* to to the men, for ſome part of the day.

Laſtly, as to diverſions, the men muſt be encouraged to them either by the example of their officers, or by ſmall premiums to thoſe who ſhall excel in any kind of ſports, as ſhall be judged moſt conducive to health; but herein great caution is neceſſary, not to allow them to fatigue themſelves too much, eſpecially in hot weather, or ſickly times; and above all, that their cloaths be kept dry, wet cloaths being the moſt frequent cauſe of camp-diſeaſes.

EXPEDITIONS *in winter*. See the article CAMPAIGN, *Append.*

EYE *(Suppl.)* — EYE-*flaps*, thoſe pieces of leather which covers the *eyes* of coach-horſes. Ruſt. Dict. in voc.

EYE-*brow*, in architecture, the ſame with liſt, or fillet. See the article FILLET, *Cycl.*

EYESSE, in falconry. See the article FALCON, *Suppl.*

F.

FABA *Græca*, in botany, a name ſometimes given to the *guiacana* of Tournefort. See the article GUIACANA, *Suppl.*

FAGG, in the ſea language, denotes the end of thoſe ſtrands which do not go through the tops, when a cable or rope is cloſed. *Blanckley*, Nav. Expoſ. p. 54.

FAINTING. Some people are extremely apt to *faint* during the operation of bleeding. In all caſes, therefore, where plentiful bleeding is indicated, it is beſt to do it in bed, in order to prevent the patient's *fainting*. It is likewiſe obſerved, that a perſon will bear the loſs of a much greater quantity of blood, if the ſtream is ſmall, than by a large orifice, which ſome think neceſſary for making a more ſpeedy revulſion. *Pringle*, Obſerv. on the Diſeaſes of the Army, p. 131. See the article LIPOTHYMIA, *Suppl.*

FAKE, in the ſea-language, one round or circle of a cable: this is otherwiſe called quoil. *Blanckley*, Nav. Expoſ. p. 54.

FAN *(Suppl.)* — FAN is alſo an inſtrument uſed in winnowing corn.

FAR, in horſemanſhip, a term uſed to denote any part of the horſe's right ſide: thus the *far*-foot, *far*-ſhoulder, *&c.* is the right foot, right ſhoulder, *&c.*

FASHIONS, a name ſometimes uſed for the farcin. See the article FARCIN, *Cycl.*

FAT *(Cycl.)* — The antients uſed the terms *adeps*, *pinguedo*, *ſevum*, indifferently: but modern anatomiſts have found it convenient to eſtabliſh a diſtinction; according to theſe *pinguedo* is made the general name for all *fat*, and *adeps* and *ſevum*, made branches or ſpecies of it: the *adeps* comprehends the thinner, ſofter, and moiſter ſort, which eaſily liquifies and difficultly coaleſces; the *ſevum*, ſuet, or leaf, includes the harder, coarſer, and drier [a].

According to an antient gloſſariſt *adeps* is properly the inner *fat*, or that which cleaves to the inteſtines [b].

The ſpecific virtues aſcribed to certain *fats* do not ſeem well warranted; ſome even doubt their being poſſeſſed of any properties different from other ſubſtances of like kind, unleſs what may ariſe out of their different conſiſtencies and degrees of volatility: that of the viper ſeems to have the moſt right to claim ſomething extraordinary upon that account [c].

The way of preparing *fat* for medicinal purpoſes, is to take out the ſkins, veins, fibres, *&c.* waſh it till it becomes unbloody; then melt, ſtrain, and preſerve it from air [d].

Some chemiſts deſcribe *adeps* as a pinguedo coagulaled or condenſed to a conſiſtence by the admixture of ſomething ſaline; for in diſtillation the ſulphureous part of the *adeps* aſcending, leaves only a ſaline matter at the bottom, the coagulation being deſtroyed, the ſubſtance ceaſes to be *adeps*, and is called *oleum adipis* [e].

[a *Blaſ.* Comm. ad Veſling, cap. i. p. 10. *Gal.* De uſu partium, lib. 16. *Gorr.* Def. Med. p. 374. *ſeq. in voc.* πιμελη. [b] See *Du Cange*, Gloſſ. Lat. tom. i. p. 56. [c] *Quinc.* Pharm. P. II. §. xii. p. 27. [d] Pharmac. Edinb. [e] See *Johnſ.* Chym. in Addit. p. 7.]

FAT, in the brewery. See the article VAT, *Cycl.*

FEATHER *(Suppl.)* — *Prince's* FEATHER, in botany, the name of a genus of plants called by authors *amaranthus*. See the article AMARANTHUS, *Suppl.*

FEE *(Cycl.)* in Latin *feudum*, and more antiently *feodum*, is defined by Stryckius [a], "Feudum eſt conceſſio dominii utilis "ſub lege fidelitatis." Theſe *feuds*, no doubt, took their origin from the conqueſts of the northern hive that overſpread Europe. The general divided the conquered country into large diſtricts, over each of which he placed one of his principal officers, and they again ſubdivided their provinces among the ſubalterns and ſoldiers; this was in lieu of pay, and theſe lands being given under the condition of fidelity, by which was chiefly meant aſſiſtance in war, made an united kingdom under the general, who generally aſſumed the title of king, as Hengiſt did in Kent, though he had it not before he made his conqueſt. [a Examen Juris Feudal. cap. ii. qu. 11.]

We muſt not imagine that *feuds* were always invariably of the ſame form; they altered much in proceſs of time. Craig diſtinguiſhes them into four ages, calling them *infantia*, *pueritia*, *adoleſcentia*, and *virilis ætas*. *Infantia* was from the firſt irruption of the northern nations, about the middle of the fifth century to *an.* 650, during which *feuds* were annual, or at moſt for life, like the Turkiſh timariots. *Pueritia* he reckons from 650 to 800, the time of Charlemagne; during which ſons crept into the ſucceſſion of their fathers. *Adoleſcentia* extended from this to Conrad II. *an.* 1022, or 1027. This emperor intending an expedition into Italy, the better to encourage his followers extended the right of ſucceſſion to grand-children and brothers. *Virilis ætas* followed, from Conrad to Frederic, *an.* 1155. in whoſe time the feudal books were compiled, and ſucceſſions to all heirs whatſoever eſtabliſhed.

This is the general account of the origin and progreſs of *feuds*. When they were firſt eſtabliſhed in this iſland has been matter of diſpute among the learned: Craig and Spelman ſay at the conqueſt; others aſſert their higher antiquity; lord chief juſtice Hale, particularly, aſſerts that the Norman cuſtoms derive from the Engliſh: this carries little probability with it. Sir Edward Coke, in the preface to his Sixth Report, brings an old Saxon charter, to prove that lands eſcheated for felony. In this charter, dated *an.* 995, Ethelred gives lands, forfeited by one Ethelſig, for ſtealing ſome ſwine, to one Ulfric, "in

" perpetuam hæreditatem," and then adds, " poſt iſtius la-
" bilis vitæ exceſſum, cuicunque ſibi libuerit ſucceſſori relin-
" quat." This clauſe of diſpoſing of his land by laſt will, and the omiſſion of fealty throughout the whole, ſhews this to have been no *feud* but rather allod, it being well known that after the conqueſt, till the time of Henry VIII, lands were not generally deviſeable by will; and that in all charters fealty was expreſſed: ſo that this forfeiture of the land, muſt rather be conſidered as a fine, or like the *confiſcatio bonorum* among the Romans, who knew nothing of *feuds*, than as a feudal eſcheat. Beſides, it muſt be obſerved in general, that no great ſtreſs can be laid on Saxon charters, moſt of them being forged by monks, and impoſed upon the ignorant Normans, when they enquired into the titles of convents to their lands. See *Rapin*, Hiſt. d'Angl. p. 500.

Craig's reaſons for affirming that the feudal law came in with William I. are, 1. That all the terms of art are French; nor does it appear that the Saxons had any words to expreſs the ſame things. 2. That the penalties inflicted for crimes, among the Saxons, were not the *amiſſio feudi*, but pecuniary, if the crimes were ſmall; and capital for thoſe of a higher nature. 3. It appears from all hiſtorians, that William aſſerted his dominion over all the lands in England, confiſcated the lands of all thoſe that followed Harold, and let others retain theirs *ſub lege fidelitatis*. Craig gives two examples of inveſtiture, one of Athelſtan, the other of the conqueror: Athelſtan's words are, " Ego Athelſtanus rex, do tibi Pauline Oddam & Roddam
" tam bona atque pulchra quam unquam mea erant, teſte Ma-
" thilde conjuge mea." The conqueror inveſted Hugo Lupus, his ſiſter's ſon, in the county of Cheſter, " tenendum
" ſibi & hæredibus ita liberé ad gladium, ut ipſe rex totam
" tenebat Angliam ad coronam." And Craig adds, " licet
" hæc poſterior diſpoſitio magis affinis inveſtituto videatur,
" neutra tamen feudalem diſpoſitionem ſapit, cum nulla ſit
" in eis ſervitiorum aut recognitionis præſtatio nulla, de do-
" mino ſuperiore mentio: propriuſque ad allodii formam ac-
" cedunt." Vide *Craig*, De Jur. Feud. lib. i. dieges. 7.

Authors are not agreed as to the etymology of *feudum* or *feodum*; their different opinions may be ſeen in *Strykii* Examen Juris Feudalis. He himſelf derives it from the Italian *fede*, with little reaſon, ſince *feuds* were by no means of an Italian but Gothic original, and therefore the Gothic languages ſhould be enquired into for the etymology of the word. That of Grotius [a] ſeems probable enough; he derives *feod* from *fe* and *od*, that is, *ſtipendii poſſeſſio*; *fe*, according to him, ſignifying of old *ſtipendium*, and *od*, or *oed*, *poſſeſſio*. This holds even now in the German language, where the word *kleinod* is uſed for a jewel, " quaſi *parvum bonum*, vel *parva poſſeſſio*." Schilter, in his Praxis Juris Romani in Foro Germanico, Exerc. lib. iv. § 23. derives *feod* pretty much in the ſame manner, *viz.* from the verb *fa* or *fahen*, which ſignifies *capere*, *in cuſtodiam tradere*, and *od*, ſignifying *bona*, *facultates*, *poſſeſſionem*, as Grotius ſays. Stryckius adds, that *feuds* were ſometimes called *leod*, from *od* and the verb *lehnen*, or *leihen*, to lend; and the Germans call a feud *lehn guht*, or ſimply *lehn*, to this day. *Leodum* and *leodes* was alſo taken for the vaſſal and for homage, as in an old record mentioned by Schilter, loc. cit. where it is ſaid, " fidelitatem præcelſo filio noſtro vel nobis
" & leode & *Samio* debeant promittere & conjurare." Where he thinks *ſamio* to be an error for *ſamto*, the abbreviation of *ſacramento*. Somner, in his Treatiſe of Gavelkind, gives another etymon (approved of by ſerjeant Wright, in his Treatiſe of Tenures) of *feod*, *viz.* from *fe*, *ſtipendium*, and the termination *hode*, *hoad*, or *head*, ſignifying a quality in abſtract: but this ſeems too metaphyſical and forced, and does not ſeem near ſo natural as the derivation from *od*, *bonum*, *poſſeſſio*, &c. [a Florum ſparſio ad Jus Juſtinian. p. 340.]

Craig defines a *feud* thus [b]: " *Feudum* eſt beneficium, ſeu be-
" nevola & libera rei immobilis aut æquipollentis conceſſio,
" cum utilis dominii tranſlatione retenta proprietate, ſeu do-
" minio directo, ſub fidelitate & exhibitione ſervitiorum ho-
" neſtorum." See his explanation, loc. cit. This is the proper and original meaning of a *feud*; time has ſo much altered it, that Hottoman thinks it ſhould be no longer called *feudum*, but *feudaſtrum*: the original intent and conſideration of granting them was for aſſiſtance in war; now, money is the chief conſideration; and variety of other than military ſervices have been introduced. [b De Jure Feudal. p. 42.]

The vaſſal or tenant could not alien his *fee* without the conſent of his lord [c]. However it ſeems that this was not long rigorouſly obſerved in England, ſince Magna Charta, cap. xxxii. provides, " quod nullus liber homo det de cætero am-
" plius alicui de terra ſua, quam ut de reſiduo terræ ſuæ poſſet
" ſufficient. fieri domino feodi ſervitium ei debitum quod per-
" tinet ad feodum illud." But neither was this well obſerved; ſince by Weſt. 3. 18 Ed. I. it was provided, that any one might alien any part, or the whole, " ita ut feoffatus teneat de
" capitali domino. In Scotland, where the feudal law is more ſtrictly obſerved, alienating half without licence, incurs a forfeiture of the whole; this they call recognition, and is the puniſhment of the vaſſal's ingratitude.

[c Stryck. Examen Juris Feudalis, cap. xix. queſt. 2.]

Writers on the feudal law have diſtinguiſhed the *ſubſtantialia*, the *naturalia*, and the *accidentalia* of *feuds*.

Subſtantialia, called by Craig *eſſentialia*, are the eſſentials, that is, qualities not implying each other, which if taken away the *feud* can no longer ſubſiſt.

Naturalia are the qualities ſuperadded by law.

Accidentalia are the qualities ſuperadded by agreement of the lord and vaſſal.

The *naturalia* are different in different places, and always preſumed, unleſs it be otherwiſe agreed between the parties. The *accidentalia* muſt be expreſſed not preſumed. Vide *Wolfii* Horæ Subſ. Marburg. an. 1729. trimeſtr. æſtiv. and *Craig*, p. 61.

Wolfius defines a *feud* thus, " Feudum eſt, dominium utile
" in re aliqua alteri a domino conceſſum ſub conditione fide-
" litatis mutuæ.
" *Subſtantialia* ſunt determinationes eſſentiales, quibus notio
" feudi in genere abſolvitur.
" *Naturalia* ſunt differentiæ ſpecificæ feudi auctoritate legis
" communiter recepta.
" *Accidentalia* ſunt differentiæ ſpecificæ ſpecierum feudorum a
" ſpecie juris auctoritate communiter recepta diverſorum."

FELIS, in zoology, the name of a very comprehenſive genus, or rather order, of animals. See the article CAT, *Suppl.* This order takes in the lion, the tyger, leopard, cat of the mountain, lynx, ounce, and the domeſtic cat. See the articles LION, TYGER, &c. *Suppl.*

FELL-*wort*, a name ſometimes given to the *gentiana*, or gentian of authors. See the article GENTIANA, *Suppl.*

FELON-*wort*, a name given to the *ſolanum*, or nightſhade of authors. See the article SOLANUM, *Suppl.*

FENNEL, in botany, the Engliſh name of a genus of plants called by authors *fœniculum*. See the article FOENICULUM, *Suppl.*

Scorching FENNEL, a name ſometimes given to a genus of plants known among authors by that of *thapſia*. See the article THAPSIA, *Suppl.*

PENNEL-*flower*, in botany, a name ſometimes given to the *nigella* of authors. See the article NIGELLA, *Suppl.*

FERMENT, *(Suppl.)* among phyſicians, is ſometimes uſed in a ſynonymous ſenſe with putrefaction, or rather for a putrid habit of body, conſidered as the cauſe of malignant diſorders.

But theſe authors are, nevertheleſs, very careful not to confound putrefaction with vegetable fermentation, accounting them only analogous proceſſes; for which reaſon they uſe the ſame term for the putrefying and fermenting agent. It were to be wiſhed, to avoid ambiguity, that we had two different words to denote the exciting cauſe of theſe two inteſtine commotions; but this is the leſs to be expected, on account of the tendency of all putrid animal ſubſtances to promote both animal putrefaction, and a vinous fermentation in vegetables. See the next article.

FERMENTATION *(Suppl.)* — In order to aſcertain the *fermentative* quality of animal ſubſtances, Dr. Pringle, in the Appendix to his Obſerv. on the Diſ. of the Army, has made ſeveral curious experiments: bread and water only ſtood ſeveral days, in a furnace, heated, as uſual, to 100 degrees; but two drams of freſh meat being added to double the former quantity of bread, and water in proportion, the mixture began to *ferment* in a few hours, and continued to do ſo about two days. For the moſt part the *fermentation* was ſo ſtrong that if the corks had not frequently given way the phials muſt have burſt. The bread and fleſh which at firſt lay at the bottom, ſoon roſe to the top, and, conſtantly, as the air elapſed, let fall ſome particles that had been buoyed up by the fluid; thus a ſediment was formed, reſembling lees, whilſt the lighteſt part, or flowers, remained on the ſurface; but the *fermentation* continuing, theſe alſo ſubſided, and the acid taſte and ſmell of the liquors, after the action ceaſed, was a farther proof of the preceding *fermentation*. This change was the more extraordinary, that when the motion began the mixture was tending to corruption, and, in effect, in a few hours afterwards, became offenſive; but next day the putrid ſmell abated, and went off, before the *fermentation* ceaſed.

The doctor made ſeveral other experiments, to the ſame purpoſe, and with nearly ſimilar effects; from all which, he thinks it probable that moſt animal ſubſtances tending to putrefaction, are endowed with a power of raiſing a *fermentation* in the farinacea, and even of renewing that action in ſuch as have undergone it before.

The effect of *fermentation* therefore is to change putrid ſubſtances to a ſtate of acidity, which they not only retain, but grow ſtill more and more acid. It is obſerved, indeed, that the acid ariſing from *fermentation* has ſomething of an auſtere and ſaltiſh taſte, but without any offenſive ſmell. Now, conſidering how much air is generated by *fermentation*, it may ſeem ſtrange that the ſame materials, uſed as food, ſhould make ſo little diſturbance in the body. And the difficulty would be the greater, did the ſaliva, as ſome ſuppoſe, promote both *fermentation* and putrefaction. See the article SALIVA.

From this theory of *fermentation* the doctor accounts for the ſourneſs or acidity of the ſtomach, a diſorder to which many people are ſubject; ſince not only a ſtrong, but an auſtere acid may be produced from the food of thoſe who live on fleſh, bread, and water only, as often as the ſtomach is relaxed,

or

or any way disabled from conveying the whole aliment into the intestines; for, what is left having time to undergo a complete *fermentation*, is thereby changed into a harsh sort of vinegar. See the article HEART-*burn*, *Append.*

Spirits, wines, acids, bitters, aromatics, and the hotter antiscorbutic plants retard alimentary *fermentation*, by their power of correcting putrefaction. However, they may have their several uses; some for checking immoderate *fermentation*, when by reason of a putrid effluvia, or a defect of it, the aliment may ferment too violently; and others, again, for bracing the stomach, and fitting it for expelling its contents in due time.

All these facts correspond with digestion; for the most nourishing and digestable food to people in health, consists in a due mixture of animal and vegetable substances with water: scorbutic or putrid habits require acids, wine, or other antiseptics. An acid abounding in the stomach, is corrected by absorbents; and, in a want of natural heat, and a debility of the stomach, wines, bitters, and warm and acid substances become necessary. See *Pringle*, Observ. on the Diseases of the Army, Append. p. 350, *seq.*

Fermentations have been usually supposed to engender great heat, and effervescence has been used as a synonimous term to express it by; it has not been imagined all this while, that many of the most violent of them are, instead of heat, attended with a very violent cold, as is easily proved by the thermometer.

It might be supposed, that water poured into spirit of wine should cool so fiery a liquor; but on the contrary, experiment proves, that there is always a considerable heat from this mixture, and that this heat is greater, as the proportion of the water is so. There is another phænomenon however in regard to spirit of wine more remarkable than this: as water, which is a cold phlegmatic liquor, might naturally be supposed to cool it, so a mixture of the essential vegetable oil might be as naturally expected to heat it; these being disposed the most readily of all bodies to take fire, and being composed almost entirely of a sulphureous matter; yet these liquors, mixed with spirit of wine, produce cold and not heat with it; and water, which generates so great a heat with spirit of wine, has no effect at all with these oils.

The reason of all this phænomena is, that water will not mix with oil, but that salts will. All spirit of wine contains a great deal of water, and all essential oils are well known to contain a great deal of essential salt. The water added to oils makes no change, because it mixes not with them; with spirit of wine it makes a heat by mixing with the water in that spirit, and dissipating the sulphur it is well known to contain; and the oils cool the spirit on the common principle of all salts cooling water, the salts originally contained in these oils immediately dissolving on the mixture, in the water contained in the spirit of wine: and the degree of cold, which is different with the different oils, is wholly regulated by the greater or lesser quantity of salt the several oils contain. Mem. Acad. Par. 1727.

FERMENTED *liquors (Suppl.)* are esteemed great antidotes to putrefaction; accordingly the abstinence from them is assigned as one cause why the Turks are more subject than other people to the plague, and other contagious distempers. It is likewise observed, that beer, wine, and spirituous liquors coming more into general use, has been one great means of suppressing putrid diseases. See *Pringle*, Observ. on the Diseases of the Army, p. 286, 294.

FERN *(Suppl.)* — *Dwarf*-FERN, the English name of a genus of plants called by botanists *filicula*. See the article FILICULA, *Suppl.*

Sweet FERN, a name by which some call the *myrrhis*, or wild chervil. See the article MYRRHIS, *Suppl.*

FERRET, the English name of an animal of the *mustela* kind. See the article MUSTELA, *Suppl.*

FERRY-*boat*. See the article BAC, *Suppl.*

FEVER *(Suppl.)* — *Ardent* FEVER. See the article INFLAMMATORY *fever*, *Append.*

Bilious FEVER. See the article BILIOUS, *Append.*

Malignant FEVER, or *jail* FEVER, the same with that called *hospital fever*. See the article HOSPITAL *fever*, *Append.*

FEVERFEW *(Suppl.)* — *Bastard*-FEVERFEW, in botany, a name sometimes given to the *parthenium* of authors. See the article PARTHENIUM, *Suppl.*

FEWMET, among sportsmen. See the article FUMET, *Append.*

FIANTS, or FUANTS, the dung of a badger, or fox, and of all other vermin. Rust. Dict. in voc.

FIDDLE, *(Cycl.)* — FIDDLE-*dock*, the name of a species of *lapathum*. See the article LAPATHUM, *Suppl.*

FIG-*tree*, *ficus*, in botany. See the article FICUS, *Suppl.*

Indian FIG, a name sometimes given to a genus of plants called by authors *opuntia*. See the article OPUNTIA, *Suppl.*

Infernal FIG, a name by which some call the *argemone*, called by authors the thorny Mexican poppy. See the article ARGEMONE, *Suppl.*

Pharaoh's FIG, a name sometimes used for a genus of plants called by authors *musa*. See the article MUSA, *Suppl.*

Marigold FIG, a name used by some for the *ficoides* of Tournefort, called by Linnæus *mesembryanthemum*. See the article FICOIDES, *Suppl.*

FIG-*shell*, a species of *dolium*. See the article DOLIUM, *Suppl.*

FILACEOUS, a term applied to such roots of plants as are full of filaments. See the article FILAMENT, *Cycl.*

FILAGO, in botany, a name used by Vaillant for the *gnaphalium*, or cud-weed. See the article GNAPHALIUM, *Suppl.*

FILBERT-*tree*, in botany, the English name of the hazle, called by authors *corylus*. See the article HAZLE, *Suppl.*

FILLAR-*horse*, that yoked immediately to a cart. See the article CART, *Suppl.*

FILLY, a term used in many parts of the kingdom for a female colt. See the article COLT, *Suppl.*

Ladies FINGER. See the article LADIES, *infra.*

FINGRIGO, in botany, a name used by some for a genus of plants called by Plumier *pisonia*. See the article PISONIA, *Suppl.*

FIR *(Suppl.)* — *Scotch* FIR, a name commonly given to the mountain-pine. See the article PINE, *Suppl.*

FIRE-*engine*, the common name of a machine to raise water by fire, or rather by the force of water turned into steam.

The first who gave a hint of the possibility of such a machine was the marquis of Worcester, in his Century of Inventions, printed at London in 1663. Captain Savery took the hint from him, and put the engine in practice: the captain's engine is described in Harris's Lexicon Technicum, under the head *Engine*. Farther improvements were afterwards made by Mess. Newcomen and Cawley, who brought it to the form in which it is now most commonly used.

The moving force in this machine is the expansion of water into steam; and that power is raised by fire, from whence the engine takes its name.

It is not possible in a few words, and without figures, to give any adequate idea of this most philosophical and useful contrivance. Dr. Desagnliers has given a very full description of the engine, in his Course of Experimental Philosophy; and as we may suppose that none of the curious in mechanics will choose to be without the doctor's book, we shall content ourselves with referring to his second volume, from p. 465 to 490.

This engine working by the steam into which water rises after it boils, should entitle it more properly to the name of the *steam-engine*, than to that of *fire-engine*, by which the engines for extinguishing fires are sometimes called.

It is considered as a defect in this fire or steam-engine, that the vessel in which the water is always kept boiling, is so large when only an inconsiderable part of the water is employed in the work. Mr. Blake has therefore endeavoured to regulate the just proportion between the altitude and base of the cylindrical vessel employed in this machine; and he finds that the broader the cylinder is, the better. See Phil. Tranlact. vol. xlvii. p. 197, *seq.*

This engine to raise water by steam seems to have received a farther improvement from Monsr. De Moura, a Portuguese gentleman, who, by an ingenious contrivance, has rendered it capable of working itself. See Phil. Transact. vol. xlvii. p. 436, *seq.*

As to the engines for putting out fires, those of Mr. Newsham seem to have merited universal approbation: for a detail of their construction, see *Desaguliers*, Course of Experim. Philos. vol. ii. p. 505, *seq.*

FIRM *ore*. See the article LEAD *ore*, *Suppl.*

FISH *(Suppl.)* — *Needle* FISH. See the article NEEDLE, *infra.*

FISH-*garth*, a wear or dam in a river for the taking of *fish*. Rust. Dict. in voc.

FITCH, or FITCHOW, a name given to the pole-cat, or to the skin or fur of that animal. See the article PUTORIUS, *Suppl.*

FIVES, among farriers, the same with VIVES. See the article VIVES, *Suppl.*

FIXEN, among sportsmen. See the article VIXEN, *Append.*

FLAG *(Suppl.)* — *Corn*-FLAG, a name by which some writers call the *gladiolus*. See the article GLADIOLUS, *Suppl.*

Sweet-scented FLAG, a name used by some for the *acorus* of botanical writers. See the article ACORUS, *Cycl.* and *Suppl.*

FLAG is also used for a kind of rush called sedge, as well as for the upper part of the turf, pared off to burn. Rust. Dict. in voc.

FLAG-*worm*, a kind of worm so called on account of its being found in flaggy ponds, and other sedgy places. Rust. Dict. in voc.

FLAREING, among seamen. See the article FLAIR, *Suppl.*

FLEA-*bane (Suppl.)* — *African* FLEA-*bane*, a term sometimes used for a genus of plants otherwise called *tarconanthus* and *parthenium*. See the article PARTHENIUM, *Suppl.*

Sweet FLEA-*bane*, the English name of a distinct genus of plants, called by Linnæus *erigeron*. See the article ERIGERON, *Suppl.*

FLIX-*weed*, the name of a genus of plants called by Tournefort and others *erysimum*. See the article ERYSIMUM, *Suppl.*

FLOAT-*boards*, those boards fixed to water-wheels of undershot mills, serving to receive the impulse of the stream, whereby the wheel is carried round. See the article *Water*-WHEEL, *Append.*

It is a disadvantage to have too great a number of *float-boards*. The best rule in this case is, to have just so many, that each of them may come out of the water as soon as possible, after it has received and acted with its full impulse; or, which comes

comes to the ſame thing, when the ſucceeding one is in a perpendicular direction to the ſurface of the water.

As to the length of theſe *float-boards*, it may be regulated according to the breadth of the ſtream. See *Deſaguliers*, vol. ii. p. 425, *ſeq*.

FLOAT-*graſs*, in botany. See the article GRASS, *Append.*

FLOWER *of Briſtol*, a name ſometimes uſed for the *lychnis* of botanical writers. See the article LYCHNIS, *Suppl.*

Gentle FLOWER, the Engliſh name of a genus of plants called by botanical writers *amaranthus*. See the article AMARANTHUS, *Suppl.*

Eternal FLOWER, a name by which ſome call the *xeranthemum* of botanical writers. See the article XERANTHEMUM, *Suppl.*

Everlaſting FLOWER, a term by which ſome call the *gnaphalium*, or cud-weed, of Linnæus and Tournefort. See the article GNAPHALIUM, *Suppl.*

FLOWER-*fence*, a term ſometimes uſed for a genus of plants known among authors by the name of *poinciana*. See the article POINCIANA, *Suppl.*

Four o' clock FLOWER, a name given by ſome to *jalap*. See the article JALAP, *Suppl.*

Side-ſaddle FLOWER, the name uſed by ſome for the *Sarracena* of botaniſts. See the article SARRACENA, *Suppl.*

Sultan-FLOWER, a name ſometimes uſed for the *cyanus*, or blue-bottle. See the article CYANUS, *Suppl.*

Sun-FLOWER, the Engliſh name of a genus of plants, called by botanical writers *helianthus* and *corona ſolis*. See the article SUN-*flower*, *Suppl.*

FLUELLIN, in botany, a name ſometimes given to ſpeed-well, called by authors *veronica*. See the article VERONICA, *Suppl.*

FLY *(Cycl.* and *Suppl.)* — *Humble-bee* FLY, the Engliſh name of a ſpecies of *culex*. See the articles HUMBLE, *Suppl.* and CULEX, *Append.*

FLY-*wort*, in botany, a name by which ſome call the *lychnis* of authors. See the article LYCHNIS, *Suppl.*

FLY, in mechanics, a croſs with leaden weights at its ends, or rather a heavy wheel at right angles to the axis of a heavy windlas or roller, by means of which the force of the power is not only preſerved, but equally diſtributed in all the parts of the revolution.

The *fly* may be applied to ſeveral ſorts of engines, whether moved by men, horſes, wind, or water; and is of great uſe in thoſe parts of an engine, which have a quick circular motion, and where the power or reſiſtance act unequally in the different parts of a revolution. In this caſe the *fly* becomes a moderator, making the motion of revolution almoſt every where equal.

The force of a *fly*, when joined with the ſcrew, for ſtamping the image upon coins, may be calculated thus: ſuppoſe its two arms to be each 15 inches long, meaſuring from the center of the weights to the axis of motion, and the weights to be 50lb. each, and the diameter of the axis preſſing upon the dye to be 1 inch; if every ſtroke be made in half a ſecond, and the weights deſcribe an half circumference, which will in this caſe be of 4 feet, the velocity will at the inſtant of the ſtroke be at the rate of 8 feet in a ſecond, and therefore the momentum 800; but the arms of the *fly* being as leavers, one brachium of which is 15 inches long, whilſt the other, *viz.* the ſemi-axis, is but of half an inch, we muſt increaſe this force 30 times, which will give 24000; an immenſe force, equal to that of 100 lb. weight falling 120 feet, or near 3 ſeconds in time; or to that of a body of 750lb. falling $16\frac{1}{12}$ feet, or one ſecond in time.

Some of theſe engines for coining crown-pieces have the arms of the *flies* five times as long, and the weights twice as heavy as thoſe here mentioned, ſo that the effect is ten times greater. *Deſaguliers*, Exper. Philoſoph. p. 245, 339.

FŒNUM *ſanctum*, *ſaint* FOIN, in botany, a name by which the *Onobrychis* of anatomiſts is ſometimes called. See the articles ONOBRYCHIS and SAINT-*foin*, *Suppl.*

FŒTUS *(Cycl.)* — The queſtion about the circulation of the blood in the *fœtus* ſeems not yet determined. See Mem. Acad. Scienc. 1699, 1701, 1703, 1717, 1725, and 1739.

FOLDAGE, among farmers, denotes the liberty of penning ſheep by night. Dict. Ruſt. in voc.

FOND, the ſame with fund. See the article FUND, *Cycl.*

FOOL's-*ſtones*, in botany, an appellation given by ſome to a genus of plants called *orchis* by botanical writers. See the article ORCHIS, *Suppl.*

FOOT-*huſks*, among herbaliſts, the ſame with the cup of a flower. See the article CALYX, *Suppl.*

FORCE, *(Cycl.)* in mechanics. — Whenever a body, which was at reſt begins to move, or has a motion which is either not uniform, or not direct, the cauſe of this change in the ſtate of the body is called *force* [a].

While a body remains in the ſame ſtate, either of reſt, or of uniform and rectilinear motion, the cauſe of its remaining in ſuch a ſtate, is in the nature of the body, and it cannot be ſaid, that any extrinſic *force* has acted on it: this internal cauſe or principle is called *inertia* [b]. [[a] Mr. *Euler*, in Mem. Acad. Berlin. 1745, p. 21. [b] *Ibid.*]

Mechanical *forces* may be reduced to two ſorts; one of a body at reſt, the other of a body in motion.

The *force* of a body at reſt, is that which we conceive to be in a body lying ſtill on a table, or hanging by a rope, or ſupported by a ſpring, *&c.* And this is called by the names of *preſſure*, *tenſion*, *force*, or *vis mortua*, *ſolicitatio*, *conatus movendi*, *conamen*, *&c.* To this claſs alſo of *forces* we muſt refer centripetal and centrifugal *forces*, though they reſide in a body in motion; becauſe theſe *forces* are homogeneous to weights, preſſures, or tenſions of any kind. But of this more particularly farther on.

The meaſure of this *force* is the weight with which the table is preſſed, or the rope ſtretched, or the ſpring is bent. And as to this meaſure there is no diſpute, notwithſtanding the diverſity of appellations by which it is called.

The *force of a body in motion* is on all hands agreed to be a power reſiding in that body, ſo long as it continues its motion, by means of which it is able to remove obſtacles lying in its way; to leſſen, deſtroy, or overcome the *force* of any other moving body, which meet it in an oppoſite direction; or to ſurmount any dead preſſure or reſiſtance, as tenſion, gravity, friction, *&c.* for ſome time; but which will be leſſened or deſtroyed by ſuch reſiſtance as leſſens or deſtroys the motion of the body.

This is called *moving force*, *vis motrix*, and by ſome late writers *vis viva*, to diſtinguiſh it from the *vis mortua* ſpoken of before: and by theſe appellations, however different, the ſame thing is underſtood by all mathematicians; namely, that power of diſplacing, of withſtanding oppoſite moving *forces*, or of overcoming any dead reſiſtance, which reſides in a moving body, and which, in whole or in part, continues to accompany it, ſo long as the body moves.

But about the meaſure of this ſort of *force*, mathematicians are divided into two parties. Both ſides agree that the meaſure of this *force* depends partly upon the maſs, or weight, of the body, and partly upon its velocity; ſo that upon any increaſe either of weight or velocity, the moving *force* will become greater. It is alſo agreed that the velocity being given, or being the ſame in two bodies, their *forces* will be in proportion to their maſſes or weights.

But when two bodies are equal, and the velocities with which they move are different, the two parties no longer agree about the meaſure of the moving *force*.

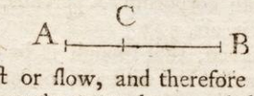
The Newtonians and Carteſians maintain, that the moving *force* is in proportion to the velocity with which the bodies move. But the Leibnitians aſſert, that the moving *force* is in proportion to the ſquare of the velocity; ſo that if the velocity of a moving body be double, triple, quadruple, *&c.* of that of another equal body, the *force* of the former will be fourtimes, nine times, ſixteen times as great as that of the latter. Hence the Newtonians pretend that the *vis motrix*, or moving *force* of bodies is in the compound ratio of their weights and velocities; and the Leibnitians maintain it to be in the compound ratio of the weights and the ſquares of the velocities. This controverſy was firſt ſtarted by the famous Mr. Leibnitz, and has been carried on by him and his followers near ſeventy years, during whith time a great number of pieces have been publiſhed on both ſides of the queſtion, and a great number of experiments have been made, or propoſed to be made in order to decide it: but tho' both parties agree in the event of the experiments, whether actually made or only propoſed, yet as the writers on each ſide have found a way of deducing from thoſe experiments a concluſion ſuitable to their own opinion, the diſagreement ſtill continues as wide as ever.

Now it muſt be owned that theſe oppoſite concluſions from the ſame experiments are not ſo much owing to falſe reaſoning on either ſide, as to their diſagreement in the principles on which the reaſoning is founded. See Dr. *Jurin*, in Phil. Tranſ. N°. 476. Thoſe who maintain that the moving *force* is as the weight into the velocity, lay down for a principle or axiom, that when two bodies meet one another in contrary directions, if their moving *forces* be equal, neither body will prevail over each other: and if their moving *forces* be unequal, the ſtronger will always prevail over the weaker. This is maintained by Mr. Mac Laurin, among others, in his piece which gained the prize in the Royal Academy of Sciences, in 1724, in his Fluxions, and lately in his Account of Sir Iſaac Newton's diſcoveries; it is alſo agreed to by all the oppoſers of the Leibnitian doctrine, though ſome do not formally lay it down as an axiom, but pretend to derive it from the more general principles of preſſure and the time it acts.

But the followers of Leibnitz deny the truth of this principle, and lay down others, which, as they pretend, are more clear and ſatisfactory, ſuch as, that it always requires a determinate degree of *force* to bend a given ſpring to a given degree, whether this be performed in a longer or ſhorter time, or *vice verſa*; that a given ſpring bent to a given degree, always communicates the ſame *force* to a body, by unbending itſelf, whether the time it takes to unbend itſelf be longer or ſhorter. Mr. 'S Graveſande's words are expreſs: *Idem elaſterium, eodem modo flexum, dum relaxatur equalem ſemper vim corpori communicat, ſive lentius ſive velocius relaxetur. 'S Graveſande*, Phyſ. Elem. Math. § 731. edit. 1742. It is true, he does not aſſume it as a principle, but derives it from a more general principle, that the *force* communicated by a preſſure is in a compound ratio of the preſſure and the ſpace through which it paſſes. But theſe propoſitions are alike denied by the Newtonians. Now if it be admitted, that thoſe bodies have equal *forces*,

which meeting each other in contrary directions, do not prevail over each other, it cannot be disputed, that bodies which have equal quantities of motion, have also equal *forces*; and consequently that the moving *forces* of bodies are in a compound ratio of their masses and velocities.

On the other hand, if it be admitted that a given spring bent to a given degree, always communicates the same *force* to whatever body it be applied to, it is no less indisputable that the *forces* of moving bodies will be in a compound ratio of their masses and the squares of their velocities. For the bending of a spring to the same degree, cannot be done by different masses with equal quantities of motion, or a spring by unbending itself cannot communicate to different masses equal quantities of motion; but the bending or unbending of the spring always corresponds to and with what the Leibnitians call the *vis viva*; that is, the product of the mass of a body by the square of its velocity. This is admitted by the Newtonians, and follows from the avowed principles of both parties.



Thus, let M and *m* denote the masses of two bodies, V and *v* their respective velocities; then if any spring, a cross-bow for instance, bent to a certain degree, give the body M a certain velocity V, the same spring or cross-bow, bent to the same degree, will never give another body *m* a velocity *v*, so that MV shall be equal to *mv*, but will always communicate such a velocity to *m*, that MVV shall be equal to *mvv*. See the article SPRING, *Suppl.*

This is admitted by the Newtonians, but the conclusion, that the *forces* of the bodies M and *m* are equal, is denied.

To put an end, therefore, to this controversy, other principles must be found. This has been attempted by several authors, and we have had no small profusion of obscure metaphysics on this occasion. Many subtile reasonings have been formed from the nature of action, cause, effect, time, space, &c. by which we believe more readers have been confounded than enlightened; and after all the controversy is still undecided, and must remain so while the Newtonians, on one hand, assume, that *equal pressures in equal times produce equal moving forces*; and that the Leibnitians, on the contrary maintain, that *equal pressures urging a body through equal spaces produce equal forces.* Hence, supposing equal pressures to act on equal bodies, either to produce motion in them, or to stop what motion they have, the question will be, *whether the force generated or destroyed be proportional to the time the pressure acts, or to the space through which it acts.* For example, let two equal bodies, with the velocities, as 1 and 2, ascend against the action of uniform gravity, according to Galileo's hypothesis; it is certain that the body whose velocity is 2, will resist the *force* of gravity twice the time that the body whose velocity is only 1 can: and it is no less certain, that the body whose velocity is 2, will ascend to four times the height that the other can. So that if we measure the forces of these bodies by the pressure and time requisite to destroy their motion these *forces* will be as the velocities of the moving bodies; but if we measure the *forces* by the pressure, and space through which it extends, requisite to destroy these *forces*, we shall find them proportional to the squares of the velocities of the moving bodies.

This holds in uniform pressures, such as gravity is supposed to be near the earth; but if the pressure be not uniform, as it is not in the action of springs, which press more or less as they are more or less bent, we must then have recourse to the fluxions of the space and time. Thus if *p* stand for the pressure, *t* for the time, *s* for the space; the fluxion, or infinitesimal element as some call it, of the velocity will, according to both parties, be expressed by $\dot{pt}$. According to the Newtonians this is also the fluxion or element of the *force*; but according to the Leibnitians the element of the *force* is proportional to $\dot{ps}^2$. As to any demonstration, either that in unform pressures on the same body, the *force* produced is in proportion to the pressure and the time it acts, and in pressures not uniform that the element of the *force* is proportional to $\dot{pt}$; or that, on the contrary, the *force* thus produced is proportional to the pressure and space in the first case, or that its element is proportional to $\dot{ps}$ in the second case, we have never been fortunate enough to meet with any conclusive argument on either side: nor do we believe any such demonstration possible, till somebody shall be metaphysician enough to analyse the notions of *force*, action, time and space farther than has hitherto been done. — [[a] See *Dan. Bernoulli* in Act. Petrop. vol. viii. p. 100.]

It has been already mentioned, that some Leibnitians do not assume it as a first principle, that action or *force* is proportional to the pressure and space; but they say, that a pressure being given, its action will be proportional to the velocity of the point moved by that pressure. Hence they infer, that the whole action of a pressure, is at its intensity, as the velocity of the point to which it is applied, and as the time the pressure acts. And space being as the time and velocity, they conclude, the action of a pressure to be as that pressure and the space through which it acts. And hence they infer, that the force communicated by the pressure is also as the pressure and space. Thus, say they, if a point runs through a determinate space AB, and presses with a certain given *force* or intensity of pressure, it will perform the same action whe-

ther it move fast or slow, and therefore the time of the action in this case ought not to be regarded. *'S Gravesande*, lib. cit. § 723—728.

But the Newtonians do not submit to this reasoning, and insist, notwithstanding, that the action of the pressure is as the intensity of the pressure, and the time during which it acts, without any regard to the space through which it acts; and they make it an axiom, that equal pressures in equal times produce equal *moving forces*.

Leibnitz himself assumed it as certain, that the action is as the effect by the velocity with which it is produced: and hence he deduces, that the power is as the mass by the square of the velocity: his words, as quoted by Wolfius, are, *Calculum virium pararum seu actionum talem instituo. Sit spatium s, tempus t, velocitas v, corpus c, effectus e, potentia p, actio a, in motu æquabili erit tv ut s, et ut cs, tp ut a. Atque hæc quidem sine demonstratione assumi possunt. Accedit quod demonstrandum, ev ut a. Huic porro plurima theoremata demonstrari possunt*, e. gr. *p ut cv*^{2}. *Nam tp ut ev: sed e ut cs & s ut tv. Ergo fit tp ut ctv*^{2}, *seu p ut cv*^{2}. Vide Act. Petrop. tom. i. p. 232.

But as we cannot pretend to give a full account of all the arguments that have been made use of in this controversy, we must refer the curious to some of the principal authors on this subject, such as Sir Isaac Newton [a], Mr. Mac Laurin [b], Dr. Jurin [c], Dr. Pemberton [d], Mr. Robins [e], Mons. de Mairan [f], and others, on one side: Mess. Leibnitz [g], John [h] and Daniel Bernoulli [i], Herman [k], Poleni [l], Wolfius [m], 'S Gravesande [n], Camus [o], and many more, on the other. But notwithstanding all that has been said, the difficulty of determining whether the element of the moving *force* be proportional to $\dot{pt}$, or to $\dot{ps}$ still remains, and till that be demonstratively decided, we do not see but the question about the measure of the *force* of bodies in motion, must remain undetermined. See *Dan. Bernoulli*, in Act. Petrop. tom. i. p. 131, *seq.*

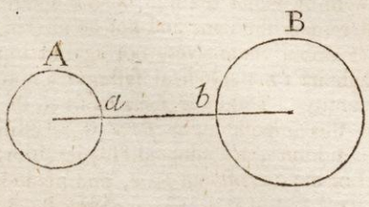
Though Leibnitz was the first that expressly asserted the *force* of a body in motion to be as the square of its velocity, yet Huygens has been thought to have led him into this notion. This eminent mathematician had demonstrated, that in the collisions of two bodies, perfectly elastic, the sum of the products of the bodies by the squares of their respective velocities, was the same after the shock as before. And this proposition is so far general as to obtain in all collisions of bodies that are perfectly elastic. It is also true when bodies of a perfect elasticity strike any immoveable obstacle, as well as when they strike one another; or when they are constrained by any power or resistance to move in directions different from those in which they impel one another [a]. These considerations might have induced Huygens to lay it down as a general rule, that bodies constantly preserve their *ascensional force* [b], that is, the product of their mass, by the height to which their center of gravity can ascend; and, therefore, in a given system of bodies the sum of the squares of their velocities will remain the same and not be altered by the action of the bodies among themselves, nor against immoveable obstacles. Leibnitz's metaphysical system led him to think that the same quantity of action or *force* subsisted in the universe; and finding this impossible, if *force* were estimated by the quantities of motion [c], he adopted Huygens's principle of the preservation of the ascensional *force*, and made it the measure of moving *forces*. But it is to be observed, that Huygens's principle is general only when bodies are perfectly elastic; and in some other cases, which Mr. Mac Laurin has endeavoured to distinguish [d]. — [[a] See *Mac Laurin*'s Fluxions, art. 571. [b] *Hæc constans lex est, corpora servare* vim suam ascendentem, *& idcirco summam quadratorum velocitatum illorm semper manere eandem. Hoc autem non solum obtinet in ponderibus pendulorum & percussione corporum durorum, sed in multis quoque mechanicis experimentis. Huygen.* Oper. tom. i. p. 248. [c] Huygens, p. 247. of the same book, observes, *Quod sæpe pereat pars motus, licet hunc in aliquo effectu edendo consumi, affirmare non possumus, ut in multis casibus percussionis durorum corporum — ita ut minime pro lege naturæ habendum sit, eandem motus quantitatem semper conservari, nisi alicui impendatur & consumatur; sed hæc constans lex est corpora servare vim suam ascendentem, &c.* Where it is to be observed, that by hard

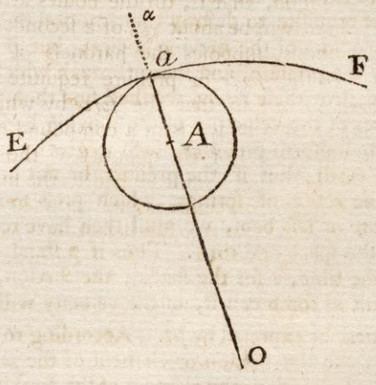


bodies Huygens means ſuch as are elaſtic, as appears from his treatiſe De motu corporum & percuſſione, oper. vol. ii. [d] *Mac Laurin*, lib. cit. art. 533.]

But it is to be obſerved, that though it be true, that in the colliſion of elaſtic bodies the *vis viva*, or aſcenſional *force* is preſerved before and after the ſhock; yet during the ſhock, while the elaſtic bodies are bending and preſs on each other, there ſeems to be a diminution of this *force*, which is afterwards reſtored by the action of their elaſticity; though the followers of Leibnitz do not allow that any *force* is loſt even during the ſhock. They ſay, the *vis viva* is communicated to the ſpring while it is bending, and then is recommunicated to the bodies by the unbending of the ſpring. They alſo deny that any *force* is loſt in the percuſſion of ſoft bodies. For though the *force* of the bodies impelling each other be diminiſhed, yet their *force* does not periſh, but is communicated to ſome other matter [e], ſuch as the ſubtle fluid cauſing coheſion and elaſticity [f]. — [e *Vis viva quæ in percuſſione amittitur, non perit, ſed conſervatur. Wolf.* Coſmol. § 486. *In toto univerſo ſemper conſervatur eadem virium vivarum quantitas.* ibid. § 487. *Vis viva — dum figura corporum in contactu mutatur, in alia materia conſervatur.* Ibid. demonſtr. § 486. [f] Mr. Dan. Bernoulli, ſpeaking of this principle of the preſervation of the *vis viva*, obſerves, *Quamvis principium univerſale ſit, non tamen eſt ſine circumſpectione adhibendum, quia ſæpe contingit ut motus tranſeat in materiam alienam. Ita verbi gratia poſitio illius valet pro regulis motuum ex percuſſione eruendis, ſi modo corpora ſint perfectè elaſtica; ſed cum talia non ſunt, facile eſt videre, partem* virium vivarum *ſive* aſcenſus potentialis *in compreſſionem corporum impenſam corporibus non reſtitui, ſed materiæ cuidam ſubtili, ad quam tranſiit, impreſſam hærere.* Hydrodynam. p. 12, 13. And Mr. Daniel Bernoulli, in this treatiſe, has aſſumed the preſervation of the *vis aſcendens* of Huygens, or, as others expreſs it, the *conſervatio virium virarum*; and, in Mr. Bernoulli's own expreſſion, *æqualitas inter deſcenſum actualem aſcenſumque potentialem*, as an hypotheſis of wonderful uſe in mechanics. But a late author contends that the concluſions drawn from this principle are oftner falſe than true. See De conſervat. virium vivarum diſſert. Lond. 1744. quarto.]

As to the eſtimation of the *force* of bodies in motion, Mr. Euler obſerves, that a body in motion may meet with two kinds of obſtacles, one oppoſing its velocity only, the other its direction. In either caſe, the body exerts its *force* on theſe obſtacles. When the velocity only of the body is changed, as it happens when two bodies in motion meet each other directly, the change reſulting is then ſaid to happen by ſhock, percuſſion, or colliſion. If the obſtacle be of ſuch a nature as only to oppoſe the direction of the body, as when it revolves in a ſling, or moves in an incurvated tube, the obſtacle then acts by preſſure, and this preſſure is called centrifugal *force*. Hence a double *force* is the reſult of the inertia of bodies: that produced by an obſtacle to its velocity is denominated *force* of percuſſion, and the other ariſing from the change of its direction is called *force* of preſſure [g]. — [g *Euler*, Mem. Acad. Berlin. p. 25.]

Leibnitz and his followers make a great difference between theſe two kinds of *forces*. They call *force* of preſſure *vis mortua*, and the *force* of percuſſion *vis viva*. By this oppoſition of terms, they not only ſignify that there is a difference between theſe *forces*, but alſo that they are heterogeneous or not comparable. Hence, though we have an exact meaſure of preſſures, they invented new rules for the meaſure and compariſon of percuſſions, and have thereby occaſioned great diſputes in the philoſophical world.



Philoſophers have ſtated this queſtion ſomewhat vaguely: to fix our notions, let us conſider the body B at reſt, and another body A ſtriking it with a given velocity, in the direction *ab*; it is manifeſt that A exerts an action of a certain *force* on B to diſturb its ſtate. The queſtion is, what

is the *force* exerted on B? Philoſophers have given themſelves little trouble to determine the true meaſure of this *force*: They have confined themſelves to the compariſon of different *forces* of the ſame kind. In eſtimating the quantity of *force* of the body A, by the quantity of the alteration which happens in the ſtate of the body B, they eaſily perceived that this change would be greater, according as the body A had a greater maſs, or a greater velocity. The Newtonians, or rather the Carteſians, and Leibnitians could not agree how to expreſs the reſults of the maſs, and velocity of the ſtriking body: the firſt inſiſt, that the *force* ſhould be expreſſed by the product of the maſs by the velocity. Leibnitz, on the other hand, pretends, that the meaſure of this *force* is the product of the maſs by the ſquare of the velocity. The diſpute has been carried on with great warmth on both ſides; but it ſeems almoſt needleſs to relate the various arguments brought by them in ſupport of their different opinions: for as they have never agreed about the effect, the quantity of which was to be the meaſure of the *force*, the diſpute often degenerated into a logomachy.

It is evident, that neither the one nor the other of theſe opinions admit any compariſon between the *force* of percuſſion and that of preſſure: for this is neither comparable to the product of the maſs by the velocity, nor to the product of the maſs by the ſquare of the velocity. The Leibnitians particularly deny the *vires mortuæ* and *vivæ* to be homogeneous; they make the ſame difference between them as between a line and a ſurface. It ſeems to them that experience confirms their notions; a ſmall blow, as that of a hammer on a nail, often producing an effect ſuperior to that of the greateſt preſſure, eſpecially if the ſame effect is to be produced in ſo ſhort a time as that of driving in the nail by the hammer. But thoſe who lay a ſtreſs on this example ſeem to think, that percuſſion is inſtantaneous. If this were true, there could be no doubt of the heterogeneity of the *vires mortuæ* and *vivæ*; for no preſſure, however great, can produce the leaſt ſenſible effect in an inſtant. Beſides, although the effect of percuſſion were not inſtantaneous, there ſtill appears ſo great a difference between the effects of ſtriking and thoſe of preſſing, that whether the force of percuſſion be proportional to its velocity, or to the ſquare or other power of its velocity, we can never produce a preſſure equivalent to a percuſſion: all which confirms the Leibnitians in their notion that preſſure and percuſſion are heterogeneous [h]. — [h Mem. Acad. Berlin. 1745. p. 29.]

Mr. Euler obſerves, with reſpect to this diſpute concerning the meaſure of vivid *force*, that we cannot abſolutely aſcribe any *force* to a body in motion, whether we ſuppoſe this *force* proportional to the velocity, or to the ſquare of the velocity: for the *force* exerted by a body, ſtriking another at reſt, is different from that which it exerts in ſtriking the ſame body in motion; ſo that this *force* cannot be aſcribed to any body conſidered in itſelf, but only relatively to the other bodies it meets with. There is no *force* in a body abſolutely conſidered, but its inertia, which is always the ſame whether the body be at reſt or in motion. But if this body be forced by others to change its ſtate, its inertia then exerts itſelf as a *force*, properly ſo called, which is not abſolutely determinable; becauſe it depends on the changes that happen in the ſtate of the body. Suppoſe, for inſtance, a body A forced to move in an incurvated tube, or along the curve ſurface E*a*F, the body in this caſe will preſs the ſurface wherever it touches it in a direction *a α* normal to the curve; and with a certain *force* commonly determined in mechanics, by the maſs of the body, its velocity, and by the radius of curvature O*a*. Now the body exerts a preſſure, or *vis mortua*;

yet it would be abſurd to aſcribe a certain and determinate *force* of preſſure to this body conſidered in itſelf, ſince this preſſure may vary very much, acording to the difference of the curvature of E*a*F. In like manner it ſeems unreaſonable to place a certain abſolute *force* of percuſſion in bodies, ſince it principally depends on the external circumſtances accompanying the ſhock.

A ſecond obſervation which has been made by ſeveral great men, is, that the effect of a ſhock of two or more bodies is not produced in an inſtant, but requires a certain interval of time. If this be ſo, the heterogeneity between the *vires vivæ* and *mortuæ* vaniſhes; ſince a preſſure may always be aſſigned, which in the ſame time, however little, ſhall produce the ſame effect. If then the *vires vivæ* be homogeneous to the *vires mortuæ*, and ſince we have a perfect meaſure and knowledge of the latter, we need require no other meaſure of the former than that which is derived from the *vires mortuæ* equivalent to them.

Now that the change of ſtate in the ſhock of two bodies does not happen in an inſtant, appears evidently from the experiments made on ſoft bodies: in theſe, percuſſion forms a ſmall cavity, viſible after the ſhock, if the bodies have no elaſticity. Such a cavity cannot certainly be made in an inſtant. And if the ſhock of ſoft bodies require a determinate time, we muſt certainly ſay as much of the hardeſt, though this time may be ſo ſmall as to be beyond all our ideas. Neither can any inſtantaneous ſhock agree with that conſtant law of nature,

by

by virtue of which nothing is performed *per saltum*. But it is needleſs to inſiſt farther on this, ſince the duration of any ſhock may be determined from from the moſt certain principles.

There can be no ſhock or colliſion of bodies, without their making mutual impreſſions on each other: theſe impreſſions will be greater or leſs according as the bodies are more or leſs ſoft, other circumſtances being the ſame. In bodies called hard, the impreſſions are ſmall; but a perfect hardneſs, which admits of no impreſſion, ſeems inconſiſtent with the laws of nature [i]: ſo that while the colliſion laſts, the action of bodies is the reſult of their mutually preſſing each other. This preſſure changes their ſtate; and the *forces* exerted in percuſſion are really preſſures, and truly *vires mortuæ*, if we will uſe this expreſſion, which is no longer proper, ſince the pretended infinite difference between the *vires vivæ* and *mortuæ* ceaſes [k].—[[i] See the article HARD *bodies*, *Suppl.* [k] *Euler*, ibid. p. 32, 33.]

The *force* of percuſſion, reſulting from the preſſures bodies exert on each other while the colliſion laſts, may be perfectly known, if theſe preſſures be determined for every inſtant of the ſhock.

The mutual action of the bodies begins the firſt moment of their contact, and is then leaſt; after which this action increaſes, and becomes greateſt when the reciprocal impreſſions are ſtrongeſt [l]. If the bodies have no elaſticity, and the impreſſions, they have received, remain, the *forces* will then ceaſe. But if the bodies be elaſtic, and the parts compreſſed reſtore themſelves to their former ſtate, then will the bodies continue to preſs each other, till they ſeparate. To comprehend therefore perfectly the *force* of percuſſion, it is requiſite to define, firſt, the time the ſhock laſts, and then to aſſign the preſſure correſponding to each inſtant of this time: and as the effect of preſſures in changing the ſtate of any body may be known, we may thence come at the true cauſe of the change of motion ariſing from colliſion. The *force* of percuſſion, therefore, is no more than the operation of a variable preſſure during a given time; and to meaſure this *force* we muſt have regard to the time, and to the variations according to which the preſſure increaſes and decreaſes. [[l] Vide infra.]

Mr. Euler has given us ſome calculations with reſpect to theſe particulars [m]. It will be ſufficient here only to illuſtrate their tendency by the inſtance he brings. Suppoſe two bodies A and B; that the hardneſs of theſe bodies is equal; and ſuch, that being preſſed together with the *force* of 100lb. the impreſſion made on each is of the depth of $\frac{1}{1000}$ part of a foot. Suppoſe, farther, B to be at reſt, and fixed, and that A ſtrikes it with the velocity of 100 feet in a ſecond; according to Mr. Euler, the greateſt *force* of compreſſion will be equivalent to 4000lb. and this *force* will produce in each of theſe bodies an impreſſion equal to $\frac{1}{25}$ of a foot; and the duration of the colliſion, that is, till the bodies arrive at their greateſt compreſſion, will be about $\frac{1}{800}$ of a ſecond. Mr. Euler, in his calculations, ſuppoſes the hardneſs of a body to be proportional to the *force* or preſſure requiſite to make a given impreſſion on it; ſo that the *force* by which a given impreſſion is made on a body, is in a compound ratio of the hardneſs of the body and of the quantity of the impreſſion. But he obſerves, that regard muſt be had to the magnitude of the bodies, as the ſame Impreſſion cannot be made on the leaſt bodies as on the greateſt, from the defect of ſpace through which their component particles muſt be driven: he, therefore, only conſiders the leaſt impreſſions, and that the bodies are of ſuch magnitudes, that with reſpect to them the impreſſions may be looked upon as nothing. What he ſuppoſes about the hardneſs of bodies, neither implies elaſticity nor its defect, elaſticity only producing a reſtitution of figure and impreſſion when the preſſing *force* ceaſes; but this reſtitution needs not be here conſidered. It is likewiſe ſuppoſed, that the bodies ſhocking have plane and equal baſes, by which they touch each other in the colliſion; ſo that the impreſſion hereby made diminiſhes the length of each body. It is farther to be obſerved, that in Mr. Euler's calculations, bodies are ſuppoſed ſo conſtituted, that they may not only receive impreſſions from the *forces* preſſing them, but that a greater *force* is requiſite to make a greater impreſſion. This excludes all bodies fluid or ſolid in which the ſame *force* may penetrate farther and farther, providing it have time, without ever being *in equilibrio* with the reſiſtance. Thus a body may continually penetrate farther into ſoft wax, although the *force* impelling it be not increaſed. In theſe, and the like caſes, nothing is required but to ſurmount the firſt obſtacles; which being once done, and the connexion of parts broken, the penetrating body always advances, meeting with the ſame obſtacles as before, and deſtroying them by an equal *force*. But Mr. Euler only conſiders the firſt obſtacles which exiſt before any ſeparation of parts, and which are, no doubt, ſuch, that a greater impreſſion requires a greater *force*. This, indeed, principally takes place in elaſtic bodies; but it ſeems likewiſe to obtain in all bodies when the impreſſions made on them are ſmall, and that the contexture of their parts is not altered. —[[m] Ibid. p. 37, *ſeq.*]

Theſe things being premiſed, let the maſs or weight of the body A be expreſſed in general by A, and let its velocity before the ſhock be that which it might acquire by falling from the height a. Farther, let the hardneſs of A be expreſſed by M, and that of B by N, and let the amplitude of the baſe, by which the impreſſion is made be cc; then will the greateſt compreſſion be made with a *force* $\sqrt{\frac{MNcc}{M+N}\times Aa}$. Therefore if the hardneſs of the two bodies, and the plane of their contact during the whole time of their colliſion be the ſame, this *force* will be $\sqrt{Aa}$, that is, as the ſquare root of the *vis viva* of the ſtriking body A. And as $\sqrt{a}$ is proportional to the velocity of the body A, the *force* of percuſſion will be in a compound ratio of the velocity and of the ſubduplicate ratio of the maſs of the body ſtriking: ſo that in this caſe neither the Leibnitian nor the Carteſian proportions take place. But this *force* of percuſſion depends chiefly on the hardneſs of the bodies; the greater this is, the greater will the *force* of percuſſion be. If M = N, this *force* will be as $\sqrt{Mcc\times Aa}$, that is, in a compound ſubduplicate ratio of the *vis viva* of the body ſtriking, of the hardneſs, and of the plane of contact. But if M, the hardneſs of one of the bodies, be infinite, the *force* of percuſſion will be as $\sqrt{Ncc\times Aa}$; at the ſame time if M = N, this force will be as $\sqrt{\frac{1}{2}Ncc\times Aa}$. Therefore all other things being equal, the *force* of percuſſion, if the ſtriking body be infinitely hard, will be to the *force* of percuſſion if both the bodies be equally hard, as $\sqrt{2}$ to 1.

Mr. Euler farther deduces from his calculation, that the impreſſion received by the body A will be as $\sqrt{\frac{N\times Aa}{M+N\times Mcc}}$ and the impreſſion on B will be as $\sqrt{\frac{M\times Aa}{M+N\times Ncc}}$. If, therefore, the hardneſs of A, that is M, be infinite, it will ſuffer no impreſſion, whereas that on B will extend to the depth of $\sqrt{\frac{Aa}{Ncc}}$. But if the hardneſs of the two bodies be the ſame, or that M = N, they will each receive equal impreſſions of the depth $\sqrt{\frac{Aa}{2Ncc}}$. So that the impreſſion received by the body B, in this caſe, will be to the impreſſion it receives in the former as 1 to $\sqrt{2}$ [n]. —[[n] Ibid. p. 46, 47.]

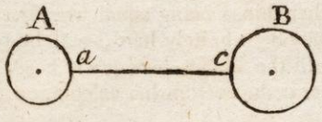
Mr. Euler has likewiſe conſidered and computed the caſe when the ſtriking body has its anterior ſurface convex, with which it ſtrikes an immoveable body whoſe ſurface is plane [o]. He has alſo examined the caſe when both bodies are ſuppoſed immoveable [p]; and from his formulæ he deduces the known laws of the colliſion of non-elaſtic and elaſtic bodies. He has alſo determined the greateſt preſſures the bodies receive in theſe caſes [q]; and likewiſe the impreſſions made on them. In particular he ſhews that the impreſſion received by the body ſtruck, or B, if moveable, is to the impreſſion received by the ſame body when immoveable as $\sqrt{B}$ to $\sqrt{A+B}$. —[[o] Ibid. p. 48. § xxiv. [p] Ibid. § xxv. xxvi. [q] Ibid. § xxvii.]

This doctrine of Mr. Euler may ſerve to ſhew, that the diſpute about the meaſure of *forces* is very needleſs in phyſics; ſince the laws of motion may, independently of any hypotheſis about the meaſure of the *vis viva*, be deduced from the moſt unconteſted principles of preſſure and time. But we doubt whether we ſhall be enabled hereby to ſettle the metaphyſical part of this diſpute to the ſatisfaction of both parties, each of which may aſſent to all that Mr. Euler ſays, and yet adhere either to the Carteſians or Leibnitians. —But whatever may be ſaid of the metaphyſical part of the diſpute, it is certain, from experience,

That the number of equal ſprings requiſite to produce any velocity in a given body, is always proportional to the ſquare of the velocity to be produced. Thus if one ſpring can, by unbending half, produce one degree of velocity in a body, it will require four equal ſprings to produce two degrees of velocity in that body; nine ſprings to produce three degrees of velocity, *&c.* See the article SPRING, *Suppl.*

Alſo, if a portion of a yielding ſubſtance, as clay, tallow, *&c.* be juſt ſufficient to ſtop the motion of a body moving with a certain degree of velocity, it will require four times the quantity of the ſame reſiſting ſubſtance to ſtop it, if the velocity of the moving body be double, *&c.* The ſame holds in the reſiſtance of wood againſt muſquet-balls, as Mr. Robins obſerves in his New Principles of Gunnery: ſo that a ball moving with twice the velocity of another, will penetrate four times as deep into earth, clay, tallow, wood, *&c.* And in like manner if the action of one man, one horſe, or other animal, can give a certain degree of velocity to a given maſs, it will require the action of four equal men, horſes, *&c.* to give the ſame maſs two degrees of velocity; nine men, horſes, *&c.* to give it three degrees of velocity; and ſo on.

Theſe practical points have been put out of all queſtion by the experiments of Poleni, 'S Graveſande, Deſaguliers, and others, and are of great uſe, although they do not decide the controverſy about the meaſure of the *force* of bodies in motion.



FORCE *of inertia*, or *vis inertiæ*. It may be a queſtion, whether the *vis inertiæ* of bodies can properly be called a *force*? As

to

to which Mr. Euler obſerves, that if we give the name of *force* to ſuch cauſes only as can change the ſtate of bodies, the *inertia*, by which all bodies remain in their ſtate of motion, or reſt, cannot properly be called *force*; although a true *force* may ſometimes be the reſult of it. For when the inertia preſerves a body in its ſtate of reſt, or an uniform and direct progreſſion, the ſame inertia may be the cauſe of a change in the ſtate of other bodies: ſo that tho' the name of *force* does not belong to this inertia, with reſpect to the body wherein it reſides, yet it may change into a *force* with reſpect to other bodies. Mr. Euler[a] even thinks it probable that all the changes which happen in the world, ariſe, without exception, from the inertia of bodies, and that there are no other *forces* in nature than what are excited by this inertia. — [[a] In Mem. Acad. Berlin. 1745. p. 22.]

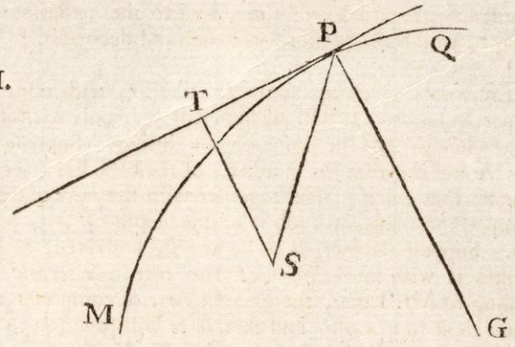
To illuſtrate this, he conſiders a body A (fig. I.) moving with a given velocity in the direction *ac*: ſo long as this body meets with no obſtacle, its motion will continue with the ſame velocity, and in the ſame direction, and thus it will perſevere in the ſame ſtate, the cauſe of this perſeverance being the inertia of the body. But ſuppoſing another body B at reſt, and that the body A has approached ſo near to B, that their extremities touch; what will happen? The bodies

Fig. I.

being impenetrable, it is plain that A cannot remain in its ſtate, without diſturbing that of B; ſince A muſt, in order to continue its motion, either drive B before it with a velocity equal to, or greater than its own, or it muſt turn aſide. Alſo the body B cannot remain in its ſtate of repoſe, unleſs A ſtops, or returns, or deflects to one ſide. All this clearly ſhews, that theſe two bodies cannot at the ſame time preſerve their ſtate. When A touches B, the ſtate of one or both muſt be changed, ſince both equally endeavour to preſerve their ſtate: there can be no reaſon why the one ſhould ſuffer a change rather than the other, and therefore the ſtate of both muſt be altered. But whatever change happens in this reſpect it muſt ariſe from the *vis inertiæ*; for when B's ſtate of reſt is changed to motion, the cauſe is the inertia of A; ſince B would have remained eternally at reſt had it not been for the appulſe of A. In like manner, the cauſe of the change which happens in the motion of the body A, can be nothing elſe than the inertia of B, ſince without this A would have preſerved its motion without any alteration. The inertia being the cauſe of the perſeverance of a body in its ſtate, cannot be conceived but as a principle of reſiſtance to any change of ſtate; ſince we could not ſay that a body has power of remaining in its ſtate, if it gave way without reſiſtance to any cauſe endeavouring to alter that ſtate. This conſideration authoriſes the giving the name of *force* to the inertia, taking the term *force* in an extenſive ſenſe. When then the body A endeavours by its inertia to preſerve its uniform rectilinear motion, it has at the ſame time the *force* to reſiſt all obſtacles; and the body B, the inertia of which exerts itſelf in the preſervation of its ſtate of reſt, has a *force* by which it reſiſts all cauſes endeavouring to draw it out of that ſtate. Hence in the ſhock of theſe two bodies, both being unable to preſerve their ſtate, becauſe of their impenetrability, and the inertia of each reſiſting a change, this inertia of the one muſt produce a change in the other; therefore, though the inertia cannot be called a *force* with reſpect to the body in which it reſides, becauſe it only produces a preſervation of its ſtate, yet with reſpect to other bodies it may become a true *force*, by which their ſtate is changed. Now as many bodies muſt ſhock each other in a world full of bodies differently moved, and that ſome muſt hinder others from perſevering in their ſtate, it follows, that the ſtate of all thoſe bodies muſt undergo perpetual changes; and the cauſe of all theſe will be the inertia by which all bodies have a tendency to preſerve their ſtate. Nor do the changes which continually happen in the world oblige us to aſcribe moving *forces* to bodies, different from their inertia, ſince this alone may produce all the alterations we obſerve[b]. — [[b] Ibid. p. 23, 24.]

The inertia, as well as impenetrability and extenſion, is an univerſal property of all matter; and this inertia is proportional to the maſs or quantity of matter. A body, whether at reſt or in motion, has the ſame inertia, or the ſame power or *force* to preſerve its ſtate. This inertia is the cauſe of a body's reſiſting either to a change of its velocity, or of its direction: and from hence ariſes the two kinds of *forces* before mentioned[c]. — [[c] Ibid. p. 25.]

Central FORCE. It may be proper here to ſubjoin ſomething on the head of *centripetal* and *centrifugal*, or, in one word, *central forces*, to what is ſaid in the *Cyclopædia*, under the head CENTRAL. The doctrine of *central* or *centripetal* and *centrifugal forces* has been much cultivated by mathematicians, as being of extenſive uſe in the theory of gravity and other phyſico-mathematical ſciences.



In this doctrine it is ſuppoſed, that a body at reſt never moves itſelf: and that a body in motion never changes the velocity or direction of its motion of itſelf; but that every motion would continue uniform, and its direction rectilinear, unleſs ſome external *force* or reſiſtance affected it. Hence, when a body at reſt always tends to move, or when the velocity of any rectilinear motion is accelerated continually, or when the direction of a motion is continually varied and a curve line deſcribed, theſe are ſuppoſed to proceed equally from the influence of ſome power that acts inceſſantly; which may be meaſured either by the preſſure of the quieſcent body againſt the obſtacle that hinders it to move, in the firſt caſe; or by the acceleration of the motion, in the ſecond; or by the flexure of the curve deſcribed, in the third caſe; due regard being had to the time in which theſe effects are produced, and the other circumſtances, according to the principles of mechanics. Effects of the power of gravity of each kind fall under our conſtant obſervation near the ſurface of the earth; for the ſame power which renders bodies heavy while they are at reſt, accelerates them when they deſcend perpendicularly, and bends their motion into a curve line when they are projected in any other direction than that of their gravity. But we can judge of the powers that act on the celeſtial bodies by effects of the laſt kind only. And hence it is that the doctrine of *central forces* is of ſo much uſe in the theory of the planetary motions.

Sir Iſaac Newton has treated of *central forces* in book i. § 2. of his principles. Mr. De Moivre has given the following elegant general theorem relating to the ſame ſubject, in the Phil. Tranſ. and in his Miſcel. Analyt. p. 231.

Let MPQ be any given curve in the perimeter of which a body moves: let P be the place of the body in the curve, S the center of *forces*, PG the radius of concavity or curvature, ST the perpendicular drawn from the center of *forces* to the tangent of the curve in P; then will the *centripetal force* be every where proportional to the quantity $\frac{SP}{PG \times ST\ cub.}$

See Miſcel. Analyt. p. 231.

Fig. II.

What is here called the *center of force*, is the point to which the *central force* is always directed.

Monſ. Varignon has alſo given two general theorems on this ſubject in the Memoirs of the Acad. Scienc. an. 1700, 1701, and has ſhewn their application to the motions of the planets. See alſo the ſame Memoirs, an. 1706, 1710.

Mr. Mac Laurin has alſo treated the ſubject of *central forces* very fully in his Fluxions, from art. 416 to 493. where he gives a great variety of expreſſions for theſe *forces*, and ſeveral elegant methods of inveſtigating them.

Sir Iſaac Newton has demonſtrated[d] this fundamental theorem of *central forces*, that the areas which revolving bodies deſcribe by radii drawn to an immoveable center, lie in the ſame immoveable planes, and are proportional to the times in which they are deſcribed. — [[d] Princip. lib. i. prop. 1.]

A late eminent mathematician obſerves that this law, which is originally Kepler's, is the only general principle in the doctrine of *centripetal forces*; but ſince this law, as Sir Iſaac Newton himſelf has proved, cannot hold whenever a body has a gravity or *force* to any other than one and the ſame point, there ſeems to be wanting ſome law that may ſerve to explain the motions of the moon and ſatellites which have a gravity towards two different centers: the law he lays down for this purpoſe is,

That where a body is deflected by two *forces* tending conſtantly to two fixed points, it will deſcribe by lines drawn from the two fixed points, equal ſolids in equal times, about the line joining thoſe fixed points. See *Machin*, of the Laws of the Moon's Motion, in the poſtſcript. This ſhort treatiſe is publiſhed at the end of the Engliſh tranſlation of Sir Iſaac Newton's Principles.

FORCE, in practical mechanics. We have ſeveral curious as well as uſeful obſervations in Deſaguliers's Experimental Philoſophy, concerning the comparative *forces* of men and horſes, and the beſt way of applying them. An horſe draws with the greateſt advantage when the line of direction is level with his breaſt: in ſuch a ſituation, he is able to draw 200lb. eight hours a day, walking about two miles and an half an hour. And if the ſame horſe is made to draw 240lb. he can work but ſix hours a day, and cannot go quite ſo faſt. On a carriage, indeed, where friction alone is to be overcome, a middling horſe will draw 1000lb. But the beſt way to try a

horſe's *force*, is by making him draw up out of a well, over a ſingle pully or roller; and in ſuch a caſe one horſe with another will draw 200lb. as already obſerved.

Five men are found to be equal in ſtrength to one horſe, and can, with as much eaſe, puſh round the horizontal beam of a mill, in a walk 40 feet wide; whereas three men will do it in a walk only 19 feet wide.

The worſt way of applying the *force* of a horſe, is to make him carry or draw up hill: for, if the hill be ſteep, three men will do more than a horſe, each man climbing up faſter with a burden of 100lb. weight, than a horſe that is loaded with 300lb. a difference which is owing to the poſition of the parts of the human body being better adapted to climb than thoſe of a horſe.

On the other hand, the beſt way of applying the *force* of a horſe, is in an horizontal direction, wherein a man can exert leaſt *force*; thus a man drawing a boat along, by means of a rope coming over his ſhoulders, cannot exert above one ſeventh part of the *force* of a horſe employed to the ſame purpoſe.

The very beſt and moſt effectual poſture in a man, is that of rowing; wherein he not only acts with more muſcles at once for overcoming the reſiſtance, than in any other poſition; but as he pulls backwards, the weight of his body aſſiſts by way of leaver. *Deſaguliers*, Exp. Phil. vol. i. p. 241, *ſeq.* where we have ſeveral other obſervations relative to *force* acquired by certain poſitions of the body, from which that author accounts for moſt feats of ſtrength and activity. Ibid. p. 254. *ſeq.*

FORCER, in mechanics, is properly a piſton, without a valve. See the article PISTON, *Cycl.*

There are ſeveral ways of making *forcers*: the moſt common of all conſiſts of a braſs cylinder, a very little leſs in diameter, at its top and bottom, than the bore of the barrel of the pump, and turned ſtill leſs at the middle, in order to let in a leathern ring or collar (made of a thick leather put round the braſs cylinder) which makes it juſt equal to the bore of the barrel, ſo as to fit it quite when it is put into it.

The ſecond ſort of *forcers* conſiſts of three braſs cylinders which can be ſcrewed together. The middle one ought to be almoſt equal in diameter to the bore of the pipe, ſo as to ſlide in it without any friction. The upper cylinder and the lower muſt be a little leſs, and equal to one another. There are two leathers which muſt be put between them when they are unſcrewed: then it is evident, that if the cylinders be ſcrewed together, and the leathers, which ought to be a little bigger than the braſs cylinders, apply themſelves folding upwards round the upper cylinder, and downwards round the lower, they will become juſt equal to the bore of the barrel; and conſequently they will hinder any air from getting through the ſides of the *forcer*, when it moves up and down in the barrel. The uſe of the middle braſs cylinder is to hinder the leathers from turning themſelves back by the motion.

This kind of *forcer* has, above the other, the advantage of having a great deal leſs friction; and beſides, as the leathers, which are applied to it, may be thin ones, they are much ſmoother than thick ones, which are uſed in the other.

But the beſt way of making *forcers*, is, to have a plunger, or ſolid braſs cylinder, equal in length to the barrel of the pump, and a little leſs in the diameter than the bore; ſo that it may move freely in it without any friction. There muſt be two hollow, ſhort, braſs cylinders, or rather rings, at the top of the barrel, which can be ſcrewed together; the upper one muſt be equal in bore to the barrel, and the lower a little leſs: there are two leathers, both having in the middle a leſs hole than the bore of the pipe; the one muſt be applied between the barrel and the lower ring, and the other between the ſame ring and the upper one; and the whole muſt be ſcrewed together. Then if the ſolid cylinder or *forcer*, be put into it, and moved up and down, it is evident that the two before-mentioned leathers, which are applied the one to the barrel and the other to the inſide of the hollow cylinder or ring, will hinder any air from getting between them and the ſolid cylinder.

The advantage of this kind of *forcer*, is, that it has no other friction but at the top of the barrel, and that the inſide of the barrel need not be ſmooth, as in other kinds of pumps; but only the outſide of the *forcer* muſt be turned true and poliſhed, which can be done with much more eaſe. See *Deſaguliers*, Courſe of Experim. Philoſ. p. 161, 162.

FORCING *pump*. See the article PUMP, *Append.*

FORCING *pipe*. See the article PIPE, *Append.*

FORFICULA, the ear-wig, in zoology, the name of a genus of inſects, the tail of which forms a kind of forceps, capable of pinching; the exterior wings are very ſhort, but dimidiated; and the antennæ are ſetaceous. See the article EAR-*wig*, *Append.*

FORM *(Cycl.)* — FORM *of a ſeries*, in algebra, is uſed for that affection of an undeterminate ſeries, ſuch as,

$Ax^n + Bx^{n+r} + Cx^{n+2r} + Dx^{n+3r}$, &c. which ariſes from the different values of the indices of x.

Thus if $n = 1$, and $r = 1$, the ſeries will aſſume the *form*, $Ax + Bx^2 + Cx^3 + Dx^4 +$, &c.

If $n = 1$, and $r = 2$, the *form* will be, $Ax + Bx^3 + Cx^5 + Dx^7 +$, &c.

If $n = \frac{1}{2}$, and $r = 1$, the *form* is,

$Ax^{\frac{1}{2}} + Bx^{\frac{3}{2}} + Cx^{\frac{5}{2}} + Dx^{\frac{7}{2}} +$, &c.

Again, if $n = 0$, and $r = -1$, the *form* of the ſeries will be $A + Bx^{-1} + Cx^{-2} + Dx^{-3} +$, &c.

When the value of a quantity cannot be found exactly, it is of uſe in algebra, as well as in common arithmetic, to ſeek an approximated value of that quantity ſufficient for practice. Thus in arithmetic, as the true value of the ſquare root of 2 cannot be aſſigned, a decimal fraction is found to a ſufficient degree of exactneſs in any particular caſe. And this decimal fraction is in reality no more than an infinite ſeries of fractions converging or approximating to the true value of the root required. For the expreſſion $\sqrt{2} = 1.41421356$, &c. is equivalent to this $\sqrt{2} = 1 + \frac{4}{10} + \frac{1}{100} + \frac{4}{1000} + \frac{2}{10000} + \frac{1}{100000} +$, &c. Or ſuppoſing

$x = \frac{1}{10}$, $\sqrt{2} = 1 + \frac{4}{x} + \frac{1}{xx} + \frac{4}{x^3} + \frac{2}{x^4} + \frac{1}{x^5} +$, &c.

$= 1 + 4x^{-1} + x^{-2} + 4x^{-3} + 2x^{-4} + x^{-5} +$, &c. which laſt ſeries is a particular caſe of the general indeterminate ſeries $Ax^n + Bx^{n+r} + Cx^{n+2r} +$, &c. when $n = 0$, $r = -1$, and the coefficient $A = 1$, $B = 4$, $C = 1$, $D = 4$, $E = 2$, &c.

But the application of the notion of approximations in numbers, to ſpecies, or to algebra, is not ſo obvious. Sir Iſaac Newton, with his uſual ſagacity, took the hint, proſecuted it, and thereby diſcovered general methods in the doctrines of infinite ſeries, which before him had only been treated in a particular manner, though with great acuteneſs, by Dr. Wallis and a few others. See *Newton*'s Meth. of Fluxions and infinite Series, with Mr. Colſon's Comment; as alſo the Analyſis per æquationes numero terminorum infinitas, publiſhed by Mr. Jones, in 1711, and ſince tranſlated and explained by Mr. Stewart, together with Sir Iſaac's Quadrature of Curves, Lond. 1745, quarto. To theſe may be added Mr. *Mac Laurin*'s Algebra, part II. chap. x. p. 244. and *Cramer*'s Analyſe des Lignes Courbes Algebriques, ch. vii. p. 148.

Among the various methods for determining the value of a quantity by a converging ſeries, that ſeems, on many occaſions, preferable to the reſt, which conſiſts in aſſuming an indeterminate ſeries equal to the quantity, the value of which is ſought, and afterwards determining the values of the terms of this aſſumed ſeries.

For inſtance, ſuppoſe a logarithm being given, it were required to find its number.

Let the number be $= 1 + x$, and the given logarithm $= z$. Then, by the nature of logarithms and fluxions (ſee the article FLUXION and LOGARITHM, *Suppl.*) $\dot{z} = \frac{\dot{x}}{1+x}$, and $\dot{z} + x\dot{z} = \dot{x}$. Suppoſe,

$x = Az + Bz^2 + Cz^3 + Dz^4 +$, &c. conſequently,

$\dot{x} = A\dot{z} + 2Bz\dot{z} + 3Cz^2\dot{z} + 4Dz^3\dot{z} +$, &c. $= \dot{z} + x\dot{z}$

$= \dot{z} + Az\dot{z} + Bz^2\dot{z} + Cz^3\dot{z} + Dz^4\dot{z} +$, &c.

Now if the correſponding terms of theſe two equal ſeries's (each being $= \dot{x}$) be compared, we ſhall have

$A = 1$, $B = \frac{1}{2}$, $C = \frac{1}{6}$, $D = \frac{1}{24}$, &c. which values being ſubſtituted in the ſeries $Az + Bz^2 + Cz^3 +$, &c. give,

$x = z + \frac{1}{2}z^2 + \frac{1}{6}z^3 + \frac{1}{24}z^4 + \frac{1}{120}z^5 + \frac{1}{720}z^6 +$, &c.

$= z + \frac{1}{1.2}z^2 + \frac{1}{1.2.3}z^3 + \frac{1}{1.2.3.4}z^4 + \frac{1}{1.2.3.4.5}z^5$

$+$, &c. And conſequently $1 + x$, the number ſought, will be $= 1 + z + \frac{1}{1.2}z^2 +$, &c.

But the indeterminate ſeries $Az + Bzz + Cz^3 +$, &c. was here arbitrarily aſſumed, and will not ſucceed in all caſes.

For inſtance, if from an arc given it were required to find the tangent. Let $x =$ tangent, $v =$ arc, the radius $= 1$. Then, from the nature of the circle, we ſhall have $\frac{\dot{x}}{1+xx} = \dot{v}$, or $\dot{x} = \dot{v} + xx\dot{v}$. Now if to find the value of x we ſuppoſe $x = Av + Bv^2 + Cv^3 +$, &c. and operate as before, we ſhall find all the coefficients B, D, F, of the even powers of v, each $= 0$. Therefore the ſeries aſſumed is not of a proper *form*. But ſuppoſing $x = Av + Bv^3 + Cv^5 + Dv^7 +$, &c. we ſhall find $A = 1$, $B = \frac{1}{3}$, $C = \frac{2}{15}$, $D = \frac{17}{315} +$, &c. and conſequently $x = v + \frac{1}{3}v^3 + \frac{2}{15}v^5 + \frac{17}{315}v^7 +$, &c.

Now to find a proper indeterminate ſeries in all caſes, tentatively, would often be very laborious, and often an impracticable work. Mathematicians have therefore endeavoured to find out a general rule for this purpoſe. But, till lately, the method has been but imperfectly underſtood and delivered. Moſt authors, indeed, have explained the manner of finding the coefficients A, B, C, D, &c. of the indeterminate ſeries $Ax^n + Bx^{n+r} + Cx^{n+2r} +$, &c. which is eaſy; but the values of n and r, wherein the main difficulty lies, have been aſſigned by many, as if they were ſelf-evident, or at leaſt diſcoverable by an eaſy trial or two, as in the laſt example.

Sir Iſaac Newton himſelf has ſhewn the method of determining the number n, by his rule for finding the firſt term of a converging ſeries, by the application of his parallelogram and ruler. For the particulars of this method, ſee the authors above cited. See alſo the article PARALLELOGRAM, *infra.*

Dr. Taylor, in his Methodus incrementorum, inveſtigates

the number r; but, according to Mr. Stirling[a], the rule given by the doctor fails sometimes. [[a] Lineæ tert. ordin. Newtonian. p. 28.]

Mr. Stirling found a correction of Dr. Taylor's rule, but says he cannot affirm it to be universal, having only found it by chance. 'S Gravesande observes, that though he thinks Mr. Stirling's rule never leads into error, yet that it is not perfect. See *'S Gravesande*, De determin. form. seriei infinit. printed at the end of his Matheseos universalis elementa, Lugd. Bat. 1727. This learned professor has endeavoured to rectify the rule. But Mr. Cramer has shewn it to be still defective in several respects; and he himself, to avoid the inconveniences to which the methods of those who wrote before him are subject, has ascended to the first principles of the method of infinite series, and has entered into a more exact and instructive detail of the whole method, than is to be met with elsewhere; for which, and for many other reasons, his treatise deserves to be particularly recommended to beginners.

But it must be observed, that in determining the value of a quantity by a converging series, it is not always necessary to have recourse to an indeterminate series: for it is sometimes more expeditious to find it by common division, or by extraction of roots. See *Newton*, Meth. of Fluxions and inf. Series, above cited. Thus, if it were required to find the arc of a circle from its given tangent, that is, to find the value of v in the fluxional equation, $\dot{v} = \frac{\dot{x}}{1+xx}$, by an infinite series: divide $\dot{x}$ by $1+xx$, the quotient will be the series $\dot{x} - x^2\dot{x} + x^4\dot{x} - x^6\dot{x} +$, &c. And taking the fluents of each term, we shall have $v = x - \frac{1}{3}x^3 + \frac{1}{5}x^5 + \frac{1}{7}x^7 +$, &c. which is the series often used for the quadrature of the circle. If $x = 1$, that is, if x be the the tangent of 45°, then will $v = 1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} +$, &c. = the length of an arc of 45°, that is, $\frac{1}{8}$ of the circumference of a circle, whose radius $= 1$; or $\frac{1}{4}$ of the circumference, if the diameter $= 1$. Consequenly, if 1 be the square of the diameter, $1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} +$, &c. = the area of the circle: because $\frac{1}{4}$ of the circumference multiplied by the diameter, gives the area of the circle. And this is Leibnitz's series, as also James Gregory's.

FORMED *stones*, in natural history. See the article *Formed* STONES, *Suppl.*

FORMICA, among sportsmen, the name of a disease incident to spaniels. See the article SPANIEL, *Suppl.*

FORMICATION *(Cycl.)* — This term is also used among builders, for an arching or vaulting.

FORMS, among sportsmen, is said of a hare when she squats in any place. Dict. Rust. in voc.

FOUCADE. See the article FOUGADE, *Cycl.*

FOULDAGE, the same with foldage. See the article FOLDAGE, *Append.*

FOUNDATION *(Cycl.)* — Architects ought to use the utmost diligence in regard to *foundations*, since of all errors which may happen in building, an error in this point is most pernicious.

The ground fit for building upon is of various kinds; sometimes it is so hard as scarce to be cut with iron; in other places it is stiff, blackish, or whitish. This last is reckoned the weakest; and, in general, that is the best which requires most labour in cutting or digging.

When the ground is very bad, you must get large oaken piles of such a length as may reach the sound ground, and whose diameter must be about one twelfth part of their length: these must be driven down with a machine, as close to one another as possible, and that under the middle walls as well as the outer ones; and upon their tops large planks are to be pinned down. But if the ground be only faulty in some places, arches may be turned over them, by which means no part of the weight of the building will rest upon them.

As to the rules necessary to be observed in constructing the ground-work, they are these: 1. That the bottom of the trench be made exactly level. 2. That the lowest ledge or row be all of stone, laid close together. 3. That the breadth of the ground-work be at least double that of the wall that is to be raised on it. However, art ought always to give way to discretion, for the breadth may be regulated according to the goodness of the ground, and the weight of the intended edifice. 4. That the *foundation* be made to diminish as it rises, only care must be taken that it do so equally on both sides. 5. That you ought never to build upon the ruins of an old *foundation*, unless well assured of its depth and goodness. Build. Dict. in voc.

FOUNDATION *of bridges*. See the article BRIDGE, *Suppl.*

FOX, *vulpes*, in zoology, an animal of the dog-kind. See the articles CANIS and VULPES, *Suppl.*

FOX *tail-grass*, in botany. See the article GRASS, *Append.*

FOYLING *of land*, among farmers, is the fallowing it in the summer or autumn. Dict. Rust. in voc.

FOYLING, among sportsmen, a term used for the footsteps of a stag, on the grass or leaves. Dict. Rust. in voc.

FRACTION *(Cycl.)* — *Infinite series of* FRACTIONS. The sums, or rather the limit of the sums of infinite series's of *fractions*, has been one of the principal objects of the modern methods of computation; and these sums may often be found. Thus the sum of $\frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \frac{1}{16} +$, &c. *ad infinitum*, or rather, the limit to which this sum may approach nearer than by a given difference is 1. So likewise the limit of the sum $\frac{1}{3} + \frac{1}{9} + \frac{1}{27} + \frac{1}{81} +$, &c. is $\frac{1}{2}$. And these and the like sums of geometric progressions may be readily found, by applying the common rule for determining the sum of geometric progressions from the first and last terms and the ratio given. For in these converging infinite geometric progressions, the last term must be considered as 0; so that the sums of the antecedents of these progressions are considered as the sum itself, because they differ from the sum of the progression by less than any assigned quantity; but in every geometric progression the sum of the antecedents is to the sum of the consequents as one antecedent to one consequent. Hence calling the sum S, the first term a, and the ratio r, we shall have $S : S - a :: a : ar :: 1 : r$.

Therefore $Sr = S - a$, or $S = \frac{a}{1-r}$. Thus if $a = \frac{1}{2}$, and $r = \frac{1}{2}$, S will $= \frac{1}{2}$ divided by $\frac{1}{2}$, or 1. And if $a = \frac{1}{3}$, and $r = \frac{1}{3}$, S will $= \frac{1}{3}$ divided by $\frac{2}{3}$, or $\frac{1}{2}$; and so of the rest.

But the series's of *fractions* that occur in the solution of problems are rarely reducible to geometric progressions; nor can any general rule, in cases so infinitely various, be given. The art here, as in most other cases, is only to be acquired by examples, and by a careful observation of the arts used by great authors in the investigation of the series's of *fractions* they have considered. And the general methods of infinite series which have been carried so far by Mr. de Moivre[a], Mr. Stirling[b], and Mr. Euler[c], are often found necessary to determine the sum of a very simple series of *fractions*. — [[a] Miscel. Analyt. passim. [b] Method. Differentialis. [c] Analys. infinitorum, & Act. Petropol. passim.]

The sum of a series of *fractions* decreasing continually, is not always finite, but sometimes infinite, that is, no limit can be assigned but what may be exceeded by the sum of a certain number of the terms of the series. This is the case of the series $\frac{1}{1} + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \frac{1}{6}$, &c. called the harmonic series, the sum of which (as has been said under the article PROGRESSION) exceeds any given number, and the analogy of this progression with the space comprehended between the Apollonian hyperbola and its asymptote, shews this. But the same may be shewn independently of the hyperbola from the nature of progressions. See *Jac. Bernoulli*, De Seriebus infinit.

The foundation of Mr. Bernoulli's demonstration is, that a number of terms, beginning from any part of the series, may be found, the sum of which shall always exceed unity, and consequently the number of terms of the series being supposed infinite, as many partial sums as we please, each exceeding unity, may thus be taken out of the series, which therefore may be continued till it exceed any given number.

But if the denominators of this harmonic series, $\frac{1}{1}, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}$, &c. be squared, that is, if we form the series $\frac{1}{1}, \frac{1}{4}, \frac{1}{9}$, &c. the common numerator of which is 1, and the denominators of which are the squares of the natural numbers 1, 2, 3, 4, &c. the sum of this series of *fractions* will not only be limited, as was said under the head PROGRESSION, *Suppl.* but this sum will be precisely equal to the sixth part of the number, which expresses the ratio of the square of the circumference of a circle to the square of its diameter. That is, if the circumference be 3.14159, &c. and the diameter 1, then will $\frac{1}{1} + \frac{1}{4} + \frac{1}{9} + \frac{1}{16} + \frac{1}{25} +$, &c. $= \frac{\overline{3.14159, \&c.}^2}{6}$. This proposition was first discovered by Mr. Euler, and his investigation may be seen in the Acta Petropolit. vol. vii. Mr. Mac Laurin[a] has since observed, that this may easily be deduced from his Fluxions, art. 822. — [[a] Philos. Transf. N°. 469.]

It would require a treatise to enumerate the various kinds of series's of *fractions* which may be summed. Sometimes the sum or limit of the infinite series cannot be assigned, either because it is infinite, as in the harmonic series $\frac{1}{1} + \frac{1}{2} + \frac{1}{3} + \frac{1}{4}$, &c. or although this sum be finite, as in the series $\frac{1}{1} + \frac{1}{4} + \frac{1}{9} + \frac{1}{16} +$, &c. yet its sum cannot be assigned in finite terms, or by the quadrature of the circle, or hyperbola, which was the case of this series before Mr. Euler's discovery; but yet the sum of any given number of the terms of the series may be expeditiously found, and the whole sum may be assigned by approximation, independently of the circle. See *Stirling*, Method. Different. and *De Moivre*, Miscel. Anal.

Besides the series's of *fractions*, the sums of which converge to a certain quantity, there sometimes occur series's of *fractions*, which converge by a continual multiplication. Of this kind is the series found by Dr. Wallis[a], for the quadrature of the circle, which he expresses thus,

$$\square = \frac{3\times3\times5\times5\times7\times7\times9\times 9\times \&c.}{2\times4\times4\times6\times6\times8\times8\times10\times \&c.}$$ where $\square$ signifies the ratio of the square of the diameter to the area of the circle. Hence the denominator of this *fraction*, continued *ad infinitum*, is to its numerator as the circle is to the square of its diameter. It may be observed, that this series is equivalent to, $\frac{3\times3}{8}\times\frac{5\times5}{24}\times\frac{7\times7}{48}\times$, &c. or to $\frac{3^2}{3^2-1}\times\frac{5^2}{5^2-1}\times\frac{7^2}{7^2-1}\times$, &c. that is, the product of the squares of all the odd

odd numbers 3, 5, 7, 9, &c. is to the product of the same squares severally diminished by unity, as the square of the diameter is to the area of the circle [b].—[[a] Arithmet. infinit. prop. cxci. Oper. vol. i. p. 469. [b] Id. Oper. vol. ii. p. 819.]

These products of *fractions*, and the like quantities arising from the continued multiplication of certain factors, have been particularly considered by Mr. Euler, in his Analysis infinit. vol. I. chap. xv. p. 221, *seq.*

Continued FRACTION is used for a *fraction* the denominator of which is a whole number with a *fraction*, the denominator of which is again a whole number and a *fraction*, and so on, whether this affection be continued *ad infinitum*, or whether the series breaks off after a finite number of terms. Thus,

$\frac{1}{2}+\frac{1}{3}+\frac{1}{4}+\frac{1}{5}+$, &c. or $\frac{1}{2}+\frac{2}{3}+\frac{3}{4}+\frac{4}{5}+$, &c. are *continued fractions*.

If we make use of letters instead of numbers, we shall have general expressions of these *fractions*, thus,

$$a+\frac{1}{b}+\frac{1}{c}+\frac{1}{d}+\frac{1}{e}+\frac{1}{f}+, \&c.$$

and

$$a+\frac{\alpha}{b}+\frac{\beta}{c}+\frac{\gamma}{d}+\frac{\delta}{e}+\frac{\varepsilon}{f}+, \&c.$$

The reduction of these *continued fractions* to those of a common form, is not difficult by the usual rules of arithmetic and algebra. Thus, to give an example, which may at the same time shew the use of these *continued fractions*, suppose the *continued fraction*

$$3+\frac{1}{7}+\frac{1}{15}+\frac{1}{1}+\frac{1}{292}+\frac{1}{1}+\frac{1}{1}+, \&c.$$

which expresses the circumference of a circle, when the diameter is one; if we stop at $\frac{1}{7}$, we shall have $3+\frac{1}{7}=\frac{21+1}{7}=\frac{22}{7}$. If we stop at $\frac{1}{15}$, we shall have

$$3+\frac{1}{7}+\frac{1}{15}=3+\frac{1}{\frac{106}{15}}=3+\frac{15}{106}=\frac{318+15}{106}=\frac{333}{106}$$

But if we stop at $\frac{1}{1}$, which is convenient on account of the small *fraction* $\frac{1}{292}$, added to the last denominator 1, we shall then find, $3+\frac{1}{7}+\frac{1}{15}+\frac{1}{1}=\frac{355}{113}$. The first of the reductions gives the proportion of Archimedes, and the last that of Adrian Metius.

But as beginning at the last denominator of the *continued fraction* makes the computation somewhat tedious, shorter methods have been contrived for the reduction of these *fractions*, and for a continued approximation to their true value. And Mr. Cotes's method for the reduction of ratios to smaller terms, may be here applied. (See the article RATIO, *Suppl.*) For it is to be observed, that when the numerators of the *continued fraction* are each units, the denominators will be the quotients arising from the continued divisions in Mr. Cotes's method; or in the common, for reducing *fractions* to a lower denomination, which is in effect the same as Euclid's method for finding the greatest common measure of two magnitudes, lib. x. prop. 3.

But a detail of these things would lead us too far, we therefore refer the reader for a farther account of these *continued fractions* to Dr. *Wallis*'s Arithmet. infinit. prop. 191. oper. vol. i. p. 469, *seq.* *Huygens*, Descript. automat. planetar. in oper. posthum. p. 173, *seq.* edit. Amstelod. 1728. and particularly to Mr. *Euler*'s Analys. infinit. vol. I. cap. xviii. p. 295, *seq.* who has shewn the use and application of this doctrine in many instances.

Lord Brouncker seems to have been the first who considered *continued fractions*, or at least who first applied them to the quadrature of curves. The hint seems useful, but has been pretty much neglected, excepting in approximations to *fractions* or ratios expressed in great numbers. See the article RATIO, *Suppl.* His series for the quadrature of the circle, is

$$\square=1-\frac{1}{2}\frac{9}{2}\frac{25}{2}\frac{49}{2}\frac{81}{2}, \&c.$$

in his and Dr. Wallis's notation, which amounts to the same thing as

$$1+\frac{1}{2}+\frac{9}{2}+\frac{25}{2}+, \&c.$$

in the notation of Huygens and Euler.

The symbol $\square$ denotes, as before, the ratio of the square of the diameter to the area of the circle.

Repetend of a decimal FRACTION, See the article REPETEND, *Append.*

FRAMBOISE, a name used by some for the *rubus*, or blackberry-bush. See the article RUBUS, *Suppl.*

FRANK *(Cycl.)* — FRANK, among farmers, denotes a place to feed a boar in. Dict. Rust. in voc.

FRAY, among sportsmen. A deer is said to *fray* her head when she rubs in against a tree to renew it, or cause the pills of her new horns to come off.

FREAM, among farmers, arable or ploughed land worn out of heart, and laid fallow till it recover.

FREAM, among sportsmen, a term used for the noise of a boar in rutting time. Dict. Rust. in voc.

FRET, in music, is used for the stops used on some instruments, especially bass viols and lutes: it consists of strings tied round the neck of the instrument at such distances, within which such and such notes are to be found. These strings or *frets* are sometimes, yet seldom, put on the bass violin for learners, and taken off again when they can find the notes without them. On lutes and viols they always remain. *Grassin.* Mus. Dict. in voc.

FRESCO *(Cycl.)* — The brushes and pencils for this work ought to be long and soft, otherwise they will rake and raise the painting. The colours should be full, and flowing from the brush; and the design perfect: for, in this work, you cannot alter or add upon any colour.

FRIAR's *cowl*, in botany, a name by which some call the *arisarum* of botanical authors. See the article ARISARUM, *Suppl.*

FRICTION *(Cycl.)* — It is hardly possible to give general and exact rules concerning *friction*, since it depends upon the structure of bodies, the form of their prominent parts and cavities, and upon their rigidity, their elasticity, their coherence, and other circumstances. Some authors have made *friction* upon a horizontal plane equal to one third of the weight; but others have found that it was only one fourth of it, and sometimes only $\frac{1}{6}$ or $\frac{1}{7}$ of it. Of late, authors have told us, that *friction* depends not on the surface of the body, but its weight only; but neither is this found to be accurately true. In lesser velocities, the *friction* is nearly in the same ratio as the velocities; but in greater velocities the *friction* increases in higher proportion, whether the bodies are dry or oiled.

It being of great importance to diminish this *friction*, several contrivances have been invented for that purpose. In wheel-carriages, the *friction* is transferred from the circumference of the wheel (where it would act if the wheel did not turn round) to the circumference of the axis; and, consequently, is diminished in the proportion of the radius of the axis to the radius of the wheel. In these, therefore, the *friction* is always diminished by diminishing the diameter of the axis, or by increasing the diameter of the wheel. The *friction* is likewise diminished by making the axis of an engine to rest upon the circumferences of wheels that turn round with it, instead of resting in fixed grooves that rub upon it; for, by this contrivance, the *friction* is transferred from the circumference of those wheels to their pivots; and the *friction* may be still diminished farther, by making the axles of those wheels rest upon other *friction*-wheels that turn round with them.

Dr. Desaguliers has treated fully of the *friction* of engines, carriages, &c. See his Course of Experim. Philos. vol. i. p. 133 to 138. and p. 182 to 254. see also p. 458 to 460.

FRIGERATORY, among builders, denotes a place designed to keep things cool in summer. Build. Dict. in voc.

FRILL, in falconry. When a hawk trembles or shivers, they say she *frills*. Dict. Rust. in voc.

FRINGE-*tree*, the English name of a genus of plants called by botanical authors *chionanthus*. See the article CHIONANTHUS, *Append.*

FRINGILLA, in zoology, the name of a bird, known in English by the name of the chaffinch, and called *spina* by the antient naturalists.

The same word is also sometimes used as the name of the brambling, a bird more frequently known by the name of the *montifringilla*, and called *orospina* by the old authors. See the article MONTIFRINGILLA, *Suppl.*

FRITTILLARIA *crassa*, in botany, a name sometimes given to the *asclepias*, or swallow-wort. See the article ASCLEPIAS, *Suppl.*

FROG, among farriers, the same with frush. See the article FRUSH, *Append.*

FRONTALIS *verus musculus*, in anatomy, a name given by Douglas, in his Myography, to one of the muscles of the face, called also by himself, and, since his time, by Albinus, *corrugator supercilii*. See the article CORRUGATOR, *Suppl.*

FROUNCE, a disease in horses, when small warts or pimples arise in the midst of the palate, which are very soft and sore, and sometimes breed in the lips and tongue.

This

This diſorder is occaſioned many ways; ſometimes by eating wet hay, whereon rats or other vermin have piſt; by drawing frozen duſt into his mouth among the graſs, &c.

As to the method of treatment, it conſiſts in letting him blood in the two largeſt veins under the tongue, and waſhing the ſore with vinegar and ſalt, or with ale and ſalt, till they bleed. Dict. Ruſt. in voc. *Camery*.

FROUNCE, in falconry, a diſeaſe incident to hawks, ariſing from moiſt and cold humours falling down to the palate and root of the tongue; by which means they loſe their appetite and cannot cloſe their clap. Waſhing with alum-water, lemon-juice, &c. is held good for it.

FROWEY, a term uſed by workmen for timber, which is evenly tempered, and works freely without tearing. Build. Dict. in voc.

FRUCTIFICATION *(Suppl.)* — The organs of *fructification* in plants are the *pointal*, generally contained in the middle of flowers; and the *threads*, which ſurround it, furniſhed at their extremities with little *heads*; theſe the botaniſts term, the firſt the *piſtillum*, the ſecond the *ſtamina*, and the third, or heads of the ſtamina, the *antheræ*, or *apices*. See the article FLOWER, *Suppl.*

The apices contain the *farina fœcundans*, a fine ſubtile matter analogous to the *ſemen maſculinum* in animals; the ſtamina ſerve only for their ſupport, and to convey nutrition to them; and the *piſtillum* is the part deſtined to receive this *farina*, and convey it to the ſeeds.

It is upon theſe principles that the excellent Linnæus has founded his ſyſtem of the vegetable world, and formed his claſſes. This author's work has been received by the learned world in all nations with the reſpect it merits; but has been too generally cenſured among the ſlighter proficients in botanical reſearches, as abſtruſe, difficult, and unintelligible. The viewing theſe things in a new light, and the neceſſity of making new words to convey new ideas, has indeed given this great attempt ſomething of the face of an abſtruſe piece; but premiſing a few general hints, it may not be difficult to vindicate the author from the heavy charges which have been laid againſt him, and give the Engliſh reader a clear and perfect view of his work.

From the ſtructure and uſe of the *piſtillum*, *ſtamina*, and *apices*, it is eaſy to conceive that the former muſt be accounted the *female*, and the two latter the *male parts* of flowers. This is the great baſis of his ſyſtem. To expreſs the different combinations of theſe in the different claſſes of plants, by formal deſcriptions to each, had been tedious, and an over burthen to the memory: to avoid this, he has excellently contrived the compriſing that deſcription, or general character, in one word. It is eaſy to conceive there could be no word already in uſe, that could expreſs what had never before been thought of; he was therefore neceſſitated to invent new ones for this purpoſe. He has ventured therefore to form twenty-four ſuch, for his claſſes, which are of that number, and has taken them from that language which all the learned have ever uſed on the ſame occaſion, the Greek; and this with the leaſt oſtentation or ſhew of learning imaginable: in ſhort, to underſtand all theſe, there is no need of knowing more Greek than that ἀνὴρ ſignifies a man, or any thing male; and γυνὴ, a woman, or female; that δυνάμις is power or efficacy; ἀδελφὸς, a brother; and thence ἀδελφὰι, brotherhoods or communities; that σὺν is together; γένεσις, generation or origin; and οἶκος, a houſe, or habitation; that πολὺς ſignifies many; γάμος, marriage; and κρυπτὸς, hidden, or concealed: and that the numbers one, two, three, four, five, ſix, ſeven, eight, nine, ten, twelve, and twenty, or their derivatives, once, twice, &c. are expreſſed by the Greek words μόνος, δὶς, τρὶς, τέτρα, πέντε, ἕξ, ἑπτὰ, ὀκτὼ, ἐννέα, δεκὰς, δώδεκα, εἴκοσι: there needs, I ſay, no more knowledge of Greek than this, to underſtand perfectly the meaning of all the terms this author, to avoid tedious deſcriptions, has uſed as the characters of his claſſes. To begin with certainty and regularity;

He firſt divides the whole vegetable world into ſuch ſpecies as have their flowers viſible and obvious to the eyes, and ſuch as have them inviſible, or at the utmoſt ſcarce diſcernible.

Thoſe which have them viſible he then divides again into ſuch as have the *ſtamina*, *apices*, and *piſtillum*, that is the male and female parts of fructification in the ſame flower: Theſe he for that reaſon calls *hermaphrodite* flowers.

And ſuch as have the male and female parts of *fructification*, that is the *apices* and *piſtillum*, either in different flowers upon the ſame ſtalk, or upon different plants of the ſame ſpecies: theſe he calls the diſtinct male and female flowers.

Thoſe which have the different organs of *fructification* lodged in the ſame flower, he again divides into ſuch as have the ſtamina in no part growing together, or cohering to one another: and ſuch as have them either growing together or cohering together mutually in ſome part, either with one another, or with the *piſtillum*.

Thoſe which have them in no part cohering either with the *piſtillum* or with one another, he again ſubdivides into ſuch as obſerve no exact or accurate proportion of length one among another; and ſuch as have ever two of the ſtamina ſhorter than the reſt.

From theſe general diviſions he deſcends to his particular claſſes, of which he eſtabliſhes twenty-four.

The firſt thirteen are of the plants which have *hermaphrodite* flowers, with the organs of *fructification* disjunct, no where cohering with one another, and obſerving no exact proportion in length.

The firſt is the *monandria:* the word is derived from the Greek μόνος and ἀνὴρ, one male part, and ſignifies a flower that has only one ſuch. This claſs accordingly comprehends thoſe plants which have an *hermaphrodite* flower, and in it only one ſingle *ſtamen:* of this claſs are the *blite*, *turmeric*, &c.

The ſecond is of the *diandria*; the word, derived from the ſame ἀνὴρ and δὶς, twice, and ſignifying a flower that has two male parts, comprehends all thoſe plants which have *hermaphrodite* flowers with two *ſtamina* in each: of this claſs are the *jaſmine*, *phillerea*, *olive*, *roſemary*, *butterwort*, &c.

The third is of the *triandria*; the word, derived from the ſame ἀνὴρ and τρὶς, thrice, ſignifies a flower that has three male parts in it, and comprehends thoſe plants which have *hermaphrodite* flowers with three *ſtamina* in each: of this claſs are the *valerian*, *ſaffron*, many of the *graſſes*, &c.

The fourth is of the *tetrandria*; the word, derived from the ſame ἀνὴρ and τέτρας, four times, ſignifies a flower that has four male parts, and accordingly comprehends thoſe plants which have *hermaphrodite* flowers with four *ſtamina* in each; of this claſs are the *teaſel*, *madder*, *plantain*, &c.

The fift his of the *pentandria*; the word derived, from the ſame ἀνὴρ and πέντε, five, ſignifies a flower with five male parts, and accordingly this claſs comprehends thoſe plants which have *hermaphrodite* flowers with five *ſtamina* in each; of this claſs are the *primroſe*, *willow-herb*, *bind-weed*, &c.

The ſixth is of the *hexandria*; the word, derived from the ſame ἀνὴρ and ἕξ, ſignifies a flower that has ſix male parts, and accordingly comprehends thoſe plants which have *hermaphrodite* flowers with ſix *ſtamina* in each; theſe *ſtamina*, the author obſerves, are either all equal in length, or alternately one ſhorter than another: of this claſs are *garlick*, *hyacinths*, *meadow-ſaffron*, &c.

The ſeventh is of the *heptandria*; the word, derived from the ſame ἀνὴρ and ἑπτὰ, ſeven, ſignifies a flower with ſeven male parts, and comprehends thoſe plants which have *hermaphrodite* flowers with ſeven *ſtamina* in each: of this claſs are the *horſe-cheſnut* and *trientalis*.

The eighth is of the *octandria*; the word, derived from the ſame ἀνὴρ and ὀκτὼ, eight, ſignifies a flower with eight male parts, and comprehends thoſe plants which have *hermaphrodite* flowers with eight *ſtamina* in each: of this claſs are the *maple*, *rue*, *heath*, &c.

The ninth claſs is of the *enneandria*; the word, derived from the ſame ἀνὴρ and ἐννέα, nine, ſignifies a flower that has nine male parts, and comprehends thoſe plants which have *hermaphrodite* flowers with nine *ſtamina* in each: of this claſs are the *bay*, *rhubarb*, &c.

The tenth claſs is of the *decandria*; the word, derived from the ſame ἀνὴρ and δεκὰς, ten, ſignifies a flower which has ten male parts, and comprehends all thoſe plants which have *hermaphrodite* flowers with ten *ſtamina* in each: of this claſs are the *Judas-tree*, *baſtard-dittany*, *caltrops*, &c.

The eleventh is of the *dodecandria*; the word, derived from the ſame ἀνὴρ and δώδεκα, twelve, ſignifies a flower which has twelve male parts in it, and comprehends thoſe plants which have *hermaphrodite* flowers with twelve *ſtamina* in each: of this claſs are the *aſarabacca*, *agrimony*, &c.

The twelfth is of the *icoſandria*; the word, derived from the ſame ἀνὴρ and εἴκοσι, twenty, ſignifies ſtrictly a flower with twenty male parts in it; the author however does not underſtand it in that ſtrict ſenſe, but uſing it as we frequently do words expreſſing large quantities, as indefinite and in an indeterminate ſenſe, defines it to mean only a larger number of *ſtamina* than are expreſſed under any other of the diſtinctions; and comprehends under it, in this claſs, all thoſe plants which have *hermaphrodite* flowers and more than twelve *ſtamina* in each; thoſe *ſtamina* alſo growing to the inner ſide of the cup of the flower, not to the receptacle of the future ſeeds: of this claſs is the *torch-thiſtle*, the *myrtle*, *ſtorax*, the *almond*, &c.

The thirteenth is of the *polyandria*; the word, derived from the ſame ἀνὴρ and πολὺς, many, ſignifies, in an exact ſenſe, no other than what he makes the *icoſandria*, the title of the laſt claſs, expreſs: theſe are, perhaps, the only two words in which his expreſſion is deficient, the name he has given the claſſes not at all importing their particular difference from one another: this, however, he has vey acurately done in the character which follows them; and comprehends under this claſs thoſe plants which have *hermaphrodite* flowers with more than twelve *ſtamina* in each, but which grow in this to the receptacle of the future ſeed, not as in the other claſs to the inner ſide of the cup of the flower; of this claſs are the *water-lilly*, *poppy*, *celandine*, &c.

Theſe are the claſſes this accurate diſtinguiſher has eſtabliſhed among the *hermaphrodite* flowers, whoſe *ſtamina* have no regular

gular proportion of length, in regard to one another. To these he next subjoins two classes of such of them as have ever two of their *stamina* shorter than the rest.

The first of these (the fourteenth class of the general order) is of the *didynamia:* the word derived from the before-mentioned δὶς and δυνάμις, power or efficacy, signifies with him such flowers as have two of their male parts of more efficacy than the rest; and in this class he accordingly comprehends all those plants which have *hermaphrodite* flowers, two of whose *stamina* are longer, and of greater efficacy in the great work of fecundating the seeds, than the rest: of this class are the *thyme*, *lavender*, *basil*, &c.

The second of these (the fifteenth class in the general order) is of the *tetradynamia:* the word derived from the before-mentioned τέτρας and δυνάμις, signifies a flower with four of its male parts of more efficacy than the rest; and in this class he comprehends the plants with *hermaphrodite* flowers, four of the *stamina* of which are longer than the rest: of this class are the *scurvy-grass*, *radish*, *mustard*, &c.

From these he proceeds to those *hermaphrodite* flowers whose *stamina* cohere, either mutually among one another, in different manners; or with the *pistillum* of the flower: these co alitions of the *stamina* he calls brotherhoods, or communities, and according to the different state of these, and their conjunctions with the *pistillum*, he establishes five classes of them.

The first of these (the sixteenth in the general order) is of the *monadelphia:* the word derived from the before-mentioned μόνος, single, and ἀδελφὰ, brotherhoods, or communities, signifies with him a flower whose *stamina*, by means of the filaments running in among one another, are all formed into one body; and under this class he comprehends those plants with *hermaphrodite* flowers, whose *stamina*, or male parts, are all bound together in one body: of this class are the *crane's-bill*, *mallow*, &c.

The second of these (the seventeenth class in the general order) is of the *diadelphia:* the word derived from the before-mentioned δὶς and ἀδελφὰ, signifies with him a flower whose *stamina* are, by the conjunction of their filaments, formed into two bodies; and under this class he comprehends those plants which have *hermaphrodite* flowers, the *stamina* of which are so clustered together into two bodies: of this are the *fumitory*, *milkwort*, *broom*, &c.

The third of these (the eighteenth in the general order) is of the *polyadelphia:* the word derived from the before-mentioned πολὺς and ἀδελφὰ, signifies with him a flower whose male parts are clustered into three or more separate bodies; and in this he comprehends those plants with *hermaphrodite* flowers, whose *stamina*, by the conjunction of their filaments, are formed into three or more clusters: of this class are the *orange*, *St. John's wort*, &c.

The fourth of these classes (the nineteenth in the general order) is of the *syngenesia:* the word derived from σὺν, together, and γένεσις, generation, origin, or formation, signifies with him such flowers as have their male parts naturally formed into a single regular congeries; and accordingly he comprehends under this class such plants as have *hermaphrodite* flowers, the *stamina* of which, by the junction of their *apices*, are formed into a single, regular, cylindric body: of this class are the *lettuce*, *succory*, *hawkweed*, &c.

The fifth of these classes (the twentieth in the general order) is of the *gynandria:* the word derived from γυνὴ, a woman, or female, and ἀνὴρ, male, signifies with this author a conjunction of the male and female parts of a flower at their origin; and he accordingly comprehends under this class those plants which have *hermaphrodite* flowers, the *stamina*, or male parts of which grow to the *pistillum*, or female part of the flower, and not to the receptacle of the seeds: of this class are the *barrenwort*, *passion-flower*, *birthwort*, &c.

Next after these he ranges those plants which have flowers not *hermaphrodite*, but regularly and distinctly male and female, as the sexes in animals are disposed; and after these such plants as have flowers irregularly of one, or the other, or sometimes of both sexes:

Of these he establishes only three classes.

The first of these (the twenty-first class in the general order) is of the *monoecia:* the word derived from the before-mentioned μόνος, and οἶκος, a habitation, signifies with this author such plants as have their distinct flowers on the same individual; and he comprehends accordingly under it those plants which have the male and female flowers distinct in themselves, but placed on the same plant, or the different stalks from the same root: of this class are the *alder*, *mulberry*, *amaranth*, *arrowhead*, &c.

The second of these (the twenty-second class in the general order) is of the *dioecia:* the word derived from the same οἶκος and δὶς, signifies with him plants which have their male and female flowers, not on the same individual; and accordingly comprehends under it such plants as have distinct male and female flowers, on different plants of the same species, either of which, the male and female plants, as they are hence called, might have arisen from the same seed: of this class are the *willow*, *misletoe*, *hemp*, and *spinach*, &c.

The third of these (the twenty-third in the general method) is of the *polygamia:* the word derived from πολὺς, many, and γάμος, marriage, signifies with this author plants which have a diversity of combinations and many ways of *fructification*, in the same species; and accordingly hs comprehends under this class those plants which have, in the same species, some flowers male, others female, each distinct and perfect in its kind; and others mixed or *hermaphrodite*, with the male and female organs of *fructification* both in each: of this class are *pellitory of the wall*, *orrache*, the *ash*, &c.

After all these he places those plants whose flowers are either absolutely invisible, or scarce discernible by the eye: of these he makes only one, his twenty-fourth and last class, the *cryptogamia:* the word derived from κρυπτὸς, hidden, or concealed, and the before-mentioned γάμος, or marriage, signifies a set of plants, in which the *fructification* is concealed: and under this last class he comprehends those plants which either flower, as is generally supposed, within the fruit, or have the organs of their *fructification* so mingled as to escape our observation: of this class are the *ferns*, *mosses*, *liverworts*, and *mushrooms*.

These are the classes into which this author has regularly and certainly reduced the whole vegetable world; the characters of which are so expressive, and the parts they are founded upon so fixed and invariable in their nature and office, that there seems no reason hereafter to perplex the world with any new system.

As the classes are here all taken from the number, site and disposition of the male parts of the flower; so the orders which make their subdistinctions are, by this author, deduced from the differences of the female parts or *pistillum*; and as that is single, double, triple, and so on, they are on the same principles named *monogynia*, *digynia*, *trigynia*, &c.

It were to be wished indeed that the characters of the different genera of these classes were as perfect and accurate as the classes themselves: this, however was more than the work of one man; the author has fixed the general distinction, and led the way; and it is easy now for a much less genius to follow him.

FROWEY, a term used by workmen for timber which is evenly tempered all the way, and works freely without tearing. Build. Dict. in voc.

FRUIT *(Suppl.)*—*Ripening of* FRUIT. For the method of forwarding this operation of nature, see the article RIPENING, *Append.*

FRUSH, or FROG, among farriers, that part of a horse's foot, which is placed from the middle of the sole towards the heel, upon both sides: it is more soft and higher raised than the rest of the sole. Dict. Rust. in voc.

FRUSTUM *(Cycl.)* — FRUSTUM *of a cone.* The cylinder generated by the revolution of the rectangle EBCF (fig. I.) about one of its sides EB, which is the height of the *frustum* of a cone, the other side BC being the radius of its greatest base, is to the *frustum* generated by the revolution of the trapezium EBCH, as the square of BC is to the rectangle contained under BC and EH, added to one third part of the square of the difference of these lines. *Archimedes.*

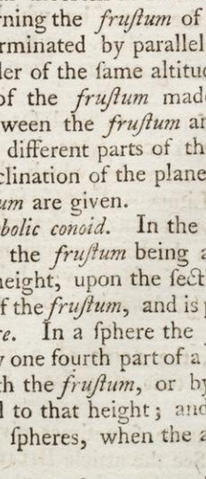


Fig. I.

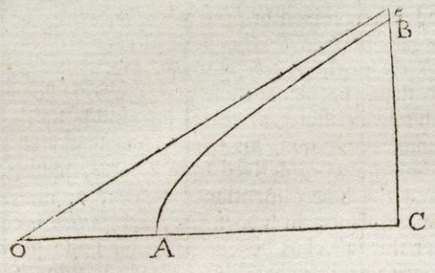
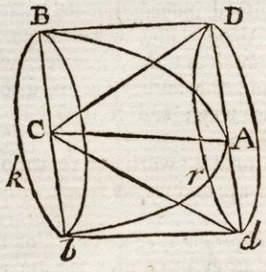
We have a general theorem in Mr. Mac Laurin's Treatise of Fluxions, concerning the *frustum* of a sphere, cone, spheroid, or conoid, terminated by parallel planes, when compared with a cylinder of the same altitude, on a base equal to the middle section of the *frustum* made by a parallel plane. The difference between the *frustum* and the cylinder is always the same in different parts of the same, or of similar solids, when the inclination of the planes to the axis, and the altitude of the *frustum* are given.



FRUSTUM *of a parabolic conoid.* In the parabolic conoid this difference vanishes, the *frustum* being always equal to a cylinder of the same height, upon the section of the conoid that bisects the altitude of the *frustum*, and is parallel to its bases.

FRUSTUM *of a sphere.* In a sphere the *frustum* is always less than the cylinder by one fourth part of a right angled cone, of the same height with the *frustum*, or by one half of a sphere of a diameter equal to that height; and this difference is always the same in all spheres, when the altitude of the *frustum* is given.

In the cone, the *frustum* always exceeds the cylinder by one fourth part of the content of a similar cone that has the same height with the *frustum*.



FRUSTUM *of an hyperbolic conoid.* In the hyperbolic conoid this excess is the same as in the cone generated by the triangle OC*e*, (fig. II.) formed by the axis OC, the asymptote O*e*, and the perpendicular C*e*, the altitude of the *frustum* and the inclination of the axis to their bases being the same in both.

Fig. II.

FRUSTUM *of a spheroid.* In the spheroid AB*kb*, (fig. III.) the cylinder exceeds the *frustum*; and the difference between them is the same as in the cone CD*rd*, the plane D*rd*, or B*kb*, being supposed parallel to those which terminate the *frustum.* In different inclinations of those planes, when the altitude of the *frustum* is given, that difference is reciprocally as the cube of the diameter B*b*, which is the conjugate of CA, the axis of the *frustum.* But if the altitude of the *frustum* be also varied so as to be reciprocally proportional to the diameter B*b*, then the difference between the *frustum* and cylinder will be always of the same magnitude in the same spheroid or conoid.

Fig. III.

When the inclination of the axis of the solid to the planes that terminate the *frustum* is given, the difference between the *frustum* and cylinder, in the same, or in similar bodies, is as the cube of their common altitude. *Mac Laurin*'s Fluxions, Introd. p. 24, 25.

These propositions concerning *frustums* are of use in gauging. See the article GAUGING, *Suppl.*

FUMAGE, a term used in some parts of the kingdom for dung, or manuring with dung.

FUMER, in zoology, a name given to the pole-cat. See the article PUTORIUS, *Suppl.*

FUMET, among sportsmen, a term used for the ordure or dung of harts, otherwise called fewmets.

FUNCTION *(Cycl.)* — The term *function* is used in algebra, for an analytical expression any way compounded of a variable quantity, and of numbers, or constant quantities. Therefore every analytical expression, in which, besides a variable quantity x, there are constant quantities, is a *function* of x. Thus $a+3x$, $ax-4xx$, $ax+b\sqrt{aa-xx}$, c^x, &c. are *functions* of x.

The difference of *functions* consists in the manner in which they are compounded; and depends, therefore, upon the operations by which quantities may be compounded and mixed. These operations are, addition, subtraction, multiplication, and division, the raising to powers, and extraction of roots, to which the resolution of equations ought to be referred. Beside these operations, which are called algebraical, there are other transcendental ones, such as exponential, logarithmic, and many others arising from the inverse method of fluxions.

Functions may arise from the most simple and analytical operations: thus we have the multiple *functions* $2z$, $3z$, $\frac{1}{2}z$, az, &c. and the powers of z, as z^2, z^3, $z^{\frac{1}{2}}$, z^{-1}, &c. are called *functions.*

Functions are divided into *algebraical* and *transcendental: algebraical* or *algebraic functions*, are those formed by algebraic operations only; such are those above specified, except c^x, which belongs to the following species.

Transcendental functions are those formed by transcendental operations: such are exponential quantities or powers, the exponents of which are variable quantities; whereas in algebraic *functions* the exponents are always constant quantities.

It is to be observed as to *transcendental functions*, that those *functions* only of a variable quantity are to be deemed transcendental, which not only enter the composition with, but also affect the variable quantity: thus if z signifies a circular arc, or a logarithm, then will ca^z, and the like expressions, be *transcendental functions* of z. But if the transcendental operation appertains only to constant quantities, the *function* is no more than algebraic: thus if c denote the circumference of a circle, the radius of which is $=1$, c will be a transcendental quantity, and yet the expressions $c+z$, cz^2, $4z^c$, are but algebraic *functions* of z. Some indeed have doubted whether z^c ought to be ranked among algebraic *functions*, or not; but the doubt is of small weight. And some choose to call the powers of z, the exponents of which are irrational numbers, *interscendent functions:* thus $z^{\sqrt{2}}$ is an interscendent *function* of z.

On the subject of *functions*, their divisions, transformations, explication by infinite series, &c. Mr. Euler should be consulted, who has treated this matter very fully in the first chapter of his Analys. infinitorum.

FURCA & *flagellum*, in our old writers, denotes the meanest of all servile tenures, when the bondman was at the disposal of his lord for life and limb. — *Ipse tenet in villenagio ad* furcam & flagellum *de domino suo*, &c.

FURROW, among gardeners, denotes a ridge or swelling on the side of a tree, stalk, fruit.

FURROW is also used for the deep trench left between ridges, to drain off the superfluous moisture.

FURZE, in botany, the English name of a genus of plants called by authors *genista spartium.* See the article GENISTA *spartium, Suppl.*

FUSTIC-*tree*, in botany. See the article FUSTUC, *Suppl.*

G.

GABLOCKS, the name by which the artificial spurs of game cocks are called. See the article COCK, *Suppl.*

GADDS, among miners. See the article DIGGING, *Suppl.*

GAFFS, a name sometimes used for the gablocks of cocks. See the article GABLOCK, *supra.*

GALANGAL, the name by which the root of a genus of plants called by Linnæus *Kæmpferia*, is commonly known. See the article KÆMPFERIA, *Append.*

GALANTHUS, in the Linnæan system of botany, the name of a distinct genus of plants, which Tournefort makes only a species of *Narcisso-leucoium.* See the article NARCISSO-*leucoium, Suppl.*

GALE, in botany, the name of a genus of plants described by Linnæus under that of *myrica.* See the article MYRICA, *Append.*

GALL-*sickness*, a name sometimes given to bilious and intermitting fevers. See the article BILIOUS *fever, Append.*

GALLY, on ship-board, a place in the cook-room, where the grates are put up, fires lighted, and the victuals boiled or roasted. *Blanckley*, Nav. Expositor, p. 62.

GAMMER-*lamb.* See the article GIMMER-*lamb, Append.*

GAMMONING, on ship-board, are several turns of rope taken round the bow-sprit, and reeved through holes in the knees of the head, for the greater security of the bow-sprit. *Blanckley*, Nav. Exp. p. 62.

GANDER, the popular name for a male goose: one of these will serve five geese.

GAR-*fish*, in ichthyology, a name used in several parts of the kingdom for the *esox.* See the article ESOX, *Suppl.*

GARGET, a disease of cattle, consisting in a swelling of the throat and the neighbouring parts; to prevent which, bleeding in the spring is recommended.

GARGIL, a distemper in geese, which by stopping the head frequently proves mortal. Three or four cloves of garlick, beaten in a mortar with sweet butter, and made into little balls, and given the creature fasting, is the ordinary cure. Dict. Rust. in voc.

GARLICK *(Suppl.)* — *Wild*-GARLICK, a name by which some call a species of onion. See the article ONION, *Suppl.*

GASKETS, on ship-board, the small cords used for fastening sails to the yards when furled up. *Blanckley*, Nav. Exp. p. 63.

GAST-

GAST-*hound*. See the article HOUND, *Append.*

GATE, among ſportſmen, a term uſed for the footſteps of a hart. Dict. Ruſt. in voc.

GATTON-*tree*, a name ſometimes given to the cornel-tree. See the article CORNUS, *Suppl.*

GAULE, in botany, a name uſed by ſome writers for the *myrica*, or ſweet-willow. See the article MYRICA, *Append.*

GAZE-*hound*, or GAST-*hound*. See the article HOUND, *Append.*

GELDER-*roſe*, the term by which ſome call the *opulus*, or water-elder. See the article OPULUS, *Suppl.*

GENERATION *(Cycl.* and *Suppl.)* — The antients believed that males and females were equally concerned in the work of *generation*, and that the fœtus was formed in the womb by a mixture of the ſeminal juices of both ſexes; without pretending to know, or determine by any ſyſtem, the manner of nature's operation.

Modern philoſophers have thought that they ſaw farther than the antients, and have, at different times, adopted the two ſyſtems of *generation* mentioned in the *Cyclopædia* under this head.

But the late experiments of Monſ. de Buffon, and of Mr. Needham, if they do not eſtabliſh a new ſyſtem, ſeem at leaſt in a great meaſure to overturn the old ones.

Monſ. de Buffon has endeavoured to prove that the ova in women and quadrupeds are chimeras, and that the ſpermatic animalcule cannot be the fœtus. He could never find any ova which had detached themſelves from the ovary, and paſſed through the Fallopian tube into the matrix. But he diſcovered a glandular body on the female teſticle, which anatomiſts had miſtaken for one of theſe; which glandular body, at certain times, ſwelled, opened and diſcharged a liquor full of the ſame animalcules, which Lewenhoek took for living creatures in the ſemen of males. And Monſ. de Buffon adds that he found bodies perfectly ſimilar to theſe, not only in the ſemina of very different animals, but in the infuſions of plants, of grains, and in the juices of fleſh-meats, dreſſed and prepared by the fire ſo as to leave no creature living in them. From whence this ingenious gentleman concludes, that theſe pretended animalcules are not future animals of the ſpecies of the father: he does not even allow them to be true animals, but ſays they are ſomething of an intermediate nature between brute matter and animals; parts organized and animated, the aſſemblage of which forms the fœtus. See Lettres de Monſ. de Maupertuis, let. 17.

But the chief difficulty conſiſts in conceiving how the fœtus is formed from theſe elements. Monſ. de Buffon thinks that every part of the body in both ſexes furniſhes theſe organic moleculæ, the reſervoirs of which are the ſeminal liquors of both ſexes; that theſe liquors arrange and unite themſelves by attraction, in certain internal moulds, in a manner which that learned author has endeavoured to explain at large; but which will not ſeem ſuſceptible of any abridgment, to thoſe who would not chooſe to run the riſque of miſrepreſenting his ſentiments on ſo obſcure a ſubject; we therefore refer to the original, that is, to the Hiſtoire Naturelle, printed at Paris, 1749, where the ſubject of the *generation* of animals takes up the greateſt part of the ſecond volume.

Monſ. de Maupertuis's ſyſtem, in his Venus Phyſique, has a near reſemblance to that of Monſ. de Buffon, and tends equally to overturn the ſyſtems of the ova, and of the ſpermatic animalcules, which have prevailed among modern phyſiologiſts. The former of theſe gentlemen, to confirm his own and Mr. de Buffon's opinion, adds an account of a ſexdigitary family, as he calls it, at Berlin, many of which had a ſupernumerary finger or toe, and ſometimes both. He ſays that this ſexdigitiſm, or quality of having ſupernumerary fingers or toes, has been tranſmitted equally by the father and by the mother; that it was loſt by alliances with thoſe who had but the common number of fingers. He adds, that he does not believe that any one will aſcribe the continuation of ſexdigitiſm in a family, to chance; theſe ſupernumerary parts might have been accidental varieties at firſt, but if they be once eſtabliſhed by a ſufficient number of *generations*, where both ſexes have had them, they then become a foundation for a diſtinct ſpecies; and perhaps all the different ſpecies diſcernible in animals of the ſame kind, have been multiplied in this way. What we may obſerve in other animals gives ground for theſe ſuſpicions. See the Letter before cited.

GEODES, in natural hiſtory, a genus of cruſtated bodies formed into large and in great part empty caſes, incloſing a ſmall quantity of earthy, or arenaceous matter. See the article SIDEROCHITA. *Append.*

Of this genus are the following known ſpecies: 1. The cracked *geodes*, with ferrugineous brown and yellow cruſts. 2. The wrinkled *geodes*, with ferrugineous reddiſh-brown and gold-yellow cruſts. 3. The ſparkling *geodes*, with ferrugineous purpliſh and orange-coloured cruſts. 4. The long ſcabrous *geodes*, with a ſingle purpliſh cruſt. 5. The long *geodes*, with a ſingle blackiſh cruſt. *Hill*, Hiſt. Foſſ. p. 541.

GERMANDER-*tree*, in botany, the Engliſh name of a genus of plants known among authors by that of *teucrium*. See the article TEUCRIUM, *Suppl.*

GESSES, the ſame with *jeſſes*. See the article JESSES, *Append.*

GHERKINS. See the article GUERKINS, *Append.*

GIDDINESS, the popular name for the diſtemper called by phyſicians *vertigo*. See the article VERTIGO, *Cycl.*

Giddineſs in horſes is cured by a glyſter and blood-letting, to be repeated after two days moderate exerciſe. Dict. Ruſt. in voc.

GIGG *(Cycl.)* — GIGGS, among farriers, ſmall bladders or bliſters on the inſide of a horſe's lips. They muſt be laid open, and cleanſed with ſalt and vinegar, or alum-water. Dict. Ruſt. in voc.

GIGGE, in the manufacture of flax, denotes a hole made in the earth, where fire is made to dry the flax laid over it. Dict. Ruſt. in voc.

GILDER. See the article GUILDER, *Append.*

GILDING *(Cycl.* and *Suppl.)* - GILDING-*knife*, a ſlip of the hollow Spaniſh cane, cut up to a ſmooth and ſharp edge, with a good pen-knife: this cane-knife cuts the gold-leaf better than one of ſteel, as it is apt to ſtick to this laſt.

GILDING-*pallet*, a flat piece of wood, about three inches long and an inch broad, covered with a piece of fine woollen cloth.

By breathing upon this pallet, to moiſten the cloth a little, and then clapping it gently down upon the gold-leaf, this may be raiſed from the cuſhion, and conveyed to the work to be gilded.

GILL-*go-by-ground*, the name uſed by ſome writers for ground-ivy. See the article IVY, *Suppl.*

GILLIFLOWER, or JULY-*flower*, in botany, the Engliſh name given to ſeveral ſpecies of *caryophyllus*. See the article PINK, *Suppl.*

Queen's GILLIFLOWER, the name by which ſome call a diſtinct genus of plants, deſcribed by authors under that of *heſperis*. See the article HESPERIS, *Suppl.*

Stock GILLIFLOWERS, the name of another diſtinct genus of plants called by botanical writers *leucoium*. See the article LEUCOIUM, *Suppl.*

GIMMER-*lamb*, or GAMMER-*lamb*, a term uſed by country-people for a female or ewe lamb. Dict. Ruſt. in voc.

GINGER, the Engliſh name of a genus of plants called by authors *zinziber*. See the article ZINZIBER, *Suppl.*

GINGIDIUM, a name uſed by ſome botaniſts for a ſpecies of fennel. See the article FOENICULUM, *Suppl.*

GINSENG, in botany, the name given by the people of the Eaſt-Indies to the *panax* of botanical writers. See the article PANAX, *Append.*

GIRDLE *(Suppl.)* — GIRDLE-*wheel*, a ſmall ſpinning-wheel made for hanging to a woman's girdle, or apron-ſtring; ſo that ſhe may ſpin with it, though walking about. Dict. Ruſt. in voc.

GIRKIN, among gardeners, denotes a ſmall kind of cucumber, uſed for preſerving, about the end of October. Ruſt. Dict. in voc.

GIRT, among builders, the ſame with fillet. See the article FILLET, *Cycl.*

GIRTHS *of a ſaddle*, the ſtrong ſtraps, made of a canvas ſtuff called *girth*-web; which being buckled under the horſe's belly, ſerve to fix the ſaddle. Ruſt. Dict. in voc.

GLADDON, or GLADWIN, in botany, the name of a plant, otherwiſe called ſpurge-wort. Ruſt. Dict. in voc.

GLADE, in zoology. See the article GLEAD.

GLADE, in gardening, an open and light paſſage made through a wood, by lopping off the branches of trees. *Miller*, Gard. Dict. in voc.

GLADWIN, a name ſometimes uſed for the *iris*, or *flower de luce*. See the aricle IRIS, *Suppl.*

GLANDULOUS *roots*, among botaniſts, ſuch tuberoſe roots as are faſtened together in large numbers by ſmall fibres or threads. Ruſt. Dict. in voc.

GLASS-*wort*, is ſometimes uſed as the name of a genus of plants deſcribed by Linnæus under that of *ſalicornia*. See the article SALICORNIA, *Append.*

GLASSES, *chemical*, how cæmented, when cracked. See the article CÆMENT, *Append.*

GLASTONBURY-*thorn*, a name ſometimes given to the *meſpilus*, or medlar. See the article MEDLAR, *Suppl.*

GLAUBER's *ſalt*. See the article SAL *mirabile*, *Suppl.*

GLAZIER, an artificer who works or deals in glaſs.

GLEAD, or GLADE, a name uſed in the northern parts of the kingdom for the *milvus*, or kite. See the article KITE, *Append.*

GLEBA *alana*, a name by which ſome call the yellowiſh white *tripoli*. See the article TRIPOLI, *Cycl.* and *Suppl.*

GLEDE, in ornithology. See the article GLEAD, *Append.*

GLISTER. See the articles CLYSTER, *Cycl.* and ENEMA, *Suppl.*

GLOBE-*daiſy*, the Engliſh name of a genus of plants called by authors *globularia*. See the article GLOBULARIA, *Suppl.*

GLOBE-*crow-foot*, a name ſometimes given to the *helleborus*, or black hellebore. See the article HELLEBORUS, *Suppl.*

GLOBE-*amaranth*, the name of a genus of plants called by botanical writers *amarantboides*. See the article AMARANTHOIDES, *Suppl.*

GLOBE-*fish*, in ichthyology, the name by which many ſpecies of the *oſtracion* are called in Engliſh. See the article OSTRACION, *Suppl.*

GLOBE-*flower*, or GLOBE-*bottle*, names ſometimes given to the *cyanus*, or blue-bottle. See the article CYANUS, *Suppl.*

GLOBE-*thiſtle*, in botany, the Engliſh name of the *echinopus*. See the article ECHINOPUS, *Suppl.*

GLORIOSA, *ſuperb lilly*, in botany, the name of a diſtinct genus of plants, the characters of which are theſe: there is no cup: the flower conſiſts of ſix oblong, lanceolated, undulated, and every way long petals, reflex nearly to the baſe; the ſtamina are ſix ſubulated filaments, patulous and ſhorter than the petals of the flower; the antheræ are incumbent; the germen of the piſtil is globoſe; the ſtyle is filiform, inclined, and longer than the ſtamina; the ſtigma is ſimple and obtuſe; the fruit is an oval pellucid capſule, conſiſting of three valves, and containing three cells; the ſeeds are numerous, globoſe, and diſpoſed in a double ſeries. *Linnæi* Gen. Plant. p. 144.

Tournefort, in the Memoirs of the Academy of Sciences, has called this genus *methonica*. Id. ibid.

GLUE *(Suppl.)* — *Bees* GLUE, a name uſed by ſome for crude or rough wax. See the article WAX, *Suppl.*

GLUT, among falconers, denotes the ſlimy ſubſtance that lies in a hawk's pannel. Dict. Ruſt. in voc.

GLUTTON, *gulo*, in zoology, a name ſometimes given to the reddiſh brown *muſtela*, with the middle of its back black. See the article MUSTELA, *Suppl.*

GNOMONIC *(Cycl.)* — GNOMONIC, or GNOMONICAL *projection*, that which repreſents the circles of an hemiſphere, upon a plane touching it in the vertex, by lines or rays from the center of the hemiſphere to all the points of the circles to be projected.

In this projection all the great circles of the ſphere are projected into right lines. Any leſſer circle parallel to the plane of projection is projected into a circle. And any leſſer circle not parallel to the plane of projection, is projected into a conic ſection.

The *gnomonic projection* is alſo called the *horologiographic projection*, becauſe it is the foundation of dialling. In other reſpects it is not much uſed, becauſe the circles of the ſphere are projected into conic ſections, which are difficult to deſcribe. However this projection has its conveniencies in the ſolution of ſome problems of the ſphere, on account of the great circles being all projected into right lines.

Mr. Emerſon, known by an ingenious treatiſe upon Fluxions, has given the theory and practice of the *gnomonic projection*, in his Treatiſe on the Projection of the Sphere, Lond. 1749, octavo. See alſo Mr. *Murdoch*'s Newtoni Geneſis Curvarum per Umbras, p. 46, *ſeq.*

GOAT's *rue*, in botany, the Engliſh name of a genus of plants called by authors *galega*. See the article GALEGA, *Suppl.*

GOAT's *ſtones*, in botany, a name ſometimes given to the *orchis* of botanical writers. See the article ORCHIS, *Suppl.*

GODWIT, in zoology, the Engliſh name of the *ægocephalus*. See the article ÆGOCEPHALUS, *Suppl.*

GODWIT, in ornithology, the Engliſh name of a ſpecies of *tringa*. See the article TRINGA, *Suppl.*

GOLD *of pleaſure*, in botany, a term by which ſome call the *myagrum* of botanical authors. See the article MYAGRUM, *Suppl.*

GOLD-*finch*, in ornithology, the name of a ſpecies of *fringilla*. See the article FRINGILLA, *Suppl.*

It is ſmaller than the common ſparrow, but of a more elegant form; its colours are extremely beautiful and gay; there is a ſpot of red at the baſe of the beak; the top of the head is black, and its hinder part white; the neck and back are of a mixed colour, compoſed of grey and reddiſh brown; the belly is white; the ground colour of the wings and tail is black, but they are elegantly variegated with yellow and white; the legs are ſhort, and the hinder toe is longer than any of the others.

GOLDEN *flower-gentle*, a name ſometimes given to ſeveral ſpecies of the *amaranth*. See the article AMARANTH, *Suppl.*

GOLDEN-*cups*, a name by which ſome call the *ranunculus*, or *crow-foot*. See the article RANUNCULUS, *Suppl.*

GOLDEN-*head*, in ornithology, a water-fowl, otherwiſe called *anas arctica*. See the article DUCK, *Suppl.*

GOLDY-*locks*, the Engliſh name of a genus of plants, called by botanical writers *elichryſum*. See the article ELICHRYSUM, *Suppl.*

GOLF, or GOUF, the name of a diverſion, or exerciſe, much uſed in Scotland, and played upon the lawns, or links, as they are there called.

It conſiſts in driving a ball with clubs, between two goals or holes, half a mile or a mile aſunder. He who can do this with the feweſt ſtrokes of his club is the conqueror.

GOMER, or HOMER, a Hebrew meaſure. See the article CORUS, *Suppl.*

GONDOLA-*ſhell*, a ſpecies of *dolium*. See the article DOLIUM.

GOOSE-*foot*, in botany, the Engliſh name of a genus of plants called by botaniſts *chenopodium*. See the article CHENOPODIUM, *Suppl.*

GOOSE-*graſs*, in botany, a name ſometimes given to the *aparine* of authors. See the article APARINE, *Suppl.*

GOOSEANDER, a name uſed in ſeveral parts of the kingdom for a ſpecies of *mergus*. See the articles MERGUS and MERGANSER, *Suppl.*

GOOSEBERRY *of Barbadoes*, a name by which ſome call the *pereſkia* or *cactus* of botanical writers. See the article CACTUS, *Suppl.* and *Append.*

American GOOSEBERRY, the name of a genus of plants called by botaniſts *melaſtoma*. See the article MELASTOMA, *Suppl.*

GORCE, in botany, See the article GORSE, *Append.*

GOREING, or GORING, is ſaid of a ſail when cut ſlanting, ſo that it is broader at the clew than at the earing, as all topſails and top-gallant-ſails are. *Blanckley*, Nav. Exp. p. 65.

GORSE, or GOSSE, in botany, a name ſometimes uſed for furze. See the articles ULEX and GENISTA *ſpartium*, *Suppl.*

GOSLINGS, a term uſed to denote young geeſe. See the article GOOSE, *Suppl.*

GOSSYPIUM, the *cotton-plant*, in botany, the name of a genus of plants, the characters of which are theſe: the cup is double, the exterior one being compoſed of one leaf deeply divided into three ſegments, and the inner one ſlightly divided into five ſegments; the flower conſiſts of five leaves adhering at the baſe, cordated at the top, plane, and patent; the ſtamina are numerous filaments, which by adhering together form a kind of cylinder at the baſe; the antheræ are kidney-ſhaped; the germen of the piſtil is roundiſh; the ſtyle columnar, and of the length of the ſtamina; the ſtigmata are four, and pretty thick; the fruit is a roundiſh capſule, divided into four cells and containing numerous egg-ſhaped ſeeds, ſurrounded with a fine downy matter. Vide *Linnæi* Gen. Plant. p. 331.

GOUF, or GOLF. See the article GOLF, *Append.*

GOURD *(Suppl.)* — *Bitter* GOURD, a name ſometimes given to the *colocynthis* of botanical writers. See the article COLOCYNTHIS, *Suppl.*

Indian tree-GOURD, a term by which the *cujete*, or *creſcentia*, of botanical writers, is ſometimes called. See the article CRESCENTIA, *Suppl.*

Sour GOURD, in botany, a name ſometimes given to the *baobab*, or *baobob*. See the article BAOBAB, *Suppl.*

GOURD-*worm*, the Engliſh name of a ſpecies of worm found in the inteſtines of ſeveral animals. It has this name from its reſembling the ſeed of the gourd in figure.

GOURDY *legs of horſes*. See the article GREASE, *Cycl.*

GOUT-*wort*, a name ſometimes given to a genus of plants called by botaniſts *angelica*. See the article ANGELICA, *Suppl.*

GRAIN *(Suppl.)* — *Oily* GRAIN, the name by which ſome call the *ſeſamum*, or *myagrum* of botanical writers. See the article MYAGRUM, *Suppl.*

Scarlet GRAIN, in botany, a term ſometimes uſed to denote the *opuntia* and *ilex* of botanical writers. See the articles OPUNTIA and ILEX, *Suppl.*

GRAMEN, *graſs*, in botany, the name by which botaniſts call a large genus of plants. See the article GRASS, *Append.*

GRAMEN *murorum, ſpicâ longiſſimâ*, the name given by Mr. Raymond to a genus of plants called by Linnæus *feſtuca*. See the article FESTUCA, *Suppl.*

GRAPE, the fruit of the vine. See the article VITIS, *Suppl.*

Sea-ſide GRAPE, in botany, a name by which ſome call the *guajabara*. See the article GUAJABARA, *Append.*

Hyacinth GRAPE, a name ſometimes uſed for the *muſcari*, a genus of plants. See the article MUSCARI, *Suppl.*

GRASS, *gramen*, in botany, the Engliſh name of a large genus of plants, the characters of which are theſe: the flower, which is diſpoſed in faſciculi, has no petals, conſiſting wholly of a number of ſtamina, ariſing, for the moſt part, out of a ſquamoſe cup; the germen of the piſtil finally becomes a roundiſh or oblong ſeed, incloſed in the cup itſelf, or in a diſtinct capſule, and containing very little farina or flour. See *Tournefort*, Inſt. Bot. p. 516. See alſo the Article GRASS, *Suppl.*

Of this genus there are a vaſt multiplicity of ſpecies, enumerated by the above-mentioned author, whom the curious may conſult on that head.

Canary-GRASS, the Engliſh name of a diſtinct genus of plants called by botaniſts *phalaris*. See the article PHALARIS, *Suppl.*

Capon's tail GRASS, the Engliſh name of a diſtinct genus of plants called by botaniſts *feſtuca*. See the article FESTUCA, *Suppl.*

Creſted-GRASS, or *Cock's foot* GRASS, names given to a diſtinct genus of plants, called by Linnæus *cynoſurus*. See the article CYNOSURUS, *Suppl.*

Couch-GRASS, a name given to the green-leav'd *triticum*, with a creeping root. See the article TRITICUM, *Suppl.*

Dog's GRASS, *gramen Caninum*, the name by which ſome call a ſpecies of *triticum*. See the article TRITICUM, *Suppl.*

Sea-dog's GRASS, a name ſometimes given to the double-ſpiked *ſecale*, or rye. See the articles SECALE and RYE, *Suppl.*

Dog's-tail GRASS, the Engliſh name of a diſtinct genus of plants called by authors *cynoſurus*. See the article CYNOSURUS. *Suppl.*

Fox-tail GRASS, the Engliſh name of a diſtinct genus of plants known among botaniſts under that of *alopecurus*. See the article ALOPECURUS, *Suppl.*

Knot-GRASS, a name given to ſeveral diſtinct genera of plants. See the articles POLYGONUM and PARONYCHIA, *Suppl.*

Love-GRASS, a name ſometimes given to a ſpecies of *briza*, a diſtinct genus of plants. See the article BRIZA, *Suppl.*

Meadow-GRASS, the Engliſh name of a diſtinct genus of plants called by authors *poa*. See the article POA, *Suppl.*

Hard Meadow-GRASS, a name ſometimes given to a ſpecies of the *cynoſurus*, or *dog's-tail graſs*. See the article CYNOSURUS, *Suppl.*

Millet-GRASS, in botany. See the article MILIUM, *Suppl.*

Oat-GRASS, in botany, a name by which ſome call a ſpecies of *feſtuca*. See the article FESTUCA, *Suppl.*

Buſh-oat-GRASS, or *tall oat*-GRASS, names given to a diſtinct genus of plants, called by botaniſts *bromus*. See the article BROMUS, *Suppl.*

Quaking GRASS, *gramen tremulum*, the name by which ſome call a ſpecies of *briza*. See the article BRIZA, *Suppl.*

GRASS *of Parnaſſus*, the Engliſh name of a diſtinct genus of plants called by authors *Parnaſſia*. See the article PARNASSIA, *Suppl.*

Pudding-GRASS, a name ſometimes given to the *pulegium*, or penny-royal, a ſpecies of mint. See the articles MENTHRA and MINT, *Suppl.*

Rattle-GRASS, a name ſometimes uſed for the *pedicularis*, or louſe-wort. See the article PEDICULARIS, *Suppl.*

Scorpion-GRASS, the Engliſh name of a genus of plants called by botaniſts *ſcorpioides*. See the article SCORPIOIDES, *Suppl.*

Shave-GRASS the name uſed by ſome writers for the *equiſetum* of botaniſts. See the article EQUISETUM, *Suppl.*

Silk-GRASS, a name by which ſome call two very different genuſſes of plants, the aloe and dog's-bane. See the articles ALOE and DOG'*s-bane*, *Suppl.*

Sword-GRASS, a name ſometimes given to the *gladiolus* of botaniſts. Ruſt. Dict. in voc.

Trefoil-GRASS, or *three-leaved* GRASS, a diſtinct genus of plants. See the article TREFOIL, *Suppl.*

Vetch-GRASS, the Engliſh name of a diſtinct genus of plants called by authors *niſſolia*. See the article NISSOLIA, *Suppl.*

Viper's GRASS, a name by which ſome call the *ſcorzonera* of botanical writers. See the article SCORZONERA, *Suppl.*

GRAVING, in the ſea language, is the bringing a ſhip a-ground, and then burning off with furze, reed, or broom, all the filth and foulneſs that ſticks to her bottom without-board, in order to pay her new. *Blanckley*, Nav. Exp. p. 67.

GRAVITY *(Cycl.)* — To determine the ſpecific *gravity* of bodies accurately, requires ſo much care, and is liable to ſo many difficulties, that we need not be ſurprized when we find authors differing from one another. The lateſt we have on this ſubject, and the beſt, is Dr. Richard Davies, in the Philoſ. Tranſact. N°. 488. This gentleman has with great pains and judgment collected all the experiments of this kind, that have been made by the moſt accurate authors, ſhewing how widely they diſagree, and pointing out the cauſes of their differences: and he has alſo given us the ſpecific *gravities* of ſeveral ſubſtances from his own obſervations; to which we refer the curious.

GRAY, the Engliſh name of a ſpecies of duck, otherwiſe called gadwall. See the article GADWALL, *Suppl.*

GRAYMILL, in botany, a name ſometimes given to the *lithoſpermum* of authors, more uſually called gromwell. See the article LITHOSPERMUM, *Suppl.*

GREEN *(Suppl.)* — *Saxon* GREEN, an extremely beautiful *green* colour, the proceſs of dying which is this: the cloth or ſilk is firſt to be dyed a Saxon blue, in the following manner; having ground nine parts of indigo with twenty of red arſenic into a fine powder, add forty-eight parts of ſtrong ſpirit of vitriol; which mixture ſwells, grows hot, and emits a ſulphureous ſmell. After ſtanding in a moderate warmth for twenty-four hours, pour off the liquid part, which will be of an extremely deep blue. A ſmall quantity of this liquor, dropt into hot water, inſtantly ſpreads, tinges it of a fine light blue, and fits it for dying the prepared wool, cloth, or ſilk; and, by increaſing or diminiſhing the proportion of the blue compoſition, the colour may be rendered deeper or lighter.

The cloth or ſilk, thus dyed blue, is next to be dipt in the yellow decoction of weld or ſuſtic, and the deſired colour will be obtained.

Or the ſubject may be died *green* at one operation, by boiling it for a little time in a mixture of the blue and yellow liquors.

By thus combining any blue and yellow dyes, in different proportions, all the ſhades of *green* may be produced, from the bluiſh *green* of the cabbage-leaf to the greeniſh yellow of the olive.

Winter-GREEN, the name of a diſtinct genus of plants called by authors *pyrola*. See the article PYROLA, *Suppl.*

GREEN-*finch*, the Engliſh name of a ſpecies of *fringilla*, which has a ſtrong tinge of *green* diffuſed over all its body; the wings and tail are black, but both variegated with a beautiful yellow. See the article FRINGILLA, *Suppl.*

GREENS, in diet. It is to be obſerved, that *greens* as well as fruit are but a flatulent diet, and therefore ought to be eaten with moderation in bilious diſorders. However, on account of their antiſeptic quality, they are eſteemed good for preventing putrid and contagious diſeaſes. *Pringle*, Obſerv. on the Diſeaſes of the Army, p. 210, 294.

GREY, or GRAY, in zoology. See the article GRAY, *Suppl.*

GREY *fly*, the name of a ſpecies of two-winged flies, called by zoologiſts *œſtrum*. See the article ŒSTRUM, *Suppl.*

GRICE, a term uſed by country people for a young wild boar. Dict. Ruſt. in voc.

GRIG, in ichthyology, a name frequently uſed for the ſand-eel or *ammodytes*. See the article AMMODYTES, *Suppl.*

GRIPES, in the dyſentery. See the article DYSENTERY.

GRISLEY *ſeeds*, among herbaliſts, denote thin, flat ſkinny ſeeds. Ruſt. Dict. in voc.

GROATS, a term uſed in many parts of the kingdom for culled oats or oat-meal only half ground. Dict. Ruſt. in voc.

GROOVE *(Suppl.)* — GROOVE, or GROVE, among joiners, denotes the channel that is made by their plough in the edge of a moulding, ſtyle, or rail.

GROOVE alſo denotes a gardener's tool for tranſplanting flowers. Dict. Ruſt. in voc.

GROTTO *(Cycl.* and *Suppl.)* — A cæment for artificial *grottos* may be made thus: take two parts of white roſin, melt it clear, and add to it four parts of bees wax; when melted together add two or three parts of the powder of the ſtone you deſign to cæment, or ſo much as will give the cæment the colour of the ſtone; to this add one part of flower of ſulphur: incorporate all together over a gentle fire, and afterwards knead them with your hands in warm water. With this cæment the ſtones, ſhells, *&c.* after being well dried before the fire, may be cæmented. *Smith*'s Laboratory, p. 169.

Artificial red coral branches, for the embelliſhmrnt of *grottos*, may be made in the following manner: take clear roſin, diſſolve it in a braſs pan; to every ounce of which add two drams of the fineſt vermillion: when you have ſtirred them well together, and have choſen your twigs and branches, peeled and dried, take a pencil and paint the branches all over whilſt the compoſition is warm; afterwards ſhape them in imitation of natural coral. This done, hold the branches over a gentle coal-fire, till all is ſmooth and even as if poliſhed.

In the ſame manner white coral may be prepared with white lead, and black coral with lamp-black.

A *grotto* may be built with little expence of glaſs, cinders, pebbles, pieces of large flint, ſhells, moſs, ſtones, counterfeit coral, pieces of chalk, *&c.* all bound or cæmented together with the above deſcribed cæment.

GROUND-*pine*, in botany. See the article CHAMÆPYTIS, *Suppl.*

Stinking GROUND-*pine*, the name by which ſome call the *polycnemum* and *camphorata* of botanical writers. See the articles POLYCNEMUM, *Append.* and CAMPHORATA, *Suppl.*

GROUND-*worm*, in the hiſtory of inſects. See the articles WORM and EARTH-*worm*, *Suppl.*

GROUNSEL, *ſenecio*, in botany, See the article SENECIO, *Suppl.*

African GROUNSEL, a name ſometimes given to a genus of plants called by Linnæus *kleinia*. See the article KLEINIA, *Append.*

GROWSE, in ornithology. See the article GROUSE, *Suppl.*

GRUB-*ax*, or GRUBBAGE, among gardeners, *&c.* a tool for grubbing up the roots of trees, weeds, *&c.* Ruſt. Dict. in voc. See GRUBBING, *Suppl.*

GUABANI, in botany, the name of a delicate fruit of the Weſt-Indies, cooling and of a ſweet taſte: it is about two hands breadth long, and has a white delicious pulp, containing a number of hard kernels or ſeeds.

GUAIACAN, in botany, a name by which ſome authors have called the tree whoſe wood is the *lignum vitæ*, or *guaiacum* of the ſhops.

GUAJABARA, the *ſea-ſide-grape*, the name of a genus of plants, the characters of which are theſe: the flower is of the roſaceous kind, conſiſting of ſix petals; in the center ariſes the pointal, which afterwards becomes a pulpy fruit, incloſing one roundiſh ſtone terminating in a point.

The ſpecies of *guajabara* are theſe, 1. The *ſea-ſide-grape*, with oblong leaves. 2. The common *ſea-ſide-grape*, with roundiſh leaves. 3. The *ſea-ſide-grape*, with very broad leaves. 4. The *ſea-ſide-grape*, with ſmaller and longer leaves.

All theſe ſorts, which are natives of the Weſt-Indies, muſt be propagated by ſeeds, ſown in pots of light rich earth, and plunged into an hot-bed of tanner's bark: the plant muſt conſtantly remain in a ſtove, being too tender to live in the open air, even in our warmeſt weather; only in ſummer they may be frequently refreſhed with water, and have freſh air admitted to them. *Miller*'s Gard. Dict. in voc.

GUANA, in zoology, a ſpecies of lizard, otherwiſe called *iguana*. See the article IGUANA, *Suppl.*

GUARANTY, in politics, an engagement of mediatorial or neutral ſtates, whereby they pledge their faith, that the articles of a particular treaty ſhall be inviolably obſerved on both ſides.

This engagement implies, that the guarantees are obliged to aſſiſt the party invaded contrary to the treaty, againſt the injurious agreſſor; but not if the war is occaſioned by any other cauſes than the violation of the articles of peace. *Puffendorff*, Law of Nature and Nations, book VIII. ch. viii. § 7.

GUAVA, a name ſometimes given to the *guajava* of Tournefort. See the article GUAJAVA, *Suppl.*

GUERKINS, a kind of cucumbers for pickling, otherwiſe called gherkins. Dict. Ruſt. in voc.

GUERNSEY-*lilly*, a name uſed for a genus of plants, called by ſome *amaryllis*, and by others *lilio-narciſſus*. See the article LILIO-NARCISSUS, *Suppl.*

GUILLEMITES, an order of monks in Flanders, whoſe habit reſembles that of the Ciſtertians: they follow the rule of St. Auguſtine, and are governed by a ſuperior, who does not take the title of provincial, aad is elected every four years. See *Broughton*'s Dict. Relig. in voc.

GUINEA-*henweed*, in botany, a name by which ſome call the *petiveria* of botanical writers. See the article PETIVERIA, *Suppl.*

GUINEA-*pepper*, the Engliſh name of a genus of plants, called by authors *capſicum*. See the article CAPSICUM, *Suppl.*

GUINEA-*wheat*, a name ſometimes given to the maiz, or Indian corn, called by botaniſts *yucca*. See the article YUCCA, *Suppl.*

GUINEA-*worm*, in the hiſtory of inſects, the ſame with what zoologiſts call *chætia*. See the article CHÆTIA, *Append.*

GULO, in zoology, a name ſometimes given to a ſpecies of *muſtela*. See the article GLUTTON, *Append.*

GUM *(Suppl.)* — Grew, in his Anatomy of Plants, makes the following remarks concerning the import of the word *gum*, and the diſtinction thereof both from a roſin and a mucilage.

A roſin, he obſerves, is originally a turpentine, or acidulous liquor, having an exceeding ſmall quantity of watery parts mixed therewith; and which, for that reaſon, will not be diſſolved in water, but only in oil: of this kind are maſtic, benzoin, tacamahaca, commonly called *gums*, though, ſtrictly ſpeaking, they are all true roſins.

A *gum*, on the other hand, is originally a milky liquor, having a greater quantity of water mixed with its oily parts; and which, for that reaſon, diſſolves either in water or oil: of this kind are ſagapenum, opopanax, ammoniac, *&c.*

A third ſort of *gum* is that which is unoily; and which, therefore, diſſolves only in water, as *gum* arabic, the *gum* of the cherry-tree, *&c.*

Theſe laſt ſubſtances, though commonly called *gums*, are only dried mucilages; being originally nothing elſe but the mucilaginous lymph iſſuing from the veſſels of the tree, in the ſame manner as it does from comfrey, mallows, *&c.* and even from the cucumber; the veſſels thereof, upon being cut acroſs yielding a lymph which is plainly mucilaginous, and which being well dried at length becomes a kind of *gum*, or rather a hardened mucilage.

In like manner, the *gums* of the plumb-tree, cherry-tree, and the like, are nothing elſe but dried mucilages.

If we will take the word in its wideſt ſenſe, all *gums* are originally either a terebinth, or a milk, or a mucilage. *Grew*, Anat. of Plants, book III. ch. iv. p. 134.

Gums, in medicine, ſhould always be ſtrained before they are uſed, as being ſeldom free from droſs and other admixtures, which hinder their operation.

Dr. Pringle, in his Obſervations on the Diſeaſes of the Army, tells us, that *gums* are all powerful antiſeptics. See the article ANTISEPTICS, *Append.*

GUM-*ſuccory*, in botany, a name by which the *chondrilla* of authors is ſometimes called. See the article CHONDRILLA, *Suppl.*

GUNDELIA, in botany, a diſtinct genus of plants called *hacub* by Vaillant; the characters of which are theſe: there is ſcarcely any common cup, except the ſurrounding leaves; the flower is of the compound kind, uniformly tubulated, being made up of equal hermaphrodite floſcules, conſiſting of a ſingle clavated petal, divided into five ſegments at the edge; the ſtamina are five very ſhort capillary filaments; and the antheræ cylindraceous, tubulated, and long: the germen of the piſtil is ovated, immerſed in the receptacle, crowned with very ſmall ſquamæ, and placed at the bottom of each floſcule; the ſtyle is filiform, and longer than the flower-petals; the ſtigmata are two in number, and turned backwards; there is no pericarpium; the ſeeds, which are ſingle, roundiſh, and acuminated, being concealed in the receptacle, which is of a conic figure. *Linnæi* Gen. Plant. p. 386.

GUNNERY *(Cycl.)* — Mr. Robins, from the experiments related in his New Principles of *Gunnery*, having concluded, that the force of fired gun-powder, at the inſtant of its exploſion, is the ſame as that of an elaſtic fluid of a thouſand times the denſity of the common air, and that the elaſticity of this fluid, like that of air, is proportionable to its denſity, propoſes the following problem:

The dimenſions of any piece of artillery, the weight of its ball, and the quantity of its charge being given, to determine the velocity which the ball will acquire from the exploſion, ſuppoſing the elaſticity or force of the powder at the firſt inſtant of its firing to be given.

In the ſolution of this problem he aſſumes the two following principles: 1. That the action of the powder on the bullet ceaſes as ſoon as the bullet is got out of the piece. 2. That all the powder of the charge is fired, and converted into an elaſtic fluid, before the bullet is ſenſibly moved from its place.

Theſe aſſumptions, and the concluſions before-mentioned, make the action of fired gun-powder to be entirely ſimilar to that of air condenſed a thouſand times; and from thence it will not be difficult to determine the velocity of the ball ariſing from the exploſion. For the force of the fired powder diminiſhing in proportion to its expanſion, and ceaſing when the ball is out of the piece; the total action of the powder may be repreſented by the area of a curve, the baſe of which repreſents the ſpace through which the ball is accelerated; and the ordinates to which, repreſent the force of the powder at every point of that ſpace. And theſe ordinates being in reciprocal proportion to their diſtance from the breech of the gun, becauſe when the ſpaces occupied by the fired powder are as 1, 2, 3, 4, *&c.* the force of the powder, or the ordinates repreſenting it, will be as, 1, $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, *&c.* it appears that the curve will be a common hyperbola, and that the area intercepted between it, its aſymptote, and the two ordinates repreſenting the force of the powder at the firſt exploſion and at the muzzle of the piece, will repreſent the total action of the powder on the ball. But if the ball were urged through the ſame ſpace, by an uniform force equal to its gravity, the total action of this force would be repreſented by a rectangle, the baſe of which would be the baſe of the curve or intercepted portion of the aſymptote before-mentioned, and the height of which would repreſent the uniform force of gravity. Hence the ſquare of the velocity of the ball reſulting from the action of the gunpowder, will be to the ſquare of the velocity reſulting from the action of gravity, as the area of the hyperbolic ſpace is to the area of the rectangle [a]. But the velocity of the ball reſulting from gravity is given, being the velocity it would acquire from a height equal to the ſpace through which the powder accelerates it; and the proportion between the hyperbolic ſpace and the rectangle is alſo given, from the analogy of hyperbolic ſpaces and logarithms [b]; therefore the velocity of the ball ariſing from the action of the fired gun-powder will be given. — [a By prop. 39. lib. i. of Newton's Principles. b See the article LOGARITHM, *Suppl.*]

To give an example of this, let us ſuppoſe the length of the barrel of a gun to be 45 inches, its diameter, or rather the diameter of the ball to be $\frac{3}{4}$ of an inch; and the ſpace occupied by the powder to be $2\frac{5}{8}$ inches; to determine the velocity which will be communicated to a leaden bullet by the exploſion, ſuppoſing the bullet laid at firſt with its ſurface contiguous to the powder.

By the theory here laid down it appears, that at the firſt inſtant of the exploſion the flame will exert, on the ball lying cloſe to it, a force one thouſand times greater than the preſſure of the atmoſphere. But the medium preſſure of the atmoſphere is eſteemed equal to that of a column of water 33 feet high; whence lead being to water as 11,345 to 1, this preſſure will be equal to that of a column of lead 34,9 inches in height, whence multiplying this by 1000, a column of lead 34900 inches high would produce a preſſure equal to what is exerted on the ball by the powder in the firſt inſtant of the exploſion; and the leaden ball being $\frac{3}{4}$ of an inch in diameter, and conſequently equal to a cylinder of lead on the ſame baſe $\frac{3}{4}$ an inch in height, the preſſure at firſt acting on it will be equal to 34900×2, or 69800 times its weight; whence the force of gravity is to that of the powder at its firſt exploſion, as 1 to 69800. Now an uniform force, as 1, accelerating the ball through a ſpace of $45 - 2\frac{5}{8} = 42\frac{3}{8}$ inches, will give it a velocity of 15.07 feet in one ſecond of time; for this is the velocity the ball would acquire in falling from a height of $42\frac{3}{8}$ inches. And an initial force, as 69800, but diminiſhing continually, as the hyperbolic ordinates, will, upon computation, be found to communicate a velocity to the ball, which will be to that communicated by gravity as 110.7 to 1. Therefore the velocity of the ball ariſing from the action of the gun-powder will be $= 110.7 \times 15.07 = 1668.249$ feet in one ſecond of time; that is, the ball, when it firſt leaves the piece, will be carried at the rate of 1668 feet in one ſecond.

As to the firſt of the principles here aſſumed, the author has obſerved, in the Philoſ. Tranſact. N° 469. p. 445, that it would be found erroneous, if examined with a geometrical rigour; ſince it cannot be queſtioned but the flame acts in ſome degree on the bullet after it is out of the piece: but in experiments no ſuch accuracy is attainable; minute irregularities

ties are the neceſſary concomitants of all complicated experiments: in the colliſion of bodies, in the running or ſpouting of water, even in ſmall velocities, irregularities happen, not reconcileable to theory or to each other: what may not then be ſuppoſed to happen from the action of ſo furious a power as gun-powder? From experiments it appears, that velocities of bullets fired from the ſame piece, charged with the ſame powder, and all other circumſtances, as nearly as poſſible, the ſame, do yet differ from each other by ſometimes more than $\frac{1}{30}$ part of the whole: but this is a ſmall degree of inaccuracy in a caſe of this nature, and if the action of the flame on the bullet, after it is out of the piece, is ſo ſmall as to produce no greater effect than what may be deſtroyed by the inevitable variations of the experiments, the neglecting it entirely is both convenient and a reaſonable procedure. Now what gives ground to think that this poſtulatum, though not rigorouſly true, may be ſafely aſſumed, is the conſideration of the ſpreading of the flame by its own elaſticity, as ſoon as it eſcapes from the mouth of the piece; for by this it may be conceived that the part of it which impinges on the bullet may be neglected, although the impulſe of the flame be a very remarkable force.

With regard to the ſecond aſſumed principle, that all the powder is fired before the bullet is ſenſibly moved from its place; it is to be obſerved, that this very poſition, having been examined by a committee of the Royal Society, was, after ſeveral experiments, determined in the negative; from whence many may be ready to conclude, that the whole theory muſt be overturned. But this requires a farther diſcuſſion, and it will appear that though this principle be not rigorouſlly true, no more than the former, yet it ſeems alſo that it may be ſafely admitted in inveſtigating the effects of powder, ſince, even in ſhort barrels, where the ſpace the bullet was impelled thro' was not five inches, and where of courſe the deficiency of velocity was greateſt, it cannot amount to one thirtieth of the whole. This will appear from the experiments made by the committee; for when the barrel was ſo ſhortned, that the bullet being placed cloſe to the wad, lay with its outer ſurface nearly level with the mouth of the piece; yet even in this ſhort tranſit of the bullet but $\frac{1}{6}$ of the whole charge, at a medium, was collected unfired; which $\frac{1}{6}$, properly reduced, amounts to but $\frac{1}{12}$ of the charge. This reduction is founded on theſe conſiderations, that the powder uſed by the committee being unequally grained, when the ſmaller grains, collected by ſifting, were uſed, the quantity remaining unfired was leſs at a medium in the ratio of 5 to 3, than when it was uſed without ſifting. Alſo, by extracting the ſalt-petre from the powder collected unfired, there was leſs ſalt-petre contained in it than in real powder, nearly in the ratio of 9 to 7. Now theſe two proportions compounded, make the proportion of 15 to 7, in which proportion muſt the quantities of powder unfired be reduced, in order to determine the quantity of fine good powder that might be ſuppoſed to remain unfired in the experiments brought to confirm the aforeſaid theory.

Now it appears by experiments, that the velocities of bullets placed in the ſame ſituation are in the ſubduplicate proportion of the charges: conſequently the deficiency of velocity ariſing from the loſs of $\frac{1}{12}$ of the charge will be about $\frac{1}{24}$ of the velocity only. And in the experiments made with a barrel $5\frac{1}{3}$ inches in length, where the ball had not three inches to move, the quantity of real powder collected unfired from a charge of 12dwt. would have been no more than 16 grains, at a medium, or $\frac{1}{18}$ of the whole charge, which would produce a deficiency of $\frac{1}{36}$ of the velocity only: a difference leſs than what frequently occurs in the exacteſt repetition of the ſame experiments.

This, it is thought, is fully ſufficient to juſtify the principle in queſtion; eſpecially as in all caſes of real uſe the length of the barrel, in proportion to the quantity of the charge, will be much greater than in the inſtances here mentioned. See Phil. Tranſ. N°. 469, p. 450, 452, *&c.* and ſee the Experiments of the committee in the Tranſactions, N°. 465, p. 172, 173, *&c.*

The greateſt part of thoſe who have written on the manner in which powder takes fire, have ſuppoſed it to be done by regular degrees; the firſt grains firing thoſe contiguous, and they the next ſucceſſively; and it has been generally thought, that a conſiderable time was employed in theſe various communications: for Mr. Daniel Bernoulli, in his *Hydro-dynamica*, has concluded from ſome experiments made at Peterſburg, that the greateſt part of the charge eſcapes out of the piece unfired, and that the ſmall part which is fired, does not take fire 'till it is near the mouth. Many theories too have been compoſed on the time of the progreſs of the fire amongſt the grains, and the different modifications which the force of powder did thence receive; and it has been generally conceived, that the proper lengths of pieces were determinable from this principle; that they ſhould be long enough to give time for all the powder to fire.

But no ſuch regular and progreſſive ſteps ſeem obſervable in the exploſion. For conſidering that by loading with a greater weight of bullet, and thereby almoſt doubling the time of the continuance of the powder in the barrel, its force receives but an inconſiderable augmentation; and that doubling and trebling the uſual charge, the powder thus added always produces a correſpondent effect in the velocity of the bullet; likewiſe, that in a piece near four feet in length, charged with an uſual charge of powder, the velocity communicated to the bullet, during the firſt three inches of its motion, is full half the velocity acquired in its whole paſſage thro' the barrel; and conſidering alſo that the elaſticity or force of the powder, in the three firſt inches of its expanſion, is at a medium near eight times greater than in the laſt two feet of the barrel; it may be concluded from all theſe circumſtances, that the time employed by the powder in taking fire was not neceſſary to be attended to in theſe computations; but that the whole maſs might be ſuppoſed to be kindled, before the bullet was ſenſibly moved from its place.

And the experiments reported by the committee of the Royal Society, in the Tranſaction, N°. 465, before-mentioned, are ſtrong proofs that the powder is not fired in the progreſſive manner uſually ſuppoſed; for when the ſhort barrel was charged with 12 penny-weight and ſix penny-weight reſpectively, the quantity of powder which was collected unfired from 12 penny-weight, did not exceed by three grains, at a medium, what was collected from ſix penny-weight, although the bullet was a leſs time in paſſing thro' the barrel with 12 penny-weight than with ſix, it having a leſs way to move; conſequently the quantity remaining unfired of the ſix penny-weight, did not continue unfired for want of time; ſince when the piece was charged with 12 penny-weight, the additional ſix penny-weight was conſumed in a ſhorter time. See Phil. Tranſ. N°. 469. p. 450.

Mr. Robins has alſo given us an ingenious way of determining, by experiments, the velocity which any ball moves with, at any diſtance of the piece it is diſcharged from.

This may be effected by means of a pendulum made of iron, having a broad part at bottom, covered with a thick piece of wood, which is faſtened to the iron by ſcrews. Then having three poles joined together by their tops and ſpreading at bottom, ſuch as are vulgarly uſed in weighing and lifting heavy bodies, and called by workmen triangles, on two of theſe poles, towards their tops, are ſcrewed on ſockets, on which the pendulum is hung by means of a croſs piece, which becomes its axis of ſuſpenſion, and on which it ought to vibrate with great freedom. Something lower than the bottom of the pendulum there ſhould be a brace, joining the two poles to which the pendulum is ſuſpended; and to this brace there is faſtened a contrivance made with two edges of ſteel, ſomething in the manner of a drawing pen; the ſtrength with which theſe edges preſs on each other being diminiſhed or increaſed at pleaſure, by means of a ſcrew. To the bottom of the pendulum ſhould be faſtened a narrow ribbon, which paſſing between the ſteel edges, may hang looſely down by means of an opening cut in the lower piece of ſteel.

The inſtrument being thus fitted, if the weight of the pendulum, the reſpective diſtances of its center of gravity, and of its center of oſcillation, from its axis of ſuſpenſion, be known, it may from thence be found, what motion will be communicated to this pendulum by the percuſſion of a body of a known weight moving with a known degree of velocity, and ſtriking it in a given point; that is, if the pendulum be ſuppoſed at reſt before the percuſſion, it will be known what vibration it ought to make in conſequence of ſuch a blow; and if the pendulum being at reſt, is ſtruck by a body of a known weight, and the vibration which the pendulum makes after the blow is known, the velocity of the ſtriking body may from thence be determined.

Now the extent of the vibration, made by the pendulum, may be meaſured by the ribbon. For if the preſſure of the ſteel edges on the ribbon be regulated by the ſcrew, ſo as to be free and eaſy, tho' with ſome minute reſiſtance to hinder its ſlipping of itſelf: then ſetting the pendulum at reſt, let the part of the ribbon between the pendulum and the ſteel edges be drawn ſtrait, but not ſtrained, and fixing a pin in the part of the ribbon contiguous to the edges, the pendulum ſwinging back by the impulſe of the ball, will draw out the ribbon to the juſt extent of its vibration, which will be determined by the interval on the ribbon between the edges and the place of the pin.

The computation by which the velocity of the ball is determined, from the vibration of the pendulum after the ſtroke, is founded on this principle of mechanics; That if a body in motion ſtrikes on another at reſt, and they are not ſeparated after the ſtroke, but move on with one common motion, then that common motion is equal to the motion with which the firſt body moved before the ſtroke: whence, if that common motion and the maſſes of the two bodies are known, the motion of the firſt body before the ſtroke is thence determined. On this principle it follows, that the velocity of a bullet may be diminiſhed in any given ratio, by its being made to impinge on a body of a weight properly proportioned to it; and hereby the moſt violent motions, which would otherwiſe eſcape our examination, are eaſily determined by the retarded motions which have a given relation to them.

See New Princip. of Gunnery, p. 28, 29, &c. See alſo the Phil. Tranſ. N. 469, p. 444. where a ſmall correction, relating to a number in Mr. Robins's 8th propoſition, is mentioned.

It is to be obſerved, that the length to which the ribbon is drawn, is always nearly the chord of the arch deſcribed by the aſcent; it being ſo placed, as to differ inſenſibly from thoſe chords which moſt frequently occur; and theſe chords are known to be in the proportion of the velocities of the pendulum acquired from the ſtroke. Hence it follows, that the proportion between the lengths of ribbon drawn out at different times, will be the ſame with that of the velocities of the impinging bullets.

Now from the computations delivered by Mr. Robins, it appears, that the velocity of the bullet was 1641 feet in one ſecond of time, when the chord of the arch deſcribed by the aſcent of the pendulum, in conſequence of the blow, was $17\frac{1}{4}$ inches. Therefore, by the proportion of any other lengths of ribbon drawn out, by any percuſſion, to $17\frac{1}{4}$, the proportion of the velocity with which the bullets impinge, to the known velocity of 1641 feet in 1″, will be determined.

As experiments of this kind are often attended with danger and difficulty, thoſe who may be diſpoſed to make any, will find ſeveral uſeful practical cautions, in p. 31, 32 and 33 of the ſaid Treatiſe.

By the experiments recited at large, in Propoſition IX. of the ſame Treatiſe, it appears, that the computations from Mr. Robins's theory, compared with thoſe experiments, which were made with barrels of various lengths, from ſeven inches to forty-five, and with different quantities of powder, from ſix penny-weight to thirty-ſix, have a remarkable coincidence, and ſuch as occurs but in few philoſophical ſubjects of ſo complicated a nature.

Suppoſing, for inſtance, the length of a barrel to be 45 inches, the quantity of powder 12 penny-weight, and the ball $\frac{3}{4}$ inch diameter, weighing $1\frac{1}{3}$ ounce, or $\frac{1}{12}$ of a pound averdupoiſe, and the windage or exceſs of the diameter of the barrel above that of the bullet about $\frac{1}{40}$ of an inch; the velocity of the bullet will, by theory, be about 1670 feet in one ſecond: and this velocity is found in theſe experiments, to be the mean velocity which the ball really receives in thoſe circumſtances. Hence we may determine the velocities with which muſket and cannon ſhot are diſcharged from their reſpective pieces by their uſual allotment of powder.

For as a leaden ball of $\frac{3}{4}$ inch diameter, and weighing nearly $1\frac{1}{3}$ ounce averdupoiſe, being fired from a barrel of 45 inches in length with half its weight of powder, will have a velocity at its iſſuing from the piece, which, if uniformly continued, would carry it near 1700 feet in 1″: ſo if inſtead of a leaden ball an iron one of the ſame diameter was placed in the ſame ſituation in the ſame piece, and was impelled by the ſame quantity of powder, the velocity of ſuch an iron bullet would be greater than that of the leaden one, in the ſubduplicate ratio of the ſpecific gravities of lead and iron; and ſuppoſing that ratio to be as 3 to 2, and computing on the foregoing principles, it will appear, that an iron bullet of 24 lb. weight, ſhot from a piece of 10 feet in length, with 16 lb. of powder, will acquire from the exploſion a velocity which, if uniformly continued, would carry it nearly 1650 feet in 1″. But if inſtead of this full charge weighing two thirds of the ball, we ſuppoſe the charge to be only half that weight, then its velocity will be no more than at the rate of 1490 feet in 1″; and the ſame would be the velocities of every leſſer bullet, fired with the ſame proportions of powder, if the lengths of all pieces were conſtantly in the ſame ratio with the diameters of their bore: and tho' this proportion does not always hold, yet the difference is not conſiderable enough to occaſion a very great variation from the velocities here aſſigned. But in theſe determinations, the windage is ſuppoſed to be no more than is juſt neceſſary for the eaſy putting down the bullet; whereas in real ſervice, either thro' negligence or unſkilfulneſs, it often happens, that the diameter of the bore ſo much exceeds the diameter of the bullet, that great part of the inflamed fluid eſcapes by its ſide; whence the velocity of the ſhot may, in this caſe, be conſiderably leſs than what is here aſſigned: however, part of this may poſſibly be compenſated by the greater heat which in all probability attends the firing of theſe large quantities of powder.

The theory here eſtabliſhed ſuppoſes what is ſaid under the head GUN-POWDER, that the powder when fired is equally hot with iron at the beginning of its white heat; but in very ſmall quantities of powder the heat is probably leſs, and conſequently the elaſticity leſs than what ariſes from this ſuppoſition. Now this decreaſe of elaſticity in ſmall quantities of powder has been found in many trials actually to take place. For inſtance, according to the theory before laid down, the velocity given the ball by the action of the powder is in round numbers 1670 feet in 1″; and this, as has been ſaid, is confirmed by the experiments taken at a medium. If now the barrel and poſition of the ball remaining the ſame, there be placed in the ſpace that contained 12 penny-weight of powder there mentioned, only one penny-weight; it follows, that if the elaſticity of the ſmaller charge be the ſame in proportion to its quantity with that of the larger, then the velocity of the bullet, when impelled by the exploſion of the ſmaller charge, will be to the velocity of a bullet impelled by a greater charge in the ſubduplicate ratio of the quantities of the reſpective charges, that is, in the ſubduplicate ratio of 1 to 12. Conſequently the velocity communicated by 12 penny-weight being known to be that of 1670 feet in 1″, the velocity communicated by one penny-weight would be that of 482 feet in 1″ nearly; but by repeated trials differing little from each other, it has been found, that the real velocity acquired by the ball in this caſe, from the exploſion of one penny-weight, was rather leſs than that of 400 feet in 1″. Whence it is evident, that the elaſticity of one penny-weight of powder, when fired, is leſs in proportion to its quantity than that of 12 penny-weight, as it ought to be by the theory.

So if three penny-weight of powder be placed in the ſame manner with the one penny-weight laſt mentioned, the real velocity the ball will acquire from the exploſion, will be from 740 to 720 feet in 1″. Whereas, ſuppoſing the elaſticity of three penny-weight, when fired, to be in ſimilar circumſtances the ſame with that of 12 penny-weight, the velocity acquired by the ball ſhould be 835 feet in 1″.

It is farther to be obſerved, that the theory eſtabliſhed under the head GUN-POWDER, ſuppoſes that in the firing of gun-powder about $\frac{3}{100}$ of its ſubſtance is converted by the ſudden inflammation into a permanent elaſtic fluid, the elaſticity of which, in proportion to its heat and denſity, is the ſame with that of the common air in the like circumſtances: it farther ſuppoſes, that all the force exerted by gun-powder in its moſt violent operations, is no more than the action of the elaſticity of the fluid thus generated; and theſe principles enable us to determine the velocities of bullets impelled from fire arms of all kinds.

From this theory appears the inconcluſiveneſs of what ſome authors have advanced relating to the advantages of particular forms, for the chambers of mortars and cannon; for all their laboured ſpeculations on this head are evidently founded on very erroneous opinions about the actions of fired powder. See lib. cit. p. 41.

But it muſt not be diſſembled, that however probable this theory may be from the experiments and reaſons on which it is founded, there ſtill remains a difficulty which ſeems not yet fully accounted for. The doubt ariſes from ſome experiments made before a committee of the royal ſociety, who hereupon gave it as their opinion, that the change of the form in the chamber will produce a change of the diſtance to which the bullet is thrown. The experiments upon which this opinion was founded, were as follows:

Three braſs chambers were made, whoſe depths were reſpectively three inches, $1\frac{1}{2}$ inch and $\frac{3}{4}$ inch; ſo turned as to fit the chamber of a braſs mortar exactly; each of theſe chambers contained, when full, one ounce troy of powder. The ball was of braſs, weighing nearly 356 ounces troy. The ball touched the powder of the charge in all theſe experiments. With the firſt chamber of three inches deep, the elevation of the mortar being 45°, the range taken at a medium of three ſhot was 741 feet: and the mean diſtance to which the ball was thrown with the chamber of $\frac{3}{4}$ inch deep, was but 464 feet. As to the chamber of $1\frac{1}{2}$ inch, it not fitting the chamber of the mortar exactly, the ranges were very irregular; but the leaſt range, tho' fired late in the damp of the evening, exceeded the fartheſt range of the $\frac{3}{4}$ inch chamber, and the fartheſt range extended to 686 feet; ſo that the committee ſeem well warranted in their opinion. The difficulty is to reconcile this with the foregoing theory. Its ingenious author has, in general obſerved, in the account of his book given in the Phil. Tranſ. N°. 469, p. 455, that when the charge is much ſmaller than the uſual allotment of powder, there are ſome irregularities, as thoſe ariſing from the different heat of ſmall and large quantities of powder, to which head too perhaps muſt be referred the experiments made by the committee on the effect of different ſmall chambers; but in cuſtomary charges, the velocities of bullets reſulting from all the experiments hitherto made, are really ſuch as the theory requires. And it appears, that theſe velocities are much greater than what they have been hitherto accounted; and there are reaſons from the theory to believe, that in cannon ſhot the velocities may ſtill exceed the foregoing computation. See Phil. Tranſ. N°. 465.

If a bullet be laid at a conſiderable diſtance from the charge, the principles before laid down cannot then be applied to determine the velocity of the ball; they being only applicable in caſes where the bullet is contiguous to the charge, or nearly ſo. For by what is ſhewn under the head GUN-POWDER, when the ſurface of fired powder is not confined by a heavy body, which it is obliged to impel before it, the flame dilates itſelf with a velocity much beyond what it can at any time communicate to a bullet by its continued preſſure; becauſe the powder having acquired a conſiderable degree of velocity of expanſion, the firſt motion of the ball will not

be

be produced by the continued preſſure of the powder, but by the percuſſion of the flame. From whence it follows, that the velocity of a bullet, laid a conſiderable diſtance before the charge, ought to be greater than what would be communicated to it by the preſſure of the powder acting as before-mentioned in this article. And this deduction from theory is confirmed from experience, by which it was found that a ball laid in a barrel, at the diſtance of $11\frac{1}{4}$ inches from the breech, and impelled by 12 penny-weight of powder, acquired in its diſcharge a velocity of about 1400 feet in 1″; whereas if it had been acted on by the preſſure of the flame only, it would not have acquired a velocity of 1200 feet in 1″. The ſame was found to hold true in all other greater diſtances (and alſo in leſſer, tho' not in the ſame degree) and in all quantities of powder. And from hence ariſes a conſideration of conſequence in practice, which is, that no bullet ſhould at any time be placed at any conſiderable diſtance before the charge, unleſs the piece be extremely well fortified: for a moderate charge of powder, when it has expanded itſelf thro' the vacant ſpace, and reaches the ball, will, by the velocity each part has acquired, accumulate itſelf behind the ball, and be thereby prodigiouſly condenſed; whence if the barrel be not extraordinary ſtrong, it muſt burſt. This is confirmed by the experience of an exceeding good tower muſket of very tough iron, which being charged with 12 dwt. of powder, and the ball being placed 16 inches from the breech; upon firing the piece, part of the barrel, juſt behind the bullet, was ſwelled out to double its diameter, and two large pieces burſt out of it. If the powder be not placed together at the breech, but ſcattered uniformly thro' the whole cavity left behind the bullet, the progreſſive motion of the flame may hence be ſuppoſed to be prevented by the expanſion of the neighbouring parts. And it was found that the ball being laid as before, $11\frac{1}{4}$ inches from the breech, its velocity, in this caſe, inſtead of 1400 feet in 1″, was only 1100 feet. See New Princip. of Gunnery, Part I. Prop. xii.

It appears from experience, that bullets of the ſame diameter and denſity impinging on the ſame ſolid ſubſtance with different velocities, will penetrate that ſubſtance to different depths, which will be in the duplicate ratio of thoſe velocities nearly. Thus a leaden bullet of $\frac{3}{4}$ of an inch in diameter, being fired againſt a ſolid block of elm with different velocities, as of 1700 feet, 730, and 400 feet in 1″; the cavities were found to be as 55, 10 and 3 reſpectively; which are nearly in the duplicate proportion of thoſe velocities: perfect regularity in caſes of this nature cannot be expected, when the unequal texture of the ſame piece of wood, and the change of the form, and the bullet by the ſtroke, are conſidered.

From the penetration being in the duplicate proportion of the velocity of the impinging body, it follows, that the reſiſtance of the wood, like that of gravity, is uniform. See New Princip. of Gunnery, p. 94, 95.

GUN-POWDER *(Cycl.)* — *Gun-powder*, fired either in a vacuum or in air, produces by its exploſion, a permanent elaſtic fluid.

If a red-hot iron be included in a receiver, and the receiver be exhauſted, and *gun-powder* be then let fall on the iron, the powder will take fire, and the mercurial gage will ſuddenly deſcend upon the exploſion; and, tho' it immediately aſcends again, yet it will never riſe to the height it firſt ſtood at, but will continue depreſſed by a ſpace proportioned to the quantity of *gun-powder* which was let fall on the iron. By this means (firing ſmall quantities at a time) the mercurial gage may be reduced from $29\frac{1}{2}$ inches to $12\frac{3}{4}$. Now this experiment, which has been often repeated, proves the propoſition with reſpect to the production of a permanent elaſtic fluid in a vacuum; for the deſcent of the gage could only be effected by the preſſure of ſome new generated fluid in the receiver, ballancing in part the preſſure of the external air. That this fluid, or ſome part of it at leaſt was permanent, appears from thence, that tho' in theſe experiments the quickſilver aſcended after the operation, yet next day it had aſcended no higher than to $22\frac{1}{2}$, at which place it ſeemed to continue fixed. And, that this fluid is elaſtic, is proved from the deſcent of the mercurial gage: ſince the quantity of matter contained in this fluid, could not by its gravity alone have ſunk the quickſilver by the leaſt ſenſible quantity; alſo from its extending itſelf through any ſpace, however great, the experiment ſucceeding in either a large or ſmall receiver, only the larger the receiver the leſs will be the deſcent of the mercurial gage to the ſame quantity of powder; the preſſure of the generated fluid diminiſhing as its denſity diminiſhes. See Phil. Tranſ. N°. 295.

The ſame production likewiſe takes place, when *gun-powder* is fired in the air [a]; for if a ſmall quantity of *powder* be placed in the upper part of a glaſs tube, and the lower part of the tube be immerged in water, and the water be made to riſe ſo near the top that only a ſmall portion of air is left in that part where the *gun-powder* is placed; if in this ſituation the communication of the upper part of the tube with the external air be cloſed, and the *gun-powder* be fired, (which may eaſily be done by a burning-glaſs) the water will, in this experiment, deſcend on the exploſion, as the quickſilver did in the laſt, and will always continue depreſſed below the place, at which it ſtood before the exploſion, and the quantity of this depreſſion will be greater, if the quantity of *powder* be increaſed, or the diameter of the tube be diminiſhed. From whence it is proved, that as well in air as in a vacuum, the exploſion of fired *powder* produces a permanent elaſtic fluid [b]. — [a *Haukſbee*, Phyſ. Mechan. Exp. p. 81. b *Robins*'s New Prin. of Gunnery, Prop. I.]

It alſo appears from experiment, that the elaſticity or preſſure of the fluid produced by the firing of *gun-powder*, is *cæteris paribus*, directly as its denſity. This follows from hence, that, if in the ſame receiver a double quantity of *powder* be let fall, the mercury will ſubſide twice as much as in the firing of a ſingle quantity. For the vapour produced from the double quantity, being contained in the ſame receiver, will be of double the denſity of that produced from the ſingle quantity; whence the elaſticity or preſſure, eſtimated by the deſcent of the mercury being likewiſe double, the preſſure is directly as its denſity. Alſo the deſcents of the mercury, when equal quantities of *powder* are fired in different receivers, are reciprocally as the capacities of thoſe receivers; and conſequently as the denſity of the produced fluid in each.

To determine the elaſticity and quantity of this elaſtic fluid, produced from the exploſion of a given quantity of *gun-powder*, Mr. Robins premiſes, that the elaſticity of this fluid increaſes by heat, and diminiſhes by cold, in the ſame manner as that of the air; and that the denſity of this fluid, and conſequently its weight, is the ſame with the weight of an equal bulk of air, having the ſame elaſticity and the ſame temperature. From theſe principles, and from his experiments, for a detail of which we muſt refer to the book itſelf, he concludes, that the fluid produced by the firing of *gun-powder* will be $\frac{3}{770}$ of the weight of the *gun-powder*; and the ratio of the reſpective bulks of the *powder*, and the fluid produced from it, will be, in round numbers, 1 to 244. See New Princip. of Gunnery, Scholium to Prop. II.

Hence we are certain, that any quantity of *powder* fired in any confined ſpace, which it adequately fills, exerts at the inſtant of its exploſion againſt the ſides of the veſſel containing it, and the bodies it impells before it, a force at leaſt 244 times greater than the elaſticity of common air, or, which is the ſame thing, than the preſſure of the atmoſphere; and this without conſidering the great addition which this force will receive from the violent degree of heat with which it is endued at that time; the quantity of which augmentation is the next head of Mr. Robins's enquiry. He determines that the elaſticity of the air is augmented, when heated to the extremeſt heat of red-hot iron, in the proportion of 796 to $194\frac{1}{3}$; and ſuppoſing that the flame of fired *gun-powder* is not leſs hot than red-hot iron, and the elaſticity of the air, and conſequently of the fluid generated by the exploſion, being augmented by the extremity of this heat in the ratio of 796 to $194\frac{1}{3}$, it follows, that if 244 be augmented in this ratio, the reſulting number, which is $999\frac{3}{4}$, will determine how many times the elaſticity of the flame of fired *powder* exceeds the elaſticity of common air, ſuppoſing it to be confined in the ſame ſpace which the *powder* filled before it was fired.

Hence then the abſolute quantity of the preſſure exerted by *gun-powder* at the moment of its exploſion, may be aſſigned; for ſince the fluid then generated, has an elaſticity $999\frac{3}{4}$, or in round numbers, 1000 times greater than common air; and ſince common air, by its elaſticity, exerts a preſſure on any given ſurface equal to the weight of the incumbent atmoſphere, with which it is in equilibrio, the preſſure exerted by fired *powder*, before it has dilated itſelf, is 1000 times greater than the preſſure of the atmoſphere, and conſequently the quantity of this force, on a ſurface of an inch ſquare, amounts to above ſix tun weight; which force, however, diminiſhes, as the fluid dilates itſelf.

Tho' it has here been ſuppoſed, that the heat of *gun-powder*, when fired in any conſiderable quantity, is the ſame with iron heated to the extremity of a red heat, or to the beginning of a white heat, yet it cannot be doubted but that the fire produced in the exploſion is ſomewhat varied (like all other fires) by a greater or leſs quantity of fuel; and it may be preſumed, that according to the quantity of *powder* fired together, the flame may have all the different degrees from that of a languid red heat to the heat ſufficient for the vitrification of metals; but as the quantity of *powder* requiſite for the production of this laſt mentioned heat, is certainly greater than what is ever fired together for any military purpoſe, we ſhall not be far from our ſcope, if we ſuppoſe the heat of ſuch quantities as come more frequently in uſe to be, when fired, nearly the ſame with the ſtrongeſt heat of red-hot iron; allowing a gradual augmentation to this heat in larger quantities, and diminiſhing it when the quantities are very ſmall.

Some authors have attributed the force of *gun-powder*, or at leaſt a conſiderable part of it, to the action of the air contained

tained either in the *powder* or between the intervals of the grains. They have ſuppoſed that air to exiſt in its natural elaſtic ſtate, and to receive all its addition of force from the heat of the exploſion; but from what was ſaid before, relating to the increaſe of the elaſticity of the air by heat, we may conclude, that the heat of the exploſion cannot augment the elaſticity to five times its common quantity; conſequently, the force ariſing from this cauſe only, cannot amount to more than the 200th part of the real force exerted on this occaſion. Ibid. p. 43.

We muſt here obſerve, that the experiment of firing *gun-powder*, in the top of a tube, by means of a burning-glaſs, and thereby making the water deſcend, and hence deducing that there is a permanent air or elaſtic fluid contained in *gun-powder*, and that thoſe who pretend to account for the effects of *gun-powder*, from the rarefaction of the natural air, alledge an inſufficient cauſe; this, I ſay, was ſo long ago as the year 1690, ſhewn by Mr. John Bernoulli in his diſſertation *De effervescentia et fermentatione*. But as the experiment of this ingenious author was made with ſo very ſmall a quantity of *powder* as four grains or corns *(granulæ)* and that the ſpace the water ſubſided was not exactly meaſured; it is no wonder that he ſhould conclude this factitious air to be only ſomething more than 100 times *(centies et amplius)* denſer than the natural air. See *Jo. Bernoulli*, Oper. vol. i. p. 35, 36.

But if this gentleman has ſuppoſed the force of *gun-powder* too little, his ſon Mr. Daniel Bernoulli, in his *Hydrodynamica*, has on the other hand ſuppoſed it a great deal too much, making its elaſticity not leſs than 10000 times greater than that of the air. His reaſons are founded, chiefly, on the great quantity of *powder* that eſcapes unfired from guns. But that this quantity of unfired *powder* is not very conſiderable, ſeems to be fully proved under the head GUNNERY.

The variations of the denſity of the atmoſphere does not any way alter the action of *powder*. By comparing ſeveral trials, made at noon in the hotteſt ſummer ſun, with thoſe made in the freſhneſs of the morning and the evening, no certain difference could be perceived; and it was the ſame with thoſe made in the night and in winter. Indeed, conſidering that the ſame quantity of that elaſtic fluid in which the force of *powder* conſiſts, is generated in a vacuum and in common air, it is difficult to conceive how this force can be affected by the greater or leſs denſity of the atmoſphere.

But the moiſture of the air has a very great influence on the force of *powder*, for that quantity which in a dry ſeaſon would communicate to a bullet a velocity of 1700 feet in one ſecond, will not in damp weather communicate a velocity of more than 12 or 1300 feet in a ſecond, or even leſs, if the *powder* be bad and negligently kept. New Princip. of Gunnery, p. 43, 44.

This agrees with an experiment made before a committee of the Royal Society, where *powder* having been dried by being put into a phial placed in boiling water, threw a ball out of a mortar twice as far as the ſame quantity of *powder* taken out of the ſame barrel before it was dried. Now the ranges under the ſame circumſtances of charge, elevation, *&c.* being as the ſquares of the velocities of the ball, theſe velocities, in this experiment, will be to each other nearly as 17 to 12, which gives ranges as 289 to 144. Phil. Tranſ. N°. 465, p. 182, 183.

If *powder* be damp, ſhot made with equal quantities of it out of the ſame parcel, will differ conſiderably from each other, perhaps ten times more than if the *powder* was in good order. A ſmall charge ſeems to loſe a greater part of its force than a larger, each being equally damp. Another circumſtance attending damp *powder* is, a remarkable foulneſs in the piece, after firing, much beyond what ariſes from an equal quantity of dry *powder*. New Princip. of Gunnery, p. 44.

That *powder* will imbibe moiſture from the air, and thereby increaſe in weight, is certain. A parcel of very good *powder* being placed on a white paper, pierced with a great number of fine holes, and held over the ſteam of hot water; the *powder* in half a minute was increaſed about $\frac{1}{50}$ in weight. Another parcel continuing longer in the ſteam was increaſed by $\frac{1}{24}$ part. That the moiſture of the atmoſphere has a like effect, appears from this; that an ounce of *powder* kept for ſome time in a room having a fire in it every day, being dried before the fire, loſt above $\frac{1}{100}$ part of its weight; one third of which it regained in leſs than two hours, by being removed to a part of the room diſtant from the fire. And as the air is often much moiſter than when this experiment was tried, and that the open air is more moiſt than a room with a fire; it cannot be doubted but that the twentieth or thirtieth part of the ſubſtance of the beſt *powder* is water. Now as a certain quantity of water mixed with *powder* will prevent its firing at all, it cannot be doubted but every degree of moiſture muſt abate the violence of the exploſion; and hence the effects of damp *powder* are not hard to account for.

It is to be obſerved, that the moiſture imbibed by *powder* does not render it leſs active when dried again. Indeed, if *powder* be expoſed to the greateſt damps without any caution, or if common ſalt abounds in it, as often happens thro' negligence in refining the nitre, the moiſture it imbibes may, in ſuch caſes, be perhaps ſufficient to diſſolve ſome part of the nitre, which is a laſting damage that no drying can retrieve. But when tolerable care is taken in preſerving *powder*, and the nitre it is compoſed of has been well purged from common ſalt, it will retain its force much longer than is uſually ſuppoſed; and it is ſaid that *powder* has been known to have been preſerved for 50 years, without any apparent damage from its age.

Some care is neceſſary in the drying of damp *gun-powder*; for there is a degree of heat, which tho' not ſufficient to fire the *powder*, will yet melt the brimſtone, and deſtroy the texture of the grains. Nay more, there is a heat with which the brimſtone will flame and burn away gradually, and yet the *powder* will not explode; of this any one may ſatisfy himſelf by heating a piece of iron red-hot, and then throwing a few grains of *powder* on it at different intervals, during the time of its cooling, for by this means he will find, that at a certain time the ſeparate grains that fall on the iron will not explode, but will burn with a ſmall blue flame for ſome ſpace of time, the grain ſtill remaining unconſumed. Indeed, when it has begun to burn in this manner, it ſometimes ends with exploding, but this more commonly happens when a number of grains lie near together, for then tho' each ſeparate flame is not ſufficient to explode its reſpective grain, yet the whole fire made by them all together grows ſtrong enough at laſt to end in a general exploſion; however, by attending to the proper temperature of the iron, and ſpreading the grains, two or three inches ſquare may be covered with a blue lambent flame, which will laſt a conſiderable time without any exploſion, and the grains afterwards will not apparently have loſt either their colour or their ſhape. Now ſince theſe grains, when the brimſtone is thus burnt or even melted out of them, will no longer act as *powder*, it is evident that *powder* may be ſpoiled by being dried with too violent a heat. Ibid. Schol. to Prop. x.

The velocity of expanſion of the flame of *gun-powder*, when fired in a piece of artillery without either bullet or other body before it, is prodigious. By the experiments of the author ſo often quoted, it ſeems this velocity cannot be much leſs than 7000 feet in a ſecond. This however muſt be underſtood of the moſt active part of the flame. For, as was obſerved before, the elaſtic fluid in which the activity of *gun-powder* conſiſts, is only $\frac{3}{10}$ of the ſubſtance of the powder, the remaining $\frac{7}{10}$ will in the exploſion be mixed with the elaſtic part, and will by its weight retard the activity of the exploſion; and yet they will be ſo completely united as to move with one common motion, but the unelaſtic part will be leſs accelerated than the reſt, and ſome of it will not even be carried out of the barrel, as appears by the conſiderable quantity of unctuous matter, which adheres to the inſide of all fire-arms after they have been uſed. Theſe inequalities in the expanſive motion of the flame, render it impracticable to determine its velocity otherwiſe than from experiments. The foundation of which determination is, that a barrel being fixed in a proper ſituation on a pendulum, ſuch as deſcribed under the head GUNNERY, and being charged with 12 dwt. of powder, without either ball or wad, the powder being only put together by the rammer; on the diſcharge the pendulum aſcended through an arch whoſe chord was 10 or $10\frac{1}{10}$ inches. Now if the piece be again loaded with the ſame quantity of powder, rammed down by a wad of tow weighing 1 dwt. it may be ſuppoſed, that this wad being very light, will preſently acquire that velocity, with which the elaſtic part of the fluid will expand itſelf when uncompreſſed; and it was accordingly found, that the chord of the aſcending arch was by this means augmented to 12 inches; ſo that by the additional weight of 1dwt. of matter moving with the velocity of the ſwifteſt part of the vapour, the pendulum aſcended through an arch whoſe chord was two inches longer than before. And by calculating upon theſe facts and the principles laid down in his book, Mr. Robins determines that the velocity with which this 1 dwt. of matter moved, muſt be about 7000 feet in one ſecond. Ibid. prop. xi.

It is this prodigious celerity of expanſion of the flame of fired *gun-powder*, which is its peculiar excellence, and the circumſtance in which it ſo eminently ſurpaſſes all other inventions, either antient or modern, for the purpoſe of military projections: for as to the quantity of motion of theſe projectiles only, many of the warlike machines of the antients produced this in a degree far ſurpaſſing that of our heavieſt cannon-ſhot or ſhells; but the great celerity given to theſe bodies cannot be in the leaſt approached by any other means than by the flame of powder. The reaſon of this difference is, that the antients could by weights, or the elaſticity of ſprings and ſtretched cords, augment their powers to any degree deſired; but then each addition of power brought with it a proportional addition of matter to be moved: ſo that as the power increaſed, thoſe parts of the machine which were to communicate motion to the projectile and were conſequently

to move with it, were likewiſe increaſed; and thence it neceſſarily happened, that the action of the power was not ſolely employed in giving motion to the impelled body, but much the greateſt part of it was ſpent in accelerating thoſe parts of the machine in which the power reſided, to enable them to purſue the body to be projected with perpetual impulſe, during its whole paſſage through the extent of their activity. Hence then it came to paſs, that, though theſe antient machines could throw enormous weights, they could project them but with ſmall degrees of celerity, compared with what we can communicate to our cannon and muſket-ſhot; whence in all operations, where theſe great velocities are uſeful, our machines are infinitely ſuperior to thoſe of antiquity; although, in more confined and ſhorter projections, theſe laſt have ſome advantage which may yet render them worthy of the attention of thoſe military geniuſes, who have capacity enough to conſider each part of the profeſſion according to its true and genuine value, independent of the partial eſtimation of the times they live in. Ibid. p. 55.

Powder being a mixture of ſulphur and charcoal, which are very inflammable ſubſtances, with ſalt-petre, which in itſelf is not, if the ſalt-petre be too much in quantity, when compared with the other two, their burning may not be ſufficient to conſume the whole of the ſalt-petre; whence the fire may be leſs violent, and conſequently the powder leſs vigorous, than if ſome of the ſalt-peter was taken away, and a like quantity of the other materials were added in its ſtead. On the other hand, if the ſalt-petre in the compoſition be leſs than what the burning of the other two ſubſtances can eaſily conſume, the fire will be leſs active than it ought to be, becauſe it is not augmented ſo much as it would be if a large quantity of ſalt-petre had been added to the compoſition.

Hence it appears that the goodneſs of powder is not to be eſtimated only from the quantity of ſalt-petre contained in it, although that ſubſtance ſeems to be the baſis of the elaſtic fluid, in which its force conſiſts. For ſince the converting of the ſalt-petre into that fluid, and the elaſticity of the fluid, afterwards, depend in ſome meaſure on the violence of the fire produced at the exploſion, it is plain that there is a certain proportion in the mixture of the materials, which will beſt contribute to this purpoſe, and conſequently to the perfection of the powder.

What this proportion is, has been aſcertained by experience, and it ſeems now to be generally agreed, that in any quantity of powder $\frac{3}{4}$ of it ſhould be ſalt-petre, the remaing $\frac{1}{4}$ conſiſting of equal quantities of ſulphur and charcoal. This is the proportion followed by the French, and by moſt nations in Europe: we, indeed, pretend to a greater degree of nicety in our proportions; though, it is ſaid, they do not greatly differ from what is here mentioned; nor is it certain that they are preferable: this however may be depended on, that no methods of proving powder, hitherto generally practiſed in England, could at all aſcertain the difference; and other powders made with the uſual proportions, are nothing inferior to ours. Ibid. p. 62.

But it is not the due proportion of the materials only, which is neceſſary to the making of good powder; another circumſtance, not leſs eſſential, is the mixing them well together; if this be not effectually done, ſome parts of the compoſition will have too much ſalt-petre in them, and others too little; and in either caſe there will be a loſs of ſtrength in the powder.

As the excellence of powder then depends on ſo many particulars, in the quality and quantity of the materials, and in the working them together, it is, doubtleſs, of great importance, that thoſe who receive the public ſtores ſhould have it in their power to ſatisfy themſelves about the goodneſs of what is delivered to them. The method moſt commonly followed for this purpoſe, here with us, ſays the author above quoted, is to fire a ſmall heap of it on a clean board, and to attend nicely to the flame and ſmoke it produces, as likewiſe to the marks it leaves behind it on the table; from all which inſtructive particulars the merit of the powder is aſcertained with great accuracy, as is pretended: but beſides this uncertain method, which, how much ſoever it may be practiſed, none will undertake ſeriouſly to defend, there are, on particular occaſions, other contrivances made uſe of, all which bear ſome analogy to the common powder-triers, ſold at the ſhops: only they are more artfully fabricated, and inſtead of a ſpring they move a weight, which is a more certain and equable power.

But theſe machines, though more perfect than the common powder-triers, are yet liable to great irregularities; for as they are all moved by the inſtantaneous ſtroke of the flame, and not by its continued preſſure, they do not determine the force of the fired powder with that certainty and uniformity which were to be deſired in theſe kinds of trials: and therefore, the method followed by the French, in the receiving of powders from the makers, ſeems to be much better. Their practice is thus:

They have, in each magazine, a ſmall mortar caſt with its bed, according to a determined pattern, which is the ſame throughout the kingdom: this mortar is always pointed at 45°, and it contains juſt three ounces of powder; and it is a ſtanding maxim, that no powder can be received into their ſtores, unleſs three ounces of it, placed in the chamber of this mortar, throws a ſolid ball of 7 $\frac{1}{2}$ inches diameter to the diſtance of at leaſt 55 French fathom. But if each barrel of powder was to be proved in this manner, the trouble of charging the mortar, &c. would be intolerable, and the delay ſo great, that no buſineſs of this kind could ever be finiſhed. The method by firing againſt a pendulum, in the manner mentioned under the head GUNNERY, ſeems a readier way; but ſtill it requires ſome nicety and time, which it were to be wiſhed could be obviated. Ibid. p. 63.

It has been obſerved that a heap of *gun-powder* of a certain diameter being fired, will always ſet fire to another heap not diſtant from the former above eight times its diameter.

Perſons keeping more than 200lb. weight of *gun-powder* at one time, within the cities of London and Weſtminſter, or their ſuburbs, &c. are liable to forfeitures if it be not removed; and juſtices of peace may iſſue warrants to ſearch for, ſeize, and remove the ſame, 5 and 11 Geo. I. and 5 Geo. II. cap. 20.

GURGIPTING, in falconry, a term uſed when a hawk is ſtiff and choaked up. Ruſt. Dict. in voc.

GUTTA *roſacea*, in medicine, denotes a red or pimpled face; a diſtemper, which, tho' not always owing its original to hard drinking, is nevertheleſs moſt incident to tiplers of ſtrong beer, wines, ſpirits, &c.

As to the cure, beſides making a revulſion by bleeding, bliſtering, cupping, iſſues, &c. the diet ought to be moiſtening and cooling, as lettuce, purſlain, ſorrel and ſpinach: the drink may be an emulſion of the cold ſeeds, milk and water, clarified whey, &c.

In the uſe, however, of this cooling regimen, great caution is neceſſary; for if a perſon be taken off at once from his ſtrong liquors, and allowed nothing but whey, or milk and water, it may coſt him his life, by haſtening a ſudden decay of heat, palling his appetite, and bringing on a leucophlegmatia, or dropſy. *James*'s Medicinal Dictionary, in voc.

As for what concerns topics, much caution is likewiſe to be uſed. If there be only redneſs without pimples, and the diſeaſe recent, refrigerants and repellants take place: but if puſtules appear, diſcutients muſt be mixed; and if theſe puſtules ſeem hard, and the diſeaſe be of long ſtanding, there may be reaſon for emollients to ripen and digeſt the tough and viſcid matter, which is afterwards to be let out. Id. ibid.

If the diſeaſe be ſtubborn, and the tubercles grown hard, we are to begin with emollients, both fotus and ointment: ſuch are the decoction of mallows, vervain, ſolomon's ſeal, and linſeed; alſo a cerate of ſperma ceti, or Bate's white cerate. Id. ibid.

GUTTER *(Cycl.)* — *Gutters* are either parallel to the horizon, or vertical. The former ſhould be made with a proper deſcent, that there may be a good current, as the workmen term it; for if laid too level, the water will be apt to ſtand in plaſhes.

As to the vertical *gutters*, or thoſe formed by two roofs meeting at right angles to each other, or by the end of one roof joining to the ſide of another, they are either made of lead, or tiles, which are either plain or concave; theſe laſt are called *gutter*-tiles, and may be eaſily laid. But in laying on the plain tiles the workman begins at one ſide of the *gutter*, and ſo works acroſs, as if it were plain work, and then brings the next row of tiles back again; ſo that he works forth and back, to and fro, from right to left. By this means the *gutters* laid after this manner are not angular, but of a kind of diſtorted curvilinear form, which prevents the mortar from being waſhed away with the rain. Build. Dict. in voc.

GWAYF, or WAIF. See WAIF, *Cycl.*

GYMNARTHRIDIA, in the hiſtory of inſects, a ſeries or claſs of inſects, which have ſoft and naked bodies, furniſhed with limbs. See INSECT, *Append.*

Theſe have been generally called *zoophytes*, a term expreſſing creatures partly of an animal, and partly of a vegetable nature; but as it is now well known that there are none ſuch, it is proper the term *zoophyte* ſhould no longer be retained.

Under this claſs are comprehended the *limax*, or the naked ſnail, the *lernea*, *meduſa*, *aphrodita*, *amphitrite*, &c. *Hill*, Hiſt. Anim. p. 87. See the articles LIMAX, LERNEA, &c. *Append.*

GYMNOSOPHISTS *(Cycl.)* — There were likewiſe African *gymnoſophiſts*, who dwelt upon a mountain in Ethiopia, near the Nile, without the accommodation either of houſe or cell. Theſe did not form themſelves into ſocieties, like thoſe of India; but each had his private retirement, where he ſtudied and performed his devotions by himſelf. If any perſon had killed another by chance, he applied to theſe ſages for abſolution, and ſubmitted to whatever penances they enjoyned. They pretended to an extraordinary frugality, and lived only upon the fruits of the earth. Lucian aſcribes to theſe philoſophers ſeveral new diſcoveries in aſtronomy, *Broughton*, Dict. Relig. in voc.

GYMNIA, in zoology, a new eſtabliſhed claſs of animalcules, containing ſuch as have neither tail, nor any viſible limbs. See the article ANIMALCULE, *Append.*

GYPSUM *(Suppl.)* — GYPSUM *ſtriatum*, *ſtriated plaſter-ſtone*, in natural hiſtory, the name commonly uſed for the whitiſh leſs gloſſy *tricheria*, with ſhort thick filaments. See the article TRICHERIA, *Suppl.*

It is of a rude, irregular and unequal ſurface, and lax, friable texture, found in maſſes of various ſizes, from one to twelve or eighteen inches over, but always broad and flat; its thickneſs being uſually but an inch and an half, and in the broadeſt pieces ſeldom much more than two inches: it is compoſed of conſiderably large and coarſe longitudinal filaments, running uſually very evenly through the maſs: it is eaſily fiſſile in a perpendicular direction, that is parallelly to the arrangement of theſe filaments: it is of a dull whitiſh colour, and its filaments, when examined ſingly, have a ſlight ſhare of tranſparency.

It will not at all give fire with ſteel, nor ferment with *aqua fortis*, but very readily calcines to a perfectly white ſubſtance. It is found in clay and marle pits, among the ſtrata of gravel, and in the fiſſures of ſtone, and is common in Yorkſhire and other parts of the kingdom.

The Germans uſe it in the fluxing the ſulphureous ores of metals; and our druggiſts ſell it under the name of Engliſh talc, for cleaning of ſilver lace. See *Hill*'s Hiſt. Foſſ. p. 89.

Tymphacian GYPSUM, a name given by the antients to the hard, fungous, alkaline, white marle, otherwiſe called *calx nativa*, or native lime. See the article CALX, *Suppl.*

GYRINUS, in zoology, the name ſometimes uſed for a ſpecies of *mordella*. See the article MORDELLA, *Suppl.*

GYRLE, among ſportſmen, See the article GIRLE, *Append.*

GYROVAGI, in eccleſiaſtical writers, monks who leaving their monaſteries, under the pretence of piety, wandered about from one religious houſe to another. *Du Cange*, Gloſſ. Lat. tom. ii. p. 683.

The ſame appellation was alſo given to prieſts, who left their pariſhes. Id. ibid.

H.

HAT

HÆMATOPUS, the *Sea Pye*, in Ornithology, a genus of birds of the order of the Scolopaces.

Its beak is of a compreſſed form, ending in a cuneiform figure, and the upper and under chaps are equal in length.

Authors deſcribe it under different names, ſome calling it the *Pica Marina*, others *Himantopus*; but *Hæmatopus* ſeems the moſt proper. See the articles HIMANTOPUS, and PICA *marina*, *Suppl.*

HAIR-*Bell*, in botany, the name by which ſome call the *Hyacinth*. See the article HYACINTH, *Suppl.*

HAIR-*Worm*, the Engliſh name of a ſpecies of worms, called by zoologiſts *Chætia*. See the article CHÆTIA, *Append.*

HAKEL, or HATCHEL. See HATCHEL, *Append.*

HALIOTIS, in the natural hiſtory of ſhells, the name of a large genus, called in Engliſh *Ear-ſhells*. See the article EAR-*Shells*, *Suppl.*

HALL (*Cycl.*) — The length of a *Hall* ſhould be at leaſt twice and a quarter its breadth, and in great buildings three times its breadth. As to the height of *Halls*, it may be two thirds of the breadth; and if made with an arched ceiling, it will be rendered much handſomer, and leſs ſubject to fire. In this caſe its height is found by dividing its breadth into ſix parts, five of which will be the height from the floor to the under ſide of the key of the arch. Build. Dict. in voc.

HALM. See the article HAUM, *Append.*

HAMMER-*headed-ſhark*, the Engliſh name of the *Zygæna*. See the article ZYGÆNA, *Suppl.*

HARDBEAM, or HORNBEAM, in botany, the name by which ſome call the *Carpinus* of authors. See the article CARPINUS, *Suppl.*

HARE. (*Suppl.*)—*Sea*-HARE, the Engliſh name of a genus of inſects, called by Dr. Hill *Lernea*. See the article LERNEA, *App.*

HARE's-*foot Trefoil*, in botany. See the articles TRIFOLIUM and TREFOIL, *Suppl.*

HARE's *Lettuce*, in botany, the name by which ſome call the *Sonchus*, or Sow-thiſtle. See the article SONCHUS, *Suppl.*

HARE's-*Strong*, in botany, the name by which the *Peucedanum* or Hog's-fennel, is ſometimes called. See the article PEUCEDANUM, *Suppl.*

HARLE, a name uſed in ſome parts of the kingdom for the *Merganſer*. See the Article MERGANSER, *Suppl.*

HARP-*Shell*, a ſpecies of *Dolium*. See DOLIUM.

HARIOT. See the article HARIOT, *Cycl.*

HART-*wort*, in botany, a name ſometimes given to the *Tordylium* of authors. See the article TORDYLIUM, *Suppl.*

Ethiopian HART-*wort*, the name by which ſome call the *Peucedanum*, or Hog's-fennel. See the article PEUCEDANUM, *Suppl*,

HART's-*horn*, in botany, the name of a genus of plants, otherwiſe called *Buck's-horn*, and by botaniſts *Coronopus*. See the article CORONOPUS, *Suppl.*

HASEL, or HASLE, in botany. See the article HAZLE, *Suppl.*

HATCHEL, or HITCHEL, in the manufactory of flax, hemp, *&c.* a tool, not unlike a card, for dreſſing and combing them into fine hairs. See the article CARD, *Cycl.*

They conſiſt of ſharp pointed iron-pins, or teeth, ſet orderly in a board. Dict. Ruſt. in voc.

Of theſe there are ſeveral ſorts, ſome with finer and ſhorter teeth, others with them coarſer and longer.

HATCHET-*Vetch*, in botany, the name by which the *Securidaca*, a diſtinct genus of plants, is ſometimes called. See the article SECURIDACA, *Suppl.*

HATCHING (*Cycl.*)—The artificial method of *hatchings* eggs, as practiſed in Egypt, has been mentioned in the Cyclopædia; and Mr. Reaumur has diſcovered, that the heat neceſſary for this purpoſe, is nearly the ſame with that mark'd 32, upon his thermometer, or that mark'd 96 on Fahrenheit's. If, therefore, eggs be kept in this degree of heat, they will as certainly *hatch*, as if the parent hen had ſat upon them; and, indeed, it is impoſſible it ſhould be otherwiſe, ſince this heat anſwers nearly to that of the ſkin of the hen, or even of mankind; ſo that the empreſs Livia, as Pliny relates, might truly *hatch* a chicken in her boſom, if ſhe had but the patience to keep an egg there, for the ſame number of days that it ought to have continued under a hen.

After many experiments, Mr. Reaumur found, that ſtoves, heated by means of a baker's oven, ſucceeded equally well with thoſe made hot by layers of dung. The furnaces of glaſs-houſes, and thoſe of the melters of metals, might, no doubt, be made to anſwer the ſame purpoſe. If, therefore, an eaſy method could be found to regulate the heat of the ſtove, it would be extremely convenient for bakers or paſtry-cooks to *hatch*, with little or no expence, a very great number

HAW

of chickens; which they might diſpoſe of to the country people, to be reared up till marketable. Should a thermometer be judged neceſſary for this purpoſe, it will be ſufficient to mark on it only ſuch degrees as are abſolutely neceſſary; by which means the inſtrument will not only come cheaper, but be more readily underſtood by the ignorant people, for whoſe uſe it is deſigned.

Such an inſtrument, however, may be wholly diſpenſed with; a lump of butter, of the ſize of a walnut, melted with half as much tallow, ſerving to indicate the heat of the ſtove with ſufficient exactneſs. When the heat is too great, this mixture, which is to be kept in a phial, will become as liquid as oil; and when the heat is too ſmall, it will remain fixed in a lump; but it will flow like thick ſyrup, upon inclining the bottle, if the ſtove be of a right temper. Great attention, therefore, ſhould be given to keep the heat always at this degree, by letting in freſh air, if it be too great, or ſhutting the ſtove more cloſe, if it be too ſmall.

But this is not all. That all the eggs in the ſtove may equally ſhare the irregularities of the heat, it will be neceſſary to ſhift them from the ſides to the center, and *vice verſa*; thereby imitating what the hens themſelves do by thoſe upon which they ſit; for hens are frequently ſeen to make uſe of their bills, to puſh to the outer parts thoſe eggs that were neareſt to the middle part of their neſts, and to bring into that middle part ſuch as before lay neareſt to the ſides of the ſame.

As to the form of the ſtoves, no great nicety is neceſſary. A chamber over an oven will do very well; only in order to aſcertain the due degree of heat, it will be neceſſary to have phials of butter, as directed above, in ſeveral parts of the room; and when the heat wants to be either increaſed or diminiſhed, it is ſufficient to diminiſh or increaſe the communication between the air in the room and that abroad, by opening or ſhutting ſome of the openings made in the wall for that purpoſe.

In order to cheriſh the new hatch'd chickens, capons may be taught to tend them in the ſame manner as hens do. Mr. Reaumur tells us, that he has ſeen above two hundred chickens at once, all led about and defended by only three or four ſuch capons; which clucked like hens, to call in the chickens that had ſtrayed too far off; and even redoubled their call, when they found any nice bits, to invite the young brood to come and pick them up. Nay cocks may be taught to do the ſame office, which they, as well as the capons, will continue to do all their lives afterwards.

But Mr. Reaumur, not ſatisfied with the aſſiſtance he could thus procure from cocks and capons, has invented a ſort of low boxes without bottoms, and lined with furs. Theſe, which he calls artificial parents, not only ſhelter the chickens from the injuries of the air, but afford a kindly warmth; ſo that they preſently grow fond of them, and take the benefit of their ſhelter as readily as they would have done under the wings of a hen.

For a few weeks after *hatching*, it will be neceſſary to keep the chickens in a room artificially heated, and furniſhed with theſe boxes; but afterwards they may be ſafely expoſed to the air in the court-yard, in which it may not be amiſs to place one of theſe artificial parents to ſhelter them, ſhould there be any occaſion.

As to the manner of feeding the young brood, they are generally a whole day after being *hatched*, before they take any food at all; and then a few crumbs of bread may be given them for a day or two, or millet-ſeeds mixed with the crumbs; after which they will begin to pick up inſects and graſs for themſelves.

People in the country, who have plenty of conveniencies for the raiſing of poultry, will hardly give themſelves the trouble to *hatch* chickens in this artificial manner. It is in villages near great towns, and principally in the neighbourhood of the capital city, that it would be of the greateſt importance to promote the eſtabliſhment of this kind of ſtoves. Vid. Mr. *Trembley*'s Abſtract of the Art of Hatching domeſtic fowls, tranſlated from the original treatiſe of Mr. Reaumur, where he explains every difficulty.

HATCHING *of Bees*. See the article *Bee*-WORM, *Suppl.*

HATCHING, among miners. See the article DIGGING, *Suppl.*

HAVER, a word uſed in ſome parts of the kingdom for oats. Dict. Ruſt. in voc.

HAUGH, the ſame with HAW. See the article HAW, *Suppl.*

HAUM, HALM, or HAWM, among farmers, denotes the ſtem or ſtalk of corn, peaſe, beans, &c. from the root to the ear. Dict. Ruſt. in voc.

HAWK (*Suppl.*)—*Make* HAWK, in falconry, a name given to an old ſtanch hawk; which, being uſed to fly, will teach a young one. Ruſt. Dict. in voc.

HAW-*thorn*, the Engliſh name of ſeveral ſpecies of Meſpilus, or Medlar. See the article MESPILUS, *Suppl.*

HAWM. See the article HAUM, *Append.*

HAZLE, or HAZEL *(Suppl.)*—*Witch*-HAZLE, a name ſometimes uſed for the *Ulmus*, or Elm. See the articles ULMUS and ELM, *Suppl.*

HEART-*burn*. In ſurfeits, or upon ſwallowing without due maſtication; when meats are eat tough and fat, or with farinaceous ſubſtances unfermented; or when by any accident the ſaliva is vitiated, too ſcanty, or not intimately mixed with the food, the fermentation becomes tumultuous, the ſtomach ſwells with air, and this extraordinary commotion being attended with an unuſual heat, brings on the uneaſineſs called the *heart-burn*; which is remedied by whatever promotes a greater ſecretion of ſalvia, or helps to mix it with our aliment. *Pringle*, Obſerv. on the diſeaſes of the army, p. 168. See the article FERMENTATION, *Append.*

HEART's-*eaſe*, a name ſometimes uſed for a ſpecies of violet, otherwiſe called *Panſay*. See the article VIOLET, *Suppl.* It is ſaid to be good for ruptures and the falling ſickneſs. Ruſt. Dict. in voc.

HEAT *(Suppl.)* — *Heat* is found to expand and dilate metals conſiderably, as uppears from an experiment of Muſchenbroek, who tells us, that having prepared cylindric rods of iron, ſteel, copper, braſs, tin, and lead, he expoſed them firſt to a pyrometer with two flames; then ſucceſſively to one with three, four, and five flames. But previous to this trial, he took care to cool them equally, by expoſing them ſome time upon the ſame ſtone; when it began to freeze, and Fahrenheyt's thermometer was at 32 degrees. The effects of which experiment are digeſted in the following table, where the degrees of expanſion are marked in parts equal to the $\frac{1}{125\,00}$ part of an inch.

Expanſion of	Iron	Steel	Copper	Braſs	Tin	Lead
By one flame	80	85	89	110	153	155
By two flames, placed cloſe together	117	123	115	220		274
By two flames 2 $\frac{1}{2}$ inches diſtant	109	94	92	141	219	263
By three flames placed cloſe together	142	168	193	275		
By four flames placed cloſe together	211	270	361			
By five flames	230	310	310	377		

It is to be obſerved of tin, that it will eaſily melt, when heated by two flames placed together. Lead commonly melts with three flames, placed together, eſpecially if they burn long.

From theſe experiments it appears at firſt view, that iron is the leaſt rarified of any of theſe metals, whether it be heated by one or more flames; and therefore is moſt proper for making machines, or inſtruments, which we would have free from any alterations by heat or cold, as the rods of pendulums for clocks, *&c.* So likewiſe the meaſures of yards or feet ſhould be made of iron, that their length may be as nearly as poſſible the ſame, ſummer and winter.

The expanſion of lead and tin, by only one flame, is nearly the ſame; that is, almoſt double of the expanſion of iron. It is likewiſe obſervable, that the flames, placed together, cauſe a greater rarefaction, than when they have a ſenſible interval between them; iron, in the former caſe, being expanded 117 degrees, and only 109 in the latter; the reaſon of which difference is obvious.

By comparing the expanſions of the ſame metal, produced by one, two, three, or more flames, it appears, that two flames do not cauſe double the expanſion of one; nor three flames three times that expanſion, but always leſs; and theſe expanſions differ ſo much the more from the ratio of the number of flames, as there are more flames acting at the ſame time.

It is alſo obſervable, that metals are not expanded equally, at the time of their melting, but ſome more, ſome leſs: Thus tin began to run, when rarified 219 degrees; whereas braſs was expanded 377 degrees, and yet was far from melting. *Deſagul.* vol. 1. p. 423, *ſeqq.*

HEAT, in Medicine. Great *Heats* are not ſo much the immediate, as the remote cauſe of a general ſickneſs, by relaxing the fibres, and diſpoſing the fibres to putrefaction; eſpecially among ſoldiers, and perſons expoſed the whole day to the ſun; for the greateſt *heats* are ſeldom found to produce epidemic diſeaſes, till the perſpiration is ſtopped by wet cloaths, fogs, dews, damps, &c. and then ſome bilious or putrid diſtemper is the certain conſequence, as fluxes, and ardent intermitting fevers. Nevertheleſs, it muſt be allow'd, that *heats* have ſometimes been ſo great, as to prove the more immediate cauſe of particular diſorders. As when centinels have been placed without cover, or frequent reliefs, in ſcorching *heats*; or when troops march, or are exerciſed in the *heat* of the day: or when people imprudently lie down and ſleep in the ſun: All theſe circumſtances are apt to bring on diſtempers, varying according to the ſeaſon of the year. In the beginning of ſummer, theſe errors produce inflammatory fevers; and, in the end of it, or in the beginning of autumn, a remitting fever, or dyſentery. *Pringle*, Obſerv. on the Diſeaſ. of the army, p. 79, *ſeqq.*

To prevent, therefore, the effects of intemperate *heat*, commanders have found it expedient ſo to order the marches, that the men come to their ground before the heat of the day; and to give ſtrict orders, that none of them ſleep out of their tents; which in fixed encampments may be covered with boughs, to ſhade them from the ſun. It is likewiſe a rule of great importance to have the ſoldiers exerciſed before the cool of the morning is over; for, by that means, not only the ſultry *heats* are avoided, but the blood being cooled, and the fibres braced, the body will be better prepared to bear the heat of the day. Laſtly, in very hot weather, it has been found proper to ſhorten the centinels duty, when obliged to ſtand in the ſun. Id. ibid. p. 95.

HEATH *(Suppl.)* — *Mountain*-HEATH, a name ſometimes given to the *Saxifrage* of botanical writers. See the article SAXIFRAGE, *Suppl.*

Berry-bearing HEATH, a name ſometimes given to a genus of plants, called by botaniſts *Empetrum*. See the article EMPETRUM, *Suppl.*

Low-pine HEATH, the name of a diſtinct genus of plants, called by botaniſts *Coris*. See the article CORIS, *Suppl.*

HECKLE, among hemp-dreſſers. See HATCHEL, *ſupra.*

HECTIC. See the article CONSUMPTION, *Append.*

HEDERA *(Suppl.)* —*Virginian*-HEDERA, the name by which Plukenet calls the *Meniſpermum* of Linnæus. See the article MENSPERMUM, *Append.*

HEDGE-*hog*, in zoology, the Engliſh name of a genus of animals, called by zoologiſts *Erinaceus*. See the article ERINACEUS, *Suppl.*

HEDGE-*hog*, in botany, the Engliſh name of a genus of plants, called by botaniſts *Erinacea*, See the article ERINACEA, *Suppl.*

Sea HEDGE-*hog*, the Engliſh name of a ſeries of ſhell-fiſh, called by different authors *Centronia*, *Echini marini*, *Echinodermata*, &c. See CENTRONIA, *Append.* and ECHINODERMA, *Suppl.*

HEDGE-*hog-Medica*, the name by which ſome call ſeveral ſpecies of *Medica*, or lucerne. See the article MEDICA, *Suppl.*

HEDGE-*hog-thiſtle*, a name ſometimes given to a diſtinct genus of plants, called by authors *Cactus*. See the article CACTUS, *Append.*

HEDGE-*hyſſop*, a name ſometimes given to a diſtinct genus of plants, called by botaniſts *Digitalis*. See the article DIGITALIS, *Suppl.*

HEDGE-*muſtard*, the name of a genus of plants, known among botaniſts by that of *Eryſimum*. See the article ERYSIMUM, *Suppl.*

HEDGE-*nettle*, a name ſometimes given to a genus of plants, called by botaniſts *Galeopſis*. See the article GALEOPSIS, *Suppl.*

HEDGE-*nettle-ſhrub*, a name by which ſome call the *Praſium*, a diſtinct genus of plants. See the article PRASIUM, *Suppl.*

HEDGE-*ſparrow*, the Engliſh name of a ſpecies of *Motacilla*, See the article MOTACILLA, *Suppl.*

HEDIUNDA, in botany, a name uſed by ſome writers for the *Ceſtrum* of Linnæus. See the article CESTRUM, *Append.*

HEDYSARUM, in the Linnæan ſyſtem of botany, the name of a large genus of plants; which that author makes to comprehend the *Hedyſarum*, *Onobrychis*, and *Alhagi* of Tournefort. See the articles HEDYSARUM and ONOBRYCHIS, *Suppl.* and ALHAGE, *Append.*

HEEL, among carpenters, denotes an inverted *Ogee*. See the article OGEE, *Cycl.*

HEINASE, among ſportſmen, a roe-buck of the fourth year. Ruſt. Dict. in voc.

HELEGUG, in zoology, a name given to the *Anas arctica*. See the article DUCK, *Suppl.*

HELENIUM, in botany, the name uſed by ſome for ſeveral ſpecies of *Aſter*, or ſtar-wort. See the article STAR-WORT, *Suppl.*

HELIANTHUS, in the Linnæan ſyſtem of botany, the name by which that author calls the *Corona ſolis*, or great *ſun-flower*. See the article SUN-*flower*, *Suppl.*

HELICHRYSUM, in botany, a name uſed by ſome authors for the *Gnaphalium*, or cudweed. See the article GNAPHALIUM, *Suppl.*

HELIOTROPE, in botany, the name by which ſome call the turnſol, a diſtinct genus of plants. See the article HELIOTROPIUM, *Suppl.*

HELIOTROPIUM is alſo a name uſed by ſome for a ſpecies of *Ricinoides*. See the article RICINOIDES, *Suppl.*

HELIOTROPIUM is likewiſe uſed by ſome for the *Helianthus*, *Corona ſolis*, or great ſun flower. See the article SUN-*flower*, *Suppl.*

HELLEBORE, in botany, the Engliſh name of a diſtinct genus of plants. See the article HELLEBORUS, *Suppl.*

Baſtard-HELLEBORE, the name of a genus of plants, called by authors *Helleborine*. See the article HELLEBORINE, *Suppl.*

White-HELLEBORE, the name of a genus of plants, otherwiſe called *Veratrum*. See the article VERATRUM, *Suppl.*

HELM, *(Cycl.)* a term uſed by country people for wheat or rye-ſtraw, bruiſed by thraſhing, or otherwiſe, and uſually bound up in bundles for thatching. See THATCHING, *Append.*

HELMET-*flower*, in botany, a name by which ſome call the *Scutellaria*, or *Caſſida* of authors. See the article CASSIDA, *Suppl.*

HEMANDIA, *(Suppl.)* This is an error of the preſs, for HERNANDIA See HERNANDIA, *Append.*

HEMEROBIUS, in zoology, a name uſed by ſome for the fly, called *Golden-eye*, and *Chryſopis*. See the article CHRYSOPIS, *Suppl.*

HEMLOCK, in botany, the Engliſh name of a genus of plants, called by botaniſts *Cicuta*. See the article CICUTA, *Suppl.*

Baſtard-HEMLOCK, the name by which ſome call a diſtinct genus of plants, known among botaniſts by that of *Cicutaria*. See the article CICUTARIA, *Suppl.*

HEMP, in botany, the Engliſh name of a diſtinct genus of plants, called by botanical writers *Cannabis*. See the article CANNABIS, *Suppl.*

Baſtard-HEMP, the Engliſh name of a genus of plants, called by Tournefort *Cannabina*. See the article CANNABINA, *Suppl.*

Water-HEMP, a name ſometimes uſed for a genus of plants, called by botanical writers, *Bidens*. See the article BIDENS, *Suppl.*

HEMP-*Agrimony*, a name ſometimes given to a diſtinct genus of plants, called by botaniſts *Eupatorium*. See the article EUPATORIUM, *Suppl.*

HEN *(Suppl.)* — HEN-*houſe*, a place or building, made for ſheltering or confining poultry. Dict. Ruſt. in voc.

HENBANE, *(Suppl.)* — *Yellow*-HENBANE, a name by which ſome call the *Nicotiana* of botanical authors. See the article NICOTIANA, *Suppl.*

HEPS, in botany, the ſame with *hips*. See the article HIPS, *Append.*

HERB-*Bennet*, *herba benedicta*, a name ſometimes given to a diſtinct genus of plants, called by authors *Caryophyllata*. See the article CARYOPHYLLATA, *Suppl.*

HERB-*Chriſtopher*, *herba Chriſtophoriana*, in botany, the name of a diſtinct genus of plants. See the article CHRISTOPHORIANA, *Suppl.*

HERB-*Gerard*, in botany, a name ſometimes given to a diſtinct genus of plants, otherwiſe called *Angelica*. See the article ANGELICA, *Suppl.*

HERB *of grace*, a name by which ſome call rue. See the article RUTA, *Suppl.*

HERB-*Robert*, a name ſometimes uſed for the *geranium*, or crane's bill. See the article GERANIUM, *Suppl.*

HERB-*Trefoil*, in botany, See the articles TREFOIL and TRIFOLIUM, *Suppl.*

HERB-*Trinity*, in botany, a name ſometimes given to the violet. See the article VIOLA, *Suppl.*

HERB-*True-love*, the name by which the *Herb-Paris* is ſometimes called. See the article HERBA-*Paris*, *Suppl.*

HERB-*Twopence*, the name of a diſtinct genus of plants, called otherwiſe *Lyſimachia*, or *Summularia*. See the article LYSIMACHIA, *Suppl.*

HERB-*Willow*, or *Willow-herb*, a name ſometimes given to two diſtinct genuſes of plants, the *Lyſimachia* and *Chamænerium*. See the articles CHAMÆNERIUM, and LYSIMACHIA, *Suppl.*

HERCULES's *Alheal*, the name of a diſtinct genus of plants, deſcribed by Linnæus under that of *Panax*. See the article PANAX, *Append.*

HEMISPHÆRIA, a name by which Dr. Hill calls the genus of flies, known in Engliſh by that of *Lady-Cow*.

Ray, and other writers, have deſcribed theſe among the Beetles. See the article SCARABÆUS, *Suppl.*

HERMIT-*fiſh*, the name by which ſome call the long-tailed Squilla, with a ſoft tail, and the right claw the larger. See the article SQUILLA, *Append.*

HERMODACTYLE, *Hermodactylus*, in botany, a name improperly uſed by ſome for the *Iris*, or flower-de-luce of botaniſts. See the article IRIS, *Suppl.*

The true *Hermodactyle* is the root of a ſpecies of *Colchicum*, or *Meadow-ſaffron*. See the article MEADOW-*ſaffron*, *Suppl.*

HERN, the ſame with *Heron*. See the article HERON, *Suppl.*

A *Hern* at ſiege, among ſportſmen, is one ſtanding at the water-ſide, watching for prey. Dict. Ruſt. in voc.

HERN-*ſhaw*, or HERNERY, a place where the Herons breed. Id. ibid.

HERNANDIA, in botany, the name of a diſtinct genus of plants, the characters of which are theſe: The petals of the flower are multifid, and placed in a circular order; the male and female flowers ſtand on diſtinct plants. There is no pericarpium; but the cup of the flower is very large, ſwelled, and roundiſh; containing a plicated oval nut, with only one cell, and a globoſe nucleus. *Linnæi* Gen. Plant. p. 516.

We know only one ſpecies of this genus, which is the *hernandia*, with a large umbilicated ivy-like leaf, commonly called in the Weſt-Indies *Jack in a box*.

It is a native of Jamaica, Barbadoes, and other parts of the Weſt-Indies; and is propagated among us in the gardens of the curious, by only ſowing the ſeed in a hot-bed in the ſpring. They muſt be conſtantly kept in the back ſtove. Vid. *Miller*'s Gard. Dict. in voc.

HERRIOT. See HARIOT, *Cycl.*

HETEROPYRÆ, in natural hiſtory, the name of a genus of ferrugineous foſſils, compoſed of ſeveral coats, incloſing a nucleus of a different ſubſtance from themſelves, and often looſe, and rattling in them. See the article SIDEROCHITA. *Append.*

Of this genus there are the following ſpecies: 1. The hard *heteropyra*, with brown and purpliſh cruſts, and a whitiſh-green nucleus. 2. The rough, purpliſh *heteropyra*. 3. The miſ-ſhapen *heteropyra*, with ferrugineous, red, and duſky yellow cruſts, and a greeniſh-white nucleus. 4. The yellow, brown, and black *heteropyra*, with a whitiſh nucleus. 5. The yellow, ferrugineous, and purpliſh-creſted *heteropyra*, with a pale-yellow nucleus. 6. The coarſe, yellow, and brown-cruſted *heteropyra*, with a browniſh-yellow nucleus. 7. The coarſe *heteropyra*, with brown, black, and orange-colour'd cruſts, and a yellow nucleus. *Hill.* Hiſt. Foſſ. p. 536.

HIGH-*taper*, in botany, a name by which ſome call the *Verbaſcum* of botaniſts. See the article VERBASCUM, *Suppl.*

HILL, in the natural hiſtory of the Earth, *&c.* See the article MOUNTAIN, *Suppl.* and *Append.*

HINNULARIA, in zoology, a name given by ſome authors to a ſpecies of Eagle. See the article PYGARGUS, *Suppl.*

HIPPO, in zoology, the name of a ſpecies of *Coluber*, the ſcuta of whoſe abdomen are one hundred and ſixty, and the ſquamæ of the tail one hundred. See the article COLUBER, *Append.*

HIPPURIS *(Suppl.)*—Pliny has made a great confuſion of plants under this name. The antients called the *Hippuris*, or horſe-tail, *Polygonum*, on account of its having ſo many joints in its ſtalks and branches; this name confounded it with the knot-graſs and Pliny has made a deſcription from the accounts of different authors, which has the characters and qualities of both, and therefore ſuits neither.

It is eaſy however to trace his errors; where he ſpeaks of the ſtalks being naked, ruſh-like, and brittle, it is plain that he is ſpeaking of the *Horſe-tail*; and where he gives it ſmall oval and pointed leaves, it is equally certain that he means this of the knot-graſs; but he adds in one place, that it has a large ſpreading root, that it grows in woods and ſhady places, and that it bears a round fruit like a coriander-ſeed. Theſe are characters belonging neither to the horſe-tail nor knot-graſs; and might ſeem to beſpeak this *Hippuris* a plant different from both; but it rather appears, that Pliny has brought in by an error of his own a third plant, to perplex the caſe, and is here tranſcribing ſome author's account of the Solomon's-ſeal, or polygonatum, a name ſounding like the word polygonum, and eaſily miſtaken for the ſame word, by ſo haſty a writer as this author appears to have been. He had before err'd in his opinion, that the polygonum and horſe-tail were the ſame plant; and here taking the polygonatum to be the ſame plant with the polygonum, he has not ſcrupled to attribute to the horſe-tail whatever he found recorded of the polygonatum.

HIPPURIS is alſo a name given by Dillenius to the *Chara* of Linnæus, a diſtinct genus of plants. See the article CHARA. *Suppl.*

HIND-*calf*, a female hart of the firſt year. She fawns in April and May. Her fleſh is ſofter than that of a hart, but not ſo ſavoury, and is dreſt after the ſame manner. If it be roaſted, it ought to be larded, dipt in a marinade or pickle, and moiſtened while it is roaſting.

HITCHEL, the ſame with *Hatchel*. See HATCHEL, *Append.*

HITCHING, in horſemanſhip, is to wriggle or move forwards by degrees, or to knock the legs together in walking. Dict. Ruſt. in voc.

HIVE-*droſs*, a name ſometimes given to crude or rough wax. See the article WAX, *Suppl.*

HOCK, the ſame with *Ham*. See HAM, *Cycl.*

HOG's-*fennel*, in botany, the Engliſh name of a genus of plants, called by botaniſts *Peucedanum*. See the article PEUCEDANUM, *Suppl.*

HOG-*plum*, the name of a diſtinct genus of plants, called by authors *Spondias*. See the article SPONDIAS, *Suppl.*

HOG-*weed*, the name of a diſtinct genus of plants, called by Linnæus *Boerhaavia*. See the article BOERHAAVIA, *Suppl.*

HOLIBUT, or HOLYBUT, in ichthyology, a name given by the people of ſome parts of England to the Turbott in general; but in other parts, only to the larger fiſhes of that ſpecies.

HOLLI, the Indian name for what the Spaniards call *ulli*; a reſinous liquor, which flows ſpontaneouſly from the tree *Holquaghuytl*, or *Chilli*. It is often mixed with chocolate in the making, in the proportion of one fourth part: it gives the chocolate in this caſe no very diſagreeable flavour; and it becomes a very powerful medicine in dyſenteries. It is uſual, however, before the making it, to mix the cacao and *Holli* on an iron plate, and torrify them thoroughly together. *Ray*'s Hiſt. Plants.

HOLLOW-*root*, in botany, a name ſometimes given to the *fumaria*, or fumitory. See the article FUMARIA, *Suppl.*

HOLLY *(Suppl.)*—The timber of *holly* is the whiteſt of all hard wood, and therefore uſed by the inlayers. See the article MARQUETRY, *Cycl.*

It is alſo fit for all ſturdy uſes, and therefore preferred to all others by the mill-wright, turner, and engraver. It makes the beſt handles and ſtocks for tools, flails, cart-whips, bowls, ſhivers, and pins for blocks; and is excelnt for door-bars, &c.

Knee-HOLLY, a name ſometimes given to the *Ruſcus*, or butchers broom. See the article RUSCUS, *Suppl.*

Sea-HOLLY, the name by which ſome call the *eryngium* of botanical writers. See the article ERYNGIUM, *Suppl.*

HOLY-*thiſtle*, or BLESSED *Thiſtle*, a name ſometimes given to the *Cnicus*, or ſaffron-flower of botaniſts. See the article CNICUS, *Suppl.*

HOLY-*Roſe*, or *Rock-Roſe*, names given to a diſtinct genus of plants, called by botaniſts *Ciſtus*. See the article CISTUS, *Suppl.*

HOMO, *Man*, in zoology. See the articles MAN, *Append.* and ANTHROPOMORPHA, *Suppl.*

HONE-*wort*, *Sium*, in botany, the name of a diſtinct genus of plants. See the article SIUM, *Suppl.*

HONESTY, in botany, a name ſometimes uſed for the *Lunaria*, or moon-wort. See the article LUNARIA, *Suppl.*

HONEY-*flower*, a name by which the *Melianthus*, a diſtinct genus of plants, is called in Engliſh. See the article MELIANTHUS, *Suppl.*

HONEY-*ſuckle*, *French* HONEY-*ſuckle*, a name ſometimes uſed for the *Hedyſarum* of botanical writers. See the article HEDYSARUM, *Suppl.*

Trumpet HONEY-*ſuckle*, the name by which ſome call the *Periclymenum* of Tournefort. See the article PERICLYMENUM, *Suppl.*

Upright HONEY-*ſuckle*, the name of a genus of plants, called by Linnæus *Lonicera*. See the article LONICERA, *Suppl.*

HOOD, *(Cycl.)* — HOOD, on ſhip-board, is a copper-frame, made to go on the top of the chimney, and to ſhift as the wind does, that the ſmoke may always fly to leeward. *Blanckly*, Nov. Expoſitor, p. 78.

HOOK-*land*, or OPE-*land*, among farmers, land ploughed and ſowed every year. Dict. Ruſt. in voc.

HOOPOE, in ornithology, the Engliſh name of the *Upupa*, See the article UPUPA, *Suppl.*

HOP-*hornbeam*, a name ſometimes given to the *Carpinus* of botaniſts. See the article CARPINUS, *Suppl.*

Wild-HOP, a name ſometimes given to the *Dodonæa*, a diſtinct genus of plants. See the article DODONÆA, *Suppl.*

HOREHOUND. *(Suppl.)*—*Black* or *ſtinking* HOREHOUND, in botany, the Engliſh name of a genus of plants, called by botanical writers *Ballote*. See the article BALLOTE, *Suppl.*

Baſe-HOREHOUND, a name by which ſome call the *Stachys* of botaniſts. See the article STACHYS, *Suppl.*

Baſtard-HOREHOUND, the Engliſh name of a genus of plants, called by botaniſts *Marrubiaſtrum*. See the article MARRUBIASTRUM, *Suppl.*

Water-HOREHOUND, the Engliſh name of a diſtinct genus of plants, called by botaniſts *Lycopus*. See the article LYCOPUS, *Suppl.*

HORNS-*and Hedge-hog*, the name of a genus of plants, called by botaniſts *Medica*. See the article MEDICA, *Suppl.*

HORNBEAM, in botany, the Engliſh name of a genus of plants, called by botaniſts *Carpinus*. See the article CARPINUS, *Suppl.*

HORNED-*Poppy*, in botany. See the article POPPY, *App.*

HORSE *(Suppl.)*—HORSE-*dung* is uſed by gardeners for making hot-beds, being eſteemed fitter than any other for this purpoſe; but it is to be obſerved, that it is ſo much the better, the higher the *Horſe* is fed. Ruſt. Dict. in voc.

HORSE-*Cheſnut*, a name given by ſome to the *Hippocaſtanum* of botanical writers. See the article HIPPOCASTANUM, *Suppl.*

Scarlet HORSE-*Cheſnut*, the Engliſh name of a diſtinct genus of plants, called by botaniſts *Pavia*. See the article PAVIA, *Suppl.*

HORSE-*heal*, a name ſometimes uſed for Elecampane, or *Helenium*. See the article HELENIUM, *Suppl.*

HORSE-*hoeing*, in *Huſbandry*. See thearticle HUSBANDRY *Suppl.*

HORSE-*Mint*, the Engliſh name given to a ſpecies of *Mint*. See the articles MINT and MENTHA, *Suppl.*

HORSE-*Radiſh*, the name of a diſtinct genus of plants, called by botaniſts *Cochlearia*, or Scurvy-graſs. See the article COCHLEARIA, *Suppl.*

HORSE-*ſhoe-vetch*, the Engliſh name of a diſtinct genus of plants, called by botaniſts *Hippocrepis*, or *Ferrum equinum*. See the article FERRUM *equinum*, *Suppl.*

HOSE-*in-Hoſe*, a name given to a genus of plants, called by botaniſts *Primula veris*. See the article PRIMULA, *Suppl.*

HOSPITAL *(Cycl.)*—Camp *Hoſpitals* are either general or regimental.

The general *hoſpitals* are of two kinds, *viz.* the flying *hoſpital*, attending the camp at ſome convenient diſtance, and the ſtationary *hoſpital*, which is fixed to one place. In the choice of both, it will be better to have them in towns than villages, as the former will afford larger wards, beſides more of other conveniencies: Theſe wards ſhould be as airy as poſſible.

As to the diſpoſition of *hoſpitals*, in regard to preſerving the purity of the air, the beſt rule is to admit but few patients into each ward. It will alſo be found a good expedient, when the ceilings are low, to remove ſome part of them, and to open the garret ſtory. The doors and windows may likewiſe be opened, and ventilators uſed to purify the air of every ward. In winter *hoſpitals*, the wards are to be warmed with chimneys, and never by ſtoves; for, though the latter may warm a large ward better, and at a leſs expence, yet by ſcarce making any draught of air, they will be apt to increaſe its putrid quality; whereas a fire, kept up in a chimney, acts like a conſtant ventilator.

The general *hoſpital* ſhould receive only ſuch ſick as the regimental ones cannot conveniently contain, together with thoſe who cannot be moved with the army. Without this diſperſion of the ſick, the general *hoſpital*, in bad ſeaſons, would have a greater number, than could be well attended; and what is equally, if not more pernicious, it would be too much crouded, by which means the contagion would ſpread, and the mortality be rendered more general.

Regimental *hoſpitals* are of the greateſt importance, and therefore ſhould be ſupplied with blankets and medicines from the public ſtores, with an allowance alſo for nurſes and other neceſſaries. Nor are they to be maintained in the field only, but alſo in winter-quarters, as there will always be a great many more ſick, than can be taken care of in the general *hoſpital*.

Barns, ſtables, grannaries, and other out-houſes, but above all, churches, make the beſt *hoſpitals*, from the beginning of June to October: for as the greateſt danger ariſes from foul air, which cannot be compenſated by diet or medicine, we may lay it down as a rule, that the more airy and large the *hoſpitals* are, the leſs danger there is of the ſickneſs ſpreading. *Pringle* Obſerv. on the Diſeaſes of the Army, p. 104, *ſeqq.*

HOSPITAL-*fever*, a name given to the *malignant catarrhal fever*, as being frequent in hoſpitals. See the article FEVER, *Suppl.*

Dr. Pringle has given us an elaborate account of the riſe, ſymptoms, and cure of this terrible diſeaſe, in his obſervations on the diſeaſes of the army. It may be owing to a great many concurring cauſes, but the principal are foul and putrid air, occaſioned by filth and impurity of any kind. Hence it is no wonder that it prevails in marſhy countries after hot ſeaſons, and in populous cities; eſpecially if low, and ill-aired, unprovided with common ſhores, or where the ſtreets are narrow and foul, the houſes dirty, water ſcarce, and where jails or hoſpitals are crouded, and not ventilated and kept clean; when in ſickly times the burials are within the towns, and the bodies not laid deep; when ſlaughter-houſes are alſo within the walls; or when dead animals or offals are left to rot in the kennels, or on dunghils; when drains are not provided, to carry off any large body of ſtagnating or corrupted water, in the neighbourhood; when fleſh-meats make the greateſt part of the diet, without a proper mixture of bread, greens, wine, or other fermented liquors; from the uſe of old and muſty grain, or what has been damaged by a wet ſeaſon; or, laſtly, when the fibres are relaxed by immoderate warm bathing.

When the diſeaſe comes on ſlowly, the ſymptoms are ſmall interchanges of heats and cold, trembling of the hands, interrupted ſleep, &c. But when it advances faſt, the above ſymptoms are all in a higher degree; and beſides theſe, the patient is afflicted with great laſſitude, a nauſea, pains in the back, a conſtant pain and confuſion in the head, a dejection of ſpirits, and an uncommon tremor of the hands. If the ſick lie warm, and have had no preceding flux, the body is generally coſtive; but when they lie cold, as they often do in field-hoſpitals, the pores of the ſkin being ſhut, a diarrhœa is a common ſymptom: in the worſt caſes, a flux appears in the laſt ſtage; when the ſtools are involuntary, colliquative, ichorous, or bloody, and of a cadaverous ſmell; which are the effects of a mortification of the bowels, and the ſigns of approaching death: ſome are never delirious, but all are under a great ſtupor or confuſion. The petechiæ are the frequent, but not inſeparable attendants of the fever; they are ſometimes of a brighter or paler red, at other times of a livid colour, but are never raiſed above the ſkin. For the moſt part, theſe ſpots are ſo little conſpicuous, that unleſs looked for attentively, they may eſcape notice. They are thickeſt on the breaſt and back, leſs on the legs and arms, and the Dr. never remembers to have ſeen any upon the face. This fever, tho' of the continued kind, has often exacerbations at night, with remiſſions, and partial ſweats next day; and, after a long continuance, is apt to change into a hectic, a remitting, or intermitting form.

Prognoſtics in it. To have a little dilirium, the ſtrength little impaired, turbid urine in the decline of the diſeaſe, and at the ſame time a gentle ſweat or moiſture diffuſed over the body, are reckoned good ſigns; and it ſeems peculiar to malignant fevers, that deafneſs is rather a good ſign.

Method of cure. This varies according to the ſtate of the diſeaſe, which may be diſtinguiſhed into three periods; the firſt continuing as long as the perſon is able to go about; the ſecond beginning with his confinement, and the third when the pulſe ſinks, and a ſtupor comes on.

In the firſt, as well as in the other periods, the cure is principally to be aimed at by removing the patient out of the foul air. When this cannot be done, the ward or room ſhould be purified by making a ſucceſſion of air by means of fires, or letting it in by doors and windows, or diffuſing the ſteams of vinegar.

The next thing to be done, is to promote a diaphoreſis, which, in this period, ſhould only be attempted by mild ſudorifics, as the *ſpiritus Mindereri*.

When the fever is confirmed, contrayerva-powders, with nitre, camphor, the common ptiſan acidulated, and ſuch medicines as are good in inflammatory caſes, ought to be given. Coſtiveneſs is to be prevented by emollient clyſters. But opiates are dangerous, both in this and the third ſtage, in which the pulſe ſinks, and ſtupor is greater, a delirium impends, and petechiæ often appear. When this is obſerved to be the caſe, the nitre and diaphoretic medicines are to make room for a decoction of ſnake-root, to which a ſmall quantity of ſtrong water may be added. It may alſo be given in ſubſtance from two to four ſcruples a day, with ſenſible good effects. Towards the decline of the fever, an equal quantity of peruvian bark may be joined with the root. Wine is alſo an excellent cordial at this period, and may be given either made into Whey, or added to the panado, which was the only food allowed to the ſick. It may be taken from half a pint to a quart a day, according to the ſtrength of the patient. Perhaps there is no rule of more importance, than to give ſtrict charge to the attendants of the ſick, never to let the patient, when low, remain above two or three hours without taking ſomething cordial and nouriſhing. But however neceſſary wine, volatiles, and other cordials are in this low ſtate of the fever, it ought to be remembered, that they muſt never be given with an intention to force a ſweat, but only as antiſeptics, and to ſupport the *vis vitæ*. If there be danger of a phrenitis coming on, it will be proper to call in the aſſiſtance of epiſpaſtics. Sinapiſms too may be uſed when the pulſe is greatly ſunk. If a diarrhœa comes on in the decline of the fever, it is to be moderated, by adding a few drops of the tinctura thebaica, to the full quantity of the alexipharmic decoction; or by giving a ſpoonful or two of an aſtringent mixture. In proportion, however, to the putrid nature of the ſtools, aſtringents are to be uſed with the more caution. When the fever is over, there are few but complain of a vertigo, and want of reſt, a continuation of the deafneſs, and other nervous ſymptoms, are frequently the conſequence of great lowneſs; in which caſe, the pillulæ Matthæi are to be given at night, with analeptics and medicines of the ſtrengthening kind. Vid. *Pringle*'s Obſerv. on diſeaſ. of army. p. 243—278.

HOSPITAL - *Ventilator*. See the article VENTILATOR, *Append*.

HOVEL, properly ſignifies a covering, or ſhelter for cattle, made of hurdles, or the like; but is alſo uſed for any other mean building. Ruſt. Dict. in voc.

HOUND (*Suppl.*)—*Gaze*-HOUND, or *Gaſt*-HOUND, one who makes more uſe of his ſight than ſmell, from the word *gaze*, to ſtare at.

Theſe dogs make excellent ſport with the fox and hare, and are much uſed in the north of England, and on champaign ground, rather than buſhy and woody places. Dict Ruſt. in voc.

HOUSE (*Cycl.* and *Suppl.*) — *Summer*-HOUSE, a little edifice erected at the corner of a garden, and contrived ſo as to let in air on all ſides; or to exclude it, as you find proper. Build. Dict. in voc. *Summer*.

HOUSING (*Cycl.*) — HOUSING, among brick-layers, a term uſed for a brick which is warped, or is caſt crooked or hollow in burning; in ſuch a caſe, they ſay it is *houſing*. Build. Dict. in voc.

HUMBLE-*bee-fly* is a ſpecies of *Culex*; it is lanigerous, and has ſomewhat obſcure wings. See the articles HUMBLE, *Suppl.* and CULEX, *Append*.

HUMBLE-*plant*, a name ſometimes given to the *mimoſa*, or ſenſitive plant. See the articles MIMOSA and SENSITIVE, *Suppl*.

HUNGARICUS *morbus*, a diſeaſe ſo called from its being firſt obſerved in the imperial army in Hungary, in the year 1566; from whence it ſpread over a great part of Europe.

It is deſcribed as a malignant fever, attended with ſickneſs at the ſtomach, a pain and hardneſs about the epigaſtric region, great thirſt from the beginning, a parched tongue, and a conſtant head-ach, ending in a delirium. It was highly contagious and mortal, and is ſuppoſed to have been a compound of the bilious and hoſpital fever, taking its riſe firſt in the camp, but acquiring that high degree of malignity from the foul air of the places in which the ſick were crouded. *Pringle*, Obſerv. on the diſeaſes of the army, p. 118, ſeq. See the articles BILIOUS and HOSPITAL-*fever*, *Append*.

HUNGRY *Evil* (*Cycl.*) — Nothing is better in this diſtemper, than to feed the horſe ſeveral times a day with wholeſome bean-bread well baked, or oats well dried and ſifted. Dict. Ruſt. in voc.

HUTCH, among farmers, denotes a veſſel or particular place in which to lay corn; alſo a kind of hollow trap for the taking of weeſels, or other vermin, alive. Dict. Ruſt. in voc.

HYACINTH (*Suppl.*) — *Grape* HYACINTH, or *Muſk* HYACINTH, the Engliſh name of a genus of plants, called by botanical writers *Muſcari*. See the article MUSCARI, *Suppl*.

HYACINTH *of Peru*, or the *Starry* HYACINTH, names ſometimes given to a diſtinct genus of plants, known among authors, by that of *Ornithogalum*, and called in Engliſh Star of Bethlehem. See the article ORNITHOGALUM, *Suppl*.

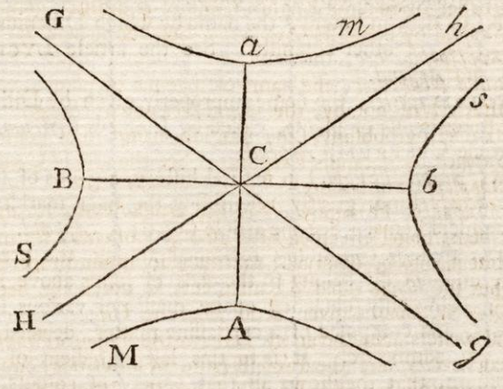
Tuberoſe HYACINTH, the name by which ſome call the *Polyanthes* of Linnæus. See the article POLYANTHES, *Append*.

HYDRA, or HYDRUS, in zoology, names given to the water-ſnake, called by authors *Natrix*. See the article NATRIX, *Suppl*.

HYDRA, is alſo the name by which Linnæus calls the *Polype*. See the articles POLYPE, *Suppl.* and BIOTA, *Append*.

HYDROCANTHARUS, the name by which ſome call the water-beetle. See the article DYTISCUS, ſupra.

HYDROCORAX, in ornithology, the name by which Barrelier calls the Indian-raven. See the article CORVUS *Indicus*, *Suppl.* and BUCEROS, *Append*.



HYDROMETER (*Suppl.*) — We have ſeveral new improvements of this inſtrument, in Deſaguliers, Experim. Philoſoph. vol. 2. p. 233, ſeq.

HYDROPHOBIA (*Cycl.*) — Vinegar is recommended by Dr. Kramer, as a ſpecific againſt the *Hydrophobia*, eſpecially, if ſome powder of Cantharides is mixed with it. The Receipt given by him is, to boil from four to ten grains of the fine powder of Cantharides, in an ounce and an half, or two ounces, of the beſt vinegar, which is to be given warm to the patient. Commerc. Norimb. 1735, hebd. 1183.

HYDROPIPER, a name uſed by ſome for the *Perſicaria*, or arſmart, of other botannical writers. See the article PERSICARIA, *Suppl*.

HYPERBOLA (*Cycl.*) — *Conjugate* HYPERBOLAS, a name given to four *Hyperbolas*, when the firſt and ſecond Axes of two oppoſite *Hyperbolas* are the ſecond and firſt Axes of two other oppoſite *Hyperbolas*.

Thus if two oppoſite *Hyperbolas* A M, *a m* have the line A *a*, for their firſt Axis, and the line B *b*, for their ſecond Axis; and if two other oppoſite *Hyperbolas* B S, *b s*, have on the contrary, B *b* for their firſt Axis, and A *a* for their ſecond Axis, theſe two *Hyperbolas* B S, *b s* are ſaid to be conjugate to the *Hyperbolas* A M, *a m*, and the four together are called conjugate *Hyperbolas*.

The Aſymptotes H C *h*, G C *g*, of the *Hyperbolas* A M, *a m*, will alſo be the Aſymptotes to the *Hyperbolas* B S, *b s*. See *L' Hopital*, Sect. Coniq. Art. 132.

HYPERICOIDES, in botany, the name by which Plumier calls the *Aſcyrum* of Linnæus, a diſtinct genus of plants. See the article ASCYRUM, *Append*.

HYPERICUM, in the Linnæan ſyſtem of botany, a large genus of plants; which, according to that author, comprehends the *Androſæmum* and *Hypericum* of Tournefort. See the articles ANDROSEMUM and HYPÆRICUM, *Suppl*.

HYPETHRE, in antient architecture, two rows of pillars all about, and ten at each face of any temple, *&c.* with a Periſtyle within of ſix columns.

I.

JAS ICE

JACEA, *knapweed*, is comprehended by Linnæus among the *Centauria*. See the article CENTAURIA, *Append.*

JACINTH, in botany, a name uſed by ſome for the *hyacinth*. See the article HYACINTH, *Suppl.*

JACK *(Suppl.)*—JACK is alſo uſed for a well known engine to turn a ſpit; for a horſe or wooden frame to ſaw timber upon; for an inſtrument to pull off a pair of boots; for a great leathern pitcher to carry drink in; for a ſmall bowl that ſerves as a mark at the exerciſe of bowling; and for a young pike. Dict. Ruſt. in voc.

JACK *by the hedge*, a name ſometimes given to the *Thlaſpi* of botanical writers. See the article THLASPI, *Suppl.*

JACK *by the hedge* is alſo uſed as the name of a ſpecies of *Heſperis*. See the article HESPERIS, *Suppl.*

JACK *in a box*, the name by which ſome call a diſtinct genus of plants, called by botaniſts *Hernandia*. See the article HERNANDIA, *Append.*

JACOB's *Ladder*, a name uſed by ſome for the *Polemonium* of botanical writers. See the article POLEMONIUM, *Suppl.*

JACOBÆOIDES, in botany, the name of a genus of plants, according to Vaillant, but comprehended under the *Solidago* by Linnæus. See the article SOLIDAGO, *Append.*

JAIL-*fever*, a name given to the *malignant catarrhal fever*, as being frequent in jails; it is likewiſe call'd the *hoſpital fever*, for a like reaſon. See the articles FEVER and HOSPITAL-*fever*, *Append.*

JALAP, a name ſometimes given to the *Convolvulus*, or bind-weed of botaniſts. See the article CONVOLVULUS, *Suppl.*

JAMBS, among carpenters and bricklayers. See the article JAUMS, *Append.*

JANNOCK, a kind of oaten bread, much uſed in the northern parts of England, and made of ſour leaven. Dict. Ruſt. in voc.

JASMINE *(Suppl.) Ilex-leaved* JASMINE, the name by which the *Lantana*, a diſtinct genus of plants, is ſometimes called. See the article LANTANA, *Suppl.*

Arabian, or *Indian* JASMINE, the Engliſh name of a genus of plants, called by Linnæus *Nyctanthes*. See the article NYCTANTHES, *Append.*

Scarlet JASMINE, a name ſometimes given to the *Bignonia*, or trumpet flower. See the article TRUMPET-*flower*, *Suppl.*

Red-JASMINE, a name given to the *Plumeria* of botanical writers. See the article PLUMERIA, *Suppl.*

Perſian-JASMINE, the name by which ſome call *Lilac*. See the article LILAC, *Suppl.*

Fennel-leaved JASMINE, a name ſometimes given to *Quamoclit*. See the article QUAMOCLIT, *Suppl.*

JASMINOIDES, in botany, the name by which Dillenius calls the *Lycium*, of other botaniſts. See the article LYCIUM, *Suppl.* and *Append.*

JASMINOIDIS *ſpecies*, the name improperly given by Dillenius to a diſtinct genus of plants, called by Linnæus *Ceſtrum*. See the article CESTRUM, *Append.*

JASPER, *Jaſpis, (Suppl.)* in natural hiſtory, a genus of ſtones of the *Scrupi*-kind, greatly reſembling the finer marbles, or ſemi-pellucid gems. See the article SCRUPI, *Append.*

Jaſpers, though commonly reckoned among the precious ſtones, undoubtedly belong to the claſs of foſſils above referred to; being only detached opake maſſes of various forms and ſizes, and compoſed of a cryſtalline matter, debaſed with an earthy admixture. It is to this laſt ingredient of their compoſition, that they owe all that variety of colours, and difference of opacity, whence naturaliſts have ſubdivided them into no leſs than ſeven orders, containing the white, the green, the red, &c. *Jaſpers*.

Of the white *Jaſpers*, there is only one known ſpecies, the hard, ſhining, white, marbly *Jaſper*, commonly called the *Nephritic ſtone*, on account of its ſuppoſed virtue in caſes of the ſtone and gravel. It is found in many parts of America, particularly the great river of the Amazons, and worn by the natives as an amulet. As to its medical virtues, they are too ridiculous to deſerve a ſerious refutation; but its other uſes merit the attention of lapidaries, ſince it is capable of being faſhioned into cups and vaſes of a beautiful poliſh, and great brightneſs.

Of the green and greeniſh *Jaſpers*, we have the following ſpecies: 1. The hard, fine green *Jaſper*. This is found in many parts of the world, as Egypt, Tartary, China, &c. and worn as an amulet againſt fluxes, hæmorrhages, &c. 2. The ſoft duſky green *Jaſper*. This ſtone, which is of much leſs beauty and value than the foregoing ſpecies, is very common in Germany, Italy, France, England, &c. 3. The hard bluiſh green *Jaſper*, with red variegations. This is the *heliotrope* of the antients, and *blood-ſtone* of the moderns. It is common in Africa, Egypt, and the Eaſt-Indies; and is worked into cups, vaſes and ſnuff-boxes. 4. The hard whitiſh-green *Jaſper*, which is the nephritic ſtone of authors. It is found in many parts of America, where the natives faſhion it into figures of birds, beaſts, fiſhes, and other forms; and formerly uſed to wear it hung to their lower lips. A thouſand amazing ſtories are told, by very grave authors, of the nephritic qualities of this ſtone. 5. The hard, yellowiſh-green *Jaſper*, celebrated likewiſe for its nephritic virtues. It is found in ſeveral parts of America, as alſo in Germany, Bohemia, and ſome other countries of Europe. 6. The bluiſh-green, marbly *Jaſper*, variegated with grey and black. 7. The hard, greyiſh-green *Jaſper*, called by authors the *Jade*, or *Lapis divinus*, the divine ſtone. 8. The dull, deep green *Jaſper*, called by different authors *Molochite*, *Molochites*, and *Malachites*. 9. The bluiſh-green, ſofter, dull *Jaſper*. This is the *borea*, or ſky-coloured *Jaſper* of the antients, and makes a very beautiful appearance in cups, vaſes, and other ornamental things. 10. The duſky-green *Jaſper*, variegated with white and fleſh colour; this, tho' a coarſer ſpecies than the preceding one, is not without its beauty.

Of the red *Jaſpers*, we know only four ſpecies: 1. The hard, variegated, purple *Jaſper*: This is the roſe-coloured *Jaſper* of authors. It is a very beautiful ſtone, and capable of a high poliſh. It is found in the Eaſt and Weſt-Indies, as alſo in Germany, Bohemia, and Spain, but of a coarſer kind. 2. The bright red *Jaſper*, variegated with white. America and Europe both afford this ſpecies; but thoſe from the former are the fineſt. 3. The dull, purple and white *Jaſper*. This, tho' of a coarſe and irregular ſtructure, is not unfrequently found manufactured into handles of knives, and other toys, both in England, Italy, and Germany. 4. The hard, dull, fleſh-coloured *Jaſper*. It is of an extremely pale whitiſh red, generally throughout.

The fourth order of *Jaſpers* contains thoſe of a brown colour, of which we have only one ſpecies, the pale-brown, hard *Jaſper*, with purple veins. It is common on the Yorkſhire and Suſſex ſhores, and alſo in many of our gravel-pits.

The fifth order contains the yellowiſh *Jaſpers*, of which there is only one known ſpecies, the yellowiſh, hard, variegated *Jaſper*. This is the turpentine-coloured *Jaſper* of the antients. It is very common in the Eaſt-Indies; and we have it alſo in Germany, Bohemia, and other parts of Europe, but inferior to the oriental ones.

The bluiſh *Jaſpers* conſtitute a ſixth order; and of theſe there are only two ſpecies: 1. The pale bluiſh *Jaſper*, with black veins and clouds; called by the antients the ſmoaky *Jaſper*. 2. The bluiſh, marbly *Jaſper*, variegated with white.

The ſeventh and laſt order of *Jaſpers* contains the black ones, whereof there are only two ſpecies: 1. The black, marbly *Jaſper*, variegated with white. 2. The black, marbly *Jaſper*, variegated with yellow. *Hill*, Hiſt. Foſs. p. 573—592.

JAUMS, among carpenters, denote the door-poſts, as alſo the upright poſts at the ends of window-frames. Build. Dict. in voc.

JAUMS, among bricklayers, *&c.* the upright ſides of chimneys, from the hearth to the mantle-tree. Id. ibid.

JAY, in zoology, the Engliſh name of a ſpecies of *Corvus*, with the upper feathers of the wings blue, variegated with black and white. See CORVUS, *Suppl.*

IBERIS *(Suppl.)* is alſo the name uſed by ſome writers for a ſpecies of *Lepidium*, or dittander. See the article LEPIDIUM, *Suppl.*

ICE-*houſe*, a building deſigned to preſerve *Ice*, for the uſe of families in the ſummer ſeaſon.

Theſe are more generally uſed in warm countries, than with us; particularly in Italy, where the meaneſt perſon, who rents a houſe, is not without his vault or cellar for keeping of *Ice*.

Ice-houſes being much more uſed with us than formerly, it may not be amiſs to give ſome general directions for the choice of the ſituation, and ſtructure of them; as alſo for the management of the *Ice*.

The ſituation, then, ſhould be upon a dry ſpot of ground; becauſe wherever there is moiſture, the *Ice* will melt: for which reaſon, too much care cannot be taken to make drains all round them. The place ſhould likewiſe be elevated, and as much expoſed to the ſun and air as poſſible.

As to the figure of the building itſelf, the proprietor may chooſe ſuch as pleaſes his own fancy; but a circular form is the beſt for the well where the *Ice* is to be preſerved, which ſhould be large in proportion to the quantity to be kept.—It is beſt to have as much as may ſerve two or three years, in caſe of a mild winter, when little or no *Ice* is to be got. At

the bottom of the well, there ſhould be a ſpace of about two feet deep left to receive any moiſture which may drain from the *Ice*; and a ſmall drain under ground ſhould be laid from this, to carry off the wet. Over this ſpace of two feet ſhould be placed a ſtrong grate of wood; and the ſides of the well ſhould be built of brick, at leaſt two bricks thick; for the thicker it is, the leſs danger there will be of the well being affected by any external cauſe.

When the well is brought up within three feet of the ſurface, there muſt be another outer arch or wall begun, which muſt be carried up to the height of the intended arch of the well; and if there is another arch turned over from this wall, it will add to the goodneſs of the houſe. The roof muſt be high enough above the inner arch, to admit of a door-way to get out the *Ice*. If the building is to be covered with ſlates, or tiles, reads ſhould be placed conſiderably thick under them, to keep out the ſun and external air; the thickneſs of ſix or eight inches, with a plaſtering of hair and lime, will be ſufficient to prevent all danger.

The external wall needs not be built circular, but of what figure the proprietor pleaſes. Sometimes the *Ice-houſe* is ſo contrived as to have an handſome alcove ſeat in its front.

Two feet diameter is ſufficient for the aperture of the mouth of the well; which ſhould have a ſtone, ſo contrived, as to ſtop it up in the exacteſt manner; and all the vacant ſpace between this aperture and the outer door, ſhould be filled up with barley-ſtraw; and this laſt is to be always ſhut, before the inner door is opened. The building thus finiſhed, ſhould have time to dry, before the *Ice* is put into it.

If a layer of reads be placed ſmooth over the grate at the bottom of the well, on which to lay the *Ice*, it will do better than ſtraw, which is commonly uſed; and as to the choice of the *Ice*, the thinner it is, the eaſier it may be broken to powder: for the ſmaller it is broken, the better it will unite, when put into the well. In putting it in, care muſt be taken to ram it as cloſe as poſſible; as alſo to allow a vacancy of about two inches all round next the ſide of the well, to give paſſage to any moiſture occaſioned by the melting of ſome of the *Ice*.

When the *Ice* is put into the well, if a little ſalt-petre be mixed with it at every ten inches, or foot thickneſs, it will cauſe the *Ice* to join more cloſely into a ſolid maſs. *Miller*'s Gard. Dict.

JEAN-CAPELLE, in ichthyology, a name given by Ruyſch, and ſome others, to the fiſh called by authors, the *Faber Indicus*, or Indian Doree; and more expreſſively named by Artedi, the Zeus with a forked tail. See the article ZEUS, *Suppl.*

JEMBUT, in the materia medica, a name uſed by Aviſenna and others, to expreſs the ſeeds in the pods of the carob tree, or ſiliqua dulcis; which they call *Charub* or *Charnub*, and the Greeks *Ceratium*. Theſe ſeeds contained in the pods of this tree, when carefully dryed, ſerved the antient phyſicians as weights; and hence is derived the Greek word Ceration for a weight which expreſſes one of theſe ſeeds. The Arabian writers mention two kinds of this tree Charnub: The one they call Alſcemi, and the other Alnabati. Theſe are tranſlated Syriaca and Nabathæa ſiliqua. Pliny, Columella, and all the other antients who have written on theſe ſubjects, mention the Syrian ſiliqua, or Charnub. This is called Scemi or Xami; and they have alſo mentioned the ſiliqua Græca, which is the common ſiliqua. The diſtinction Aviſenna makes between the Syrian and Nabathæan ſiliqua or Charnub is, that the firſt was a purgative, and gave relief in colics, and other pains in the bowels; and that the other was an aſtringent, and was very ſucceſsful in the cure of fluxes of blood, particularly in profluvia of the menſes; and that it was for this purpoſe both eaten and put up as a peſſary.

JERGUER, in the Cuſtom-houſe, an officer who overſees the actions and accounts of the waiters. Dict. Ruſt. in voc.

JERSEY, among wool-combers, denotes the fineſt wool taken out of other ſorts, by dreſſing it with a *Jerſey-comb*. Dict. Ruſt, in voc.

JERUSALEM-*cowſlip*, a name by which ſome call the *Pulmonaria* of botaniſts. See the article PULMONARIA, *Suppl.*

JERUSALEM-*ſage*, a name ſometimes given to two diſtinct genuſes of plants, the *Pulmonaria* and *Phlomis*. See the articles PHLOMIS and PULMONARIA, *Suppl.*

JESSES denote the ribbons hanging down from garlands and crowns; alſo the ſhort ſtraps of leather faſtened to a hawk's legs, and ſo to the vervels. Dict. Ruſt. in voc.

JESSAMIN, or JESSAMY, in botany, the ſame with *Jaſmine*. See JASMINE, *Suppl.*

JESUITS *Bark*, the name of a medicinal drug, otherwiſe called *cortex peruvianus*, and *quinquina*, or *quinaquina*. See the articles QUINQUINA, *Cycl.* and PERUVIAN, *Cycl.* and *Suppl.*

Falſe JESUIT's-*Bark*, a name ſometimes given to the *Balſamita* of botaniſts. See the article BALSAMITA, *Append.*

JETAIBA, in botany, a name uſed by ſome authors for the tree which affords the Gum Anime of the ſhops. *Piſo*, p. 60.

JEWS *Mallow*, a name by which the *corchorus*, a diſtinct genus of plants, is ſometimes called. See the article CORCHORUS, *Append.*

INCENDIARY, *Incendiarius*, is applied to one who is guilty of maliciouſly ſetting fire to another's houſe. This offence is called *Arſon* in our law.

Among the antients, criminals of this kind were to be burnt. *Qui ædes, acervumque frumenti juxta domum poſitum ſciens, prudenſque dolo malo combuſſerit, vinctus, igni necatur. Pitiſc.* Lex Ant. in voc.

INCINERATED *Salts*, in Chemiſtry, the ſame with lixivial ſalts. See INCINERATION and LIXIVIOUS, *Cycl.* and SALTS, *Suppl.*

INDEX *of Relation*, in Algebra, the ſame as *Scale of Relation*. See SCALE *of Relation* and SERIES, *Append.*

INDIAN-*arrow-root*, in botany, a name ſometimes given to the *Maranta* of botaniſts. See the article MARANTA, *Ap.*

INDIAN-*fig*, the name by which ſome call the *Opuntia* of botaniſts. See the article OPUNTIA, *Suppl.*

INDIAN *god-tree*, the name given by ſome to a ſpecies of fig-tree. See the article FICUS, *Suppl.*

INDIAN-*reed*, a name given to the *Cannacorus* of botanical writers. See the article CANNACORUS, *Suppl.*

INFARCTION of the Liver. See HEPATIS *infarctus*, *Sup.*

INFLAMMATION *of the Eyes*, the ſame with what phyſicians call *Ophthalmia*. See the article OPHTHALMIA, *Cycl.*

INFLAMMATORY *Diſeaſes*. To theſe are to be referred coughs, pleuriſies, peripneumonies, acute rheumatiſms, *Inflammations* of the brain, bowels, and other parts, attended with a fever; alſo leſſer *Inflammations* without a fever, and fevers of an *inflammatory* kind, where no part is ſo peculiarly affected as to give name to the diſeaſe. And, laſtly, all chronic diſorders ariſing from *Inflammations*, whereof the chief are old coughs, conſumptions, and the rheumatiſm without a fever.

All theſe diſeaſes are the conſequences of catching colds, and are prevented by the ſame means as colds. See the article COLD, *Append.*

Bleeding is the moſt indiſpenſible remedy in the cure of all *inflammatory* diſeaſes, and therefore to the delaying this too long, or not repeating it, it is owing, that colds end in dangerous fevers, rheumatiſms, or conſumptions. See the article BLEEDING, *Append.*

In all *inflammatory* diſorders, the principal intention of cure is to diminiſh the force of the blood, to thin it, and to relax the fibres; on which account, bleeding, attenuants, and diaphoretics, are the chief remedies. An early ſweat tends alſo to prevent an *inflammatory* fever; for which purpoſe, the diaphoretic draught of the Edinburgh diſpenſatory is recommended; or, inſtead of it, a ſpoonful of the plain Spiritus Mindereri may be given every two hours, till a ſweat breaks out; or two ſcruples of the ſalt of hartſhorn, ſaturated with about three ſpoonfuls of common vinegar, may be given in one draught at bed-time. *Pringle*, Obſerv. on the the Diſeaſes of the army, p. 73, 77, 127, ſeq.

INFLAMMATORY *fevers*. Theſe may be diſtinguiſhed into two ſtages; the firſt whilſt the pulſe continues hard, in which it is proper to bleed; and the ſecond, when, the *inflammatory* ſymptoms ſtill remaining, the pulſe is too low for that evacuation. In this laſt ſtate, bliſters are the chief remedy, and which, except in a few ſingular caſes, are not to be uſed ſooner. If the bliſters are large, it is better to apply them gradually, than many at a time. It is uſual to begin with the back, and, if neceſſary, to apply them next to the legs or thighs, reſerving the arms laſt, that the patient may be ſo much the longer conveniently moved. In great lowneſs, attended with a delirium, ſinapiſms applied to the ſoles of the feet, have frequently more efficacy than bliſters, in raiſing the pulſe, and relieving the head.

If the body has been coſtive before the diſeaſe, it is proper to open it by a laxative, after bleeding; and after recovery, ſome lenient phyſic is generally requiſite, for preventing a too haſty repletion incident to convaleſcents, upon indulging their appetites. *Pringle*, Obſerv. on the Diſ. of the army, p. 134.

There is no caution more neceſſary to a young phyſician, than to abſtain from all opiates throughout theſe fevers, however much the patient may complain of pain or watchfulneſs. Indeed, if the fever be accompanied with a diarrhœa, which is not critical, the looſeneſs is to be gradually checked by diaſcordium, after giving rhubarb, and endeavouring to turn the humours to the ſkin by the uſe of diaphoretics, (omitting the nitre) with the uſe of the white decoction for common drink. Id. ibid. 136.

INK-*fiſh*, the ſame with the *Sepia*, or cuttle-fiſh. This animal, when it is in danger of being taken, emits a black liquor like ink, out of its mouth in conſiderable quantities, whereby the water being obſcured, it finds an opportunity of eſcaping; and from this property it has got the name of the *Ink-fiſh*. See the article SEPIA, *Append.*

INSECTS. (*Suppl.* — Dr. Hill, in his hiſtory of animals, has eſtabliſhed a new ſyſtem of *Inſects*; which is this:

He firſt ſubdivides them into three general ſeries, each whereof comprehends under it ſeveral claſſes, and thoſe again many diſtinct genera.

The firſt ſeries of *Inſects* is called *Apteria*; becauſe under it are comprehended all *Inſects* of what kind ſoever, having neither wings nor limbs.

Of this ſeries there are two claſſes, the *Anarthra* and *Podaria*. See the articles ANARTHRA and PODARIA, *Append.*

The ſecond ſeries of *Inſects* is called *Pteraria*, as comprehending all the winged kinds.

Of this ſeries there are likwiſe two orders or ſubdiviſions: 1. The *Pteraria Diptera*, or *Inſects* with two wings. 2. The *Pteraria Tetraptera*, or thoſe with four wings. See the article PTERARIA, &c. *Append.*

The third and laſt ſeries of *Inſects* is called *Gymnarthridia*, and comprehends all thoſe *Inſects* which have ſoft and naked bodies, furniſhed with limbs. See GYMNARTHRIDIA.

INTERCALATION. See the article INTERPOLATION, *infra.*

INTERMITTING *fever*. See the article BILIOUS *fever*, *Append.*

INTERPOLATION, *(Cycl.)* in algebra, is uſed, for the finding an intermediate term of a ſeries, its place in the ſeries being given. This is alſo called *Intercalation.*

The method of doing this is called the *Method of Interpolations*, or *Intercalations.*

When the algebraic equation of the ſeries is given, the term required, whether it be a primary or intermediate term, may be found by the reſolution of affected equations; but when this equation is not given, as it often happens, the value of the term ſought muſt be exhibited by a converging ſeries, or by the quadrature of curves. See *Stirling*, Method. Different. p. 86. ſeq. *Meier*, in act. petrop. Tom. II. p. 180, ſeq.

When the firſt, ſecond, or other ſucceſſive differences of the terms of a ſeries become at laſt equal, the *interpolation* of any term of ſuch a ſeries may be found by Sir Iſaac Newton's Differential Method. See DIFFERENTIAL *Method*, *App.*

INTERSCENDENT, in Algebra, is applied to quantities, when the exponents of their powers are radical quantities. Thus $Z^{\sqrt{2}}$, $z^{\sqrt{m}}$, &c. are *interſcendent* quantities. *Euler*, introduct. ad Analyſ. infinit. Vol. I. pag. 6. Hence, an *interſcendent* Series or Function is eaſily underſtood. See the article FUNCTION, *Append.*

IN-TURN, among wreſtlers, is when one puts his thigh between thoſe of his adverſary, and lifts up his thigh. Dict. Ruſt. in voc.

JOCKEY, in the management of horſes, the perſon who trims up, and rides about horſes for ſale. Ruſt. Dict. in voc.

JOCKLET, or YOCLET, a term uſed in ſome parts of Kent for a little farm which requires but one yoke of oxen to till it. Dict. Ruſt. in voc.

JOHN's *bread*, or St. JOHN's *bread*, a name ſometimes given to the *ceratonia*, or carob-tree, called by Tournefort *Siliqua*, See the article SILIQUA, *Suppl.*

JOHN's, or *Sweet* JOHN's, a name ſometimes given to the *Caryophyllus*, or pink. See the article PINK, *Suppl.*

JOINT-*Clerks of the Acatery*. See the article ACATERY, *Cycl.*

JOKY. See the article JOCKEY, *Append.*

JONQUIL, a name given by ſome to the *Narciſſus* of botaniſts. See the article NARCISSUS, *Suppl.*

JOVIS *barba*, in botany, the name of a diſtinct genus of plants. See the article BARBA *Jovis*, *Suppl.*

IRON *(Suppl.)* —For the expanſion of *Iron* by heat. See the article HEAT, *Append.*

IRON-*wood*, in botany, the name of a genus of plants, called by botaniſts *Sideroxylum*. See the article SIDEROXYLUM, *Append.*

Filings of Iron, in medicine, when reduced to an impalpable powder, is an excellent form to be given in female diſorders, in which the body is weak, languid, and full of acidities; the juices are themſelves the beſt menſtruum in the world for it, as appears from its producing eructations of the ſmell of garlick, and by its tinging the excrements as black as ink. The natural heat, before wanting, is always excited by this means.

IRRIGATION, *Irrigatio*, denotes the watering of a meadow, garden, &c. Dict. Ruſt. in voc.

ISARUS, in zoology, a name given by the antients to the chamoy-goat. See the article RUPICAPRA, *Suppl.*

ISOPERIMETRICAL *(Cycl.)* — *Iſoperimetrical* lines and figures have greatly engaged the attention of mathematicians ſince the invention of fluxions. The analyſis of the general problem concerning figures, that among all thoſe of the ſame perimeter produce maxima and minima, was given by Mr. James Bernoulli, from computations that involve ſecond and third fluxions. [a] And ſeveral inquiries of this nature have been ſince proſecuted in like manner, but not always with equal ſucceſs. Mr. Mac Laurin, to vindicate the doctrine of fluxions from the imputation of uncertainty, or obſcurity, has illuſtrated this ſubject, which is commonly conſidered as one of the moſt abſtruſe parts of this doctrine, by giving the reſolution and compoſition of theſe problems by firſt fluxions only; and in a manner that ſuggeſts a ſynthetic demonſtration, ſerving to verify the ſolution [b]. [a *Analyſis magni problematis iſoperimetrici*, Act. erudit. Lipſ. 1701. p. 213, ſeq. b See *Mac Laurin's* Fluxions, B. I. chap. 13. p. 486, ſeq. See alſo Mem. Acad. Scienc. 1706. 1718. and *Jo. Bernoulli*, oper. Tom. I. p. 202, 208, 424, ſeq. Tom. II. p. 235, ſeq.]

ISSUES *(Suppl.)* — *Iſſues* above the ſhoulder-blades are good in aſthmatic caſes; and Dr. Mead thinks that their benefit in this and ſome other diſtempers, lies not only in giving vent to the humours, but likewiſe in leſſening the over great tenſion of the nerves. Monit. et Pract. medic. cap. v.

The uſe of *Iſſues* or ſetons, made in the ſide on the part moſt affected, is recommended inſtead of bleeding in conſumptive caſes. See the article CONSUMPTION, *Append.* and ISSUE, *Suppl.*

ITCH *(Cycl.)* —Sulphur is ſpecific in this diſorder, being both more ſafe and more efficacious than mercury. For unleſs a mercurial ointment were to touch every part of the ſkin, there can be no dependance on it; whereas by a ſulphureous one, a cure may be procured only by partial unctions.

It would ſeem, as if the *Itch*-inſects, like other animals, were killed by the ſteams of brimſtone, though only raiſed by the heat of the body.

As to the internal uſe of mercury, which ſome have accounted ſpecific, there are many inſtances of people who have undergone a complete ſalivation for the cure of the venereal diſeaſe, without curing the *Itch.*

A pot of ſulphureous ointment may be prepared thus: take of common ſulphur one ounce; of the root of white hellebore, two drams; or one dram of crude ſal ammoniac; make them into an ointment with two ounces and an half of hog's lard. This quantity will ſerve for four unctions, once every night. But to prevent any diſorder that might ariſe from ſtopping too many pores at once, it will be proper to anoint only one fourth of the body at one time.

Though the *Itch* may be thus removed by one pot of ointment, it will be proper to renew the application, and to touch the parts moſt affected, for a few nights longer, till a ſecond quantity, equal to the firſt, is alſo exhauſted; and, in the worſt caſes, to ſubjoin the internal uſe of ſulphur. Now, as the fumes of the ſulphur may heat the blood, at a time when the perſpiration is ſo much impeded, the patient ſhould live all the while on a cool diet, and guard againſt cold. If he be of a full habit, or in any degree feveriſh, it will be proper to bleed and take phyſic; otherwiſe, neither of the two evacuations is neceſſary. See the article SCABIES, *Suppl.*

ITCH-*animal*, a creature found in the puſtules of the *Itch*; it is a ſpecies of *Acarus*. See the article ACARUS, *Append.*

JUCCA, in botany, the name of a diſtinct genus of plants, otherwiſe called *Yucca*. See the article YUCCA, *Suppl.*

JUCKING, the notes of a cock-partridge, inviting the hen to come to him. Theſe ſerve the ſportſman in good ſtead for finding the places where they are. Ruſt. Dict. in voc.

JUCURUTA, a very beautiful ſpecies of owl, found in the Brazils, and variegated with black and yellow.

JUFFERS, among carpenters, a term uſed for pieces of wood, about four or five inches ſquare, and of ſeveral lengths.

JUGLANS, in the Linnæan ſyſtem of botany, the name of a diſtinct genus of plants, called by Tournefort ſimply *Nux*; and in Engliſh the *Walnut-tree*. See the article NUX, *Suppl.*

JUJUBE-*tree*, the Engliſh name of a diſtinct genus of plants, called by authors *Ziziphus*. See the article ZIZIPHUS, *Suppl.*

JULIANS, the name of a diſtinct genus of plants, called by botaniſts *Heſperis*. See the article HESPERIS, *Suppl.*

JULY-*flowers*, the Engliſh name for ſeveral ſpecies of *Caryophyllus*, or pink. See the article PINK, *Suppl.*

JUNCUS *odoratus*, *aromaticus*, and *rotundus*, in botany, names given to the *Schænanth*. See the article SCHÆNANTH, *Suppl.*

IVORY *(Cycl.* and *Suppl.)*—*Staining or Dying of* IVORY. To ſtain *Ivory* of a fine green colour, take to two parts of verdigreaſe one part of ſal armoniac.

JUTTY-*heads*, in the ſea-language, platforms ſtanding on piles, near the docks, and projecting without the wharfs for the more convenient docking and undocking ſhips. *Blanckley*, Nav. Expoſitor, p. 84.

JUG, a ſort of earthen pot, or pitcher, to hold drink; alſo a term uſed in many parts for a common, paſture, or meadow. Ruſt. Dict. in voc.

JUNAMES, in huſbandry, denotes land ſown with the ſame grain, as it had been the preceding year.

JUPITER's-*beard*, the Engliſh name of a diſtinct genus of plants, called by Tournefort *Barba Jovis*. See the article BARBA *Jovis*, *Suppl.*

IVY *(Suppl.)* —*Ground*-IVY, *Hedera terreſtria*, the name of a genus of plants, the characters of which are theſe; the cup is a one-leaved perianthium, tubulated, cylindric, ſtriated, very ſmall, and permanent; with its mouth divided into five acuminated, unequal ſegments. The flower is monopetalous, and ringent; the tube is ſlender and compreſſed, the upper lip being erect, obtuſe, and ſemibifid; the under one patent, large, obtuſe, and trifid. The ſtamina are four, ſtanding under the upper lip of the flower; each of the two pair of antheræ is arranged in the form of a croſs. The germen of the piſtil is quadrifid; the ſtyle is filiform, and inclinated; the ſtigma bifid and acute. There is no pericarpium beſide the cup; the ſeeds, which are ovated, and four in number, being contained in it. *Linnæi* Gen. Plant. p. 269.

Virginian-IVY, a name uſed by ſome writers for the *Meniſpermum*, a diſtinct genus of plants. See the article MENISPERMUM, *Append.*

K.

KAB, in Jewiſh antiquity. See the article CAB, *Suppl.*

KÆMPFERIA, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: The cup is a ſimple ſpatha, conſiſting only of one leaf, and opening on one ſide. The flower conſiſts of a ſingle petal; the tube is long and thin, the limb is plane, and divided into ſix parts, three of the ſegments being alternately lanceolated in figure, and equal in ſize; two other of the ſegments are of an ovated form, and the ſingle lower one is divided into five parts, which are each vertically cordated; all the ſegments are equal in length. The ſtamen is a ſingle filament, of a membranaceous ſtructure, and ſomewhat ovated figure, and is emarginated. The anthera is of a lineal figure, it grows to the filament all its length, and ſcarce emerges out of the tube of the corolla. The germen of the piſtil is roundiſh; the ſtyle is of the length of the tube, and the ſtigma is obtuſe. The fruit is a roundiſh, and ſomewhat trigonal capſule, compoſed of three valves, and containing three cells, in each of which there are a great number of ſeeds. Vid. *Linnæi* Gen. Plant. p. 4.

The root of the *Kæmpferia*, of which there is only one known ſpecies, is the *Galangal* of the ſhops. See the article GALANGAL, *Suppl.*

KAHIASEE, in the turkiſh court, an officer of ſtate, anſwering to our maſter of the ceremonies.

KANTREF, or KANTREV. See the article CANTRED, *Suppl.*

KARFE, a kind of Cinnamon. See the article CINNAMUM, *Suppl.*

KARLE *(Cycl.)* — KARLE-*hemp*, a term uſed by country people for the latter green hemp. Dict. Ruſt. in voc.

KASTRIL, in zoology, the ſame with *Keſtril*, a bird of the hawk-kind. See the article KESTRIL, *Suppl.*

KATKIN. See the article CATKIN, *Suppl.*

KEELERS, in the ſea language, ſmall tubs for holding ſtuff to grave a ſhip's bottom. *Blanckley*, Nav. Expoſ. p. 85.

KEEVE, or KEEVER, a large tub, or brewing veſſel, in which ale or beer ferments before it is tunned. Dict. Ruſt. in voc.

KENNEL, a term uſed indifferently for a puddle, a watercourſe in the ſtreets, a houſe for a pack of hounds, and the pack or cry of hounds themſelves. Dict. Ruſt. in voc.

Among ſportſmen, a fox is ſaid to *kennel*, when he lies cloſe in his hole. Id. ibid.

KERSEY, a kind of coarſe woollen cloth, made chiefly in Kent and Devonſhire. Dict. Ruſt. in voc.

KESITAH. This word is to be met with in Geneſis [a], and in Job [b]; and is tranſlated in the ſeptuagint and vulgate Sheep or Lambs. But the Rabbins and modern interpreters are generally of opinion, that *Keſitah* ſignifies rather a piece of money. Bochart and Eugubinus are of opinion the ſeptuagint meant *Minæ*, and not *Lambs*; in Greek *hecatonmnon*, ἑκατομνων inſtead of ἑκατον ἀμνων. Now a Mina was worth ſixty Hebrew ſhekels, and conſequently ſix pounds ſixteen ſhillings and ten pence halfpenny ſterling [c]. M. de Pelletier of Rouen, is of opinion, that *Keſitah* was a Perſian coin, ſtamped on one ſide with an archer (*Keſitah*, or *Keſeth*, in Hebrew, ſignifying a Bow) and on the other with a Lamb; that this was a gold coin known in the eaſt by the name of a Daric [d], and was in value about twelve livres and ten pence French money. Several learned men, without mentioning the value of the *Keſitah*, ſay it was a ſilver coin, the impreſſion whereof was a ſheep; for which reaſon the ſeptuagint and vulgate tranſlate it by this name. Calmet is of opinion, that *Keſitah* was a purſe of gold or ſilver. In the eaſt they reckon at preſent by purſes. The word *Kiſta* in Chaldee ſignifies a meaſure, a veſſel. And *Euſtathius* ſays, that *Kiſta* is a Perſian meaſure. Jonathan and the *Targum* of *Jeruſalem* tranſlate *Keſitah* a pearl [e].

[a] Gen. XXXIII. 19.—[b] Job XLII. 11.—Or Nine pounds *Engliſh*, ſuppoſing, as Dr. *Prideaux* does, that a ſhekel is worth three ſhillings.— [d] A Daric is a piece of gold, worth, as Dr. *Prideaux* ſays, five and twenty ſhillings *Engliſh*. See his Connect. P. I. p. 101.— [e] See *Calmet* Comment. upon Gen. XXXIII. 19. Gen. XXV. 12, &c. and Dict. Bibl.]

KEY *(Suppl.)* — KEYS, a name commonly given to the ſeeds of aſh-trees. Dict. Ruſt. in voc.

KID, in zoology, the Engliſh name of the young of goats. See the article GOAT, *Suppl.*

KIDNEYS *(Cycl.)* — The lymphatic veſſels of the *Kidneys* appear upon blowing by the ureter into the pelvis of the *Kidney*. See Hiſt. de l'Acad. des Sciences, 1733.

KIDNEY-*bean-tree*, the name by which ſome call the *Glycine*. See the article GLYCINE, *Suppl.*

KIDNEY-*wort*, in botany, a name promiſcuouſly uſed for two diſtinct genuſes of plants, called by botaniſts *Geum*, and *Cotyledon*. See the articles GEUM and COTYLEDON, *Suppl.*

KILLOS, a name given by the miners of Cornwall to a ſtone of the ſlate kind, found in the mines there. See the article GROWAN, *Suppl.*

KINE, in zoology. See the articles COW and BO, *Suppl.*

KING-*fiſher*, the Engliſh name of a genus of birds, called by zoologiſts *Iſpida*. See the article ISPIDA, *Suppl.*

KING's-*ſpear*, a name ſometimes uſed for the *Aſphodelus* of botaniſts. See the article ASPHODELUS, *Suppl.*

KINKS, in the ſea language. When ropes are new, or too hard laid, they are apt in folding, to make turns, which are called *Kinks*. *Blanckley*, Nav. Expoſ. p. 16.

KIPE, a kind of oſier baſket, wide in the middle, and narrow at both ends, uſed for taking fiſh. Ruſt. Dict. in voc.

KIPE is alſo the name of a game, which conſiſts in throwing ſomething into a hole, called the *Kipe*-hole.

KIRTLE, a term uſed for a ſhort jacket; alſo for a quantity of flax, about an hundred weight. Ruſt. Dict. in voc.

KITE, in ornithology, the Engliſh name of a bird of the hawk-kind, with a brown body, and a white head; its tail is forked, and the wings are immoderately long and large, meaſuring nearly three times the length of the body. See the article MILVUS, *Suppl.*

KLEINIA, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: The cup is cylindric, and covered with ſquamæ; the compound flower is tubuloſe; the proper one infundibuliform, inſenſibly terminating in a tube; the ſtamina are five very ſhort capillary filaments; the antheræ are cylindraceo-tubuloſe; the germen of the piſtil is coronated; the ſtyle is filiform, and of the length of the ſtamina; the ſtigmata are two, oblong, and revolute. There is no pericarpium. The ſeeds are ſolitary, oblong, and covered with very long capillary down. The receptacle is naked, plane, and punctated. *Linnæi* Gen. Plant. p. 394.

Linnæus queries whether this genus be not the ſame with the *Tithymaloides* of Tournefort. See the article TITHYMALOIDES, *Suppl.*

KNAG, a term uſed by country people for a knot in wood; alſo for the branches which grow out in the hart's-horns, near the forehead. Ruſt. Dict. in voc.

KNEE-*holm*, or KNEE-*holly*, the name by which ſome call the *Ruſcus*, or Butcher's-broom. See the article RUSCUS, *Suppl.*

KNIGHT's *Croſs*, a name ſometimes uſed for the *Lychnis*, a diſtinct genus of plants. See the article LYCHNIS, *Suppl.*

KNOLL, a term uſed in many parts of the kingdom for the top of a ſmall hill, or for the hill itſelf. Ruſt. Dict. in voc.

KNOT-*berries*, in botany, the name by which ſome call the *Rubus*. See the article RUBUS, *Suppl.*

KNOT-*graſs*. *(Suppl.)*—*Mountain* KNOT-*graſs*, or *ſingle* KNOT-*graſs*, the name ſometimes given to a diſtinct genus of plants, called by botaniſts *Paronychia*. See the article PARONYCHIA, *Suppl.*

L.

LABURNUM, in botany, the name uſed by Rivinus, for the cytiſus of other botaniſts. See the article CYTISUS, *Suppl.*

LACRYMA *Jobi*, in botany, the name of a genus of plants, the characters of which are theſe: The male flowers are formed into a lax ſpike; the female ones are fewer in number, and are ſituate at the baſe of the male ſpike on the ſame plant. In the male flowers the cup is a glume, containing two flowers, and has no awns; the corolla is alſo a glume, without any ariſtæ or awns. The ſtamina are three capillary filaments; the antheræ are oblong, and quadragonal. In the female flowers, the cup is alſo a glume, containing two flowers, as is the corolla, both being without any awns. The germen of the piſtil is of an oval form; the ſtyle is ſhort, and divided into two parts. The ſtigmata are two in number, corniculated, and longer than the flower. The ſeed, which is ſingle and roundiſh, is covered by the indurated cup. Vid. *Linnæi* Gen. Plant. p. 445.

LADDER *to heaven*, the name by which ſome call the *Polygonatum*, a diſtinct genus of plants. See the article POLYGONATUM, *Suppl.*

LADIES *bed-ſtraw*, in botany, the Engliſh name of a diſtinct genus of plants, called by botaniſts *Gallium*. See the article GALLIUM, *Suppl.*

LADIES *bower*, or *Virgin's bower*, names given to a diſtinct genus of plants, called by botaniſts *Clematitis*. See the article VIRGIN'S *bower*, *Suppl.*

LADIES *comb*, or VENUS'S *comb*, in botany, the name of a diſtinct genus of plants, called by botaniſts *Scandix*. See the article SCANDIX, *Suppl.*

LADLE *(Suppl.)* — LADLE-*boards*, thoſe boards diſpoſed on the circumference of the water-wheels of over-ſhot mills; forming hollows, or receptacles not unlike ladles to receive the water that falls upon the wheel. See the article *Water*-WHEEL, *Append.*

LADIES *finger*, the name by which ſome call a ſpecies of *Vulneraria*. See the article VULNERARIA, *Suppl.*

LADIES *mantle*, in botany, the name of a genus of plants, known among authors by that of *Alchimilla*. See the article ALCHIMILLA, *Suppl.*

LADIES *ſeal*, a name ſometimes given to a diſtinct genus of plants, called by botaniſts *Tamnus*. See the article TAMNUS, *Suppl.*

LADIES *traces*, a name ſometimes uſed for the *Orchis*, a diſtinct genus of plants. See the article ORCHIS, *Suppl.*

LADY *cow*, the Engliſh name of a genus of beetles, called by ſome *Hemiſphæria*. See the articles SCARABÆUS, *Suppl.* and HEMISPHÆRIA, *Append.*

LAKE-*weed*, in botany, a name ſometimes uſed for the *Perſicaria*, or arſmart. See the article PERSICARIA, *Suppl.*

LAMB'S *Lettuce*, a name by which ſome call the *Valerianella*, a diſtinct genus of plants. See the article VALERIANELLA, *Suppl.*

LAMPADIAS is uſed by ſome authors for a kind of bearded comet, which, as they pretend, reſembles a burning lamp, being of ſeveral ſhapes; its flame or blaze tapering upward ſometimes like unto a ſword, and being at others double or triple pointed.

LANIARDS. See the article LANNIERS, *Suppl.*

LANIO, in ornithology, the name uſed by Linnæus for the butcher-bird. See the article LANIUS, *Suppl.*

LANNAR, in ornithology, a bird of the hawk-kind. See the article LANNARIUS, *Suppl.*

LANYARDS. See the article LANNIERS, *Suppl.*

LAPIS *Calaminaris*, in natural hiſtory. See the article CALAMINARIS *Lapis*, *Suppl.*

LAPPA, in botany, a name uſed by ſome for the *Xanthium*, or burdock. See the article XANTHIUM, *Suppl.*

LAPWING, in ornithology, the Engliſh name of the black-breaſted *Tringa*, with a hanging creſt. See the article TRINGA, *Suppl.*

Were the *Lapwing* leſs common, it would be highly eſteemed for its beauty. It is very frequent in our fenny countries, and in the wet places of moſt other parts of Europe.

Authors have deſcribed it under the names *Vanellus*, *Capra*, and *Capella*. See the article CAPELLA, *Suppl.*

LARCH-*tree*, in botany, the Engliſh name of a diſtinct genus of plants, called by botaniſts *Larix*. See the article LARIX, *Suppl.*

LASER-*wort*, in botany, the name of a diſtinct genus of plants, See the article LASERPITIUM, *Suppl.*

LASK, a term uſed by farriers for a looſeneſs in horſes, frequently fatal to them. Ruſt. Dict. in voc.

LATCHETS, the ſame with *Laſkets*. See the article LASKETS, *Suppl.*

LATHYRUS is alſo a name uſed by ſome for the *Niſſolia* of others. See the articles LATHYRUS and NISSOLIA, *Suppl.*

LAVENDER, the Engliſh name of a diſtinct genus of plants, called by authors *Lavendula*. See the article LAVENDULA, *Suppl.*

Cotton LAVENDER, the name by which ſome call the *Santolina* of botaniſts, a diſtinct genus of plants. See the article SANTOLINA, *Suppl.*

French LAVENDER, a name ſometimes given to a diſtinct genus of plants, called by authors *Stoechas*. See the article STOECHAS, *Append.*

Hollow-leaved Sea LAVENDER, a name ſometimes uſed for a ſpecies of *Sarracena*. See the article SARRACENA, *Suppl.*

Sea LAVENDER, the Engliſh name of a diſtinct genus of plants, known among botaniſts by that of LIMONIUM. See the article LIMONIUM, *Suppl.*

LAVER, in botany, the Engliſh name of a genus of plants, called by botaniſts *Tremella*. See the article TREMELLA, *Suppl.*

LAUREL, *Laurus*, in botany, the name given by Linnæus to a large genus of plants. See the article LAURUS, *Append.*

Alexandrian LAUREL, a name ſometimes given to the *Ruſcus*, or butcher's broom. See the article RUSCUS, *Suppl.*

Dwarf LAUREL, or *ſpurge* LAUREL, names ſometimes given to the *Thymelæa* of botaniſts. See the article THYMELÆA, *Suppl.*

Portugal LAUREL, the name of a diſtinct genus of plants, called by authors *Padus*, or *Lauro-Ceraſus*. See the article LAURO-*Ceraſus*, *Suppl.*

Sea-ſide LAUREL, a name ſometimes given to the *Phyllanthus*, a diſtinct genus of plants. See the article PHYLLANTHUS, *Suppl.*

LAUROTAXA, in botany. See the article RUSCUS, *Suppl.*

LAURUS, in the Linnæan ſyſtem of botany, the name of a large genus of plants, comprehending the *Laurus*, or common bay-tree, of Tournefort; the *Cinnamon-tree*, the *Camphor-tree*, and the *Perſea*, *Borbonia*, *Benzoe*, and *Saſſafraſs* of others.

The characters of this genus are theſe: There is no calyx, the corolla much reſembles a calyx, and has been miſtaken for one; it conſiſts of ſix erect, hollow, ovo-acuminated petals, alternately exterior; the nectarium is compoſed of three coloured, acuminated turbercles, terminating each in two hairs, and ſtanding round the germen; the ſtamina are nine filaments, ſhorter than the corolla, compreſſed, obtuſe, and placed in threes; the antheræ adhere to the edge of the upper part of the filaments on each ſide; and there are two globoſe corpuſcles, affixed, by a very ſhort filament, to each of the ſtamina of the inner ſeries, near the baſe; the germen is oval; the ſtyle is ſimple, equal, and of the length of the ſtamina; the ſtigma is obtuſe and oblique; the fruit is a drupe of an oval, acuminated figure, containing only one cell, and contained in the corolla; the ſeed is a ſingle ovato-acuminated nut; its kernel is of the ſame ſhape.

The greater number of the ſpecies of this genus, as the cinnamon-tree, camphor-tree, &c. are of the hermaphrodite kind; but ſome, as the common bay, have the male flowers on ſeparate trees: In this caſe the ſtamina vary in number from eight to fourteen, and the corolla is naked, and divided into four parts. The little bodies adhering to ſome of the filaments, are the great characteriſtics of the genus. Vid. *Linnæi* Gen. Plant. p. 174.

LAURUSTINE, the Engliſh name of a genus of plants, known among authors by that of *Tinus*. See the article TINUS, *Suppl.*

LAW-*Day*, *Lagedayum*, in our old Law-writers, was any day of open court, and commonly uſed for the courts of a county or hundred. It is alſo called *View of frank-pledge*, or *Court-leet*. — *Et quieti ſint de Sectis Comitatuum & Hundredorum noſtrorum, de viſu franci plegii & Lawdayorum*, &c. Chart. 39. H. 3. *Terms of law.*

LAYR. See the article LAIR, *Cycl.*

LAYES, or LEYES, a term uſed in many parts of England, for ſuch paſture ground, as formerly had been tilled and ſown. Ruſt. Dict. in voc.

LAZEROLE, in botany, a name uſed for ſeveral ſpecies of medlar. See the articles MESPILUS and MEDLAR. *Suppl.*

LEAM, or LIAM, among ſportſmen, the line for holding a hawk or dog, more uſually called a Leaſh. See the article LEASH, *Cycl.*

LEDGERS, among builders. See the article PUTLOGS, *Cycl.*

LEE *(Suppl.)* — LEE-*ſangs* are ropes reeved into the cringles of a yacht's or hoy's ſails. *Blankley*'s Naval Expoſitor, p. 93.

LEECH, the ſame with LEETCH. See the article LEETCH, *Suppl.*

LEEK *(Suppl.)* — *Houſe*-LEEK, the Engliſh name of a genus of plants, called by botanical writers *Sedum*. See the article SEDUM, *Suppl.*

LEMNA, *Duckweed*, in the Linnæan ſyſtem of botany, the name of a genus of plants, called by others LENTICULA and HYDROPHACE.

The characters of it are theſe: It produces diſtinct hermaphrodite and female flowers on the ſame plant. In the hermaphrodite flowers the cup is monophyllous, of a roundiſh figure, and opens ſidewiſe; it is dilated obliquely outwards, and is large, expanded, obtuſe, and not divided at the edges. There is no corolla; but in this calyx there ſtands two ſubulated, crooked filaments, of the length of the cup, and on theſe double globoſe antheræ. In the female flower there is no corolla; the calyx is the ſame as in the other. The germen of the piſtil is of an oval form; the ſtyle is ſhort and permanent, the ſtigma ſimple. The fruit is a rounded capſule, but terminating in a point, and contains only a ſingle cavity; in which are lodged a ſmall number of ſeeds, of an oblong figure, pointed at each end, and ſtriated on one ſide. Vid. *Linnæi* Gen. Plant. p. 508.

The ſpecies of *Lemna* enumerated by authors are theſe. 1. The roundiſh leaved, ſingle rooted *Duck-weed*. 2. The ſingle rooted *Lemna*, with oblong leaves. 3. The many rooted, broad, oval leaved *Duck-weed*. 4. The ſingle rooted, oval leaved *Lemna*. 5. The oval leaved *Lemna* with no root. 6. The ramoſe, pediculated *Lemna*, with oblong leaves. Vid. *Hill*'s Hiſt. Plant. p. 128.

Beſides theſe ſix diſtinct ſpecies of *Lemna*, there are two varieties that may eaſily be miſtaken for diſtinct ſpecies alſo: theſe are a very ſmall, oblong, and thick leaved kind; and a larger, roundiſh, and thin leaved one.

The common *Lemna* is recommended, as a refrigerant, and reſtringent; and Bates tells us of a wonderful cure performed by an infuſion of it in wine, in an obſtinate jaundice. Id. ibid. p. 130.

LEMON-*tree*, *Limon*, in botany. See the article LIMON, *Suppl.*

The culture of the *Lemon-tree* is much the ſame with that of the Orange-tree. See the article ORANGE, *Suppl.*

However, it is proper to obſerve, that the common *Lemons* are ſomewhat hardier than the orange, and require a greater ſhare of freſh air in winter, for which reaſon they ſhould be placed nearer to the doors or windows of the green-houſe. Another difference likewiſe deſerves to be mentioned; and that is, that the *Lemons* require to be more plentifully watered than the orange. But as to the tender kinds of *Lemons*, they muſt be treated with more care. *Miller*, Gard. Dict.

Water-LEMON, a name ſometimes given to the *Granadilla*, or paſſion flower. See the article GRANADILLA, *Suppl.*

LENTIL, in botany, the Engliſh name of a diſtinct genus of plants, called by botanical writers, *Lens*. See the article LENS, *Suppl.*

Lentils make excellent ſweet fodder; and are therefore to be preferred to all other kinds for calves and other young cattle. They likewiſe are the beſt as well as cheapeſt food for pidgeons. Ruſt. Dict. in voc.

Peruvian-LENTISK, the name ſometimes given to the *Molle* of botanical authors. See the article MOLLE, *Suppl.*

LEOPARD, in zoology, the Engliſh name of the long-tailed *Felis*, with the upper ſpots round, and the lower ones virgated. See the article FELIS, *Suppl.*

LEPRAS, in ichthyography. See the article TURDUS, *Suppl.*

LEPROSY *(Cycl.)* — The leſſer degrees of *Leproſy* are frequently confounded with the ſcurvy, and even itch; from which, however, it may be diſtinguiſhed by the hardneſs of the ſkin in one or more parts of the body, attended with a dry ſcurf, ſometimes oozing puſtules, or dry ſcabs, and always with ſome degree of itching; whereas the true ſcorbutic ſpots are of a livid colour, not commonly ſcurfy or raiſed above the ſkin, and are attended with manifeſt ſigns of a lax ſtate of the fibres, and corruption of the blood. For a real ſcurvy imports a flow, but general reſolution or putrefaction of the whole frame; whereas the ſcabies, impetigo, or leproſy may be found to affect thoſe of a very different conſtitution. *Pringle*, Obſerv. on Diſeaſ. of the Army, p. 306.

This diſorder is ſo far from being curable by externals only, that it is ſometimes dangerous to attempt to remove the ſcurfs of *leprous* people in that manner. On the contrary, it is neceſſary to change the humours, by a ſpare diet, exerciſe, alterative mercurials, or frequent purges of the ſaline kind. Id. ibid.

Dr. Mead recommends the Tincture of Cantharides in this diſtemper. *De morbis biblicis*.

LEPTURA, in the hiſtory of inſects, the name of a genus of four-winged flies, the antennæ of which are oblong, ſlender, and ſetaceous; the exterior wings are truncated at their extremity, and the thorax is of a ſubcylindric figure. *Hill*, Hiſt. Anim. p. 46.

Theſe flies have been, by the generality of authors, reckoned among the beetles. See the article SCARABÆUS, *Suppl.*

LEPTURUS, the name is of Greek origin, and is form'd of the λεπτος ſlender, and ουρα a tail; expreſſing that this fiſh has a very long and ſlender tail.

LEPUS *Marinus*, a name uſed by many authors for the *Lernea*. See the article LERNEA, *Append.*

LERNEA, in zoology, the name of a genus of naked inſects. Its body is of an oblong, cylindric figure, from one to two inches long; and is perforated in the forehead; the tentacula reſemble ears.

It is found on rocks waſhed by the ſea, and even on the ſides of the bream, carp, and roach, in many of our ponds and rivers.

Authors have called it *Lepus marinus*, the ſea-hare; of which they enumerate a great many ſpecies. *Hill*, Hiſt. Anim. p. 88.

LESSES, a term uſed by ſportſmen for the dung of a wild boar, bear, or wolf. Ruſt. Dict. in voc.

LETTUCE — *(Suppl.)* *Lamb*'s LETTUCE, in botany, the name of a genus of plants, called by botaniſts *Valerianella*. See the article VALERIANELLA, *Suppl.*

Wild-LETTUCE, a name ſometimes given to the *Prenanthes*. a diſtinct genus of plants. See the article PRENANTHES, *Suppl.*

LEUCO-*Narciſſo-lirion*, a name uſed by *Lobel*, for the plant called by Linnæus *Galanthus*, and comprehended by Tournefort among the *Narciſſo-Leucoiums*. See the article NARCISSO-*Leucoium*, *Suppl.*

LEUCOIUM *bulboſum*, a name ſometimes given to a ſpecies of *Narciſſo-Leucoium*, according to Tournefort, but made a diſtinct genus by Linnæus, under the name *Galanthus*. See the article NARCISSO-*Leucoium*, *Suppl.*

LEUCORHOEA. See the article FLUOR *Albus*, *Suppl.*

LIBELLULA, in zoology, the name of a genus of two winged flies, the mouth of which is furniſhed with jaws, the antennæ ſhort, and the tail terminated by a kind of forceps.

The ſpecies of this genus are very numerous, ſome carrying their wings erect when they ſit, and others horizontally. Vid. *Hill*, Hiſt. Anim. p. 73.

LICE *of trees*. See the article APHIS, *Append.*

LIFE *(Suppl.)* — *Annuity for* LIFE. Dr. Halley's Table of the values annuities for lives for different ages, inſerted in the Cyclopædia, under ANNUITY, was computed at a high rate of intereſt, and coincides nearly with Mr. De Moivre's Tables at 6 per Cent; but as intereſt is now much fallen, it may be proper here to ſhew the values of ſuch Annuities, when intereſt is eſtimated at 3, 3½, 4, and 5 per Cent.

Value of an Annuity for life of 1 £. Intereſt being,

The columns marked 3 per Ct. &c. ſhew the values of annuities for LIFE in years purchaſe, and decimals of a year; thus an annuity for LIFE at 3 per Ct. for an age of 56, will be 10. 90. that is worth 10 $\frac{9}{10}$ years purchaſe.

Dr. Halley alſo publiſhed a Table [a] for eſtimating the probabilities of life, grounded on the Breſlau Bills of Mortality; and the values of annuities for *life* have been commonly determined from this Table, and from the rate of intereſt. See *De Moivre*, Doct. of Chances, p. 211, ſeq.

We ſhall here inſert Dr. Halley's Table, divided into ſeveral columns, ſhewing alternately the age, and the number of perſons living of that age.—[[a] Philoſ. Tranſ. N° 196. Lowthorp's Abridg. Vol. III. p. 671.]

Age	Perſons	Age	Perſons	Age	Perſons	Age	Perſons
1	1000	22	586	43	417	64	202
2	855	23	579	44	407	65	192
3	798	24	573	45	397	66	182
4	760	25	567	46	387	67	172
5	732	26	560	47	377	68	162
6	710	27	553	48	367	69	152
7	692	28	546	49	357	70	142
8	680	29	539	50	346	71	131
9	670	30	531	51	335	72	120
10	661	31	523	52	324	73	109
11	653	32	515	53	313	74	98
12	646	33	507	54	302	75	88
13	640	34	499	55	292	76	78
14	634	35	490	56	282	77	68
15	628	36	481	57	272	78	58
16	622	37	472	58	262	79	49
17	616	38	463	59	252	80	41
18	610	39	454	60	242	81	34
19	604	40	445	61	232	82	28
20	598	41	436	62	222	83	23
21	592	42	427	63	212	84	20

By the help of this table we may find what the reſpective probabilities are for a man of a certain age, 30, for inſtance, living 1, 2, 3, 4, &c. years. Thus, look for the number 30 in one of the columns of age; then over-againſt that number in the next adjacent column on the right hand, you will find 531, under which are written 523, 515, 507, 499, &c. each correſponding, reſpectively, to the numbers written in the column of age; the meaning of which is, that out of 531 perſons living of the age of 30, there remain but 523, 515, 507, 499, &c. that attain the reſpective ages of 31, 32, 33, 34, &c. and who conſequently do from that term of 30, live 1, 2, 3, 4, &c. years reſpectively.

Hence ſuppoſing the quantities A, B, C, D, E, &c. to repreſent reſpectively the perſons living at a given age, and the ſubſequent years, it is evident, that there being A perſons of the age given, and one year after B perſons remaining, the probability which the perſon of the given age has to continue in life, for one year, is meaſured by the fraction $\frac{B}{A}$ and that the probability which he has to continue in life for two years, is meaſured by the fraction $\frac{C}{A}$ and ſo on. Therefore, if money bore no intereſt, it would be ſufficient to multiply thoſe probabilities by the ſum to be received annually, and the ſum of the products would expreſs the preſent value of the annuity. But as money bears intereſt, all thoſe values muſt be properly diſcounted at compound intereſt according to a given rate, and the new reſulting value will be the true value of an annuity for a given life at a given rate of intereſt.

Mr. De Moivre obſerved, that in Dr. Halley's Table the probabilities of life decreaſed nearly in an arithmetic progreſſion, when conſidered from a term given, and hence he found an eaſy rule for the value of an annuity on a life of a given age. His rule is, $\frac{1 - \frac{r}{n} P}{r - 1}$ where P repreſents the value of an annuity certain of 1 £ for as many years as are intercepted between the age given, and the extremity of old age, ſuppoſed at 86, and that interval of life is expreſſed by n. r ſtands for the amount of the principal and intereſt of 1 £ in one year.

The rule, therefore, in words at length, will be, Take the value of an annuity certain for ſo many years as are denoted by the complement of life; multiply this value by the rate of intereſt, and divide the product by the complement of life; then let the quotient be ſubtracted from 1, and let the remainder be divided by the intereſt of 1 £; then this laſt quotient will expreſs the value of an annuity for an age given. See *Complement* of LIFE, *infra*.

Thus ſuppoſe it were required to find the preſent value of an annuity of 1 £ for an age of 50, intereſt being at 5 per cent. The complement of life being 36; let the value of an annuity certain, according to the given rate of intereſt, be taken from the tables of ſuch annuities [a], and this value will be found to be 16.5468. Let this value be multiplied by the rate of intereſt 1. 05; the product will be 17. 3741. Let this product be divided by the complement of life, that is, in this caſe, by 36, the quotient will be 0. 04826; ſubtract this quotient from unity, the remainder will be 0.5174. Laſtly, divide this quotient by the intereſt of 1 £; that is, in the preſent caſe, 0. 05, and the new quotient will be 10. 35, which will expreſs the value of an annuity of 1 £ to continue during a life of 50, or, in other words, how many years purchaſe a life of 50 is worth [b].—[[a] See *Dodſon*'s Calculator, p. 11.—[b] *De Moivre*'s Annuit. Probl. I. and Doctr. of Chances, p. 213, ſeqq.

The following queſtions being of frequent uſe, we have here inſerted them, with the rules for their ſolution.

I. The values of two ſingle lives being given, to find the value of an annuity granted for the time of their joint continuance; or, the value of two ſingle lives being given, to find the value of the joint lives.

Multiply together the values of the two lives, and reſerve the product. Let that product be again multiplied by the intereſt of 1 £; and let that new product be ſubtracted from the ſum of the values of the lives, and reſerve the remainder. Divide the firſt quantity reſerved by the ſecond, and the quotient will expreſs the value of the two joint lives.

Thus ſuppoſing one life of 40 years of age, the other of 50, and intereſt at 5 per Cent; the value of the firſt life will be found in the tables to be 11. 83; the value of the ſecond 10. 35; and the product will be 122. 4405, which product muſt be reſerved. Multiply this again by the intereſt of 1 £; that is, by 0. 05, and this new product will be 6. 122025. which being ſubtracted from the ſum of the lives, or 22. 18, the remainder will be 16. 057975, and this is the ſecond quantity reſerved. Now dividing the firſt quantity reſerved by the ſecond, the quotient will be 7. 62 nearly; and this expreſſes the values of the two *joint lives*.

II. The values of two ſingle lives being given, to find the value of an annuity upon the longeſt of them; that is, of an annuity to continue ſo long as either of them is in being.

From the ſum of the values of the joint lives, ſubtract the value of the joint lives, and the remainder will be the value of the longeſt.

Suppoſe for inſtance, two lives, one worth 13 years purchaſe, the other 14, and intereſt at 4 per Cent. The ſum of the values of the lives is 27; the value of the two joint lives by the rule before given is 9. 23; and ſubtracting 9. 23 from 27, the remainder 17. 77 is the value of the longeſt of the two lives.

III. The values of three ſingle lives being given, to find the value of an annuity upon the longeſt of them:

Take the ſum of the three ſingle lives, from which ſum ſubtract the ſum of all the joint lives combined two and two; then to the remainder add the value of the three joint lives, and the reſult will be the value of the longeſt of he three lives.

Thus ſuppoſing the ſingle lives to be 13, 14, and 15 years purchaſe, the ſum of the values will be 42; the values of the firſt and ſecond joint lives are 9. 24; of the firſt and third 9. 65; of the ſecond and third 10. 18; the ſum of all which is 29. 06; which being ſubtracted from the ſum of the lives, that is, from 42, the remainder will be 12. 94; to which adding the value of the three joint lives 7. 41, the ſum 20. 35, will be the value of the longeſt of the three joint lives.

IV. To find the preſent value of a remainder in fee, after a life of a given age. That is, ſuppoſing A to be in poſſeſſion of an annuity for his life; and that B after the deceaſe of A, is to have the annuity for him and his heirs for ever, to find the preſent value of the remainder; or, as ſome call it, the reverſion.

From

From the value of the fee ſimple or perpetuity, ſubtract the value of the *life* in poſſeſſion; what remains will be the value of the reverſion.

Thus ſuppoſing that A is 60 years of age; an annuity upon his *life*, intereſt at 5 per Cent. would be 8. 39; which being ſubtracted from the value of the fee, or perpetuity 20, the remainder will be 11. 61; which is the preſent value of the expectation of B.

By this rule the value of an eſtate ſubject to a jointure may be determined.

In like manner, ſuppoſing that C were to have an annuity for him and his heirs for ever, after the *lives* of A and B, then from the perpetuity or fee ſimple ſubtracting the value of the longeſt of the two *lives* A and B, the remainder will expreſs the value of C's expectation.

Thus, ſuppoſing the ages of A to be 40, and of B to be 50, the value of an annuity upon the longeſt of theſe two *lives* would be found by the foregoing rule to be 14. 56: and this being ſubtracted from the perpetuity 20, the remainder is 5. 44; which is the value of C's expectation.

V. To find the value of an annuity for *life*, after another annuity for *life*.

Suppoſe for inſtance, that A is in poſſeſſion of an annuity for his *life*, and that B, after the *life* of A, is to have the annuity for his *life* only, and that his heir or repreſentative is to have nothing, in caſe A ſurvives B; what is the value of the *life* of B, after the *life* of A.

From the preſent value of the *life* of B, ſubtract the preſent value of the joint *lives* of B and A, and the remainder will be the value of B's expectation.

There are many other uſeful queſtions, the determinations of which depend on the values of annuities for *lives*, joint *lives*, and ſucceſſive *lives*; but it would lead us too far to inſert them here: We muſt therefore refer the reader to M. De Moivre's annuities on *lives*; eſpecially the fourth edition, which is more correct than the former. See alſo the Doctrine of Chances, page 211, 212, &c.

We think it proper to add, that Mr. Kerſeboom's Table of the value of annuities for *life*, does not agree entirely with thoſe of M. De Moivre, either at 3, or 3 ½ per Cent. intereſt. But as Mr. Kerſeboom ſeems to have taken great pains in his obſervations on the probabilities of *life*, it may be worth while here to inſert his Table.

Mr. Kerſeboom's table of annuities for *life*.

Let the annuity be 100 guilders a year upon a *life* under a year old.

	Guilds.	
Its preſent value is - - - - - -	1667	that is 6 per Ct.
Upon a *life* of 5 years to 1 incluſive, is	1869	- - 5. 35
10 - - 6 - -	1835	- - 5. 45
15 - - 11 - -	1770	- - 5. 65
20 - - 16 - -	1667	- - 6. 00
25 - - 21 - -	1587	- - 6. 30
30 - - 26 - -	1515	- - 6. 60
35 - - 31 - -	1429	- - 7. 00
40 - - 36 - -	1334	- - 7. 50
45 - - 41 - -	1212	- - 8. 25
50 - - 46 - -	1093	- - 9. 15
55 - - 51 - -	971	- - 10. 30
60 - - 56 - -	840	- - 11. 40
65 - - 61 - -	709	- - 14. 10
70 - - 66 - -	570	- - 17. 55

See Phil. Tranſ. N° 450. Sect. 15.

Monſieur de Parcieux has alſo given us many uſeful obſervations tending to determine the probability of the duration of the *life* of man. See Eſſai ſur les probabilités de la durée de la vie humaine, Paris, 1746. 4to.

According to this gentleman's eſtimate, the values of annuities for *life* are higher than thoſe of M. De Moivre's Tables. Thus ſuppoſing intereſt at 5 per Cent. Mr. De Parcieux eſtimates an annuity for *life* of 100 livres, according to the following table.

Table of the values of an annuity of 100 livres for *life*, according to Monſieur de Parcieux. Intereſt at 5 per Cent.

Age	Livres	Age	Livres	Age	Livres
3	1557	14	1602	25	1523
4	1582	15	1594	26	1516

54	1068	74	532	94	47
55	1045	75	506	95	00

Complement of LIFE, is uſed by Mr. De Moivre, for that time which remains from a given age to the extremity of old age, eſtimated by that author at 86 years. Annuit. on Lives, p. 14. Doctrine of Chances, p. 213, ſeq.

Thus, ſuppoſing an age of 50, the *Complement of life* will be 36; becauſe this number is the difference between 86 and 50.

Expectation of LIFE, is uſed by Mr. De Moivre, for the time which a perſon of a given age may juſtly expect to continue in being, that is when the chance for his living or dying becomes equal.

According to that gentleman's calculation, upon the ſuppoſition of an equal decrement of *life*, the *Expectation of life* would be expreſſed by $\frac{1}{2}n$, if n denotes the complement of *life*. Thus the *expectation of life* for a man of 50 years of age will be, $18=\frac{36}{2}$: That is, he had an equal chance, or of 1 to 1, of living 18 years. But if that interval be once attained, there ariſes a new expectation of $\frac{1}{4}n$; and afterwards of $\frac{1}{8}n$, &c. Annuities p. 65, 66.

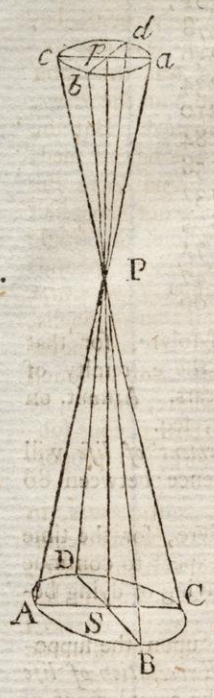
Hence he gives the ſolution of the following problem: To find the *expectation* of two joint *lives*, that is, the time which two *lives* may expect to continue together in being.

For this the rule is, from one half of the ſhorteſt complement ſubtract the ſixth part of its ſquare, divided by the greateſt complement, the remainder will expreſs the number of years ſought.

Thus ſuppoſing a *life* of 40, and another of 50; the ſhorteſt complement will be 36; the greateſt 46; ½ of the ſhorteſt will be 18; the ſquare of 36 is 1296, whereof the ſixth part is 216, which being divided by 46, the quotient will be $\frac{216}{46}$ = 4. 69; and this being ſubtracted from 18, the remainder 13. 31 will expreſs the number of years due to the two joint *lives*. As to the probability of one *Life*'s ſurviving others, ſee *de Moivre*, Annuit. p. 54. Doct. of Chances, p. 223.

Inſurance upon LIVES. The value of inſurances upon *Lives* depends upon the probability of the continuance of any propoſed *life* or *lives*, during any propoſed term. Any queſtions of this kind may be determined from Dr. Halley's Table, and from the principles of the Doctrine of Chances. But, as far as we can learn of the practice on ſuch occaſions, the premiums paid to inſurers are generally higher than any computation founded on obſervations concerning the probabilities of human *life*, will warrant. Thus it is not unuſual to make a perſon pay 5 per Cent. for the inſurance of his *life* for a twelvemonth, that is, in caſe the perſon dies within the year, the inſurer is to pay 100 *l.* for every 5 *l.* received. Now it appears from Dr. Halley's Table, which eſtimates the probability of *life* low enough, that 5 per Cent. is an adequate value only for a *life* of an advanc'd age, ſuch as 64.

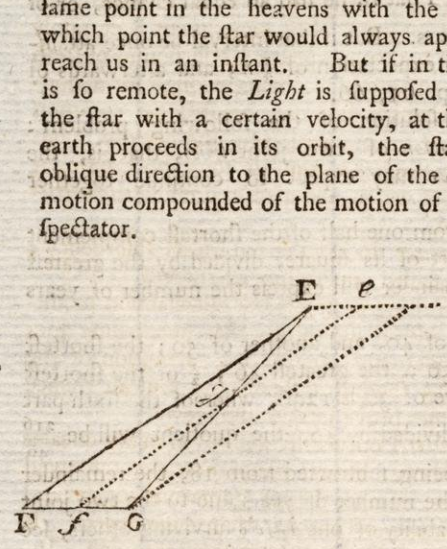
LIFE *everlaſting*, a name by which the *Elichryſum*, or *Gnaphalium*, of botanical writers, is ſometimes called. See the article GNAPHALIUM, *Suppl.*



LIGHT *(Cycl.)* — The motion of *Light* was deduced from the obſervations of an apparent inequality in the times of the eclipſes of the ſatellites of Jupiter, by Mr. Romer [a]; but the concluſion was attacked by Monſieur Caſſini. Mr. Romer's opinion found an able advocate in Dr. Halley [b]; who removed Caſſini's difficulty, and left Mr. Romer's concluſion in itsfull force. In the year 1707, Monſieur Maraldi endeavour'd to give a new ſtrength to Caſſini's arguments; but Monſieur Romer's doctrine found a new defender in Mr. Pound [c]. — [[a] See Phil. Tranſ. N° 136. Lowthorp's Abridg. Vol. I. p. 409. [b] Phil. Tranſ. abr. by Lowth. Vol. I. p. 409, 422. [c] 'sGrav. Phyſ. Elem. N° 2636, ſeqq.]

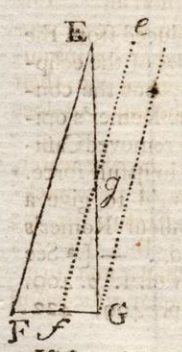
Mr. Romer's deduction from his theory was, that *Light* ſpent about eleven minutes in its paſſage from the ſun to us; but it hath ſince been concluded by others, from the like eclipſes of Jupiter's ſatellites, that it is propagated as far in about ſeven minutes. — [[b] Phil. Tranſ. N° 406, *'sGraveſande*, Phyſ. Elem. N 2638.]

Our excellent aſtronomer, Dr. Bradley, has found nearly the ſame velocity of *Light*, from his accurate obſervations, and moſt ingenious theory, to account for ſome apparent motions in the fixed ſtars. Phil. Tranſ. N° 406. See the article STAR, *Suppl.*



To underſtand this, it muſt be premiſed, that the fixed ſtars are luminous bodies, and at reſt, with reſpect to our planetary ſyſtem, from which they are vaſtly remote. In this ſyſtem alſo the earth is conſidered as one of the planets, and moving about the ſun.

Fig. 1.



Suppoſe the ſun repreſented in S, (Fig. 1.) and that the circle A B C D repreſents the path of the earth, or the ecliptic. At the center S ſuppoſe a perpendicular S P raiſed to the plane of the ecliptic, and that this perpendicular paſſes thro' any fixed ſtar. If a ſpectator were placed in S, he would ſee the ſtar in the ſame perpendicular; but if the ſpectator paſſes over the circle A B C D, the diameter of which is ſuppoſed to bear a ſenſible, tho' ſmall proportion to the diſtance of the ſtar, it will be perceived to change its ſituation in the heavens. For a ſpectator in A would ſee the ſtar in the line A P *a*; in C he would ſee the ſame ſtar in the line C P *c*; and ſo in any other point of his progreſs: Whence it follows, that the ſtar would ſeem to deſcribe a circle in the heavens repreſented by *a b c d*. If the diſtance of the ſtar was ſo very great, that in reſpect of it the diameter of the earth's orbit A C might be eſteemed a point; in this caſe, the foreſaid circle would be entirely inſenſible; all the lines drawn from the points of the orbit to the ſtar might paſs for perpendiculars to the plane of the ecliptic, and in appearance would correſpond to the ſame point in the heavens with the perpendicular in S, in which point the ſtar would always appear, if its light would reach us in an inſtant. But if in this caſe, where the ſtar is ſo remote, the *Light* is ſuppoſed to be propagated from the ſtar with a certain velocity, at the ſame time that the earth proceeds in its orbit, the ſtar will be ſeen in an oblique direction to the plane of the orbit; becauſe of the motion compounded of the motion of *Light*, and that of the ſpectator.

Fig. 2.

Suppoſe the *Light* to move in the line E G (Fig. 2.) making an angle with the line F G, in which the ſpectator is carried along; whom we ſhall conceive placed in F. Let the velocity of the ſpectator be to the velocity of the *Light*, as F G to E G. While the ſpectator moves along F G, the *Light* does the ſame along E G; and the particle of *Light*, which is in E, when the ſpectator is in F, enters the eye only when he arrives at G. Now the direction of the *Light*, with reſpect to the eye, makes with the line F G the angle E F G. For if we conceive the line F E drawn, and to be carried with a parallel motion along with the eye, ſo that in reſpect thereof it be at reſt, while this continues moving, the *Light* will reach the eye in the direction of the ſaid line; for when the eye ſhall be in *f*, the middle point between F and G, the transferred line will cut E G in its middle point *g*, to which the particle of *Light* has reached, and which is likewiſe the middle point of the transferred line *f e*. Wherefore the particle of *Light*, which was in E, in the extremity of the line E F, arrives at, and will enter the eye in the direction *e g*.

Fig. 3.

Let the angle E G F (Fig. 3.) be a right one, and E G to F G as the velocity of the *Light* to the velocity of the earth in its orbit; then E F G will be the angle, which the ray of *Light* entering the eye, makes with the plane in which the earth moves round the ſun.

If the earth be in B, (Fig. 4.) it moves in the direction of the tangent to its orbit in this point; that is, if we ſuppoſe the ſpectator in the ſun, the direction of the earth's motion is parallel to S C; and making the angle *a* S C equal to the angle E G F, in the former figure, the line S *a* will repreſent the line in which the ſpectator would ſee the ſtar.

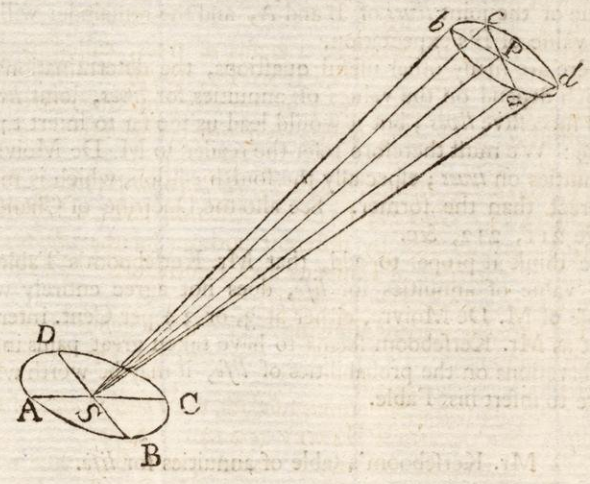


Fig. 4.

In the ſame manner when the earth is in D, the ſpectator in the ſun will ſee the ſtar in S *c*, the angles P S *c* and P S *a* being equal; and this line S *a* or S *c*, by its revolution about P S, would deſcribe a cone, whoſe baſe in the heavens would be a circle repreſenting the apparent path of the ſtar thro' a whole year: Let us ſuppoſe this circle to be *a b c d*, as in the annexed figure.

When the ſtar is not in the perpendicular to the plane of the ecliptic, but the line P S (Fig. 5.) is inclined to that plane, the lines which determine the apparent motion of the ſtar in the heavens, will form cones, as in the caſes already explained; only they would be oblique, and in both caſes the apparent path of the ſtar in the heavens would be determined as above; but in this laſt caſe it would be an ellipſis, the greater diameter of which would be equal to the diameter of the circle *a b c d*, of the former figures; ſo that knowing this ellipſis, the circle might eaſily be found, which the ſtar would deſcribe, if placed in the perpendicular to the plane of the ecliptic.

Fig. 5.

The only way to determine, whether the ſtars deſcribe ſuch ellipſes, is by obſervations; in making which there are great difficulties, which however Mr. Bradley has with incomparable induſtry ſurmounted.

Nothing can immediately be determined concerning the foreſaid elliptic motion. The diſtance of the ſtar from the pole of the world muſt be meaſured at different times of the year; and from the different diſtances, the elliptic motion is to be determined by calculation, allowing for the motion of the pole itſelf during the ſpace of time between the obſervations; for the pole moves in a leſſer circle, one degree of which it paſſes over in ſeventy years. Mr. Bradley, making all neceſſary allowances, obſerved ſeveral ſtars at different times of the year, whereby he immediately diſcovered, that their diſtances from the pole of the world varied; and was convinced that this variation could not be attributed to the nutation of the pole; for he examined two ſtars at equal diſtances from the pole, but ſo oppoſite, that the one ought to have receded from the pole as much as the other acceded to it, if the motion was in the pole itſelf. But this did not fall out ſo; for the change of the one ſtar was double of that of the other; a proper allowance being always made for the pole's motion ariſing from above the revolution. However this indefatigable obſerver inferr'd from his obſervations, that the ſtars in certain times receded from, and acceded to, the pole of the world with a motion entirely analogous to that which is performed in an ellipſis; and alſo that they move in ſuch curves, for each of which the motion in the ſame little circle, as *a b c d*, (Fig. 5.) anſwers, when the ſtars are referred to the perpendicular in S to the plane of the ecliptic; and the diameter of this minute circle for them all is $40'' \frac{1}{2}$.

It is plain from obſervations, to which of the abovementioned cauſes we are to aſcribe the motion of the ſtar. For if the firſt takes place, the ſtar would be carried from *a* to *c*, while the earth paſſed over the part A B C of its orbit; but this being contrary to obſervation, this cannot be the true cauſe. But this change in the ſituation of the ſtar takes place according to the obſervations, while the earth deſcribes the part B C D of its orbit, which is juſt what the ſecond cauſe requires.

If both the cauſes took place at the ſame time, the arc, deſcribed by the earth, would differ from that indicated by either of them; beſides, this concurrence of the cauſes is contrary to the obſervations; unleſs perhaps it may be thought reaſonable to attribute a little influence to the firſt cauſe, but ſo very ſmall a portion, as not to be ſenſibly perceived in the obſervations.

From all which the following concluſions may be deduced: 1. That the ſecond cauſe alone takes place here, viz. That the diſtance of the ſtars is ſo great, that the diameter

ter of the earth's orbit has no ſenſible proportion to it. 2. That the angle F E G (Fig. 2.) in the abovementioned triangle, is 20″¼; and conſequently that the ratio of E G to F G, or the velocity of the *Light* to the velocity of the earth in its orbit, as 10210 to 1; whence it follows that the *Light* comes from the ſun to us in eight minutes and an half. 3. That the *Light* proceeds with the ſame velocity from all the ſtars; for all have the ſame angle F E G. Whence, (if we ſuppoſe that all the ſtars are not equally diſtant from us, as many arguments prove) it will follow, that the motion of *Light*, all the way it paſſes through the immenſe ſpace, above our atmoſphere, is æquable or uniform. 4. Laſtly, It muſt be conſidered, that very ſmall differences cannot be perceived; and no body will deny, but that in meaſuring a ſmall angle, an error of a ſecond may be committed, whatever care is uſed to prevent it; and therefore, although we have ſaid, that the firſt cauſe is to be rejected, we do not deny that the ſtars may poſſibly by its influence deſcribe a minute circle whoſe diameter is 1″, or even a little more. *s'Graveſande* Phyſ. Elem. Math. L 2. c. 1. p. 709. ſeq. Hence it appears, that the ſucceſſive propagation of *Light* will cauſe an *aberration* in the appearances of the ſtars, planets, and comets. After Mr. Bradley had diſcovered this cauſe of error in the apparent places of the fixed ſtars, Mr. Clairaut [a] and others [b], inveſtigated ſeveral rules for the computation of this aberration. Mr. Euler [c] alſo has lately given us a paper on this ſubject. —[[a] Mem. Acad. Scienc. 17. —[b] Mr. Simpſon, in his Eſſays. —[c] Mem. de L'Academ. de Berlin, Tom. 2. Pp. 141, ſeq.]

LIGNUM *Vitæ*, the wood of a genus of trees, called by botaniſts *Thuya*. See the article THUYA, *Suppl.*

Lignum Vitæ is much valued by turners; making extremely beautiful cups, bowls, boxes, and other curioſities. Ruſt. Dict. in voc.

LILLY *(Suppl)*—*Aſphodel*-LILLY, *Belladonna* LILLY, *Daffodel*-LILLY, *Guernſey*-LILLY, *Mexican*-LILLY, *Japan*-LILLY, names uſed by different authors for the *Amaryllis*, or *Lillio-Narciſſus* of Linnæus and Tournefort. See the article LILIO-NARCISSUS, *Suppl.*

LILLY-*Daffodel*, a name ſometimes given to a genus of plants, known among authors by that of *Pancratium*. See the article PANCRATIUM, *Append.*

Day-LILLY, a name ſometimes uſed for the *Hemerocallis* of botaniſts. See the article HEMEROCALLIS, *Suppl.*

Hyacinth-LILLY, in botany, a name given by ſome writers to the *Scilla*, or *Lillio-Hyacinthus*, of botaniſts. See the article LILLIO-HYACINTHUS, *Suppl.* and SCILLA, *Append.*

May-LILLY, the name by which ſome call the *Convallaria* of Linnæus, a large genus of plants, comprehending the *Lillium-Convallium*, *Polygonatum*, &c. of other writers. See the article CONVALLARIA, *Append.*

Perſian-LILLY, a name ſometimes given to the *Fritillaria*, a diſtinct genus of plants. See the article FRITILLARIA, *Suppl.*

Superb-LILLY, the Engliſh name of a diſtinct genus of plants, called by Linnæus *Glorioſa*. See the article GLORIOSA, *Append.*

Water-LILLY, *Nymphæa*, in botany, the name of a genus of plants. See the article NYMPHÆA, *Suppl.*

LIMAX, in the hiſtory of inſects, the name of a genus of theſe animals, comprehending all the naked ſnails, See the article SNAIL, *Suppl.*

The body of the *Limax* is of a figure approaching to cylindric, and is perforated at the ſide; the tentacula are four in number, and two of them have the appearance of eyes.

Of this genus authors enumerate the following ſpecies: 1. The black naked *Snail*. 2. The red naked *Snail*. 3. The yellow one, called the *Amber Snail*, variegated with ſpots of a greyiſh colour. 4. The very large grey *Limax*, ſpotted with a duſky-brown. 5. The little ſhort and thick grey *Limax*, without ſpots. 6. The ſmooth-bodied, reddiſh-brown *Limax*. 7. The ſmall duſky-brown, furrow'd *Limax*. 8. The deep chocolate-coloured *Limax*. *Hill*, Hiſt. Anim. p. 87.

LIME *(Cycl.)* — LIME-*water*. It appears now from the ingenious Dr. Alſton's experiments, that one part of quick *Lime* is ſufficient for five or ſix hundred parts of water. Water will diſſolve but a certain portion of quick *Lime*; and how much that is cannot be eaſily aſcertained. So far ſeems certain from Dr. Alſton's experiments, that one pound of quick *Lime* is ſufficient for making ſix hundred pounds of good *Lime* water; and that thoſe who with Charas have ſuppoſed, that the ſecond and third *Lime-water* is weaker than the firſt, have been led into error by the ſmall quantity of water they uſed. And it has been generally believed, that in order to obtain good *Lime-water*, the quick *Lime* muſt not only be recent, and fully calcined, but alſo for one part of quick *Lime* only eight, ten, or at moſt twelve parts of water taken; as if it could impregnate no more. But the Doctor ſays he has found by many experiments, that it is altogether indifferent whether the water be hot or cold, poured on gradually, or at once, the water poured on the *Lime*, or the *Lime* thrown into the water; whether the quick *Lime* be in ſhells, or ſlaked; or even expoſed to the air for ſeveral months, for ſuch quantities of the water as are commonly uſed; and if the quick *Lime* be freſh, whether for one pound of it, eight, ten, twenty, fifty, or five hundred pounds of water be taken. Only it is neceſſary, even for the firſt water after the ebullition is over, to ſtir and mix the *Lime* with the water, and allow it time to impregnate itſelf; which is beſt known by the cruſt formed on its ſurface. Filtration indeed is not neceſſary, if it be not to prevent any undiſſolved *Lime* being mixed with it; or cruſts diminiſhing its tranſparency.

The Doctor, for his own uſe, poured about eight pounds of boiling water upon a pound of ſtone quick *Lime* in a glazed earthen veſſel. He drank about a pint and an half of this *Lime-water*, daily for about ſixteen months; filling up the veſſel, when neceſſary, with freſh water, ſometimes hot, and ſometimes cold, without obſerving any difference in the *Lime-water*, which he conſtantly filter'd through grey paper, before he drank it. He obſerved, that the *Lime* was not exhauſted after two years and two months, nor was the water ſenſibly weaker, when it ſtood a ſufficient time on the *Lime*, which he knew by the cruſts that were formed. But the *Lime* becoming conſiderably lighter, after it is long thus uſed, it at length requires ſeveral days to ſubſide, and form the cruſts, and after the cruſts are formed, it does not leave half the water clear, as it did at firſt. On the whole, this ſingle pound of *Lime* afforded the Doctor about ſix hundred pounds of *Lime-water*. He adds, that having taken *Lime-water* made indifferently of Lime-ſtone, or of Chalk, or of Shells, and ſometimes made of all the three together, he was never able to diſcover any difference in their effects. But ſo much *Lime-water* is not to be obtained from quick-lime, unleſs it be freſh, completely calcined, and free from heterogeneous ſubſtances; for if defective in any of theſe, it will yield proportionably leſs *Lime-water*.

Lime-water, which was long looked on as a cauſtic, was, in the laſt century, found to be a very ſafe and valuable remedy. It is uncertain who firſt ventured to give it inwardly; but Willis, Bates, and Moreton ſeem to have uſed it much. *Lime-water* kills worms, and many other, if not all, inſects; hence Dr. Alſton concludes it might prove a good anthelmintic for children, and experience has confirmed this notion.

It is probable, that *Lime-water* may be of great uſe in long ſea voyages, in preventing the corruption of water, or inſects breeding in it, as well as curing the diſeaſes to which ſeafaring people are moſt ſubject. The experiment is certainly ſafe, eaſy, and attended with no expence; one pound of freſh well-burnt quick-lime of any kind, being enough for a hogſhead of water, which may not only be uſed for common drink by the diſeaſed, or for prevention by the healthy; but alſo by boiling and expoſing it to the air for a ſhort time, it may be reduced to ſweet water, and uſed in dreſſing the victuals of the moſt delicate.

The virtues of *Lime-water* do not depend on its abſorbency; and it may as juſtly be called antalcaline, as antacid.

Lime-water prevents or long protracts the putrefaction of animal ſubſtances. Dr. Alſton alſo thinks that quick-lime in a ſhip's well, would effectually prevent the corruption of the water, and conſequently the putrid ſteams, or foul air thence ariſing, which ſometimes prove fatal to the crew.

The virtues of *Lime-water* outwardly applied in many diſeaſes of the ſkin, in excoriations, ulcers, gangrenes, &c. are well known. Perhaps there is not a better gargariſm for ſeveral ſorts of ſores in the mouth and throat, than *Lime-water*. It has alſo been known to be of great uſe in the tooth-ach. Inwardly taken, *Lime-water* has all the virtues of the pure element, which are not a few; and on which probably depend the good effects of mineral waters, more than on the minerals they contain. Dr. Alſton never found it cauſed thirſt; on the contrary, he found it quenched thirſt, as well as ſimple-water, and cuſtom rendered it agreeable. *Lime-water* is notably detergent and attenuating, even more ſo than ſoap itſelf, of mucous, viſcid, and other animal ſordes, which makes it preferable, in many caſes, to the pureſt, as well as to mineral waters. In a word, *Lime-water* may be ſaid, in general, to purify the blood, with as good reaſon, as any one medicine whatever, eſpecially from any putrid, purulent, or ſcorbutic foulneſs.

That *Lime-water* is lithontriptic has been ſhewn ſufficiently by Dr. Hales, and more fully by Dr. Whytt; and this has been further confirmed by Dr. Alſton, who has ſhewn the efficacy of *Lime-water* in this reſpect, not only when made by the firſt infuſion, and aſſiſted by artificial heat; but even after fifty or more infuſions, and in the common air. The Doctor thinks that the energy of *Lime-water* in this caſe probably conſiſts in its penetrating detergency, whereby inſinuating itſelf among the ſolid parts of the calculi, or into their pores, it ſeparates them, or diminiſhes their coheſion, but does not diſſolve them.

Since there is but a ſmall proportion of *Lime* in the water, it may be thought that taking a few grains of the quick-lime in ſubſtance would prove much more effectual in the Stone, than large quantities of *Lime-water*. But this is a miſtake; and hence Mrs. Stephens's egg-ſhells and ſnail-ſhells, if burnt to quick-lime, can never be equally ſucceſsful with *Lime-water* for the Stone.

As for the *aquæ benedictæ compoſitæ*, or *compound Lime-waters*, they are not to be compared with ſimple *Lime-water* in the gravel; nor, in Dr. Alſton's opinion, in any diſeaſe requiring this water.

The Doctor adds, in his Appendix, that though he cannot yet determine how far *Lime-water* may be proper, even in

acut

acute diſtempers, yet he has found it ſafe in feveriſh colds; and by the caſes he there mentions, it ſeems probable that *Lime-water*, by its diluent, and diuretic qualities, may prove more uſeful in fevers, than is at preſent believed.

However, this may prove on farther trials, it may be ſaid, in general, that *Lime-water* is diluent, detergent, antiſeptic, anthelmintic, diuretic, and vulnerary; uſeful in all diſeaſes proceeding from, or accompanied with obſtructions in the bowels or glands, viſcid phlegm, calculous concretions, or putrefaction; and commended for the ſcurvy, ſcrophulæ, gravel, conſumption, empyema, aſthma, arthritis vaga, œdematous ſwellings, diabetes, fluor albus, fluxes, &c. and outwardly for diſeaſes of the ſkin, ulcers, gangrenes, &c. It may be taken to the quantity of a pound, once, twice, or thrice a day; or uſed for common drink. See Dr. Alſton's Diſſertation on quick-lime, and *Lime water*, Edinb. 1752.

The ingenious and learned Dr. Whytt of Edinburgh, has greatly recommended *Lime-water*, in the ſtone and gravel. See his eſſay on the virtues of *Lime-water*, in the cure of the ſtone. This gentleman prefers oyſter-ſhell *Lime-water* to any other for thoſe diſtempers. Dr. Alſton ſeems to think this a matter of indifference, and was himſelf cured chiefly by the ſtone quick-lime water before-mentioned.

LIMER, or LIME-*Hound*, names ſometimes uſed for the blood-hound. See the article HOUND, *Suppl.*

LIMITED, adjunct. See the article ADJUNCT, *Cycl.*

LIMITS *(Suppl.)* — We may add to what is ſaid under this head in the *Supplement*, that there being two caſes of variable quantities and ratio's tending to a *Limit*, it might have conduced to perſpicuity, and prevented diſputes, to have diſtinguiſhed theſe different *Limits* by ſome addition. As in the firſt caſe, to have called it a *Limit* or ultimate ratio *incluſive*; becauſe the *Limit* is the laſt of the quantities or ratio's limited: And in the ſecond, to have called it a *Limit* or ultimate ratio *excluſive*; becauſe the quantities limited never attain to the *Limit*, tho' they approach to it indefinitely.

This diſtinction may perhaps receive ſome farther illuſtration from the following example. It is known that the oſculatory circle is a circle that touches a curve ſo cloſely that no other circle can be drawn through the point of contact between them, all other circles paſſing within or without them both; and hence the oſculatory circle is ſuppoſed to have an equal curvature with the curve at that point. See Mr. *Mac Laurin*'s flux. art. 364.

Now if we conceive the oſculatory circle at the end of the great axis of an ellipſis, it will fall entirely within the ellipſis; and the curvatures of the ellipſis and oſculatory circle may both be ſaid to be *limits* of the curvatures of all the circles falling wholly within, and touching the ellipſis at the end of its great axis. But the term *Limit* will not in both caſes have preciſely the ſame meaning; for the oſculatory circle is a *Limit incluſive*, being the laſt of the circles limited; and the ellipſis is a *Limit excluſive*, none of the circles limited ever coinciding with it. As to the circles which fall wholly without the ellipſis, and touch it at the end of its great axis, they have no *Limit incluſive*, no circle touching the ellipſis ſo cloſely, that no other can paſs between; the only *Limit* here is *excluſive*, the ellipſis itſelf.

The contrary of this happens at the endo f the leer axis. At any other point of the ellipſis one half of every oſculatory circle is a *Limit incluſive* of the ſemicircles that fall within, and the other half is a *Limit incluſive* of thoſe that fall without.

May we not aſk, if a curve is the *Limit* of its inſcribed or circumſcribed polygons in any other ſenſe, than the curvature of the illipſis is the *Limit* of the curvatures of the circles before deſcribed, which approach nearer and nearer to the curve, but never coincide with it? It is true we hear it often ſaid, that the oſculatory circle is æquicurval, and ſo coincides with the ellipſis; but this ſeems a conſequence of the language of infiniteſimals. It would be more accurate to ſay, that the curvature of the ellipſis is the *Limit excluſive* of all the before mentioned circles, and that the oſculatory circle is their *Limit incluſive*. That excellent geometer, Mr. Simſon, in his Conic Sections, Lib. v. Prop. 36. Cor. ſays only, after demonſtrating the chief property of the oſculatory circle, that *eandem habere cum ſectione conica curvaturam dicitur*, giving this only as an appellation, but not as a propoſition.

LIMNOPEUCE, in botany, the name by which Vaillant calls the *Hippuris* of Linnæus. See the article HIPPURIS, *Suppl.*

LINE *(Cycl)* — *Algebraic* LINES are divided into different orders, according to the degree of their equations. Theſe degrees are eſtimated, as in determined equations, by the degree of the higheſt term of the equation.

Thus $a + by + cx = 0$ is a general equation, expreſſing the nature of *Lines* of the firſt order, or of ſtrait *Lines*.

The equation $a + by + cx + dyy + exy + fxx = 0$ repreſents the *lines* of the ſecond order; that is, the conic ſections, and the circle, which is one of them.

And the equation $a + by + cx + dyy + exy + fxx + gy^3 + hxyy + ix^2y + lx^3 = 0$, expreſſes in general the *lines* of the third order. And the *Lines* of the fourth and higher orders may be expreſſed in the like manner. See *Cramer*, Introd. a l'analyſe des lignes courbes. p. 52, ſeq.

Mr. Cramer uſes the terms, *Line* of the ſecond, third, fourth, &c. order, and *Curve* of the ſecond, third, fourth, &c. order, indifferently. Sir Iſaac Newton has made a diſtinction: according to him,

LINE *of the third order* is the ſame as CURVE *of the ſecond kind*; becauſe a *Line* of the firſt order, cannot, ſtrictly ſpeaking, be called a Curve.

Lines of the third order may be cut by a right line in three points, and by a circle in ſix points.

We have a ſhort treatiſe by Sir Iſaac Newton upon the *Lines* of the third order, entitled, *Enumeratio linearum tertii ordinis*, which was firſt printed at the end of Dr. Clarke's latin tranſlation of Sir Iſaac's Optics; and ſince publiſhed more correctly by the late Mr. Jones in 1711, with the treatiſe of quadratures, and other tracts of its illuſtrious author.

This enumeration is ſo conciſe, as to need a comment. Mr. Stirling gave one in 1717; but this comment is too difficult for beginners. Mr. Cramer has lately explained this ſubject very fully, in his *Introduction a l'analyſe des lignes courbes algebriques*, printed at Geneva 1750, 4to, to which the curious may have recourſe; as alſo to the Appendix to Mr. Mac Laurin's Algebra, entitled, De linearum geometricarum proprietatibus generalibus; and to Mr. *Euler*'s Analyſis infinitorum, Vol. II.

An algebraic *Line* of the order m can cut another algebraic *Line* of the order n, in the number of points expreſſed by mn, but not in more. Thus if $m = 1$ and $n = 2$, the *lines* of thoſe orders can interſect each other in two points only; and if $m = 2$ and $n = 2$, then may they interſect each other in four points, as is well known; ſince a ſtrait *Line* cannot interſect a conic ſection in more than two points; nor can one conic ſection interſect another in more than four points. In like manner if $m = 5$ and $n = 4$, then may the *lines* of theſe orders interſect each other in 20 points; but not in more. See *Cramer*, Anal. des lignes courbes, p. 75, 76.

The number of the ſpecies of the *Lines* of the third order amount to 78. See Mr. *Murdoch*'s Geneſis Curvarum per Umbras. Sir Iſaac reckoned only 72 ſpecies of the third order; but Mr. Stirling and Mr. Stone have ſhewn his enumeration to be imperfect; and Mr. Murdoch has ſince found ſome new ſpecies.

LION. The *Lion* is comprehended among the *felis*, or cat-kind of animals. See the article FELIS, *Append.*

LION'*s leaf*, the Engliſh name of a genus of plants, deſcribed by Tournefort under that of *Leontopetalon*. See the article LEONTOPETALON, *Suppl.*

LION'*s foot*, the Engliſh name of a diſtinct genus of plants, called by botaniſts *Catanance*. See the article CATANANCE, *Suppl.*

LIQUID *Amber*, in botany, the name of a diſtinct genus of plants, called by botaniſts *Anthoſpermum*, and *Tournefortia*. See the articles ANTHOSPERMUM, *Append.* and TOURNEFORTIA, *Suppl.*

LIQUORICE *(Suppl.)*—*Vetch*-LIQUORICE, the Engliſh name of a genus of plants, called by botaniſts *Orobus*. See the article OROBUS, *Suppl.*

Wild LIQUORICE, the name of a diſtinct genus of plants, called by authors *Aſtragalus*. See the article ASTRAGALUS, *Suppl.*

LIQUORS, fermented. See the article FERMENTED *liquors*, *Suppl.* and *Append.*

LIST, in the ſea-language, the ſame with *luſt*. See the article LUST, *Suppl.*

LITHONTRIPTIC *(Suppl.)* — The reward which the parliament of England gave to Mrs. Stephens, the inventreſs of ſome medicines, which were ſaid to be a perfect and certain cure for the *Stone*, made the generality of the world believe, that they were really as efficacious as they were pretended to be; but it appeared, on examination, that the opinion of a cure in the very inſtances on the ſucceſs of which the reward was given, was erroneous; and that the *Stones* had all the time remained in the bladders of the patients, tho' ſuppoſed to have been voided, after being diſſolved and waſhed away by the medicines.

The principal inſtance of a ſuppoſed cure was Mr. Gardiner. This man was in December 1748, examined by able ſurgeons, and found to have a ſtone in his bladder; after this he took Mrs. Stephens's medicines for eight months without intermiſſion; and at the end of that time he declared himſelf free from all his uſual complaints; and on ſearching him, there could no ſtone be found in the bladder. Mr. Gardiner died about three years afterwards, and his body was opened. When the bladder was examined, there were found in it ſix preternatural apertures of different ſizes; but the biggeſt capable of admitting the end of a finger. Each of theſe apertures led to a ſeparate bag form'd by an enlargement of the internal membrane of the bladder, protruded between the fibres of its muſcular coat. Theſe bags were eaſily ſeen on the back part of the bladder a little above the veſiculæ ſeminales, and when viewed on the outſide, they ſeemed to be but two, tho' in reality equal in number to the openings within, and divided from one another by the duplicature of the internal membrane, which form'd a ſeptum between each of them. Philoſ. Tranſ. N° 462. p. 12.

As to Mrs. Stephens's medicine, it is a compoſition of ſoap, and lime made of different ſhells, which every body knows

knows to be highly cauſtic; and is therefore condemned by Dr. Mead; ſince its corroſive quality muſt be injurious to the bladder. However, under proper management, he thinks it may be of ſome ſervice in expelling gravel by the urinary paſſages; tho' it will never be able to break calculi of the hardneſs of ſtone: And beſides, its long continued uſe muſt be attended with great danger, for the reaſons above given. And as for its ſubſtitute, the ſoap-lees, though it be a medicine of a more commodious form for taking, yet it will not prove much ſafer in its conſequences, for the ſame reaſons. *Mead*, Monit. and Pract. Medic. pag. 199, ſeq.

Dr. Whytt of Edinburgh, after conſidering the inconveniencies, and ſometimes the miſchiefs alſo, of this celebrated ſpecific, reſolved to omit the ſoap, and try what virtues lime-water might have in diſſolving the calculus. See the article LIME-*water*, *Append.*

His firſt experiments were made on ſeveral fragments of calculi, with lime-water, from common quick-lime; and afterwards reſolving to try the power of animal lime, he repeated them with lime-water made with oyſter-ſhells and cockle-ſhells, well calcined, by pouring ſeven or eight pints of water on one pound of the freſh calcined ſhells. The experiments ſucceeded with both ſorts; but he ſoon found, that the oyſter and cockle-ſhell lime-water poſſeſſed a much greater power of diſſolving the calculus, than that of the ſtone-lime.

He therefore propoſes the drinking of ſhell-lime-water to the quantity of four pints, every day, for adults; and for children leſs in proportion: And he concludes with inſtances of the happy effects of this method. However, as ſtones of great hardneſs can never be diſſolved by any medicine whatſoever, Dr. Mead recommends, in theſe caſes, a new method of cutting for the Stone. Id. ibid. See the article LITHOTOMY, *Append.*

Dr. Hartley has publiſhed, in the London Gazette, the following receipt for making a *lithontriptic* electuary. Take five pounds of Alicant ſoap, ſhaved, and one pound of oyſter-ſhell lime; put them into a tin veſſel, and pour upon them five quarts of water; make the water boil, till the ſoap be perfectly diſſolved in it, and then ſtrain all into a glazed earthen veſſel. Expoſe this maſs to the air, ſtirring it every day, till it becomes both mild to the taſte, and of a proper conſiſtence to be formed into pills, or long pellets, without ſticking to the fingers. This may be expected to happen in two or three months. If it becomes ſufficiently mild before it has acquired a due conſiſtence, it may be brought to this, by being heated over the fire, in a tin veſſel: If it acquires a too hard conſiſtence, before it is ſufficiently mild, it muſt be ſoftened with water. This is what the Doctor calls the *lithontriptic* maſs or electuary; which he orders to be made in a tin veſſel, becauſe a braſs or copper one would make it emetic.

He gives another more expeditious way of making it, which is this: Pour two gallons of water upon a pound of oyſter-ſhell lime; ſtir it two or three times, and when it has fallen to the bottom, pour off the clear part of the water. Repeat this fifteen or twenty times, or till the clear water, which is poured off, be almoſt taſteleſs; leaving about five pints of water upon the lime, after the laſt ablution. Then pour this mixture of water and dulcified lime upon five pounds of Alicant-ſoap, ſhaved; and proceed as directed in the firſt receipt. The maſs, prepared in this manner, will be fit for uſe in a few days, or even immediately; but then the Doctor prefers the foregoing receipt, where time can be allowed for it.

If the maſs of ſoap and oyſter-ſhell lime, dulcified in either of the above-mentioned ways, be made of the conſiſtence of an electuary, it is then called the *lithontriptic* electuary; which for cure is more convenient than the maſs, for thoſe who deſire to take the medicine diſſolved in a liquid vehicle, as milk, water ſweetened with honey or ſugar, water flavoured with brandy or rum, and ſmall beer.

Where a perſon is ſuppoſed to have a large Stone in the kidneys or bladder, he ought to take every day as much of the maſs, or electuary, as contains two ounces of the ſoap, unleſs his pain and provocation to make water be violent; in which caſe it will be proper to begin with about half this quantity, and to increaſe it as he can bear. The medicine ought alſo, in this caſe, to be dulcified, in an extraordinary degree.

By this medicine, the Doctor thinks the generation of gravel, and gravel-ſtones, may be entirely prevented. See the article STONE, *Append.*

It is likewiſe recommended in diſorders of the ſtomach and bowels, ariſing from, or attended with acidities there; and in gouty habits. The patient may, in many of theſe caſes, begin with ſuch a quantity every day, as contains an ounce of ſoap, and afterwards increaſe or leſſen this quantity, as he finds occaſion.

LITHOTOMY *(Cycl.)* — We have an hiſtory of the lateral operation for the ſtone by Monſ. Morand, who argues, that the methods of Celſus, Frere Jacques, Rau, and Cheſelden, are in the main the ſame. See Mem. de L'Acad. des Sciences, 1731.

Mr. Cheſelden's method is deſcribed in his anatomy, Chap. VI. of the fifth edition This method of cutting for the ſtone is much recommended by Dr. Mead; who aſſures us, that now not only children and youths, but alſo perſons advanced in years, may ſubmit to this operation, without great danger; and in caſe the ſtone prove too big to be extracted without tearing the neck of the bladder, it is now no longer neceſſary to ſplit the ſtone, before the extraction; the invention of which is aſcribed to Ammonius, a Greek phyſician, who from thence was ſurnamed λιθοτόμος, the lithotomiſt. *Mead*, Monit. and Pract. Med. p. 203.

Mr. Houſtet has collected a great many inſtances of ſtones lodged in ſacs formed in the bladder, from which it was impoſſible to extract them, without tearing the bladder, or cutting on one ſide of the ſac, which Mr. Garengeot did once with ſucceſs. In ſome of the caſes which he mentions, the veſſels of the bladder were in appearance grown into the ſtone, and the extraction of the ſtone was attended with a mortal hæmorrhage. See Mem. de L'Acad. de Chirurg. Tom. I.

The diſtenſion of the bladder with a liquor in performing the high operation for the Stone, is attended with difficulties, eſpecially in women. Dr. Kulm has therefore contrived an elevatory catheter for that ſex. The bending of the inſtrument is fitted to the turn of the os pubis, and its great curve, inſtead of being only furrowed, is pierced quite through. He introduces this, with its convexity to one ſide, then gently raiſes it to the hypogaſtrium, and cuts ſecurely upon it. See Nov. Act. Erudit. Lipſ. Mart. 1732.

LITHOZUGIA, in natural hiſtory, the name of a genus of foſſils, of the claſs of the *Scrupi*, compoſed of a cryſtalline matter a little debaſed, and containing within them various extraneous bodies, as pebbles, &c. See the article SCRUPI, *Append.*

Dr. Woodward has ranked this genus among the pebbles, becauſe of the pebbles they contain; which is by no means a ſufficient reaſon for confounding two ſuch different foſſils; the *Lithozugia* approaching to the nature of flint.

Mercatus and other naturaliſts have called the *Lithozugia* *oculati lapides*; and among Engliſh lapidaries they are known by the name of *Pudding-ſtones*. See the article OCULATUS *Lapis*, *Suppl.*

Of this genus we have the following ſpecies, 1. The yelloviſh-white *Lithozugium*, filled with pebbles. 2. The greeniſh-white *Lithozugium*, filled with pebbles. 3. The red *Lithozugium*, filled with pebbles. Vid. *Hill*, Hiſt. Foſſ. p. 557.—559.

Beſides theſe, there are other *Lithozugia* of a coarſer texture, approaching to the nature of quarry-ſtone; of theſe we have the following ſpecies: 1. The fleſh-coloured *Lithozugium*, filled with reddiſh, impure, cryſtalline nodules. 2. The bluiſh and glittering *Lithozugium*, filled with white, impure, cryſtalline nodules. 3. The whitiſh-green elegant *Lithozugium*, filled with cryſtalline nodules: And, 4. The friable, pale-red *Lithozugium*, variegated with white veins, and red nodules. *Hill*, Hiſt. Foſſ. p. 560—562.

LIVE *ever*, a name ſometimes given to the *anacampſeros*, or orpin, a diſtinct genus of plants. See the article ANACAMPSEROS, *Suppl.*

LIVE *in idleneſs*, a name ſometimes uſed for the violet. See the article VIOLA, *Suppl.*

LIVER *(Suppl.)* — *Infarction of the* LIVER. See the article HEPATIS *Infarctus*, *Suppl.*

LIZARD's *tail*, the Engliſh name of a genus of plants, deſcribed by Linnæus under that of *Saururus*. See the article SAURURUS, *Suppl.*

LOCKER-*gowlans*, a name by which ſome call a ſpecies of Hellebore. See the article HELLEBORUS, *Suppl.*

LOCUST, or *St.* JOHN's *bread*, in botany, names uſed by ſome for the *Ceratonia*, or *Siliqua*, of botaniſts, See the article SILIQUA, *Suppl.*

Baſtard LOCUST, a name ſometimes uſed for a diſtinct genus of plants, called by botaniſts *Courbaril*, or *Hymenæa*. See the article HYMENÆA, *Suppl.*

LOCUST *of Virginia*, a name by which a ſpecies of *acacia* is ſometimes called. See the article ACACIA, *Suppl.*

LOCUST-*tree*, in botany, a name given by the people of the Weſt-Indies to a ſpecies of *Acacia*. See the article ACACIA, *Suppl.*

LOGARITHM *(Suppl.)* — In the common tables of *Logarithms* we find the *Logarithm* correſponding to any given number within the limits of the table, by inſpection; but it is of uſe alſo to have a table wherein the *Logarithms* are placed in their natural order, from 0 to 100,000 for inſtance, and with the correſponding natural numbers; ſo that a *Logarithm* being given, we may find the correſponding number by inſpection only, which can ſeldom be done by the common tables; nor can the correſponding number to a *Logarithm* not in the table be found without ſome trouble.

A table of this ſort is called by Dr. Wallis an *anti-logarithmic canon*; and by this canon a *Logarithm* being given, its number may be found with the ſame facility that a *Logarithm* of a given number may be found by the common canon.

Dr.

Dr. Wallis tells us, that a canon of this kind was formed many years ago. It was begun, perhaps, by Harriot, and it was finiſhed at leaſt, and prepared for the preſs, if not begun, by Warner. This canon ſeems to have been loſt; but the loſs has been ſupplied by Mr. Dodſon. See the *Anti-logarithmic canon* by James Dodſon, Lond. 1742. fol. where the author alſo ſhews the conſtruction and uſe of his table at large.

Imaginary LOGARITHM is uſed for the *logarithm* of negative and imaginary quantities [a], ſuch as $a - \sqrt{-a}$, &c. Thus alſo the fluents of certain imaginary fluxionary expreſſions, ſuch as $\frac{\dot{x}}{x\sqrt{-1}}$, $\frac{a\dot{x}}{2bx\sqrt{-1}}$, &c. are *imaginary logarithms*.

[a *Euler*, Analyſ. infin. Vol. 1. pag. 72, 74.]

The expreſſion $\frac{\dot{x}}{x}$ repreſents the fluxion of the *Logarithm* of x, and the fluent therefore of $\frac{\dot{x}}{x}$ is the *Logarithm* of x; but no *Logarithm* can repreſent the fluent of $\frac{\dot{x}}{x\sqrt{-1}}$, which is therefore called an *imaginary Logarithm*.

However, when theſe *imaginary Logarithms* occur in the ſolutions of problems, they may be transformed into circular arcs or ſectors; that is, the imaginary *Logarithm*, or imaginary hyperbolic ſector becomes a real circular ſector. See *Bernoulli*, Oper. Tom. I. p. 400. and p. 512. *Mac Laurin*'s Fluxions, Art. 762, ſeq. *Walmeſley*, Anal. des meſ. p. 63.

LOGARITHMIC. This head is referred to in the *Append.* from the article CURVE, in the *Suppl.* by miſtake. But ſee the article LOGARITHMIC, *Suppl.*

LOGGERHEAT, in the ſea-language, denotes a large round ball of iron, with a long handle, for heating pitch. *Blanckley*'s Nav. Expoſ. p. 100.

LOGWOOD, the wood of a genus of plants, called by Linnæus *Hæmatoxylum*. See the article HÆMATOXYLUM, *Suppl.*

LONDON *pride*, a name uſed among Gardeners for the *geum*, a diſtinct genus of plants. See the article GEUM, *Suppl.*

LONICERA, *(Suppl.)* in the Linnæan ſyſtem of botany, the name of a large genus of plants, comprehending, according to that author, the *Caprifolium*, *Periclimenum*, *Chamæceraſus* and *Xyloſteum* of Tournefort, and other botaniſts; together with the *Trioſteoſpermum* and *Symphoricarpos* of Dillenius. See the articles CAPRIFOLIUM, &c. *Suppl.*

The characters are theſe. The cup is a ſmall perianthium, placed on the germen, and divided into five ſegments. The flower conſiſts of a ſingle petal, the tube is oblong, and gibboſe downwards, the limb is divided into five ſegments, one of which is more deeply ſerrated than the reſt, and all turn backward. The ſtamina are five ſubulated filaments, nearly of the length of the flower; the antheræ are oblong, the germen is roundiſh, and placed under the receptacle, the ſtyle is filiform, and of the length of the flower, the ſtigma is obtuſely capitated. The fruit is a roundiſh, umbilicated berry, containing two cells; the ſeeds are roundiſh and compreſſed.

As they all agree in theſe general characters, they are to be accounted only one genus. *Linnæi* Gen. Plant. p. 75.

LOOKING *Glaſs (Suppl.)*—*Venus's* LOOKING *glaſs*, in botany, a name by which ſome call the *Campanula*. See the article CAMPANULA, *Suppl.*

LOOSE *ſtrife*, a name ſometimes given to the *Lyſimachia*, or willow-herb of botaniſts. See the article LYSIMACHIA, *Suppl.*

Podded LOOSE *ſtrife*, the name of a genus of plants, called by botaniſts *Epilobium*, or *Chamænerium*. See the article CHAMÆNERIUM, *Suppl.*

Spiked LOOSE *ſtrife*, the name of a genus of plants, called by botaniſts *Salicaria*. See the article SALICARIA, *Suppl.*

LORANTHUS, in the Linnæan ſyſtem of botany, the name of a genus of plants, called by others *Lonicera*. See the article LONICERA, *Suppl.*

LORD *in groſs*, he who is *Lord*, not by reaſon of any manor, as the king in reſpect of his crown, &c. *Termsof law*, *Blount*, *Cowel.*

LOTE-*tree*, in botany, the name of a genus of plants, called by authors *Celtis*. See the article CELTIS, *Suppl.*

LOTUS *Africanus*, in botany, a name by which ſome call the *Guaiacana* of Tournefort. See the article GUAIACANA, *Suppl.*

Bladder LOTUS, a name ſometimes given to a ſpecies of *Vulneraria*. See the article VULNERARIA, *Suppl.*

LOVE-*graſs*, in botany. See the article GRASS, *Append.*

LOVE *in a miſt*, a name uſed among gardeners for the *Granadilla*, or paſſion-flower. See the article GRANADILLA, *Suppl.*

LOVE *lies a-bleeding*, a popular name for the *Amaranth*. See the article AMARANTH, *Suppl.*

LOUSE *(Suppl.)* — *Tree*-LOUSE, a genus of inſects, called by zoologiſts *Aphis*. See the article APHIS, *Append.*

LOUSE-*wort*, a name uſed by ſome for the *Delphinium* of botannical writers. See the article DELPHINIUM, *Suppl.*

LOUSE-*wort* is alſo the Engliſh name of a genus of plants, called by botaniſts *Pedicularis*. See the article PEDICULARIS, *Suppl.*

LOWINGS, in falconry. See the article LUNES, *Append.*

LUMBRICUS, in zoology, the name of a genus of inſects, called in Engliſh earth-worms. See the articles WORM and EARTH-*worms*, *Suppl.*

The *Lumbricus* is an inſect of the larger kind, of an oblong form, conſiderably thick rounded in ſhape, and covered with a ſoft and ſlender ſkin, marked with annular ridges, and furrows. When full grown, it is often ten inches, or more, in length, and more than a third of an inch in diameter. Its colour is a duſky red.

It is common every where, at little depths, under the ſurface of the earth; it is not unfrequently alſo met with in the human inteſtines, as well as in thoſe of other animals, in which ſtate it has been ſuppoſed a different creature, and called by a new name.

Beſides the common earth-worm, there is found another ſpecies of *Lumbricus* in the mud about the Sea-ſhores, very large, growing very often to a foot or more in length; it entirely reſembles the other, only that it is of a paler red, and has its ſkin covered with little prominences, which makes it rough or ſcabrous to the touch. Vid. *Hill*, Hiſt. Anim. p. 15.

LUNES, or LOWINGS, in falconry, leaſhes, or long lines to call in hawks. Ruſt. Dict. in voc.

LUNGS *(Suppl.)* — *Sea*-LUNGS, the Engliſh name of the *Meduſa*, agenus of inſects. See the article MEDUSA, *Append.*

Ships-LUNGS, a name given to the ventilators of ſhips. See the article VENTILATOR, *Append.*

LUNG-*wort (Suppl.)*— *Cow's* LUNG-*wort*, a name ſometimes given to the *Verbaſcum*, or Mullein. See the article VERBASCUM, *Suppl.*

LURCHER, among ſportſmen, a kind of hunting dog, like a mongrel greyhound, with pricked ears, a ſhaggy coat, and generally of a yellowiſh-white colour. Ruſt. Dict. in voc.

LUST-*wort*, a name by which ſome call *Ros ſolis*, a diſtinct genus of plants. See the article ROS *ſolis*, *Suppl.*

LYCIUM, *Avignon-berry*, *Avignon-thorn*, or *box-thorn*, in botany, the name of a genus of plants, the characters of which are theſe: The cup is a ſmall, erect, obtuſe, permanent perianthium, divided into five ſegments; the flower conſiſts of a ſingle infundibuliform petal; the tube is cylindric, patent and crooked; the limb is ſmall, divided into five ſegments, obtuſe and patulous; the ſtamina are five ſubulated filaments, growing out of the tube of the flower; they are ſhorter than it, and inclinated; the antheræ are erect; the germen of the piſtil is roundiſh; the ſtyle is ſimple, and longer than the ſtamina; the ſtigma is bifid and thick; the fruit is a roundiſh berry, containing two cells; the ſeeds are numerous, and kidney-ſhaped; and the receptacles are convex. Vid. *Linnæi* Gen. Plant. p. 81.

This genus comprehends likewiſe the *Jaſminoides* of other authors.

LYCOCTONUM. See the article ACONITE, *Cycl.*

LYING *under the ſea*, is when, in a ſtorm, the ſhip is a-hull, and the helm ſo faſtened a-lee, that the ſea breaks upon her bow, or broadſide. *Blanckley*, Nav. Expoſ. p. 102.

LYNCHET, among farmers, a line of green ſward, ſerving as a boundary to ſeparate plowed land, in common fields. Ruſt. Dict. in voc.

LYSIMACHIA *filiquoſa*, the name by which ſome call the *Chamænerium* of Tournefort. See the article CHAMÆNERIUM, *Suppl.*

M.

MAD MAI

MACAO, in zoology, the name of a ſpecies of parrot. See the article MACAW, *Suppl.*

MACAW, *(Suppl.)* or MACAW-*tree*, in botany, the name of a ſpecies of palma, or *Phœnix*. See the article PHOENIX, *Suppl.*

MACHINE *(Cycl.)* — The ſimple *Machines*, or mechanical powers, according to their different ſtructure, ſerve for different purpoſes; and it is the buſineſs of the ſkilful mechaniſt to chooſe them, or combine them, in the manner that may be beſt adapted to produce the effect required, by the power which he is poſſeſſed of, and at the leaſt expence. The lever can be employed to raiſe weights a little way only, unleſs the engine itſelf be moved; as, for inſtance, to raiſe ſtones out of their beds in quarries. But the axis and wheel may ſerve for raiſing weights from the greateſt depths. Pullies being eaſily carried, are therefore much employed in ſhips. The wedge is excellent for ſeparating the parts of bodies; and the ſcrew for compreſſing or ſqueezing them together; and its great friction is even ſometimes of uſe, to preſerve the effect already produced by it. The ſtrength of the *Machine*, and of its parts, muſt be proportioned to the effects which are to be produced by it. Thus, when the center of motion is placed between the power and the weight, it muſt ſuſtain the ſum of their efforts: a ſmall ballance, therefore, ought not to be employed for weighing great weights; for theſe diſorder its ſtructure, and render it unfit for ſerving that purpoſe with accuracy. Neither are great *Machines* proper for producing ſmall effects. It were to be wiſhed, that we had a detail of all theſe things drawn up by ſome ſkilful and experienced mechaniſt.

From theſe ſimple *Machines*, compounded ones are formed by various combinations, and ſerve for different purpoſes; in all which the ſame general laws take place; and particularly this, that the power and weight ſuſtain each other, when they are in the inverſe proportion of the velocities which they would have in the directions wherein they act, if they were put in motion.

But in practice the friction of *Machines* is to be conſidered, without allowing for which we ſhall often find ourſelves at a loſs See the article FRICTION, *Append.*

Accurate deſcriptions and draughts of *Machines* would be a very curious and uſeful work. But to make a collection of this kind as advantageous as poſſible, it ſhould, beſides the deſcriptions of *Machines*, contain an analyſis of them; pointing out their advantages and diſadvantages; the reaſons of the conſtructions; and the general problems, implied in theſe conſtructions, with their ſolutions, ſhould be extracted. None of theſe things have as yet been done, in a complete and ſatisfactory manner, in any treatiſe of this kind. However, many curious particulars may be gathered from Strada, Beſſon, Beroaldus, Auguſtinus de Ramellis, Bockler, Leupold, Beyer, Limpergh, Van Zyl, Perault, and others; a ſhort account of whoſe works we find in *Wolfii* commentatio de præcipuis ſcriptis mathematicis. Elem. Mathef. Univ. Tom. 5. pag. 84. ſeq. To theſe muſt be added, Monſieur Belidor's Architecture Hydraulique, and Dr. Deſaguliers's Courſe of Experimental Philoſophy. The Royal Academy of Sciences at Paris have alſo given us a collection of *Machines* and inventions approved of by them. This work, publiſhed by Monſieur Gallon, conſiſts of ſix volumes in 4to, containing engraved draughts of the *Machines*, with their deſcriptions annexed. But a complete inſtitution of practical *Mechanics* is ſtill wanting. See the article MECHANICS, *Append.*

MACHINE *of Marly (Cycl.)* — This *Machine* was made by a common mechanic of Liege, and has a great many excellent contrivances; but yet does not raiſe all the water that it might have done, becauſe the maker did not know how to give the River Seine all the advantages of which it was capable. Hence appears the neceſſity of a mechanic's being well acquainted with mathematics; or that able mathematicians would apply themſelves to mechanics more than they do, and not think it below them to direct workmen. See *Deſagul.* Exper. Philoſ. Vol. II. p. 442, to 449.

According to Dan. Bernoulli's computation, the effect of the *Machine of Marly* is not more than $\frac{1}{56}$ of its abſolute force; that is, there is a loſs of $\frac{55}{56}$ of that force. *Dan. Bernoul.* Hydrodyn. p. 182.

MACHINES *for raiſing water*. See the article *Raiſing* WATER, *Append.* See alſo the article FIRE-*engine*.

MACROCERCI, the name eſtabliſhed by Dr. Hill for a large genus of animalcules, diſtinguiſhed from all others by having tails longer than their bodies. See the article ANIMALCULE, *Cycl. Suppl.* and *Append.*

MAD-*wort*, the Engliſh name of a genus of plants, called by botaniſts *Alyſſon*. See the article ALYSSON, *Suppl.*

MADDER *(Suppl.)* — *Petty*-MADDER, the Engliſh name of a genus of plants, known among authors by that of *Rubeola*. See the article RUBEOLA, *Suppl.*

MADNESS — Dr. Michelotti relates the cure of a young man, who, after being expoſed to very hot weather at ſea, and having committed violent debauches in drinking, became mad, without any fever. He was cured by violent bleeding, ſtarving, weak very cold drink, the cold bath, and pouring cold water on his head. Hiſt. de l'Acad. des Scienc. 1734. See the article MANIA, *Suppl.*

MAGNESIA, the ſame with *Manganeſe*. See the article MANGANESE, *Suppl.*

MAGNET *(Cycl.)* — *Armed* MAGNET. See the article LOAD-STONE, *Suppl.*

The power of natural *Magnets* may be greatly increaſed by art; and this ſeems to have received farther and very great improvements from Dr. Knight. See Philoſ. Tranſ. N° 474. p. 163. ſeq.

The poles of natural *Magnets* may be inverted, or their directions may be changed. Remarkable inſtances of this may be ſeen in the Phil. Tranſ. N° 101. p. 164. ſeq. and N° 476. p. 36. ſeq. Thus the magnetical virtue may be placed in ſuch a manner, that the two oppoſite ends of a ſtone ſhall become, both, ſouth poles; and the middle quite round, a north pole. Or, the two oppoſite ends may be north poles; and the two oppoſite ſides ſouth poles. Half of the ſurface of the ſtone may be made a north pole, and the other half a ſouth pole. A north pole may be placed ſo as to be ſurrounded by a ſouth pole; and at the other end of the ſtone, a ſouth ſurrounded by a north pole; ſo that the edges of each ſurface have a pole of a different denomination from that which occupies the middle. See Phil. Tranſ. N° 476. p. 361. ſeq.

Artificial MAGNET. *Artificial Magnets* have been made in great perfection by the before mentioned gentleman. See the Phil. Tranſ. N° 474, p. 161. ſeq. where various experiments of the force of theſe *Artificial Magnets* are recorded; one in particular weighing, without its armour, juſt an ounce, and with the armour, cramps, and rings, one ounce 17 pen. wt. lifted ſix pounds ten ounces troy weight. See pag. 166, N° cit.

It is hoped, that Doctor Knight will ſoon oblige the world with his diſcoveries in magnetiſm. In the mean time, the ingenious Mr. Canton has found out a method of making artificial *Magnets*, without the uſe of, and yet far ſuperior to, natural ones. This gentleman has ſucceeded ſo well in his attempts to convey a conſiderable magnetic virtue to bars of hardened ſteel, as to be able to impregnate ſuch bars with this virtue, to as high a degree as any of the ſame weight and dimenſions which he had yet ſeen or heard of; and to as high a degree, as, he apprehends, the ſame bars in their preſent ſtate are capable of being impregnated. Mr. Canton has publiſhed the deſcription of his proceſs, with ſuch directions, that any perſon may readily perform the ſame.

The apparatus, beſides the bars of hard and ſoft ſteel, conſiſts only in an iron poker and tongs, the larger they are, and the longer they have been uſed, the better. But for the application of this apparatus, we muſt refer to the ingenious author himſelf, who has expreſſed himſelf clearly and conciſely, and added figures for the more eaſy intelligence of his proceſs. See a method of making artificial *Magnets*, without the uſe of natural ones, by *John Canton*, M. A. London, 1751. See alſo Phil. Tranſ. Vol. 47. p. 31.

MAGPYE, in ornithology, the Engliſh name of a large order of birds. See the article PICA, *Suppl.*

MAHOGANY, a well known, and, juſtly, much valued wood, brought from Jamaica, and other parts of the Weſt-Indies.

It is the wood of a very beautiful tree, with pinnated leaves, but hitherto not reduced to any certain claſs or genus of plants. Cateſby, indeed, who ſaw only the withered remains of its flower, tells us, that he could plainly perceive it to be pentapetalous, or conſiſting of five leaves. Its fruit has ſome, tho' but a remote, reſemblance to that of the pine.

MAIDEN-*hair (Suppl.)* — *Black* MAIDEN-*hair*, a name ſometimes given to the *Filicula*, or dwarf Fern. See the article FILICULA, *Suppl.*

Engliſh MAIDEN-*hair*, the name of a genus of plants, called by botaniſts *Trichomanes*. See the article TRICHOMANES, *Suppl.*

White MAIDEN-*hair*, the name by which ſome call the *Ruta-muraria*, or wall-rue. See the article RUTA-*muraria*, *Suppl.*

MAILLS, on ſhip-board, are ſquare machines, compoſed of a number of rings interwoven net-wiſe, and uſed for rubbing

off the loose hemp which remains on lines or white cordage, after it is made. *Blanckley*'s Nav. Expos. p. 102.

MAKE-*Hawk*, in falconry. See the article HAWK, *Append.*

MALIGNANT *(Cycl.)* — *Malignant* fevers and fluxes are frequent, not only in marshy countries, after hot seasons, but in populous cities. See the article CITY, *Append.*

History abounds with examples of *malignant* or pestilential fevers, added to the other calamities of a siege: Nay, there is scarce any instance of a town being long invested, without some fatal malady of this kind; which may, in great part, be attributed to the filth of the place, crowded with people and cattle. Corrupted grain, and meats long salted becoming putrid, have likewise given rise to *malignant* diseases.

It is remarkable how much the plague, and other pestilential fevers, hot scurvies, and dysenteries have abated in Europe within this last century; a blessing we can ascribe to no other second cause, than to the improvement of every thing relating to cleanliness, and to the more general use of Antiseptics. See the article ANTISCEPTICS, *Append.*

In regard to diet too, it may be observed, that hopped beer, wine, and spirituous liquors coming more into general use, have been a great means of suppressing putrid and *malignant* diseases. Greens and fruit are likewise more universally eat, and salted meats make a much less part of diet than formerly. To this add the more general consumption of tea and sugar. All which are no inconsiderable antiseptics. *Pringle*, Observ. on Dis. of the army, p. 284, 288, 293.

As to the contageous nature of all putrid disorders, Dr. Pringle thinks that the putrid effluvia, received into the blood, have a power of corrupting the whole mass, of which he conceives the resolution of the blood, and sometimes even its smell, in the advanced state of a *malignant* fever, the offensiveness of the sweats, and other excretions, the livid spots, blotches, and mortifications incident to this distemper, to be sufficient proofs. By the acrimony of these effluvia, the nerves are affected with various spasms, the pulse is always quickened, at first raised, but soon depressed. Id. ibid. p. 298.

Were putrefaction the only change made in the body by contagion, it would be easy to cure such fevers, at any period, by the use of acids, or other antiseptics. But, as this cannot be effected, till the stated time of their decline, it seems probable, that whilst the sceptic progress goes on, the fever is chiefly supported by an inflammation in the brain; so that a cure cannot be expected, till the obstructing matter is resolved or suppurated. Id. ibid.

That this is the case, appears from the method of cure. Thus, before the inflammation is fixed, the sceptic particles may be expelled by sweating; after that period, the most effectual method is to support the strength; but so as not to increase the inflammation; and near the end of the last stage of the disease, the humours being resolved by putrefaction, the obstruction is thereby removed; at which time the stronger antiseptic and cordial medicines have place, in order to correct and expel what is so much vitiated. In this low state the volatiles are often necessary for raising the pulse: Wine is a constant cordial; and not only wine, but camphor, snake-root, and the bark, are endowed with strong antiseptic qualities. Id. ibid. p. 299. seq. See the articles BILIOUS *fever*, HOSPITAL-*fever*, DYSENTERY, &c. *Append.*

MALABAR-*nut*, in botany, the English name of a genus of plants, called by botanists *Adhatoda*. See the article ADHATODA, *Suppl.*

MALL, or *Sea*-MALL, the name by which we call several species of the *Larus*, or gull. See the article LARUS, *Suppl.*

MALLOW, in botany, the English name of a genus of plants, called by botanists *Malva*. See the article MALVA, *Suppl.*

Jews MALLOW, the name by which some call the *Corchorus*, of botanists. See the article CORCHORUS, *Append.*

Indian MALLOW, a name given to two different genuses of plants, called *Sida* and *Urena*, by botanists. See the articles SIDA and URENA, *Suppl.*

Marsh-MALLOW, the English name of a genus of plants, called *Althæa* by botanical writers. See the article ALTHÆA, *Suppl.*

Syrian MALLOW, or *Venetian* MALLOW, names by which some call the *Ketmia*, of botanical authors. See the article KETMIA, *Suppl.*

Vervain MALLOW, the English name of a distinct genus of plants, known among botanists by that of *Alcea*. See the article ALCEA, *Suppl.*

Yellow MALLOW, a name sometimes given to the *Sida* of Linnæus. See the article SIDA, *Suppl.*

MALOBATHRUM, among the Romans, a precious kind of ointment, brought from the Indies through Syria to Rome. *Pitisc.* in voc.

MALTSTER, a person whose employment it is to make malt, or one who trades with it. Rust. Dict. in voc.

MALVINDA, in botany, the name given by Dillenius, to a genus of plants, called by Linnæus *Sida*. See the article SIDA, *Suppl.*

MALUS, the *Apple-tree*, in botany, the name of a genus of plants, the characters of which are these; the flower is rosaceous, and consists of several leaves; the fruit is fleshy, almost round, and for the most part umbilicated at both ends; it is divided into several cells or partitions, in each of which is contained an oblong callous seed.

The species of *Apple-tree*, enumerated by Mr. Tournefort, are these: 1. The *Apple* with a full or double flower. 2. The *Dwarf-Apple*, with white fruit; this is rather a shrub than a tree. 3. The *Dwarf-Apple*, with reddish fruit. 4. The *Crab-tree*, or wild *Apple*, with very sour fruit. 5. The wild *Apple*, with acid fruit. 6. The wild *Apple*, with white and acid fruit. 7. The large *Apple*, with very tender and early ripening fruit. 8. The cultivated *Apple*, with green spots both without and within the fruit. 9. The garden *Apple*, with fruit almost without a pedicle. 10. The garden *Apple*, with roundish pale green fruit, of a sweetish acid taste. 11. The garden *Apple*, with greenish iron coloured fruit. 12. The garden *Apple*, with fruit full of protuberances. 13. The garden *Apple*, with orbicular, sweet-scented fruit. 14. The garden *Apple*, with bright purple fruit. 15. The garden *Apple*, with blood coloured fruit, of a sweetish sour taste. 16. The garden *Apple*, with large reddish and very acid fruit, and a long pedicle. 17. The garden *Apple*, with deep red and violet scented fruit. 18. the garden *Apple*, with pale red, scentless, and large fruit. 19. The garden *Apple*, with deep blood-red coloured fruit, variegated with rust-coloured spots. 20. The garden *Apple*, with turbinated, tender fruit. 21. The garden *Apple*, with oblong, hard, chesnut-tasted fruit. 22. The garden *Apple*, with globose fruit, partly red and partly yellow, and of a sweetish-sour taste. 23. The garden *Apple*, with orbicular sessile fruit, of a vinous taste. 24. The garden *Apple*, with pentagonal stelliform fruit, and somewhat acid taste. 25. The garden *Apple*, with polygonal fruit, of a vinous and somewhat acid taste. 26. The large, angular, vinous-tasted garden *Apple*. 27. The garden *Apple*, with large pileiform greenish-yellow fruit. 28. The garden *Apple*, with striated fruit, variegated with yellowish-red spots. 29. The garden *Apple*, with fruit partly white, and partly reddish, variegated with red spots. 30. The angular, sweet, garden *Apple*, dissolving in the mouth. 31. The angular, whitish, citron-coloured garden *Apple*. 32. The fructiferous *Apple*, with fading flowers. 33. The garden *Apple*, with oblong, sugar tasted, Anis-scented, greyish iron-coloured fruit. 34. The garden *Apple*, with whitish fruit partly punctated, and partly variegated with deep-red striæ. 35. The hard, sugar tasted garden *Apple*, with purple fruit. 36. The garden *Apple*, with very sweet, red, sessile fruit. 37. The oblong, somewhat arched, very white garden *Apple*, of a sweetish acid Taste. *Tournef.* Inst. Bot. 634, seq.

MAN, *Homo*, in zoology, is ranked by Linnæus at the head of a class of animals, which he calls *Anthropomorpha*. See the article ANTHROPOMORPHA, *Suppl.*

He distinguishes *Men*, according to their colours; into the European, or white *Men*; the American, or reddish-coloured *Men*; the Asiatic, or tawney-brown-coloured men; and lastly, those of Africa, or the blacks. *Linnæi*, system. Natur. p. 63. Mons. Bufon, among many other curious particulars, has given us several relating to the natural history of *Man*. See Histoire Naturelle Vol. III. pag. 305. Edit. Paris. That ingenious author has entered into a considerable detail with respect to the varieties of the human species. See Vol. III. pag. 371, seq. of the same work.

MANCHINEEL-*tree*, the English name of a genus of plants, called by botanists *Mancanilla*. See the article MANCANILLA, *Suppl.*

MANGLES, in botany, the name by which Plumier calls the *Rhizophora* of Linnæus. See the article RHIZOPHORA, *Suppl.*

MANGROVE-*tree*, a name by which some call the *Ketmia*. See the article KETMIA, *Suppl.*

MANGROVE-*grape*, the name of a genus of plants, known among authors by that of *Guajabara*. See the article GUAJABARA, *Append.*

MANIS, in zoology, the name of the scaly lizard, otherwise called *Lacertus squamosus*. See the article LACERTUS *squamosus*, *Suppl.*

MANNING *(Suppl.)* — MANNING *of a hawk*, in falconry, is the making her tractable, gentle, and tame. Dict. Rust. in voc.

MANTLE *(Suppl.)* — *Ladies*-MANTLE, in botany, the English name of a genus of plants, known among authors by that of *Alchimilla*. See the article ALCHIMILLA, *Suppl.*

MARACOCK, a name sometimes used for the *Granadilla* of botanical writers. See the article GRANADILLA, *Suppl.*

MARANTA, *Indian arrow-root*, in botany, the name of a genus of plants, the characters of which are these; the cup is a small perianthium affixed upon the germen, of a lanceolated figure, and consisting of three leaves; the flower is monopetalous, and of the ringent kind; the tube is oblong, compressed, crooked, and oblique; the limb is divided into six parts, the alternate exterior segments being of an ovated figure, equal in size, and small, one standing below,

below, and two above; whereas the two lateral ſegments are very large, of a roundiſh figure, and repreſent a lower lip; the the upper one being ſmall, and bipartite. The ſtamen is a ſingle membranaceous filament, much reſembling a ſegment of the corolla; the anthera is of a linear figure, and affixed to the ſide of the filament; the germen of the piſtil is roundiſh, and is placed beneath the receptacle of the flower; the ſtyle is ſimple, and of the length of the flower; and the ſtigma is ſomewhat trigonal and bent. The fruit is a roundiſh capſule, ſomewhat obſcurely trigonal, and compoſed of three valves, in each of which there is a ſingle, hard, rugoſe ſeed, of an ovated figure.

It is a native of America, deſcribed by Plumier, and is nearly allied to the Canna, but cannot be joined with it. Vid. Linnæi Gener. Plantar. p. 2.

MARJORAM *(Suppl.)* — *Spaniſh* MARJORAM, a name uſed by ſome for the *Urtica*, with pellitory leaves and round balls. See the article URTICA, *Suppl.*

Sweet MARJORAM, a name given by ſome to a genus of plants, called by others *Parthenium*. See the article PARTHENIUM, *Suppl.*

MARKING-*Yarn*, in ſhips of war, is white yarn ſpun the wrong way, and put into all cordage of three inches and upwards, as the king's mark. *Blanckley*'s Naval Expoſitor, p. 103.

MARSH-*Elder*, or *Water-Elder*, the name by which ſome call the *Opulus*. See the article OPULUS, *Suppl.*

MARSH-*fever*, is a ſpecies of bilious *fever*. See the article BILIOUS, *Append.*

Thoſe, ſeized with the *Marſh-fever*, are tormented with a burning heat, and violent head-ach. They complain likewiſe of intenſe thirſt, aking of the bones, a pain of the back, great laſſitude and inquietude; and frequently of a nauſea, ſickneſs, or a pain about the pit of the ſtomach; which is ſometimes attended with a vomiting of green or yellow bile, of an offenſive ſmell. The head is ſometimes ſo ſuddenly and violently affected, that without any previous complaint, the patients run about in a wild manner, as if they were mad; and would throw themſelves out of windows, or into the water, if not prevented. *Pringle*, Obſerv. on the Diſ. of the Army, p. 171.

MARSH *trefoil*, the name of a genus of plants, called by authors *Menyanthes*. See the article MENYANTHES, *Suppl.*

MARSHY *Countries*. It is to be obſerved, that neither canals, nor even large inundations, where the water is deep, are nearly ſo dangerous in regard to peoples health, or exhale ſo much noxious vapours, as *marſhy* grounds, or meadows that have been once floated, and but lately drained; and that fields, tho' dry in appearance, may nevertheleſs be moiſt, by the tranſpiration of ſubterraneous water. *Pringle*, Obſerv. on the Diſ. of the Army, p. 82.

By this exhalation, as well as by that of ditches and canals, in all which innumerable plants and inſects die and rot, the atmoſphere is filled, eſpecially during the latter part of ſummer and autumn, with moiſt, putrid, and inſalutary vapours. Add to this, that *marſhy* countries being low, and without hills to receive the winds, or direct them in ſtreams upon the lower grounds, the air is apt to ſtagnate and corrupt. The common water too, being either collected from rains, and preſerved in ciſterns, or drawn from ſhallow wells, is, in hot and dry ſeaſons, ſoon corrupted; ſo that every thing conſpires, in ſummer, not only to relax the ſolids, but to diſpoſe the humours to putrefaction. Id. ibid. p. 2.

In *marſhy* countries rainy and moiſt ſeaſons differ greatly; ſince intenſe and continued heats occaſion the greateſt moiſture in the atmoſphere, by the immenſe exhalations they raiſe; whereas frequent ſhowers, during the hot ſeaſon, cool the air, check the exceſs of vapours, dilute and refreſh the corrupted ſtagnating water, and precipitate all putrid and noxious effluvia. But, if heavy rains in the beginning of ſummer, are ſucceeded by great and uninterrupted heats, thoſe rains, by overflowing the meadows, ſerve only for matter of more exhalation, and to make the ſeaſon more ſickly, and the diſtempers more fatal. Id. ibid. p. 5.

The epidemic of the hot ſeaſon, and the great endemic of *marſhy* countries, is a fever of an intermitting nature, commonly of a tertian ſhape, but of a bad kind; which in the damper places and worſt ſeaſons, appears in the form of a double tertian, remittent, continued, putrid, or even an ardent fever. *Marſhy* countries are likewiſe ſubject, more than any others, to the cholera morbus, dyſentery, and a kind of ſcurvy, peculiar to a moiſt and corrupted air; the ſymptoms of which laſt agree ſo much with the ſea-ſcurvy, that they may be accounted the ſame diſeaſe; the exhalations of the canals and *marſhes*, in hot weather, acting like the vapour which riſes from the bildge-water of a ſhip. Id. ibid. p. 6, ſeq.

As to the diet neceſſary in moiſt places, it may be obſerved in general, that thoſe who can afford to live above the common rate, keep freeſt from the diſeaſes of the *marſhes*. For ſuch climates require dry houſes, the apartments raiſed from the ground, proper exerciſe, without labour in the ſun, or in the evening damps, a juſt quantity of vinous liquors, and victuals of good nouriſhment. Without ſuch helps, not only ſtrangers, but the natives themſelves, are extremely ſickly after hot and cloſe ſummers. Id. ibid. p. 9.

MARTAGON, the name given by ſome to ſeveral ſpecies of *Lilly*. See the article LILIUM, *Suppl.*

MARTIN, in ornithology, the Engliſh name of the black *Hirundo*, with only the throat white. See the article HIRUNDO, *Suppl.*

MARYGOLD *(Suppl.)* — *Fig*-MARYGOLD, the name by which ſome call the *Ficoides* of botaniſts. See the article *Suppl.* and *Append.*

MASH, the name of a drink given to horſes or cattle. It is made of half a peck of ground malt, put into a pail; on which is poured as much hot ſcalding water, as will wet it well; then ſtirring it about half an hour, till it becomes lukewarm, and ſweet like honey, it is to be given to the horſe.

A *maſh* is only given after a purge, to make it work better; after hard labour, or for drink in time of ſickneſs. Ruſt. Dict. in voc.

MASTER-*wort*, a name ſometimes given to the *Aſtrantia* of botanical writers. See the article ASTRANTIA, *Suppl.*

MASTIC-*tree*, the name by which ſome call the *Lentiſcus* of authors. See the article LENTISCUS, *Suppl.*

MASTIC-*tree of Jamaica*, a name ſometimes given to the *Calaba*, or *Caryophillum*. See the article CARYOPHILLUM, *Append.*

Indian MASTIC, the name by which the *Molle*, or Peruvian Lentiſk is ſometimes called. See the article MOLLE, *Suppl.*

MATFELON, a name ſometimes gived to the *Jacea* of botaniſts, more uſually called *Knapweed*. See the article JACEA, *Suppl.*

MATURATION *of fruit*. For the ſeveral ways of haſtening the *maturation of fruit*, ſee the articles HOT-*beds*, FORCING, and CAPRIFICATION, *Suppl.*

MAUDLIN, the Engliſh name of a genus of plants, called by botaniſts *Ageratum*. See the article AGERATUM, *Suppl.*

MAUROCENIA, in botany, the name of a genus of plants, the characters of which are theſe; the cup is a very ſmall one-leaved perianthium, divided into five ſegments, and permanent; the flower conſiſts only of one leaf, divided into five oval, patent ſegments; the ſtamina are five erect ſubulated filaments, longer than the flower; the antheræ are ſimple; the germen of the piſtil is conic; there is no ſtyle; the ſtigmata are three, and gibbous; the fruit is an oval berry, umbilicated with the ſtigmata; the ſeeds are three, oblong, and ſcarce ſeparable from the pulp.

Dillenius makes this genus a ſpecies of Frangula. Vid. *Linnæi* Gen. Plant. p. 125.

MAW, or SEA-MAW, the ſame with the *Sea-Mall*. See the article MALL, *ſupra.*

MAY-*buſh*, in botany, a name ſometimes given to the *Meſpilus*, or Medlar. See the article MESPILUS, *Suppl.*

MAY-*duke*, a name uſed among Gardeners for a ſpecies of cherry-tree. See the article CERASUS, *Suppl.*

MAY-*lilly*, a name ſometimes uſed for the *Convallaria*, or *Lilium Convallium*. See the article LILIUM CONVALLIUM, *Suppl.*

MAY-*weed*, a name by which ſome call the *Chamæmile*. See the article CHAMÆMELUM, *Suppl.*

MAZE, in gardening, the ſame with *Labyrinth*. See the article LABYRINTH, *Cycl.* and *Suppl.*

MEADOW-*graſs*, in botany. See the article GRASS, *Append.*

MEADOW-*rue*, the Engliſh name of a genus of plants, called by botaniſts *Thalictrum*. See the article THALICTRUM, *Suppl.*

MEADOW-*ſweet*, in botany, the Engliſh name of a genus of plants, called by authors *Ulmaria*. See the article ULMARIA, *Suppl.*

MEALY-*tree*, in botany, a name ſometimes given to the *Viburnum*. See the article VIBURNUM, *Suppl.*

MECHANICS *(Cycl.)* — The term *Mechanics* has of old been, and ſtill is, uſed in a double ſenſe in very different ſciences, both with reſpect to their objects and principles. For the name *Mechanics* is applied equally to that ſcience which treats of the equilibrium and compariſon of powers; and to that ſcience in which the nature, generation, and alteration of motion is explained. To avoid ambiguity, therefore, it would be proper to give the name *Statics* to the ſcience of the equilibrium and compariſon of powers, and to reſtrain the term *Mechanics* to the ſcience of motion.

Theſe two ſciences not only differ as to their objects and principles, but alſo with reſpect to the times in which they have been cultivated. Some of the principles of *Statics* were eſtabliſhed by Archimedes; but Galileo laid the firſt foundation of Mechanics, when he inveſtigated the deſcent of heavy bodies; and ſince his time, by the aſſiſtance of the new methods of computation, a great progreſs has been made, particularly by Sir Iſaac Newton, in his Principia. This admirable work is now rendered more acceſſible to beginners by the learned comment of the fathers le Seur and Jacquier, printed, with the text, at Geneva,

1739, 4to, 1742, 4 vols. 4to. We have alſo the ſciences of Statics and *Mechanics* treated of under the name of Phoronomia, by the late learned profeſſor Herman. Amſt. 1716. 4to. Mr. Euler's *Mechanica, ſive de motus ſcientia*; is ſufficiently recommended by the name of the author, well known as one of the moſt eminent mathematicians in Europe. This work, however, did not eſcape the cenſure of a late ingenious writer; but granting the juſtneſs of his remarks, it may be ſaid, that a few inaccurate expreſſions, owing to analogies carried too far, and to the ſtyle of infiniteſimals, are but ſmall flaws in ſuch a work. As to ſtatics, the ſubject has been almoſt exhauſted by Varignon, in his Mecanique, Paris, 1725, 2 vol. 4to.

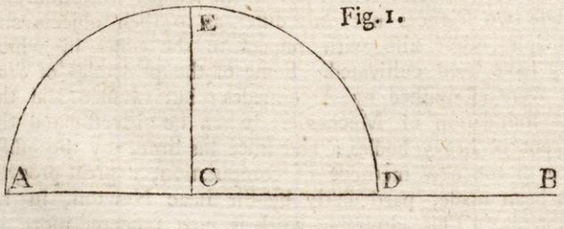
The doctrine of machines or engines is a principal branch of *Mechanics*; but has not as yet been treated as it deſerves. We ſhall here inſert a few obſervations on this uſeful ſubject, from a late eminent author.

In treating of machines, we ſhould conſider the weight that is to be raiſed, the power by which it is to be raiſed, and the inſtrument or engine by which this effect is to be produced. There are two principal problems that ought to be reſolved in treating of each of them.

The firſt is, to determine the proportion which the power and weight ought to have to each other, that they may juſt ſuſtain one another, or be in æquilibrio.

The ſecond is, to determine what ought to be the proportion of the power and weight to each other, in a given machine, that it may produce the greateſt effect poſſible, in a given time.

All the writers on *Mechanics* treat of the firſt of theſe problems, but few have conſidered the ſecond, tho' equally uſeful with the other.



As to the firſt problem, this general rule holds in all powers: Suppoſe the engine to move, and reduce the velocities of the power and weight to the reſpective directions in which they act; find the proportions of thoſe velocities; then if the power be to the weight, as the velocity of the weight is to the velocity of the power, or, which amounts to the ſame thing, if the power multiplied by its velocity, gives the ſame product as the weight multiplied by its velocity, this is the caſe wherein the power and weight ſuſtain each other, and are in equilibrio; ſo that in this caſe, the one would not prevail over the other, if the engine was at reſt; and if it is in motion, it would continue to proceed uniformly, if it were not for the friction of its parts, and other reſiſtances.

The ſecond general problem in *Mechanics*, is, to determine the proportion which the power and weight ought to bear to each other, that when the power prevails, and the machine is in motion, the greateſt effect poſſible may be produced by it in a given time. It is manifeſt, that this is an inquiry of the greateſt importance, tho' few have treated of it. When the power is only a little greater than that which is ſufficient to ſuſtain the weight, the motion is too ſlow; and tho' a greater weight is raiſed in this caſe, it is not ſufficient to compenſate the loſs of time. When the weight is much leſs than that which the power is able to ſuſtain, it is raiſed in leſs time; and this may happen not to be ſufficient to compenſate the loſs ariſing from the ſmallneſs of the load. It ought, therefore, to be determined when the product of the weight multiplied by its velocity, is the greateſt poſſible; for this product meaſures the effect of the engine in a given time, which is always the greater in proportion as the weight which is raiſed is greater, and as the velocity with which it is raiſed is greater. We ſhall therefore ſubjoin ſome inſtances of this kind, that may be demonſtrated from the common elementary geometry; wiſhing that farther improvements may be made in this moſt uſeful part of *Mechanics*.

When the power prevails, and the engine begins to move, the motion of the weight is at firſt gradually accelerated. The action of the power being ſuppoſed invariable, its influence in accelerating the motion of the weight decreaſes, while the velocity of the weight increaſes. Thus the action of a ſtream of water, or air, upon a wheel, is to be eſtimated only from the exceſs of the velocity of the fluid above the velocity already acquired by the part of the engine which it ſtrikes, or from their relative velocity. On the other hand, the weight of the load that is to be raiſed, and the friction, tend to retard the motion of the engine; and when theſe forces, viz. thoſe that tend to accelerate it, and thoſe that tend to retard it, become equal, the engine then proceeds with the uniform motion it has acquired.

Let A B (Fig. 1.) repreſent the velocity of the ſtream, A C, the velocity of the part of the engine which it ſtrikes,

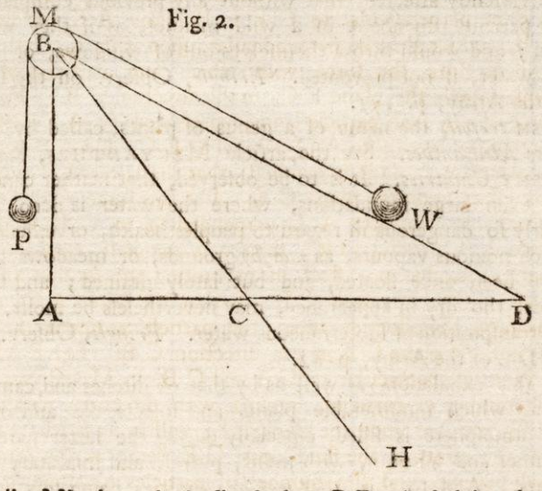


Fig. 1.

when the motion of the machine becomes uniform; and C B will repreſent their relative velocity, upon which the effect of the engine depends. It is known that the action of a fluid, upon a given plane, is as the ſquare of this relative velocity; conſequently the weight raiſed by the engine, when its motion becomes uniform, being equal to this action, it is likewiſe as the ſquare of C B. Let this be multiplied by A C, the velocity of the part of the engine impelled by the fluid; and the effect of the engine in a given time will be proportional to $A C \times C B^2 =$ (ſuppoſing C B to be biſſected in D) $A C \times 2 C D \times 2 D B = 4 A C \times C D \times D B$; conſequently, the effect of the engine is greateſt, when the product of A C, C D, and D B is greateſt. But it is eaſy to ſee, that this product is greateſt, when the parts A C, C D, and D B, are equal; for if you deſcribe a ſemicircle upon A D, and the perpendicular C E meet the circle in E, then $A C \times C D = C E^2$, and is greateſt, when C is the center of the circle; ſo that in order that $A C \times C D \times D B$ may be the greateſt poſſible, A D muſt be biſſected in C; and C B having been biſſected in D, it follows, that A C, C D, D B, muſt be equal; or that A C, the velocity of the part of the engine impelled by the ſtream, ought to be but one third of A B, the velocity of the ſtream. In this caſe, when (abſtracting from friction) the engine acts with the utmoſt advantage; the weight raiſed by it is to the weight that would juſt ſuſtain the force of the ſtream, as the ſquare of C B, the relative velocity of the engine and ſtream, to the ſquare of A B, which would be the relative velocity, if the engine was quieſcent; that is, as 2×2 to 3×3, or 4 to 9. Therefore, that the engine may have the greateſt effect poſſible, it ought to be loaded with no more than $\frac{4}{9}$ of the weight, which is juſt able to ſuſtain the efforts of the ſtream. See *Mac Laurin*'s Account of Sir Iſaac Newton's Diſcov. p. 171. ſeq. and Fluxions, Art. 908.

Again ſuppoſe that a given weight P, (Fig. 2.) deſcending by its gravity in the vertical line, raiſes a greater weight W likewiſe given, by the rope P M W (that paſſes over the fixed

Fig. 2.

pully M) along the inclined plane B D, the height of which B A is given; and let it be required to find the poſition of this plane, along which W will be raiſed in the leaſt time, from the horizontal line A D to B. Let B C be the plane upon which if W was placed, it would be exactly ſuſtained by P; in which caſe, P is to W as A B to B C. But W is to the force with which it tends to deſcend along the plane B D, as B D to A B; conſequently the weight P is to that force, as B D to B C. Therefore the exceſs of P above that force (which exceſs is the power that accelerates the motions of P and W) is to P, as B D — B C to B D; or taking B H upon B C equal to B D, as C H to B D. But it is known that the ſpaces deſcribed by motions uniformly accelerated, are in the compound ratio of the forces which produce them and the ſquares of the times; or that the ſquare of the time is directly as the ſpace deſcribed in that time, and inverſely as the force; conſequently, the ſquare of the time, in which B D is deſcribed by W, will be directly as B D, and inverſely as $\frac{C H}{B D}$, and will be leaſt when $\frac{B D^2}{C H}$ is a minimum; that is, when $\frac{B C^2}{C H} + C H + 2 B C$, or (becauſe 2 B C is invariable) when $\frac{B C^2}{C H} + C H$ is a minimum. Now as when the ſum of two quantities is given, their product is a maximum, when they are equal to each other; ſo it is manifeſt, that, when their product is given, their ſum muſt be a minimum, when they are equal. Thus it is evident, that as in Fig. 1. the rectangle or product of the equal parts A C and C D was equal to $C E^2$; ſo the rectangle of any two unequal parts, into which A D may be divided, is leſs than $C E^2$, and A D is the leaſt ſum of any two quantities, the product of which is equal to $C E^2$. But the product of $\frac{B C^2}{C H}$ and C H is $B C^2$, and conſequently given; therefore the ſum of $\frac{B C^2}{C H}$ and C H is leaſt, when

theſe

theſe parts are equal, that is, when C H is equal to B C, or B D equal to 2 B C. It appears, therefore, that when the power P and weight W are given, and W is to be raiſed by an inclined plane, from the level of a given point A to the given point B in the leaſt time poſſible; we are firſt to find the plane B C, upon which W would be ſuſtained by P, and to take the plane B D double in length of the plane B C; or we are to make uſe of the plane B D, upon which a weight that is double of W could be ſuſtained by the power P.

For another example, ſuppoſe a fluid, moving with the velocity and direction A C, (Fig. 3.) ſtrike the plane C E; and ſuppoſe that this plane moves parallel to itſelf in the direction C B, perpendicular to C A, or that it cannot move in any other direction. Then let it be required to find the moſt advantageous poſition of the plane C E, that it may receive the greateſt impulſe from the action of the fluid. Let A P be perpendicular to C E in P, draw A K parallel to C B, and let P K be perpendicular upon it in K, and A K will meaſure the force with which any particle of the fluid impells the plane E C, in the direction C B. For the force of any ſuch particle being repreſented by A C, let this force be reſolved into A Q parallel to E C, and A P perpendicular to it; and it is manifeſt, that the latter A P only has any effect upon the plane C E. Let this force A P be reſolved into the force A L perpendicular to C B, and the force A K parallel to it; then it is manifeſt, that the former, A L, has no effect in promoting the motion of the plane in the direction C B: ſo that the latter A K, only, meaſures the effort by which the particle promotes the motion of the plane C E in the direction C B. Let E M and E N be perpendicular to C A and C B, in M and N; and the number of particles, moving with directions parallel to A C, incident upon the plane C E, will be as E M. Therefore the effort of the fluid upon C E being as the force of each particle, and the number of particles together, it will be as A K × E M; or, becauſe A K is to A P (= E M,) as E N to C E, as $\frac{EM^2 \times EN}{CE}$; ſo that C E being given, the problem is reduced to this, to find when $EM^2 \times EN$ is the greateſt poſſible, or a maximum. But becauſe the ſum of EM^2 and of EN^2 (= CM^2) is given, being always equal to CE^2, it follows, that $EN^2 \times EM^4$, is greateſt, when $EN^2 = \frac{1}{3} CE^2$; in the ſame manner as it was demonſtrated above, that when the ſum of A C and C B (Fig. 1.) was given, $AC \times CB^2$ was greateſt, when $AC = \frac{1}{3} AB$. But when $EN \times EM^4$ is greateſt, its ſquare root $EN \times EM^2$ is of neceſſity at the ſame time greateſt. Therefore the action of the fluid upon the plane C E in the direction C B is greateſt when $EN^2 = \frac{1}{3} CE^2$, and conſequently $EM^2 = \frac{2}{3} CE^2$; that is, when E M, the ſine of the angle A C E, in which the ſtream ſtrikes the plane, is to the radius, as the $\sqrt{2}$ to $\sqrt{3}$; in which caſe it eaſily appears, from the trigonometrical tables, that this angle is of 54°. 44′.

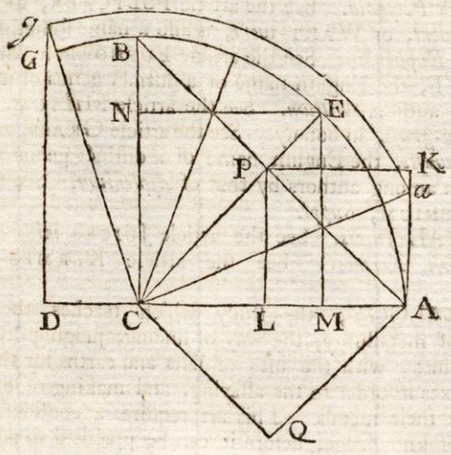

Fig. 3.

Several uſeful problems in *Mechanics* may be reſolved by what was ſhewn in the preceding paragraph. If we repreſent the velocity of the wind by A C, a ſection of the ſail of a wind-mill perpendicular to its length by C E, as it follows from the nature of the engine, that its axis ought to be turned directly towards the wind, and the ſail can only move in a direction perpendicular to the axis, it appears, that, when the motion begins, the wind will have the greateſt effect to produce this motion, when the angle A C E, in which the wind ſtrikes the ſail, is of 54°. 44′. In the ſame manner, if C B repreſent the direction of the motion of a ſhip, or the poſition of her keel, abſtracting from her lee-way, and A C be the direction of the wind, perpendicular to her way, then the moſt advantageous poſition of the ſail C E, to promote her motion in the direction C B, is when the angle A C E, in which the wind ſtrikes the ſail, is of 54°. 44′. The beſt poſition of the rudder, where it may have the greateſt effect in turning round the ſhip, is determined in like manner. And the ſame angle enters likewiſe into the determination of the figure of the rhombuſes that form the baſes of the cells in which the bees depoſite their honey, in the moſt frugal manner. See the article BEE, *Suppl.*

But it is to be carefully obſerved, that when the ſine of the angle A C E is to the radius as $\sqrt{2}$ to $\sqrt{3}$; or, which is the ſame thing, when its tangent is to the radius, as the diagonal of a ſquare to its ſide; this is the moſt advantageous angle only at the beginning of the motion of the engine; ſo that the ſails of a common wind-mill ought to be ſo ſituated, that the wind may indeed ſtrike them in a greater angle than that of 54°. 44′. For it is demonſtrable, that when any part of the engine has acquired the velocity c, the effort of the wind upon that part will be greateſt, when the tangent of the angle in which the wind ſtrikes it is to the radius, not as the $\sqrt{2}$ to 1, but $\sqrt{2} \times \frac{9cc}{4aa} \times \frac{3c}{2a}$ to 1, the velocity of the wind being repreſented by a. If, for example, $c = \frac{1}{3} a$; then the tangent of the angle A C E ought to be double of the radius; that is, the angle A C E ought to be of 63° 26′. If $c = a$; then A C E ought to be of 74° 19′. This obſervation is of the more importance, becauſe, in this engine, the velocity of the parts of the ſail remote from the axis, bears a conſiderable proportion to the velocity of the wind, and perhaps ſometimes is equal to it; and becauſe a learned author, Mr. Daniel Bernoulli, has drawn an oppoſite concluſion from his computations in his *Hydrodynamics*, by miſtaking a minimum for a maximum; where he infers, that the angle in which the wind ſtrikes the ſail, ought to decreaſe as the diſtance from the axis of motion increaſes; that if $c = a$, the wind ought to ſtrike in an angle of 45°; and that if the ſail be in one plane, it ought to be inclined to the wind, at a medium, in an angle of 50°. How he fell into theſe miſtakes, is ſhewn by Mr. *Mac Laurin*, in his Fluxions, §. 914.

In like manner, though the angle A C E of 54°. 44′. be the moſt advantageous at the beginning of the motion, when a ſhip ſails with a ſide wind; yet it ought to be enlarged afterwards as the motion increaſes. In general, let A a, parallel to C B, be to A C, as the velocity which the engine has already acquired in the direction C B, to that of the ſtream; upon A C produced take A D to A C as 4 to 3, draw D G parallel to C B, and let a circle deſcribed from the center C with the radius C a, meet D G in g; and the plane C E ſhall be in the moſt advantageous ſituation for promoting the motion of the engine, when it biſſects the angle $a C g$.

It is generally ſuppoſed, that a direct wind always promotes the motion of a ſhip, the ſail being perpendicular to the wind, more than any ſide-wind; and this has been affirmed in ſeveral late ingenious treatiſes; but, to prevent miſtakes, we are obliged to obſerve, that Mr. *Mac Laurin* has demonſtrated the contrary, in his Treatiſe of Fluxions, §. 919; where other inſtances of this ſecond general problem in *Mechanics* are given, to which we refer. See *Mac Laurin's* Account of Sir Iſaac Newton's Philoſophical Diſcoveries, B. II. c. 3. p. 173. ſeq.

MECHOACAN, *(Cycl.)* the name by which the great American *Convolvulus*, or bindweed, is known in the ſhops. See the article CONVOLVULUS, *Suppl.*

MEDIC-*vetching*, a name by which ſome call the *Onobrychis*. a diſtinct genus of plants. See the article ONOBRYCHIS, *Suppl.*

MEDICA *(Suppl)*—*Baſtard*-MEDICA, the Engliſh name of a genus of plants, called by botanical writers *Medicago*. See the article MEDICAGO, *Suppl.*

MEDLAR *(Suppl.)* — *Parſley-leaved* MEDLAR, the name by which ſome call a ſpecies of *Cratægus*. See the article CRATÆGUS, *Suppl.*

MEDUSA, in zoology, the name of a genus of inſects, of the order of the *Gymnarthria*. See the article GYMNARTHRIA, *Append.*

The body of the *Meduſa* is of an orbiculated convex figure of a gelatinous ſubſtance, and not hairy. The tentacula, or the plicæ, which ſerve inſtead of them, are ſituated in the center of the under part of the animal. Authors have deſcribed them under the names *Urticæ marinæ*, and *Pulmones marini*. See the article URTICA *Marina*, *Suppl.*

MELANCHOLY *thiſtle*, *Cirſium*, in botany, the name of a ſpecies of *Thiſtle*. See the article THISTLE, *Suppl.*

MELANTHIUM, in botany, a name uſed by ſome authors for a ſpecies of *Nigella*. See the article NIGELLA, *Suppl.*

MELOE, in zoology, the name of a genus of four-winged flies, whoſe antennæ are ſlender and filiform; and the exterior wings dimidiated. It is called in Engliſh the *oil-beetle*, as being ſoft and mucuous to the touch. It is black, but not at all gloſſy, and has been deſcribed by authors under the names *Scarabæus mollis*, *Cantharus unctuoſus*, and *Proſcarabæus*. See the article SCARABÆUS, *Suppl.*

MELON *(Suppl.)* — *Water*-MELON, the name of a genus of plants, called by botaniſts *Anguria*. See the article ANGURIA, *Suppl.*

Thiſtle-MELON, *Cactus*, in botany, the name of a genus of plants. See the article CACTUS, *Suppl.* and *Append.*

MENIANTHES, in botany, the ſame with *Menyanthes*, a diſtinct genus of plants. See the article MENYANTHES, *Suppl.*

MENISPERMUM, in botany, the name of a diſtinct genus of plants, the characters of which are theſe: The cup is a deciduous perianthium, compoſed of ſix ovato-oblong leaves, erecto-patent, and of the length of the corolla; which conſiſts of ſix ovato-oblong, obtuſe, hollow petals, erecto-patent, like the leaves of the cup; the ſtamina are ſix very ſhort filaments; the antheræ are ſimple, and ſhorter than the corolla; the germina are three, ſuboval, and terminate in as many patenti-reflex ſtyles, of the length of the corolla; the ſtigmata are obtuſe and emarginated. The fruit is compoſed of three oval berries, each containing a ſingle cell, and in it a large, ſingle, lunulated, compreſſed ſeed. *Linnæi* Gen. Plant. p. 155.

Plukenet calls this genus the one-leaved Virginian *hedera*, with the leaves of convolvulus.

MERCURY *(Suppl.)* — *Virgin*-MERCURY, called *Jungfraw* by the German miners, is uſed for that which diſcovers itſelf without the aſſiſtance of fire. This is ſometimes ſeen in drops, globules, or larger maſſes in the ore, or falls in drops from the crevices in the roof or walls of the mine, or finally is found in large quantities in the hollows of the rocks. Theſe large collections of pure virgin quickſilver often diſcover themſelves by burſting out in ſmall ſtreams in the mines of Friuli. They ſometimes are ſurpriſed with a ſtream of it like a thread, which gradually increaſing to the thickneſs of a packthread, continues to run three or four days, and diſcharges in that time a vaſt quantity of the quickſilver; if the miners can follow this ſpring to the head, they generally obtain a large quantity more; and often this ſort of ſpringing up of it leads them to very rich veins of the mine which they did not before know of. They give the ſame name of *Jungfraw* or virgin-quickſilver alſo to that *Mercury* which has no need of fire for the ſeparation, but is waſh'd out of its ores by a ſieve and large quantities of water, continually and forcibly running on it.

The ores of quick-ſilver often contain a large quantity of that mineral embedded in them in this form, and often ſo mix'd in other parts with ſulphurs, as to be diſguiſed into cinnabar; in this caſe a great deal is ſeparated by this waſhing, which at the ſame time frees the ore from dirt, and renders it fitter for the operation of the fire, by which a great deal more is then extracted.

The union of *Mercury* with antimony is very difficult, but has been effected by Monſ. Malouin. See Hiſt. Ac. Scienc. 1740.

The ſame gentleman ſucceeded alſo in uniting *Mercury* with tin and lead, ſo as to improve theſe metals in ſome reſpects, rendering them harder, whiter, and more ſonorous. Hiſt. Ac. ibid.

Engliſh MERCURY, the name of a diſtinct genus of plants, called by botaniſts *Chenopodium*. See the article CHENOPODIUM, *Suppl.*

MERLIN, in ornithology, the Engliſh name of the yellow-legged *Falco*, with a variegated back, and a brown and white belly. See the article FALCO, *Suppl.*

This bird is alſo called *Oeſalon*. See the article ŒSALON, *Suppl.*

MESHES *of nets*, the openings and vacancies in net-works. Ruſt. Dict. in voc.

MESSES *of ſoldiers*, in what reſpect uſeful. See the article DIET, *Append.*

METALS are expanded by *Heat*, but in different degrees. See the articles HEAT and PENDULUM, *Append.*

By what may be learned from the analyſes of metals, ſo far as that ſubject has yet been proſecuted, it ſeems that they all contain a running *Mercury* fixed in them, as water is fixed in dry, animal, and vegetable ſubſtances; and joined with a ſulphur or an inflammable part, and an earth, with a little ſalt in ſome of them. *Shaw*'s Lectures, p. 162.

METHONICA, in botany, the name given by Tournefort to a diſtinct genus of plants, called by Linnæus *Glorioſa*. See the article GLORIOSA, *Append.*

METOPE *(Cycl.)* — Le Clerc obſerves, that the beauty of *Metopes* conſiſts in their regularity, on appearing to be perfect ſquares; and yet when they are equally ſquare, they appear to be leſs in height than in breadth, on account of the projecture of the little bandelet; for which reaſon they ſhould be made a minute or two more in height than in breadth, in order to make their appearance uniform.

He alſo obſerves, that when the triglyphs and *Metopes* follow each other regularly, the columns muſt only ſtand one by one; excepting thoſe of the inner angles, which ought always to be accompanied by two others, one on each ſide; and here it is worth remarking, that theſe two columns which accompany that of the angle, are not leſs neceſſary on account of the ſolidity of the building, than of the regularity of of the intercolumniations.

MEU, MEW, or SPIGNEL, a name ſometimes given to the *Meum* of botaniſts. See the article MEUM, *Suppl.*

MEWING, a diſorder incident to all kind of birds, being the caſting of their feathers. Ruſt. Dict. in voc.

MIDAS's *Ear-ſhell*, a name uſed by ſome for a ſpecies of *buccinum*, or trumpet-ſhell. See the article TRUMPET-*ſhell*, *Suppl.*

MILFOIL, a name ſometimes given to the *Milleſolium*, or yarrow, of other writers. See the article MILLEFOLIUM, *Suppl.*

MILK-*vetch*, the name of a genus of plants, called by botaniſts *Aſtragalus*. See the article ASTRAGALUS, *Suppl.*

Baſtard MILK-*vetch*, a name ſometimes given to the *Phaca*, or *Aſtragaloides*, of botaniſts. See the article ASTRAGALOIDES, *Suppl.*

MILK-*wort*, the name of a diſtinct genus of plants, called by authors *Polygala*. See the article POLYGALA, *Suppl.*

MILK-*wort*, or WART-*wort*, is alſo a name ſometimes given to the *Euphorbia*. See the article EUPHORBIA, *Suppl.*

MILLET, the Engliſh name of a diſtinct genus of plants, called by authors *Milium*. See the article MILIUM, *Suppl.*

MILLET-*graſs*, in botany. See the article GRASS, *Append.*

MILT-*waſte*, the Engliſh name of a diſtinct genus of plants, known among authors by that of *Aſplenium*. See the article ASPLENIUM, *Suppl.*

MINERAL *Juices*. See the article JUICES *mineral*, *Suppl.*

MINERAL *Kermes*. See the article KERMES *mineral*, *Suppl.*

MINERALOGY, the ſtudy which teaches the previous part of metallurgy, the way of finding, judging of, and digging mines; with the uſes of ſalts and earths for the making of fluxes in order to the aſſaying, and making of ores to ſeparate their metals. This art requires a conſiderable compaſs of knowledge, before it can be practis'd to advantage; for as it includes the diſcovery, ſinking, and working of mines, it requires a competent knowledge of the nature of effluvia, and the effects of all mineral matters, ſalts, ſulphurs, &c. as well as the knowledge of all valuable mineral ſubſtances, as earths, bitumens, ſtones, ores, gems, and metals. It likewiſe requires a knowledge in the internal ſtructure of the earth, and its various ſtrata, with a competent ſkill in menſuration, hydraulics, meaſuring, and mechanics; for without theſe we can never judge what mountain, plain, or valley is proper to be dug, or in what manner to dig it, how to diſcharge the water that may flow into the works, how the beds of ore and ſtone will dip and run, how the various kinds of earth, marble, and other mineral or metalic matter, are to be cut through or broken, or how the general proceſs of mining ſhould be conducted, in order to procure, with the leaſt expence, the matter of the ore. *Shaw*'s Lectures, p. 240.

MINT *(Suppl.)* —*Corymbiferous* MINT, in botany, a name given by ſome to a ſpecies of Tanzy. See the article TANACETUM, *Suppl.*

Spear-MINT, the name commonly given to the narrow leaved ſpiked *Mint*. See the articles MENTHA and MINT, *Suppl.*

Cat's-MINT, the Engliſh name of a genus of plants, called by botanical writers *Cataria*. See the article CATARIA, *Suppl.*

MIRE-*Drum*, and MIRE-*Snipe*, names uſed in different parts of the kingdom for the *ardea ſtellaris*, or bittern. See the articles BITTERN and HERON, *Suppl.*

MISCARRIAGE, the popular term for *Abortion*. See the articles ABORTION, *Cycl.* and PREGNANCY, *Suppl.*

MISLETOE, the Engliſh name of a diſtinct genus of plants, called by botaniſts *Viſcum*. See the article VISCUM, *Suppl.*

MITCHELS, among builders, are purbeck ſtones, from fifteen inches ſquare to two feet, ſquared and hewed ready for paving. Ruſt. Dict. in voc.

MITHRIDATE-*muſtard*, in botany, the name by which ſome call the *Thlaſpi*, or treacle muſtard. See the article THLASPI, *Suppl.*

Baſtard-MITHRIDATE-*muſtard*, a name ſometimes given to the *Thlaſpidium* of botaniſts. See the article THLASPIDIUM, *Suppl.*

MITRE-*ſhell*, the Engliſh name of the ſmooth and ſlender buccinum, with a ſplit roſtrum. See the article TRUMPET-*ſhell*, *Suppl.*

MOCK-*orange*, a name by which the *ſyringa*, or pipe-tree, is ſometimes called. See the article SYRINGA, *Suppl.*

MOCK-*privet*, a name ſometimes given to the *Phyllerea* of botaniſts. See the article PHYLLEREA, *Suppl.*

MODILLION *(Cycl.)* — In the Corinthian order it is uſual to have a leaf which takes up the whole breadth, and almoſt the whole length, of the modillions; but Le Clerc is of opinion, that they would be more graceful if this leaf were leſs, both in length and breadth. The leaf ought likewiſe to be of the ſame kind with thoſe which make the ornament of the capital. Build. Dict. in voc.

MOISTURE. The bad effects of too much *moiſture*, in regard to health, has been conſidered under the article MARSHY *Countries*, *Append.*

Stink-

MOMORDICA *(Suppl.)* — *Stinking* MOMORDICA, a name uſed by ſome for the large fruited white *bryony* of Ceylon. See the article *Bryonia alba*, *Suppl.*

MONBIN, in botany, the name given by Plumier to a genus of plants, called by other botaniſts *Spondias*. See the article SPONDIAS, *Suppl.*

MONEDULA, in ornithology, a name uſed by ſome writers for the *Jackdaw*, a ſpecies of *Corvus*. See the articles CORVUS, and JACKDAW, *Suppl.*

MONEY-*wort*, the Engliſh name of a diſtinct genus of plants, known among botaniſts by that of *Nummularia*. See the article NUMMULARIA, *Suppl.*

MONK's-*rhubarb*, the Engliſh name of the broad-leaved garden *Lapathum*, or dock. See the article LAPATHUM, *Suppl.*

MONKEY, in zoology, a name given by way of diſtinction to thoſe apes which have tails; the others, or thoſe without tails, being more properly called *apes*.

The ſame diſtinction holds in latin, the tailed ones being called *Cercopitheci*, and thoſe without tails *Simiæ*. See the articles CERCOPITHECUS and SIMIA, *Suppl.*

MONKEY, in the ſea-language, a block made of iron, with a catch, uſed in gins for driving piles. *Blanckley*'s Naval Expoſitor, p. 107.

MONOCEROS *piſcis*. Beſides the two kinds of unicorn-fiſh deſcribed in the Supplement under the article MONOCEROS, there is another very large one of the ſame genus. See the article UNICORN, *Suppl.*

MONOCULUS, in zoology, the name of a genus of inſects, of the Podaria kind. See the article PODARIA, *Append.*

Its body is ſhort, of a roundiſh figure, and covered with a firm cruſtaceous ſkin; the fore legs are ramoſe, and ſerve for leaping and ſwimming. It has but one eye, which is large, and compoſed of three ſmaller ones.

Of this genus, many of which have been reckoned among the microſcopic animals, authors enumerate a great number of ſpecies; for which ſee *Hill*, Hiſt. Anim. p. 22.

MONORCHIS. Beſide the common ſignification of this word as the name of a plant, phyſicians have alſo us'd it to expreſs a man who has but one teſticle.

MONOTRIGLYPH, in architecture, denotes the ſpace of one *Triglyph*, between two pillaſters or two columns. Build. Dict. in voc. See the article TRIGLYPH, *Cycl.*

MOON *(Cycl.)* — The path of the *moon* is concave towards the ſun throughout.

In other ſecondary planets, as the ſatellites of the ſuperior planets, that part of the path of theſe ſatellites which is neareſt the ſun, is convex towards the ſun, and the reſt is concave. And we often find in elementary treatiſes of aſtronomy, the *Moon*'s path repreſented in the ſame manner; that is, as partly convex and partly concave towards the ſun; but this is a miſtake. For it is to be obſerved, in general, that the force which bends the courſe of the ſatellite into a curve, when the motion is referred to an immoveable plane, is, at the conjunction, the difference of its gravity towards the ſun, and of its gravity towards the primary. When the former prevails over the latter, the force that bends the courſe of the ſatellite tends towards the ſun; and conſequently the concavity of the path is towards the ſun; and this is the caſe of the *Moon*. When the gravity towards the primary exceeds the gravity towards the ſun, at the conjunction, then the force that bends the courſe of the ſatellite tends towards the primary, and therefore towards the oppoſition of the ſun; conſequently the path is there convex towards the ſun; and this is the caſe of the ſatellites of Jupiter. When theſe two forces are equal, the path has, at the conjunction, what mathematicians call a point of rectitude; in which caſe, however, the path is concave towards the ſun throughout.

The gravity of the *Moon* towards the ſun having been found to be greater, at her conjunction, than her gravity towards the earth, ſo that the point of equal attraction, where thoſe two powers would ſuſtain each other, falls then between the *Moon* and earth, ſome [a] have apprehended that either the parallax of the ſun is very different from that which is aſſign'd by aſtronomers, or that the *Moon* ought neceſſarily to abandon the earth. This apprehenſion may be removed eaſily, by attending to what has been ſhewn by Sir Iſaac Newton, and is illuſtrated by vulgar experiments concerning the motions of bodies about one another, that are all acted upon by a third force in the ſame direction. Their relative motions not being in the leaſt diſturbed by this third force, if it act equally upon them in parallel lines; as the relative motion of the ſhips in a fleet, carried away by a current, are no way affected by it, if it act equally upon them; or as the rotation of a bullet or bomb, about its axis, while it is projected in the air; or the figure of a drop of falling rain, are not at all affected by the gravity of the particles of which they are made up, towards the earth. It is to the inequality of the action of the ſun upon the earth and *Moon*; and the want of parallelism in the directions of theſe actions, only, that we are to aſcribe the irregularities in the motion of the *Moon*.

[a] The ingenious Mr. *Baxter*, author of *Matho*, or coſmotheoria puerilis.]

But it may contribute towards removing this difficulty to obſerve, that if the abſolute velocity of the *Moon*, at the conjunction, was leſs than that which is requiſite to carry a body in a circle there around the ſun, ſuppoſing this body to be acted on by the ſame force which acts there on the *Moon* (i. e. by the exceſs of her gravity towards the ſun, above her gravity towards the earth) then the *Moon* would, indeed, abandon the earth. For, in that caſe, the *Moon* having leſs velocity than would be neceſſary to prevent her from deſcending within that circle, ſhe would approach to the ſun, and recede from the earth. But tho' the abſolute velocity of the *Moon*, at the conjunction, be leſs than the velocity of the earth in the annual orbit, yet her gravity towards the ſun is ſo much diminiſhed by her gravity towards the earth, that her abſolute velocity is ſtill much ſuperior to that which is requiſite to carry a body in a circle, there, about the ſun, that is acted on by the remaining force only. Therefore, from the moment of the conjunction, the *Moon* is carried without ſuch a circle, receding continually from the ſun to greater and greater diſtances, till ſhe arrives at the oppoſition; where being acted on by the ſum of thoſe two gravities, and her velocity being now leſs than what is requiſite to carry a body in a circle, there, about the ſun, that is acted on by a force equal to that ſum, the *Moon* thence begins to approach to the ſun again. Thus, ſhe recedes from the ſun, and approaches to it by turns, and in every month her path hath two apſides, a perihelium at the conjunction, and an aphelium at the oppoſition; between which ſhe is always carried in a manner ſimilar to that in which the primary planets revolve between their apſides. The planet recedes from the ſun at the perihelium, becauſe its velocity, there, is greater than that with which a circle could be deſcribed about the ſun at the ſame diſtance by the ſame centripetal force; and approaches towards the ſun from the aphelium, becauſe its velocity, there, is leſs than is requiſite to carry it in a circle, at that diſtance about the ſun. See *Mac Laurin*'s Account of Sir Iſaac Newton's Phil. Diſc. Book 4. c. 5.

MOON-*wort*, the Engliſh name of a diſtinct genus of plants, called by botaniſts *Lunaria*. See the article LUNARIA, *Suppl.*

MOON-*trefoil*, a name by which the *Medicago* of botaniſts is ſometimes called. See the article MEDICAGO, *Suppl.*

MOON-*ſeed*, in botany, the Engliſh name of a genus of plants, called by botaniſts *Meniſpermum*. See the article MENISPERMUM, *Append.*

MOOR-*buzzard*. See the article BUZZARD, *Suppl.*

MOOTER, in the dock-yards, the perſon who forms and ſmooths the tree-nails for uſe. *Blanckley*'s Nav. Expoſitor, p. 108.

MORBUS *Hungaricus*. See the article HUNGARICUS *morbus*, *Append.*

MORDELLA, a name given by ſome writers to the *Ear-wig*. See the article EAR-*wig*, *Append.*

MORDELLA, in zoology, the name of a genus of four-winged flies, diſtinguiſhed by having the laſt joint of the antennæ globoſe; moſt of the ſpecies have alſo legs for leaping. See the article FLY, *Suppl.*

Of this genus there are a great many ſpecies, for which ſee *Hill*, Hiſt. Anim. p. 49.

MORILLES, a kind of muſhroom, about the bigneſs of a wallnut, pierced with holes like a honey-comb, and ſaid to be good for creating an appetite. They are alſo accounted reſtorative, and frequently uſed in ſauces and ragouts.

MORMYLUS, in ichthyology, the name of a ſpecies of *Sparus*, with the upper jaw longeſt, and with twelve parallel, tranſverſe black lines on each ſide. See the article SPARUS, *Suppl.*

MORTAR *(Cycl.)* — It is ſaid, that the ſpherical figure is beſt for the chamber of a *mortar*. Hiſt. Acad. Scienc. 1740.

But this propoſition ſeems doubtful. By ſome experiments made before the Royal Society in 1742, it appeared, that the longeſt cylindrical chambers of the ſame capacity threw the ball fartheſt; which may give ground to ſuſpect that a long cylinder might be a better figure for the chamber of a *Mortar* than a ſphere of equal capacity. See the article GUNNERY, *Append.*

Coehorn MORTAR, a ſmall kind of *Mortar*, invented by the famous engineer baron Coehorn, to throw ſmall ſhells or granades. Theſe *Mortars* are commonly fixed, to the number of a dozen, to a block of oak, at an elevation of 45°.

MORTIFICATION, in medicine. See the article SPHACELUS, *Cycl.* and *Suppl.*

MOSCHUS, the *muſk animal*. See the articles MOSCHIFERUM *animal*, and MUSK, *Suppl.*

MOTH, in zoology, the Engliſh name of a large claſs of butterflies, comprehending all the nocturnal ones, or thoſe which fly by night, and called *Phalenæ* by authors. See the article PHALENÆ, *Suppl.*

MOTH-*mullein*, in botany, the Engliſh name of a diſtinct genus of plants, known among botanical writers by that of *Blattaria*. See the article BLATTARIA, *Suppl.*

MOTHER-*wort*, the name for two diſtinct genuſes of plants, the *cardiaca* and *matricaria*, of botanical writers. See the articles CARDIACA and MATRICARIA, *Suppl.*

MOTHER *of thyme*, the Engliſh name of a diſtinct genus of plants, called by botaniſts *ſerpyllum*. See the article SERPYLLUM, *Suppl.*

MOUNTAIN, or HILL. It has been found by experiment, that *hills*, though they meaſure twice as much as the plain ground they ſtand on, yet the produce of one can be no more than that of the other; and therefore in purchaſing lands, the hills ought to be eſtimated, not according to their ſuperficies, but according to the baſe on which they ſtand. So that in ſome caſes; that is, if the ſoil be equally rich, two acres on the ſide of a hill ought to paſs for no more than one upon the plain of equally rich land.

The reaſon of this is evident; for as long as all plants preſerve their upright method of growing, *hilly* ground can bear no more plants in number than the plain at the baſe. Again, as to building on a *hill*, the two ſides can bear only the ſame number of houſes as the baſe on which it ſtands. The ſame holds in regard to park-pailing over an *hill*; for tho' the meaſure over it be ſometimes near double the line at the bottom, yet both may be incloſed by the ſame number of pales of the ſame breadth. *Miller*'s Gard. Dict. in voc. *Hills*.

The method often uſed for meaſuring the heights of *Mountains*, by the ſinking of the mercury in the barometer, is very far from being accurate in practice. That the mercury generally falls, when the barometer is carried up to a higher ground, is true, and has been known ever ſince the time of Paſcal. The only queſtion is, in what proportion? and this queſtion is not yet determined with ſufficient accuracy. The rule followed by the generality of authors, is, that the heights of *Mountains*, or other riſing grounds, are as the logarithms correſponding to the heights of the mercury in the barometer. And the foundation of this rule is, that the denſity of the air is every where proportional to the weight of the ſuperincumbent air. But the application of this principle is improper in the preſent caſe, becauſe it can hold true only when the air is of the ſame degree of heat, which it ſeldom is, on the different parts of high *Mountains*, in the valleys, and at the ſurface of the ſea. In aſcending the Cordelleras of Peru, for inſtance, the air is found to be of all temperatures, from the hotteſt ſummer, to the coldeſt winter. And experiments are directly contrary to the rule. For by Father Feuillée's obſervations on the Pic of Tenerif, the mercury in the barometer ſtood at 17 inches five lines Paris meaſure, at the height of 13158 Paris feet above the ſurface of the ſea, when the barometer at that ſurface ſtood at 27 inches 10 lines. But, according to the rule abovementioned, the barometer on the Pic ought to have been above two inches and two lines lower than what it was found to be by the experiment.

A difference may alſo be perceived between the computed and obſerved heights of the barometer, at much ſmaller elevations; ſuch as 1542 feet; where the obſerved height of the mercury exceeded that found by computation above a line and an half; which would make a very conſiderable error in the height of the place.

From whence it follows, that the elaſticity or ſpring of the air at different heights, is not proportional to its denſity, or which amounts to the ſame thing, that the mean degree of heat is different at different heights from the ſurface of the earth; for it is well known, that a difference of heat will make a difference of elaſticity in the air, its denſity remaining the ſame. See *Daniel Bernoulli* Hydrodynamic. p. 213. ſeq.

This learned author obſerves, that father Feuillée's experiment on the Pic of Tenerif, overturns all the rules and hypotheſes hitherto contrived for diſcovering the heights of places, from the fall of mercury in the barometer. Mr. Bernoulli has given a new hypotheſis of his own, and has founded ſome computations on it, which agree pretty well with the experiments he mentions; but it were to be wiſhed that this ſubject were re-examined with more care by a greater variety of experiments than has been done hitherto.

Monſ. Caſſini de Thuri has given us [c] a detail of ſeveral obſervations made with care on two high *Mountains* of Auvergne, and upon the *Mountain* Canigou, one of the higheſt of the Pyrenees. From theſe obſervations it appears, that the variations of the heights of the mercury in the barometer, correſponding to the elevation of places above the level of the ſea, follow no regular progreſſion; there having been found ſometimes an inch of difference between the height of the mercury found by obſervation on the *Mountain* Canigou, from the height that reſulted from the progreſſion eſtabliſhed in the Memoirs of the Royal Academy in 1703. This progreſſion being deduced from obſervations made at ſmall elevations, proved erroneous; nor have any of the hypotheſes made ſince been ſufficient to reconcile the irregularities in obſervations, the exactitude of which admits of no doubt. [c Mem. Acad. Scienc. 1740. p. 94.]

MOUNTAIN-*heath*, the name by which ſome call the *Saxifrage* of botanical writers. See the article SAXIFRAGE, *Suppl.*

MOURAILLE, or BARNACLES, among farriers, is an inſtrument compoſed of two branches joined at one end with a hinge. It is commonly made of iron, and ſerves to take hold of a horſe's noſe, and keep it tight by bringing to, or almoſt cloſing the other end of the branches, and ſo tying them with a ſtrap.

MOUSE *(Suppl.)* — MOUSE, in the ſea language, is a large knot artificially made by the riggers on the ſhip's ſtays. *Blanckley*'s Nav. Expoſ. p. 108.

MOUSE-*ear*, a name ſometimes given to the *Hierachium*, or hawkweed of botaniſts. See the article HIERACHIUM, *Suppl.*

MOUSE-*tail*, the Engliſh name of a diſtinct genus of plants, known among botaniſts by that of *Myoſurus*. See the article MYOSURUS, *Append.*

Dor-MOUSE, the Engliſh name of a genus of animals, called by authors *Sorex*. See the article SOREX, *Suppl.*

Sea-MOUSE, the Engliſh name of a genus of inſects, called by Dr. Hill *Aphrodita*. See the article APHRODITA, *Append.*

MULBERRY-*blite*, a name uſed by ſome for a ſpecies of blite. See the article BLITUM, *Suppl.*

MULCH, a term uſed by gardeners for rotten dung, or the like, thrown upon beds of young plants, to preſerve them from the bad effects of cold or drought.

MULES, among farriers, a diſorder incident to horſes, otherwiſe called *Scratches*. See the article SCRATCHES, *Cycl.*

MULLEIN, the Engliſh name of a diſtinct genus of plants, called by botaniſts *Verbaſcum*. See the article VERBASCUM, *Suppl.*

MULLET *(Suppl.)* is alſo uſed as the name of ſeveral ſpecies of *Trigla*. See the article TRIGLA, *Suppl.*

MUNDICK *(Cycl.)* — This mineral ſubſtance is of an arſenical nature. See *Geoffroi*, in Mem. Acad. Scienc. 1738. p. 107. edit. Paris.

MUS-*marinus*, a name uſed by ſome for the *Aphrodita*, a genus of ſea inſects. See the article APHRODITA, *Append.*

MUSCA, *Crabroniformis* and *Rapax*, names ſometimes uſed for the Fly. See the article ASILUS, *ſupra.*

MUSCA *Veſpiformis*, the Waſp-fly. See the article ASILUS, *ſupra.*

MUSCLE *(Suppl.)* — *Acceleratory* MUSCLES. See the article ACCELERATOR, *Cycl.*

MUSCUS, *Moſs*, in botany, a very comprehenſive claſs of plants, containing a great many diſtinct genera. See the article MOSS, *Suppl.*

MUSICAL *Accent*, among Hebrew grammarians. See the article ACCENT, *Cycl.*

MUSICAL *Numbers (Suppl.)* — A table of *muſical* numbers within any propoſed limit may be thus expeditiouſly formed. Place the terms of the progreſſion 1, 5, 25, 125, &c. in a column under each other; and multiply every term of this progreſſion by 3, continually, till you foreſee that the products will exceed the propoſed limit. Then if all the numbers thus found be doubled continually, till it be foreſeen that the doubled numbers would exceed the propoſed limit; all theſe products together, with the powers of 2, will give the *muſical* numbers required.

Thus if it were required to find all the *muſical* numbers within the compaſs of eleven octaves; that is, between 1 and 2048; form the column 1, 5, 25, &c. and multiply every term by 3, continually, as in the annexed example;

1. 3. 9. 27. 81. 343. 729, &c.
5. 15. 45. 135. 405. 1215, &c.
25. 75. 225. 675. 2025, &c.
125. 375. 1125, &c.
625, 1875, &c.
&c.

The numbers of which being doubled as often as poſſible within the limit 2048, and collected and ranged in order with the powers of 2, will give the following numbers, 1. 2. 3. 4. 5. 6. 8. 9. 10. 12. 15. 16. 18. 20. 24. 25. 27. 30. &c. as in the following table;

Table of *muſical* numbers, contained in eleven octaves.

Num.	Chord Aſc.	Chord Deſc.	Num.	Chord Aſc.	Chord Deſc.	Num.	Chord Aſc.	Chord Deſc.
1	F	B	144	G	A	750	B ♯	F♭
2	F¹	B¹	150	G ♯	A♭	768	C	E
3	C	E	160	A	G	800	C ♯	E♭
4	F²	B²	162	Ȧ	G·	810	Ċ ♯	Ė♭
5	A	G	180	B	F	864	D	*D*
6	C	E	192	C	E	900	D ♯	*D*♭
8	F³	B³	200	C ♯	E♭	960	E	C
9	G	A	216	D	*D*	972	Ė	Ċ
10	A	G	225	D ♯	*D*♭	1000	E ♯	C♭
12	C	E	240	E	C	1024	F¹⁰	B¹⁰
15	E	C	243	Ė	Ċ	1080	F ♯	B♭
16	F⁴	B⁴	250	E ♯	C♭	1125	F ♯ ♯	B♭♭
18	G	A	256	F⁸	B⁸	1152	G	A
20	A	G	270	F ♯	B♭	1200	G ♯	A♭
24	C	E	288	G	A	1215	Ġ ♯	Ȧ♭
25	C ♯	E♭	300	G ♯	A♭	1250	G ♯ ♯	A♭♭
27	D	*D*	320	A	G	1280	A	G
30	E	C	324	Ȧ	G·	1296	Ȧ	Ġ
32	F⁵	B⁵	360	B	F	1350	Ȧ ♯	Ġ♭
36	G	A	375	B ♯	F♭	1440	B	F
40	A	G	384	C	E	1458	Ḃ	F
45	B	F	400	C ♯	E♭	1500	B ♯	F♭
48	C	E	405	Ċ ♯	Ė♭	1536	C	E
50	C ♯	E♭	432	D	*D*	1600	C ♯	E♭
54	D	*D*	450	D ♯	*D*♭	1620	Ċ ♯	Ė♭
60	E	C	480	E	C	1728	D	*D*
64	F⁶	B⁶	486	Ė	Ċ	1800	Ḋ ♯	*D*♭
72	G	A	500	E ♯	C♭	1875	D ♯ ♯	*D*♭♭
75	G ♯	A♭	512	F⁹	B⁹	1920	E	C
80	A	G	540	Ḟ ♯	B♭	1944	Ė	Ċ
81	Ȧ	Ġ	576	G	Ȧ	2000	E ♯	C♭
90	B	F	600	G ♯	A♭	2025	Ė ♯	Ċ♭
96	C	E	625	G ♯ ♯	A♭♭	2048	F¹¹	B¹¹
100	C ♯	E♭	640	A	G			
108	D	*D*	648	Ȧ	Ġ			
120	E	C	675	Ȧ ♯	Ġ♭			
125	E ♯	C♭	720	B	F			
128	F⁷	B⁷	729	Ḃ	F			
135	F ♯	B♭						

To underſtand this table it is to be obſerved, that by dividing a given ſtretched ſtring or chord, by means of a moveable bridge, the ſounds produced by its parts will be higher in pitch than thoſe produced by the given chord. And, on the contrary, if we multiply a chord, that is, by a moveable bridge lengthen the ſounding part of a chord, we ſhall have ſounds lower in pitch than the given chord. Hence we have the foundation of an aſcending, and of a deſcending ſcale of muſical ſounds. The firſt column of each diviſion of the table, marked *Num.* expreſſes the muſical numbers; the ſecond column marked *Aſc.* the names of the notes in the aſcending ſcale; and the third column marked *Deſc.* the names of the notes of the deſcending ſcale. Thus if the given chord be unity, and called F, then will 15 be E in the the fourth octave aſcending of F; 45 will be B in the ſixth octave of F, &c. In the deſcending ſcale unity will be B; 15 will be C in the fourth octave deſcending from B; and 45 will be F of the ſixth octave, &c.

The reaſon why unity is marked F in the aſcending ſcale, and B in the deſcending ſcale, is, becauſe according to the received notation of what is called the natural ſcale among muſicians; F has no fourth in aſcending, nor B a fourth in deſcending. Now it is plain that no aliquot diviſion of a ſtring can give a fourth, or any of its octaves aſcending; nor can any multiple of a ſtring, give the fourth, or any of its octaves, in deſcending. For the fourth being expreſſed by $\frac{3}{4}$ in aſcending; and by $\frac{3}{4}$ in deſcending, its octaves will be $\frac{3}{32}$, $\frac{3}{64}$, $\frac{3}{128}$, &c. in the firſt caſe, and $\frac{3}{8}$, $\frac{3}{16}$, $\frac{3}{32}$, &c. in the ſecond caſe, none of which numbers can be multiples, or ſubmultiples of a given ſtring.

F and B being the given ſounds, their octaves will be expreſſed by F¹, F², F³, &c. and B¹, B², B³, &c. which are, reſpectively, the firſt, ſecond, and third octaves above the F and below B.

A dot marked over a letter ſhews that it ſignifies a ſound higher by a comma than the ſound expreſſed by the letter itſelf. And a dot placed below, denotes the ſound to be lowered by a comma. Thus, in the table I find 81 to be Ȧ | G, which denotes that A, or the ſharp in the ſeventh octave of F, aſcending, is raiſed a comma; and that G or the ſharp third from B, deſcending, is lowered by the ſame interval.

If B in the deſcending ſcale be ſuppoſed to be a tritonus, that is, two tones major, and one tone minor above F of the aſcending ſcale, then will A in one of theſe ſcales correſpond or be denoted by the ſame numbers with G in the other ſcale; and C will correſpond to E, but D in the aſcending ſcale will not be expreſſed by the ſame numbers as in the deſcending ſcale: For in the former D will be a tone major above C, whereas in the latter D muſt by analogy be a tone major below E, and therefore only a tone minor above C, which is the reaſon why *D* is in Italicks in the deſcending ſcale.

Mr. Henſling has mentioned the diſtinction between an aſcending and a deſcending ſcale in the Miſcel. Berolinens. He places unity in the aſcending ſcale in F, as it ought; but in the deſcending ſcale he places unity in E, which diſturbs the analogy of the two ſcales.

The trumpet and french horn, not having (commonly) a compaſs beyond four octaves; and their ſounds being formed in a manner analogous to thoſe produced by the diviſion of a ſtring, it follows that all the true notes of theſe inſtruments will be repreſented by the muſical numbers, 1, 2, 3, 4, 5, 6, 8, 9, 10, 12, 15, 16, &c. This is a fact well known [a], and a confirmation of the truth of that theory which derives all muſical proportions from the elements 2, 3, and 5[b]. — [a See the article TRUMPET, *Append.* and Philoſ. Tranſ. N° 195. [b] See Phil. Tranſ. loc. cit.]

MUSK *Hyacinth*, a name ſometimes given to a diſtinct genus of plants, called by botaniſts *Muſcari*. See the article MUSCARI, *Suppl.*

MUSK-*ſeed*, a name uſed by ſome writers for the *Ketmia*. See the article KETMIA, *Suppl.*

MUST *(Suppl.)* — A *muſt* for artificial wine may be thus made: Take twenty pounds of fine ſugar; five gallons of water; four ounces of white tartar finely pulverized, or cream of tartar, and boil them in a large veſſel over a gentle fire.

MUSTARD *(Suppl.)*—*Mithridate*-MUSTARD, the name of a genus of plants, called by botaniſts *Thlaſpi*. See the article THLASPI, *Suppl.*

Baſtard-Mithridate-MUSTARD, the ſame with the *Thlaſpidium* of botanical writers. See the article THLASPIDIUM, *Suppl.*

Rough-Podded MUSTARD, the name by which a ſpecies of *Syſimbrium* is ſometimes called. See the article SYSIMBRIUM, *Suppl.*

Tower-MUSTARD, the Engliſh name of a diſtinct genus of plants, called by botaniſts *Turritis*. See the article TURRITIS, *Suppl.*

Treacle-MUSTARD, a name promiſcuouſly uſed for two diſtinct genuſes of plants, the *Thlaſpi* and *Jonthlaſpi*. See the articles THLASPI and JONTHLASPI, *Suppl.*

MUTULE *(Cycl.)* — Le Clerc makes *Mutules* in the entablement of the Doric order, not only to diſtinguiſh it the more from other entablements, but alſo becauſe they agree very well with the nobleneſs of this order, and add ſomething of a maſculine beauty to it.

Mutules are commonly made of the ſame breadth with the triglyphs; but the ſame author thinks it would be much better if they were made of the ſame breadth with the capitals of the triglyphs. Nor does he run his *Mutules* ſo near the extremity of the larmier or drip, as is uſually done; leaving a ſpace of three or four minutes between the two, that the profile may appear the more diſtinctly.

MYOCTONUM. See the article ACONITE, *Cycl.*

MYOSURUS, *Mouſe-tail*, in botany, the name of a diſtinct genus of plants, the characters of which are theſe: the cup is a deciduous perianthium, compoſed of five ſemi-lanceolate, obtuſe, reflex, coloured leaves, joined on above the baſe. The corolla, which is conſiderably ſmaller than the cup, conſiſts of five extremely minute petals, and is tubulated at the baſe, and opens obliquely inwards. The ſtamina are five filaments, of the length of the cup; the antheræ are erect, and oblong: the germina are very numerous, and are placed on the receptacle in form of a conic, oblong cluſter; there are no ſtyles; the ſtigmata are ſimple; there is no pericarpium; the receptacle is extremely long, ſtyliform, and covered with numerous, oblong, and acuminated ſeeds, laid in an imbricated manner. *Linnæi* Gen. Plant. p. 134.

This genus has a great affinity with the ranunculus, and is common in our corn fields. Dodonæus calls it *Cauda Murina*.

MYRICA, *Sweet William*, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: The male flowers are arranged in an oblong amentum; the cup is a ſquama of a lunulated figure; there is no corolla, nor proper perianthium; the ſtamina are four, rarely ſix, thread-like filaments, longer than the cup; the antheræ are two in number, and didymous. The female flowers are the ſame as the male ones; the germen of the piſtil is of an oval ſhape; the ſtyles are two; and the ſtigmata ſimple; the fruit is an unilocular berry, containing only one ſeed. *Linnæi* Gen. Plant. p. 474.

This genus comprehends the *Gale* of Tournefort and others; and is nearly allied to the *Piſtachia-nut* tree, a ſpecies of *Terebinthus*. See the article TEREBINTHUS, *Suppl.*

MYRTLE, the Engliſh name of a genus of trees, called by botaniſts *Myrtus*. See the article MYRTUS, *Suppl.*

Dutch-MYRTLE, or *Candleberry*-MYRTLE, names ſometimes given to the *Myrica*, or *Gale* of botaniſts. See the article MYRICA, *Append.*

MYRTLE-*Sumach*. See the article SUMACH, *infra*.

N.

NAIA, in zoology, the name of a ſpecies of *Coluber*, the ſcuta of whoſe abdomen are one hundred and ninety in number, and the ſquamæ of the tail ſixty. See the article COLUBER, *Append.*

NAMES. *Specific* NAMES. See the article SPECIFIC, *Suppl.*

NAPELLUS. See the article ACONITE, *Cycl.*

NAPHA, a name given by many of the writers in pharmacy to orange-flower water.

NASEBERRY *tree*, the Engliſh name of a diſtinct genus of plants, called by botaniſts Cainito, or *Chryſophyllum*. See the article CHRYSOPHYLLUM, *Append.*

NASTURTIUM *aquaticum*, the name by which C. Bauhine calls the *Syſimbrium*. See the article SYSIMBRIUM, *Suppl.*

NASTURTIUM-*Indicum*, in botany, a name uſed by ſome for a genus of plants, called by others *Cardamindum*, and *Trapæolum*. See the articles CARDAMINDUM, *Suppl.* and TRAPÆOLUM, *Append.*

NAVEL *(Suppl.)* — NAVEL-*boods*, in ſhip-building, large pieces of ſtuff fitted into the hawſe-holes, to keep the cables from wearing them. *Blanckley*'s Nav. Expoſ. p. 110.

NAVEL-*line*, on ſhip-board, a rope reeved through a block made faſt to the middle rib, and another block made faſt to the maſt-head.

NAVEL-*wort (Suppl.)*— *Baſtard* NAVEL-*wort*, a name ſometimes given to the *Craſſula* of botanical writers. See the article CRASSULA, *Append.*

Venus's NAVEL-*wort*, the name of a genus of plants, called by authors *Omphalodes*. See the article OMPHALODES, *Suppl.*

Water NAVEL-*wort*, a name ſometimes given to the *Hydrocotyle* of botaniſts. See the article HYDROCOTYLE, *Suppl.*

NECKIB-*el-eſheraf*, in Egypt, the head of the ſherif, or relations of Mahomet, who has the great cognizance of their actions, and the power of inflicting puniſhments upon them. *Pocock*'s Egypt, p. 171.

NECKLACE-*ſnake*. See the article SNAKE, infra.

NECTYDALIS, in zoology, the name of a genus of four-winged inſects, diſtinguiſhed by having the antennæ ſetaceous, the exterior pair of wings dimidiated, and the interior pair membranaceous. *Hill*, Hiſt. Anim, p. 55.

Some have called it a *cimex*, and others a *forficula*, or ear-wig, but both erroneouſly. Id. p. 56.

NEEDLE-*fiſh*, the Engliſh name of the *Syngnathus*, with the middle of the body hexangular, and the tail pinnated. See the article SYNGNATHUS, *Suppl.*

It is the ſame fiſh with the *Acus Ariſtotelis ſpecies altera major*. See the article ACUS, *Suppl.*

NEEDLE-*ſhell*, the Engliſh name of a ſpecies of *Centronia*, or *Echinoderma*. See the articles ECHINODERMA, *Suppl.* and CENTRONIA, *Append.*

NEEDLE-*ſhell* is alſo the Engliſh name of a ſpecies of *Turbo*, which is ſlender, and has ventricoſe ſpires, and a ſmall mouth. See the article TURBO, *Suppl.*

Touch-NEEDLES. See the article TOUCH-*needles*, *Suppl.*

Shepherd's-NEEDLE, the name by which ſome writers call the *Scandix*, or *Venus's-comb*. See the article SCANDIX, *Suppl.*

NEGRO-*oil*, a name by which the *palma* of botaniſts is ſometimes called. See the article PALMA, *Append.*

NEP, *Nepeta*, a name ſometimes uſed for the Cat-mint, or *Cataria* of botaniſts. See the article CATARIA, *Suppl.*

NEPA, the name by which ſome call a genus of inſects, otherwiſe known by that of *Scorpio paluſtris*, the water-ſcorpion. See the article SCORPIO, *Suppl.*

NEREIS, in zoology, a genus of inſects of the gymnarthria kind, the body of which is of a cylindric figure; the tentacula are four in number, but two of them are uſually very ſhort. *Hill.* Hiſt. Anim. p. 92.

Authors have deſcribed this genus under the name of *Scolopendra marina*. See the article SCOLOPENDRA *marina*, *Suppl.*

NERIUM, or NERION, in botany, the name of a genus of plants, called in Engliſh *Oleander*. See the article NERION, *Suppl.*

NETTLE *(Suppl.)* — *Sea*-NETTLE, the Engliſh name of a genus of inſects, called by Dr. Hill *Meduſa*. See the article MEDUSA, *Append.*

Hedge-NETTLE, a name by which ſome call the *Galeopſis* of botanical writers. See the article GALEOPSIS, *Suppl.*

Shrubby Hedge NETTLE, the name given by ſome writers to the *Praſſium*, a diſtinct genus of plants. See the article PRASIUM, *Suppl.*

NEUROPTERA, in zoology, the name by which Dr. Hill calls a claſs of four-winged flies, from their wings being membranaceous with nerves, and being diſpoſed in a reticulated form. Vid. *Hill*, Hiſt. Anim. p. 69.

NIGHT *(Cycl.)* — For the diviſions of the *Night* among the antients, ſee the articles DAY, HOUR, *&c. Cycl.*

NIGHTSHADE, *Climbing* NIGHTSHADE, a name ſometimes uſed for the *Baſella* or *Cuſcuta* of botaniſts. See the article CUSCUTA, *Suppl.*

Deadly NIGHTSHADE, a name by which ſome call the *Belladonna*, a diſtinct genus of plants. See the article BELLADONNA, *Suppl.*

Inchanter's NIGATSHADE, the Engliſh name of a genus of plants, called by botaniſts *Circæa*. See the article CIRCÆA, *Suppl.*

American NIGHTSHADE, a name given to the *Solonoides*, or *Rivinia*, of botaniſts. See the article RIVINIA, *Suppl.*

Virginian NIGHTSHADE, the name by which ſome call a ſpecies of *Phytolacca*. See the article PHYTOLACCA, *Suppl.*

NINDSI, or NINZI, the name of a diſtinct genus of plants, called by botaniſts *Sium*. See the article SIUM, *Suppl.*

NINSI, in botany, a name uſed by ſome for the *Panax*, or All-heal of Linnæus. See the article PANAX, *Append.*

NINTH, in muſic, one of the diſſonant intervals in muſic. It is properly the ſecond doubled; but is differently uſed. When an upper part ſyncopates, the ſecond is accented and treated as a *Ninth*; i. e. it is reſolved by an eighth, and accompanied by a third or fifth, and often a ſyncopated ſeventh. But when the lower part ſyncopates, the ſecond is not thus uſed, but is accompanied by the fourth and ſixth. In thorough baſs, as the *Ninth* has always, or at leaſt commonly, an eight placed after it thus, 9 8; to ſhew that that is reſolved by deſcending to the Octave. Vid. *Broſſ.* Dict. Muſ. in voc.

NOLI *me tangere*, the name uſed by ſome for a ſpecies of *Balſamine*. See the article BALSAMINA, *Suppl.*

NONE-*ſo-pretty*, a popular name for the *Geum* of botanical authors. See the article GEUM, *Suppl.*

NONE-*ſuch*, a name ſometimes given to the *Lychnis* of botaniſts. See the article LYCHNIS, *Suppl.*

NOSE-*bleed*, in botany, a popular name for the *Millefolium* of botanical writers. See the article MILLEFOLIUM, *Suppl.*

NOTOPEDA, in zoology, a name ſometimes given to the *Elater*, a genus of four-winged flies. See the article ELATER, *Append.*

NUMB-*fiſh*, or *Cramp-fiſh*, names given to the *Torpedo*, which is a ſpecies of *raja*, See the articles RAJA, *Suppl.* and TORPEDO, *Cycl.*

NUMBER *(Cycl.)* — *Figurate* NUMBERS. Thoſe of the firſt order are 1, 1, 1, 1, &c. Thoſe of the ſecond order the ſucceſſive ſums of thoſe of the firſt order, viz. 1, 2, 3, 4, 5, &c. and form an arithmetical progreſſion. Thoſe of the third order are the ſucceſſive ſums of thoſe of the ſecond, viz. 1, 3, 6, 10, 15, and are the triangular numbers. Thoſe of the fourth order are the ſucceſſive ſums of the third, viz. 1, 4, 10, 20, 35, and are the pyramidal numbers, and ſo on.

The figurate *Numbers* of any order may be found without computing thoſe of the preceding orders, by taking the ſucceſſive products of as many of the *Numbers* 1, 2, 3, 4, 5, &c. in their natural order, as there are units in the *Number*, which denominates the order of figurates required, and dividing thoſe products always by the firſt product. Thus the triangular *Numbers* are found by dividing the products 1×2, 2×3, 3×4, 4×5, 5×6, &c. each by the firſt product 1×2. The pyramids alſo are found by dividing the products $1 \times 2 \times 3$, $2 \times 3 \times 4$, $3 \times 4 \times 5$, $4 \times 5 \times 6$, &c. each by $1 \times 2 \times 3$. In general, the figurate *Numbers* of any order denoted by M, are found by ſubſtituting ſucceſſively 1, 2, 3, 4, 5, &c. in the place of x in the general expreſſion $\frac{x.\ x+1.\ x+2.\ x+3.\ \&c.}{1.\ 2.\ 3.\ 4.\ \&c.}$ where the factors in the numerator and denominator are ſuppoſed to be multiplied by each other, and to be continued, till the number in each be equal to that which expreſſes the order of the figurates required, diminiſhed by unity. And when a figurate *Number* of any order is divided by the correſponding figurate of any higher order, the numerator of the quotient is invariable, and x. is in its denominator of as many dimenſions as there are units in the difference of the *Numbers* that denote thoſe orders. See *Mac Laurin*'s fluxions Art. 351 in the notes.

Figural NUMBERS. See the article FIGURAL, *Append.*

Muſical NUMBERS. See the article MUSICAL, *Append.*

NUMBERING *Rods*. See the article NEPER's *Bones*, *Cycl.*

NUMMULARIA, *Money-wort*, the name by which ſome call the *Lyſimachia* of botaniſts. See the article LYSIMACHIA, *Suppl.*

NUT *(Suppl.)*—*Bladder*-NUT, the Engliſh name of a diſtinct genus of plants, called by botaniſts *Staphylæa*, and *Staphylodendron*. See the article STAPHYLODENDRON, *Suppl.*

Cocoa-NUT, the name of a genus of plants, called by botaniſts *Cacao*. See the article CACAO, *Suppl.*

Earth-NUT, in botany, a name given to two diſtinct genuſes of plants, called by botaniſts *Bulbocaſtanum* and *Arachis*. See the articles BULBOCASTANUM, *Suppl.* and ARACHIS, *Append.*

Hazle-NUT, in botany. See the article HAZLE, *Suppl.*

Malabar-NUT, the name of a genus of plants, known among botaniſts by that of *Adhatoda*. See the article ADHATODA, *Suppl.*

Peas-NUT, the name by which ſome call the *Lathyrus* of botanical writers. See the article LATHYRUS, *Suppl.*

Phyſic NUT, a name ſometimes given to the *Ricinoides* of Tournefort. See the article RICINOIDES, *Suppl.*

Pig-NUT, a name by which the *Bulbocaſtanum*, or earth-*nut*, is ſometimes called. See the article BULBOCASTANUM, *Suppl.*

Spaniſh-NUT, a name by which ſome call the *Siſyrinchium* of botanical writers. See the article SISYRINCHIUM, *Suppl.*

Wall-NUT, the name of a well known genus of trees, called by Linnæus *Juglans*, and by Tournefort ſimply *Nux*. See the article NUX. *Suppl.*

NYCTANTHES, in the Linnean ſyſtem of botany, the name of a genus of plants, the characters of which are theſe; the cup is a one-leaved perianthium, very ſmall, of a cylindric figure, lightly divided into eight ſegments, or denticulæ, of a ſubulated figure, and permanent. The flower conſiſts of a ſingle petal, and is of a hypocrateriform kind; the tube is cylindric, and longer than the cup; the limb is plain, divided into eight ſegments of an oblong figure, and patent; the ſtamina are two extremely ſmall filaments, affixed to the receptacle, and of a ſubulated figure; the antheræ are erect, and ſomewhat acute; the germen of the piſtil is roundiſh and depreſſed; the ſtyle is ſimple, and of the length of the tube; the ſtigmata are two, and are erect; the fruit is a didymous berry, of a roundiſh figure, and contains two cells; the ſeeds are roundiſh and large, and one only is contained in each cell. *Linnæi* Gen. Plant. p. 6.

O.

OAK *(Cycl.)* — OAK-*of-Jeruſalem*, the Engliſh name of a genus of plants, called by botaniſts *Chenopodium*, See the article CHENOPODIUM, *Suppl.*

Poiſon-OAK, a name ſometimes given to the *Toxicodendron* of botaniſts. See the article TOXICODENDRON, *Suppl.*

OAT-*graſs*, in botany. See the article GRASS, *Append.*

OBELIAS, among the antients, a kind of ſmall cakes, which were toaſted on little ſpits, and ſerved to table as a deſert to be eaten dipped in ſweet wine, called *Paſſum*. *Pitiſc.* in voc.

OBELLISCOTHECA, the name given by Vaillant to a genus of plants, called by Linnæus *Rudbeckia*. See the article RUDBECKIA, *Append.*

OBTUSE *(Cycl.)* — OBTUSE-*angular Section of a Cone*, a name given to the hyperbola by antient geometricians, becauſe they conſidered it only in ſuch a cone, whoſe ſection by the axis is a triangle, *obtuſe*-angled at the vertex.

OCKHAM, or OCHAM, See the article OAKHAM, *Cycl.*

OCTAETIS, in natural hiſtory, a name given by Linnæus, and many other authors, to a kind of ſtar-fiſh of the aſtrophyte claſs, the rays of which are eight in number, where they firſt part from the body, but ſoon divide into many more.

OIL-*beetle*, the Engliſh name of a genus of inſects, called by Dr. Hill *Meloe*. See the article MELOE, *Append.*

OILY-*grain*, the name by which ſome call the *Seſſamum*, of botanical authors. See the article SESSAMUM, *Append.*

OLD-*wife-fiſh*, the name by which a ſpecies of *Balliſtes* is called in ſeveral of our plantations. See the article BALLISTES, *Suppl.*

OLD-*wife* is alſo a name given to the *wraſſe*, a ſpecies of *Labrus*. See the article LABRUS, *Suppl.*

OLIVE *(Suppl.)* — *Spurge*-OLIVE, a name ſometimes given to the *Thymelæa* of botaniſts. See the article THYMELÆA, *Suppl.*

Wild-OLIVE, the Engliſh name of a diſtinct genus of plants, called by Linnæus *Elæagnus*. See the article ELÆAGNUS, *Suppl.*

Wild-OLIVE *of Barbadoes*, a name by which ſome call the *Bontia*, a diſtinct genus of plants. See the article BONTIA, *Suppl.*

ONE-*berry*, a name by which the *herba Paris* is ſometimes called. See the article HERBA *Paris*, *Suppl.*

ONE-*blade*, or ONE-*leaf*, names ſometimes given to the *Smilax* of botanical writers. See the article SMILAX, *Suppl.*

ONION *(Suppl.)*— *Sea*-ONION, a name by which the *Scilla* of botaniſts is ſometimes called. See the article SCILLA, *Append.*

OPERCULUM, in the hiſtory of ſhell-fiſh, denotes the cartilaginous cover, with which nature has furniſhed the mouths of the univalve water-ſhells; for as to the land ones, they have only a viſcid liquor to ſupply the place of an *Operculum*.

ORACH, a name by which the *Chenopodium* of botanical authors is ſometimes called. See the article CHENOPODIUM, *Suppl.*

ORANGE-*Mint*, the name of a ſpecies of *Mint*. See the articles MENTHA and MINT, *Suppl.*

Mock-ORANGE, a name ſometimes given to the *Syringa*, or pipe-tree. See the article SYRINGA, *Suppl.*

ORELLANA, in botany, a name given to a ſpecies of *Mitella*. See the article MITELLA, *Suppl.*

ORPHEUS. This fiſh has been called *Orphos*, *Orphus*, and *Cernua*, by different writers. It is a ſpecies of *Sparus*, with the tail not forked, and with a black ſpot near it. See the articles SPARUS and ORPHEUS, *Suppl.*

ORPINE, in botany, the Engliſh name of a genus of plants, known among botanical writers by that of *Telephium*. See the article TELEPHIUM, *Suppl.*

Baſtard-ORPINE, a name given to two diſtinct genuſes of plants, called by botaniſts *Anacampſeros* and *Andrachne*. See the articles ANACAMPSEROS, and ANDRACHNE, *Suppl.*

ORRERY, an aſtronomical inſtrument, or rather machine, for repreſenting the motions and various appearances of the planets; and hence, with greater propriety, called *Planetarium*. See the article PPANETARIUM, *Append.*

The reaſon of its being called an *Orrery*, was this: Mr. Rowley, a mathematical inſtrument-maker, having got one from Mr. George Graham, the original inventor, to be ſent abroad with ſome of his own inſtruments, he copied it, and made the firſt for the Earl of *Orrery*. Sir Richard Steel, who knew nothing of Mr. Graham's machine, thinking to do juſtice to the firſt encourager, as well as to the inventor, of ſuch a curious inſtrument, called it an *Orrery*, and gave Mr. Rowley the praiſe due to Mr. Graham. *Deſaguliers*, Experiment. Phil. vol. 1. p. 430.

Since that time *Orreries* have been much in vogue, and executed in the moſt ornamental manner.

ORTHOCEROS, the ſame as *Orthocerites*. See the article ORTHOCERITES, *Suppl.*

ORYZA, *Rice*, in botany, the name of a genus of plants, of which we know only one ſpecies: The characters are theſe: The cup is a glume, compoſed of two valves, with a ſingle flower; it is very ſmall, and the valves are acuminated, and nearly equal in ſize; the flower is alſo compoſed of two obtuſe and permanent valves; the nectarium conſiſts of two very ſmall deciduous leaves; the ſtamina are ſix capillary filaments of the length of the flower; the antheræ are bifid at the baſe; the germen of the piſtil is of a turbinated figure; the ſtyles are two, capillary, and reflex; the ſtigmata are plumoſe; there is no pericarpium; the ſeed is ſingle, large, oblong, obtuſe, and compreſſed. *Linnæi* Gen. Plant. p. 152.

OSCULATION in geometry, is uſed for the contact between any given curve and its oſculatory circle; that is, the circle of the ſame curvature with the given curve. See the article CURVATURE, *Append.*

OSCULATORY-*circle*, in geometry, is uſed chiefly by foreign mathematicians, for the circle of curvature; that is, the circle having the ſame curvature with any curve at any given point. See the article CURVATURE, *Append.*

OSCULATORY-*Parabola*. See the article PARABOLA, *Append.*

OSCULATORY-*point*, the point of contact between a curve and its *oſculatory* circle. See the article CURVATURE, *Append.*

OSIER, the Engliſh name for the willow with very long and narrow leaves. See the article SALIX, *Suppl.*

OTARDES, in ornithology. See the article OTIS, *Suppl.*

OUZEL, or *Ring*-OUZEL, the Engliſh name of the black *Turdus*, with a white ring round its neck. See the article TURDUS, *Suppl.*

OWL, in ornithology, a large genus of birds, for the characters of which ſee the article STRIX, *Suppl.*

Grey-OWL. See the article ULULA, *Suppl.*

Great-white OWL, a very large ſpecies, nearly equal to a gooſe in bigneſs; of a beautiful bright white all over, only ſprinkled, as it were, with little ſpots of a blackiſh colour.

The other ſpecies are: 1. The black and white horned *Owl*. 2. The leſſer horned *Owl*. 3. The yellow *Owl*. 4. The hazel-eyed *Owl*. 5. The yellow-eyed *Owl*. 6. The *Owl*, with a variegated tail. 7. The little *Owl*. 8. The common brown *Owl*, or Jay-*Owl*. 9. The *Scops*. 10. The German horned *Owl*. 11. The church *Owl*, or leſſer barn *Owl*. 12. The white-beaked *Owl*. 13. The yellow-beaked American *Owl*. 14. The *Jacurutu*. *Hill*, Hiſt. Anim. p. 119. ſeq.

OX-*eye*, in botany, the Engliſh name of a genus of plants, called by botaniſts *Buphthalmum*. See the article BUPHTHALMUM, *Suppl.*

Ox-*eye-daiſy*, a name ſometimes given to the *Leucanthemum* of botannical writers. See the article LEUCANTHEMUM, *Suppl.*

Ox-*lip*, a name by which the *Primula veris*, primroſe, or prime roſe, is ſometimes called. See the article PRIMULA, *Suppl.*

P.

PADDLE, or PADDLE-*ſtaff*, a ſmall ſtaff, ſhod with iron, for cleanſing the plough from ſtubble, clods, earth, &c. Dict. Ruſt. in voc.

It is alſo much uſed by mole-catchers.

PADUS, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: The cup is a permanent perianthium, formed of a ſingle leaf, of a campanulated figure, villoſe at the baſe, divided into five ſegments, patent, and ſcarce at all reflex; the flower conſiſts of five large, roundiſh, patent petals, inſerted by their ungues into the edge of the calyx; the ſtamina are twenty or thirty filaments, of a ſubulated figure, nearly of the length of the flower, and inſerted into the calyx; the antheræ are roundiſh; the germen is roundiſh; the ſtyle is filiform, and of the length of the ſtamina; the ſtigma is obtuſe and entire; the fruit is a roundiſh drupe; the ſeed is an oval, acuminated nut, with a furrow; the receptacle of the flower, which inveſts the inner ſurface of the cup, is hairy in this genus; which comprehends the *Lauroceraſus*, and *Ceraſus avium* of authors. Vid. *Linnæi* Gen. Plant. p. 215.

PAIGLES, a name ſometimes uſed for the *Primula*, or *Cowſlip*. See the article PRIMULA, *Suppl.*

PAINS, or *After*-PAINS in Midwifry. See the articles DELIVERY and LYING-*in-women*.

PALM-*tree*, *Palma*, in botany, the name of a diſtinct genus of plants, called by Linnæus *Phœnix*. See the article PHOENIX, *Suppl.*

PALMA *Chriſti*, a name frequently given to the common *Ricinus*. See the article RICINUS, *Suppl.*

PALMETTO, the name by which ſome call a ſpecies of the palm or date-tree, deſcribed by Linnæus under that of *Phœnix*. See the article PHOENIX, *Suppl.*

PANAX, in the Linnæan ſyſtem of botany, the name of a diſtinct genus of plants, the characters of which are theſe: The umbel of the calyx is ſimple, equal and thick; the involucrum is very ſmall, and formed of a number of leaves, ſubulated and permanent; the perianthium of each flower is very ſmall, divided into five ſegments, and permanent; the general corolla is uniform, and the peculiar ones conſiſt of five oblong, crooked, equal petals. The ſtamina are five very ſhort filaments; the antheræ are ſimple; the germen of the piſtil is roundiſh, and placed below the perianthium; the ſtyles are two, and ſmall; and the ſtigmata are ſimple; the fruit is a roundiſh berry, having one cell, and is coronated with the cup; the ſeeds are two, and of a kidney-like ſhape.

This genus comprehends the famous *Ginſeng*, *Araliaſtrum*, *Ninſi*, and *Aureliana* of other writers.

PANCRATIUM, the *ſea-daffodil*, in botany, the name of a genus of plants, the characters of which are theſe: The cup is an oblong, obtuſe, compreſſed ſpatha, opening in the plane ſide, and deciduous; the nectarium of the flower is formed of a ſingle leaf, of a cylindraceo-infundibuliform ſhape, coloured at top, and with an open mouth, divided into ten ſegments; the petals are ſix, lanceolated and plane, and are inſerted externally into the tube of the nectarium, above the baſe; the ſtamina are ſix ſubulated filaments, affixed to the apex of the nectarium; the antheræ are oblong, and incumbent; the germen of the piſtil is trigonal, and placed under the receptacle; the ſtyle is filiform, and ſomewhat longer than the ſtamina; the ſtigma is obtuſe; the fruit is a roundiſh, triquetrous capſule, formed of three valves, and containing three cells; the ſeeds are numerous and globoſe; and the receptacle is columnar. Vid. *Linnæi* Gen. Plant. p. 138.

PANIC, *Panicum*, in botany, the name of a diſtinct genus of plants. See the article PANICUM, *Suppl.*

PANICLE, *Panicula*, among botaniſts. See the article PANICULA, *Cycl.* and *Append.*

PANICULA *(Cycl.)* — According to Mr. Miller, the *Panicula*, or panicle, is a ſtalk diffuſed into ſeveral pedicles, or foot-ſtalks, ſuſtaining the flowers or fruits, as in oats, &c. *Miller*, Gard. Dict.

PANORPA, the *ſcorpion-fly*, in zoology, a genus of four-winged inſects of the *Neuropetra* kind, the diſtinguiſhing characters of which are theſe: Its roſtrum or trunk is of a cylindric figure, and horny ſtructure; and its tail is furniſhed with a weapon of the cheliform kind. See the article SCORPION-*fly*, *Suppl.*

PANSEY, or PANSY, a ſpecies of violet, otherwiſe called the *Heart's-eaſe*. See the articles VIOLA, *Suppl.* and HEART'S EASE, *Append.*

PAPAW, the name by which ſome call the *Papaya*, a diſtinct genus of plants. See the article PAPAYA, *Suppl.*

PAPPOSE-*plants*, among botaniſts, ſuch whoſe ſeeds are covered with a *Pappus*, or down. See the article PAPPUS, *Cycl.*

PARABOLA *(Cycl.)* — *Oſculatory*-PARABOLA, in geometry, is uſed particularly for that *Parabola* which not only oſculates or meaſures the curvature of any curve at a given point, but alſo meaſures the variation of the curvature at that point. See *Mac Laurin*'s Appendix to his Algebra, p. 17. *Cramer*, Analyſ. des Lignes Courbes, p. 559. See the article CURVATURE, *Append.*

A curve, ſtrictly ſpeaking, may have an indefinite number of *Oſculatory Parabolas* at any of its points; but the appellation may be reſtrained to that particular *Parabola* which meets the curve ſo cloſely, that no other parabolic arc can be drawn between them; and this *Parabola* will meaſure the variation of the curvature of the curve at that point. See the article VARIATION of *curvature*, *Suppl.*

PARABOLIFORM *Curves*, a name ſometimes given to the parabolas of the higher kind.

PARADISE *(Cycl.) Bird of* PARADISE. See the articles PARADISÆA and MANUCODIATA, *Suppl.*

PARALLELOGRAM *(Cycl.* and *Suppl.)* — *Newtonian*, or *Analytic*. PARALLELOGRAM, in algebra, an appellation uſed for an invention of Sir Iſaac Newton's, to find the firſt term of an infinite converging ſeries.

This is ſometimes called the method of the *Parallelogram* and *Ruler*; becauſe a ruler or right line is alſo uſed in it.

This *analytic Prallelogram* is formed by dividing any *Parallelogram* into equal ſquares or *Parallelograms*, by lines drawn horizontally and perpendicularly through the equal diviſions of the ſides of the *Parallelogram*. The cells thus formed are filled with the dimenſions of the ſpecies x and y, and their products. The powers, $y^0 = 1$, y, y^2, y^3, y^4, &c. of y, for inſtance, being placed in the loweſt horizontal range of cells, and the powers of x, or $x^0 = 1$, x, x^2, x^3, &c. in the vertical column to the left, or vice verſa; ſo that theſe powers and their products will ſtand thus:

A

x^4	$x^4 y$	$x^4 y^2$	$x^4 y^3$	$x^4 y^4$	
x^3	$x^3 y$	$x^3 y^2$	$x^3 y^3$	$x^3 y^4$	
x^2	$x^2 y$	$x^2 y^2$	$x^2 y^3$	$x^2 y^4$	
x	$x y$	$x y^2$	$x y^3$	$x y^4$	
1	y	y^2	y^3	y^4	

B C

Then, when any literal equation is propoſed, mark ſuch of the the *Parallelograms* or cells, as correſpond to all its terms; and let a ruler be applied to two, or perhaps more, of the *Parallelograms* ſo marked, of which let one be the loweſt in the left-hand column at A B, the other touching the ruler towards the right-hand; and let all the reſt not touching the ruler lie above it. Then ſelect theſe terms of the equation which are repreſented by the *Parallelograms* that touch the ruler, and from them find the quantity to be put in the quote.

This is Sir Iſaac Newton's famous rule, of the application of which he has left us ſome examples in his method of fluxions and infinite ſeries, p. 9 and 10. but without demonſtration; which has been ſince ſupplied by others. See Mr. *Colſon*'s Comment on that treatiſe, p. 192, ſeq. *Mac Laurin*'s Algebra, p. 251, ſeq. and particularly Monſ. *Cramer*'s Analyſ. des Lignes Courbes, chap. 7. p. 148, ſeq.

This learned author obſerves [a], that this invention, which is the true foundation of the method of ſeries, was but imperfectly underſtood, and not valued as it deſerved for a long time. He thinks it more convenient in practice to uſe the *Analytic Triangle* [b] of the Abbé de Gua, which takes in no more than the diagonal cells lying between A and C, and thoſe which lie between them and B. [a In his preface, p. 11. b Lib. cit. p. 156.]

PARALLELOPLEURON, a term uſed by ſome writers for an imperfect parallelogram, or a kind of trapezium, having unequal angles and ſides, but which obſerve a certain regularity and proportion.

PARAMECIUM, in zoology, the name given by Dr. Hill to a genus of animalcules of the *Gymnia* kind, and of an irregular oblong figure. See the articles ANIMALCULE *Cycl. Suppl.* and *Append.* and GYMNIA, *Append.*

Of this genus authors deſcribe ſeveral ſpecies; for which ſee *Hill*, Hiſt. Anim. p. 4. ſeq.

PARASITICAL *Plants*. See the article PARASITE, *Cycl.*

PARK *Leaves*, a name by which the *Androſæmum*, or *Tutſan*, is ſometimes called. See the article ANDROSÆMUM, *Suppl.*

PARENCHYMA *(Cycl.)* — Beſides the veſſels and canals of the human body, the antients ſuppoſed a ſimple homogeneous and firm matter, peculiar to each part, and thereby diſtinguiſhing

the habit of one part from that of another. But ſome moderns have denied the exiſtence of a *Parenchyma*, or pulpy matter, and have aſſerted, that the whole body is compoſed of veſſels and canals. The chief promoter of this opinion was Ruyſch, who having laid the injected parts of the body in rectified ſpirit of wine, and then dried them in the air; whatever was not injected, was thereby diſſipated, and the remainder conſiſted merely of veſſels; from whence he concluded, that the whole was compoſed of veſſels. But it ſeems certain, that a freſh muſcle can never be ſo injected, as to appear wholly compoſed of canals. If indeed, after injection, it be ſuffered to dry, the parts not injected will exhale, and the more the muſcle is dried, the more it will appear compoſed of veſſels. What is here ſaid of a muſcle, holds true of all other parts of the body. Thus many veſſels run through the ſubſtance of a bone; but no one has yet been able to demonſtrate, that the whole bone is compoſed of veſſels. There always remains a ſubſtance peculiar to bones, which has never yet been ſhewn to be vaſcular. In the brain alſo there always remains ſomething which cannot be demonſtrated vaſcular.

The *Parenchyma* is ſenſibly full of juices, ſo that very little of truly ſolid matter remains, when theſe juices are exhaled.

PARIS-*herb*, in botany, the name of a diſtinct genus of plants. See the article HERBA *Paris*, *Suppl.*

PAROTID-*glands*. In a ſuppuration of theſe, one caution only is needful; namely, to open the abſceſs, as ſoon as it can be ſuppoſed to have formed matter; without waiting for a fluctuation, or even ſoftneſs of the tumour, that may never happen; the pores being here ſo very viſcid, that after it is ripe, the part will feel as hard as if the ſuppuration had not begun. *Pringle*, Obſerv. on the Diſeaſes of the Army, p. 277.

PARROQUET, in ornithology, the name by which we call the ſmaller ſpecies of Parrots. See the article PSITTACUS, *Suppl.*

There are a great number of diſtinct ſpecies of *Parroquets*, as well as of Parrots, which having got peculiar names, are deſcribed under their reſpective articles.

PARSLEY *(Suppl.)* — *Baſtard*-PARSLEY, the name of a genus of plants, known among botaniſts by that of *Caucalis*. See the article CAUCALIS, *Suppl.*

Corn-PARSLEY, *Field*-PARSLEY, and *Macedonian*-PARSLEY, names uſed by ſome for a ſpecies of *Sium*. See the article SIUM, *Suppl.*

Fool's-PARSLEY, the name given by ſome writers to a ſpecies of *Cicuta*, or hemlock. See the article CICUTA, *Suppl.*

Macedonian-PARSLEY, the name by which the *Myrrhis* of botaniſts is ſometimes called. See the article MYRRHIS, *Suppl.*

Mountain-PARSLEY, the Engliſh name of a genus of plants, called by botaniſts *Oreoſelinum*. See the article OREOSELINUM, *Suppl.*

PARSLING, on ſhip-board, ſmall pieces of old canvas, cut four inches broad, and wrapped about ſhrouds, ſtays, ſtraps for blocks, &c. before ſerved with ſpun yarn. *Blanckley*'s Nav. Expoſ. p. 115.

PARSNEP *(Suppl.)* — *Cows*-PARSNEP, the Engliſh name of a diſtinct genus of plants, called by botaniſts *Sphondylium*. See the article SPHONDYLIUM, *Suppl.*

Sea or *Prickly-headed* PARSNEP, names given to the *Echinophora* of botaniſts. See the article ECHINOPHORA, *Suppl.*

Water-PARSNEP, the name uſed by ſome for a ſpecies of *Sium*, See the article SIUM, *Suppl.*

PASSION-*flower*, the Engliſh name of a genus of plants, called by botaniſts *Granadilla*. See the article GRANADILLA, *Suppl.*

PASTE *(Suppl.)* — *Chryſolite* PASTE. See the article CHRYSOLITE, *Append.*

PASTINACHA *(Suppl.)* — is alſo uſed for the carrot, or *Daucus* of botaniſts. See the article DAUCUS, *Suppl.*

PEA *(Suppl.)* — *Everlaſting*-PEA, or *Earth-nut* PEA, names ſometimes given to the *Lathyrus*. See the article LATHYRUS, *Suppl.*

Heart-PEA, or *Bladder*-PEA, names by which the *Corindum* of botaniſts is ſometimes called. See the article CORINDUM, *Suppl.*

Indian-PEA, the name by which a ſpecies of *Orobus* is ſometimes called. See the article OROBUS, *Suppl.*

Pigeon-PEA, a name ſometimes given to the *Cytiſus*, or ſhrub-trefoil. See the article CYTISUS, *Suppl.*

Scarlet-PEA, in botany, the Engliſh name of a genus of plants, called by Linnæus *Glycine*. See the article GLYCINE, *Suppl.*

Winged-PEA, a name by which ſome call the *Lotus*. See the article LOTUS, *Suppl.*

PEACOCK, in ornithology, the Engliſh name of a genus of birds, called by zoologiſts *Pavo*. See the article PAVO, *Suppl.*

PEACOCK-*fiſh*, the Engliſh name of a fiſh of the *Turdus*, or wraſſe-kind. See the article PAVO, *Suppl.*

PEAR *(Suppl.)* — *Prickly*-PEAR, a name ſometimes uſed for the *Opuntia Cereus*, *Melocactus*, &c. all comprehended by Linnæus under that of *Cactus*. See the article CACTUS, *Suppl.* and *Append.*

PEDALES. See the article ABBOT, *Cycl.*

PEEVIT, the Engliſh name of a bird of the *Larus*, or gull-kind, with a black head, and grey coloured body. See the article LARUS, *Suppl.*

PELLITORY *of Spain*, the Engliſh name of a genus of plants called by different authors *Chamæmelum* and *Buphthalmum*. Linnæus deſcribes it under this laſt. See the article BUPHTHALMUM, *Suppl.*

The root of this plant is known in the ſhops by the name of *Pyrethrum*. See the article PYRETHRUM, *Suppl.*

Double PELLITORY, a name ſometimes given to the *Ptarmica*, or ſneezewort, of botanical writers. See the article PTARMICA, *Suppl.*

PENDULUM *(Cycl.* and *Suppl.)* — Huygens having diſcovered that the vibrations of a *Pendulum* movingin a cycloid, would be performed in equal times, even tho' the vibrations were unequal, this principle was applied to the conſtruction of *Pendulum*-clocks; but great inequalities were ſtill obſerved in their motions; and many years paſſed before any ſucceſsful attempts were made to remedy theſe irregularities. The late excellent artiſt Mr. George Graham apprehending, that the irregularities in the motions of clocks aroſe from a change of length in the *Pendulum*, by the influences of heat and cold, made ſeveral trials in order to diſcover whether there was any conſiderable difference of expanſion between braſs, ſteel, iron, ſilver, &c. when expoſed to the ſame degrees of heat; conceiving that it would not be very difficult, by making uſe of two ſorts of metals differing conſiderably in their degrees of expanſion and contraction, to remedy, in a great meaſure, the irregularities to which common *Pendulums* are ſubject. But no hopes of ſucceſs ariſing from the experiments he then made, he turned his thoughts to the application of the obſervations he had made about the extraordinary expanſion of quickſilver by heat, and he found out a proper method of applying a column of that fluid to the *Pendulum* of a clock, in order to prevent the irregularities ariſing from its different lengths by the effects of heat and cold, which ſucceeded extremely well, and is what is now called Mr. Graham's *Quickſilver Pendulum*.

After this, Mr. John Harriſon, of Barrow, in Lincolnſhire, one of the moſt ingenious artiſts of the age, and famous for his invention of the clock for finding the difference of longitude at ſea, without having the leaſt knowledge of what Mr. Graham had done before him, made ſeveral experiments upon wires of different metals, in order to find their different degrees of expanſion and contraction. He thought that by a proper combination of wires of two different metals, differing conſiderably in their expanſion and contraction, he might be enabled to keep the center of oſcillation of a *Pendulum* always at the ſame diſtance, from the point of ſuſpenſion. In conſequence of theſe experiments, he made a *Pendulum* conſiſting of one ſteel wire, at the end of which is the bob or weight; and on each ſide of this wire, four wires alternately braſs and ſteel, ſo diſpoſed and contrived, as to raiſe the *Pendulum* by the ſame quantity that it is lengthened by heat, and to let down the *Pendulum* in the ſame proportion as it is raiſed by cold.

Mr. Harriſon, in his firſt machine for meaſuring time at ſea, likewiſe applied this combination of wires of braſs and ſteel, to prevent any alterations by heat and cold. And in the two machines or clocks he has ſince made for the ſame purpoſe, a like method of guarding againſt the irregularities ariſing from this cauſe is uſed.

Mr. Graham alſo made a *Pendulum* conſiſting of three bars, one of ſteel between two of braſs, and the ſteel bar acted upon a lever, ſo as to raiſe the *Pendulum*, when lengthened by heat, and to let it down, when ſhortened by cold; but he found this clock liable to ſudden ſtarts and jerks in its motion. See Mr. Short, in the Phil. Tranſ. vol. 47. p. 517. ſeq. who there alſo mentions a *Pendulum* of this kind made by Mr. Fotheringham, a quaker in Lincolnſhire.

The ingenious Mr. Ellicot [a] has given a deſcription of two methods uſed by himſelf, by which the irregularity of the motion of a clock, ariſing from the influence of heat and cold, upon the rod of the *Pendulum*, may be prevented. Mr. Ellicot tells us, that having by many experiments with his pyrometer [b] found a great difference between the expanſion of braſs and iron, he made a *Pendulum* compoſed of thoſe two metals, and applied it ſo ſucceſsfully to regulate the motion of a clock, that he avoided all the jerks to which it was ſuſpected the motion of the machine would be liable. [a Phil. Tranſ. vol. 47. p. 479. ſeq. b See the article PYROMETER, *Append.*]

Beſides the irregularities ariſing from heat and cold, *Pendulum*-clocks are liable to others from friction, and from foulneſs, owing to the oil uſed. But Mr. Harriſon has ſeveral excellent contrivances by which his clocks are almoſt entirely free from friction; and therefore he uſes no oil, ſo that there is no neceſſity of ever cleaning. See Mr. *Short*, ubi ſupra. See alſo Monſ. Caſſini, in Mem. Acad. Scienc. 1741.

PENGUIN, or PINGUIN, in botany, the name by which Dillenius calls the *Ananas* of Tournefort. See the article ANANAS, *Suppl.*

PENNY-*wort*, a name ſometimes given to the *Cotyledon*, or navel-wort of botanical writers. See the article NAVEL-WORT, *Suppl.*

Marſh-PENNY-*wort*, the Engliſh name of a genus of plants, called by botaniſts *Hydrocotyle*. See the article HYDROCOTYLE, *Suppl.*

PENTELASMIS, in the hiſtory of ſhell-fiſh, the name by which Dr. Hill calls the *conchæ anatiferæ* of other writers. See the article ANATIFERA *concha*, *Suppl.*

The *Pentelaſmis*, according to him, is a genus of animals, compoſed of a ſhelly body, affixed to a fleſhy and ſoft pedicle; the body is compoſed of five valves, and the pedicle is ſometimes ſhort, and ſometimes long. The animal itſelf belongs to the *Tritons*. See the article TRITON, *Append.*

PEONY, or PIONY, in botany, the Engliſh name of a diſtinct genus of plants, called by botaniſts *Pæonia*. See the article PÆONIA, *Suppl.*

PEPPER *(Suppl.)* — *Indian* PEPPER, or *Guinea* PEPPER, names by which ſome call the *Capſicum* of botaniſts. See the article CAPSICUM, *Suppl.*

Poor-man's-PEPPER, a name ſometimes given to the *Lepidium*. See the article LEPIDIUM, *Suppl.*

Water-PEPPER, a name ſometimes given to a ſpecies of *Sedum*, or Houſe-leek. See the article SEDUM, *Suppl.*

PEPPER-*mint*, the name of a ſpecies of mint. See the articles MENTHA and MINT, *Suppl.*

PEPPER-*wort*, a name by which ſome call the *Lepidium*, or dittander. See the article LEPIDIUM, *Suppl.*

PEPPER-*bird*, the Engliſh name of the *Rhamphaſtos*, with a yellow rump, otherwiſe called *Toucan*. See the article TOUCAN, *Suppl.*

PERESKIA, in botany, a name given by Plumier to a genus of plants, comprehended under the *Cactus* of Linnæus. See the articles CACTUS, *Append.* and MELOCACTUS, *Suppl.*

PERSEA, in botany, the name given by Plumier to a ſpecies of the Laurel of Linnæus. See the article LAURUS, *Append.*

PERSIMON, in botany, a name ſometimes given to the *Lachryma Jobi*, or Job's tears. See the article LACHRYMA, *Append.*

PESTILENCE-*wort*, a name ſometimes given to the *Petaſites*, or butter-burr. See the article PETASITES, *Suppl.*

PETAL *(Suppl.)* — The *Petal* of a plant is that part which, for want of a more diſtinct expreſſion, we call in Engliſh the leaves of the flower. See the article FLOWER, *Suppl.*

That great botaniſt, the late Mr. Pitton Tournefort, fixed upon the moſt ſtriking and ſhewy parts of vegetables, as the foundation of his method and generical diviſions of the vegetable world; which he has accordingly rang'd into twenty-two claſſes.

The firſt is of the plants with a *monopetalous* or one-leaved flower, form'd like a bell; and the flowers of this claſs he afterwards ſubdivides into four kinds; firſt, the *bell-faſhioned* flowers properly ſo called, as being very nearly of the regular ſhape of a bell: Secondly, the *tubulate bell-faſhioned* flowers, which are narrow and oblong: Thirdly, the *expanded*, which open in form of a wide baſon: And, fourthly, the *globoſe*; the mouth of which is narrower than the body. In this claſs he comprehends the *Mandrake*, *Lilly of the valley*, &c.

The ſecond claſs is of the plants with *monopetalous funnel-faſhioned*, and *rotated*, or wheel-like flowers. The flowers of this claſs he divides into two kinds only; the one repreſenting at its mouth, the bottom of an inverted cone, the other a ſalver or ſawcer; and theſe he diſtinguiſhes by the names of *funnel-faſhioned* and *ſalver-like* flowers: Of this claſs are the *Tobacco*, *Henbane*, &c.

The third claſs is of what he calls the plants with *anomalous*, *monopetalous* flowers; of theſe he makes the variouſly-ſhaped *monopetalous* flowers of *Birthwort*, *Foxglove*, *Figwort*, and ſome others; ſome of which repreſent a face, and others the ſnout of an animal: To diſtinguiſh the plants of this claſs the author however is oblig'd fairly to confeſs the imperfection of the method of claſſing by the *Petals* alone, and call in the aſſiſtance of the different ſtructure of the ſeed veſſels. In this claſs he comprehends the *Toadflax*, *Butterwort*, &c.

The fourth claſs is of the plants, which have a *monopetalous*, *labiated*, or lipp'd flower; which he defines to be ſuch an one as is narrow, like a pipe within, and expanded; and in form of lips at the mouth. In this claſs are comprehended the *Sage*, *Clary*, *Deadnettle*, *Mint*, *Baum*, &c.

The fifth claſs is of the plants with a *polypetalous*, *cruciform* flower; that is, ſuch an one as is compoſed of a number of leaves, diſpoſed in form of a croſs; and theſe he afterwards more nicely defines to be ſuch as are always compoſed of four *Petala*, or leaves only, and thoſe ever diſpoſed in form of a croſs. Of this claſs are the *Creſſes*, *Muſtard*, *Scurvy-graſs*, &c.

The ſixth claſs is of the plants which have a *roſaceous*, or roſe-like flower. This he defines to be ſuch an one as is compoſed of many leaves or *Petals*, diſpoſed like thoſe of the roſe into a round figure: The number of *Petals*, he adds, is uncertain and indeterminate in this claſs; and that they are frequently five, and more rarely four than two. Of this claſs are the *Chickweed*, *Orpine*, *Saxifrage*, *Rue*, &c.

The ſeventh claſs is of the plants with *umbelliferous* flowers. Theſe he defines to be *polypetalous*, *roſaceous* flowers, whoſe cup goes off into a fruit compoſed of two ſeeds, cohering firmly together while green, but naturally ſeparating, when ripe; and obſerves, that in this claſs the flowers are generally diſpoſed in great numbers together, and in the form of what the ladies call an *umbrella*, us'd to be carry'd over them to keep off the ſun; but he does not make this a neceſſary character of the claſs. The plants comprehended under this are *Carrots*, *Parſneps*, *Earth-nuts*, *Chervel*, *Fennel*, &c.

The eighth claſs is of the plants with a *caryophyllous* or pink-like flower, which he defines to be ſuch an one as is compoſed of many *Petals*, diſpoſed in an orbicular form, and ariſing each from the bottom of the cup, as from a tube, in the ſame manner as they do in the common pink. Of this claſs are the *Catchfly*, *Sea-lavender*, *Flax*, &c.

The ninth claſs is of the plants which have a *liliaceous*, or lilly-like flower, which he defines to be ſuch an one as is compoſed of ſix *Petals*, ſometimes indeed but three, but always divided however into ſix at the end. Here the author alſo again acknowledges the imperfection of claſſing by the *Petals*, ſince here he takes in the aſſiſtance of the figure and diviſion of the ſeed veſſel, which he ſays muſt always in this claſs be tricapſular, or divided into three cells; and plants which have this ſeed veſſel, tho' their flowers are not ſtrictly of the lilly ſhape, are allowed to be truly of the claſs. Of this are the *Aſphodel*, *Saffron*, *Flower-de-luce*, *Tulip*, *Crown-Imperial*, &c.

The tenth claſs is of the plants with a *polypetalous*, *papilionaceous* flower, or one that is compoſed of many *Petals*, and in form reſembles a butterfly. Theſe flowers the author defines to be compoſed of four diſſimilar *Petals*, which iſſue from a one-leaved cup, which is hollow, and like the conic paper-caſes people twiſt up to put ſpices, &c. in; and divided into many ſegments at the rim; and from this cup ariſes alſo the *Piſtil* of the flower. The upper leaf in theſe flowers which in ſome ſort repreſents the colours carried by ſoldiers in battle, he calls the *Vexillum* or *Enſign*; the lower, which is hollow'd, and in form of a boat, the *Hulk*; and the two ſide ones the *wings*. The plants comprehended under this claſs are the *Liquorice*, *Peas*, *Fenugreek*, &c.

The eleventh claſs is of plants with an *anomalous* or irregular *polypetalous* flower. Among theſe he comprehends ſuch of the *polypetalous* flowers as are of various ſhape, and compoſed of diſſimilar or irregular *Petals*, and could not well be comprehended under any one expreſſive or determinate character. Of this claſs are the *Violet*, *Fumitory*, *Dier's-weed*, *Woolfsbane*, &c.

The twelfth claſs is of the plants with a *floſculous* flower. This he defines to be one compoſed of a number of ſmall flowers, crowded cloſe together, and comprehended in the ſame general *Calyx*, or cup; theſe flowers, which together compoſe this complex one, he obſerves are generally compoſed of only one *Petal*, which is wider at the mouth, than at the other end, and generally notched or divided there into many ſegments. He alſo has recourſe to the other parts of the flower for farther deſcriptions; and comprehends under it the *Thiſtles*, *Knapweed*, *Bluebottle*, &c.

The thirteenth claſs is of the plants with a *ſemifloſculous* flower. Theſe he defines to be compoſed of a multitude of half flowers, each compoſed of one *Petal*, hollow in its lower part, but in its middle and upper part flat and plain; and diſpoſed into a ſingle or manifold circle. He here alſo deſcribes the fructification of the plants of this claſs, and comprehends in it the *Lettuce*, *Dandelion*, *Hawkweed*, &c.

The fourteenth claſs is of the plants with a *radiated* flower. Theſe flowers the author deſcribes to have two parts, a middle or *diſk*, compoſed of ſmall *fiſtular* flowers, and a *rim*, or *edge*, called the *corona*, which is made up of half flowers; and ſometimes, though ſeldom, of plain flat *Petals*. Under this claſs are comprehended the *Starwort*, *Ragwort*, *Golden-rod*, *Sunflower*, &c.

The fifteenth claſs is of the plants which have flowers compoſed of *ſtamina* or *threads*, ſuſtaining the *apices* or *capſules* of the fecundating farina. The author diſtinguiſhes theſe alſo by their *Piſtil* changing into a ſingle ſeed envelop'd in a huſk, and of this claſs makes the *Sorrel*, *Arſmart*, *Orrach*, the *Graſſes*, *Horſetails*, &c.

The ſixteenth claſs is of thoſe plants which the author ſuppoſes to have no flower at all; and yet to produce ſeeds. Of this claſs he determines the *Ferns*, *Liverwort*, and *Adder's-tongue*, to be.

The ſeventeenth claſs is of thoſe plants whoſe flowers and fruit he ſays are both ordinarily wanting. Theſe he afterwards divides into the earth and water plants; among the firſt he reckons the *Moſſes*, *Muſhrooms*, &c. And among the others the *Fucuſes*, *Algas*, *Corallines*, &c. the flowers and ſeeds of which he obſerves we are as yet at leaſt ignorant of.

The eighteenth claſs is of the trees and ſhrubs, which have *apetalous* flowers, or flowers without *Petals* or leaves at all. Of this claſs are the *Aſh*, *Box*, &c.

The nineteenth class is of the trees and shrubs which have *Catkins* or *Iuli* for their flowers. These the author says consist either of *stamina* and *apices* alone, that is, of the threads or capsules of the farina; or they are composed of these with some little leaves affixed to a long slender axis: These *Catkins* he observes are always in a different place from the fruit; and that, sometimes on the same, sometimes on different trees. Of this class are the *Walnut*, *Oak*, *Beech*, &c.

The twentieth class is of trees and shrubs, which have a *monopetalous* flower; and of this are the *Elm*, *Lilac*, *Storax*, *Olive*, &c.

The twenty first class is of the trees and shrubs which have a *rosaceous* flower; and among these are comprehended the *Lime*, *Sumach*, *Ivy*, *Vine*, &c.

And the twenty second, or last class, is of the trees and shrubs with a *papilionaceous* flower; among which are reckoned the *Broom*, *Bean*, *Trefoil*, *Judas-tree*, &c.

It is very easily seen, that this is far from a strictly accurate method; the author has indeed assisted it with figures, which are very useful and instructive; and, as the judicious Linnæus observes, more is in reality to be learned from them, than from all the author has said. *Linnæus* has well observed, that this method is neither perfect nor sufficiently distinctive; the glory of instructing the botanist with truth and certainty was indeed reserved for that author alone, who when he had shewn the imperfection and uncertainty of all the before established methods, plan'd out an absolutely new one, founded on the unalterable parts of plants, their organs of fructification. See the article FRUCTIFICATION, *Append.*

PETER'S *wort*, or St. PETER's-*wort*, the English name of a genus of plants, called by botanists *Hypericoides* and *Ascyrum*. See the article ASCYRUM, *Append.*

PETOLA, in zoology, the name of a species of *coluber*, the scuta of whose abdomen are two hundred and nine, and the squamæ of the tail ninety. See the article COLUBER, *Suppl.*

PETREL, the name of a very remarkable bird, called *Procellaria*, by authors. See the article STORM-*fink*, *Suppl.*

The feet are large, the toes are slender, and connected by a fine, thin, black membrane; there is no hinder toe, but the claw in that part is small, and connected immediately to the back of the foot. The middle toe is shortest, and has only two joints; the outer is longer, and has four; and the interior has three, and is longer than either. *Hill*, Hist. Anim. p. 514.

PETRIDIA, in Natural History, the name of a genus of fossils of the *Scrupi*-kind, of a plain uniform structure, of no great variety of colours, and emulating the external form of pebbles. See the article SCRUPI, *Append.*

Of this genus the following are all the known species: 1. The various sized, pellucid, colourless, crystalline *Petridium*, commonly called *Pebble-crystal*. 2. The purple, semipellucid, crystalline *Petridium*. 3. The snow-white, opake, crystalline *Petridium*. 4. The opake, whitish, reddish, or yellowish, crystalline *Petridium*, commonly called red, white, or yellow sparry pebbles. 5. The yellowish-white pumicose, or spungy *Petridium*. 6. The hard, porous, whitish, crystalline *Petridium*. 7. The greyish-white, opake, stony *Petridium*. 8. The friable, shining, white, arenaceous *Petridium*. 9. The white, crystalline *Petridium*, spotted with small yellow dots. 10. The whitish-brown, dull *Petridium*. 11. The bluish-white, hard, crystalline *Petridium*. 12. The browniſh white, hard, shining *Petridium*. Vid. *Hill*, Hist. Foss. p. 563—572.

PETTY-*Whin*, a name by which some call the *Ulex*, or *Genista Spartium*. See the article GENISTA SPARTIUM, *Suppl.*

PHACA, in the Linnæan system of botany, the name of a distinct genus of plants, called by Tournefort *Astragaloides*. See the article ASTRAGALOIDES, *Suppl.*

PHALÆNÆ, in the history of insects, the name by which zoologists call the night-butterflies, or moths, as they are vulgarly called. See the article PHALENÆ, *Suppl.*

PHASIANUS, the *Pheasant*, in ornithology, the name of a genus of birds of the gallinaceous kind. See the articles GALLINÆ, and PHEASANT, *Suppl.*

The distinguishing characteristic of this genus of birds, is, that the area or space about the eyes is naked, and that they have no wattles.

The species are these: 1. The common *Pheasant*, with a blackish purple-colour'd breast. 2. The red, or scarlet-breasted *Pheasant*: This is nearly of the size of the common *Pheasant*, and its breast is of a high scarlet, and the belly red, but not so bright. 3. The East-India *Pheasant*: This is an extremely beautiful bird, the whole body of which is variegated with a profusion of the brightest colours, yellow, red, bluish-green, and almost every other tinge. *Hill*, Hist. Anim. p. 486.

PHEASANT's-*eye*, in botany, a name sometimes given to the *Adonis*. See the article ADONIS-*flos*, *Suppl.*

PHEASANT's-*eye Pink*, the name of a species of *Caryophyllus*. See the article PINK, *Suppl.*

PHOCA *(Suppl.)* — Dr. Parsons has lately given us a dissertation upon the class of the *Phocæ marinæ*. See Phil. Transf. vol. 47. pag. 109.

Phoca is the generic name, and all the species have a great likeness to each other, and may all alike have the names *phoca*, *vitulus marinus*, *sea-cow*, *sea-lion*, &c. The *manati*, the *soil* or *seal*, the *walrus* or *mors*, are so many species of this genus. Phil. Transf. ib.

PHYSIC *nut*, the English name of a distinct genus of plants, called by botanists *Ricinoides*. See the article RICINOIDES, *Suppl.*

PHRYGANIUM, in the history of insects, a genus of four-winged flies, of the *Neuroptera* class. See the article NEUROPTERA, *Append.*

The wings of the *Phrygania*, of which there are a great many species, are incumbent; they have four tentacula, two on each side.

PICKTOOTH *(Suppl.)*— *Spanish* PICKTOOTH, a name by which some call the *Visnaga* of Ray, a species of *Daucus*. See the article DAUCUS, *Suppl.*

PIECES. Plants may be propagated from their cuttings, slips, or *Pieces*; and it has been found that some kinds of animals have the like property, which may be called a reproduction of the animal or plant from a part of it. See the articles REPRODUCTION and PLANT, *Append.* and POLYPE, *Suppl.*

PIGEON-*Pea*, a name sometimes used for the *Cytisus*, or shrub-trefoil. See the article CYTISUS, *Suppl.*

PILE *(Suppl.)* — To estimate the force of the rammer made use of to drive *Piles*, its weight ought to be multiplied into the velocity it acquires in falling. Thus, if a rammer which weighs 500 *lb.* be let fall from four feet, it will fall that height in half a second, and have at the time of percussion a velocity capable to carry it eight feet in half a second, without any farther help from gravity; so that we must multiply 500 by 16, or its weight by the number of feet it would fall in a second, and the product 8000 gives the momentum of the stroke. If a capstan, pullies, or windlas be made to raise the rammer to a considerable height, and then by an easy contrivance lopsen it at once from its hook, the momentum of the stroke will always be as the square root of the height from which the rammer fell. *Desaguliers*, Experim. Phil. p. 336, seq.

But it is to be observed, that the effect of the blow of the rammer will be as the square of its velocity; that is, as the height from whence it falls, and not as the square root of that height. Thus if the blow of the rammer drive the *Pile* 6 foot deep; a blow given with twice the velocity, will, cæteris paribus, drive it four feet deep. This follows from the nature of the force of bodies in motion. See the article FORCE, *Append.*

We have the figure and description of a new machine for driving *Piles*, invented by Mr. Vauloue, in Desaguliers, Experim. Philosoph. p. 417, seq.

PILE-*wort*, a name by which some call the *Ranunculus*, or Crowsfoot. See the article RANUNCULUS, *Suppl.*

PIMPILLO, a name sometimes given to the *Opuntia* of botanical writers. See the article OPUNTIA, *Suppl.*

PIMPINEL *(Suppl.)* is also a name by which the *Sanguisorba*, or burnet, of botanists is sometimes called. See the article SANGUISORBA, *Suppl.*

PINASTELLA, in botany, the name by which Dillenius calls the *Hippuris* of Linnæus. See the article HIPPURIS, *Suppl.*

PINASTER, the name of several species of pine. See the article PINE, *Suppl.*

Ground-PINE, or *Dwarf*-PINE, names by which the *Chamæpitys* of botanical writers is sometimes called. See the article CHAMÆPITYS, *Suppl.*

Wild-PINE, a name sometimes given to the *Karatas*, or *Ananas*, of botanical writers. See the article ANANAS, *Suppl.*

PINQUIN, or PENQUIN, the names by which the *Ananas* of Tournefort is sometimes called. See the article ANANAS, *Suppl.*

PINK *(Suppl.)* — *Sea*-PINK, a name by which some call the *Statice*. See the article STATICE, *Suppl.*

PINTLE *(Suppl.)*—*Priest*'s PINTLE, a name sometimes given to the *Arum*, or wake-robin. See the article ARUM, *Suppl.*

PIPE *(Cycl.)* — *Air*-PIPE, an invention of the late ingenious Mr. Sutton to clear ships of foul air. This he does by a *Pipe*, the branches of which are laid in the hold, and the extremity of which is fixed into the ash-hole of the furnace. Mr. Watson has shewn how these *Pipes* may be laid, so as to be no way inconvenient, and relates the success of a trial of them, made on a hulk. See Phil. Transf. N° 462. p. 12.

We have now three different contrivances published for cleaning ships, and other close places, of foul air.

One by Dr. Desaguliers, which will change the air in the chamber of sick people, in a little time; either by drawing out the foul air, or driving in fresh; or doing both successively, without opening doors or windows. See Phil. Transf. N° 437.

The other by Mr. Sutton before mentioned; and the third by means of Dr. Hale's ventilators, which seems to be the most expeditious and simple method. See the article VENTILATORS, *Append.*

PIPE-*tree*, the English name of a genus of plants, called by botanists *Lilac* and *Syringia*. See the articles LILAC and SYRINGIA, *Suppl.*

Pudding-

Pudding-PIPE-*tree*, a name by which the *Caſſia* of botaniſts is ſometimes called. See the article CASSIA, *Suppl.*

PIPER, in ichthyology, the Engliſh name of a ſpecies of *Trigla*, with a bifid roſtrum, and tubuloſe noſtrils. It is called by the generality of authors LYRA. See the articles TRIGLA and LYRA, *Suppl.*

PIPERIDGE-*tree*, a name ſometimes given to the *Berberis*, or barberry-buſh. See the article BERBERIS, *Suppl.*

PIQUET, a well-known game at cards, and which has in ſome caſes been the object of mathematical computations.

Thus Mr. de Moivre has propoſed and ſolved the following problems:

1° To find at *Piquet* the probability which the dealer has for taking one ace or more in three cards, he having none in his hands. He concludes from his computation, that it is 29 to 28 that the dealer takes one ace or more.

2° To find at *Piquet* the probability which the eldeſt has of taking an ace or more in five cards, he having no ace in his hands. Anſwer; 232 to 91, or 5 to 2, nearly.

3°. To find at *Piquet* the probability which the eldeſt has of taking both an ace and a king in five cards, he having none in his hand. Anſwer; the odds againſt the eldeſt hand taking an ace and a king are 331 to 315, or 21 to 20 nearly.

4°. To find at *Piquet* the probability of having twelve cards dealt to, without king, queen, or knave; which caſe is commonly called *cartes blanches*. Anſwer; the odds againſt *chartes blanches* are 323 to 578956, or 1791 to 1 nearly.

5°. To find how many different ſets eſſentially different from one another, one may have at *Piquet* before taking in. Anſwer; 28,967,278. This number falls ſhort of the ſum of all the diſtinct combinations, whereby twelve cards may be taken out of 32, this number being 225,792,840; but it ought to be conſidered, that in that number ſeveral ſets of the ſame import, but differing in ſuit, might be taken, which would not introduce an eſſential difference among the ſets.

Mr. de Moivre alſo gives ſome obſervations on this game, which he had from an experienced player. See Doctrine of Chances, pag. 151 to 159.

Monſ. de Monmort has alſo treated of *Piquet* in his Analyſe des jeux de Hazard, pag. 162.

PISHAMIN, or PERSIMON, names by which ſome call the *Lacryma Jobi*, a diſtinct genus of plants. See the article LACRYMA, *Append.*

PISTACHIA, in the Linnæan ſyſtem of botany, the name of a genus of trees, called by Tournefort *Terebinthus*. See the article TEREBINTHUS, *Suppl.*

Wild-PISTACHIA, a name given to the *Staphylodendron*, or bladder-nut-tree. See the article STAPHYLODENDRON, *Suppl.*

PISTON *(Cycl.)* — There are two ſorts of *Piſtons* uſed in pumps; the one with a valve, which is called a *Bucket*; and the other without a valve, which is called a *forcer*. See the articles FORCER and PUMP, *Append.*

PITCH-*tree*, in botany, a name ſometimes given to the *Fir-tree*. See the article FIR, *Suppl.*

PITCHING, a word ſometimes uſed for paving. See the article PAVEMENT, *Cycl.*

PITH *(Suppl.)* — Dr. Hales ſhews that the *Pith* ſerves to ſupply the dilating moiſture for the tender ſhoots of plants, and that the figure of theſe may be oblong, and not round, like the fruit, there are tough diaphragms, or partitions in the *Pith* at ſmall diſtances from each other, which check the lateral expanſion; as alſo horizontal fibres, which ſerve for the ſame purpoſe.

Of the ſame ſort is the *Pith* in the large growing feathers of birds; being compoſed of veſicles that can be diſtended lengthwiſe, but have ſphincters at the ends, to prevent too large a lateral dilation. Vid. *Hales*'s Veget. Statics, vol 1. p. 337.

PLAGIURI. Under this claſs of fiſhes are comprehended the following genera: The Phyſeter, Delphinus, Balæna, Monodon, Catodon, and Thrichechus; which ſee under their reſpective articles PHYSETER, &c.

PLANE-*tree (Suppl.)*— *Baſtard* or *Falſe* PLANE-*tree*, a name by which ſome call the *Acer*, or Maple-tree. See the article MAPLE, *Suppl.*

PLANETARIUM, an aſtronomical machine, made to repreſent the motions of the planets, as they really are in nature, or at leaſt agreeably to the Copernican ſyſtem, and commonly called an *Orrery*. See the article ORRERY, *Suppl.*

The moſt remarkable of theſe machines was that invented by Huygens, and deſcribed by himſelf. See Deſcript. Automati planetarii, ap. *Huygen.* Opuſcul. poſthum. Tom. 2. p. 157. edit. Amſt. 1728.

In this *Planetarium*, the five primary planets perform their revolutions about the ſun; and the moon performs her revolution about the earth, in the ſame time that theſe revolutions are really performed in the heavens. The orbits alſo of the moon and planets are repreſented with their true proportions, excentricity, poſition, and declination, from the ecliptic or orbit of the earth: So that by this *Planetarium* the ſituation of the planets, their conjunctions, oppoſitions, &c. may not only be known for the preſent time, but for any time paſt, or future, as in a perpetual ephemeris.

This machine is now preſerved among the curioſities of the univerſity of Leyden.

But the *Planetariums* or Orreries now moſt commonly uſed, do not repreſent the true times of the celeſtial motions; but only their proportions; and are of uſe to beginners, to give them an idea of the planetary ſyſtems, as alſo, if conſtructed with ſufficient accuracy, to ſolve ſeveral queſtions relating to the motions of the planets, and of the earth and moon, &c.

Theſe machines are made of various ſizes, ſome repreſenting more planets than others. However, theſe complex ones are far from being improvements upon the original *Planetarium*, or Orrery, which ſhewed only the motion of the moon round the earth, and of the earth and moon round the ſun. They give but very confuſed, and even falſe ideas of the diſtances and bigneſs of the planets; which muſt always be ſo whilſt the orbits of the moon, and other ſecondary planets, are fixed to the ſame machine, which contains the primary ones. In the original one, every thing was well and properly executed; as the phænomena of day and night, and their gradual increaſe and decreaſe, according to the ſeaſons; the places of the earth where the ſun is ſucceſſively vertical, and ſeems to deſcribe its parallels; the real annual motion of the earth, which gives the ſun an apparent annual motion; the rotation of the ſun about its axis; the periodical and ſynodical month; the ſolar and ſydereal days; the ſucceſſive illumination of all the parts of the moon, &c.

It is therefore proper to have a machine for repreſenting the general ſolar ſyſtem by itſelf; the ſun moon, and earth ought alſo to be ſhewn ſeparately; and the ſyſtem of any other primary planet; as Jupiter, for inſtance, with all its ſatellites, ſhould have a ſeparate machine ſo contrived, as to repreſent in true proportion their magnitudes, diſtances, and other phænomena.

As to the magnitudes of the primary and ſecondary planets, if the ſun's diameter be ſuppoſed 100, that of Saturn will be $7\frac{5}{10}$, of Jupiter 10, of Mars $\frac{53}{100}$, of the Earth 1, of Venus 1, of Mercury $\frac{54}{100}$, and of the Moon $\frac{2853}{10000}$. As to the ſatellites of Jupiter and Saturn, they are ſuppoſed to be about the bigneſs of our Earth.

Again, if the diſtance of the Earth from the Sun be divided into 10 parts, Mercury will be diſtant from the Sun four of theſe parts, Venus ſeven, Mars fifteen, Jupiter fifty-two, and Saturn ninety-five.

Dr. Deſaguliers deſcribes a *Planetarium* of his own contrivance, the frame of which, containing the clock-work, is made of ebony; its outſide is adorned with twelve pilaſters, between which are painted, on as many vertical planes, the twelve ſigns of the zodiac. The upper ſurface is flat, and made of poliſhed braſs; on the outward circumference of which are ſcrewed ſix braſs pillars, ſupporting a large flat ſilvered ring. On this ring, which repreſents the ecliptic, are drawn ſeveral circles; the three innermoſt being divided into twelve parts for the ſigns of the zodiac, and each of theſe into 30 degrees; and among thoſe degrees are graved in their proper places, the nodes, aphelia, and greateſt north and ſouth latitudes of the planets. The next three circles have the months and days of the months, exactly correſponding to the Sun's place at noon each day throughout the year; and upon the braſs ſurface of the machine graduated are ſilver circles, which carry the planets, repreſented by ſilver balls, and raiſed upon arbors or ſtems to the height of the ecliptic.

Above the ecliptic ſtand ſome of the principal circles of the ſphere, according to their reſpective ſituation in the heavens, viz. the two colures, one half of the equinoctial circle, the tropic of cancer, the arctic circle, &c. The whole machine is alſo ſo contrived, as to be ſet to any latitude, without injuring any of the inſide motions.

Within the ecliptic ſtand the Sun and other planets; the Sun being in the center of the whole ſyſtem, and the reſt repreſented agreeably to the above-mentioned magnitudes and diſtances. When things are thus diſpoſed, by turning about the handle, or winch of the *Planetarium*, all the planets perform their revolutions round the Sun, according to their periodical times; and being furniſhed with indices of blued-ſteel, theſe ſhew the longitudes of the planets, by pointing to the diviſions on the graduated ſilver circles, as they move round.

As the diſtances of the planets are in their true proportions to each other, ſo likewiſe are their magnitudes; but it cannot be expected, that the diameters of the planets ſhould be in proportion to the diameters of their orbits; for to effect this, the machine muſt either be made 3000 times bigger than uſual, or the balls repreſenting the planets 3000 times leſs than uſual; whereby they would all be rendered inviſible, excepting the Sun, and even it would be leſs than $\frac{1}{100}$ part of an inch in diameter. For the ſame reaſon it is found impracticable to repreſent the ſun by a ball, proportionally bigger than thoſe repreſenting the other planets.

Now as the orbit of the Moon, as well as of the ſatellites of Jupiter and Saturn, bear no manner of proportion to the orbit of the primary planets, the diſproportion between theſe and their ſatellites muſt be ſtill greater. Hence appears the abſurdity of crowding them all into one machine, as is the caſe in the common *Orreries*.

To give a right notion of the diſtances and magnitudes of the ſatellites with reſpect to their primary planets, it will be neceſſary to have a ſeparate machine for each ſyſtem; or, the

ſame machine may be ſo contrived, as to repreſent one ſyſtem after another, by ſhifting and adjuſting the magnitudes and diſtances of the balls. In this manner, the general ſolar ſyſtem may be firſt exhibited; then that of the Moon and Earth round the Sun; afterwards that of Jupiter and its ſatellites: and, laſtly, that of Saturn and its ſatellites.

We have already taken notice of ſome of the phænomena explained by the general *Planetarium*, as well as of that contrived to exhibit the revolution of the Earth and Moon round the Sun. By theſe is likewiſe plainly ſhewn the cauſes of eclipſes, as well as of the apparent ſtationary and retrograde motions of the planets.

By the *Planetarium* adapted to the ſyſtem of Jupiter, and its ſatellites, are exhibited the immerſion or entrance of a ſatellite into the ſhadow of Jupiter; its emerſion out of the ſhadow; when theſe are viſible; when a ſatellite is hidden by the body of Jupiter, before it comes into, or after it is gone out of the ſhadow; when a ſatellite may be ſeen to croſs the body of Jupiter; when a ſatellite makes a ſolar eclipſe in Jupiter; and when ſatellites eclipſe one another.

PLANT *(Suppl.)—Propagation of* PLANTS. Tho' the moſt natural, as well as moſt univerſal method of propagating *Plants*, is that of ſowing the ſeeds of each kind in a proper ſoil; yet ſuch is the prolific power of nature, that in ſome inſtances, like the polype-animal, they may be propagated by ſets, pieces, ſlips, or cuttings taken from the parent tree, or *Plant*, and ſet in ſuch a ſoil as they are known to delight in. The whole family of willows are propagated in this manner with the greateſt eaſe. Thoſe ſorts which grow to be large trees, and are cultivated for timber, are generally planted from ſets of about ſeven or eight feet long, ſharpened at their larger ends, which is thruſt into the ground by the ſides of ditches and banks where the ground is moiſt; in which places they make a conſiderable progreſs, and are a great improvement to ſuch eſtates; becauſe their tops will be fit to lop every fourth or fifth year. The ſallows are planted of leſſer ſets, only three feet long, thruſt two feet into the ground, and one foot above it. The rows ſhould be three feet aſunder, and the ſets in each row eighteen inches; obſerving always to place the rows ſloping, in the ſame manner as the ground. The beſt ſeaſon for planting theſe cuttings is in February; and if the ſoil be good, they will produce a great crop of ſhoots every year, which will produce, at a moderate computation ten pounds per acre. See *Miller*'s Gard. Dict. in voc. *Salix*.

Beſides the willow-kind, the plane-tree, mint, &c. may be propagated in this manner; only it ought to be remarked, that in providing the ſlips, ſprigs, or cuttings, ſuch branches as have knots or joints, ſhould be cut off two or three inches beneath them; and that ſmall top ſprigs of two or three years growth, are the beſt for this operation. Ruſt. Dict. in voc. *Cuttings*.

Another way of propagating *Plants*, is by parting or dividing their roots, each part of which will, by proper management, thrive and ſend out freſh roots, which may be ſeparated in the ſame manner. See the article ROOT, *Cycl.* and *Suppl.*

The manner of propagating *Plants*, by laying the tops of branches in the ground, is deſcribed under the head LAYER, *Cycl.* and *Suppl.* And the common way by ſowing of the ſeeds, is ſufficiently explained under the articles NURSERY, SOWING, SEED, &c. *Cycl.* or *Suppl.*

Syſtems of PLANTS. Ray's Syſtem of *Plants* is delivered in the Cyclopædia under this head PLANT. The ſyſtem of Linnæus is to be found in the Appendix, under the head FRUCTIFICATION; and the Syſtem of Tournefort in the Appendix under the head PETAL.

Vegetation and œconomy of PLANTS. The theory of the growth and œconomy of *Plants* has received great improvmenets from the experiments of the ingenious Dr. Hales, in his vegetable ſtatics.

It appears from a great number of experiments made by that gentleman, that *Plants* imbibe and perſpire moiſture very copiouſly.

As to the quantity of moiſture perſpired by *Plants* and trees, there appears to be a very conſiderable difference in different vegetables. The lemon-tree, which is an ever-green, perſpires much leſs than the ſun-flower, or than the vine, or the apple-tree, whoſe leaves fall off in winter. Thus, from equal areas, the lemon-tree was found to perſpire only $\frac{1}{248}$ of an inch in height, during twelve hours of the day in the month of July; the apple-tree $\frac{1}{162}$; a cabbage $\frac{1}{80}$; a vine $\frac{1}{191}$; and a ſun-flower $\frac{1}{163}$ in a day and night. *Hale*'s Veget. Stat. Vol. 1. p. 20, ſeq.

In order to try what moiſture *Plants* would imbibe, the Dr. cut off ſeveral branches of apple-trees, pear, cherry, and apricot-trees; and having immerſed them into a known quantity of water, he found ſome of them imbibed 15 ounces, ſome 20 ounces, and others 25 or 30 ounces in 12 hours day more or leſs, according to the quantity of leaves they had; and and yet when he weighed them at night, they were lighter than in the morning, which undoubtedly was owing to their perſpiration. The quantity imbibed decreaſed very much every day, the ſap veſſels being probably ſhrunk at the tranſverſe cut, and too much ſaturated with water, to let any more paſs; ſo that uſually in four or five days the leaves faded and withered much. Id. ibid. p. 29.

The Doctor made the ſame experiments with elm-branches, oak, oſier, willow, ſallow, aſpen, curran, gooſberry, and philbert branches; but none of theſe imbibed ſo much as the foregoing, and ſeveral ſorts of ever-greens very much leſs. Id. ibid.

He alſo made ſeveral experiments to aſcertain the force with which *Plants* imbibe moiſture. This he did by putting the ſtump of a branch into one end of a glaſs tube, cementing it faſt; and then immerſing the other end of the tube, after being firſt filled with water, into a ciſtern of mercury; on which removing his finger that ſtopped up the lower end of the tube, the ſtump imbibed the water with ſo much vigour, that in ſix minutes time the mercury was raiſed eight inches in the tube. It is obſervable, that in all the experiments of this ſort, the mercury roſe higheſt, when the ſun was very clear and warm; and that it ſubſided in the night-time, and roſe again the next day, as the ſun ſhone upon the branch; only it was neceſſary to fill the tube with water; otherwiſe it would not riſe at all. It is alſo remarkable, that the top or ſmall end of a branch imbibed the water as well as the ſtump end. Id. ibid. p. 85, ſeq.

The imbibing force of a great variety of trees being tried in the ſame manner, by immerſing branches of them in aqueo-mercurial gages, it was found that the pear, quince, cherry, walnut, peach, apricot, plum, black-thorn, white-thorn, gooſeberry, water-elder, and ſycamore, raiſed the mercury from three to ſix inches high. The elm, oak, horſe-cheſnut, filbert, fig, mulberry, willow, ſallow, oſier, aſh, lynden, and curran raiſed the mercury only one or two inches. But the ever-greens, and the following trees and plants, viz. laurel, roſemary, lauruſtine, phyllerea, fuz, rue, barberry, jeſſamine, cucumber-branch, pumkin, Jeruſalem artichoak, &c. did not raiſe it at all. Id. ibid. p. 101.

In order to diſcover with what force the ſap of the vine is puſhed forth in the bleeding ſeaſon, the following experiments were made. Dr. Hales cut off a vine on a weſtern aſpect, within ſeven inches of the ground; the remaining ſtump having no lateral branches, and being four or five years old, and $\frac{3}{4}$ inch diameter. To the top of this ſtump he fixed a glaſs tube, twenty five feet high; ſecuring the joint with ſtiff cement made of bees-wax and turpentine, beſides ſeveral folds of wet bladder faſtened over it with Packthread. As the ſtem did not at firſt bleed into the tube, he filled the tube two feet high with water, which the ſame afternoon was imbibed by the ſtem within three inches of the bottom. Next day the ſtem began to bleed, ſo that the ſap in the tube continued riſing daily, till itwas above twenty-one feet high, and would very probably have riſen higher, if the joint had not ſeveral times leaked. In the chief bleeding ſeaſon, it would continue riſing night and day; but much more in the day than night; and moſt of all in the greateſt heat of the day. When the ſun ſhone hot upon the vine, there was always a continued ſeries of air bubbles aſcending from the ſtem through the ſap in the tube, in ſo great plenty, as to make a large froth on the upper part of the ſap, which ſhews the great quantity of air drawn in through the roots and ſtem. Id. ibid. p. 108.

This force of the riſing ſap is five times greater than the force of the blood in the great crural artery of a horſe; ſeven times greater than the force of the blood in the like artery of a dog; and eight times greater than the blood's force in the ſame artery of a fallow doe. Id. ibid. p. 114.

The free communication of the ſap veſſels of *Plants* appears from hence; that tho' deep gaps or notches be cut in a branch, it will nevertheleſs imbibe water in the manner already mentioned. In order to try whether it would not be the ſame in branches, as they grow on trees, the Dr. cut two ſuch oppoſite gaps in a duck-cherry-branch, three inches diſtant from each other, notwithſtanding which, the leaves of this branch continued green, within eight or ten days as long as the leaves on the other branches of the ſame tree. Id. ibid. p. 129.

However, it is the opinion of this excellent author, that there is no uniform circulation of the ſap in trees, like that of the blood in animals; for this reaſon, that if there were ſuch a circulation, the leaves of the ilex grafted upon the Engliſh oak would fall in winter equally with thoſe of the oak itſelf, which is not found to be the caſe. Id. ibid. p. 149.

And, that the ſap does not deſcend between the bark and the wood, as the favourers of a circulation ſuppoſe, ſeems evident from hence, viz. that if the bark be taken off for three or four inches breadth quite round, the bleeding of the tree above that bared place will much abate, which ought to have the contrary effect, by interrupting the courſe of the refluent ſap, if the ſap deſcended by the bark. But the reaſon of the abatement of the bleeding in this caſe may be accounted for, from hence, that the ſap is ſtrongly attracted upwards by the vigorous operation of the perſpiring leaves. Id. ibid. p. 150.

We have a great many other curious experiments and obſervations, in the ſame book, relative to the vegetation and analyſis of *Plants*; which are compoſed of the following principles, viz. ſulphur, volatile ſalt, water, earth, and air. See the article AIR, *Suppl.*

The leaves of *Plants* ſerve not only as excretory ducts to ſeparate and carry off the redundant watery fluid, which by

being long detained in the *Plants*, would turn rancid and prejudicial to them; but likewiſe to imbibe the dew and rain, which contain ſalt, ſulphur, &c. and to be of the ſame uſe to *Plants*, that the lungs are to animals. However, the Dr. remarks, that as *Plants* have not a dilating and contracting thorax, their inſpirations and expirations will not be ſo frequent as thoſe of animals, but depend wholly on the alternate changes from hot to cold for inſpiration, and *vice verſa* for expiration. Id. ibid. p 326.

But it is from the roots, that by far the greater part of the nouriſhment of *Plants* is derived. Theſe, therefore, are always found to bear a conſiderable proportion to the body of the *Plant* above ground; the ſuperficies of the former being about four tenths of that of the latter. Hence, appears the neceſſity of cutting off many branches from a tranſplanted tree; becauſe in digging it up, a great part of the roots are cut off. See *Hales*'s Veget. Statics, vol. 1. p. 6, 16.

Paraſitical PLANTS, among botaniſts. See the article PARASITE, *Cycl.*

Senſitive PLANT, the Engliſh name of a diſtinct genus of *Plants*, called by botaniſts *Mimoſa*. See the article MIMOSA, *Suppl.*

PLANTAIN-*tree*, the Engliſh name of a genus of trees, called by botaniſts *Plantago*. See the article PLANTAGO, *Suppl.*

PLANTAIN-*tree* is alſo a name given to the *Muſa* of Linnæus. See the article MUSA, *Append.*

Buckſhorn PLANTAIN, the name given by ſome to a ſpecies of *Coronopus*. See the article CORONOPUS, *Suppl.*

PLANTAIN-*ſhot*, a name by which ſome call the *Canna* and *Cannacorus* of botaniſts. See the articles CANNA and CANNACORUS, *Suppl.*

Water-PLANTAIN, a name given to ſeveral ſpecies of *Ranunculus*. See the article RANUNCULUS, *Suppl.*

PLANTATION *(Cycl.)* — As *Plantations* of trees are not only profitable to the owner, as well as ornamental to the country around them, but a national advantage, it may not be improper to give ſome directions concerning them.

Firſt, then, care muſt be taken to prepare the ground before trees are taken out of the earth; becauſe they ſhould never be ſuffered to remain long out of the ground. Care likewiſe is to be taken not to tear or bruiſe the roots of the trees, in raiſing them in order to be tranſplanted. When taken up, the next thing to be done is to prepare them for planting; which is done by cutting off all the ſmall fibres of the roots, and ſuch roots as are any wiſe injured in pulling up, or which croſs one another. The downright roots of fruit trees are likewiſed to be pruned off, as ſhould all their irregular branches; that when agitated by the wind, they may not rub againſt or bruiſe each other. However, the main ſhoots ought by no means to be cut off, as is but too often injudiciouſly practiſed.

Having thus prepared the trees for *planting*, they are next to be fixed in the ground; in doing which, care muſt be taken to place them deeper or ſhallower, according to the nature of the ſoil; but the beſt method of all is to raiſe a hill of earth, wherein to *plant* them. They ſhould be placed as erect as may be, and the earth gently preſſed down about their roots; for it is a fault to make it too hard. Pales or ſtakes ſhould be fixed round them, in order to prevent their being diſplaced or blown down by the wind.

When the trees are thus *planted* and ſecured, a little mulch ſhould be laid upon the ſurface of the ground, to prevent its drying; and as to watering them, it ought to be done with great moderation, nothing being more hurtful to them, than over-watering.

The ſeaſons for *planting* are various, according to the different ſorts of trees, or the ſoil in which they are to be *planted*. For ſuch trees whoſe leaves fall off in winter, the beſt time is the beginning of October, provided the ſoil be dry; but for a wet ſoil, it is better to defer it to the latter end of February, or the beginning of March; and for many kinds of evergreens, the beginning of April is by far the beſt ſeaſon; tho' they may be ſafely removed at Midſummer, provided they are not to be carried far. They ſhould always be removed in a cloudy moiſt ſeaſon, by which means they will take root in a few days.

As the method of cultivating moſt trees, eſpecially garden ones, is explained under their reſpective articles, there is the leſs reaſon to be particular on that head in this place. However one thing more deſerves to be well attended to, as regarding *Plantations* in general. It is this; that *Plantations* ſhould be raiſed always from trees tranſplanted from nurſeries, and never from hedge-rows, or trees of a large ſize, becauſe theſe laſt ſeldom come to good account, often dying after continuing alive for many years.

Another general rule in regard to *Plantations*, is, to keep the ground clear of weeds, at leaſt for the ſpace of ſeven years; for which purpoſe it ſhould be annually dug, or plowed, where that can be done. This will encourage the roots of the trees to extend themſelves, whereby they will draw a larger proportion of nouriſhment. *Miller*'s Gard. Dict.

PLANTING *Reverſe*. It has been already obſerved, that the branches of trees may be made to ſerve inſtead of roots; the putting of which in practice is called *Planting Reverſe*. See the article BRANCH, *Suppl.*

Mr. Fairchild of Hoxton gives the following directions on this head. When you have made choice of a young tree of one ſhoot, whether alder, elm, willow, &c. that will eaſily take root by layers, the top of the ſhoot is to be bent gently down into the earth, there to remain till it has taken root; the tree all the while reſembling a bow or arch above ground. When the top end is judged to have ſtruck ſufficiently ſtrong roots, the old root is to be gently raiſed out of the ground, and kept in an upright poſition; after which all the injured parts of the raiſed roots are to be pruned off, as well as the buds or ſhoots on the ſtem of the tree; taking care to rub over theſe pruned parts with a compoſition made of four ounces of tallow, as many of bees-wax, two ounces of roſin, and as many of turpentine, melted together in a pipkin; this to be uſed moderately warm. Vid. *Miller*'s Gardeners Dict.

PLATANOCEPHALUS, in botany, a name uſed by ſome botanical writers for the *Cephalanthus*. See the article CEPHALANTHUS, *Suppl.*

PLATANUS, the *Plane-tree* in botany. See the article PLANE-*tree*, *Suppl.*

PLAY *(Cycl.)* — See the article GAMING, *Cycl.*

Duration of PLAY, in the Doctrine of Chances is uſed for the probability of the play's ending in a given number of games.

In the Cyclopædia, under the article GAMING, the two laſt problems relate to the duration of *Play*; but this difficult ſubject has been further purſued by Mr. De Moivre in the ſecond edition of his Doctrine of Chances, p. 162—211.

PLOVER *(Suppl.)*— *Baſtard*-PLOVER, a name uſed in ſome parts of the kingdom for the *Capella*, or lapwing. See the article CAPELLA, *Suppl.*

PLOUGHMAN, in huſbandry, the perſon who guides the plough in the operation of tilling, or tillage. See the articles PLOUGH and TILLAGE, *Cycl.* and *Suppl.*

PLOUGHMAN's *Spikenard*, the Engliſh name of a genus of plants, called by botaniſts *Conyza*; it is likewiſe called by us *Flea-bane*. See the article FLEA-*bane*, *Suppl.*

PLUM *(Suppl.)* — *American* PLUM, *Maiden* PLUM, or *Black* PLUM, names given to a diſtinct genus of plants, called by botaniſts *Chryſobalanus*. See the article CHRYSOBALANUS, *Suppl.*

Hog-PLUM, the Engliſh name of a diſtinct genus of plants, called by botaniſts *Spondias*. See the article SPONDIAS, *Suppl.*

Indian date PLUM, a name ſometimes given to the *Dioſpyros* of Linnæus, and *Guajacana* of Tournefort. See the article GUAJACANA, *Suppl.*

PLUNGER, in Mechanics, a ſolid braſs cylinder uſed as a forcer in forcing pumps. See the articles FORCER and *Forcing* PUMP, *Append.*

POCCOON, a name by which ſome call the *Sanguinaria*. See the article SANGUINARIA, *Suppl.*

POCK-*wood*, a name ſometimes given to *Guaiacum*. See the article GUAIAC, *Cycl.*

PODARIA, in the hiſtory of inſects, a claſſical name comprehending all ſuch inſects as have limbs, but no wings. See the article APTERIA, *Append.*

Of this claſs there are two ſubdiviſions. 1. Such *Apteria Podaria* as have oblong bodies with numerous legs, or more than ſix pair: Theſe are the *Iulus*, or gally-worm; the *Scolopendra*, or *Centipes*; and the *Oniſcus*, or wood-louſe. 2. The *Apteria Podaria* with ſhorter bodies, and leſs numerous legs, or fewer than ſix pair; This ſubdiviſion contains numerous genera, as the Pulex, the Podura or Puceron, the Pediculi of various kinds, the Monoculi, the Acari, the Araneï, the Scorpio, and a great many others. See the articles GALLY-*worm*, SCOLOPENDRA, &c. *Suppl.*

PODOPHYLLUM, in the Linnæan ſyſtem of botany, the name of a genus of plants, called by Tournefort *Anapodophyllum*. See the article ANAPODOPHYLLUM, *Suppl.*

PODURA, in the hiſtory of inſects, the name by which Dr. Hill calls the *Pucerons*. See the article PUCERON, *Suppl.*

The body of theſe animals is ſhort and roundiſh; the tail is crooked and forked, and aſſiſts them in leaping. They have three pair of legs, which ſerve only for walking. The eyes are only two, but each compoſed of eight others. *Hill*, Hiſt. Anim. p. 20.

They belong to the claſs of inſects which have limbs, but no wings, and are called by the ſame author *Podaria*.

POET's *Roſemary*. See the article ROSEMARY, infra.

POINT *(Cycl. and Suppl.)*—In the Cyclopædia, a *Point* is defined to be a quantity, which has no parts, or which is indiviſible; and Euclid's authority is quoted for this. But it ought to be obſerved, that the calling a *Point* a quantity; or ſpeaking of indiviſible quantities, are abſurdities, of which Euclid was never guilty. As to the demonſtrations of the proportions of mathematical *Points* to each other, mentioned in the Cyclopædia; they are mere paralogiſms. Thus in Mr. Robartes's reaſoning [a], ſuppoſing with him that the chord of a greater circle, touching a ſmaller circle at the extremity of its diameter, is $= z$, and the chord of the ſmaller circle cor-

responding to the common verſed ſine $= x$, the diameter of the greater circle $= R$, and the diameter of the leſſer circle $= S$, it is certain, that $zz = 4Rx - 4xx$ and that $yy = 4Sx - 4xx$, as Mr. Robartes ſays. But what follows from thence? No more than this, that the ratio of zz to yy is the ſame with the ratio of $4Rx - 4xx$ to $4Sx - 4xx$, or dividing both theſe terms by $4x$, as $R - x$ is to $S - x$; and that the ultimate or limiting ratio of zz to yy, is the ſame with the ultimate or limiting ratio of $R - x$ to $S - x$. But the ultimate ratio of $R - x$ to $S - x$ is the ratio of R to S, and conſequently, the ratio of R to S is the ultimate ratio of zz to yy; or, the ratio of $\sqrt{R}$ to $\sqrt{S}$ is the ultimate ratio of z to y. But what then? Does it follow that the terms of this ultimate ratio muſt be conceived as *Points*? Nothing leſs. The ultimate ratio of z to y does not imply that the quantities z and y ever exiſt under this ultimate ratio of $\sqrt{R}$ to $\sqrt{S}$, but only that they may approach to this ratio, ſo as to differ from it by leſs than any aſſigned ratio. Mr. Robartes was miſled by the too prevailing language of infiniteſimals. See the article FLUXION and LIMITS, *Suppl.*—[[a] Phil. Tranſ. N°. 334.]

Singular POINT in geometry, is uſed for any *Point* of a curve, which has ſomething peculiar to diſtinguiſh it from the other *Points* of the curve. *Cramer*, Analyſ. des lign. courbes, p. 148.

Of theſe *Points* there are various kinds, ſuch as *double*, *triple*, &c. or in general, *multiple Points*; *Points of Inflexion* or contrary flexure, *&c.*

Every *Point* of a curve is *ſimple*, or *multiple*.

A *ſimple* POINT, is that which belongs only to one branch of a curve.

A *multiple* POINT is that which is common to ſeveral branches of a curve, in particular:

Double POINT is that which is common to two branches of a curve. The conic ſections or lines of the ſecond order have no double *Points*; but we find them in the lines of the third order.

Triple POINT is that which is common to three ſeveral branches of a curve.

Hence the terms *quadruple*, *quintuple*, &c. *Point* are eaſily underſtood.

If a *Point* be ſuppoſed to deſcribe a curve, it will paſs twice thro' a *double Point*; thrice thro' a *triple Point*, &c.

A *ſimple* POINT is ſometimes *ſingular*, as when it becomes a *Point* of contrary flexure, of double inflexion, and in many other caſes; for a detail of which we refer to *Cramer*, Analyſ. de lignes courbes, chap. x. p. 400. ſeq. and chap. xiii. p. 568. ſeq.

In the caſe mentioned in the Supplement, under the head POINT *of contrary Flexure*, where a double infinitely ſmall flexure or inflexion is ſaid to be formed in a *Point*, this *Point* is called by ſome a *Point of double inflexion*, and by Monſieur de Maupertuis[a], and Mr. Cramer[b], *Point de Serpentement*, and by others, *Point of rectitude*. — [[a] Mem. Acad. Scien. 1729. p. 277. Ed. Paris. [b] Analyſ. des lignes courbes.]

POINT *of Rectitude*, is defined by Sir *Iſaac Newton*, to be that in which the radius of flexure becomes infinite, or its center at an infinite diſtance: ſuch it is at the vertex of the parabola $a^3x = y^4$.

The *Point of Rectitude* is commonly the limit of contrary flexure: but there are alſo *Points of Rectitude*, which do not come between the parts of contrary flexure. For the method of inveſtigating theſe *Points*, ſee *Newton*'s Meth. of Flux. and Inf. Series. pag. 72.

Theſe *Points of rectitude* are not found in lines of a lower order than the fourth. In lines of this, and of higher orders, a tangent at a *Point* of inflexion may alſo meet the curve in another *Point*, and if the diſtance between this *Point* and the *Point* of inflexion be ſuppoſed to be infinitely diminiſhed, the ſecant will become a tangent, and the contact in this caſe will be equivalent to four interſections, in the ſame manner that the contact at a *Point* of contrary flexure is equivalent to three interſections. See *Cramer*, lib. cit. p. 403. and *Newton*, Method of Fluxions p. 72.

Theſe *Points of double Inflexion*, are alſo called *Points of inviſible Inflexion*; becauſe in effect they are not ſenſible, but only known by their analytical properties. Analyſts have conſidered ſeveral degrees of theſe *Points*. *Cramer*, loc. cit.

POINTERS, in ſhip-building, are pillars in an oblique poſition, from the floor-rider heads on each ſide, pointing or meeting each other at the middle of the gun-deck beams. *Blanckley*'s, Naval Expoſitor, p. 121.

POISON *(Suppl.)*—In the Philoſophical Tranſactions vol. 47. pag. 75. ſeq, we have an account of ſeveral experiments made by Monſieur Heriſſan, on living animals, with the Indian *Poiſon* brought over by Monſieur de la Condamine; and mentioned in the Supplement under this head.

This *Poiſon* which ſeems to be of a very ſubtile and dangerous nature is extracted by fire from divers plants, eſpecially from thoſe which the French call Lianes. The Indians in various places of South America prepare this *Poiſon*, and make uſe of it for the killing of wild beaſts, in this manner:

Thoſe ſavages are very dextrous at making long trunks, which are the moſt common weapon uſed by them in hunting. To theſe trunks or tubes they fit little arrows made of palm-tree, on which they put a little roll of cotton exactly fitting the bore of the tube. They ſhoot theſe with their breath, and ſeldom miſs the mark. They dip the points of theſe little arrows, as well as of thoſe of their bows, in this *Poiſon*; which is ſo active, that in leſs than a minute, eſpecially when freſh, it kills certain animals, from which the arrow has drawn blood.

Tho' a very ſmall drop of this *Poiſon*, conveyed into the blood by puncture is ſometimes ſufficient to kill a man, or at leaſt to cauſe great diſturbance in the animal œconomy, it is quite otherwiſe when taken in at the mouth; for then it does no ſort of miſchief. See Phil. Tranſ. loc. cit.

POISON-*Buſh*, a name by which ſome call the *Tithymalus*. See the article TITHYMALUS, *Suppl.*

POKE or PORK *Phyſic*, the name by which the *Phytolacca* of botaniſts is ſometimes called. See the article PHYTOLACCA, *Suppl.*

POLE-*cat*, in zoology, the Engliſh name of a creature of the weaſel-kind, called by authors *Putorius*. See the article PUTORIUS, *Suppl.*

POLEY-*Mountain*, in botany, the Engliſh name of a diſtinct genus of plants, called by botaniſts *Polium*. See the article POLIUM, *Suppl.*

POLYANTHES, in the Linnæan ſyſtem of botany, the name of a diſtinct genus of plants, called by ſome *Tuberoſa*, and *Tuberoſe Hyacinth*.

The characters are theſe: There is no cup; the flower conſiſts of one leaf, of an infundibuliform ſhape; the tube is oblong and crooked; the limb is divided into ſix ſegments; the ſtamina are ſix ſubulated filaments, connivent, and of the length of the limb; the antheræ are linear; the germen is roundiſh, and ſtands in the bottom of the corolla; the ſtyle is filiform, and ſhorter than the corolla; the ſtigma is trifid, thick, and covered with a honey-like juice; the fruit is a capſule, of a roundiſh, but obtuſely trigonal form, compoſed of three valves, containing three cells, and wrapped up in the baſe of the corolla; the ſeeds are numerous, ſemiorbicular, plane, and placed in a double ſeries. *Linnæi* Gen. Plant. p. 140.

POLYANTHUS, the name by which the *primula veris* of botaniſts is ſometimes called. See the article PRIMULA, *Suppl.*

POLYCNEMUM, in the Linnæan ſyſtem of botany, the name of a diſtinct genus of plants, called by Tournefort *Camphorata*. See the article CAMPHORATA, *Suppl.*

The characters of it are theſe: The cup is a ſubulated, acute, and permanent perianthium, conſiſting of three leaves; the flower conſiſts of five petals, extremely like thoſe of the cup, only ſhorter; the ſtamina are three capillary filaments, ſhorter than the flower; the antheræ are obtuſe; the germen of the piſtil is roundiſh; the ſtyle is bifid, and of the length of the ſtamina; the ſtigmata are obtuſe; the ſeed, which follows every flower, is ſingle, and has ſcarce any covering, at moſt, only a very thin membrane. *Linnæi* Gen. Plant. p. 21.

POLYTRICHUM, πολύτριχον. See the article ADIANTUM, *Suppl.*

POND-*weed (Suppl.)*— *Water* POND-*weed*, a name ſometimes given to a ſpecies of *Perſicaria*. See the article PERSICARIA, *Suppl.*

POOR-*man's Pepper*, a name ſometimes given to the *Lepidium* of botanical writers. See the article LEPIDIUM, *Suppl.*

POPPY *(Suppl.)*— *Prickly* POPPY, a name by which ſome call the *Argemone*, a diſtinct genus of plants. See the article ARGEMONE, *Suppl.*

Spatling POPPY, a name by which the *Lychnis* is ſometimes called. See the article LYCHNIS, *Suppl.*

POPULUS, the *Poplar* in botany, the name of a genus of trees. See the article POPLAR, *Suppl.*

PORCUPINE-*fiſh*, in ichthyology, the Engliſh name of ſeveral ſpecies of *Oſtracion*. See the article OSTRACION, *Suppl.*

POROPHYLLUM, a name given by Vaillant to a genus of plants, called by Linnæus *Kleinia*. See the article KLEINIA, *Append.*

POSSET *(Suppl.)* — *Beer*-POSSET. See the article ZYTHOGALA, *Suppl.*

POSTULATE, or POSTULATUM *(Cycl.)* — Authors are not agreed as to the ſignification of the term *poſtulatum*. Many, with whom the Cyclopædia agrees, make the difference between axioms and *poſtulata*, to be the ſame as that between theorems and problems; axioms, according to thoſe authors, being indemonſtrable theoretical truths, and *poſtulata* indemonſtrable practical truths.

But others will have it, that axioms, or common notions are primitive, and common to all things partaking of the nature of quantity, and which therefore may become the objects of mathematical ſcience, ſuch as number, time, extenſion, weight, motion, &c. and that *poſtulata* relate particularly to magnitudes ſtrictly ſo called, or to things having local extenſion,

ſion, ſuch as lines, ſurfaces and ſolids; ſo that in this ſenſe of the word *poſtulatum*, Euclid, beſides axioms, or thoſe principles which are common to all kinds of quantity, has aſſumed certain *poſtulata* to be granted him, peculiar to extenſive magnitude. Hence ſeveral of the principles aſſumed in his elements, and ranked among the axioms by the moderns, are by Proclus ranked among the *poſtulata*; which has induced Dr. Wallis to judge, that the laſt of the two ſenſes given to the term *poſtulatum* is moſt agreeable to the meaning of the antient geometers. And thoſe who contend for this ſenſe of the word, add, that Euclid, in *poſtulating* to draw a right line from one point to another, does not mean that any man can actually do this, but only that it may be conceived as poſſible. So that *poſtulata* are axioms no leſs than the other principles aſſumed in the elements of geometry, but axioms relating to a particular ſubject, and not common to all. *Wallis's* Oper. Vol. 1. p. 667, 668. See the article PRINCIPLE, *Append.*

POTATOES, the Engliſh name of the tuberoſe-rooted, eſculent *Lycoperſicon* or *Solanum* of botanical writers. See the article SOLANUM, *Suppl.*

The Engliſh name ſeems evidently formed from *Batatas*, the Indian name of the ſame plant. See the article POTATOES, *Suppl.*

Spaniſh POTATOE, the name by which ſome call ſeveral ſpecies of *Convolvulus*, or bindweed. See the article CONVOLVULUS, *Suppl.*

POTENTILLA, a name uſed by ſome for ſeveral ſpecies of *Cinquefoil*. See the article CINQUEFOIL, *Suppl.*

POUCH *(Suppl.)* — *Shepherd's*-POUCH, a name ſometimes given to the *Alyſſon*, or mad-wort. See the article ALYSSON, *Suppl.*

POWER *(Cycl.* and *Suppl.)* — *Arithmetical* POWER is uſed by Mr. Machin, for compoſite numbers or quantities whoſe factors are in arithmetical progreſſion. See Phil. Tranſ. N° 447, and Dr. Martyn's Abridg. Vol. 8. p. 78.

Mr. Machin uſes a particular notation for quantities of this kind. The quantity expreſſed by this notation has a double index; that at the head of the root at the right hand, but ſeparated by a hook to diſtinguiſh it from the common index, denotes the number of factors; and that above, within the hook on the left hand, denotes the common difference of the factors proceeding in a decreaſing or increaſing arithmetical progreſſion.

Thus the quantity $\overset{a}{\smile}\!\!\left(\overline{n+a}\right.^{m}$ denotes by its index m on the right hand, that it is a compoſite quantity, conſiſting of ſo many factors as there are units in the number m; and the index a above on the left, denotes the common difference of the factor's decreaſing in an arithmetical progreſſion, if it be poſitive; or increaſing, if it be negative; and ſo ſignifies, in the common notation, the common number or quantity, $\overline{n+a}\,.\,\overline{n+a-n}\,.\,\overline{n+a-2a}$. &c.

For example, $\overset{2}{\smile}\!\!\left(\overline{n+5}\right.^{6}$ is $= \overline{n+5}\,.\,\overline{n+3}\,.\,\overline{n+1}\,.\,\overline{n-1}\,.\,\overline{n-3}\,.\,\overline{n-5}$, conſiſting of ſix factors whoſe common difference is 2. After the ſame manner, $\overset{2}{\smile}\!\!\left(\overline{n+4}\right.^{5} = \overline{n+4}\,.\,\overline{n+2}\,.\,\overline{n-2}\,.\,\overline{n-4}$, conſiſting of five factors. According to which method it will eaſily appear, that if a be an integer, then $\overset{2}{\smile}\!\!\left(\overline{n+2a+1}\right.^{2a+2}$ will be $= \overline{nn-1}\,.\,\overline{nn-9}\,.\,\overline{nn-25}$ continued to ſuch a number of double factors as are expreſſed by $a+1$, or half the index, which in this caſe is an even number. Thus alſo $\overset{2}{\smile}\!\!\left(\overline{n+2a}\right.^{2a+1}$ will be equal to $n.\,\overline{nn-4}\,.\,\overline{nn-16}\,.\,\overline{n-36}$, and ſo on, where there are to be ſo many double factors, as with one ſingle one n, will make up the index $2a+1$, which is an odd number.

If the common difference a be an unit, it is omitted: Thus $\smile\!\!\left(\overline{n}\right.^{6} = n.\,\overline{n-1}\,.\,\overline{n-2}\,.\,\overline{n-3}\,.\,\overline{n-4}\,.\,\overline{n-5}$, containing ſix factors. So $\smile\!\!\left(\overline{6}\right.^{6} = 6.\,5.\,4.\,3.\,2.\,1.$ and the like for others.

If the common difference a be nothing, the hook is omitted, and it becomes the ſame with the geometrical *power*: Thus $\overset{0}{\smile}\!\!\left(\overline{n+a}\right.^{m} = \overline{n+a}\,|^{m}$ according to the common notation.

The learned author above quoted applies this doctrine of arithmetical *powers* to the inveſtigation of the principal rule in the method of fluxions, and its inverſe, which is, that if the ordinate $y = m\,\dot{z}^{\frac{m-1}{n}}$, then will the area, or rather the form of the quantity for the area, be $= z^{m}$; or vice verſa, that if the area be z^{m}, the ordinate will be $m\,\dot{z}\,z^{m-1}$; on which occaſion he obſerves, that the ſymbol $\dot{z}$, conſidered as a component part of the rectangle z, may bear a plain interpretation, viz. that it is the meaſure according to which the quantity z is meaſured. See Phil. Tranſ. loc. cit. in the poſtſcript. See alſo FLUXION, *Suppl.*

PRECESSION *(Cycl.)* — The *preceſſion* of the equinoctial points varies; nor are aſtronomers entirely agreed as to the quantity of the variation, ſo as to eſtabliſh what the mean *preceſſion* is. Dr. Bradley aſſumes the mean *preceſſion* to be one degree in ſeventy one years and an half. See Phil. Tranſ. N° 485. p. 22.

According to this eſtimate, the platonic or great year would be equal to 25740 ſolar years.

Sir Iſaac Newton, in determining the quantity of the annual *preceſſion* from the theory of gravity, upon ſuppoſition that the equatorial is to the polar diameter of the earth, as 230 is to 229, finds the ſun's action ſufficient to produce a *preceſſion* of $9''\frac{1}{8}$ only; and collecting from the tides the proportion between the ſun's force and the moon's to be as 1 to $4\frac{1}{2}$, he ſettles the mean *preceſſion* reſulting from their joint actions, at 50″. But ſince the difference between the polar and equatorial diameter is found, by the late obſervations of the gentlemen of the Royal Academy of Sciences at Paris, to be greater than what Sir Iſaac had computed it to be; the *preceſſion* ariſing from the ſun's action muſt likewiſe be greater than what he has ſtated it at, nearly in the ſame proportion. From whence it will follow, that the moon's force muſt bear a leſs proportion to the ſun's, than $4\frac{1}{2}$ to 1. See Dr. *Bradley* in Philoſoph. Tranſ. N° 485, pag. 37.

PREVENTERS, on board a ſhip of war, are ropes of different ſizes, cut into ſhort lengths, and knotted at each end, to be ready in caſe a ſhroud ſhould be ſhot or broke, that they may be ſeized to them. *Blanckley's* Naval Expoſitor, p. 123.

PRICKET, among ſportſmen. See the article SPITTER, *Append.*

PRICK-*Madam*, the name of a ſpecies of *Sedum*; the ſame with the yellow houſe-leek, with ſharp-pointed leaves. See the article SEDUM, *Suppl.*

PRICK-*Timber*, a name ſometimes given to the *Euonymus*, or ſpindle-tree. See the article EUONYMUS, *Suppl.*

PRIEST'S *Pintle*, in botany, a name by which *Arum*, or wake-robin is ſometimes called. See the article ARUM, *Suppl.*

PRIMROSE, the Engliſh name of a genus of plants, called by botaniſts *Primula veris*. See the article PRIMULA VERIS, *Suppl.*

PRIMROSE-*tree*, or *Night*-PRIMROSE, the Engliſh name of a genus of plants, known among authors by that of *Onagra*. See the article ONAGRA, *Suppl.*

PRINCIPLE *(Cycl.)* — Philoſophers and mathematicians are generally agreed in admitting that there are axioms, that is, certain indemonſtrable truths, which muſt be reckoned among the principles of human knowledge in the ſtricteſt ſenſe. Hobbes ſeems to advance the contrary, when he ſays, in his logic, or firſt part of his book de Corpore, that definitions, or their parts, are the only primary propoſitions *(propoſitiones primæ)* that is, *principles* in an abſolute and ſtrict ſenſe. But this doctrine of Hobbes cannot be admitted. For however true it may be in itſelf, and with reſpect to the divine mind, it ſeems certain, that the human mind has never yet attained, and perhaps never will attain to a perfect analyſis of its own notions in all caſes. And wherever this analyſis ceaſes, definitions ceaſe with it; and where definitions ceaſe, we are forced, if we would demonſtrate any thing of the undefined ſubject, to have recourſe to axioms, or to indemonſtrable truths admitted by all men, tho' never yet demonſtrated by any one. This will appear evident to thoſe who attentively conſider Euclid's Elements. This great geometer, it is known, does not, ſtrictly ſpeaking, define a right line; becauſe he could not probably, analyſe the notion of rectitude; for that which is commonly called his definition of a right line, in the beginning of his elements, is no definition, nor is it ever applied afterwards, as the definitions of an equilateral triangle, a ſquare, and a circle are. But to ſupply the place of a definition, he has aſſumed the axioms, that two right lines cannot comprehend a ſpace; and that they cannot have a common ſegment; and theſe axioms become of uſe more than once afterwards. No one has as yet been able to ſupply with ſucceſs what Euclid omitted to do; for tho' ſome, both ancients and moderns, have demonſtrated ſeveral very plain axioms, as that the whole is greater than its part, yet none have demonſtrated all the principles of extenſive magnitude aſſumed by Euclid, which Proclus and others choſe to diſtinguiſh by the name of *Poſtulata*. See the article POSTULATE, *Append.*

Hobbes brings this very inſtance of the demonſtration that a whole is greater than its part, to prove, that the propoſitions commonly called axioms, are not, ſtrictly ſpeaking, primary, but only ſecondary propoſitions, and really deducible from definitions. Had he attempted the demonſtration of all Euclid's axioms and poſtulata, he would ſoon have found that he had made a raſh induction; and what he gives for a demonſtration of the properties of parallels, evidently ſhews, how little able he was to ſupply what Euclid had omitted. What is here ſaid of Hobbes, may be applied to others who have attempted to refine upon Euclid, and who have been fond of carrying the analyſes of their demonſtrations beyond

him.

him. They have all ſhewn their inability of demonſtrating, without taking ſome axioms or poſtulata for granted; and indeed moſt of them expreſly admit this, only contending that the *principles* they aſſume are more evident than thoſe of Euclid. But whether they be ſo, or not, is of no importance to the preſent queſtion, which is, whether we are not often obliged to have recourſe to axioms, that is, to ſelf-evident, or indemonſtrable truths, in the ſtricteſt ſenſe; and whether theſe can be ſupplied by deductions, or ſyllogiſtic reaſoning, from definitions only. We ſhould not have taken any notice of this queſtion, had not Hobbes and other metaphyſicians and logicians of repute run counter to the common opinion.

But tho' we are forced to aſſume axioms and poſtulata in geometry, it may be a queſtion, whether any thing of this kind be neceſſary in arithmetic, or the ſcience of numbers; and whether the analyſes of our notions may not here be carried up to the notions of unity, and of the act of addition, *tamquam poſſibilia prima*; and whether it was not ſome conſideration of this kind that led Ariſtotle to ſay, that arithmetic was more accurate (ακριβεστερον) than geometry. It is certain at leaſt, that the analyſis may be, though it ſeldom is, carried farther in the former than in the latter of theſe ſciences. Becauſe the axioms commonly aſſumed, and peculiar to arithmetic, ſuch as the addition and multiplication tables, are no more than the aggregates of the ſimple ſigns, or ſimple notations of numbers; and may eaſily be demonſtrated from the definitions of the ſimple ſigns made uſe of; ſuch as that $1 + 1 = 2$; $2 + 1 = 3$; $3 + 1 = 4$, &c.

Biſhop Berkeley [a] obſerves very juſtly, that the *principles* of ſcience are neither objects of ſenſe nor imagination, but notions of relation, that is, acts of the mind. Thus, ſpace, time, number [b] are not objects of ſenſe or imagination, altho' the things coextended with ſpace or time, or things numbered, be objects of ſenſe. This is moſt evident in number, which is plainly different from the perception of the things numbered. Nor can the act by which we number be taught or exemplified. For inſtance, that act of the mind by which we conceive $1 + 1 = 2$, cannot be explained or analyſed into others; and ſuppoſing it could, we muſt ſtill ſtop ſomewhere, and wherever that be, there is ſomething a diſciple muſt have *a ſe*, *non a præceptore*, as Ariſtotle ſays. So that, ſtrictly ſpeaking, *principles* are not taught. And thoſe who maintain them innate, are perhaps not ſo abſurd as Locke pretends. [[a] Reflections on Tar-water, Art. 264. [b] Ibid. Art. 288.]

Leibnitz maintained, that the *principles* of contradiction, and of a ſufficient reaſon, were the foundations of all ſcience; that the firſt was ſufficient for the demonſtration of all neceſſary, and the other of all contingent, truths. But though it be true, that the *principle* of contradiction, that is, the *reductio ad abſurdum*, often occurs expreſly, and is oftner implied in geometry, yet by what has been ſaid it appears, that this *principle* alone is not ſufficient to demonſtrate all the other univerſally received *principles* of that ſcience. Far leſs is it true, that we are enabled by the *principle* of a ſufficient reaſon, which amounts to the excluſion of pure chance out of the univerſe, to demonſtrate all phyſics and morals; but additional *principles* derived from experience, muſt be aſſumed.

PRIVIES *of a Camp*. See the article CAMP, *Append.*

PRIVET *(Suppl.)* — *Mock* PRIVET, a name ſometimes given to the *Phillyrea* of botaniſts. See the article PHILLYREA, *Suppl.*

PROCELLARIA, in ornithology, the name uſed in the Stockholm Tranſactions, and elſewhere, for the *ſtorm-fink*, or *ſtorm-bird*. See STORM, *Suppl.* and PETREL, *Append.*

PROBABILITY *(Cycl.)* — In the doctrine of *Probability*, one important obſervation may be made, *viz.* that if one premiſs only of an argument be probable, the concluſion is neceſſarily probable. But if two or more premiſſes be *probable* the concluſion will not be neceſſarily *probable*. Thus for inſtance, ſuppoſing the *Probability* of each premiſs expreſſed by $\frac{7}{10}$, the *Probability* of the concluſion will be but $\frac{49}{100}$, which ſhews it to be improbable. For we may call any thing *improbable*, if the meaſure of the chance for its happening is leſs than $\frac{1}{2}$. If there had been three premiſſes, and the *Probability* of each equal to $\frac{7}{10}$, the *Probability* of the concluſion would be $\frac{343}{1000}$, which is conſiderably improbable. Again, ſuppoſing the *Probability* of the truth of each premiſs to be 2 to 1 or expreſſed by $\frac{2}{3}$, the probability of the concluſion in the caſe of the two premiſſes would be $\frac{4}{9}$. Where three premiſſes are aſſumed to infer a concluſion, this would be $\frac{8}{27}$; and in caſe of four premiſſes, the *Probability* of the concluſion would be but $\frac{16}{81}$, which is leſs than $\frac{1}{5}$, ſo that one might with advantage lay 4 to 1 againſt the truth of a concluſion founded on four probable premiſſes, for the truth of which ſeparately taken 2 to 1 might be laid. It is to be obſerved in all theſe caſes, that the premiſſes are ſuppoſed independent, that is, not neceſſarily connected with each other.

Hence it is eaſy to account, how it happens, that the moſt plauſible political and phyſical reaſonings, lead ſo often to concluſions falſe in fact.

Mr. de Moivre has ſolved two problems, tending to eſtabliſh the degree of aſſent that ought to be given to experience. He determines from his ſolutions, that if after taking a great number of experiments, it ſhould have been obſerved, that the happenings or failings of an event have been very near in a ratio of equality, it may ſafely be concluded, that the *Probabilities* of its happening or failing, at any one time aſſigned, are very near equal.

And if after taking a great number of experiments, it ſhould be perceived, that the happenings and failings have been nearly in a certain proportion, ſuch as 2 to 1, it may ſafely be concluded, that the *Probabilities* of happening or failing at any one time aſſigned, will be very near in that proportion; and that the greater the number of experiments has been, ſo much the nearer the truth will the conjectures be, that are derived from them.

Chance very little diſturbs the events which, in their natural inſtitution, were deſigned to happen or fail according to ſome determined law. For if in order to help our conception we image a round piece of metal, with two poliſhed oppoſite faces, differing in nothing but their colour, whereof one may be ſuppoſed to be white and the other black, it is plain that this piece may with equal facility exhibit a white or black face; and we may even ſuppoſe that it was framed with that particular view of ſhewing ſometimes the one face, ſometimes the other; and that conſequently, if it be toſſed up, chance will decide the appearance. But altho' chance may produce an inequality of appearance, and that a greater inequality, according to the length of time in which it may exert itſelf, ſtill the appearance, either one way or the other, will perpetually tend to a proportion of equality. This is, in like manner applicable to a ratio of inequality; and thus in all caſes it will be found, that although chance produces irregularities, ſtill the odds will be infinitely great, that in proceſs of time, thoſe irregularities will bear no proportion to the recurrency of that order which naturally reſults from original deſign. See *De Moivre*'s Doctrine of Chances, p. 231. — 243.

PROBLEM *(Cycl.)* — *Kepler*'s PROBLEM *(Cycl.)* — As to the ſolution of this *problem*, the late excellent mathematician Mr. Machin obſerves, that many attempts have been made, at different times, but never yet with tolerable ſucceſs, towards the ſolution of the *problem* propoſed by Kepler: To divide the area of a ſemicircle into given parts, by a line from a given point of the diameter, in order to find an univerſal rule for the motion of a body in an elliptic orbit. For among the ſeveral methods offered, ſome are only true in ſpeculation, but are really of no ſervice. Others are not different from his own, which he judged improper. And as to the reſt, they are all ſome way or other ſo limited and confined to particular conditions and circumſtances, as ſtill to leave the *problem* in general untouch'd. To be more particular, it is evident, that all conſtructions by mechanical curves are ſeeming ſolutions only, but in reality unapplicable; that the roots of infinite ſerieſes are, upon account of their known limitations in all reſpects, ſo far from affording an appearance of being ſufficient rules, that they cannot well be ſuppoſed as offered for any thing more than exerciſes in a method of calculation. And then, as to the univerſal method, which proceeds by a continued correction of the errors of a falſe poſition, it is, when duly conſidered, no method of ſolution at all in itſelf; becauſe unleſs there be ſome antecedent rule or hypotheſis to begin the operation (as ſuppoſe that of an uniform motion about the upper focus, for the orbit of a planet; or that of a motion in a parabola for the perihelion part of the orbit of a comet; or ſome other ſuch) it would be impoſſible to proceed one ſtep in it. But as no general rule has ever yet been laid down to aſſiſt this method, ſo as to make it always operate, it is the ſame in effect as if there were no method at all. And accordingly in experience it is found, that there is no rule now ſubſiſting but what is abſolutely uſeleſs in the elliptic orbits of comets; for in ſuch caſes there is no other way to proceed but that which was uſed by Kepler. To compute a table for ſome part of the orbit, and therein examine if the time to which the place is required, will fall out any where in that part. So that, upon the whole, it appears evident, that this *problem* (contrary to the received opinion) has never yet been advanced one ſtep towards its true ſolution. Vid. *Machin*, in Phil. Tranſ. N° 447. and Martyn's Abridg. Vol. 8. p. 73.

Mr. Machin afterwards proceeds to give his own ſolution of this *problem*, which is particularly neceſſary in orbits of a great excentricity; and he illuſtrates his method by examples, for the orbits of Mercury, of Venus, of the Comet of the year 1682, and of the great Comet of the year 1680, all which ſhew the univerſality of that method. See Phil. Tranſ. loc. cit.

PROPERTY *(Cycl.)* — In the law of England, ſtrictly ſpeaking, that which is called an *eſtate* in lands and tenements, is termed a *property* in perſonal chattels, the law conſidering the firſt as permanent, the other as temporary and precarious. Peer Williams's Reports, p. 3.

PROSCARABÆUS, in zoology, the name by which ſome call the *Meloe*, a genus of four-winged flies. See the article MELOE, *Append.*

PSEUDO-*Fumaria*, in botany, a name uſed by ſome for a ſpecies of *Fumitory*. See the article FUMARIA, *Suppl.*

PSEUDO-*Lotus*, in botany, a name by which ſome call the *Guaiacana* of Tournefort. See the article GUAIACANA, *Suppl.*

PSEUDO-*Viburnum*, in botany, the name given by Rivinus to a ſpecies of *Lantana*. See the article LANTANA, *Suppl.*

PUDDING-*graſs*, a name by which the *pulegium*, or penny-royal, a ſpecies of mint, is called. See the articles MENTHA and MINT, *Suppl.*

PUDDING-*pipe-tree*, the Engliſh name of a genus of plants, called by botanical writers *Caſſia*. See the article CASSIA, *Suppl.*

PUDENDUM-*regale*, a name uſed by Columna for the *Aphrodita*, a genus of ſea-inſects. See the article APHRODITA, *Append.*

PULEX-*Aquaticus*, the *water-flea*, a name ſometimes uſed for the water beetles. See the article DYTISCUS, ſupra.

PULMONES-*marini*, in zoology, a name uſed by ſeveral authors for the *Urticæ marinæ*. See the article URTICA *marina*, *Suppl.*

PUMP (*Cycl.*) — The deſcription of the *Forcing-pump*, given in the Cyclopædia, is erroneous. This kind of *Pump* conſiſts of a barrel, in which there is a forcer, that is, a piſton, or embolus without a valve, which moves up and down in the barrel. This communicates with two pipes, the one called a *ſucking pipe*, which goes down into the well, and the other called a *forcing pipe*, which goes upwards. There are two valves; the one at any place of the ſucking pipe, the other in the forcing pipe, both of which let the water go up, and hinder it from going down. Then when the forcer is moved upwards, as it rarifies the air in the ſucking pipe (for the valve in the forcing pipe hinders the outward air, which preſſes upon it, from going through) the water riſes in it, till after ſeveral ſtrokes it comes to the forcer; then at every time the forcer goes down, the water that is preſſed downwards, being hindered from going through the valves of the ſucking pipe, opens and goes through the valves in the forcing pipe. When the forcer goes up again, then the water in the forcing pipe ſhuts the valves there by its preſſure, and conſequently the water in the well will riſe up in the part of the forcing pipe, between that valve and the ſucking pipe; and the ſame happens at every motion of the forcer.

It is to be obſerved in the *Forcing-pump*, that the nearer the forcer comes to the well, the better it is. See *Deſagulier*'s Courſe of Experim. Philoſ. p. 160, 161.

As to the various kinds of *Forcers*, ſee the article FORCER *Append.*

The *Pump* deſcribed in the Cyclopædia, under the name *Forcing-pump*, is properly a *lifting-pump*; and the common *Pump*, which works by the preſſure of the air, is called a *Sucking-pump*. Dr. Deſaguliers, in his courſe of Experimental Philoſophy, [a] has given a full account of the conſtruction of of all theſe kinds of *Pumps*, and of ſome others more complex; as alſo of their buckets, valves, and other parts belonging to them. [[a] Vol. 2. p. 152, to 166.]

Air-PUMP. See the article AIR-*pump*, *Cycl.*

There are ſeveral inconveniencies attending AIR-*pumps* of the common form, tho' much improved from what they uſed to be formerly. Theſe inconveniencies are enumerated, and a method ſhewn to remedy them, by Mr. *Smeaton*, in the Phil. Tranſ. Vol. 47. p. 415, ſeq.

This ingenious artiſt has ſucceeded ſo well in his conſtruction of the *Air-pump*, as to be able to rarify air a thouſand times; whereas the beſt of the common *Air-pumps*, eſteemed good in their kind, and in complete order, never rarified it above one hundred and forty times.

Mr. Smeaton's *Air-pump* acts alſo as a condenſing engine, by the very ſimple apparatus of turning a cock. So that this *Air-pump* is an univerſal engine, for ſhewing any effect ariſing from an alteration in the denſity or ſpring of the air, and with a little addition may be made to ſhew the experiments of the air-fountain, wind-gun, &c. See the Phil. Tranſ. loc. cit. p. 422, ſeq.

PUMPELMOES, a name ſometimes uſed for a ſpecies of Orange. See the article ORANGE, *Suppl.*

PURGING-*nut*, or *Phyſic-nut*, the name by which ſome call the *Ricinoides*, a diſtinct genus of plants. See the article RICINOIDES, *Suppl.*

PURPLE-*wort*, a name given to ſeveral ſpecies of trefoil, of a purple colour. See the article TREFOIL, *Suppl.*

PURSLAIN (*Suppl.*)—*Sea*-PURSLAIN, a name by which ſome call two very different genuſes of plants, the *Atriplex* and *Chenopodium*. See the articles ATRIPLEX and CHENOPODIUM, *Suppl.*

PUTREFACTION (*Suppl.*) — It is an obſervation of Lord Bacon, that an inquiry into the means of preventing or ſtaying *putrefaction*, is of excellent uſe in phyſic. Dr. Pringle has made a great many curious experiments and remarks on this ſubject, which are publiſhed by way of Appendix to his Obſervations on the Diſeaſes of the Army.

Putrefaction is one of the inſtruments of nature, by which many great changes are brought about. With regard to medicine, we know that neither animal nor vegetable ſubſtances can become aliment, without undergoing ſome degree of *Putrefaction*. Many diſtempers proceed from a deficiency of this action. The criſis of fevers ſeems to depend upon it; and even animal heat, according to Dr. Stevenſon, does the ſame. See the article HEAT, *Suppl.*

Now, that the concoction of the humours is nothing elſe but *Putrefaction*, ſeems probable from hence, that whenever they are in that ſtate, they are always more fluid, and fitter to paſs through the ſmaller veſſels, where they ſtagnated before. Again, the offenſiveneſs of the ſweats, or other excretions conſequent on a criſis, is likewiſe a ſure ſign of a high degree of corruption. The time of reſolution or *Putrefaction* depends on the degree of heat, the habit of the patient, and on the part obſtructed. Reſolution is the *Putrefaction* of the impacted humour only, but ſuppuration implies a corruption of the veſſels alſo. This manner of ſpeaking, indeed, has been diſuſed, from the prejudice that nothing was putrid but what was offenſively ſo; whereas, in fact, every fibre becoming more tender, and humour thinner, may be conſidered as putrid in ſome degree, whether the change tends to the better health, or to the deſtruction of the perſon, or whether it becomes grateful or offenſive to the ſenſes. *Pringle*, Obſerv. on Diſeaſ. of the Army. p. 337.

Mr. Boyle has uſed the words *fermentation* and *Putrefaction* of the blood promiſcuouſly, in his treatiſe on the human blood. Stahl and other celebrated chemiſts likewiſe uſe the terms *putrid ferment*. See the article FERMENT, *Suppl.* *Putrefaction* is always found to generate air. Hence, though fleſh, as well as blood, be ſpecifically heavier than water, yet dead bodies are found to float, after lying ſome time at the bottom, from air generated in the bowels by *Putrefaction*. Now, as it has been found by experiments, that the blood and other animal ſubſtances begin to emit air, before they are ſo far corrupted, as the ſame frequently are in putrid diſeaſes, it is probable that ſeveral of the ſymptoms in deep ſurfeits may be owing to the action of the confined air.

As all the humours of animal bodies become thinner by *Putrefaction*, ſo the ſolid or fibrous parts are thereby relaxed or rendered more tender. And hence the extraordinary bulk of the heart, liver, and ſpleen, incident to perſons labouring under putrid diſeaſes, may be accounted for. It is remarkable, that in diſſections of people who die of the plague, the heart is almoſt always found of an uncommon bigneſs; and as to the ſcurvy, the liver and ſpleen are ſometimes inlarged to ſuch a degree, that the tumour may be ſeen outwardly. Id. ibid. p. 391, ſeq.

It being a received opinion, that bodies become highly alkaline by *Putrefaction*, the Doctor made the following experiments, in order to diſcover how far this might be true.

The ſerum of human blood *putrified*, made, with a ſolution of ſublimate, firſt a turbid mixture, and afterwards a precipitation; which is indeed one of the teſts of an alkali, but not to be admitted here, ſince the ſame thing was done with the recent urine of a perſon in perfect health, which is never accounted alkaline. The ſame ſerum did not tinge the ſyrup of violets green, and made no efferveſcence when the ſpirit of vitriol was poured upon it. The experiment was twice made upon portions of different ſerums, both highly putrid; and once on water, in which corrupted fleſh had been ſometime infuſed; and the moſt that could be found was, that a reddiſh caſt having been previouſly given to the ſyrup with an acid, this colour was rendered fainter, but not deſtroyed by the *putrid* humours. And as to efferveſcence, the ſpirit of vitriol being dropped into thoſe liquors unmixed, and alſo diluted with water, the mixture was quiet, and only a few air-bubbles appeared on ſhaking the glaſſes.

Upon the whole, though there were ſome marks of a latent alkali in the putrid ſerum, they were ſo very faint, that a quantity of water equal to that of the putrid liquors, mixed with only one drop of ſpirit of hartſhorn, being put to the ſame trial, ſhewed more of an alkaline nature, than any of the other.

It has alſo been a maxim, that all animal ſubſtances, after *Putrefaction*, being diſtilled, ſend forth a great quantity of volatile ſalt in the firſt water; but Mr. Boyle found, that this held good only in urine; and that in the diſtillation of the ſerum of human blood *putrefied*, the liquor which came over firſt had little ſtrength, either as to its ſmell or taſte, and did not at firſt efferveſce with an acid. And here it may be obſerved, that the chemiſts have generally applied thoſe properties which they diſcovered in urine, to all the humours indifferently; whereas, in fact, there is a great diverſity: for ſome animal ſubſtances, ſuch as urine, the bile, and the craſſamentum of the blood, ſoon putrefy; the ſerum, the ſaliva, and the white of an egg, ſlowly. Yet thoſe that ſooneſt corrupt, do not always arrive at the higheſt degree of *Putrefaction*: thus, the bile is ſooneſt corrupted, but the rankneſs of it is not to be compared to that of fleſh; and the white of an egg is not only much leſs diſpoſed to putrify than the yolk, but when corrupted, yields a different and leſs offenſive ſmell.

Doctor Pringle farther obſerves, that it ſeems peculiar to ſtale urine to contain an alkaline ſalt, which, without diſtillation,

makes a ſtrong efferveſcence with acids. Whereas moſt other animal humours putrefied, though of a more intolerable feltor, yet contain leſs volatile ſalt, leſs extricable, and then not efferveſcing with acids. But, what makes the difference between ſtale urine, and other putrid ſubſtances ſtill more ſpecific, is its inoffenſiveneſs with regard to health; whilſt the ſteams of moſt other corrupted bodies are often the cauſe of putrid and malignant diſeaſes. So far then from dreading the volatile alkali as the deleterious part of corrupted bodies, it ſhould rather ſeem to be a corrector of *Putrefaction*. *Pringle* obſerv. on the diſ. of the army.

But ſtill there remains a prejudice, as if theſe ſalts being the produce of corruption, ſhould therefore haſten *Putrefaction*; and that not only in diſtempers where they are unwarily taken, but alſo in experiments out of the body. As to the effects ariſing from the internal uſe of them, little can be ſaid, unleſs the kind of diſeaſe were preciſely ſtated: for ſuppoſing theſe ſalts were by their nature diſpoſed to promote *Putrefaction*; yet if that is already begun, from a languor of circulation, and obſtruction, then may the volatiles, by their ſtimulating and apperient qualities, be the means of ſtopping its progreſs; and, on the other hand, though they were really antiſeptic, yet, if the humours are diſpoſed to corrupt, from exceſs of heat or motion, theſe very ſalts by adding to the cauſe, may augment the diſeaſe. So that upon the whole, it ſeems to be the faireſt criterion of the true nature of theſe volatiles, to enquire whether they accelerate or retard *Putrefaction* out of the body.

In order to decide this queſtion, repeated experiments were made, by joining both the ſpirit and the ſalt of hartſhorn to various animal ſubſtances; and it was conſtantly found, that ſo far from promoting *Putrefaction*, they evidently hindered it, even more powerfully than common ſea-ſalt. Hence, the Doctor thinks it probable, that the ſame taken by way of medicine, will likewiſe prove antiſeptic; or at leaſt, that we cannot juſtly ſuppoſe them corrupters of the humours, more than fermented ſpirits or ſea-ſalt.

With regard to the *Putrefaction* of dead bodies, it is found that ſome parts corrupt much ſooner than others. Thus, as the abdominal viſcera and muſcles corrupt the ſooneſt, it is a rule with anatomiſts, to begin their diſſections and demonſtrations with thoſe parts, the quick *Putrefaction* of which may be aſcribed to the putrid ſteams of the fæces. Next to the abdominal viſcera and adjacent parts, the lungs are commonly ſooneſt tainted; either from the air ſtagnating in the veſiculæ bronchiales, or from ſome remains of perſpirable matter, that by acting as a ferment, may haſten the *Putrefaction*. Id. ibid. p. 392.

It is obſervable, that the *Putrefaction* of meat, and other ſubſtances, advances quicker in a confined than free air; for, as the moſt putrid parts are alſo the moſt fugitive, they inceſſantly iſſue from a corruptible ſubſtance, and diſperſe with the wind; but, in a ſtagnation of air, they remain about the body; and, in the nature of a ferment, excite its corruption.

Putrefaction is one cauſe of bilious and intermitting fevers, the dyſentery, malignant or peſtilential fevers, the ſcurvy, lepra Arabum, &c. See the articles BILIOUS, DYSENTERY, MALIGNANT, &c. *Append.*

Thoſe ſubſtances which reſiſt *Putrefaction*, are called *Antiſeptics*, and the promoters of it *Septics*. See the articles ANTISEPTICS and SEPTICS, *Append.*

Putrefaction of the blood. See the article BLOOD, *Append.*

PUTRID *ferment.* See the article FERMENT, *Suppl.*

PUTRID *fever.* See the articles BILIOUS and MALIGNANT.

PUTREFIERS, among phyſicians, the ſame with *Septics*. See the article SEPTICS, *Append.*

PYE, or MAGPYE, in ornithology. See the article PICA, *Suppl.*

Sea-PYE, in ichthyology, the Engliſh name of the *Pica marina*. See the article PICA *marina*.

PYROMETER, the name of a machine contrived to meaſure the alteration of the dimenſions of metals, ariſing from heat.

Muſchenbroek, who was the original inventor of this machine, has given a table of the expanſion of the different metals, in the ſame degree of heat. See the article HEAT, *Append.*

As to the conſtruction of the *Pyrometer*, the curious may conſult Deſagul. Experim. Philoſoph. p. 421, ſeq.

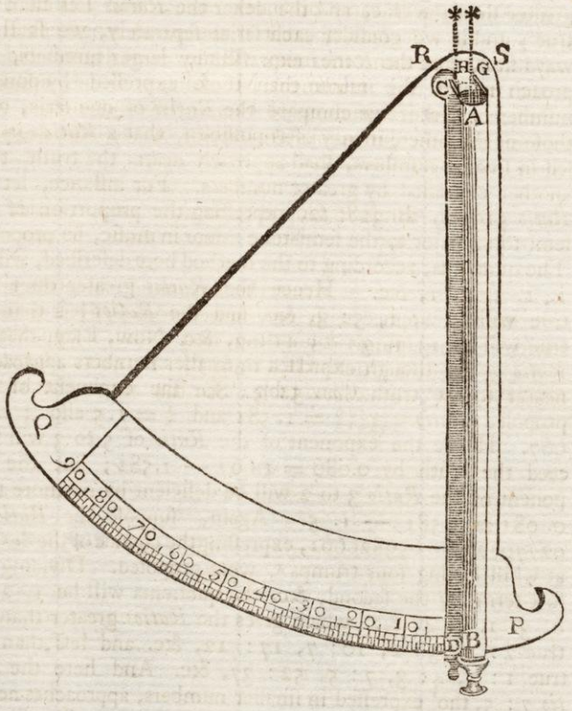
But it has been obſerved, that Mr. Muſchenbroek's *Pyrometer* was liable to ſome objections, and theſe have been removed, in a good meaſure, by Mr. Ellicott, who has given a deſcription of his improved *Pyrometer* in the Philoſophical Tranſactions, N° 443. This may alſo be ſeen in Dr. Martyn's Abridgment, vol. 8. p. 464.

In this *Pyrometer* the lengthening of a bar of metal by heat $\frac{1}{25}$ of an inch, will carry an index once round a circle divided into 360 degrees, ſo that if the metal lengthens the 7200th part of an inch, the index will move one degree. ibid.

By the help of this inſtrument Mr. Ellicott found, upon a medium, that the expanſions of bars of different metals, as nearly of the ſame dimenſions as poſſible, by the ſame degree of heat, were as follows:

Gold,	Silver,	Braſs,	Copper,	Iron,	Steel,	Lead,
73	103	95	89	60	56	149

The great difference between the expanſions of iron and braſs, has been applied with good ſucceſs to remedy the irregularities in pendulums ariſing from heat. Phil. Tranſ. Vol. 47. p. 485. See the articles HEAT and PENDULUM, *Append.*



PYTHAGORIC, or *Abacus* table. See the article TABLE, *Cycl.*

Q.

QUADRANT *(Cycl.)* — *Davis*'s QUDDRANT. When the horizon is obſcured by hazy weather, *Davis*'s *Quadrant* is of no uſe; and this often occaſions melancholy conſequences. Means have therefore been ſought after to remedy this defect. Mr. Leigh propoſes a water-level to be fixed to the *Quadrant*; and he likewiſe has given the deſcription and uſe of an apparatus to be added to this inſtrument, conſiſting of a mercurial level, which he prefers, no doubt juſtly, to a water-level. See Phil. Tranſ. N° 431. Sect. 1 and 2.

Hadley's QUADRANT, the common name for the juſtly eſteemed *Quadrant*, invented by the late John Hadley, Eſq; This *Quadrant*, which at firſt had the fate of all other ingenious inventions, to be neglected by ignorant and obſtinate men, even though highly uſeful to them in their profeſſion, ſeems at laſt to have made its way, in ſpite of habit and prejudice.

We cannot here inſert a full deſcription and draught of this inſtrument; but we muſt obſerve, that though the late Mr. Hadley was undoubtedly the inventor of it, yet the principle upon which his invention turns, had not eſcaped the ſagacity of Sir Iſaac Newton, long before, as appears from a paper in his hand-writing found among the papers of the late Dr. Halley. But this was totally unknown to Mr. Hadley, and ſeemed to have been forgot by Dr. Halley himſelf. The account of Sir Iſaac's invention is inſerted in the Philoſophical Tranſactions, N° 465, and in Dr. Martyn's Abridgment, vol. 8. p. 129. and is as follows:

P Q R S denotes a plate of braſs accurately divided in the limb D Q, into $\frac{1}{2}$ degrees, $\frac{1}{2}$ minutes, and $\frac{1}{12}$ minutes, by a diagonal ſcale; and the $\frac{1}{2}$ degrees, $\frac{1}{2}$ minutes, and $\frac{1}{12}$ minutes, counted for degrees, minutes, and $\frac{1}{6}$ minutes. A B is a teleſcope, three or four feet long, fixed on the edge of the braſs plate. G is a ſpeculum, fixed on the ſaid braſs plate perpendicularly, as near as may be to the object glaſs of the teleſcope, ſo as to be inclined 45 degrees to the axis of the teleſcope, and intercept half the light which would otherwiſe come through the teleſcope to the eye. C D is a moveable index, turning about the center C, and, with its fiducial edge, ſhewing the degrees, minutes, and $\frac{1}{6}$ minutes, on the limb of the braſs plate P Q; the center C, muſt be over-againſt the middle of the ſpeculum G. H is another ſpeculum, parallel to the former, when the fiducial edge of the index falls on $00^d\ 00'\ 00''$; ſo that the ſame ſtar may then appear through the teleſcope, in one and the ſame place, both by the direct rays and by the reflected ones; but if the index be turned, the ſtar will appear in two places, whoſe diſtance is ſhewed, on the braſs limb, by the index.

By this inſtrument the diſtance of the moon from any fixed ſtar is thus obſerved: view the ſtar through the perſpicil by the direct light, and the moon by the reflected (or, on the contrary) and turn the index till the ſtar touch the limb of the moon, and the index ſhall ſhew upon the braſs limb of the inſtrument, the diſtance of the ſtar from the limb of the moon; and though the inſtrument ſhake, by the motion of your ſhip at ſea, yet the moon and ſtar will move together, as if they did really touch one another in the heavens; ſo that an obſervation may be made as exactly at ſea as at land. And, by the ſame inſtrument may be obſerved, exactly, the altitudes of the moon and ſtars, by bringing them to the horizon; and thereby the latitude, and times of obſervations, may be determined more exactly than by ways formerly practiſed. In the time of obſervation, if the inſtrument move angularly about the axis of the teleſcope, the ſtar will move in a tangent of the moon's limb, or of the horizon; but the obſervation may notwithſtanding be made exactly, by noting when the line, deſcribed by the ſtar, is a tangent to the moon's limb, or to the horizon. To make this inſtrument uſeful, the teleſcope ought to take in a large angle: And to make the obſervation true, let the ſtar touch the moon's limb, not on the outſide of the limb, but on the inſide. Vid. Philoſoph. Tranſact. N° 465. p. 155, 156.

For the common uſes at ſea a teleſcope is not neceſſary; Mr. Hadley's Quadrants are therefore generally made without one, which renders the uſe of them much more ready. He has alſo added ſome contrivances to facilitate their uſe; which are deſcribed in the printed papers uſually ſold with the inſtrument: Other *Quadrants* have been contrived ſince, by ſome ingenious artiſts, all of which have their merit, but the particulars of their conſtructions are too many for this place; and perhaps on the whole nothing preferable to Mr. Hadley's invention has yet been found.

Mural QUADRANT. Mr. Gerſten has lately given us a deſcription of a new aſtronomical *mural Quadrant*, which he ſays is free from many of the uſual inconveniencies attending the uſe of ſuch inſtruments. See Phil. Tranſ. N° 483. Sect. 18.

QUADRIGA, in ſurgery, otherwiſe called CATAPHRACTA, is a ſtrong bandage made uſe of in fractures of the *Sternum*. It is compoſed of a double headed roller about ſix Paris ells long, and three or four fingers broad. See *Heiſter*'s Surgery, P. III. Ch. 4. §. 14.

QUADRILLE, a well known game at cards; and which has been, in ſeveral caſes, the object of mathematical computations. See Mr. *De Moivre*'s Doctrine of Chances, 2d edit. p. 83 to 90.

QUAKING-*graſs*, in botany. See the article GRASS, *Append.*

QUANTITY *(Cycl.)* — The note in the Cyclopædia, from Mr. Machin's paper in the Phil. Tranſ. N° 447. ſhould have been extended, as it ſerves to render the notions of mathematical *Quantity* more diſtinct and adequate than any thing that is commonly to be met with in authors on this ſubject. Not to give the reader the trouble of turning to the Cyclopædia for the ſake of a few lines, we ſhall inſert the whole. Mr. Machin, in the poſtſcript to the ſolution of Kepler's problem, inſerted in the before cited number of the Phil. Tranſ. ſays,

That he takes a mathematical *Quantity*, and that for which any ſymbol is put, to be nothing elſe but number with regard to ſome meaſure which is conſidered as one. For we cannot know preciſely and determinately, that is, mathematically, how much any thing is but by means of number. The notion of continued *Quantity*, without regard to any meaſure, is indiſtinct and confuſed; and although ſome ſpecies of ſuch *Quantity*, conſidered phyſically, may be deſcribed by motion, as lines by points, and ſurfaces by lines, and ſo on; yet the magnitudes or mathematical *Quantities* are not made by that motion, but by numbering according to a meaſure.

Accordingly, all the ſeveral notations that are found neceſſary to expreſs the formations of *Quantities*, do refer to ſome office or property of number or meaſure; but none can be interpreted to ſignify continued *Quantity* as ſuch.

Thus ſome notations are found requiſite to expreſs number in its ordinal capacity, or the *numerus numerans*, as when one follows or precedes another, in the firſt, ſecond, or third place from that upon which it depends; as the *Quantities* $x^{\prime}$, $x^{\prime\prime}$, x, x', x'', referring to the principal one x.

So, in many caſes, a notation is found neceſſary to be given to a meaſure as a meaſure; as for inſtance, Sir Iſaac Newton's ſymbol for a fluxion $\dot{x}$; for this ſtands for a meaſure of ſome kind, and accordingly he uſually puts an unit for it, if it be the principal one upon which the reſt depend.

So ſome notations are expreſly to ſhew a number in the form of its compoſition, as the index to the geometrical power x^n, denoting the number of equal factors which go to the compoſition of it, or what is analogous to ſuch.

But that there is no ſymbol or notation but what refers to diſcreet *Quantity*, is manifeſt from the operations, which are all arithmetical.

And hence it is, there are ſo many ſpecies of mathematical *Quantity* as there are forms of compoſite numbers, or ways in the compoſition of them; among which there are two more eminent for their ſimplicity and univerſality than the reſt; one is the *geometrical power*, formed from a conſtant root; and the other, though well known, yet wanting a name, as well

well as a notation, may be called the *arithmetical power*; or the power of a root uniformly increaſing or diminiſhing. This is the Power whoſe notation is deſigned in the article *Arithmetical* POWER, *Append.*

QUARTER *(Cycl.* and *Suppl.)* — QUARTER-*round*, in architecture, denotes any moulding whoſe contour is either a perfect quadrant, or *Quarter* of a circle, or that approaches near to that figure. Build. Dict. in voc.

QUARTERS, — *Winter*-QUARTERS, in military affairs. *Winter-Quarters*, when cold and moiſt, are productive of inflammatory diſorders, particularly hard coughs, with inflammations of the pleura and lungs. See the article BARRACKS, *Append.*

In very hot countries it has ſometimes been cuſtomary, to put armies into *Summers quarters.*

QUEEN'S *Gilliflower*, the name by which ſome call the *Heſperis* of botanical writers. See the article HESPERIS, *Suppl.*

QUICK, the name by which ſome call a ſpecies of *Meſpilus*, or medlar. See the article MESPILUS, *Suppl.*

QUICK-*beam*, a name ſometimes given to the *Sorbus*, or ſervice-tree. See the article SORBUS, *Suppl.*

QUICK-*graſs*, the Engliſh name of a genus of plants, called by Linnæus *Agroſtis*. See the article AGROSTIS, *Suppl.*

QUICKEN-*tree*, a name alſo given to the *Sorbus*.

QUICKSILVER-*water*. See the article WATER, *Append.*

R.

RAR

RADICULA, in botany, the name by which Dillenius calls the *Siſymbrium* of other botaniſts. See the article SISYMBRIUM, *Suppl.*

RADISH *(Suppl.) Horſe*-RADISH, a popular name for a ſpecies of *Cochlearia*, or ſcurvy graſs. See the article COCHLEARIA, *Suppl.*

Water-RADISH, the name by which ſeveral ſpecies of *Siſymbrium* are ſometimes called. See the article SISYMBRIUM, *Suppl.*

RADIUS *of Concavity*, in geometry, is ſometimes uſed [a] for the *Radius* or ray of curvature, or the *Radius* of the oſculatory circle. See the article CURVATURE, *Append.* [[a] De Moivre, Miſcel. Analyt. p. 231.]

RADIUS *of Curvature*, in geometry. See the article CURVATURE.

RADIUS *Oſculi* is alſo uſed in the ſame ſenſe.

RADIUS *Vector*, in mechanics, is uſed for a right line drawn from the center of force in any curve in which a body is ſuppoſed to move by a centripetal force, to that point of the curve where the body is ſuppoſed to be. See the article *Central* FORCE, *Append.*

RAGGED *Robin*, a name uſed ſometimes for the *Lychnis*. See the article LYCHNIS, *Suppl.*

RAIN *(Suppl.)* — Beſides the cauſes of rain mentioned in the Cyclopædia, Deſaguliers thinks it owing to the loſs of electricity in the vapours whereof the clouds are formed. See the articles VAPOUR and ELECTRICITY, *Append.*

RAISING *Pieces*, in carpentry, the pieces which lie on the tops of the poſts and punchions, and under the beams; thoſe lying on the brick work being called platbands. Build. Dict. in voc.

RAMMER *for piles*. See the article PILE, *Append.*

RAMPHASTOS, in ornithology, the name by which Dr. Hill calls the *Toucan* of other writers. See the article TOUCAN, *Suppl.*

The *Ramphaſtos* is a diſtinct genus of birds, of the *Pica*, or magpie kind. Its beak is remarkably large, equal, in moſt ſpecies to the whole body in magnitude. There are no viſible noſtrils. The feet have each four toes, two of which ſtand forward, and the other two backward, as in the parrot. *Hill*, Hiſt Anim. p. 381. The ſpecies are theſe: 1. The *Ramphaſtos* with a red rump 2. The *Ramphaſtos* with a yellow rump. 3. The *Ramphaſtos* with a white rump. 4. The green *Ramphaſtos*, with a party-coloured beak.

Theſe birds have been called by Linnæus, and other writers, *Roſtratæ*, from the largeneſs of their beaks.

RAMPION is alſo a name given to the blue-flowered *Campanula*, or bell-flower, with an eſculent root. See the article CAMPANULA, *Suppl.*

RAMSONS, a name given to the broad-leaved wild *Allium*, or Garlick. See the article GARLICK, *Suppl.*

RANGLE, in falconry, is when gravel is given a hawk to bring her to her ſtomach. Dict. Ruſt. in voc.

RANUNCULUS *(Suppl.)* — *Globe*-RANUNCULUS, a name ſometimes given to a ſpecies of *Hellebore*. See the article HELLEBORUS, *Suppl.*

RAPE, a name ſometimes uſed for the *Napus*, or navew. See the article NAPUS, *Suppl.*

Wild-RAPE, the Engliſh name of a genus of plants, called by botaniſts *Rapiſtrum*. See the articles RAPISTRUM, *Suppl.*

RAPHIDIA, in the hiſtory of inſects, the name by which Dr. Hill calls a genus of four-winged flies, of the neuroptera-kind. See the article NEUROPTERA, *Append.*

The head of the *Raphidia* is of a horny ſubſtance, and is depreſſed. The tail is armed with a weapon of a ſlender form, ſharp, horny, and ſimple, not biſid at the extremity. *Hill*, Hiſt. Anim. p. 70.

RARATAS, in botany, the name by which Plumier calls

REE

the *Ananas*, or pine-apple of Tournefort. See the article ANANAS, *Suppl.*

RAT *(Suppl.)* — *Mountain*-RAT, the Engliſh name of a creature, otherwiſe called the *Marmotte*. See the article MARMOTTE, *Suppl.*

RATIO *(Suppl.)* — It is to be obſerved, that in this article of the Supplement the method deſcribed of inſerting ſecondary *Ratios*, gives two ſeries, the one containing the *Ratios* greater than the true, and the other the *Ratios* leſs than the true; and if we conſider each ſeries ſeparately, we ſhall always find, that the *Ratios* expreſſed by larger numbers, approach nearer the truth than thoſe expreſſed by ſmaller numbers. But if we compare the *Ratios* of one ſeries with thoſe of the other, it may often happen, that a *Ratio* expreſſed in ſmaller numbers, ſhall approach nearer the truth, than another expreſſed by greater numbers. For inſtance, let the *Ratio* 519529 to 328612, expreſſing the proportion of the ſemi-tone major to the ſemi-tone minor in muſic, be propoſed. The quotients, according to the method here deſcribed, will be 1. 1. 1. 2. 1, &c. Hence the *Ratios* greater than the true will be 2 : 1, 5 : 3, &c. and the *Ratios* leſs than the true will be 1 : 1, 3 : 2; 11 : 7, &c. Now, I ſay, that the *Ratio* 3 : 2, though expreſſed in ſmaller numbers approaches nearer to the truth than 5 : 3; for the exponent of the propoſed *Ratio* $\frac{5}{3}\frac{1}{2}\frac{9}{8}\frac{5}{6}\frac{2}{1}\frac{9}{2} = 1.581$ and $\frac{3}{2} = 1.5$ alſo $\frac{5}{3} = 1.667$. Hence the exponent of the *Ratio* of 5 to 3 will exceed the truth by $0.086 = 1.667 - 1.581$; but the exponent of the *Ratio* 3 to 2 will be deficient by no more than $0.081 = 1.581 - 1.5$. Again, ſuppoſe the *Ratio* of 927707238 to 659826661, expreſſing the chance of the dealer's at whiſt having four trumps [a], were propoſed. Dividing the firſt term by the ſecond, &c. the quotients will be 1. 2. 2. 6. 3. 1. 1. 4, &c. which gives the *Ratios* greater than the true 2 : 1, 3 : 2, 10 : 7, 17 : 12, &c. and leſs than the true 1 : 1, 4 : 3, 7 : 5, 52 : 37, &c. And here the *Ratio* 7 : 5, tho' expreſſed in ſmaller numbers, approaches nearer to the truth, than either 10 : 7, or 17 : 12, as will eaſily appear by reducing their exponents to decimals, But no inconveniencies of this kind can happen, if we content ourſelves with the principal and primary *Ratios*, they being alternately greater and leſs, and continually approaching nearer to the truth. — [[a] See the article WHIST, *Append.*]

RATTLE-*graſs*, a name ſometimes uſed for a ſpecies of *Pedicularis*, or Louſe-wort. See the article PEDICULARIS, *Suppl.*

RATTLE-*net*. See the article WOLF-*net*, *Suppl.*

RATTLE-*ſnake-root*, in botany, a name ſometimes uſed for the *Polygala*, or Milk-wort. See the article POLYGALA, *Suppl.*

RAVEN *(Suppl.)* — *Indian*-RAVEN, the Engliſh name of the *Buceros*. See the articles BUCEROS, *Append.* and CORVUS-*Indicus*, *Suppl.*

RAY, in geometry, is often uſed for *Radius*.

RAY *of Curvature*. See the article CURVATURE.

RAZOR-*fiſh*, is a name frequently given to a ſpecies of *Coryphæna*, otherwiſe called *Novacula piſcis*. See the articles CORYPHÆNA and NOVACULA, *Suppl.*

REBUS *(Suppl.)* — REBUS, in heraldry, a coat of arms which bears an alluſion to the name of the perſon; as three caſtles, for Caſtleton; three cups, for Butler, three conies, for Coniſby; a kind of bearings which are of great antiquity.

RED-*breaſt*, in ornithology, the Engliſh name of a ſpecies of *Motacilla*, called alſo *Rubecula* and *Erithacus*. See the articles MOTACILLA and RUBECULA, *Suppl.*

REED *(Suppl.)* — *Indian flowering* REED, the name by which the *Canna* of botaniſts is ſometimes called. See the article CANNA, *Suppl.*

REEMING-*irons*, a kind of chiſſels, broader than ordinary, uſed for opening the ſeams of ſhips, before they are caulked. *Blankley*'s Nav. Expoſ. p. 130.

REFRACTION *(Cycl.)* — The *Refraction* of the air has many times ſo uncertain an influence on the places of celeſtial objects, very remote from the zenith, that wherever *Refraction* is concerned, the concluſions deduced from obſervations that are much affected by it, will always remain doubtful, and too precarious in many caſes to be relied upon. See Dr. *Bradley*, in Phil. Tranſ. N° 485.

REGIMENTAL *Hoſpital*. See the article HOSPITAL, *Append.*

REIN-*deer*, the Engliſh name of the *Rangifer*, a creature of the deer-kind. See the articles DEER and RANGIFER, *Suppl.*

RELL-*mouſe*, the Engliſh name of the white bellied mouſe, with a blackiſh back, and long body. See the article GLIS, *Suppl.*

REPRESENTATIVE *(Cycl.)*--REPRESENTATIVE *Power*, in metaphyſics, a term introduced by Leibnitz, to ſignify that power of the human ſoul, by which it repreſents to itſelf the univerſe, according to the ſituation of the body in the univerſe. See the article IDEA, *Suppl.*

Wolfius calls this power *vis repreſentativa*, to denote its being an active power, or rather a force actually exerting itſelf. For he expreſly ſays, *quod vis conſiſtat in continuo agendi conatu.* And he thinks that from this principle of a *vis repreſentativa*, every phænomenon of the human mind may be accounted for. See his Phſycholog. Ration. Art. 529.

But it may be preſumed, that many will find this principle too obſcure to be admitted.

When it is ſaid, that our ideas are *repreſentative* of things without us, or of the univerſe; it may be aſked in what ſenſe this is to be underſtood? Do they *repreſent* it 1° as a picture does its original? or 2° as an effect of a cauſe? or 3° as a ſign repreſents the thing ſignified? The firſt opinion is exploded in part by Locke and the Carteſians, and totally by Dr. Berkely, late Biſhop of Cloyne. The ſecond is admitted by Hobbes, but denied by Leibnitz himſelf, and the idealiſts. The third ſhould ſeem to be the opinion of Leibnitz, but he is not ſufficiently explicit.

Dr. Berkeley admits ideas to be ſigns; but according to him they are arbitrary ſigns, depending on the immediate will of the deity: hence the viſual language; and ideas, only ſignify or ſuggeſt each other, and ſpirits; but not bodies, the exiſtence of which is totally unknown.

REMITTENTS, or REMITTING *fevers*, the ſame with the bilious ones. See the article BILIOUS, *Append.*

REMOTION, *Remotio*, in rhetoric. See the article METASTASIS, *Suppl.*

REPETEND, in arithmetic, is uſed for that part of an interminate decimal fraction, which is continually repeated ad infinitum.

Thus in the interminate decimal fraction 317. 45 316 316 316, &c. the figures 316 are called the *Repetend*. *Cunn*, Treat. of Fractions.

Theſe *Repetends* often ariſe in the reduction of vulgar fractions to decimals, thus $\frac{1}{3} = 0.3333$, &c. $\frac{1}{7} = 0.142857\ 142857$, &c. $\frac{1}{11} = 0.090909$, &c.

Single REPETEND, is that where one figure only is repeated, as in 0. 3 3 3, &c.

Compound REPETEND, is that where two or more figures are repeated, as in 0. 09 09, &c. or in 0. 142857 142857, &c.

Decimals with *Repetends* may always be reduced to vulgar fractions. For either the *Repetend* begins with the decimal, or not:

If the *Repetend* begins with the firſt place of decimals, make it the numerator of a vulgar fraction, and make the denominator conſiſt of as many 9's as the *Repetend* has figures, then will this vulgar fraction be equal to the decimal.

Thus, if the *Repetend* be ſingle, as in 0. 3 3 3 3, the vulgar fraction equal to it will be $= \frac{3}{9} = \frac{1}{3}$. So if the *Repetend* be compound, as in 0. 09 09, &c. the equivalent vulgar fraction will $= \frac{09}{99} = \frac{9}{99} = \frac{1}{11}$.

And in like manner 0. 142857 142857, &c. $= \frac{142857}{999999} = \frac{1}{7}$.

The reaſon is obvious from this conſideration, that the decimal 0. 3 3 3, &c. is $= \frac{3}{10} + \frac{3}{100} + \frac{3}{1000}$, &c. the ſum of which by the rule mentioned under FRACTION, *Suppl.* will be equal to $\frac{3}{10}$ divided by $1 - \frac{1}{10} = \frac{9}{10} = \frac{1}{3}$, and ſo of the reſt.

If the *Repetend* does not begin with the firſt place of decimals, but at ſome place farther on towards the right, as in the decimal 0. 8 3 3 3 3, &c. where the *Repetend* does not begin till the ſecond place of decimals, *obſerve*, that 0. 8333 + &c. $= \frac{8}{10} + \frac{3}{100} + \frac{3}{1000} +$ &c. $= \frac{8}{10} + \frac{1}{10} \times \frac{3}{10} +$ $\frac{1}{10^2} +$ &c. But $\frac{1}{10} + \frac{1}{10^2} +$ &c $= \frac{3}{9} = \frac{1}{3}$, as before. therefore the propoſed decimal is $= \frac{8}{10} + \frac{1}{10} \times \frac{1}{3} = \frac{8}{10} + \frac{1}{30} = \frac{24}{30} + \frac{1}{30} = \frac{25}{30} = \frac{5}{6}$.

Thus alſo if the decimal 0. 2 27 27, &c. were propoſed, we ſhall find it $= \frac{2}{10} + \frac{1}{10} \times \frac{27}{100} + \frac{27}{100^2} +$ &c. And $\frac{27}{100} + \frac{27}{100^2} +$ &c. being $= \frac{27}{99} = \frac{3}{11}$, the decimal will be $= \frac{2}{10} + \frac{1}{10} \times \frac{3}{11} = \frac{2}{10} + \frac{3}{110} = \frac{22+3}{110} = \frac{25}{110}$. The reaſon of which is obvious from what has been ſaid.

It may perhaps be worth while to obſerve, that if the numerator of a vulgar fraction be unity, and the denominator any prime number, except 2 and 5, the decimal equal to the propoſed fraction will always be a *Repetend*, beginning at the firſt place of decimals; and this *Repetend* muſt neceſſarily be a ſubmultiple, or an aliquot part of a number expreſſed by as many 9's as the *Repetend* has figures; that is, if the *Repetend* have 6 figures, it will be a ſubmultiple of 999999; if four figures, it will be a ſubmultiple of 9999, &c. From whence it follows, that if any prime number be called p, the ſeries 9999, &c. produced as far as is neceſſary will always be diviſible by p, and the quotient will be the *Repetend* of the decimal fraction $= \frac{1}{p}$.

REPRODUCTION *(Cycl.)* — It is very well known, that trees and plants are to be raiſed from ſlips and cuttings, and ſome late obſervations have ſhewn, that there are ſome animals which have the ſame property.

The Polype was the firſt inſtance we had of this; but we had ſcarce time to wonder at the diſcovery Mr. Trembley had made, when Mr. Bonett diſcovered the ſame property in a ſpecies of water-worm. See the articles POLYPE and WATER-WORM, *Suppl.*

Amongſt the plants which may be rais'd from cuttings, there are ſome which ſeem to poſſeſs this quality in ſo eminent a degree, that the ſmalleſt portion of them will become a complete tree again. See the article PLANT, *Append.*

It deſerves enquiry, whether or not the great author of nature, when he ordained that certain inſects as theſe polypes and worms ſhould reſemble thoſe plants in that particular, allowed them this power of being *reproduced* in the ſame degree; or, which is the ſame thing, whether this *Reproduction* will or will not take place in whatever part the worm is cut: In order to try this, Mr. Bonett entered on a courſe of many experiments on the water-worms which have this property. Theſe are, at their common growth, from two to three inches long, and of a browniſh colour, with a caſt of reddiſh. From one of theſe worms he cut off the head and tail, taking from each extremity only a ſmall piece of a twelfth of an inch in length, but neither of theſe pieces were able to *reproduce* what was wanting. They both periſhed in about twenty-four hours; the tail firſt, and afterwards the head. As to the body of the worm from which theſe pieces were ſeparated, it lived as well as before, and ſeemed indeed to ſuffer nothing by the loſs, the head-part being immediately used as if the head was thereon, boring the creature's way into the mud. There are, beſides this, two other points in which the *Reproduction* will not take place, the one of theſe is about the fifth or ſixth rim from the head, and the other the ſame diſtance from the tail; and in all probability the condition of the great artery in theſe parts is the cauſe of this.

What is ſaid of the want of the *reproductive* power of theſe parts, relates only to the head and tail ends; for as to the body, it feels very little inconvenience from the loſs of what is taken off, and very ſpeedily *reproduces* thoſe parts. Where then does the principle of life reſide in ſuch worms, which after having their heads cut off, will have, not only the ſame motions, but even the inclinations, that they had before; and yet this difficulty is very ſmall, compared to ſeveral others, which at the ſame time offer themſelves to our reaſon? Is this wonderful *Reproduction* of parts only a natural conſequence of the laws of motion, or are there lodged in the body of the creature a chain of minute buds or ſhoots, a ſort of little embryos already formed and placed in ſuch parts where the *Reproductions* are to begin? Are theſe worms only mere machines, or, are they like more perfect animals, a ſort of compound, the ſprings of whoſe motions are actuated or regulated by a ſort of ſoul? And if they have themſelves ſuch a principle, how is it that this principle is multiplied and is found in every ſeparate piece? Is it to be granted, that there are in theſe worms not a ſingle ſoul (if it is to be ſo called) in each, but that each contains as many ſouls as there are pieces capable of *reproducing* perfect animals? Are we to believe with Malpighi, that theſe ſorts of worms are all heart and brain from one end to the other? This may be, but yet if we knew that it was ſo, we ſhould know in reality but very little the more for knowing it; and it ſeems after all, that in caſes of this kind we are only to admire the works of the great Creator, and ſit down in ſilence.

The nice ſenſe of feeling in ſpiders has been much talked of by naturaliſts; but it appears that theſe worms have yet ſomewhat more ſurprizing in them in regard to this particular. If a piece of ſtick, or any other ſubſtance, be brought near them, they do not ſtay for its touching them, but begin to leap and friſk about, as ſoon as it comes towards them. There want however ſome farther experiments to aſcertain whether this be really owing to feeling or to ſight; for tho' we can diſcover no diſtinct organs of ſight in theſe creatures, yet they ſeem affected by the light of the ſun or a candle, and always friſk about it in the ſame manner at the approach of either; nay even the moon-light has ſome effect upon them.

A twig of willow, poplar, or many other trees being planted in the earth, takes root, and becomes a tree, every piece of which will in the ſame manner produce other trees. The caſe is the ſame with theſe worms; they are cut to pieces, and theſe ſeveral pieces become perfect animals; and each of theſe may be again cut into a number of pieces, each of which will in the ſame manner produce an animal. It had been ſuppoſed by ſome, that theſe worms were oviparous; but Mr. Bonett, on cutting one of them to pieces, having obſerved a ſlender ſubſtance reſembling a ſmall filament to move at the end of one of the pieces, ſeparated it, and on examining it with glaſſes, found it to be a perfect worm of the ſame form with its parent, which lived and grew larger in a veſſel of water into which he put it. Theſe ſmall worms are eaſily divided, and very readily complete themſelves again, a day uſually ſerving for the production of a head to the part that wants one, and in general the ſmaller and ſlenderer the worms are, the ſooner they complete themſelves after this operation. When the bodies of the large worms are examined by the microſcope, it is very eaſy to ſee the appearance of the young worms alive and moving about within them; but it requires great preciſion and exactneſs to be certain of this; ſince the ramifications of the great artery have very much the appearance of young worms, and they are kept in a ſort of continual motion by the ſyſtoles and diaſtoles of the ſeveral portions of the artery which ſerve as ſo many hearts. It is very certain, that what we force in regard to theſe animals by our operations, is done alſo naturally every day in the brooks and ditches where they live. A curious obſerver will find in theſe places many of them without heads or tails, and ſome without either; as alſo other fragments of various kinds, all which are then in the act of completing themſelves; but whether accidents have reduced them to this ſtate, or they thus purpoſely throw off parts of their own body for the *Reproduction* of more animals, is not eaſy to determine. They are plainly liable to many accidents, by which they loſe the ſeveral parts of their body, and muſt periſh very early, if they had not a power of *reproducing* what was loſt; they often are broken into two pieces, by the reſiſtance of ſome hard piece of mud, which they enter; and they are ſubject to a diſeaſe, a kind of gangrene rotting off the ſeveral parts of their bodies, and muſt inevitably periſh by it, had they not this ſurprizing property.

This worm was a ſecond inſtance after the polype, of the ſurprizing power in an animal of recovering its moſt eſſential parts, when loſt; but nature does not ſeem to have limited her beneficence in this reſpect to theſe two creatures; Mr. Bonett tried the ſame experiments on another ſpecies of water-worm, differing from the former in being much thicker: This kind of worm, when divided in the ſummer ſeaſon, very often ſhews the ſame property; for if it be cut into three or four pieces, the pieces will lie like dead for a long time, but afterwards will move about again, and will be found in this ſtate of reſt to have recovered a head, or a tail, or both. After recovering their parts, they move very little, and according to this gentleman's experiments, ſeldom live more than a month.

It ſhould ſeem that the more difficult ſucceſs of this laſt kind of worm, after cutting, and the long time it takes to recover the loſt parts, if it do recover them at all, is owing to its thickneſs; ſince we always find in that ſpecies of worms which ſucceeds beſt of all, that thoſe which are thinneſt always recover their parts much ſooner than the others.

The water inſects alſo are not the only creatures which have this power of recovering their loſt parts. The earth affords us ſome already diſcovered to grow in this manner from their cuttings, and theſe not leſs deſerving our admiration than thoſe of the water; the common earth worms are of this kind. Some of theſe worms have been divided into two, others into three or four pieces, and ſome of theſe pieces, after having paſſed two or three months without any appearance of life or motion, have then begun to *reproduce* a head or a tail, or both. The *Reproduction* of the anus, after ſuch a ſtate of reſt is no long work; a few days does it, but it is otherwiſe with the head, that does not ſeem to perform its functions in the divided pieces, till about ſeven months after the ſeparation. It is to be obſerved, that in all theſe operations both on earth and water-worms, that the hinder part ſuffers greatly more than the fore part in the cutting, for it always twiſts itſelf about a long time, as if actuated by ſtrong convulſions; whereas the head uſually crawls away without the appearance of any great uneaſineſs.

REVERSION *of Series (Cycl.)* — The problems mentioned under this head in the Cyclopædia may indeed be ſolved by the method of *Reverſion of Series*, but are only particular caſes of it, and not a general account of that method, which is to be underſtood thus: The value of any indefinite quantity, y, for inſtance, being expreſſed by an infinite *Series* of ſimple terms, including different powers of another variable quantity, x, the value of x is thence to be found, by a kind of reverſed operation, expreſſed in a *Series* of ſimple terms, including different powers of the quantity y. Thus, if $y = x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \frac{1}{4}x^4 +$ &c. by the *Reverſion of the Series*, we ſhall have, $x = y + \frac{1}{2}y^2 + \frac{1}{6}y^3 + \frac{1}{24}y^4 + \frac{1}{120}y^5$. Thus alſo, if $dx + bx^2 + cx^3 + dx^4 +$ &c. $= gy + hy^2 + iy^3 + ky^4 +$ &c. x may be found by this method, expreſſed by the powers of y.

There are various ways of doing this. One, which is often convenient, is, by aſſuming a *Series* with indeterminate coefficients of a certain form; examples of which are given under the head FORM *of a Series*, *Append.* See Mac Laurin's Algebra, pag. 263. and Mr. De Moivre, in the Phil. Tranſ. N° 240.

Other methods may be ſeen in Mr. Stuart's explanation of Sir Iſaac Newton's Treatiſe of Analyſis by equations of an infinite number of terms, p. 455.

RESERVATORY, a term ſometimes uſed in a ſynonymous ſenſe with *Reſervoir*, See the article RESERVOIR, *Cycl.*

RETURN, in the military language, denotes the liſt of the ſick, given in once a week by the ſurgeon to the commanding officer of a regiment.

Commiſſioned officers are not put in the *Returns*, which, on that account, are but an imperfect liſt of the ſick.

Twelve ſick, in a battalion of 780 private men, is the loweſt *Return* that can be expected, even in the moſt healthy ſeaſon and climate, as well as beſt quarters. *Returns* are often much higher, but ſeldom exceed ſeventy in a battalion.

It is to be obſerved, that *Returns* include all accidents unfitting a ſoldier for duty. See *Pringle*, Obſerv. on the Diſ. of the Army, p. 12, 36.

RHAPONTICOIDES, in botany, a diſtinct genus of plants, according to Vaillant, but eſteemed only a ſpecies of *Centauria* by Linnæus. See the article CENTAURIA.

RHAPONTICUM, a diſtinct genus of plants, according to Vaillant, but comprehended under the *Centauria* by Linnæus. See the article CENTAURIA, *Append.*

RHETORICAL *Accent*, among Hebrew grammarians. See the article ACCENT, *Cycl.*

RHEUM, in botany, the name given by Linnæus to *Rhubarb*. See the article RHUBARB, infra.

RHEUMATISM *(Cycl.)* — This is a diſeaſe incident to winter, and owing, chiefly, to a ſuppreſſion of perſpiration.

In a complete and obſtinate *Rheumatiſm*, the joints are often conſiderably ſwelled and inflamed; but in fevers with *rheumatic* pains, this is ſeldom the caſe. Accordingly, in theſe laſt, the cure may be effected in a few days, by twice or thrice bleeding, and promoting a diaphoreſis by the cooler medicines, particularly vinegar-whey. But if the *Rheumatiſm* be attended with violent pains or ſwelling of the joints, ſweating is reckoned improper; ſo that the cure muſt be obtained by repeated and almoſt daily bleedings, till the fever is gone, and the pains either entirely removed, or rendered much eaſier.

If the pain and ſwelling of the joints remain after the fever is abated, three or four leeches may be applied to the part where the inflammation and tumour are greateſt; letting the blood ooze, till it ſtops of itſelf. As the relief hereby obtained is ſometimes conſiderable, and the evacuation but ſmall, the repetitions need not be limited. But, then, no benefit is to be expected from leeches in any pains of the joints, not attended with both inflammation and ſwelling.

In the true acute *Rheumatiſm*, internal medicines avail little. The beſt perhaps are the neutral ſalts, with very ſmall doſes of camphor, ſo as neither to heat or force a ſweat. As to diet, it ought to be of the loweſt kind. Outward applications are alſo to be omitted, as long as any fever or inflammation remains. The ſpirituous and volatile liniments inflame, and the emolient fomentations, though they give eaſe for the time, do harm by relaxing, unleſs very ſparingly uſed. If there is no inflammation, the aking parts may be rubbed with flannel, and anointed with the linimentum volatile or ſaponaceum, according as the ſkin is too much hardened or relaxed by the uſe of the one or other. After the patient has continued ſome time in this courſe, his recovery will be quickened by the uſe of the cold-bath, or the bark; and to thoſe who can afford it, riding is ſpecific. *Pringle*, Obſerv. on the Diſ. of the Army, p. 152, ſeq.

RHUBARB, in botany, the Engliſh name of a diſtinct genus of plants, of which there is only one known ſpecies. See the article RHABARBARUM, *Suppl.*

Monk's-RHUBARB, the name of a ſpecies of *Lapathum*, or dock. See the article LAPATHUM, *Suppl.*

RIB-*wort*, a name ſometimes given to the *Plantago* of botaniſts, See the article PLANTAGO, *Suppl.*

RIBBAND-*Screw-ſhell*, the Engliſh name of the *Turbo*, with broad ſpiral faſciæ, and a ſmall mouth. See the article TURBO, *Suppl.*

RIBES, in botany, a general name given by Linnæus to the gooſberry and currant buſhes, which he makes one genus of plants, called by others *Groſſularia*. See the article GROSSULARIA, *Suppl.*

RICE, the Engliſh name of a genus of plants, known among botaniſts by that of *Oryza*. See the article ORYZA, *Append.*

RIFTS, a diſeaſe in horſes ariſing from corruption lodged in the palate of the mouth. Ruſt. Dict. in voc.

RIG, or RIGLING, the ſame with *Ridgling*. See the article RIDGLING, *Cycl.*

RING-*Ouzel*, the Engliſh name of the black *Turdus*, with a white ring round its neck. See the article TURDUS, *Suppl.*

RIPENING *of fruit*, in gardening, may be forwarded ſeveral ways. The method practiſed in the Levant, for maturating the domeſtic fig-tree, has been already mentioned; alſo the great uſe of hot beds, for bringing to maturity many exotic plants, which could not be otherwiſe effected in cold climates. See the articles CAPRIFICATION, *Suppl.* and HOT-*beds*, *Cycl.* and *Suppl.*

Several other methods of haſtening the fructifications of trees, and other vegetables, have likewiſe been taken notice of under the article *Forcing*. See the article FORCING, *Suppl.*

ROBIN *(Suppl.)* — RAGGED-ROBIN, a name ſometimes uſed for the *Lychnis*. See the article LYCHNIS, *Suppl.*

Wake-ROBIN, the Engliſh name of a genus of plants, called by botaniſts *Arum*. See the article ARUM, *Suppl.*

ROCK-*roſe*, a name ſometimes given to the *Ciſtus* of botaniſts. See the article CISTUS, *Suppl.*

ROCKET, in botany, the Engliſh name of a genus of plants, called by botaniſts *Eruca*. See the article ERUCA, *Suppl.*

Corn-ROCKET, or *ſquare-podded* ROCKET, a diſtinct genus of plants, called by botaniſts *Erucago*. See the article ERUCAGO, *Suppl.*

Garden-ROCKET, a name by which the *Heſperis* of botaniſts is ſometimes called. See the article HESPERIS, *Suppl.*

Water-ROCKET, or *Winter*-ROCKET, the name of a ſpecies of *Siſymbrium*. See the article SISYMBRIUM, *Suppl.*

ROD *(Suppl.)* — *Shepherd*'s-ROD, *Dipſacus*, in botany, the Engliſh name of a diſtinct genus of plants. See the article DIPSACUS, *Suppl.*

ROE-*buck*, the Engliſh name of the *Cervus* with ramoſe, cylindric, and erect horns. It is the ſmalleſt of the deer-kind, and has been called *Capreolus* and *Caprea*, tho' without the leaſt reſemblance of the goat-kind. See the article CAPREOLUS, *Suppl.*

ROLLER *(Suppl.)* is alſo the name by which ſome call the *Ampelis*, or *Garrulus Bohemicus*. See the article AMPELIS, *Suppl.*

ROOT *(Suppl.)* — The *roots* of plants may be reverſed and turned into branches; and *vice verſa*, the branches into roots. This is called *Planting reverſe*. See the articles PLANT and PLANTING *reverſe*, *Append.*

Seminal-ROOT. See the article SEMINAL, *Suppl.*

ROPE *(Cycl.* and *Suppl.)* — Though it be difficult to give a certain account of the forces required to bend *ropes* of different diameters, in making them go round bodies of different bigneſſes, yet to make no allowance for the loſs of motion ſuſtained thereby, would be as prejudicial to the practice of mechanics, as it would be to overlook the friction of the parts of engines. The difficulty of aſcertaining this force ariſes from the different materials of which they are made, their different ſtiffneſs, according as they are more or leſs twiſted; and ſometimes from the temperature of the air, as to moiſture and dryneſs.

Dr. Deſaguliers has computed the forces required to bend *Ropes* of different diameters, ſtretched by different weights, round rollers of different bigneſſes: The reſult of his experiments is expreſſed in the following table.

Diameters of the *Ropes* of three ſtrands, expreſſed in tenth parts of an inch	Weights ſtretching the *ropes*, expreſſed in *lb.* avoirdupois.	Reſiſtance about a roller of half an inch diameter, in *oz.* avoirdupois	Reſiſtance about a roller of one inch diameter in *oz.* avoirdupois	Reſiſtance about a roller 1 ½ inches diameter in *oz.* avoirdupois.
0, 5	60 *lb.*	225 *oz.*	112 ½ *oz.*	75 *oz.*
0, 2	60	90	45	30
0, 1	60	45	22 ½	15
0, 5	40	150	75	50
0, 2	40	60	30	20
0, 1	40	30	15	10
0, 5	20	75	37 ½	25
0, 2	20	30	15	10
0, 1	20	15	7 ½	*

On the whole, it has been found by experiments, that the difficulty of bending a *rope* round a roller decreaſes directly as the diameter of the roller increaſes; or is, inverſely, as the diameter of the roller. See *Deſaguliers*, Experim. Phil. vol. 1. p. 233, ſeq.

ROSE *(Suppl.)* — *Bay*-ROSE, the name of a genus of plants, called by botaniſts *Nerium*, or *Nerion*. See the article NERION, *Suppl.*

Campion-ROSE, a name ſometimes given to the *Lychnis*. See the article LYCHNIS, *Suppl.*

China-ROSE, the name by which ſome call the *Ketmia* of botaniſts. See the article KETMIA, *Suppl.*

Mountain-Bay ROSE, a name by which the *Chamærhododendros* of botaniſts is ſometimes called. See the article CHAMÆRHODODENDROS, *Suppl.*

Gelder-ROSE, a name ſometimes given to the *Opulus*, or water-elder. See the article OPULUS, *Suppl.*

ROSE of *Jericho*, a name by which ſome call the *Heſperis*. See the article HESPERIS, *Suppl.*

South-Sea ROSE, a name ſometimes given to the *Nerion* of botaniſts. See the article NERION, *Suppl.*

Rock-ROSE, the name by which the *Ciſtus* of botaniſts is ſometimes called. See the article CISTUS, *Suppl.*

ROSE-*Root*, a name by which ſome call the *Anacampſeros*, or Orpin. See the article ANACAMPSEROS, *Suppl.*

ROSEMARY *(Snppl.)* — *Spaniſh*-ROSEMARY, a name ſometimes given to the *Thymelæa* of botaniſts. See the article THYMELÆA, *Suppl.*

Poet's-ROSEMARY, a name ſometimes given to the *Caſſia* of botaniſts. See the article CASSIA, *Suppl.*

ROSTRATA, in zoology, a name uſed by ſeveral zoologiſts for the *Ramphaſtos* or Toucan, a genus of birds. See the article RAMPHASTOS, *Append.*

ROTHER, a term uſed by *Blanckley*, in his Naval Expoſitor, for *Rudder*. See the article RUDDER, *Cycl.* and *Suppl.*

ROUCOU, in botany, a name given to a ſpecies of Mitella.

ROVES, in ſhip-building, ſmall ſquare pieces of iron, with a hole punched in the middle through which the nail goes, where it is clenched, and binds together the boards of pinnaces, yawles, &c. *Blanckley*'s Naval Expoſitor, p. 137.

ROUGHINGS, a word uſed in many parts of the kingdom for the graſs which comes after mowing. Ruſt. Dict. in voc.

ROUP, in poultry, is a filthy boil or ſwelling upon their rumps, known by the ſtaring, or turning back of the feathers.

The *Roup*, if not ſoon remedied, will corrupt the whole body; to prevent which, the feathers are to be pulled away, the ſwelling laid open, and the matter preſſed out; after which the part is to be waſhed with ſalt and water, or brine. Ruſt. Dict. in voc.

ROWLUCKS, among ſhip-carpenters, ſmall ſpaces left in the gunwale, where two thoals are let in at ſuch a diſtance from each other, as to admit the oar, at the end of the loom to lie on to row the boat. *Blanckley*'s Naval Expoſitor, p. 188.

RUDBECKIA, in the Linnæan ſyſtem of botany, the name of a genus of plants, called by Vaillant *Obeliſcotheca*, and in Engliſh the *Dwarf-ſun-flower*.

The characters are theſe: The common cup is compoſed of a double order of leaves, ſix in each order, and covered with plane, broad, but ſhort ſquamæ; the compoſite flower is radiated; the proper one tubuloſe, infundibuliform, with its mouth divided into five ſegments; the ſtamina are five very ſhort, capillary filaments; the antheræ cylindric; the germen of the piſtil is placed under the receptacle; the ſtyle is filiform, and of the length of the flower; the ſtigma is divided into two parts, which bend backwards; the receptacle is paleaceous and conic; the ſeeds are ſingle and oblong. Vid. *Linnæi* Gen. Plant. p. 415.

The ſpecies of *Rudbeckia* are theſe. 1. The *Rudbeckia*, with the lower leaves divided into three lobes, and the upper ones undivided. 2. The compoſite laciniated-leaved *Rudbeckia*. 3. The oblong, hairy-leaved *Rudbeckia*. 4. The great, ſcabrous *Rudbeckia*. 5. The broad-leaved, many-flowered *Rudbeckia*. 6. The tall *Rudbeckia*, with red ſtalks. 7. The ſmall, ſhort-leaved *Rudbeckia*. 8. The great-flowered, hairy *Rudbeckia*. Vid. *Hill*, Hiſt. Plant. p. 584.

RUDBECKIA is alſo a name uſed by Houſton for the *Conocarpus* of Linnæus. See the article CONOCARPUS, *Append.*

RUE *(Suppl.)* — *Dog*'s-RUE, a name ſometimes given to the *Scrophularia*, or fig-wort. See the article SCROPHULARIA, *Suppl.*

Meadow-RUE, the Engliſh name of a genus of plants, called by botaniſts *Thalictrum*. See the article THALICTRUM, *Suppl.*

Wall-RUE, the Engliſh name of a diſtinct genus of plants, called by botaniſts *Ruta muraria*. See the article RUTA *muraria*, *Suppl.*

RULE *(Cycl.)* — RULE *of five*, or, *Compound* RULE *of Three*. What is ſaid in the Cyclopædia of this *rule*'s being more eaſily performed by two ſimple *rules of three*, is ſometimes true, but not always. In ſome caſes, not only five, but ſeven, or nine terms may be given, from whence it is neceſſary to determine an eighth, or a tenth, which indeed might be performed by repeated applications of the ſimple *rule of three*, but not ſo expeditiouſly. Mr. Jones has therefore given a general *rule* by which all caſes of the *rule of Three* or of proportion may be ſolved.

The *rule* is, 1°. Set down the terms expreſſing the condition of the queſtion, in one line. 2°. Under each conditional term ſet its correſponding one in another line. 3°. Multiply the *producing terms* of one line, and the produced term of the

the other line continually, and take the result for a dividend. 4°. Multiply the remaining terms continually, and let the product of them be a divisor. 5°. The quotient of this division will be the term required.

By *producing terms* here, are meant, whatever necessarily and jointly produce any effect; as the Cause and the Time; length, breadth, and depth; buyer and his money; seller and his goods; all necessarily inseparable in producing their several effects.

In a question where a term is understood, and not expressed that term may be expressed by unity.

Example. If 250 *l.* serve six persons for nine months; how long will 1000*l.* serve four persons at the same rate?

Here the terms which express the condition are.

	£.	*P.*	*M.*
	250	6	9
corresponding terms	1000	4	Q

Where Q is put to represent the term required.

Among the conditional terms, six persons and nine months are producing, and 250*l.* is produced: among their corresponding terms four persons and Q are producing, and 1000*l.* are produced.

But it being impossible to multiply the producing terms in the second line, and the produced in the first, because Q is unknown; therefore multiply the producing terms of the first line, by the produced in the second, and divide by the product of the rest.

Then will $Q = \frac{6 \times 9 \times 1000}{4 \times 250} = 6 \times 9 = 54$.

See Mr. *Dodson*'s Anti logarithmic Canon, pag. 38. seq.

But if the notion of producing and produced terms should seem obscure, those who have a knowlege of the doctrine of compound ratios, will easily perceive that in the foregoing question, Q is to 9 months in the compound ratio of 4 persons to 6 persons inversely, and of 1000*l.* to 250*l.* directly, that is, $\frac{Q}{9} = \frac{6}{4} \times \frac{1000}{250}$, therefore $Q = \frac{6 \times 9 \times 1000}{4 \times 250} = 54$ as before. And in like manner may other questions, relating to the compound rule of proportion, be stated and solved, however complex.

RUNT *(Suppl.)* — RUNT is also a name given to Scotish or Welch neat, or cows of a small size. Dict. Rust. in voc.

RUPTURE, *(Cycl.)* in surgery. See the article HERNIA, *Cycl.* and *Suppl.*

RUPTURE-*Wort*, the English name of a genus of plants, called by botanists *Herniaria*. See the article HERNIARIA, *Suppl.*

RUSH *(Suppl.)* — *Flowering*-RUSH, the English name of a genus of plants, called by botanists *Butomus*. See the article BUTOMUS, *Suppl.*

RUSSET, a country word for a dark brown colour. Rust. Dict. in voc.

RUT *(Suppl.)* — RUT is also the term used for the track or mark of a wheel in the road. Rust. Dict. in voc.

RYE-*Grass*, in botany, the same with what is otherwise called *Rey-grass*. See the article REY-*Grass*, *Suppl.*

S.

S.

SAFFRON (*Suppl.*)—*Indian* SAFFRON, a name ſometimes given to turmeric. See TURMERIC, *Cycl.*

Baſtard-SAFFRON, the Engliſh name of a genus of plants, called by botaniſts *Carthamus*. See the article CARTHAMUS, *Suppl.*

SAGE (*Suppl.*)—SAGE *of Jeruſalem*, a name ſometimes given to a ſpecies of *pulmonaria*. See PULMONARIA, *Suppl.*

SAGE *of Jeruſalem*, or SAGE-*tree*, names by which the *phlomis* of botaniſts is ſometimes called. See the article PHLOMIS, *Suppl.*

Wild SAGE, a name ſometimes given to the *lantana* of botaniſts. See the article LANTANA, *Suppl.*

Wood-SAGE, the name by which ſome call the *ſcordium* or *teucrium* of botaniſts. See the article TEUCRIUM, *Suppl.*

SAGITTA, in architecture, a name ſometimes uſed for the key-piece of an arch. See KEY and ARCH, *Cycl.*

SAGREE, a name ſometimes given to the *galeus ſpinax*, or prickly hound-fiſh. See the article GALEUS, *Suppl.*

It is a ſpecies of *ſqualus*. See the article SQUALUS, *Suppl.*

SAINT-*foin*, in botany, the Engliſh name of a genus of plants, called by botaniſts *onobrychis*. See the articles ONOBRYCHIS and SAINT-FOIN, *Suppl.*

This plant is propagated as clover for the food of cattle. It will hold well in the ground, and continue to grow and be of uſe for twenty years; but then the main crop is always to be mowed, and not to be eaten upon the ground.

SAKER (*Suppl.*)—SAKER, in ornithology, the ſame with *ſacre*. See the article SACRE, *Suppl.*

SALACIA, in zoology, the name of a genus of inſects of the *gymnarthria* kind; the body of which is ovato-oblong, and the tentacula are numerous, and diſpoſed in little cluſters. See GYMNARTHRIA, *Append.*

It is called by different authors *priapus marinus*, and *mentula marina*. See the article PRIAPE *de mer*, *Suppl.*

SALICORNIA, in botany, the name of a genus of plants, the characters of which, according to *Linnæus*, are theſe: the cup is of a tetragonal form, truncated, bellied out, and permanent. There is no corolla. The ſtamen is a ſingle, ſimple, capillary filament. The anthera is roundiſh. The germen of the piſtil is of an oblong ovated figure: the ſtyle is ſimple and placed under the ſtamen, and the ſtigma is bifid. There is no pericarpium, but the cup becomes more ventricoſe, and contains a ſingle ſeed. Vid. *Linnæi* Gen. Plant. p. 4.

There are only two ſpecies of this genus, which are, 1. The ſhort-jointed *ſalicornia*, and 2. The longer-jointed *ſalicornia*. *Hill*, Hiſt. Plant. p. 154.

SALIVA (*Cycl*)—Dr. *Pringle*, in the appendix to his obſervations on the diſeaſes of the army, has given the reſult of ſeveral experiments made to aſcertain the effects of the *ſaliva* in digeſtion.

By adding a ſmall portion of it to ſome raw beef, he remarked, that this mixture putrefied ſlower than another which had no *ſaliva* in it; from whence he infers its antiſeptic nature.

Another experiment, made to aſcertain the fermentative power of *ſaliva*, was this: he took two drachms of freſh meat, the ſame quantity of bread, and to theſe added as much *ſaliva* as he ſuppoſed neceſſary to digeſtion. This mixture being beat in a mortar, was put into a cloſe phial, and ſet in the furnace, where it remained about two days, with ſcarce any viſible fermentation; but, on the third day, this action became manifeſt. The bread and fleſh were then found riſen in the water, a ſediment forming, and bubbles of air continually mounting. In ſhort, the fermentation was complete, being diſtinguiſhed by a vinous ſmell, as in ordinary working liquors. The action continued about twice as long as when no *ſaliva* was uſed; it was likewiſe much more moderate, and generated air with little tumult. When the fermentation intirely ceaſed, the mixture had a pure acid taſte; and what was equally remarkable, had no putrid ſmell during the whole proceſs.

From theſe experiments the doctor concludes, that if the *ſaliva* is well prepared, is in a ſufficient quantity, and well mixed with the aliment, it is qualified for reſiſting putrefaction, preventing immoderate fermentation, flatulence, and acidity in the primæ viæ. But if the *ſaliva* is deficient, unſound, or not well mixed with what is ſwallowed, that the aliment may firſt putrefy, then grow acid, and in that action ferment ſtrongly, and generate much air in the ſtomach and bowels. *Pringle*, Obſerv. p. 355.

Accordingly, in ſurfeits, or upon ſwallowing without due maſtication; when meats are eat tough and fat, or with farinaceous ſubſtances unfermented; or, when by any accident the *ſaliva* is vitiated, too ſcanty, or not intimately mixed with the food, the fermentation becomes tumultuous, the ſtomach ſwells with air; and this extraordinary commotion being attended with an unuſual heat, brings on that uneaſineſs called the *heart-burn*, and occaſions that exceſſive ſourneſs of the ſtomach, whereby the teeth are not only ſet on edge, but the throat excoriated. This laſt, however, only happens when the ſtomach is relaxed, or any wiſe diſabled from conveying the whole aliment into the inteſtines; for, what is left having time to undergo a complete fermentation, is thereby changed into a harſh ſort of vinegar. Id. ibid. p. 368.

Since one great uſe of *ſaliva* is to moderate fermentation, it is probable, that ſuch ſubſtances as reſemble it moſt in this quality, will prove the beſt ſtomachics whenever that humour fails. Of this claſs are acids, wines, ſpirits, and bitters; but as all theſe retard as well as moderate fermentation, they may be frequently leſs proper than ſome of the antiſcorbutics, as horſe-radiſh, muſtard, and garden ſcurvy-graſs, which, at the ſame time that they moderate, retard fermentation but little. As to aromatics, however aſſiſting they may be in digeſtion by their heat and ſtimulus, they promiſe leſs of a carminative quality than either the bitters or antiſcorbutics; in as much as they are more diſpoſed to increaſe than to moderate fermentation, and conſequently to produce air inſtead of ſuppreſſing it. Id. ibid. p. 376.

SALLOW, a name by which ſeveral ſpecies of the *ſalix*, or willow, are frequently called. See the article SALIX, *Suppl.*

SALMON (*Suppl.*)—SALMON-*peel*, the name of a fiſh found in great plenty in the rivers of Wales, agreeing in the colour of its fleſh, and perhaps in kind with the common ſalmon. Ruſt. Dict. in voc.

SALMON-*ſewſe*, a name ſometimes uſed for the young fry of ſalmon.

SALOMON's *ſeal*, in botany, the ſame with *ſolomon's ſeal*. See SOLOMON's *ſeal*, infra.

SALT (*Suppl.*)—*Ætna* SALT. See the article ÆTNA, *Suppl.*

SALT-*wort*, a name ſometimes given to the *ſalicaria* or willow-herb, of other writers. See the article SALICARIA, *Suppl.*

SAMPHIRE, the Engliſh name of a genus of plants, called by botaniſts *crithmum*. See the article CRITHMUM, *Suppl.*

Prickly SAMPHIRE, the name given by ſome writers to a ſpecies of *echinophora*. See the article ECHINOPHORA, *Suppl.*

SAND (*Suppl.*)—SAND-*eel*, in ichthyology, the Engliſh name of the *ammodytes*. See the article AMMODYTES, *Suppl.*

SAND-*ſnake*, a ſpecies of ſerpent. See the article AMMODYTES, *Suppl.*

SANICLE, the Engliſh name of a genus of plants, called *ſanicula* by botaniſts. See the article SANICULA, *Suppl.*

Water-SANICLE, a name ſometimes given to a genus of plants, called by botaniſts *geum*. See the article GEUM, *Suppl.*

Bear's ear SANICLE, the name by which ſome call the *cortuſa* of botaniſts, a diſtinct genus of plants. See the article CORTUSA, *Suppl.*

SAPLING, among gardners, a name by which they call any young tree that is full of ſap. Ruſt. Dict. in voc.

SAPONARIA, *ſoap-wort*, in botany, the name of a genus of plants, the characters of which are theſe. The cup is a permanent perianthium, formed of a ſingle leaf, oblong and divided into five ſegments at the edge. The flower conſiſts of five petals: the ungues are narrow, angulated, and of the length of the cup: the limb is plane, the bracteæ broadeſt towards the extremity, and obtuſe. The ſtamina are ten ſubulated filaments, of the length of the tube of the flower, alternately inſerted into the ungues of the flower: the antheræ are oblong and incumbent. The germen of the piſtil is cylindric; the ſtyles are two, ſtrait, parallel, and of the length of the ſtamina: the ſtigmata are acute. The fruit is a covered capſule, nearly of the length of the cup, and containing only one cell; in which are included numerous ſmall ſeeds. The receptacle is free. The germen and capſule are, in ſome ſpecies, more ſhort and rounded, and the ſegments of the cup are deeper in ſome than in others; in ſome they are almoſt five leaved. Vid. *Linnæi* Gen. Plant. p. 191.

Dillenius and others make this genus only a ſpecies of *ſpergula*. See the article SPERGULA, *Append.*

SAPPADILLA, a name uſed by ſome for the *cainito*, or *chryſophyllum*, of botaniſts. See the article CHRYSOPHYLLUM, *Append.*

SARACEN's *conſound*, a name ſometimes given to the *ſolidago* or *virga aurea* of botaniſts. See the article VIRGA *aurea*, *Suppl.*

SARFE, the Engliſh name of a ſpecies of *cyprinus*, with the iris of the eye, and all the fins and tail red. See CYPRINUS, *Suppl.*

It is otherwiſe called *erythrophthalmus*, or the *red-eye*. See the article ERYTHROPHTHALMUS, *Suppl.*

SASSAFRAS-*tree*, in botany, the names of a ſpecies of *laurus*, according to Linnæus, with undivided and trilobate leaves. See LAURUS, *Append.*

It is a native of America, and called by C. Bauhine, *ſaſſafras arbor ficulneo folio.*

The bark of this tree is an excellent diaphoretic and attenuant, the wood is alſo in much eſteem. See SASSAFRAS, *Cycl.* and *Suppl.*

SATTIN *(Cycl.)*—*White* SATTIN, in botany, a name given by ſome to the *lunaria*. See the article LUNARIA, *Suppl.*

SATYRIUM, in the linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe: the cup is formed of vague ſpathæ. There is no perianthium. The flower conſiſts of five ovato-oblong petals. The nectarium is monophyllous. The ſtamina are very ſhort and ſlender filaments; the antheræ are ovated; the germen of the piſtil is contorted; the ſtyle is very ſhort; and the ſtigma compreſſed and obtuſe. The fruit is an oblong capſule, containing one cell; in which are numerous, very ſmall ſeeds, like ſaw-duſt. *Linnæi* Gen. Plant. p. 432.

This genus is called *orchis* or *tragoorchis* by other botaniſts. See the article ORCHIS, *Suppl.*

SAUCE-*alone*, a name ſometimes uſed for the *heſperis* of botaniſts. See the article HESPERIS, *Suppl.*

SAVIN *(Suppl.)*—*Indian* SAVIN, the name of a genus of plants, deſcribed by Linnæus under that of *bauhinia*. See the article BAUHINIA, *Suppl.*

SAW-*wort*, in botany, the Engliſh name of a genus of plants, known among botaniſts by that of *ſerratula*. See the article SERRATULA, *Suppl.*

SAXIFRAGE *(Suppl.)*—*Pimpernel*-SAXIFRAGE, or *burnet*-SAXIFRAGE, names uſed for the *tragoſelinum* of botanical writers. See the article TRAGOSELINUM, *Suppl.*

SCALD, a burn cauſed by ſome boiling liquor. See the article BURN, *Suppl.*

SCALE—*differential* SCALE, is uſed for the ſcale of relation ſubtracted from unity. See SERIES, *Append.*

SCALE *of relation*, in algebra, an expreſſion denoting the relation of the terms of recurring ſeries to each other. See the article SERIES, *Append.*

SCALLOP, in conchyliology, the Engliſh name of the *pecten*. See the article PECTEN, *Suppl.*

SCAMMONY *(Cycl.)*—SCAMMONIA, in botany, the name uſed in the ſhops and among medicinal writers for a ſpecies of bind-weed. See the article CONVOLVULUS, *Suppl.*

SCARE-*crow*, the Engliſh name of a bird of the *larus*, or gull kind, with grey wings, red legs, and the reſt of the body black. See the article LARUS, *Suppl.*

SCARLET *lychnis*, in botany, the name of a ſpecies of *lychnis*. See the article LYCHNIS, *Suppl.*

SCARLET *cardinals flower*, the name of a ſpecies of *rapuntium*. See the article RAPUNTIUM, *Suppl.*

SCARLET *oak*, the Engliſh name of a ſpecies of *ilex*, called by antient writers *ſmilax*. See the article ILEX, *Suppl.*

SCAVEL *ſpitter*, denotes a ſmall ſpade, ſhod only half way, and uſed in digging clay. *Blanckley*, Naval Expoſitor, p. 142.

SCELASIUS, in zoology, the name by which Dr. Hill has called a genus of animalcules with viſible legs.

It is common in ditch-water, and is leſs quick in its motions than moſt other animalcules. *Hill*, Hiſt. Anim. p. 10.

SCIATICA *(Cycl.)* See the article GOUT, *Cycl.* and *Suppl.*

SCIATICA-*creſs*, a name by which ſome call the *cardamine*, or ladies ſmock. See the article CARDAMINE, *Suppl.*

SCIATICA-*creſs* is alſo a name ſometimes given to a ſpecies of *lepidium*, or dittander. See the article LEPIDIUM, *Suppl.*

SCILLA, *ſquill*, in the linnæan ſyſtem of botany, the name of a diſtinct genus of plants, the characters of which are theſe; there is no cup; the flower conſiſts of ſix oval, deciduous, and very patent petals: the ſtamina are ſix ſubulated filaments, of half the length of the flower; the antheræ are oblong, and incumbent, the germen of the piſtil is roundiſh; the ſtyle is ſimple, of the length of the ſtamina, and deciduous; the ſtigma is ſimple: the fruit is a ſmooth capſule, of a ſuboval figure, marked with three furrows, formed of three valves, and containing three cells: the ſeeds are numerous and roundiſh.

This genus comprehends the *liliohyacinthus*, and the *hyacinthus ſtellaris* of other botanical writers; and is reckoned only a ſpecies of *ornithogalum* by Tournefort, Vid. *Linnæi* Gen. Plant. p. 145.

SCORCHING *fennel*. See FENNEL, ſupra.

SCORDIUM, in botany, the name by which ſome call the *teucrium* of other botanical writers. See the article TEUCRIUM, *Suppl.*

SCORPION-*inſect*, the Engliſh name of a ſpecies of *acarus*, called by ſome *Araneus coccineus*. See ACARUS, *Append.*

SCORPION-*ſhell*, the Engliſh name of a ſpecies of murex, otherwiſe called the *ſpider-ſhell*. See the article MUREX, *Suppl.*

Water-SCORPION, the Engliſh name of a genus of four winged flies, called by authors *nepa*. See the article NEPA, *Append.*

SCORPION-*graſs*, the Engliſh name of a genus of plants, called by botaniſts *ſcorpioides*. See the article SCORPIOIDES, *Suppl.*

SCORPION-*ſena*. See the article SENA, infra.

SCORPIURUS, in the linnæan ſyſtem of botany, the name of a genus of plants, called by Tournefort *ſcorpioides*, and in Engliſh *ſcorpion-graſs*. See the article SCORPIOIDES, *Suppl.*

SCOURINGS, among farriers, ſuch gentle purges as preſerve horſes from noxious humours. Vid. Ruſt. Dict. in voc.

SCREEN, an inſtrument for keeping off the wind, or the heat of the fire.

SCREEN is alſo uſed for a frame of laths to ſift earth, ſand, gravel, &c.

SCREEN likewiſe denotes a wire frame for ſeparating of corn from duſt, ſand, cockle, &c. Dict. Ruſt. in voc.

SCRUPI, in natural hiſtory, the name of a claſs of foſſils, formed in detached maſſes, without any cruſts; of no determinate figure, or regular ſtructure; and compoſed of a cryſtalline or ſparry matter, debaſed by an admixture of earth, in various proportions.

Under this claſs are comprehended, 1. The *telaugia*. 2. The *petridia*. 3. The *Lithozugia*. 4. The *Jaſpides*, or *Jaſpers*. See the articles TELAUGIA, PETRIDIA, &c. *Append.*

All theſe genera ſtrike fire with ſteel, only ſome more readily than others. Vid. *Hill*, Hiſt. Foſſ. p. 546, ſeq.

SCRY, in falconry, denotes a great flock of fowl. Ruſt. Dict. in voc.

SCULL-*cap*, a name ſometimes given to a genus of plants, called *ſcutellaria* or *caſſida* by botaniſts. See the article CASSIDA, *Suppl.*

SCUT, among ſportſmen, a term uſed for the tail of a hare or rabbit. Dict. Ruſt. in voc.

SEA-*apple*, or SEA-*egg*, the Engliſh name of the roundiſh *Centronia*, with crooked and faſciculated ſpines. See the article CENTRONIA, *Append.*

SEA-*dragon*, the Engliſh name of the *cottus*, with the ſecond back-fin white. See the article COTTUS, *Suppl.*

SEA-*eagle*, *aquila marina*, the Engliſh name of the *raja*, with a long ſerrated ſpine on a finny tail. See the articles RAJA, and AQUILA *marina*, *Suppl.*

SEA-*hare*, in the hiſtory of inſects, the Engliſh name of the *lernea*. See the article LERNEA, *Append.*

SEA-*horſe*, a name ſometimes, though improperly, given to the *Hippopotamus*, or river-horſe. See the article HIPPOPOTAMUS, *Suppl.*

SEA-*lungs*, in the hiſtory of inſects, the Engliſh name of a ſpecies of *meduſa*. See the article MEDUSA, *Append.*

SEA-*mouſe*, in the hiſtory of inſects, the Engliſh name of the *aphrodita*. See the article APHRODITA, *Append.*

SEA-*nettle*, in zoology, a name improperly given to the *meduſa*, a genus of naked-bodied inſects. See the article MEDUSA, *Append.*

SEA-*pearch*, *perca marina*, in ichthyology. See the article PERCA *marina*, *Suppl.*

SEA-*ſerpent*, *ſerpens marinus*, the Engliſh name of the cylindric *muræna*, with the tail naked and acute. See the articles SERPENT and MURÆNA, *Suppl.*

SEA-*water*. See the article WATER, *Append.*

SEA-*worms*, See the article WORMS *of the ſea*, *Append.*

SEAL *(Suppl.)*—*Ladies* SEAL, in botany, the name by which ſome call the *tamnus*, a diſtinct genus of plants. See TAMNUS, *Suppl.*

Solomon's SEAL, the Engliſh name of a diſtinct genus of plants, called by authors *polygonatum*. See the article POLYGONATUM, *Suppl.*

SEAMS, or SEYMS, in horſes, certain clefts in their quarters, occaſioned by the dryneſs of the foot, or by riding upon hard ground. Ruſt. Dict. in voc.

SEAN, a kind of long and large net. Ruſt. Dict. in voc.

SECRETION *(Suppl.)*—It is the opinion of ſeveral authors that all *ſecretion* is performed by glands, but this ſeems very doubtful, not to ſay falſe.

SEELING *(Suppl.)*—SEELING, in falconry, is the running a thread through the eye-lids of a hawk, when firſt taken, to make her endure the head the better. Ruſt. Dict. in voc.

SELANDERS, in horſes, the ſame with the *malanders*. See the article MALANDERS, *Cycl.*

SELF-*heal*, a name by which the *prunella* or *brunella* of botaniſts is ſometimes called. See the article PRUNELLA, *Suppl.*

SELF-*heal* is alſo a name given to ſanicle, on account of its great efficacy in healing freſh wounds, ſtopping fluxes and the gonorrhœa. Ruſt. Dict. in voc. SANICLE.

SELINUM, a name given by ſome to a ſpecies of *ſium*. See the article SIUM, *Suppl.*

SEMENDA, in ornithology, a ſpecies of birds found in the inland parts of the Eaſt-Indies. Scaliger makes no doubt but it is the ſame with the *phœnix*. *Hofm.* Lex. in voc. See the article PHOENIX, *Cycl.*

SENA *(Suppl.)*—This genus of plants is comprehended by Linnæus under the *caſſia*. See CASSIA, *Suppl.* and *Append.*

Baſtard SENA, in botany, a name by which authors call *caſſia*. See the article CASSIA, *Suppl.*

Bladder-SENA, the Engliſh name of a genus of plants, called by botaniſts *colutea*. See the article COLUTEA, *Suppl.*

Podded-SENA, the name by which the *coronilla* of botanical writers is ſometimes called. See the article CORONILLA, *Suppl.*

Scorpion-SENA, the name of a genus of plants, called by authors *emerus*, See the article EMERUS, *Suppl.*

SENGREEN, a name ſometimes given to *ſedum*, or houſe-leek. See the article SEDUM, *Suppl.*

SENNA, in botany, &c. See SENA, *Cycl.* and *Suppl.*

SENSITIVE *plant*, *mimoſa*, in botany, the Engliſh name of a diſtinct genus of plants. See the article MIMOSA, *Suppl.*

SEPELAER. See PLATEA, *Suppl.*

SEPIA, in zoology, the name of a genus of ſea-inſects of the gymnarthria kind, called by us the *cuttle-fiſh*, and *ink-fiſh*. See INK-*fiſh*, *Append.*

The body of the *ſepia* is of an oblong figure, and depreſſed; it is furniſhed with ten tentacula, two of which are longer than the others, and are pedunculated. It is often ſix inches in length, and three and a half in diameter.

It is ſupported by an oblong, light and ſpungy ſubſtance, of a friable texture, and lined with a light fungous pith. This is uſed by the ſilver-ſmiths, and as a dentifrice under the name of *os ſepium*, *os ſepiæ*, or cuttle-fiſh-bone. *Hill*'s Hiſt. of Anim. p. 97.

SEPTICS, among phyſicians, an appellation given to all ſuch ſubſtances as promote putrefaction. See PUTREFACTION, *Append.*

From the many curious experiments, made by Dr. Pringle to aſcertain the *ſeptic* and *antiſeptic* virtues of natural bodies, it appears that there are very few ſubſtances of a truly *ſeptic* nature. Thoſe commonly reputed ſuch by authors, as the alcaline and volatile ſalts, he found to be no wiſe *ſeptic*. However, he diſcovered ſome, where it ſeemed leaſt likely to find any ſuch quality: theſe were chalk, common ſalt, and the teſtaceous powders. He mixed twenty grains of crabs eyes, prepared with ſix drachms of ox's gall, and an equal quantity of water. Into another phial he put an equal quantity of gall and water but no crabs-eyes. Both theſe mixtures being placed in the furnace, the putrefaction began much ſooner, where the powder was, than in the other phial. On making a like experiment with chalk, its *ſeptic* virtue was found to be much greater than that of the crabs-eyes: nay, what the doctor had never met with before, in a mixture of two drachms of fleſh, with two ounces of water and thirty grains of prepared chalk, the fleſh was reſolved into a perfect mucus in a few days.

To try whether the teſtaceous powders would alſo diſſolve vegetable ſubſtances, the doctor mixed them with barley and water, and compared this mixture with another of barley and water alone. After a long maceration by a fire the plain water was found to ſwell the barley, and turn mucilaginous and ſour; but that with the powder kept the grain to its natural ſize, and though it ſoftened it, yet made no mucilage and remained ſweet.

Nothing could be more unexpected, than to find ſea-ſalt a haſtener of putrefaction; but the fact is thus. One drachm of ſalt preſerves two drachms of freſh beef in two ounces of water, above thirty hours, uncorrupted, in a heat equal to that of the human body; or, which is the ſame thing, this quantity of ſalt keeps fleſh ſweet twenty hours longer than pure water. But then half a drachm of ſalt does not preſerve it above two hours longer. Twenty five grains have little or no antiſeptic virtue, and ten, fifteen, or even twenty grains manifeſtly both haſten and heighten the corruption. The quantity, which had the moſt putrefying quality, was found to be about ten grains to the above proportion of fleſh and water.

Many inferences might be drawn from this experiment. One is, that ſince ſalt is never taken in aliment beyond the proportion of the corrupting quantities, it would appear that it is ſubſervient to digeſtion, chiefly by it's *ſeptic* virtue, that is, by ſoftening and reſolving meats: an action very different from what is commonly believed.

It is to be obſerved that the above experiments were made with the ſalt kept for domeſtic uſes. See *Pringle*, Obſerv. on the diſeaſes of the army, p. 848, ſeq.

SERAPH (*Cycl.*)—SERAPH is alſo the name of a Turkiſh gold-coin, worth about five ſhillings ſterling. Dict. Ruſt. in voc.

SERCIL *feathers of a hawk*, the ſame with thoſe called pinions in other fowl. Dict. Ruſt. in voc.

SERE, in falconry, the yellow between the beak and eyes of a hawk. Dict. Ruſt. in voc.

SERJEANT of the acatery, See ACATERY, *Cycl.*

SERIES, in algebra (*Cycl.*)—The notion of a *ſeries* given in the Cyclopædia is too limited, when confined to ranks or progreſſions of quantities increaſing or decreaſing in ſome conſtant ratio: for the term *ſeries* is indifferently uſed whether the terms of any number of quantities following each other have a conſtant ratio, or even relation or not. And, ſtrictly ſpeaking, a *ſeries* of quantities increaſing or decreaſing in a conſtant ratio is no more than what is commonly called a geometric progreſſion.

The doctrine of *ſeries* is of extenſive uſe in mathematics, and has been carried far; though not ſo far as could be wiſhed. It would far exceed the limits of our deſign to enter into a detail of the diſcoveries relating to this ſubject. Something, however, ſhould be added to what has been ſaid in the Cyclopædia, to give a notion of the principal kinds of *ſeries*, and the method of notation uſed in treating of them.

A *ſeries* being propoſed, one of the principal queſtions concerning it, is, to find the law of its continuation. For this no univerſal rule can be given; but it often happens, that the terms of the *ſeries* taken two and two, three and three, or in greater numbers have an obvious and ſimple relation, by which the *ſeries* may be determined and produced indefinitely. Thus if unity be divided by $1-x$, the quotient will be a geometric progreſſion, any term of which will be to the next antecedent term as x to 1. And by this property the *ſeries* $1 + x + x^2 + x^3 +$ &c. may be diſtinguiſhed and produced *ad infinitum*. In like manner in other caſes of diviſion, other *ſeries's* will ariſe, the terms of which will have a conſtant relation to each other, and this relation recurring always throughout the *ſeries*, they have been called recurring *ſeries* by Mr. de Moivre, who firſt conſidered them, and applied them to the ſolution of ſeveral intricate problems. See *Recurring* SERIES, *infra*.

In many caſes, the relation of the terms of a *ſeries* is not conſtant, as it is in thoſe ariſing from diviſion. Yet this relation often varies according to a certain law obvious upon inſpection. Thus in the *ſeries* $1 + \frac{2}{3}x + \frac{8}{15}x^2 + \frac{16}{35}x^3 + \frac{128}{315}x^4 +$ &c. The terms may be continued indefinitely by the continued multiplication of theſe fractions $\frac{2}{3}$, $\frac{4}{5}$, $\frac{6}{7}$, $\frac{8}{9}$, &c. And the following *ſeries*. $1 + \frac{1}{6}x + \frac{3}{40}x^2 + \frac{5}{128}x^3 + \frac{35}{1152}x^4 +$ &c. may be continued by the multiplication of the fractions $\frac{1\times1}{2\times3}$, $\frac{3\times3}{4\times5}$, $\frac{5\times5}{6\times7}$, $\frac{7\times7}{8\times9}$, &c.

Series's of this kind may be defined by *differential equations*. The equation defining a *ſeries* is that which aſſigns the relation of the terms generally by their diſtances from the beginning. To do this Mr. Stirling conceives the terms of the *ſeries* to be placed as ſo many ordinates on a right line given by poſition, and he, for the ſake of ſimplicity, takes unity as the common interval of theſe ordinates. The initial terms of the *ſeries* he denotes by the initial letters of the alphabet, A, B, C, D, &c. A being the firſt, B the ſecond, C the third &c. And he denotes any term in general by the letter T, and the reſt following it in order, T′, T″, T‴, T⁗, &c. He denotes the diſtance of the term T from any given term, or from any given intermediate point between two terms, by the indeterminate quantity z: ſo that the diſtances of the terms T′, T″, T‴, &c. from the ſaid term or point, will be, $z+1$, $z+2$, $z+3$ &c. for the increment of the abſciſs is the common interval of the ordinates, or terms of the *ſeries* applied to the abſciſs.

Theſe things being premiſed let this *ſeries* be propoſed, $1, \frac{1}{2}x, \frac{3}{8}x^2, \frac{5}{16}x^3, \frac{35}{128}x^4, \frac{63}{256}x^5$ &c. in which the relations of the terms are $B = \frac{1}{2}Ax$, $C = \frac{3}{4}Bx$, $D = \frac{5}{6}Cx$, $E = \frac{7}{8}Dx$ &c. The relation in general will be defined by the equation, $T' = \frac{z+\frac{1}{2}}{z+1}Tx$, where z denotes the diſtance of T from the firſt term of the *ſeries*. For by ſubſtituting 0, 1, 2, 3, 4, &c. ſucceſſively in the place of z, the relations of the terms of the propoſed *ſeries* will ariſe. In like manner, if z be the diſtance of T from the ſecond term of the *ſeries*, the equation will be $T' = \frac{z+\frac{2}{3}}{z+2}Tx$, as will appear by ſubſtituting the numbers -1, 0, 1, 2, 3, 4, &c. ſucceſſively for z. Or if the indeterminate z denotes the place of the term T in the *ſeries*, its ſucceſſive values will be 1, 2, 3, 4, &c. and the equation will be $T' = \frac{z-\frac{1}{2}}{z}Tx$.

It appears therefore that innumerable differential equations may define one and the ſame *ſeries*, according to the different points from whence the origin of the abſciſſa z is taken. And on the contrary the ſame equation defines innumerable different *ſeries's* by taking different ſucceſſive values of z. For in the equation $T' = \frac{z-\frac{1}{2}}{z}Tx$, which defines the *ſeries* above mentioned, when 1, 2, 3, 4, &c. are the ſucceſſive values of the abſciſſæ; if $1\frac{1}{2}$, $2\frac{1}{2}$, $3\frac{1}{2}$, $4\frac{1}{2}$, &c. be ſucceſſively ſubſtituted for z, the relations of the terms ariſing will be $B = \frac{2}{3}Ax$, $C = \frac{4}{5}Bx$, $D = \frac{6}{7}Cx$, &c. from whence the *ſeries* $A, \frac{2}{3}Ax, \frac{8}{15}Ax^2, \frac{16}{35}Ax^3, \frac{128}{315}Bx^4$, &c. will ariſe, which is different from the former. But the equation will always determine the *ſeries* from the given values of the abſciſſa and of the firſt term, when the equation includes but two terms of the *ſeries*; as in the laſt example, where the firſt term being given, all will be given. But when the equation includes three terms, two muſt be given; and three muſt be given, when it includes four, and ſo forth.

If the *ſeries* $x, \frac{1}{6}x^3, \frac{1}{40}x^5, \frac{5}{112}x^7, \frac{35}{1152}x^9$ &c. be propoſed, where the relations of the terms are, $B = \frac{1\times1}{2\times3}Ax^2$, $C = \frac{3\times3}{4\times5}Bx^2$, $D = \frac{5\times5}{6\times7}Cx^2$, &c. the equation defining

this

this *series* will be $T' = \frac{2z-1 \times 2z-1}{2z \times 2z+1} T x^2$, or $T' = \frac{4zz-4z+1}{4zz+2z} T x^2$, where the succeſſive values of z are 1, 2, 3, 4, &c. See Mr. *Stirling*'s *methodus differentialis*, in the introduction.

This may ſuffice to convey a notion of theſe differential equations, defining the nature of *ſeries's*. But as to the application of theſe equations in finding the ſums of *ſeries's*, it would require a treatiſe to explain it. We muſt therefore refer the curious to that excellent one juſt quoted, as alſo to Mr. de Moivre's *Miſcellanea Analytica*; and ſeveral curious papers by Mr. Euler in the acta Petropolitana.

A *ſeries* often converges ſo ſlowly as to be of no uſe in practice. Thus if it were required to find the ſum of the *ſeries* $\frac{1}{1.2} + \frac{1}{3.4} + \frac{1}{5.6} + \frac{1}{7.8} + \frac{1}{9.10} +$ &c. which lord Brounker found for the quadrature of the hyperbola true to 9 figures, by the mere addition of the terms of the *ſeries*, Mr. Stirling computes that it would be neceſſary to add a thouſand millions of terms for that purpoſe; for which the life of man would be too ſhort. But by that gentleman's method the ſum of the *ſeries* may be found by a very moderate computation. See Meth. Diff. p. 26, ſeq.

Recurring SERIES, is uſed for a *ſeries* which is ſo conſtituted, that having taken at pleaſure any number of its terms, each following term ſhall be related to the ſame number of preceding terms according to a conſtant law of relation.

Thus in the following *ſeries*,

A B C D E F

$1 + 2x + 3xx + 10x^3 + 34x^4 + 97x^5 +$ &c.

in which the terms being reſpectively repreſented by the capitals A, B, C, D, &c. we ſhall have

$D = 3Cx - 2Bxx + 5Ax^2$

$E = 3Dx - 2Cxx + 5Bx^3$

$F = 3Ex - 2Dxx + 5Cx^3$ &c.

Where it is evident, that the law of relation between D and E is the ſame as between E and F, each being formed in the ſame manner from the three terms which precede it in the *ſeries*.

The quantities $3x - 2xx + 5x^3$ taken together and connected with their proper ſigns is what Mr. de Moivre calls the *Index* or the *ſcale of relation*. Sometimes the bare coefficients $3 - 2 + 5$ are called the ſcale of relation. And this ſcale of relation ſubtracted from unity is called the *differential ſcale*. Thus in the foregoing *ſeries* the ſcale of relation being $3x - 2xx + 5x^3$, the differential ſcale will be $1 - 3x + 2xx - 5x^3$.

On the ſubject of recurring *ſeries* ſee Mr. de Moivre's Miſcellan. Analytic. p. 27. ſeq. and p. 72. ſeq. as alſo his doctrine of chances 2d Edit. p. 193. ſeq. and Mr. Euler's analyſ. infinit. Tom. I. p. 175. ſeq.

A recurring *ſeries*, with its ſcale of relation being given, the ſum of that *ſeries* continued *in infinitum* will alſo be given. For inſtance, ſuppoſe a *ſeries* $a + bx + cxx + dx^3 + ex^4 +$ &c. where the relation of the coefficient of any term to the coefficients of any two preceding terms may be expreſſed by $f - g$; that is, $e = fd - ge$; and $d = fc - gb$ &c. Then will the ſum of the *ſeries* continued *in infinitum* be, $\frac{a + bx - fax}{1 - fx + gxx}$

To facilitate the intelligence of this rule by a particular example, aſſume any *ſeries* whereof the two firſt coefficients are given, ſuch as 2 and 5, and ſuppoſe f and g to be reſpectively 2 and 1; then we ſhall have the following *ſeries*, $2 + 5x + 8xx + 11x^3 + 14x^4 + 18x^5 +$ &c.

And the ſum $= \frac{2 + 5x - 4x}{1 - 2x + xx} = \frac{2 + x}{1 - x^2}$

For the proof divide 1 by $1 - x^2$

$1 - 2x + xx)\ 1\ (1 + 2x + 3xx + 4x^3 +$ &c. which multiplied by $2 + x$

gives $2 + 4x + 6xx + 8x^3 +$ &c.

$+ x + 2xx + 3x^3 +$ &c.

the product $= 2 + 5x + 8xx + 11x^3 +$ &c. $=$ the given *ſeries*.

Analogous rules might be derived for more complex caſes; and Mr. de Moivre's general rule is,

1°. Take as many Terms of the *ſeries* as there are parts in the ſcale of relation. 2°. Subtract the ſcale of relation from unity, the remainder is the differential ſcale. 3°. Multiply the terms taken in the *ſeries* by the differential ſcale, beginning at unity, and ſo proceeding orderly, remembring to leave out what would naturally be extended beyond the laſt of the terms taken. Then will the product be the numerator, and the differential ſcale will be the denominator of a fraction expreſſing the ſum required.

But we muſt here obſerve that when the ſum of a recurring *ſeries* extended *ad infinitum* is found by Mr. de Moivre's rule, it ought to be ſuppoſed, that the *ſeries* converges indefinitely, that is, that the terms may become leſs than any aſſigned quantity. For, if the *ſeries* diverges, that is, if its terms continually increaſe, it is not true, that the rule gives the ſum. For the ſum in ſuch caſes is infinite, or greater than any given quantity, whereas the ſum exhibited by the rule will often be finite. The rule therefore in this caſe only gives a fraction, the reduction of which into a *ſeries* gives the propoſed *ſeries*. Thus $\frac{1}{1 - x^2}$ reduced to an infinite *ſeries* gives the recurring *ſeries* $1 + 2x + 3xx +$ &c. whoſe ſcale of relation is $2 - 1$, and its ſum by the rule will be $\frac{a + bx - fax}{1 - fx + gxx} = \frac{1 + 2x - 2x}{1 - 2x + xx} = \frac{1}{1 - x^2} =$ the quantity from which the *ſeries* aroſe. But this quantity cannot in all caſes be deemed equal to the infinite *ſeries* $1 + 2x + 3xx$ &c. For ſtop where you will, there will always be a ſupplement required to make the product of the quotient by the diviſor equal to the dividend. When the *ſeries*, indeed, converges infinitely, the ſupplement diminiſhing continually, it becomes leſs than any aſſigned quantity, and is therefore, without error, reputed nothing; but in diverging *ſeries*, this ſupplement becomes indefinitely great, and the *ſeries* deviates indefinitely from the truth. See Mr. *Colſon*'s comment on Sir *Iſ. Newton*'s method of fluxions and infinite *ſeries* p. 152. Mr. *Stirling*'s method. Differentialis p. 36. *Bernoulli*, de Serieb. infinit. p. 249. *Cramer*, Analyſe des lignes Courbes, p. 174.

A *recurring ſeries* being given, the ſum of any number of the terms of that *ſeries* may be found. This is prob. III. p. 73. Miſcel. Analyſ. and prop. V. p. 196. of the Doctrine of chances. One ſolution of the ſimpleſt caſe will be ſufficient to give an idea of the method there uſed.

Let there be a geometric progreſſion $a + ax + ax^2 + ax^3 +$ &c: it is required to find the ſum of a number n of its terms. Then will the laſt term be ax^{n-1}. Suppoſe the progreſſion continued *ad infinitum*, and we ſhall have two infinite progreſſions, the firſt beginning with a and the ſecond with ax^n. Now the difference of the ſum of theſe two muſt be the ſum of the number n of terms. By the rule the ſum of the firſt infinite progreſſion will be $\frac{a}{1 - x}$; and the ſum of the ſecond will be $\frac{ax^n}{1 - x}$. But $\frac{a}{1 - x} - \frac{ax^n}{1 - x} = \frac{a - ax^n}{1 - x}$, which will therefore be the ſum of a number n, of terms.

This quantity $\frac{a - ax^n}{1 - x}$ is equal to $\frac{ax^n - a}{x - 1}$, which laſt expreſſion, calling $ax^{n-1} = l$, will be equivalent to this, $\frac{lx - a}{x - 1}$, which is the common rule for finding the ſum of any geometric progreſſion of which a, the firſt term; x, the ratio; and l the laſt term are given.

The *ſeries* reſulting from the diviſion of unity by $\overline{1 - x^p}$ or $\frac{1}{1 - x^p} = \overline{1 - x}^{-p}$ is $1 + px + p \times \frac{p+1}{2} xx + p \times \frac{p+1}{2} \times \frac{p+2}{3} x^3 +$ &c. And the ſum of any number of terms expreſſed by n of this *ſeries* will be $\frac{\overline{1 - x}^n}{1 - x^p} - \frac{nx^n}{1 - x^{p-1}} - \frac{n}{1} \times \frac{n+1}{2} x^n - \frac{n}{1} \times \frac{n+1}{2} \times \frac{n+2}{3} x^n -$ &c. which is to be continued till the number of terms $= p$. See Miſcel. Analyſ. pag. 167. Doctrine of chances. p. 196. This theorem is of uſe in finding the ſums of progreſſions of figurate numbers, and others.

Suppoſe, for inſtance, it were required to find the ſum of any number n of terms of the geometric progreſſion $1 + x + xx + x^3 +$ &c. generated by $\frac{1}{1 - x}$. Here $p = 1$. And the ſum will conſequently be $= \frac{1 - x^n}{1 - x^p} = \frac{1 - x^n}{1 - x}$.

Again, if the ſum of a number n of terms of the *ſeries* $1 + 2x + 3xx + 4x^3 +$ &c. were required. The *ſeries* is generated from $\frac{1}{1 - x^2}$. Then $p = 2$. And the ſum $= \frac{1 - x^n}{1 - x^2} - \frac{nx^n}{1 - x}$. Suppoſe $x = 1$ then will the ſum be $\frac{nn + n}{2} = n \times \frac{n+1}{2}$ which is the ſum of the arithmetical progreſſion $1 + 2 + 3 + 4 +$ &c. continued to the number n of terms. But it is to be obſerved that it requires a particular artifice to derive this ſum from the general rule: for at firſt ſight the ſum appears under this form $\frac{1 - 1}{\overline{1 - 1}^2} - \frac{n}{1 - 1}$

$\frac{n}{1-1}$ which determines nothing. See Miſc. Analyſ. loc. cit.

In like manner, the ſum of a number n of terms of the *ſeries* of triangular numbers will be found to be $n \times \frac{n+1}{2} \times \frac{n+2}{3}$, as in Miſcel. Analyſ. p. 168.

By the like methods the ſum of any number of ſquares, cubes, &c. of the natural *ſeries* of numbers may be found. Which may alſo be done by Sir Iſaac Newton's differential method. See DIFFERENTIAL *method*, *Append.*

3° In a recurring *ſeries* any term may be obtained whoſe place is aſſigned. For after having taken ſo many terms of the *ſeries* as there are terms in the ſcale of relation, the *ſeries* may be protracted till it reach the place aſſigned. But if that place be very diſtant from the beginning of the *ſeries*, the continuation of the terms will prove laborious: other methods have therefore been contrived. See Miſcel. Analyſ. p. 33, ſeq. and Doct. of chances, p. 197, ſeq.

Theſe queſtions have been reſolved in many caſes, beſides thoſe of *recurring ſeries*. But as there is no univerſal method for the quadrature of curves, neither is there one for the ſummation of *ſeries*; there being a great analogy between theſe things, and ſimilar difficulties ariſing in both. See the authors before cited.

The inveſtigation of Mr. Daniel Bernoulli's method for finding the roots of algebraic equations, which is inſerted in the article EQUATION, *Suppl.* depends upon the doctrine of *recurring ſeries*. See *Euler*, Analyſis infinitorum, Tom. I. pag. 276, ſeq.

In general algebraic quantities may be expreſſed by a *ſeries*, either by diviſion or by the extraction of roots, in a method analogous to that uſed in arithmetic for expreſſing vulgar fractions and roots by decimals. And the conſideration of this analogy ſeems to have given riſe to Sir Iſaac Newton's doctrine of infinite *ſeries*. See his method of fluxions and infinite *ſeries* in the beginning.

But the ſame great author had alſo another method of throwing quantities into an infinite *ſeries*, by means of a general form aſſumed for that purpoſe. See FORM.

Interſcendent SERIES. See INTERSCENDENT *ſeries*.

Tranſcendental SERIES. See TRANSCENDENTAL *ſeries*.

Hyperbolic SERIES is uſed for a *ſeries* whoſe ſum depends upon the quadrature of the hyperbola. Such is the *ſeries* $\frac{1}{1} + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} +$ &c. *De Moivre*, Miſc. Analyſ. p. 111.

Circular SERIES, is uſed for a *ſeries* whoſe ſum depends on the quadrature of the circle. Such is the *ſeries* $1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \frac{1}{9} -$ &c. *De Moivre*, Miſc. Analyſ. p. 111. or the ſum of the *ſeries* $1 + \frac{1}{4} + \frac{1}{9} + \frac{1}{16} + \frac{1}{25} +$ &c. continued *ad infinitum*, according to Mr. Euler's diſcovery.

Mixt SERIES, that *ſeries* whoſe ſum depends partly on the quadrature of the circle and partly on that of the hyperbola. *De Moivre*, Miſc. Analyſ. p. 111.

Determinate SERIES, a *ſeries* the terms of which proceed by the powers of a determinate quantity. If that determinate quantity be unity, the *ſeries* is ſaid to be *determined by unity*. *De Moivre*, Miſcel. Analyſ. p. 111.

Reverſion of SERIES. See REVERSION *of ſeries*.

Summable SERIES, is uſed when the ſum of the terms of a *ſeries* may be found. Such is the *ſeries* $\frac{1}{2} + \frac{1}{4} + \frac{1}{8} +$, &c. the ſum of which is ſaid to be equal to unity, or, to ſpeak more accurately, the limit of whoſe ſum is unity. See the article PROGRESSION, *Suppl.*

An indefinite number of ſummable infinite *ſeries's* may be found: ſuch are, for inſtance, all infinite recurring *ſeries*, when converging, and many others, for which Meſſieurs De Moivre [a], Bernoulli [b], Stirling [c], Euler [d], and Mac Laurin [e], may be conſulted.—[[a] Miſcel. Analyſ. p. 110, ſeq. [b] De Serieb. infinit. paſſim. [c] Method. Different. p. 34, ſeq. [d] Acta Petropolit. paſſim. [e] Fluxions, Art. 350, ſeq. See alſo PROGRESSION, *Suppl.*]

SERMOUNTAIN, a name ſometimes given to the plant called *ſeſili*, or *ſiler* by authors. See the articles SESILI and SILER, *Suppl.*

SERPENT's *tongue*, or ADDER's *tongue*, names by which the *ophioglоſſum* of botaniſts is frequently called. See the article OPHIOGLOSSUM, *Suppl.*

SERPYLLUM (*Suppl.*) is alſo uſed by ſome as the name of a ſpecies of *thymbra*. See the article THYMBRA, *Suppl.*

SERVICE-*tree*, in botany, the Engliſh name of a genus of trees, called by botanical writers *ſorbus*. See the article SORBUS, *Suppl.*

Wild SERVICE, a name by which ſome call the *cratægus* of botanical writers. See the article CRATÆGUS, *Suppl.*

SESAMUM, *oily grain plant*, in botany, the name of a genus of plants, the characters of which are theſe. The cup is a one-leaved perianthium, divided into five ſegments; the uppermoſt of which is ſhorteſt. The flower conſiſts likewiſe of one petal of a campanulated form, and divided into five ſegments; of which the loweſt is by far the longeſt. The ſtamina are four filaments, ſhorter than the flower; the antheræ are oblong, acute, and erect. The germen of the piſtil is oval and rough; the ſtyle is filiform; the ſtigma is lanceolated, and divided into two parts. The fruit is an oblong capſule, containing four cells, in which are numerous ſeeds of an oval figure. *Linnæi* Gen. Plant. p. 293.

SESSION (*Suppl.*)—The court of *ſeſſion*, otherwiſe called the *college of juſtice*, is the ſupreme court in Scotland for all civil cauſes. It conſiſts of one conſtant preſident and fourteen other judges, who are lords by their office, which they hold by patent *quamdiu ſe bene geſſerint*. The Lord High Chancellor preſides here when preſent. The king names ſeveral other extraordinary lords, who ſit, but are not obliged to attendance, becauſe they have no ſalaries; but they may vote among the reſt.

The court ſits from the firſt of November, old ſtyle, to the laſt of February, and from the firſt of June to the laſt of July, all incluſive; which holds of all the inferior courts or judicatories in Scotland. In time of *ſeſſion*, or term, they ſit from nine o'clock to twelve in the forenoon, every day in the week but Sunday and Monday: ſometimes they ſit in the afternoon, to end concluded cauſes, or to hear ſuch long debates as the forenoon was too ſhort to hear, which gives a great diſpatch to cauſes that come before them. The lords, both ordinary and extraordinary, when in the inner houſe, ſit on a ſemicircular bench in their robes; where the advocates debate their clients cauſes before them. There are ſix principal clerks belonging to this court. Nine of the lords make a quorum in the inner houſe, otherwiſe they cannot vote in any caſe, except ſuch as are referred to one or more of the whole lords; and one of the ordinary lords (the preſident being always excepted) is weekly appointed judge in the outer houſe, for diſcuſſing of ordinary actions, and has ſix under clerks to attend him. He meddles with no extraordinary caſes, except where it is remitted to him by all the lords to be diſcuſſed in the outer houſe for diſpatch.

That the lords may have time to read informations, petitions, &c. and the ſuitors be eaſed of the trouble of going with them to their houſes, every lord has a box ſtanding upon a table in the waiting room in the inner houſe from two to four o'clock in the afternoon every day; wherein all who have papers to offer, may put them by a ſlit in the cover. Each of the principal clerks have alſo a box, and parties muſt put their bills, anſwers, or informations of cauſes to be reported, into the clerk of the proceſs's box.

The rolls of the court bring in all cauſes in their due order. Cauſes of the greateſt conſequence are at firſt adviſed by the whole lords in the inner houſe. Other cauſes are called of courſe before an ordinary in the outer houſe, who decides the controverſy, if clear, without farther trouble or expence; and, in caſe of difficulty, takes ſome little time to adviſe it himſelf, or to adviſe with the whole lords upon it. And if any of the parties think themſelves wronged by the ſentence of the ordinary, they may complain to the lords, and get their anſwer upon a bill. See *Chamb.* Preſ. State of Gr. Brit. p. 381, ſeq.

An appeal lies from this court to the Houſe of Lords.

SETTER-*wort*, a name by which hellebore is ſometimes called. See the article HELLEBORUS, *Suppl.*

SETTING, (*Suppl.*) among cock-maſters, is the placing a cock, that has fought ſo that he cannot ſtand, beak to beak againſt the other cock, and if he does not ſtrike the battle is won. Dict. Ruſt. in voc.

SETTING *down*, in falconry, is when a hawk is put into the mew. Id. ibid.

SETTING-*dog*, one trained up to find out and diſcover to the ſportſman whereabouts fowl are.

SETTS *for ſaws*, inſtruments for ſetting their teeth when out of order. *Blanckley*, Nav. Expoſ. p. 145.

SETWELL, in botany, a name ſometimes uſed for a ſpecies of *valerian*. See the article VALERIAN, *Suppl.*

SEWEL, among ſportſmen, denotes any thing that is ſet or hung up, to keep a deer out of any place. Ruſt. Dict. in voc.

SEYMS, among farriers. See SEAMS.

SHADDOCK, in botany, the name by which ſome call a ſpecies of orange. See the article ORANGE, *Suppl.*

SHAKLES, aboard a ſhip. See SHACKLES, *Suppl.*

SHAKY, or SHAKEN, among builders, an appellation given to timber which is cracked either with the heat of the ſun, or the drought of the wind. Build. Dict. in voc.

SHAVE-*graſs*, a name ſometimes uſed for the *equiſetum*, or horſe-tail. See the article EQUISETUM, *Suppl.*

SHAVING-*irons*, among gardeners, tools to keep a garden free from weeds, otherwiſe called *edging-irons*. Ruſt. Dict. in voc.

SHAW (*Suppl.*)—SHAW-*fowl*, an artificial bird, made for fowlers to ſhoot at. Ruſt. Dict. in voc.

SHEAT, or SHUT, a name by which ſome call a young hog. Ruſt. Dict. in voc.

SHELDAPLE, a name uſed in ſeveral parts of the kingdom for the chaffinch. Ruſt. Dict. in voc.

SHELL (*Suppl.*)—*Caterpillar*-SHELL, the Engliſh name of a ſpecies of *turbo*. See the article TURBO, *Suppl.*

Crown imperial SHELL, the Engliſh name of a ſpecies of *voluta*. See the article VOLUTA, *Suppl.*

Chalice-SHELL, or *cup*-SHELL, the Engliſh name of a ſpecies of *balanus*. See the article BALANUS, *Suppl.*

Dog-tooth SHELL, the Engliſh name of a ſpecies of *dentale*. See the article DENTALE, *Suppl.*

Needle-SHELL, the Engliſh name of a ſpecies of *centronia*. See the article CENTRONIA, *Append.*

Needle-SHELL. See the article NEEDLE, ſupra.

Scorpion-SHELL, or *Spider*-SHELL, names uſed for a ſpecies of *murex*. See the article MUREX, *Suppl.*

Tiger-SHELL, the Engliſh name of the red *voluta* with large white ſpots. See the article VOLUTA, *Suppl.*

Toe-SHELL, the Engliſh name of a genus of *ſhells*, otherwiſe called *pollicipes*. See the article POLLICIPES, *Suppl.*

Turtle-SHELL, the Engliſh name of two ſpecies of different kinds of *ſhells*, the *murex* and *voluta*. See the articles MUREX and VOLUTA, *Suppl.*

SHELL-*drake*, in zoology, a common Engliſh name for the *tadorna*. See the article TADORNA.

SHEPHERD, in country affairs, a perſon who keeps or looks after ſheep. Dict. Ruſt. in voc.

SHEPHERD'*s needle*, a name by which the *ſcandex* of botaniſts is ſometimes called. See the article SCANDEX, *Suppl.*

SHEPHERD'*s pouch*, *alyſſon*, in botany, the name of a diſtinct genus of plants, otherwiſe called *madwort*. See the article ALYSSON, *Suppl.*

SHEPHERD'*s ſtaff*, or SHEPHERD'*s rod*, in botany, names given to the *dipſacus* of botanical writers. See the article DIPSACUS, *Suppl.*

SHERBET, or SHERBIT, a compound drink, firſt brought into England from Turkey and Perſia, conſiſting of fair water, lemon juice, ſugar, amber, and other ingredients. Another kind of it is made of violets, honey, juice of raiſins, *&c.*

The word *ſherbet*, in the Perſian language, ſignifies *pleaſant liquor*. Dict. Ruſt. in voc.

SHRIMP, the Engliſh name of the common *ſquilla* with a long tail, and the ſnout ſerrated above, and tridentated below. See the article SQUILLA, *Append.*

SHROVE, in zoology, the ſame with *ſhrew*. See the article SHREW, *Suppl.*

SHUT, among farmers. See SHEAT, *Append.*

SICYANIA, the *gourd-worm*, the name of a genus of worms; the body of which is of an oblong form, flat on the belly, and rounded on the back; its ſkin is ſoft, and its mouth large, horizontal, and emarginated, or dented in the middle. It reſembles the common gourd in figure, and from thence has got this name of *vermis cucurbitinus*, or the *gourd-worm*. It is frequently found in the inteſtines of animals. *Hill*, Hiſt. Anim. p. 16.

SIDE-*ſaddle-flower*, a name ſometimes given to the *ſarracena* of botanical writers. See the article SARRACENA, *Suppl.*

SIDEROCHITA, in natural hiſtory, a claſs of cruſtated ferrugineous bodies, of a moderately firm and compact texture, compoſed of ferrugineous mixed with earthy matter, and formed of repeated incruſtations, making ſo many coats or cruſts round a ſofter or harder nucleus, or round looſe earths, or an aqueous fluid. Vid. *Hill*, Hiſt. Foſſ. p. 531. Under this claſs are comprehended the *empherepyra*, *heteropyra*, *geodes*, and *enhydri*. See the article EMPHEREPYRA, &c. *Append.*

SIDEROXYLUM, in the Linnæan ſyſtem of botany, the name of a diſtinct genus of plants, the characters of which are theſe: the cup is a ſmall erect perianthium, compoſed of a ſingle leaf, divided into five ſegments, and permanent. The flower conſiſts of a ſingle petal, divided into five roundiſh, erect, concave ſegments; and, at the baſe of every one of theſe, there is placed a cuſpidated, ſerrated denticle, bending inwards. The ſtamina are five ſubulated filaments, of the length of the flower: the antheræ are ſimple: the germen of the piſtil is roundiſh; the ſtyle is ſubulated, and of the length of the ſtamina; the ſtigma is ſimple. The fruit is a roundiſh berry, containing only one cell. The ſeeds are four in number. *Linnæi* Gen. Plant. p. 81.

SILK-*graſs*, a name uſed for two very different genuſes of plants, the *aloe* and *dog's bane*. See the articles ALOE and DOG'S BANE, *Suppl.*

SILK-*machine*. See the article MACHINE, *Append.*

SILVER-*bruſh*, a name ſometimes given to the *barba jovis* of botaniſts. See the article BARBA-*jovis*, *Suppl.*

SILVER-*weed*, *potentilla*, or *argentina*, in botany, the name of a diſtinct genus of plants. See the articles ARGENTINA and PENTAPHYLLOIDES, *Suppl.*

SILVERING (*Cycl.*)—This is a ſpecies of gilding, and may be done thus: take as much aqua fortis as you think there is occaſion for, put it into a glaſs, which ſet in warm aſhes; then put in your quantity of ſilver, after having beaten it very thin, and cut it into little ſhreads. When the ſilver is diſſolved, take it off the aſhes; and, mixing that liquid with as much white tartar as will make it like paſte; rub with this mixture the metal you want to ſilver. Copper, braſs, or any other metal may be thus made to appear like ſilver itſelf. Copper, braſs, ſteel, or iron may be *ſilvered*, ſo as not to come off, unleſs made red-hot, in the following manner. Take urine which is made in the morning, cover it, and let it ſtand a whole month, and it will ferment; put it afterwards into an earthen pot, and let it boil; ſkim it, and when the third part is evaporated, take to two pints of urine one ounce of tartar, and one ounce of galiz-ſtone; mix them all together, and let them boil once up. When you would *ſilver* any metal, rub it well with brick-duſt on a wet woollen rag, till it is clean and fine, then put it twenty-four hours in the prepared urine; afterwards dry it, and where you deſign to *ſilver*, rub it over with quick-ſilver, which muſt be laid on thin with an iron ſpatula that has alſo lain two hours in urine. The quick-ſilver thus laid on, muſt be then rubbed on with a ſoft woollen rag, and it will make a fine *ſilvering*.

Braſs may be *ſilvered*, by boiling it with filings of good pewter and white tartar, in equal quantities. There are ſeveral other methods of *ſilvering*, for which ſee *Smith*'s Laboratory, p. 37. ſeq.

SINGLE (*Suppl.*)—SINGLE, among ſportſmen, the tail of a buck, or any of the deer kind. Ruſt. Dict. in voc.

SISON, the officinal name of a ſpecies of *ſium*. See the article SIUM, *Suppl.*

SKEETS, in the ſea language, narrow oblong ladles, for weting the ſails or ſides of a ſhip. *Blanckley*'s Nav. Expoſ. p. 152.

SKEPE, or SKUTTLE, in country affairs, a ſort of flat, broad baſket for winnowing of corn. Dict. Ruſt. in voc.

SKIDS, wooden fenders laid on the outſide of a ſhip for the conveniency of hoiſting things into the ſhip. *Blanckley*'s Nav. Expoſ. p. 152.

SKREEN. See SCREEN, *Append.*

SLEEPER, in zoology, a name peculiarly given to the dormouſe, or *mus avellanorum* of authors. See the article MUS, *Suppl.*

SLEEPER, in building, a name uſed for the oblique rafter that lies in a gutter. Build. Dict. in voc.

SLIPPER (*Suppl.*)—*Lady*'s SLIPPER, the Engliſh name of a genus of plants, called by botaniſts *helleborine*. See the article HELLEBORINE, *Suppl.*

SLIPPER is alſo a name ſometimes uſed for a *plinth*. See the article PLINTH, *Cycl.*

SLOTH, in zoology. See SLOATH, *Suppl.*

SNAIL, in the hiſtory of inſects, the Engliſh name for the *limax*. See the articles SNAIL, *Suppl.* and LIMAX, *Append.*

SNAIL is alſo the name of the animal inhabiting many kinds of ſhells, as the patella, cochlea, nerite, buccinum, turbo, trochus, voluta, murex, purpura, lyra, and concha veneris. *Hill*, Hiſt. Anim. p. 114. See the articles PATELLA, COCHLEA, *&c.*

SNAIL *trefoil*. See the article TREFOIL, infra.

SNAKE (*Suppl.*)—*Coach-whip*-SNAKE, the name by which ſome call a ſpecies of *coluber*. See the article COLUBER, *Append.*

Corn-SNAKE, the name of another ſpecies of *coluber*.

Necklace-SNAKE, the Engliſh name of the *natrix torquata* of zoologiſts. See the article NATRIX, *Suppl.*

Sand-SNAKE, the Engliſh name of a kind of ſerpent found in Lybia, and ſome parts of Italy. See the article AMMODYTES, *Suppl.*

SNAKE-*root*, *ariſtolochia*, in botany, the name of a genus of plants, otherwiſe called *birthwort*. See the article ARISTOLOCHIA, *Suppl.*

Rattle-SNAKE-*root*, a name ſometimes given to *polygala*, a diſtinct genus of plants. See the article POLYGALA, *Suppl.*

SNAP-*tree*, *adhatoda*, in botany, the name of a diſtinct genus of trees. See the article ADHATODA, *Suppl.*

SNEAD, or SNEATH, in country affairs, the handle of a ſcythe, or the like tool. Ruſt. Dict. in voc.

SNEEZE-*wort*, *ptarmica*, in botany, the Engliſh name of a diſtinct genus of plants. See the article PTARMICA, *Suppl.*

SNET, among ſportſmen, denotes the fat of all kinds of deer. Ruſt. Dict. in voc.

SNIPE (*Suppl.*)—*Mire*-SNIPE, the name uſed in ſome parts of the kingdom for the *ardea ſtellaria*, or bittern. See the article BITTERN, *Suppl.*

SNIPE-*bills*, in the ſea language, a kind of hooks uſed for faſtening the axel-trees of the chain-pumps to the bitts. *Blanckley*'s Nav. Expoſ.

SNOW-*drop*, the Engliſh name of a diſtinct genus of plants, according to Linnæus, who calls it *galanthus*, but is made only a ſpecies of *narciſſo-leucoium* by *Tournefort*. See the article NARCISSO-LEUCOIUM, *Suppl.*

SNOW-*drop-tree*, the Engliſh name of a genus of trees, called by botaniſts *chionanthus*. See the article CHIONANTHUS, *Append.*

SOAP-*berry-tree*, *ſapindus*, in botany, the name of a genus of trees. See the article SAPINDUS. *Suppl.*

SOAP-*wort*, the Engliſh name of the *ſaponaria* of botaniſts. See SAPONARIA, *Append.*

SOAR (*Suppl.*)—SOAR-*age*, in falconry, denotes the firſt year of a hawk's age. Ruſt. Dict. in voc.

SOLAN-

SOLANDERS, in farriery. See MALANDERS, *Cycl.*

SOLANOIDES, in botany, the name of a genus of plants, called by Linnæus *rivinia*. See the article RIVINIA. *Suppl.*

SOLDIER (*Suppl.*)—Not only humanity but intereſt require that great care ſhould be taken of the health of *ſoldiers*. Much inſtruction may be drawn for this purpoſe from Dr. Pringle's excellent treatiſe, called obſervations on the diſeaſes of the army. He there remarks, that the circumſtances of *ſoldiers* in time of war, differ from thoſe of other people, in that they are more expoſed to the injuries of the weather, and always crouded together, whether in camp, barracks, or hoſpitals: wherefore the moſt general diviſion of theſe diſtempers, may be into ſuch as ariſe from the intemperature of the weather, and thoſe from infection.

Military diſeaſes depending on the weather, are reducible to two ſorts, *viz.* to thoſe of ſummer, and to thoſe of winter. However, as expoſitions to cold are unavoidable upon the firſt encampment, as alſo for ſome time before the army uſually goes into winter-quarters, the winter diſorders beginning about the end of autumn, will not entirely ceaſe before the ſummer is well advanced; and, on the other hand, as the heats of ſummer and damps of autumn diſpoſe the body to ſickneſs, the camp-diſtempers are never quite over with the campaign, but continue ſome time after the troops retire into winter-quarters.

The ſummer diſeaſes are all of a bilious or putrid nature, as thoſe of winter are inflammatory. See BILIOUS and INFLAMMATORY, *Append.*

Diſeaſes of SOLDIERS, ariſing from heat and cold. See the articles HEAT and COLD, *Append.*

Diet of SOLDIERS. See DIET, *Append.*

Exerciſe of SOLDIERS. See EXERCISE. See alſo the articles CAMP, HOSPITAL, FEVER, &c.

Freſh-water SOLDIER, a name given in ſeveral parts of England to the *ſtratiotes*, a diſtinct genus of plants, called by Boerhaave *aloides*. See the article STRATIOTES, *Append.*

SOLEMN *acceptance*. See ACCEPTANCE, *Cycl.*

SOLIDAGO, in the Linnæan ſyſtem of botany, the name of a very comprehenſive genus of plants, taking in the *virga aurea* of Tournefort, with ſeveral ſpecies of the *jacobæa* of the ſame author. *Linnæi* Gen. Plant. p. 403. See the article VIRGA *aurea*, *Suppl.*

The great characteriſtic of this genus, is, that the receptacle is naked, the down ſimple, the ſquamæ of the cup imbricated, and the radii of the corollulæ about five.

SOLINE, among carpenters, a joiſt, rafter, or piece of wood, either ſlit or ſawed, wherewith the builders lay their ceilings. Build. Dict. in voc.

The word is French.

SOLOMON's *ſeal*, the Engliſh name of a diſtinct genus of plants, called by botaniſts *polygonatum*. See the article POLYGONATUM, *Suppl.*

SOPES. See the article SOAP, *Cycl.* and *Suppl.*

SOPHIA *chirurgorum*, a name ſometimes given to a ſpecies of *ſiſymbrium*. See the article SISYMBRIUM, *Suppl.*

SORREL (*Suppl.*)—*Wood* SORREL, the Engliſh name of a genus of plants, called by botaniſts *lujula*, or *oxys*. See the article OXYS, *Suppl.*

Indian SORREL, a name ſometimes given to *ketmia*. See the article KETMIA, *Suppl.*

SOURE-*ſop*, or SOWRE *ſop*, in botany, a diſtinct genus of plants, called by botaniſts *guanabanus* and *anona*. See the article ANONA, *Suppl.*

SPACE (*Cycl.*)—Some authors have aſſerted that *ſpace* is a ſubſtance. The Carteſians, who do not allow of any diſtinction between *ſpace* and matter, were naturally enough led to the opinion, that *ſpace* or extenſion was a ſubſtance. Others who admit a vacuum, and conſequently an eſſential difference between *ſpace* and matter, aſſert alſo that *ſpace* is a ſubſtance. Among theſe we find *s'Graveſande*, Introd. ad Philoſ. ſect. 19.

Others put *ſpace* into the ſame claſs of beings as time and number; that is, they make it to be no more than a notion of the mind. Hence, according to theſe authors, abſolute *ſpace*, of which the Newtonians ſpeak, is a mere chimera. See the writings of the late biſhop of Cloyne, *paſſim.*

SPADE (*Suppl.*)—SPADE alſo denotes any gelded beaſt, or a deer three years old. Ruſt. Dict. in voc.

SPAID, or SPAYD, a term uſed by ſportſmen for a red male deer that is three years old. Ruſt. Dict. in voc.

SPANISH-*broom*, *ſpartium*, in botany. See the article SPARTIUM, *Suppl.*

SPANSHAKLE, aboard a ſhip, a large claſp of iron, which goes round the end of the davit upon the forecaſtle. *Blanckley*, Naval Expoſitor, p. 155.

SPARING, among cock-fighters. See the article SPARRING, *Suppl.*

SPARROW (*Suppl.*)—*Reed*-SPARROW, the Engliſh name of a bird of the *picus*, or wood-pecker kind. See the article REED-*ſparrow*, *Suppl.*

SPARROW-*hawk*, the Engliſh name of the yellow-legged *falco*, with a white undulated breaſt, and a faſciated brown tail. See the article FALCO, *Suppl.*

SPAT, a term uſed by the fiſhermen for the ſpawn of oyſters, which is caſt in the month of May. Dict. Ruſt. in voc.

SPEAR-*mint*, in botany, the Engliſh name of the narrow-leaved, aromatic-ſcented mint. See the articles MINT and MENTHA, *Suppl.*

SPERGULA, *ſpurry*, in the Linnæan ſyſtem of botany, makes a diſtinct genus of plants, but is comprehended by Tournefort among the *alſines*. See the article ALSINE, *Suppl.*

SPHERES, poliſhed ſpherical maſſes of a mixt metalline compoſition, uſed in optics. The manner of making them is as follows. Take of pure tin three pounds, copper one pound; melt theſe two metals together, and when in fuſion caſt upon the maſs ſix ounces of burnt tartar, and an ounce and half of ſalt petre; and laſtly, a quarter of an ounce of alum, and two ounces of arſenic: let all theſe matters evaporate and burn away, and then caſt the pure metal into the figure of a *ſphere*, and it will be capable of a high and elegant poliſh. *Neri*'s Art of Glaſs, p. 166.

SPIDER-*ſhell*, the Engliſh name of ſeveral ſpecies of *murex*. See the article MUREX, *Suppl.*

SPIDER-*wort*, (*Suppl.*) is alſo the name by which many call the *ephemerum* of botanical writers. See the article EPHEMERUM, *Suppl.*

SPIKES (*Suppl.*)—The word *ſpikes*, among botaniſts, denotes flowers ſet thick above each other. Dict. Ruſt. in voc.

SPIKE-*lavender*. See the article LAVENDULA, *Suppl.*

SPIKENARD, (*Cycl.*) *nardus*, in botany. See the article NARDUS, *Suppl.*

Ploughman's SPIKENARD, the Engliſh name of a genus of plants, otherwiſe called *conyza*, and *flea-bane*. See the article FLEA-*bane*, *Suppl.*

SPILES, in a ſhip, are ſmall wooden pins, which are driven into the nail-holes, when a ſhip's ſheathing is taken off. *Blanckley*, Naval Expoſitor, p. 156.

SPINACH (*Suppl.*)—*Strawberry*-SPINACH, a name ſometimes given to *blite*. See the article BLITUM, *Suppl.*

SPINDLE (*Suppl.*)—The ſtaff which ſupports the vane at the maſt-head, is likewiſe called a *ſpindle*. *Blanckley*, Naval Expoſitor, p. 156.

SPINDLE-*ſhell*, the Engliſh name of a ſpecies of buccinum. See the article TRUMPET-*ſhell*, *Suppl.*

SPINDLE-*tree*, the Engliſh name of a genus of trees, called by botaniſts *euonymus*. See the article EUONYMUS, *Suppl.*

African SPINDLE-*tree*, the Engliſh name of a genus of plants, called *euonymoides* and *celaſtrus* by authors. See the article CELASTRUS, *Append.*

SPINDLING, a term uſed by gardeners for the firſt appearance or putting forth of flowers, ſtems; or their running up in length. Ruſt. Dict. in voc.

SPIRKETTING, among ſhip-carpenters, denotes ſtrakes of thick plank wrought from the lower edge of each port to each deck reſpectively within ſide of the ſhip. *Blanckley*, Naval Expoſitor, p. 156.

SPIT-*deep*, a term uſed among farmers for a ſoil as deep as can be dug up at once with a *ſpit* or ſpade. Dict. Ruſt. in voc.

SPITTER, among ſportſmen, a red male deer near two years old, whoſe horns begin to grow up ſharp and ſpitwiſe. It is otherwiſe called a *brocket* and *pricket*. Ruſt. Dict. in voc.

SPLEEN-*wort*, a name ſometimes uſed for a genus of plants, called by botaniſts *aſplenium*, and in Engliſh more commonly *milt-waſte*. See the article ASPLENIUM, *Suppl.*

SPOON-*bill*, in ornithology, the Engliſh name of the *platea*. See the article PLATEA, *Suppl.*

SPOON-*wort*, a name by which ſome call the *cochlearia*, or ſcurvy-graſs. See the article COCHLEARIA, *Suppl.*

SPRAINTS, among ſportſmen, a term uſed for the dung of the otter. Ruſt. Dict. in voc.

SPRAT, the Engliſh name of the little *clupea*, with the lower jaw longeſt, and the belly very acute. See the article CLUPEA, *Suppl.*

SPROUTS, a word uſed by country people for ſmall ſhoots of old cabbage. Ruſt. Dict. in voc.

SPUNK, a term uſed indifferently for half-rotten wood, match for guns, and a ſubſtance growing on the ſides of trees. Dict. Ruſt. in voc.

SPUR-*ſhell*, a name ſometimes given to the little elevated *cochlea*, with the edge of the volutions ſerrated. See the article COCHLEA, *Suppl.*

SPURGE-*olive*, the Engliſh name of a genus of plants, called by botaniſts *chamelæa*. See the article CHAMELÆA, *Suppl.*

Sun-SPURGE, a name by which ſome call ſeveral ſpecies of *tithymalus*. See the article TITHYMALUS, *Suppl.*

SQUASH, the Engliſh name of a genus of plants, called by authors *melopepo*. See the article MELOPEPO, *Suppl.*

SQUILL, *ſquilla*, in zoology, a large genus of animals, comprehending the ſhrimp or *ſquilla*, properly ſo called, the cray-fiſh, the crab, and lobſter: all which, according to Dr. Hill, make one genus of inſects, of the podaria kind. See the articles INSECT, *Suppl.* and *Append.* and PODARIA, *Append.*

The characteriſtics of this genus are, that they have ten legs, the foremoſt pair cheliform, or made for pinching and holding

holding things; that they have only two eyes, and that the tail is foliated.

The *squillæ* may be conveniently arranged under three ſubdiviſions. 1. The ſmaller long-tailed *squillæ*, commonly called *ſhrimps*. 2. The larger long-tailed *squillæ*, or the *lobſter* and *cray-fiſh* kind. 3. The ſhort-tailed kind, called alſo *canceres*, and in Engliſh *crabs*.

Of thoſe denominated *ſhrimps* we have the following ſpecies. 1. The long-tailed *squilla*, with the ſnout ſerrated above, and tridentated below. This is the common *ſhrimp*. 2. The long-tailed *squilla*, with a ſmooth ſnout, called the ſmooth-noſed *ſhrimp*. 3. The long-tailed *squilla*, with a ſoft tail, and the right claw largeſt. This is called the *hermit*. 4. The larger, long-ſnouted ſea-*squilla*. 5. The ſmaller, narrow-ſnouted ſea-*squilla*. 6. The freſh-water ſmall *squilla*.

Of the ſecond order of *squillæ*, commonly called *lobſters*, or *cray-fiſh*, we have the following ſpecies. 1. The common *lobſter*. 2. The thick-horned, ſlender-bodied *lobſter*. 3. The ſhort and broad-bodied *lobſter*. 4. The very long-bodied *lobſter*. 5. The ſmall-bodied *lobſter*. 6. The great ſea *cray-fiſh*. 7. The *cray-fiſh* with the ſnout ſerrated above, and with a ſingle denticulation at the baſe. This laſt ſpecies, though only three inches and an half in length, greatly approaches to the figure of the common *lobſter*.

Of thoſe *squillæ*, called *crabs*, *canceres*, there are the following ſpecies. 1. The common large *crab*. 2. The *wart-crab*, *cancer verrucoſus*. 3. The *ſpider-crab*, or long-legged, ſhort-tailed *squilla*. 4. The *king-crab*, or *molucca-crab*, called the *squilla clypeata*. 5. The rough-bodied, ſmooth-clawed *squilla*, called *cancer mæas*. 6. The ſmooth and long-clawed *crab*, called by Johnſton the female of the common kind. 7. The little ſquall *crab*. 8. The little woolly *crab*. 9. The thick-bodied duck *crab*. 10. The round-bodied duck *crab*. 11. The common, or oval-bodied duck *crab*. 12. The very long-armed duck *crab*. 13. The very ſmall-bodied, rough, long-armed *crab*. 14. The lunar *crab*. 15. The florid *crab*. 16. The frog *crab*. 17. The prickly and hairy, long-armed *crab*. 18. The great prickly, long-armed *crab*. 19. The ſhort-bodied, reticulated *crab*. 20. The elliptic-bodied *crab*. 21. The ſmooth, long-legged *crab*. Vid. *Hill*, Hiſt. Anim. p. 28, ſeq. and Table of Cruſtaceous Animals, N° 18, 19, *&c.*

SQUILL, *ſcilla*, in botany, the Engliſh name of a diſtinct genus of plants. See the article SCILLA, *Append.*

SQUILL, *ſcilla*, in botany, the Engliſh name of a diſtinct genus of plants, according to Linnæus; but comprehended under the *ornithogala* by Tournefort. See the article ORNITHOGALUM, *Suppl.*

STAFF (*Suppl.*)—*Shepherd's* STAFF, or *ſhepherd's rod*, in botany, the name of a genus of plants, called by botaniſts *dipſacus*. See the article DIPSACUS, *Suppl.*

STAG-*beetle*, in the hiſtory of inſects, the Engliſh name of a ſpecies of *ſcarabæus*, with ramoſe horns. See the article SCARABÆUS, *Suppl.*

STAG's *horn-tree*, a name ſometimes given to the *rhus*, or ſumach, a diſtinct genus of plants. See the article RHUS, *Suppl.*

STAGGARD, among ſportſmen, a young male deer only four years old. Ruſt. Dict. in voc.

STAINING (*Suppl.*)—STAINING *of horn*. See the article HORN, *Append.*

STAINING *of ivory*. See IVORY, *Append.*

STANDARD (*Suppl.*)—STANDARDS, in ſhip-building, a ſort of knees fayed from the deck to the ſides of the ſhip within board, to ſtrengthen her. *Blanckley*, Naval Expoſitor, in voc.

STAPHYLÆA, in the Linnæan ſyſtem of botany, the name of a genus of plants, called by Tournefort *ſtaphylodendron*. See the article STAPHYLODENDRON, *Suppl.*

STAPHYLINUS, in zoology, the name of a genus of four-winged flies, the antennæ of which are ſlender and filiform. There are two veſicles ſituated above the tail. The exterior wings are dimidiated and ſhort.

Of this genus there are a great many ſpecies, diſtinguiſhed from each other by the colour of the ſeveral parts of their bodies. Vid. *Hill*, Hiſt. Anim. p. 57.

STAR (*Suppl.*)—Our excellent aſtronomer, Dr. Bradley, had no ſooner diſcovered the cauſe, and ſettled the laws of the aberration of the fixed *ſtars* [b], than his attention was again excited by another new phænomenon, *viz.* an annual change of declination in ſome of the fixed *ſtars*, which appeared to be ſenſibly greater than a proceſſion of the equinoctial points of 50″ in a year, the mean quantity now uſually allowed by aſtronomers, would have occaſioned.—[b See the article LIGHT, *Append.*]

This apparent change of declination was obſerved in the *ſtars* near the equinoctial colure; and there appearing at the ſame time an effect of a quite contrary nature, in ſome *ſtars* near the ſolſtitial colure, which ſeemed to alter their declination leſs than a proceſſion of 50″ required, Dr. Bradley was thereby convinced, that all the phænomena in the different *ſtars* could not be accounted for merely by ſuppoſing that he had aſſumed a wrong quantity for the proceſſion of the equinoctial points. He had alſo, after many trials, ſufficient reaſon to conclude, that theſe ſecond unexpected deviations of the *ſtars* were not owing to any imperfection of his inſtruments. At length, from repeated obſervations, he began to gueſs at the real cauſe of theſe phænomena.

It appeared from the Doctor's obſervations, during his reſidence at Wanſted, that ſome of the *ſtars* near the ſolſtitial colure had changed their declinations 9″ or 10″ leſs than a proceſſion of 50″ would have produced; and, at the ſame time, that others near the equinoctial colure had altered theirs about the ſame quantity more, than a like preceſſion would have occaſioned: the north pole of the equator ſeeming to have approached the *ſtars*, which come to the meridian with the ſun, about the vernal equinox and the winter ſolſtice; and to have receded from thoſe, which come to the meridian with the ſun, about the autumnal equinox and the ſummer ſolſtice.

From the conſideration of theſe circumſtances, and the ſituation of the aſcending node of the moon's orbit when he firſt began to make his obſervations, he ſuſpected that the moon's action upon the equatorial parts of the earth might produce theſe effects. For, if the preceſſion of the equinox be, according to Sir Iſaac Newton's principles, cauſed by the actions of the ſun and moon upon thoſe parts; the plane of the moon's orbit being, at one time, above ten degrees more inclined to the plane of the equator, than at another; it was reaſonable to conclude, that the part of the whole annual preceſſion, which ariſes from her action, would in different years be varied in its quantity; whereas the plane of the ecliptic, wherein the ſun appears, keeping always nearly the ſame inclination to the equator, that part of the preceſſion, which is owing to the ſun's action, may be the ſame every year; and from hence it would follow, that although the mean annual preceſſion, proceeding from the joint actions of the ſun and moon, were 50″; yet the apparent annual preceſſion might ſometimes exceed, and ſometimes fall ſhort of that mean quantity, according to the various ſituations of the nodes of the moon's orbit.

In the year 1727, the moon's aſcending node was near the beginning of Aries, and conſequently her orbit was as much inclined to the equator, as it can at any time be; and then the apparent annual preceſſion was found, by the Doctor's firſt year's obſervations, to be greater than the mean; which proved, that the *ſtars* near the equinoctial colure, whoſe declinations are moſt of all affected by the preceſſion, had changed theirs, above a tenth part more than a preceſſion of 50″ would have cauſed. The ſucceeding year's obſervations proved the ſame thing; and in three or four years time the difference became ſo conſiderable, as to leave no room to ſuſpect that it was owing to any imperfection either of the inſtrument, or obſervations.

But ſome of the *ſtars*, that were near the ſolſtitial colure, having appeared to move, during the ſame time, in a manner contrary to what they ought to have done, by an increaſe of the preceſſions; and the deviations in them being as remarkable as in the others, it was evident that ſomething more than a mere change in the quantity of the preceſſion would be requiſite to ſolve this part of the phænomenon. Upon comparing the obſervations of *ſtars* near the ſolſtitial colure, that were almoſt oppoſite to each other in right aſcenſion, they were found to be equally affected by this cauſe. For whilſt γ Draconis appeared to have moved northward, the ſmall *ſtar*, which is the 35th Camelopardali Hevelii, in the Britiſh catalogue, ſeemed to have gone as much towards the ſouth; which ſhewed, that this apparent motion in both thoſe *ſtars* might proceed from a nutation in the earth's axis; whereas the compariſon of the Doctor's obſervations of the ſame *ſtars*, formerly enabled him to draw a different concluſion, with reſpect to the cauſe of the annual aberrations ariſing from the motion of light. For the apparent alteration in γ Draconis, from that cauſe, being as great again as in the other ſmall *ſtar*, proved, that that did not proceed from a nutation of the earth's axis; as, on the contrary, this may. Upon making the like compariſon between the obſervations of other *ſtars*, that lie nearly oppoſite in right aſcenſion, whatever their ſituations were with reſpect to the cardinal points of the equator, it appeared, that their change of declination was nearly equal, but contrary; and ſuch as a nutation or motion of the earth's axis would effect.

The moon's aſcending node being got back towards the beginning of Capricorn in the year 1732, the *ſtars* near the equinoctial colure appeared about that time to change their declinations no more than a preceſſion of 50″ required; whilſt ſome of thoſe near the ſolſtitial colure altered theirs above 2″ in a year leſs than they ought. Soon after the annual change of declination of the former was perceived to be diminiſhed, ſo as to become leſs than what 50″ of preceſſion would cauſe; and it continued to diminiſh till the year 1736, when the moon's aſcending node was about the beginning of Libra, and her orbit had the leaſt inclination to the equator. But by this time, ſome of the *ſtars* near the ſolſtitial colure had altered their declinations 18″ leſs, ſince the year 1727, than they ought to have done from a preceſſion of 50″. For γ Draconis, which in thoſe nine years ſhould have gone about 8″ more ſoutherly, was obſerved

in 1736, to appear 10″ more northerly than it did in the year 1727.

As this appearance in γ Draconis indicated a diminution of the inclination of the earth's axis to the plane of the ecliptic, and as ſeveral aſtronomers have ſuppoſed that inclination to diminiſh regularly; if this phænomenon depended upon ſuch a cauſe, and amounted to 18″ in nine years, the obliquity of the ecliptic would, at that rate, alter a whole minute in thirty years; which is much faſter than any obſervations before made, would allow. The Doctor had therefore reaſon to think that ſome part of this motion at leaſt, if not the whole, was owing to the moon's action upon the equatorial parts of the earth; which he conceived might cauſe a libratory motion of the earth's axis. But as he was unable to judge, from only nine years obſervations, whether the axis would entirely recover the ſame poſition that it had in the year 1727, he found it neceſſary to continue his obſervations through a whole period of the moon's nodes; at the end of which he had the ſatisfaction to ſee, that the *ſtars* returned into the ſame poſitions again, as if there had been no alteration at all in the inclination of the earth's axis: which fully convinced him that he had gueſſed rightly as to the cauſe of the phænomenon. This circumſtance proves likewiſe, that if there be a gradual diminution of the obliquity of the ecliptic, it does not ariſe only from an alteration in the poſition of the earth's axis, but rather from ſome change in the plane of the ecliptic itſelf: becauſe the *ſtars*, at the end of the period of the moon's nodes, appeared in the ſame places, with reſpect to the equator, as they ought to have done, if the earth's axis had retained the ſame inclination to an invariable plane.

The Doctor having communicated theſe obſervations, and his ſuſpicion of their cauſe, to the late Mr. Machin, that excellent geometer ſoon after ſent him a table, containing the quantity of the annual preceſſion in the various poſitions of the moon's nodes, as alſo the correſponding nutations of the earth's axis; which was computed upon the ſuppoſition that the mean annual preceſſion is 50″, and that the whole is governed by the pole of the moon's orbit only: and therefore Mr. Machin imagined that the numbers in the table would be too large; as, in fact, they were found to be. But it appeared that the changes which Dr. Bradley had obſerved, both in the annual preceſſion and nutation, kept the ſame law, as to increaſing and decreaſing, with the numbers of Mr. Machin's table. Thoſe were calculated upon the ſuppoſition, that the pole of the equator, during a period of the moon's nodes, moved round in the periphery of a little circle, whoſe center was 23° 29′ diſtant from the pole of the ecliptic: having itſelf alſo an angular motion of 50″ in a year, about the ſame pole. The north pole of the equator was conceived to be in that part of the ſmall circle, which is fartheſt from the north pole of the ecliptic, at the time when the moon's aſcending node is in the beginning of Aries: and in the oppoſite point of it, when the ſame node is in Libra.

If the diameter of the little circle, in which the pole of the equator moves, be ſuppoſed equal to 18″; which is the whole quantity of the nutation, as collected from Dr. Bradley's obſervations of the *ſtar* γ Draconis; then all the phænomena in the ſeveral *ſtars* which he obſerved will be very nearly ſolved by his hypotheſis. But for the particulars of his ſolution, and the application of his theory to the practice of aſtronomy, we muſt refer to the excellent author himſelf [b]; our intention being only to give the hiſtory of the invention.—[[b] See Phil. Tranſ. N° 485.]

The corrections ariſing from the aberration of light, and from the nutation of the earth's axis, muſt not be neglected in aſtronomical obſervations; ſince ſuch neglects might produce errors of near a minute in the polar diſtances of ſome *ſtars*. See Phil. Tranſ. loc. cit. p 26.

As to the allowance to be made for the aberration of light, Dr. Bradley aſſures us, that having again examined thoſe of his own obſervations, which were moſt proper to determine the tranſverſe axis of the ellipſis, which each *ſtar* ſeems to deſcribe, he found it to be neareſt to 40″; and this is the number he makes uſe of in his computations relating to the nutation. Ibid. p. 23.

Monſieur d'Alembert has publiſhed a treatiſe, intitled, *Recherches ſur la preceſſion des equinoxes et ſur la nutation de la terre dans le ſyſteme Newtonien*, 4to. Paris, 1749. The calculations of this learned gentleman agree, in general, with Dr. Bradley's obſervations. But Monſieur d'Alembert finds, that the pole of the equator deſcribes an ellipſis in the heavens, the ratio of whoſe axes is as 4 to 3 [c]; whereas, according to Dr. Bradley, the curve deſcribed is either a circle, or an ellipſis, the ratio of whoſe axes is as 18 to 16 [d]. —[[c] Journal. Britan. par Monſieur *Maty*, Jan. 1750, p. 93. [d] Phil. Tranſ. ibid. p. 35.]

Dr. Bradley [e] ſays, in general, that experience has taught him that the obſervations of ſuch *ſtars* as lie neareſt the zenith, generally agree beſt with one another, and are therefore the fitteſt to prove the truth of any hypotheſis.—[[e] Phil. Tranſ. loc. cit. p. 29.]

From the reſult of the compariſon of our beſt modern obſervations, with ſuch as were formerly made with any tolerable degree of exactneſs, there appears to have been a real change in the poſition of ſome of the fixed *ſtars*, with reſpect to each other; and ſuch as ſeems independent of any motion in our ſyſtem, and can only be referred to ſome motion in the *ſtars* themſelves. Arcturus affords a ſtrong proof of this: for if its preſent declination be compared with its place, as determined either by Tycho or Flamſteed, the difference will be found to be much greater, than what can be ſuſpected to ariſe from the uncertainty of their obſervations.

It is reaſonable to expect, that other inſtances of the like kind muſt alſo occur among the great number of viſible *ſtars*; becauſe their relative poſitions may be altered by various means. For if our own ſolar ſyſtem be conceived to change its place with reſpect to abſolute ſpace, this might, in proceſs of time, occaſion an apparent change in the angular diſtances of the fixed *ſtars*: and in ſuch a caſe, the places of the neareſt *ſtars* being more affected than of thoſe that are very remote, their relative poſition might ſeem to alter, though the *ſtars* themſelves were really immoveable. And, on the other hand, if our ſyſtem be at reſt, and any of the *ſtars* really in motion, this might likewiſe vary their apparent poſitions; and the more ſo, the nearer they are to us, or the ſwifter their motions are, or the more proper the direction of the motion is to be rendred perceptible by us. Since then the relative places of the *ſtars* may be changed from ſuch a variety of cauſes, conſidering the amazing diſtance at which it is certain ſome of them are placed, it may require the obſervations of many ages, to determine the laws of the apparent changes, even of a ſingle *ſtar*: much more difficult, therefore, muſt it be to ſettle the laws relating to all the moſt remarkable *ſtars*.

When the cauſes which affect the places of all the *ſtars* in general are known; ſuch as the preceſſion, aberration, and nutation; it may be of ſingular uſe, to examine nicely the relative ſituations of particular *ſtars*; and eſpecially of thoſe of the greateſt luſtre, which, it may be preſumed, lie neareſt to us, and may therefore be ſubject to more ſenſible changes, either from their own motion, or from that of our ſyſtem. And if, at the ſame time that the brighter *ſtars* are compared with each other, we likewiſe determine the relative poſitions of ſome of the ſmalleſt that appear near them, whoſe places can be aſcertained with ſufficient exactneſs; we may perhaps be able to judge to what cauſe the change, if any be obſervable, is owing. The uncertainty that we are at preſent under, with reſpect to the degree of accuracy wherewith former aſtronomers could obſerve, makes us unable to determine ſeveral things relating to this ſubject: but the improvements, which have of late years been made in the methods of taking the places of the heavenly bodies, are ſo great, that a few years may hereafter be ſufficient to ſettle ſome points, which cannot now be ſettled, by comparing even the earlieſt obſervations with thoſe of the preſent age. See Dr. *Bradley*, in Phil. Tranſ. N° 485.

STAR-*apple*, the Engliſh name of a genus of plants, called by botaniſts *cainito* and *chryſophyllum*. See the article CHRYSOPHYLLUM, *Suppl.*

STAR-*thiſtle*, the Engliſh name of a ſpecies of centaury, called by ſome *calcitrapa*. See the article CENTAUREA, *Append.*

STARCH *(Cycl.)*—In the hiſtory of the royal Academy of Sciences 1739, p. 24, Edit. Paris, a kind of *ſtarch* is mentioned, made of potatoes and red truffles. By the ſhort account there given, this *ſtarch* ſeems not to be ſo good as the common, but might be of uſe in caſe of a ſcarcity of wheat.

STARLING, the Engliſh name of a genus of birds, called by authors *ſturnus*. Some, erroneouſly, account it a ſpecies of *turdus*, or thruſh.

Of this genus there is only one ſpecies, which is the *ſtarling*, the beak of which is of a ſubulated figure, depreſſed in an angulated manner, and obtuſe at the extremity; and it's tongue is marginated and acute. It is of the ſize of the common black-bird. The beak is near half an inch long, and is yellow in the male, and brown in the female. The general colour is black, but variegated with ſpots of grey; and the tips of the feathers of the neck and back are yellowiſh. It has alſo various other tinges, according to the light it is ſeen in. The wing and tail-feathers are brown, with ſome yellow at their edges. *Hill*, Hiſt. of Animals, p. 496.

STEEL *(Suppl.)*—The manner of hardening *ſteel* for magnetical bars, which Mr. Canton [a] ſays proved better than any other he could meet with, is as follows: Cut a ſufficient quantity of the leather of old ſhoes into very ſmall pieces; provide an iron pan, a little exceeding the length of a bar, and wide enough to lay two ſide by ſide without touching each other or the pan, and at leaſt an inch deep. This pan is to be nearly half filled with the bits of leather, upon which the two bars are to be laid, a ſmall wire being faſtened to the end of each to take them out by. Then fill the pan quite with the leather, and place it on a gentle flat fire, covering and ſurrounding it with charcoal. The pan being brought to ſomewhat more than a red heat, and kept ſo for about

about half an hour, the bars are to be ſuddenly quenched in a large quantity of cold water.—[a See Method of making artificial magnets, Lond. 1751.]

For the expanſion of *ſteel* by heat, ſee the article HEAT, *Append.*

STELLULARIA, in the Linnæan ſyſtem of botany, the name of a genus of plants, called by Tournefort *alſine*. See the article ALSINE, *Suppl.*

STICK-*a-door*, a name ſometimes uſed for the *ſtoechas*. See the article STOECHAS, *Suppl.*

STILLATORY, a name ſometimes uſed for a ſtill-houſe. See the article STILL-*houſe*, *Suppl.*

STILOBATUM, in architecture, denotes the body of the pedeſtal of any column. See PEDESTAL, *Cycl.*

STIRK, or STURK, a word uſed among country people for a young ox or heifer. Ruſt. Dict. in voc.

STITCH-*wort*, a name ſometimes given to the *alſine*, or *ſtellularia* of botaniſts, otherwiſe called *chickweed*. See the article ALSINE, *Suppl.*

STITHY, or STUTHY, is uſed either for a ſmith's anvil, or a diſeaſe in oxen, cauſing the ſkin to ſtick ſo cloſe to the ribs that they cannot ſtir. Ruſt. Dict. in voc.

STIVER, a Dutch coin, twenty of which make a guilder. See the article COIN, *Cycl.*

STOCK-*July-flower* (*Suppl.*)—*Dwarf* STOCK-*July-flower*, a name given by ſome to the *heſperis*. See the article HESPERIS, *Suppl.*

STOECHAS, in botany, the name of a genus of plants, printed *ſtaechas* in the Supplement by an error of the preſs. See STÆCHAS, *Suppl.*

STOMATIA, in zoology, the name of a genus of ſhell-fiſh, frequently confounded with the *ear-ſhell*. See the article EAR-*ſhell*, *Suppl.*

The ſhell of the *ſtomatia* is formed of one piece, has no perforations in any part of its ſurface, and is of a depreſſed, flat figure; and its mouth is the moſt patent of all the univalve ſhells, the limpet only excepted. It has a ſhort ſpiral turn running into the mouth at the head.

There are ſeveral ſpecies of this genus. See *Hill*, Hiſt. Anim. p. 119, ſeq.

STONE (*Cycl.*)—We have not only accounts of *ſtones* of various degrees of hardneſs taken out of the bladders of perſons affected with this terrible malady, but even of extraneous matter lodged within, and ſerving for the nucleus of thoſe *ſtones*. Thus, in the Philoſophical Tranſactions, there is an account of a boy who for a long time voided hair by urine, and afterwards being troubled with the *ſtone*, on being cut for it, the *ſtone* taken away was very hard and heavy, and of the bigneſs of a gooſe's egg: it was covered with a cruſt, looking like the mortar of an old wall, and this was full of cracks and chinks, out of every one of which there was found to grow hair.

The hairs, which he had been uſed to void by urine, certainly grew alſo out of the clefts of this *ſtone*, for they would often hang out at the end of the penis; and on pulling them away, ſeemed to grow faſt to ſomething, and to be pulled out by the roots.

In another boy of about five or ſix years of age, who was cut for the *ſtone*, the *ſtone* taken out being broken by accident, there was diſcovered within it a piece of flint, of the ſhape and figure, as well as bigneſs, of a common piſtol flint. This ſerved as the nucleus to the other *ſtony* matter which encruſted it over. It is utterly impoſſible that a flint, of this ſhape, ſhould have been formed in the bladder, nor is it eaſy to account for its coming there; the boy muſt have ſwallowed it at ſome time, but then its making its way into the bladder, is a very hard matter to account for. A perſon, who uſed himſelf to ſwallow piſtol bullets, is recorded in the ſame place to have voided them by urine, cruſted over with *ſtony* matter; but all this is equally hard to account for. Philoſ. Tranſ. N° 266. p. 688.

Dr. Cheyne ſays, that ſoap lees, ſoftened with a little oil of ſweet almonds, drunk about a quarter of an ounce twice a day, on a faſting ſtomach; or ſoap and egg-ſhell pills, with a total milk and ſeed diet, and Briſtol-water; will either diſſolve the *ſtone* in the kidneys or bladder, or make it eaſy. See Nat. Meth. of Curing, p. 266.

We often meet with hiſtories, in medical writers, of the *ſtone*, or human calculus, making its way through unuſual places, as the perineum, ſcrotum, &c. See Philoſ. Tranſ. N° 456.

Mr. le Dran aſſures us, when a ſmall *ſtone* is lodged in the neck of the bladder, the patient only is pained in piſſing till the firſt drops of the urine come away; when the *ſtone* is large, his greateſt pain is while the laſt drops are evacuated; but when the difficulty of urining depends on the diſeaſes of the coats of the bladder, the pain continues all the time of the evacuation. By obſerving theſe ſymptoms, he has declared people to have no *ſtone* in the bladder, after ſeveral others had aſſured them there was a *ſtone*; and his opinion was confirmed by probing with the catheter. He names one inſtance of this, in a perſon who had laboured under what he calls a contracted hardened bladder, whom he cured after ſeveral bleedings and purges, by injecting into the bladder a decoction of marſh-mallow roots and linſeed, which he changed afterwards for barley-water, with ſome honey of roſes. By theſe he removed the pain, and brought the bladder, which at firſt could ſcarce contain two ſpoonfuls of liquor, to the ordinary capacity.

We have an account, in the Philoſophical Tranſactions, of a *ſtone* weighing above ten ounces, taken out of the bladder of a large maſtif: on cutting the *ſtone* aſunder, a piece of dog-graſs was found in its center. Vid. Philoſ. Tranſact. N° 482. ſect. 1.

We read of a *ſtone* in the bladder formed on a needle. See Med. Eſſ. Edinb. Vol. IV. art. 16.

Mr. Hales is of opinion that all paſſable *ſtones*, which have lately fallen from the kidneys into the bladder, and which have broken off from larger ones, might readily and eaſily be brought out thence, by conveying into the empty bladder, by a catheter, ſome very mucilaginous ſubſtance, ſuch as ſyrup of marſh-mallows, or a ſolution of gum arabic, or barley-water: ſuch ſubſtances would bring away the *ſtones* ſoon, and with great eaſe to the patient; and thereby not only prevent much pain by the fruitleſs endeavours to bring them away with the weak force of the urine, but alſo effectually ſecure the patient from the danger of their growing too big to come away, by long continuing in the bladder. Phil. Tranſ. N° 477.

Pitcarn recommends the uſe of milk for common drink, in the *ſtone*, with barley-water and a little ſugar. He adds, that he cannot give any better reaſon why milk is ſerviceable to nephritics, than becauſe the ſame is always found ſerviceable to gouty perſons. The ſymptoms of both diſeaſes are the ſame, excepting what relates to the parts affected.

Dr. Mead ſeems to think, that the proximate cauſe of this diſeaſe is a tartarous ſalt conveyed out of the blood into the ſmall ducts of the kidneys: for it is the nature of theſe ſalts to contain a conſiderable quantity of that ſubtile matter which Newton [a] has ſhewn to be the cauſe of the coheſion of bodies. Thus, the calculus is a ſubſtance compoſed of earth and a very large ſhare of air concreted in the renal ducts; and either remains therein, or drops down into the urinary bladder.

As to the method of cure the Doctor obſerves, to prevent thoſe ſalts from ſhooting into cryſtals, lixivial ſalts ſeem to be very proper. Next to keep the cryſtals from coaleſcing into a calculous ſubſtance, oily medicines are very efficacious; and this rule ought to take place with regard to diet as well as medicines.

But when calculous concretions are actually formed in the kidneys, and are to be brought away by the ureters, the caſe requires very prudent management. It is a very common error in practice to give ſtrong forcing diuretics with an imaginary view of driving out the gravel with the urine: whereas this intention is anſwered with greater ſafety in moſt caſes by relaxing and lubricating medicines; eſpecially, if in caſe of violent pain, bleeding be premiſed, and anodynes interſperſed. For a *ſtone* is never forced out while the patient is in great torture; though when the pain ceaſes it ſometimes comes away unexpectedly, and almoſt of its own accord, with the urine; and the reaſon of this is, that pain conſtringes the fibres of the parts, which reſume their natural ſtate, and perform their functions properly when the troubleſome ſenſation is over. Wherefore three or four grains of opium, diſſolved in five or ſix ounces of the common decoction, may be given by way of clyſter; which will greatly relieve the pain, and ſometimes procure greater advantages. However, there are conjunctures, after the pain is abated, when powerful diuretics may be adminiſtred; but with this precaution, that as ſoon as they have had their effect, they are no longer to be continued.—[a See Life of Mr. Boyle prefixed to his works.]

All this while the body ſhould conſtantly be kept open: wherefore, in caſe of coſtiveneſs, it will be expedient to give clyſters, and ſometimes to purge gently with infuſion of ſena and manna: but ſtrong cathartics are to be avoided.

Of the lubricating medicines abovementioned, the chief are oil of ſweet almonds, ſyrup of marſh-mallows, emulſions made with almonds, and the like; to which may be added, the uſe of the warm bath. But among the powerful diuretics, turpentine and ſoap are the beſt.

Such is the courſe to be purſued in the paroxyſm of the diſeaſe. But out of it the patient ſhould uſe bodily exerciſe, eſpecially riding every day, but ſo as not to fatigue: his food ſhould be mild, and of eaſy digeſtion; and his drink either ſmall wine and water, or new ſoft ale; which will be rendered better and wholſomer, if ground-ivy leaves be infuſed in it, while it is working. Mead is likewiſe a proper drink; for honey is an excellent diuretic. A ſpoonful alſo of honey in a glaſs or two of the infuſion of marſh-mallows roots, is an admirable cleanſer of the kidneys, if uſed for a conſtancy. The wines ought to be the ſofteſt and ſmootheſt that can be had; and the lighteſt, cleareſt river, or running water, is preferable to all other. For, as Pliny [b] ſays, thoſe ſprings are particularly condemned, the waters

of which line the veſſels, in which they are boiled, with thick cruſts.—[b *Plin.* Nat. Hiſt. lib. 31. cap. 3.] See the articles LITHONTRIPTIC and LITHOTOMY, *Append.*

But particular care ſhould be taken, not to put the patient into a courſe of powerful diuretics, with a view of preventing the gravel from concreting in the kidneys: becauſe, whatever great things may be ſaid of this ſort of medicines by ignorant pretenders, they certainly injure the parts by their heat and acrimony. *Mead*, Monit. & Pract. Med. p. 191, ſeq.

The Leipſic Acts give a very remarkable inſtance of *ſtones* in the blood veſſels, diſcovered by accident on opening a vein in the arm: the ſurgeon finding it neceſſary to make a large orifice, ſeveral ſmall but very hard *ſtones* were diſcharged at it with the blood. The patient was a man of ſeventy two years of age.

STONES *in animals*. We meet with great variety of forms and appearances in the *ſtones* produced by different animals, and in their different parts. Wedelius deſcribes a vaſt number of various kinds taken from dogs, hogs, cows, and other animals which he had opened: but the moſt ſingular inſtance is of one which was taken from a cow, and was of the colour of burniſhed gold. Dr. Liſter confirms this ſingular obſervation with another of a like kind, that came within his own knowledge: this was of two hundred ſmall globular *ſtones*, the largeſt not exceeding the ſize of a ſmall tare, and the ſmaller not bigger than pins heads. They were covered with a frothy ſubſtance in the bladder, and adhered to one ſide of it; but when cleaned and dried, they reſembled ſeed pearl in ſhape, and were of a fine gold colour. They were finely poliſhed, even when viewed by the microſcope; and when broken, and examined in the ſame manner, it was found to be only a thin ſkin of gold colour that covered them in this manner, their inner ſubſtance being coarſe and opake, ſomewhat reſembling ſugar-candy, but not ſo fine. *Wedel.* Obſerv. N° 106. Philoſ. Tranſ. N° 206.

Corner STONES. See the article CORNER, *Append.*

STONE-*break*, a name by which ſome writers call the *alchimilla*, or ladies mantle. See the article ALCHIMILLA, *Suppl.*

STONE-*crop*, a name ſometimes given to the *ſedum*, or houſeleek. See the article SEDUM, *Suppl.*

STONE-*crop-tree*, in botany, the name by which ſome call the *blitum*, or blite, of other authors. See the article BLITUM, *Suppl.*

STOOK, a term uſed in many parts of the kingdom for a ſhock of corn, containing twelve ſheaves. Ruſt. Dict. in voc.

STOOL, (*Suppl.*) in ſhip-building, the name of the ſupporters of the poop and top lanterns. *Blanckley*, Naval Expoſitor, in voc.

STORAX-*tree*, in botany, the Engliſh name of the *ſtyrax*. See the article STYRAX, *Suppl.*

STORK, the name of a bird of the *ardea*, or heron kind. See the article HERON, *Suppl.*

The *ſtork* has been deſcribed under the name *ciconia* by ſeveral authors. See the article CICONIA, *Suppl.*

STOVE (*Suppl.*)—STOVES, at ſea, are ſquare boxes made of planks, and lined with brick, for burning charcoal in to dreſs the admiral's victuals. *Blanckley*, Nav. Expoſ.

STOVER, a word uſed by country people for ſtraw or fodder for cattle. Ruſt. Dict. in voc.

STRATIOTES, in the Linnæan ſyſtem of botany, the name of a diſtinct genus of plants, the characters of which are theſe. The cup is a two-leaved ſpatha, compreſſed, obtuſe, connivent, and carinated on each ſide. Beſide this, there is alſo a perianthium, which is formed of a ſingle leaf, divided into three ſegments, and is erect and deciduous. The flower conſiſts of three obverſely cordated, erect and patent petals, of double the ſize of the cup. The ſtamina are twenty filaments, of the length of the perianthium, and inſerted into the receptacle. The antheræ are ſimple. The germen of the piſtil ſtands under the receptacle of the perianthium. There are ſix ſtyles, divided each into two parts, and of the length of the ſtamina. The ſtigmata are ſimple. The fruit is an oval berry, attenuated at each end, ſomewhat hexaedral, and contains ſix cells. The ſeeds are numerous, oblong, crooked, and as it were alated.

There is only one known ſpecies of this genus. Vid. *Linnæi* Gen. Plant. p. 253.

STRATIOTES, in botany, is alſo a name by which ſome call the *hottonia* of Linnæus. See the article HOTTONIA, *Suppl.*

STRAWBERRY-*cinquefoil*, the name by which ſome call the *pentaphylloides* of botaniſts. See the article PENTAPHYLLOIDES, *Suppl.*

STRAWBERRY-*blite*. See the article BLITUM, *Suppl.*

STRAWBERRY-*ſpinach*. See SPINACH, ſupra.

STRICKLE, or STRICKLESS, an inſtrument for ſtriking off the over-meaſure of corn, &c. Ruſt. Dict. in voc.

STUBBING, among farmers, is the pulling up of ſhrubs, broom, hops, or the like, out of lands. Ruſt. Dict. in voc.

STUBBLE, that part of the ſtalks of corn which remains on the land, after the corn is reaped.

STUFF, among joiners, &c. a term uſed for the wood they work on. Build. Dict. in voc.

STURGEON, the Engliſh name of the *ſturio* of ichthyologiſts. See the article STURIO, *Suppl.*

STURK, the ſame with *ſtirk*. See the article STIRK, *Append.*

STURLING, the Engliſh name of a bird called by zoologiſts *ſturnus*. See the article STURNUS, *Suppl.*

STUTHY, the ſame with *ſtithy*. See the article STITHY, *Append.*

STYE, in the management of ſwine, a place for keeping or fattening them. Ruſt. Dict. in voc.

STYLOBATUM, in architecture, the ſame with pedeſtals. See the article PEDESTAL, *Cycl.*

SUBSTANCE, (*Cycl.*) is uſually diſtinguiſhed into thinking and unthinking *ſubſtances*. Of the former claſs is the human ſoul; and of the latter, philoſophers commonly conſider matter only. But ſome [b] reckon ſpace among *ſubſtances*. The Carteſians conſider ſpace and matter as the ſame. The Leibnitians put ſpace in the ſame claſs of being with number and time, and make them all alike notional. Leibnitz ſaid, *agere eſt character ſubſtantiarum.*—[b s'*Graveſande*, Introd. ad Philoſ. ſect. 19.]

The idealiſts deny matter to be a *ſubſtance*, making it a mere phænomenon. See biſhop *Berkley*'s Dialogues.

The materialiſts, on the other hand, deny ſpirit to be a *ſubſtance*. But as they cannot deny the exiſtence of thought, as the idealiſts deny the exiſtence of matter, the materialiſts are forced either to allow all matter to have perception, eſſentially; or to ſay, that it is ſuperadded to matter, or a modification thereof. All which lead to inextricable difficulties.

SUCCORY (*Suppl.*)—*Gum*-SUCCORY, the name by which ſome call the *chondrilla* of botaniſts. See the article CHONDRILLA, *Suppl.*

SUCCULENT *plants*, among botaniſts, thoſe which are plump and full of juice. Ruſt. Dict. in voc.

SUCKER, or SUCK-*fiſh*, in ichthyology. See the article REMORA, *Suppl.*

Stone-SUCKER, the Engliſh name of a genus of fiſhes. See the article PETROMYZON, *Suppl.*

Great SUCKER, the Engliſh name of a ſpecies of *hirundo*, or ſwallow, with an undivided tail, and briſtles at the mouth. See HIRUNDO, *Suppl.*

The generality of authors have erroneouſly made this bird a ſpecies of owl; it much reſembles the cuckow in ſhape, and has been called the *churn-owl*, and *caprimulgus*. See the article CAPRIMULGUS, *Suppl.*

SUDORIFICS (*Cycl.* and *Suppl.*)—*Sudorifics*, if taken in time, are the beſt medicines for preventing inflammatory and feveriſh diſorders of all kinds. See the articles FEVER and INFLAMMATORY, *Append.*

Dr. Pringle condemns the uſe of treacle, given with this intention, on account of its heating quality. However, he obſerves, that it is rendered more *ſudorific*, and leſs narcotic, by adding ten grains of ſalt of hartſhorn to a common doſe, and promoting the ſweat by a large draught of vinegar-whey. Inſtead of this compoſition, two ſcruples of ſalt of hartſhorn, ſaturated with about three ſpoonfuls of common vinegar, may be given at bed-time. *Pringle*, Obſerv. on the Diſeaſes of the Army, p. 131.

SUGAR-*cane*, *ſaccharum*, in botany, the name of a diſtinct genus of plants, according to Linnæus. See the article SACCHARUM, *Suppl.*

SULL, a word uſed in the weſtern parts of England for a plough. Ruſt. Dict. in voc.

SULPHUR-*wort*, the name by which *peucedanum*, or hog's fennel is ſometimes called. See the article PEUCEDANUM, *Suppl.*

SULTAN-*flower*, a name ſometimes uſed for the *cyanus*, or blue bottle. See the article CYANUS, *Suppl.*

SUMACH, the Engliſh name of a genus of plants, called by botaniſts *rhus*. See the article RHUS, *Suppl.*

Coriars SUMACH, or *myrtle* SUMACH, the name by which *coriaria*, a diſtinct genus of plants is ſometimes called. See the article CORIARIA, *Append.*

Venetian SUMACH, a name by which ſome call the *coccygria*, or *cotinus* of botaniſts. See the article COTINUS, *Suppl.*

SUMMITS *of flowers*, the ſame with the antheræ, or tops of the ſtamina. See the article FLOWER, *Suppl.*

SUN-*flower* (*Suppl.*)—*Dwarf* SUN-*flower*, the Engliſh name of a genus of plants, called by botaniſts *rudbeckia*. See the article RUDBECKIA, *Append.*

SUN-*ſpurge*, in botany. See the article SPURGE, *ſupra.*

SUPERCILIUM *terræ*. See ADIANTUM.

SUPPLICATION, *ſupplicatio*, in antiquity, a religious ſolemnity obſerved on account of ſome remarkable ſucceſs againſt an enemy; and eſpecially when the army had conferred the title of *imperator* on their general, in whoſe name the ſenate ordered the temples to be opened for the reception of the people, and thanks to be rendered to the Gods.

On ſuch an occaſion the imperator ſent meſſengers crowned with laurel with letters to the ſenate, which were likewiſe adorned with laurel, to demand of them the title of *imperator*, and the honour of a *ſupplication*. This ſolemnity conſiſted in ſacrificing and feaſting in the temples, with giving thanks to the gods for the ſucceſs obtained, and praying for the continuance of their aſſiſtance. At firſt there were only a few days taken up in ſuch feſtivals; but afterwards they were increaſed gradually, till they came to no leſs than fifty. On ſubduing the Sabines, in the year of the city 304, a *ſupplication* of one day only was ordained; on the taking of Veii, Camillus had a *ſupplication* of four days decreed him; Pompey had twelve on putting an end to the Mithridatic war; Cæſar had fifteen, and afterwards twenty for reducing Gaul; Octavianus and Panſa had fifty days of *ſupplication* for delivering the colony of Mutina.

SWALLOW (*Suppl.*)—*Sea*-SWALLOW, the Engliſh name of a genus of birds, called by authors *ſterna*. See the article STERNA, *Suppl.*

SWARTH, among country people, the ſame with *ſwath*. See the next article.

SWATH, (*Cycl.*) a word uſed by country people for a row of graſs or corn, as laid by the mower. Ruſt. Dict. in voc.

SWEALING *a hog*, a word uſed in ſome parts of the kingdom for ſinging him. Ruſt. Dict. in voc.

SWEATH, the ſame with *ſwath*. See the article SWATH, ſupra.

SWEET-*apple*. See the article APPLE, ſupra.

SWEET-*Johns*. See the article JOHNS, ſupra.

SWEET-*William of Barbadoes*, the Engliſh name of a genus of plants, called by botaniſts *quamoclit*. See the article QUAMOCLIT, *Suppl.*

SWEET-*willow*. See the article WILLOW, infra.

SWINE's *creſs*, a name given to a ſpecies of *naſturtium*. See the article NASTURTIUM, *Suppl.*

SWIVELS, a kind of rings made to turn round in a ſtaple, or other ring. Theſe are uſed when a ſhip lies at her moorings; alſo in tedders for cattle, that they may turn round without unwarping the tedder.

SWORD-*fiſh*, the Engliſh name of the *xiphias*, a genus of fiſhes. See the article XIPHIAS, *Suppl.*

SWORD-*graſs*. See ACORUS, *Cycl.*

SYMPHORICARPOS, in botany, the name of a genus of plants, according to Dillenius, but made a ſpecies of *lonicera* by Linnæus. See the article LONICERA, *Append.*

T.

TADORNA, the name of a ſpecies of duck, printed *tadoma* in the Supplement, by an error of the preſs. See the article TADOMA, *Suppl.*

TANNER, a perſon who dreſſes hides by tanning. See the article TANNING, *Cycl.* and *Suppl.*

TANSEY, or TANZY, the Engliſh name of a genus of plants. See the article TANACETUM, *Suppl.*

Wild TANSEY, a name by which ſome call the *potentilla*. See the article POTENTILLA, *Suppl.*

TARE, *vicia*, in botany, the name of a genus of plants, otherwiſe called vetch. See the article VICIA, *Suppl.*

TARRAGON, a name ſometimes given to *abrotanum*, or ſouthernwood. See the article SOUTHERNWOOD, *Suppl.*

TEA, *thea*, in botany, is made a diſtinct genus of plants. See the article THEA, *Append.*

TEDDER, or TETHER, a rope tied to a horſe's foot, that he may graſe within a certain compaſs. Ruſt. Dict. in voc.

TEG (*Suppl.*)—TEG, among ſportſmen, denotes a doe of the ſecond year. Ruſt. Dict. in voc.

TELAUGIA, in natural hiſtory, the name of a genus of *ſcrupi*, of a glittering appearance, uſually containing flakes of talc, and emulating the ſtructure of the granites. *Hill*, Hiſt. Foſſ. p. 547. See SCRUPI, *Append.*

Of this genus we have the following ſpecies. 1. The hard, ſhining, black and white *telaugium*. 2. The hard, ſhining, red and white *telaugium*. 3. The red *telaugium*, variegated with white and black. 4. The hard, heavy *telaugium*, of a greyiſh black, variegated with white. 5. The browniſh red *telaugium*, variegated with white and yellowiſh. 6. The reddiſh white *telaugium*, variegated with black and gold colour. 7. The hard, white *telaugium*, variegated with brown. 8. The bluiſh white, brittle *telaugium*. 9. The brown, friable *telaugium*, variegated with yellow. 10. The hard, purpliſh brown *telaugium*, variegated with white and yellow. 11. The heavy, red *telaugium*, variegated with black and white. 12. The hard, bluiſh green *telaugium*, variegated with white. Id. ibid. p. 547—556.

TELEPHIASTRUM, *baſtard orpine*, in botany, the name of a genus of plants, called by Linnæus *anacampſeros*. See the article ANACAMPSEROS, *Suppl.*

TELESCOPE (*Cycl.*)—Mr. James Gregory was undoubtedly the firſt inventor of reflecting *teleſcopes*. The conſtruction of his *teleſcope* is different from that of Sir Iſaac Newton, and in ſome reſpects not ſo advantageous, as is ſhewn in Phil. Tranſ. N° 83.

Mr. Gregory deſcribes this *teleſcope* at the end of his *Optica Promota*, publiſhed in 1663; being led into the invention of it, not by the conſideration of the different refrangibility of the rays of light, which was not then known, but by an inconvenience he foreſaw would follow from an hyperbolic object-glaſs. For he obſerves, that if it be ſufficiently broad to receive light enough into a *teleſcope* that ſhall magnify very much, it muſt of conſequence be very thick; in which caſe, the cleareſt glaſs would hinder too much of the light from being tranſmitted. He might alſo have added another inconvenience, that though it will collect a pencil of rays coming parallel to its axis into a ſingle point, yet it cannot collect the rays of an oblique pencil ſo accurately as a glaſs conſiſting of ſpherical ſurfaces will do, as has been found by experience; and therefore ſpherical lenſes, upon this and ſome other accounts, are fitter for optical uſes than thoſe of any other figure.

Theſe reflecting *teleſcopes* were not brought into practice till 1719, by Mr. John Hadley; Sir Iſaac Newton's firſt, and that of Mr. Gregory ſoon after. This laſt, in ſmall lengths, has an excellent effect, and is exceeding commodious. We have a deſcription of it by Dr. Smith [a], which differs from that of its inventor chiefly in this, that he directs his larger reflecting concave lens to be made of a parabolic figure, and his leſſer of an elliptical one, inſtead of the ſpherical ones now uſed, as being the only figures that can be poliſhed without inſuperable difficulties.—[a Optics, in the remarks, ſect. 137, ſeq.]

Reflecting *teleſcopes* have been greatly improved by Mr. Short; but the particulars of his method are not publiſhed. For the theory of theſe and other *teleſcopes*, ſee Dr. Smith's Optics.

TELESCOPE-*ſhell*, the Engliſh name of a ſpecies of *turbo*, of a conic figure, with plane, ſtriated, and very numerous ſpires. See the article TURBO, *Suppl.*

TEMPERAMENT (*Suppl.*)—As Huygens has not given the names of all the intervals that occur in his *temperate* ſcale, we ſhall here inſert them in the octave, from C to *c*, with their reſpective meaſures in commas, and tenths of a comma.

Intervals.		Names.	Meaſures.
From C to	D 𝄫.	1. Diminiſhed ſecond, extreme flat ſecond, or enharmonic dieſis,	1.8.
	C ♯.	2. Semitone minor, or chromatic dieſis,	3.6.
	D ♭.	3. Flat ſecond, or ſemitone major,	5.4.
	C ♯♯.	4. Double ſemitone minor,	7.2.
	D.	5. Second, or tone,	9.0.
	E 𝄫.	6. Diminiſhed third, or extreme flat third,	10.8.
	D ♯.	7. Superfluous ſecond,	12.6.
	E ♭.	8. Third minor, or flat third,	14.4.
	D ♯♯.	9. Extreme ſuperfluous ſecond,	16.2.
	E.	10. Third major, or ſharp third,	18.0.
	F ♭.	11. Diminiſhed fourth,	19.8.
	E ♯.	12. Superfluous third,	21.6.
	F.	13. Fourth,	23.4.
	G 𝄫.	14. Extreme diminiſhed fifth,	25.2.
	F ♯.	15. Falſe fourth, or tritonus,	27.0.
	G ♭.	16. Falſe fifth, or ſemidiapente,	28.8.
	F ♯♯.	17. Extreme ſuperfluous fourth,	30.6.
	G.	18. Fifth,	32.4.
	A 𝄫.	19. Diminiſhed ſixth, or extreme flat ſixth,	34.2.
	G ♯.	20. Superfluous fifth,	36.0.
	A ♭.	21. Flat ſixth, or ſixth minor,	37.8.
	G ♯♯.	22. Extreme ſuperfluous fifth,	39.6.
	A.	23. Sharp ſixth, or ſixth major,	41.4.
	B 𝄫.	24. Diminiſhed ſeventh, or extreme flat ſeventh,	43.2.
	A ♯.	25. Superfluous ſixth,	45.0.
	B ♭.	26. Flat ſeventh, or ſeventh minor,	46.8.
	A ♯♯.	27. Extreme ſuperfluous ſixth,	48.6.
	B.	28. Sharp ſeventh, or ſeventh major,	50.4.
	c ♭.	29. Diminiſhed octave,	52.2.
	B ♯.	30. Superfluous ſeventh,	54.0.
	c.	31. Octave,	55.8.

The *temperate* dieſis enharmonica of Huygens being 1.8 comma, nearly, which is eaſily remembred, the meaſure of any interval in the octave may be found by multiplying it by the number denoting the place of that interval. Thus the ſixth minor, being the twenty-firſt interval, will be $= 1.8 \times 21 = 37.8$. The octave being the thirty-firſt, will be $= 31 \times 1.8 = 55.8$, which does not differ from the truth by more than 0.00237, that is, not by $\frac{1}{400}$ of a comma, and therefore perfectly inſenſible. See INTERVAL, *Suppl.*

All the intervals in the foregoing table, either have received names, or at leaſt might receive them, from a perfect analogy to the names in uſe among practical muſicians; but many of theſe intervals are as yet unheard of among practitioners. Perhaps, if all the genera of antient muſic were reſtored, every interval here mentioned might be of uſe, either in melody or harmony, and thereby greatly add to the variety of compoſition.

TENDERLINGS, a name given to the ſoft tops of deer's horns, when they begin to ſhoot forth. Ruſt. Dict. in voc.

TENDREL, a term peculiarly applied to the young ſhoot, or ſprig of a vine.

TENEBRIO, the *ſtinking beetle*, the name of a genus of beetles, the antennæ of which are oblong, ſlender, and filiform.

It has no interior wings, in which ſingular deficiency it differs widely from all other beetles; but the form and ſtructure of all its other parts refer it to this claſs. See the article SCARABÆUS, *Suppl.*

Mouffet has called it the *blatta fœtida*. There are ſeveral ſpecies of it.

TERRA *alana*, a name ſometimes given to the yellowiſh white *tripoli*. See the article TRIPOLI, *Cycl.* and *Supplement.*

TETHYS, in zoology, the name of a genus of naked ſea-inſects, the bodies of which are formed, as it were, of two lips, with an oblong cartilaginous body between them. They have four tentacula, ſhaped like ears, and there are two perforations in moſt ſpecies near the tentacula.

There are ſeveral ſpecies of this genus. Vid. *Hill*, Hiſt. Anim. p. 92.

THATCH, a common covering for houſes in moſt parts of the country.

The beſt kind of *thatch* is that called *helm*, or ſtiff unbruiſed wheat-ſtraw, with the ears cut off, and bound up in bundles. This being diſpoſed in an uniform and longitudinal

order on the roof, is fixed on with laths, withies, or ropes. Ruſt. Dict. in voc.

THEA, the *tea-tree*, in botany, the name of a genus of plants, the characters of which are theſe. The cup is a very ſmall, plane, permanent perianthium, divided into ſix roundiſh, obtuſe leaves. The flower conſiſts of ſix large roundiſh, concave, and equal petals. The ſtamina are numerous filaments, about two hundred, and are very ſlender, capillary, and ſhorter than the flower. The antheræ are ſimple. The germen of the piſtil is globoſe and trigonal. The ſtyle is ſubulated, and of the length of the ſtamina. The ſtigma is ſimple. The fruit is a capſule, formed of three globular bodies, growing together: it contains three cells, and opens into three parts at the top. The ſeeds are ſingle, globoſe, and internally angulated. *Linnæi* Gen. Plant. p. 233.

Of this genus there is only one known ſpecies, which is the tree whereon our common *tea* is produced. See the article TEA, *Cycl.*

THEAVE, among country people, denotes an ewe lamb of the firſt year. Ruſt. Dict. in voc.

THERMOMETER (*Cycl.*)—In the Philoſophical Tranſactions [b] we have the deſcription of a *thermometer*, made with a rod of metal, either braſs or iron.—[[b] N° 485. p. 128–130.]

This inſtrument is compoſed of an upright ſtaff or bar of the beſt iron, four feet long, and an inch and a quarter broad, having a poliſhed braſs bar of the ſame length and width ſcrewed to it before it, with four ſteel ſcrews, and being alſo capped with ſteel, and thereon a lever moving upon a ſtud of ſteel, which communicates with another leſs lever, which is alſo upon a ſtud, having a chain at the end of it, which laps round an axis, whereto the index is fixed, which ſhews the degrees marked on a ſemicircular arch. Under the ſteel ſcrew heads there are ſmall ſlits in the braſs bar, except the lowermoſt which is fixed, which admit of its expanding, whereby it protrudes and operates on the firſt mentioned lever, which being raiſed moves the leſs lever, and thereby draws the chain which turns the axis affixed to the index, which ſhews the degree of warmth of the weather marked on the ſemicircular arch. There is a ſcrew through two ſtuds to draw the great lever backwards and forwards, as occaſion may be; and there is alſo a counterbalance to the ſmall lever, to draw the hand back when the braſs bar ſhrinks.

Dr. Mortimer laid claim to a like invention, and gave the deſcription of his *thermometer* in the Phil. Tranſ. N° 484, in the Appendix, p. 672.

The late Dr. George Martine, in his Book of Eſſays printed at London 1740, has treated the ſubject of *thermometers* very fully. Among other curious things, he has given a plate of ſeveral *thermometers*, which he compares, in order to ſhew the correſponding degrees in each.

As a fixed and unalterable point of heat is not yet found, the conſtruction of *thermometers* ſtill remains imperfect. For the heat of boiling water is not always preciſely the ſame, neither can we depend abſolutely on the point of freezing.

Fahrenheit has placed the freezing point at 32, and that of boiling water at 212; ſo that he divides the diſtance between the freezing point and that of boiling water into 180 degrees.

Sir Iſaac Newton [c], in his ſcale of the degrees of heat, marks the freezing point 0, and that of boiling water 34. Hence one of his degrees correſponds to $5\frac{5}{17}$ degrees of Fahrenheit's *thermometer*.—[[c] See Phil. Tranſ. N° 270.]

It is to be obſerved, that if two *thermometers* be filled with different ſpirits, they cannot be adjuſted to correſpond by comparing together their ſcales: for example, if the firſt *thermometer* riſes 4 diviſions, when the ſecond riſes but 3, it is not to be expected that the ſecond ſhall juſt riſe 6, 9 or 12 diviſions, when the firſt riſes 8, 12 or 16; becauſe the ſpirit will not dilate in one in the ſame proportion that it does in the other; ſo that unleſs the liquor be made to go its whole range in each of them, and the one be new marked for every degree of the other, they will not be brought to correſpond. Mr. de Reaumur being aware of this, attempted in a very ingenious way to eſtabliſh a general conſtruction of ſuch *thermometers*, which might be copied at all times, and in all countries; and ſo to ſettle a general correſpondence of obſervations to be made by ſuch inſtruments. He took a large ball and tube, and knowing well the contents of the ball and that of the tube in every part, he graduated the tube, ſo that the ſpace from one diviſion to another might contain $\frac{1}{1000}$ part of the liquor, which contained 1000 parts when it ſtood at the freezing point. Then putting the ball of his *thermometer* and part of the tube into boiling water, he obſerved whether it roſe 80 diviſions, which if it exceeded, he changed his liquor, and adding water to it lowered it ſo, that on the next trial from the freezing point to the point of boiling water it ſhould only riſe 80 diviſions: but if the liquor being too low, fell ſhort of 80 diviſions, he raiſed it by adding rectified ſpirit to it. The liquor thus prepared fitted his purpoſe, and would ſerve for making a *thermometer* of any ſize, whoſe ſcale would agree with his ſtandard. Such liquor or ſpirits being nearly of the ſtrength of brandy may be eaſily had, and may be made of a proper degree of denſity by raiſing or lowering it.

Dr. Martine finds ſome faults in this *thermometer*; one of which is, that the ball or bulk of the *thermometer* being large, is not heated or cooled ſoon enough to ſhew the quick variation of the weather. And, indeed, this is a fault common to all *thermometers*, which have bulbs to hold their liquor; a cylinder being much better, whatever liquor is uſed, except where great degrees of heat are to be meaſured, as in Sir Iſaac Newton's linſeed-oil *thermometer*. For though moſt ſpirit *thermometers* have the degree of the heat of boiling water marked upon them, as one of their boundaries; yet the heat of boiling water is always greater than that of boiling ſpirits, and therefore they are unfit to meaſure that degree of heat. But linſeed-oil is capable of ſuſtaining much greater degrees of heat; for it will bear a greater degree than what will melt lead, without firing or having the glaſs ball of the *thermometer* melted. Whereas water is only capable of a certain degree of heat, much lower, at which it will evaporate; but this is only when water boils in open veſſels.

Of late years quickſilver has been made uſe of for *thermometers*, and theſe are found to be the moſt uſeful of any; becauſe they will bear ſuch degrees of heat or cold as will burſt ſpirit-*thermometers*, or freeze the liquor in them. This laſt inconveniency happened to the French philoſophers, who went to the north polar circle to examine into the figure of the earth; for the ſpirit in their *thermometers* froze, but their mercurial ones were as uſeful as any where elſe. Fahrenheit of Amſterdam may be looked upon as the inventor of this *thermometer*; and though Prins, and ſome others in England, Holland, France, and other countries, have made this inſtrument as well as Fahrenheit, yet ſtill they may be called Fahrenheit's, as being graduated according to his ſcale.

For the different kinds of theſe *thermometers*, ſee *Deſaguliers*, Exper. Phil. Vol. II. p. 295. See alſo Dr. *Martine*'s Eſſays before mentioned.

Sir Iſaac Newton filled his *thermometer* with linſeed-oil, which will bear a very great heat. He aſſumes the rarefaction of the oil to be proportional to its heat [d]; and this aſſumption ſeems juſt from his experiments. However, it were to be wiſhed that this ſubject were farther examined.—[[d] See the Phil. Tranſ. loc. cit.]

Dr. Hales places the freezing point at 0, and the heat of water on which floating wax begins to melt at 100. In his *thermometer* the heat of boiling water anſwers to $146\frac{1}{3}$.

We ſhall here inſert a table of ſome obſervations made, with the *thermometers* of Fahrenheit, Reaumur, Sir Iſaac Newton, and Dr. Hales, communicated by Mr. Labelye.

1. *Obſervations by Fahrenheit*'s thermometer.

Deg.	
at 212	Boiling water.
190	Brandy boils.
174	Alcohol boils.
156	Serum of blood, and white of eggs hardens.
146	Killing heat for animals, in a few minutes.
108	A hen hatching eggs, but ſeldom ſo hot.
from 107 to 103	Heat of ſkin in ducks, geeſe, hens, pigeons, partridges and ſwallows.
at 106	Heat of ſkin in a common ague and fever.
from 103 to 100	Heat of ſkin in dogs, cats, ſheep, oxen, ſwine and other quadrupeds.
from 99 to 92	Heat of the human ſkin, in health.
at 97	Heat of a ſwarm of bees.
96	A perch died in three minutes, in water ſo heated.
80	Heat of the air in the ſhade, in very hot weather.
74	Butter begins to melt.
64	Heat of the air in the ſhade, in warm weather.
48	Temperate air, in England and Holland.
43	Oil of olive begins to ſtiffen and grow opaque.
32	Water juſt freezing, or ſnow and ice juſt thawing.
30	Milk freezes.
28	Urine and common vinegar freezes.
25	Blood out of the body freezes.
20	Good Burgundy, ſtrong claret and Madera freezes.
7	One part of ſpirits of wine mixt with three parts water freezes.
5	Greateſt cold in Penſilvania in 1731-2, 40° lat.
4	Greateſt cold at Utrecht in 1728-9.
0	A mixture of ſnow and ſalt, which is able to freeze oil of tartar *per deliquium*, but not brandy.

We muſt here obſerve, that the heat of a hen hatching chickens is placed, by this table, at 108 of Fahrenheit's *thermometer*; but it appears from Mr. Reaumur's experiments, that eggs will hatch in a heat no greater than that of the human ſkin. See HATCHING, *Append.*

2. *Obſervations by Reaumur*'s thermometer.

$97\frac{1}{2}$	Anſwers to the heat of boiling water.
80	Spirit of wine in Reaumur's *thermometer* boils.

Deg.

at $29\frac{2}{3}$ } Greateſt heat of the air in the ſhade; obſerved at Paris in 1706, 1707, 1724.

$10\frac{1}{4}$ } Conſtant heat of the caves of the obſervatory of Paris.

0 Artificial congelation of water.

$14\frac{1}{4}$ Lower than (0) greateſt cold at Paris, in 1709.

3. *Obſervations by Sir Iſaac Newton's* thermometer.

34 Water boils vehemently.

$28\frac{6}{11}$ Heat between water boiling and wax melting.

24 Heat of water on which floating wax melts.

$20\frac{2}{11}$ } Heat of water on which floating melted wax begins, by cooling, to loſe its fluidity and tranſparency.

17 Heat of a bath ſupportable to the hand at reſt.

$14\frac{3}{11}$ } Heat of a bath ſupportable to the hand in motion. The heat of blood juſt let out, is almoſt the ſame.

12 } Heat of *thermometer*, in contact with a human body. The heat of a bird hatching her eggs much the ſame.

6, 5, 4 } Heats of the air in the ſummer.

4, 3, 2 } Heats of the air in ſpring and autumn.

2, 1, 0 } Heat of the air in the winter.

0 Water begins to freeze.

4. *Obſervations by Dr. Hales's* thermometer.

$146\frac{1}{3}$ Anſwers to the heat of boiling water.

100 } Heat of water on which floating wax begins to melt.

59 Leaſt proper heat for the melon-thiſtle.

56 ——————— ananas, or pine-apple.

53 ——————— pimiento.

51 ——————— euphorbium.

48 ——————— cereus.

45 ——————— aloes.

43 ——————— Indian fig.

40 ——————— ficoides.

38 ——————— orange.

36 ——————— mirtle.

0 Freſh water juſt freezing.

THICKET, a thick buſh, or place full of buſhes and brambles. Ruſt. Dict. in voc.

THILL, the beam, or draught-tree of a cart or waggon, upon which the yoke hangs. Ruſt. Dict. in voc.

THILLER, or THILL-*horſe*, the horſe that is put under, or immediately yoked to the *thill*. Ruſt. Dict. in voc.

THIMBLE, a cover for the finger, made of braſs, ſteel or ſilver, and uſed by all people who ſow, as taylors, milliners, *&c.*

THIMBLE, in the ſea language, a ſort of ring, the outſide of which is conſiderably hollowed to receive ropes. *Thimbles* are fixed as loops, to prevent the tackle-hook from galling the rope. *Blanckley*, Naval Expoſ. p. 169.

THIRDENDALE, a liquid meaſure in uſe at Saliſbury, containing three pints. Ruſt. Dict. in voc.

THIRST (*Suppl.*)—We find warm druggs, as liquorice, ſometimes effectual in allaying *thirſt*: nay pepper will, in ſome caſes, have a like effect, by cauſing a more plentiful flow of the ſaliva.

In feveriſh diſorders, the patient is frequently tormented with a violent *thirſt*, which is moderated by acidulating the barley-water, or ſage-tea, with ſpirit of vitriol, or with lemon-juice; but by nothing ſo much, as allowing the patient ſome ſlices of an orange. *Pringle*, Obſerv. on Diſeaſ. of Army, p. 135.

THISTLE (*Suppl.*)—*Bleſſed* THISTLE, a name by which ſome call the *cnicus*, or ſaffron-flower. See the article CNICUS, *Suppl.*

Carline-THISTLE, *carlina*, in botany, the name of a genus of plants. See the article CARLINA, *Suppl.*

Diſtaff-THISTLE, in botany, the name of a genus of plants, called by botaniſts *atractylis*. See ATRACTYLIS, *Append.*

Fiſh-THISTLE, a name ſometimes uſed for the *cinara*, or artichoak. See the article CINARA, *Suppl.*

Fuller's THISTLE, the name by which ſome call the *dipſacus*, or teaſel. See the article DIPSACUS, *Suppl.*

Melon-THISTLE, or *Torch*-THISTLE, the Engliſh name of a genus of plants, called by botaniſts *cactus*. See the article CACTUS, *Suppl.* and *Append.*

Melancholy-THISTLE, the ſame with the *gentle thiſtle*, or *cirſium*. See the article *gentle*-THISTLE, *Suppl.*

Sow-THISTLE, the Engliſh name of a genus of plants, called *ſonchus* by botaniſts. See the article SONCHUS, *Suppl.*

Star-THISTLE, the name by which ſome call the *calcitrapa*, a ſpecies of *centauria*. See the article CENTAURIA, *Appendix.*

THORN, a name denoting, or characterizing ſeveral different genera of prickly plants. Thus:

THORN-*apple* is the Engliſh name of the *ſtramonium* of botaniſts. See the article STRAMONIUM, *Suppl.*

Black-THORN, the name by which ſome call the *prunus ſylveſtris*, or wild plum, more uſually called *ſloe*. See the article PRUNUS, *Suppl.*

Box-THORN, or *Avignon*-THORN, names given to the *lycium* of botanical writers. See the article LYCIUM, *Append.*

Buck-THORN, the name of a genus of plants. See the article RHAMNUS.

Chriſt's THORN, the Engliſh name of a genus of plants, called *paliurus* by botanical writers. See PALIURUS, *Suppl.*

Egyptian-THORN, a name ſometimes given to *acacia*. See the article ACACIA, *Suppl.*

Goat's THORN, the Engliſh name of a genus of plants, called by botaniſts *tragacanth*. See the article TRAGACANTH, *Suppl.*

Haw-THORN, *White*-THORN, *Ever-green*-THORN, *&c.* names given to the *meſpilus*. See the article MESPILUS, *Suppl.*

Purging-THORN, a name ſometimes given to the *rhamnus*. See the article RHAMNUS, *Suppl.*

THORNBACK, the Engliſh name of a ſpecies of ray-fiſh, prickly on the back, and with tuberculoſe teeth, and a tranſverſe cartilage in the belly. See the article RAIA, *Suppl.*

THOROUGH-*wax*, in botany, a name by which ſome writers call the *bupleurum*, or hare's ears. See the article HARE'S *ears*, *Suppl.*

THREE-*leaved graſs*. See the articles TREFOIL and TRIFOLIUM, *Suppl.*

THRICHECUS, in zoology, the name uſed by Dr. Hill for the *manati*, or ſea-cow. See the article MANATI, *Suppl.*

THROAT-*wort*, a name given to ſeveral ſpecies of *campanula*. See the article CAMPANULA, *Suppl.*

THROPPLE, among country people, denotes the windpipe of a horſe. Ruſt. Dict. in voc.

THROSTLING, a diſeaſe of black cattle, proceeding from humours gathering under their throats; by which means their throats are ſo dangerouſly ſwelled, that they will be choaked unleſs ſeaſonably relieved by bleeding. Ruſt. Dict. in voc.

THRUSH, in ornithology, the Engliſh name of a large genus of birds, called by authors *turdus*. See the article TURDUS, *Suppl.*

THYME (*Suppl.*)—*Wild* THYME, *Lemon*-THYME, or *Mother-of*-THYME, names uſed for a diſtinct genus of plants, called by botanical writers *ſerpyllum*. See the article SERPYLLUM, *Suppl.*

Maſtich-THYME, a name uſed for the *marum*, *maſtichina*, or *thymbra*. See the article THYMBRA, *Suppl.*

THUYA (*Suppl.*)—The leaves of this tree ſmell like ointment, and in fact prove an excellent one for freſh wounds, cloſing them ſpeedily. Ruſt. Dict. in voc. *lignum.*

TICK, in the hiſtory of inſects, the name of the ſheep-louſe, called by authors *acarus*. See the article ACARUS, *Suppl.*

TIER, in the ſea language, the name of the ſeveral ranks of guns; which, according as they are placed on the lower, middle, or upper decks, are called the lower, middle, or upper *tier*. *Blanckley*, Nav. Expoſ. p. 169.

TIERCEL, in falconry, a name given to a male hawk, as being a third part leſs in ſize than the female. Ruſt. Dict. in voc.

TIGER (*Suppl.*)—The ſkull of this creature, both as to the teeth and other particulars, very much reſembles that of the cat, except that, in the room of the tranſverſe ſutures of the cat's, there is in the *tiger's* one in the figure of a great Y, ſo cloſe and firm, that the bones ſeem contiguous.

Its tuſks are a little crooked, like thoſe of the dog and cat; their exerted part very white, and the bow of ſome of them very long, not leſs than five inches. Its claws are whitiſh, and ſemitranſparent, very flat, ſharp and pointed, and extremely hooked; every way in colour and ſhape like the claw of a cat. Uſually, on the fore paws of the larger *tigers*, theſe are at the baſis an inch broad, and are two inches and a half long. The bone on which the claw is ſet receives it into a little groove, and is by a double epiphyſis itſelf inſerted into the claw; by which means the claw is firmly held in its place. *Grew's* Muſ. p. 13.

TIGER-*ſhell*, the Engliſh name of the red *voluta*, with large white ſpots. See the article VOLUTA, *Suppl.*

TIKE (*Suppl.*)—TIKE is alſo uſed for a ſmall bullock or heifer, and for a ſort of worm. Ruſt. Dict. in voc.

TILLER, (*Cycl.*) a term uſed by farmers to ſignify, that the produce of the grain branches out into ſeveral ſtalks. In which ſenſe, it denotes the ſame thing with the Latin word *fruticare*. Vid. *Tull's* Horſe-hoeing Huſbandry, p. 105.

TILTH, a country term for tillage, manuring, or improving of ground. Ruſt. Dict. in voc.

TIMBER (*Suppl.*)—*Prick*-TIMBER, a name by which ſome call the *euonymus*, or ſpindle-tree. See the article EUONYMUS, *Suppl.*

TIN, how expanded by heat. See the article HEAT, *Append.*

TIPULA (*Suppl.*)—*Waſp*-TIPULA, in natural hiſtory, the name of an inſect, the deſcription of which ſee under the article WASP-*tipula*, *Suppl.*

TIRING,

TIRING, in falconry, is the giving a hawk a leg or pinion of a pullet to pluck at. Dict. Ruſt. in voc.

TIT-*lark*. See ALAUDA, *Suppl.*

TOBACCO, *nicotiana*, the Engliſh name of a diſtinct genus of plants. See the article NICOTIANA, *Suppl.*

TOE-*ſhell*, the Engliſh name of a genus of ſhells, called by authors *pollicipes*. See the article POLLICIPES, *Suppl.*

TOFT (*Cycl.*)—TOFT alſo ſignifies a grove of trees. Dict. Ruſt. in voc.

TOLK, in ornithology, a name ſometimes given to the black, brown, and white, mottled *tringa*. See the article TRINGA, *Suppl.*

TONGUE (*Suppl.*)—To the inſtances briefly mentioned under this head in the Supplement, we may add the following account of a man at Montagu, in the Bas Poictou, who being ſeized with the ſmall-pox in his fifth or ſixth year, loſt his whole *tongue* by gangrene, or putrefaction; yet, notwithſtanding, performed in perfection the five actions belonging to the *tongue*, *viz.* ſpeaking, taſting, ſpitting, chewing, and ſwallowing [a]; nature having, with infinite artifice, given a new conformation to the mouth, proper to ſupply the want of the laſt organ.—[a *Jac. Rolandi Agloſtomographia, ſive deſcriptio oris ſine lingua quod perfectè loquitur et reliquas ſuas functiones naturaliter exercet*; firſt publiſhed in French, at Saumur, in 1630; tranſlated into Latin by Car. Ruygerus, and publiſhed in the Ephem. German. D. an. 3. p. 481—513.]

For ſpeech, inſtead of the ordinary proviſion, the little fleſhy part of the *tongue* remaining was inflected in the middle towards the palate, the teeth inverted, and long inwards, the muſculi buccinatores eaſily contracting between the dentes molares. In fine, there was a diſpoſition in all the organs to produce ſpeech without a *tongue*: for the breath iſſuing at the oval aperture of the larynx, was further broken, and rendered vocal by the inflation of the fleſhy body, the motion of the lips, the retraction of the buccinatores, the tremulous agitation of the uvula, and the commotion of the lower jaw. Laſtly, by the inverſion of the teeth, the depreſſion of the palate, the abundance of ſaliva, and the capacity of the mouth, the ſound was ſtill further modified and determined, ſo as to render it articulate. Habit too, and the repeated attempts to ſpeak at an age when the parts were eaſily flexible, had contributed greatly to the diſtinctneſs of it. For taſting, it is evident from this, as well as other conſiderations, that the *tongue* is not the only organ of it, but that the palate is alſo a ſeat of this ſenſe. For chewing, the office of turning the meat in the mouth was here performed by the lips and cheeks, the muſcles whereof repelled towards the maxillares; ſuch parts, as in maſtication might fall from one ſide to the other. For the firſt morſel he took, he could only chew on that ſide into which he put it with his hand; the ſecond he put in like manner on the other ſide; and thus varied and ſupplied each alternately. For ſwallowing, the gravity of the food contributed ſomething to this; which he further promoted by ſtretching out his neck, inclining his head, and drawing back the buccinatores within his teeth; all which were ſeconded by the mouth and fauces, being well moiſtened with plenty of ſaliva. In effect, divers animals, as the tortoiſe and the crocodile, ſtork, *&c.* ſwallow without any *tongue*; and fiſhes, though their *tongue* is fixed immoveable to their palate. For ſpitting, it was performed by the lips, aided by the internal contraction of the mouth, and the retraction of the buccinatores over the grinders.

Roland's inſtance was ſingular at that time, but a parallel one has been ſince obſerved in a girl at Liſbon fifteen years old; of which an account was given in 1718 to the Royal Academy of Sciences, by M. de Juſſieu [b]. Upon inſpecting the mouth of this girl, there appeared nothing in all that part ordinarily poſſeſſed by the *tongue*, but a little eminence in form of a papilla, between three and four lines high, in the middle of her mouth, ſcarce perceivable by the eye. Upon preſſing this with the finger, a kind of motion of contraction and dilatation was perceived in it; which ſhewed, that though the *tongue* was wanting, the muſcles of which it was formed, and which are deſtined to give it motion, were nevertheleſs there. With the help of theſe ſhe ſpoke as diſtinctly and eaſily, as if nothing had been wanting: ſhe diſtinguiſhed taſtes like other people. For maſtication, it was chiefly effected by the motion of the lower jaw, which ſhe drew nearer to, or further from the grinders of the upper, under which the food to be chewed was. In this action ſhe ſometimes alſo made uſe of her fingers, but much more in the action of ſwallowing, in order to protrude the maſticated food towards the orifice of the œſophagus. For drinking, ſhe performed it like other people, excepting the attention ſhe employed to prevent the liquor going down too faſt; in order to which, ſhe kept her head a little inclined forwards. Laſtly, the action of ſpitting was ſupplied by the muſcles of the papilla, which filled the lower part of her mouth: theſe riſing almoſt to a level with the teeth of the lower jaw, and the buccinatores approaching towards both jaws, expreſſed the ſaliva, and conducted it to the ſphincter of the lips, from whence the air, driven with violence from the larynx, ſerved as a vehicle to expel it out of the mouth [c].—[b Mem. de l'Acad. Scienc. an. 1718. p. 6—16. c *Juſſieu*, loc. cit. p. 7, ſeq.]

Serpent's TONGUE, or *Adder's* TONGUE, names given to the *ophioglоſſum*, a diſtinct genus of plants. See the article OPHIOGLOSSUM, *Suppl.*

TONIC *accent*. See the article ACCENT, *Cycl.*

TOOTH-*pick*, a name by which ſome call the *viſnaga*, a ſpecies of *daucus*, according to Linnæus. See the article DAUCUS, *Suppl.*

TOOTH-*wort*, the Engliſh name of a genus of plants, called by botanical writers *dentaria*. See the article DENTARIA, *Suppl.*

TORROCK, a bird of the larus or gull kind, with a white head, and a ſpot of black on each ſide. See the article LARUS, *Suppl.*

TOUCH-*me-not*, the name of a ſpecies of *balſamine*. See the article BALSAMINA, *Suppl.*

TOURNEFORTIA, in botany, a name given by Pontedera to a genus of plants, called by Linnæus *anthoſpermum*. See the article ANTHOSPERMUM, *Append.*

TOWER-*muſtard*, the Engliſh name of a genus of plants, called *turritis* by botaniſts. See the article TURRITIS, *Suppl.*

TRACES (*Suppl.*)—*Ladies* TRACES, in botany, the name of a diſtinct genus of plants, called by botaniſts *orchis*. See the article ORCHIS, *Suppl.*

TRACHELIUM (*Suppl.*) is alſo a name uſed by many for ſeveral ſpecies of *campanula*. See the article CAMPANULA, *Suppl.*

TRADESCANTIA, in the Linnæan ſyſtem of botany, the name given to the *ephemerum* of Tournefort. See the article EPHEMERUM, *Suppl.*

TRAGO-*orchis*, in botany, a name uſed by ſome authors for the *ſatyrium* of Linnæus. See the article SATYRIUM, *Append.*

TRAJECTORY (*Cycl.*)—This term is often uſed, in general, for the path of any body moving either in a void, or in a medium that reſiſts its motion; or even for any curve paſſing through a given number of points. Thus Newton, Princip. lib. 1. prop. 22. propoſes to deſcribe a *trajectory* that ſhall paſs through five given points.

TRAVE, among farriers, the ſame with *travice*. See the article TRAVICE, *Suppl.*

TRAVELLER'*s joy*, a name by which the *clematitis*, or virgin's bower, is ſometimes called. See the article VIRGIN'*s bower*, *Suppl.*

TREACLE-*muſtard*. See the article MUSTARD, ſupra.

TREE (*Suppl.*)—*Cork*-TREE, the Engliſh name of a genus of plants, called by botaniſts *ſuber*. See the article SUBER, *Suppl.*

Chaſte TREE. See the article VITEX, *Suppl.*

Germander TREE. See the article TEUCRIUM, *Suppl.*

White-leaf, or *mealy* TREE, a name by which ſome call the *viburnum*. See the article VIBURNUM, *Suppl.*

TREE *of life*, the Engliſh name of a genus of *trees*, called *thuya* by botaniſts. See the article THUYA, *Suppl.*

TREE-*louſe*. See the article LOUSE, ſupra.

TREFOIL (*Suppl.*)—*Bean* TREFOIL, a name ſometimes given to the *cytiſus*. See the article CYTISUS, *Suppl.*

Bird's foot TREFOIL, a name given by ſome writers to the *lotus*. See the article LOTUS, *Suppl.*

Marſh-TREFOIL, the name of a genus of plants, called by botaniſts *menyanthes*. See MENYANTHES, *Suppl.*

Moon-TREFOIL, the name by which many call the *medicago* of botanical writers. See the article MEDICAGO, *Suppl.*

Shrub-TREFOIL, a name given to very different plants; as the *ptelea* of Linnæus, the *cytiſus*, and *dorycnium*, or the ſilvery *convolvulus*. See the articles PTELEA, CYTISUS, *&c. Suppl.*

Snail TREFOIL, *medica*, in botany, the name of a diſtinct genus of plants. See the article MEDICA, *Suppl.*

TRELLIS, an aſſemblage of wooden bars, croſſing one another, either in a ſtrait line, or ſlopewiſe, deſigned to ſupport wall-trees.

There is another kind of *trellis*, made of iron-wire. See Build. Dict. in voc.

TRILATERAL, in geometry, an appellation given to all three-ſided figures. See TRIANGLE, *Cycl.*

TRILOCULAR, in botany, is applied to a capſule having three cells. See CAPSULE, *Append.*

TRIM, in carpentry, is to fit one piece of timber into another. Build. Dict. in voc.

TRIOSTEOSPERMUM, in botany, the name by which Dillenius calls a ſpecies of *lonicera*. See the article LONICERA, *Append.*

TRIPETALOUS *plants*, ſuch whoſe flower conſiſts of three petals or leaves. Ruſt. Dict. in voc.

TRITON, in zoology, the name by which Dr. Hill calls a genus of inſects of the *gymnarthria*, or naked kind.

The body of the *triton* is oblong; the roſtrum at the mouth is of a ſpiral form; the tentacula are fourteen in number, and twelve of them cheliferous. Vid. *Hill*, Hiſt. Anim. p. 89, ſeq.

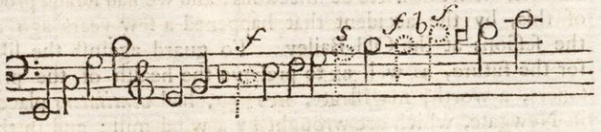
TROAT, among ſportſmen, the cry of a buck in rutting time. Dict. Ruſt. in voc.

TROCHING, the ſmall branches on the top of a deer's head. Ruſt. Dict. in voc.

TROPÆOLUM, in the Linnæan ſyſtem of botany, the name of a genus of plants, called by Tournefort *cardamindum*, and by C. Bauhine *naſturtium indicum*.

The characters are theſe: The cup is a deciduous perianthium, compoſed of a ſingle leaf, divided into five ſegments, erecto-patulous, acute, coloured, and the two lower ones narrower than the reſt. The flower conſiſts of five roundiſh petals, inſerted into the diviſions of the cup; the two upper petals are ſeſſile; the three others have very long and barbated ungues. The ſtamina are eight ſhort, ſubulated, declinated, unequal filaments. The antheræ are erect, oblong, quadrilocular, and aſſurgent. The germen is roundiſh, ſtriated, and formed of three lobes. The ſtyle is ſimple, erect, and of the length of the ſtamina. The ſtigma is trifid and acute. The fruit conſiſts of three capſules, convex, ſulcated, and ſtriated on one ſide, and angular on the other. The ſeeds are three in number, gibbous on one ſide, and angulated on the other; but, upon the whole, ſomewhat roundiſh, and ſtriated deeply. Vid. *Linnæi* Gen. Plant. p. 158. See the article CARDAMINDUM, *Suppl.*

TROPHY (*Cycl.*)—TROPHY, in architecture, an ornament repreſenting the trunk of a tree, charged or encompaſſed all round with arms, or military weapons, both offenſive and defenſive. Build. Dict. in voc.



TROUGH, (*Cycl.*) a hollow wooden veſſel for kneading bread in, or to beat apples in for cyder; alſo a piece of the trunk of a tree made hollow, to feed ſwine in, or an open pipe or channel, made of boards, for the conveyance of water. Dict. Ruſt. in voc.

TRUE-*love*, or *Herb* TRUE-*love*, the name of a genus of plants, called *herba Paris* by botaniſts. See the article HERBA *Paris*, *Suppl.*

TRUG (*Cycl.*)—TRUG is alſo a country word for a milk-tray, or a hod to carry mortar in.

TRUMPET (*Cycl.*)—The uſual ſounds of the *trumpet* are repreſented by the following muſical notes.

1. 2. 3. 4. 5. 6. 7. 8. 9. 10. 11. 12. 13. 14. 15. 16.

Here the loweſt ſound being denoted by 1, the pitch of the reſt, or the number of their reſpective vibrations, during the time that C vibrates once, will be expreſſed by the numbers denoting the order of the ſounds, 2, 3, 4, 5, &c. The ſounds expreſſed by the muſical numbers, that is, by 2, 3, 5 [a], and their compoſites, which are 4, 6, 8, 9, 10, 12, 15, 16, are all perfectly in tune; but the ſounds expreſſed by numbers not muſical, as 7, 11, 13, 14, are falſe. Three of theſe, *viz.* B♭, its octave, and A, diſtinguiſhed by *f* placed over them, are too flat; and the remaining note F, marked with an S, is too ſharp.—[[a] See MUSICAL *numbers*, *Suppl.* and *Append.*]

The reaſon of which is, that B♭ ought to be a tone major below C; that is, its pitch to that of C will be as 8 to 9; but the proportion given by the *trumpet* is as 7 to 8; which being a leſs proportion than that of 8 to 9, it follows, that B♭ will be too flat. The ſame holds true of its octave. And A being a tone minor above G, it ought to be to G as 10 to 9: but in the *trumpet*, it is to G as 13 to 12; which being leſs than the proportion of 10 to 9, it follows, that A will be too flat. On the other hand, F ought to be a ſemitone major above E; that is, F ought to be to E, as 16 to 15; but, in the *trumpet*, F is to E, as 11 to 10; which being a greater proportion than that of 16 to 15, it follows that F is too high or too ſharp.

This ſyſtem of *trumpet* notes is an effectual confutation of thoſe who are for introducing 7, 11, 13, and other primes into muſic.

TRUMPET-*honeyſuckle*. See the article HONEYSUCKLE, ſupra.

TRUNK (*Suppl.*)—TRUNK is alſo uſed for a ſtrong cheſt, or box, of a roundiſh form, at leaſt on the upper ſide. Ruſt. Dict. in voc.

TUBEROSA, a name given by Heiſter to a genus of plants, called by Linnæus *polyanthes*. See POLYANTHES, *Append.*

TUE-*iron*, in ſmithery, the iron through which a ſmith's bellows blow. *Blanckley*, Naval Expoſ. p. 178.

TUEL, among ſportſmen, denotes the fundament of a horſe, or wild beaſt. Dict. Ruſt. in voc.

TULIP (*Suppl.*)—*African* TULIP, or *Cape* TULIP, names uſed by ſome for the *hæmanthus*, a diſtinct genus of plants. See the article HÆMANTHUS, *Suppl.*

TULIP-*tree*, the Engliſh name of a genus of trees, called by botaniſts *tulipifera*, and *liriodendrum*. See the article LIRIODENDRUM, *Suppl.*

Laurel-leaved TULIP-*tree*, a name ſometimes given to the *magnolia* of botanical writers. See the article MAGNOLIA, *Suppl.*

TUMPING, the making a kind of fence in the fields, by ſetting trees almoſt on the ſurface of the ground, and covering their roots with mould. Ruſt. Dict. in voc.

TUN-*hoof*, a name ſometimes uſed for ground-ivy. See the article IVY, *Suppl.* and *Append.*

TURBITH, in botany, a name uſed by many for the *thapſia*, or deadly carrot. See the article THAPSIA, *Suppl.*

Mineral TURBITH (*Cycl.*)—We read of this preparation's being given to the quantity of ten grains, with the ſame quantity of camphor, and fifteen grains of the pilul. ex duob. to remove the ſwelling of the teſticles. This medicine, which in the beginning vomited and purged, at laſt operated chiefly as an alterative. It is ſaid to be ſucceſsful in obſtinate venereal and ſcrophulous diſorders. See Medic. Eſſ. Edinb. Vol. IV. art. 4.

TURCOIS (*Cycl.*)—This gem has many virtues attributed to it; but all that we know of it at preſent is, that, like other bodies which contain copper, it is a violent emetic, and not at all fit to be received into practice.

TURCOIS *colour*, the pale blue of the natural *turcois* gem. This is a very favourite colour in the glaſs trade, and is given to glaſs in the following manner. Firſt calcine common ſea-ſalt, and beat it to a fine powder; then make a pot of the ſea-green glaſs, of a fair and full colour: to this, when in fuſion, throw in at times the powder of ſalt, till the maſs has loſt all its tranſparence, and is become paler and opake; then add, by very ſmall quantities at a time, more and more ſalt, till the colour is exactly that of the *torcois* gem; and when it is ſo work it immediately, for the ſalt is ſoon burnt off, and the glaſs becomes tranſparent, and of its green colour. If it become tranſparent while working, more ſalt muſt be thrown in, and that will reduce it to the ſame opacity again. *Neri*'s Art of Glaſs, p. 57.

TURCOIS *enamel*, an enamel exactly of the colour of the *torcois* gem, and very much reſembling it in many reſpects. It is made in the following manner: Take of the common matter of enamels ſix pounds, melt it, refine it, and caſt it into the furnace again; when it is melted and refined put in, of thrice-calcined braſs three ounces, zaffer prepared ninety-ſix grains, wherewith mix well forty-eight grains of manganeſe; mix theſe well, and put them into the matter at four times; let the whole incorporate, and afterwards take a proof to ſee if it be right, or if it require more of any of the powders. *Neri*'s Art of Glaſs, p. 149.

TURK's *cap*, a name uſed by ſome for a ſpecies of lilly. See the article LILIUM, *Suppl.*

TURK's *head*, a name ſometimes uſed for the *cactus*, a diſtinct genus of plants. See the article CACTUS, *Append.*

TURKY-*baum*. See the article BAUM, ſupra.

TURKY-*wheat*, a name ſometimes given to *maiz*, or *yucca*. See the articles YUCCA and MAIZ, *Suppl.*

TURNEP (*Suppl.*)—*French* TURNEP, the name by which ſome call the *napus* of botanical writers. See the article NAPUS, *Suppl.*

TURNEP-*cabbage*, in botany. See the articles BRASSICA and CABBAGE, *Suppl.*

TURTLE-*ſhell*, (*Suppl.*) is alſo the name of ſeveral ſpecies of the *teſtudo*, or tortoiſe. See the article TESTUDO, *Supplement.*

TUSK (*Cycl.*)—TUSK, in carpentry, a bevel ſhoulder, made to ſtrengthen the iron of the joiſt, which is let into the girder. Build. Dict. in voc.

TWITCH-*graſs*, the ſame with *quick-graſs*, a weed very hurtful to the farmers. Ruſt. Dict. in voc.

TWYBLADE, a name uſed by ſome for the *ophris* of botanical writers. See the article OPHRIS, *Suppl.*

TYPH-*wheat*, a kind of corn very like rhye. Ruſt. Dict. in voc.

U.

VACCA *marina*, in zoology, a name ſometimes uſed for the *manati*, or ſea cow. See the article MANATI, *Suppl.*

VALERIAN (*Suppl.*)—*Greek* VALERIAN, a name frequently uſed for the *polemonium* of botaniſts. See the article POLEMONIUM, *Suppl.*

VALERIANOIDES, in botany, a name given by Petiver to the *cephalanthus* of Linnæus. See the article CEPHALANTHUS, *Append.*

VALLEY (*Cycl.*)—VALLEYS, in building, denote the gutters over the ſleepers in the roof of a building. Build. Dict. in voc.

VALLOR, VALLOW, or VATE, among country people, a hollow mould, in which a new-made cheeſe is preſſed. Ruſt. Dict. in voc.

VARVELS, in falconry, ſmall ſilver rings about a hawk's leg, with the owner's name on them. Ruſt. Dict. in voc.

VATE, in the making of cheeſe. See VALLOR, ſupra.

VAULT (*Suppl.*)—*Going to the* VAULT, a term uſed by ſportſmen for a hare's taking the ground like a coney, which ſhe ſometimes does. Ruſt. Dict. in voc.

VEGETABLE (*Suppl.*)—*Perſpiration of* VEGETABLES. See PERSPIRATION, *Append.*

VELLICULA, a name ſometimes uſed for the *forficula*, an inſect called in Engliſh the *ear-wig*. See the article EAR-*wig*, *Append.*

VELLING, a term uſed by huſbandmen in the weſt of England for plowing up by the turf. Ruſt. Dict. in voc.

VENTILATOR, a machine by which the noxious air of any cloſe place, as an hoſpital, gaol, ſhip, chamber, *&c.* may be changed for freſh.

The noxious qualities of bad air have been long known, tho' not ſufficiently attended to in practice; but it is to be hoped, that the indefatigable pains taken by Dr. Hales to ſet the miſchiefs ariſing from foul air in a juſt light, and the eaſy remedy he has propoſed by the uſe of his *ventilators*, will at length prevail over that unaccountable ſloth, or obſtinacy, which, where particular intereſts are not immediately concerned, ſeems to poſſeſs the generality of mankind, and which rarely allows them to give due attention to any new diſcovery.

The *ventilators* invented by that ingenious author conſiſts of a ſquare box of any ſize; in the middle of one ſide of this box a broad partition, or midriff is fixed by hinges, and it moves up and down by means of an iron rod, fixed at a proper diſtance from the other end of the midriff, and paſſing through a ſmall hole in the cover of the box. Two boxes of this kind may be employed at once, and the two iron rods may be fixed to a lever moving on a fixed center; ſo that by the alternate raiſing and preſſing down of the lever, the midriffs are alſo alternately raiſed and depreſſed, whereby theſe double bellows are at the ſame time both drawing in air, and pouring it out through apertures with valves made on the ſame ſide with, and placed both above and below the hinges of the midriffs. For a farther account of this machine we refer to the author himſelf, who gives a full detail of it, and of its manner of working. See Deſcription of *Ventilators*, by Stephen Hales, D. D. Lond. 1743, 8vo.

The Doctor has ſhewn the uſe of his *ventilators* very fully. As to ſhips, in particular he obſerves that the wind-ſail, made uſe of at ſea to introduce freſh air between decks, is far from being ſufficient for that purpoſe; nor can it be uſed with equal ſafety to the ſick, and thoſe who are ſleeping, by means of the ſtrength of the wind which conveys the air with too much violence. But when the foul air is carried off by means of *ventilators*, notwithſtanding the great velocity with which they throw out the air, which they may do at the rate of ſixty tuns in a minute, yet the motion of it downwards into the hold, to ſupply what is carried off, is ſo very gentle, that it cannot be perceived; becauſe the ſum of all the open paſſages for it through the deck exceeds the opening of the trunk of the *ventilator*, in ſo great a proportion as 100 to 1, or more. Beſides, in a calm the wind-ſail can do little or no good; nor when the ſhip is under ſail, at which time the wind-ſail is not uſed. And it is to be obſerved, that it is not the *ventilating* of a ſhip now and then with a wind-ſail, when wind and weather ſerve, that will ſuffice; it ought to be done daily, if due regard be had to the health of the ſhip's crew. The great quantity of rancid noxious vapours, which are inceſſantly exhaling from a number of live human bodies, the ſtench that inceſſantly ariſes from the bilge water, and from the hot, ſtagnant, putrid air in the hold, makes it very adviſeable to refreſh ſo bad an air continually, either with the wind-ſail, when that can be properly uſed, or elſe with *ventilators*, which are intended to ſupply the defects of the wind-ſail.

Ventilators muſt alſo be of particular ſervice in new ſhips, which are obſerved to be more unhealthy, on account of a greater quantity of ſappy wreak which ariſes from new timber, and makes the confined air the more unwholeſome. They will alſo be an effectual preſervative of horſes in tranſports, where they are ſometimes ſuffocated, when in a ſtorm there is a neceſſity to ſhut the hatches down.

Theſe *ventilators* will alſo drive out of the hold of a ſhip that dangerous vapour which ariſes from corn, which is ſo noxious, that ſometimes they dare not venture into the hold, till after the hatches have been opened for ſome time.

Ventilation will not only be of ſervice to preſerve ſeveral kinds of goods, but alſo the timbers and planks of the hold itſelf, when laid up in ordinary, as well as when in uſe, and will make the air in the hold leſs noxious, though it will ſtill be offenſive to the ſmell, by reaſon of the bilge water. But this may be made leſs offenſive, by often letting in ſweet water from the ſea, and then pumping it out; which good practice ought to be continued, notwithſtanding the uſe of the *ventilators*.

What is here ſaid of the foul air of ſhips may be applied to that of mines, gaols, work-houſes, barracks and hoſpitals. In mines, *ventilators* may guard againſt the ſuffocations, and other terrible accidents ariſing from damps. The air of gaols has been often known to be infectious; and we had a fatal proof of this, by the accident that happened a few years ago at the ſeſſions at the Old-Bailey. To guard againſt the like for the future, as well as to preſerve the health of the priſoners, a worthy magiſtrate, in 1752, had *ventilators* placed in Newgate, which are wrought by a wind-mill: and in the beginning of the preſent year, 1753, Dr. Hales gave an account of the good ſucceſs attending the uſe of theſe machines, by a remarkable decreaſe in the uſual mortality and ſickneſs of that place.

The Doctor is alſo of opinion, that a *ventilation* of warm dry air from the adjoining ſtove, with a cautious hand, might be of ſervice to trees and plants in green-houſes; where it is well known that an air full of the rancid vapours, which perſpire from the plants, is very unkindly to them, as well as the vapours from human bodies are to men. For freſh air is as neceſſary to the healthy ſtate of vegetables, as of animals.

The larger kinds of *ventilators*, uſed by the Doctor, are ten feet long, five feet broad, and two feet high, in the clear within. Thoſe he uſed by way of experiment on board the Captain, a ſeventy gun ſhip, were ten feet long, four feet three inches wide, in the clear within, and thirteen inches deep; one inch of which being occupied by the midriff, there remained a foot depth for it to riſe and fall in. A *ventilator* of theſe dimenſions will, through a trunk of a foot ſquare, drive the air at the rate of twenty-five miles in an hour, which is double of what Mariotte aſſigns for the velocity of a pretty ſtrong wind.

But beſides theſe large *ventilators*, the Doctor made a ſmaller ſort, four feet in length, ſixteen inches in breadth, and thirteen inches, all in the clear within. This ſmaller *ventilator* may be very uſeful in preſerving the bread, in the bread-room of a ſhip, ſweet and dry. Peaſe alſo, and oatmeal, which are apt to heat and ſpoil in caſks, may be preſerved, by putting them into a large bin, with a falſe bottom of hair cloth laid on bars, whereby freſh air may be blown upwards through them with theſe ſmall *ventilators*.

Ventilators are alſo of excellent uſe for the drying of corn, hops, and malt. *Hales*, lib. cit. p. 100, 108, 129, 151. Gunpowder may be thoroughly dried, by blowing air up through it by means of *ventilators*. *Hales*, ib. p. 119, ſeq. What advantage dry gunpowder has over that which is damp, may be ſeen by the experiment mentioned in the article GUNPOWDER, *Append.*

VENUS (*Cycl.*)—Signior Bianchini has given the deſcription of a globe for *Venus*, the principal properties of which are, that the plane of the ecliptic makes an angle of 15° with the axis, the tropics are 75° from the equator, and the polar circles only 15° from it. For a farther account of it, ſee *Deſaguliers*, Experim. Philoſoph. Vol. II. p. 552, ſeq.

VENUS's *comb*, the Engliſh name of a genus of plants, called by botanical writers *ſcandix*. See the article SCANDIX, *Suppl.*

VENUS's *looking-glaſs*, a name ſometimes uſed for the *campanula*, or bell-flower. See the article CAMPANULA, *Suppl.*

VENUS's *navel-wort*, the name by which ſome call the *omphalodes*, a diſtinct genus of plants. See the article OMPHALODES, *Suppl.*

VERGE, among gardeners, generally denotes the edge or outſide of a border; but more particularly, is uſed for a ſlip of graſs adjoining to gravel-walks, and dividing them from the borders in the parterre-garden. *Miller*, Gard. Dict.

VERMIS *aureus*, the name by which Bartholine, and others, call the *aphrodita*, a genus of ſea-inſects. See the article APHRODITA, *Append.*

VERVAIN *mallow*, the Engliſh name of a diſtinct genus of plants, called by botanical writers *alcea*. See the article ALCEA, *Suppl.*

VESSEL (*Cycl.*)—*Chemical* VESSELS. The article of *chemical* APPARATUS, *Suppl.* having been accidentally forgot, we are forced to inſert it under this title VESSEL, though ſomewhat improperly, the word APPARATUS being of much more extenſive ſignification.

Dr. Shaw, in his Eſſay on the uſe of a portable laboratory, has given a liſt of all the apparatus neceſſary for it, which will ſerve alſo, in general, for a complete chemical apparatus for all ordinary caſes, and common courſes of chemical experiments: for extraordinary purpoſes it may be enlarged at diſcretion, according to the views of the operator.

The chemical apparatus may be divided into two kinds, the remote and immediate; or, in other words, ſuch as are preparatory to the operations, and ſuch as are actually employed in them. The remote apparatus conſiſts of ſeveral particulars. Among theſe are firſt ſuch as are neceſſary to the exactitude of the proceſs, for every chemical operation is to be performed in an exact manner. Good ſcales and weights are neceſſary for the exactly determining the quantity of the ſubject to be employed, weight being the true index of the quantity of matter in bodies; but in common caſes, or where water, or other liquors of nearly the ſame ſpecific gravity with water are uſed, the work is conſiderably ſhortened by the uſe of a meaſure, which in water very nearly correſponds to weight in the common acceptation, a pint of it very nearly anſwering to a pound in weight. Hence the next thing to a ſet of ſcales and weights, in the chemical apparatus, is a ſet of nice meaſures; but they muſt be uſed with great diſcretion, and though ever ſo exact as to their contents, they muſt not be truſted to in the nicer operations. A pint of ſpirit of wine falls conſiderably ſhort of a pound, and a pint of quickſilver weighs fourteen pounds; between the ſeveral weights of theſe there is a great variety.

Many ſolid ſubſtances require to be reduced into ſmall parts, before they can be made the ſubjects of chemical operations; and for this reaſon there will be a neceſſity for mortars, ſieves, raſps, files, hammers, ſlicers, and forceps. Next to theſe come the inſtruments uſed in the management of the fire; theſe are ſhovels, hooks, tongs, and blow-pipes: and for charging the veſſels with the ſubject matters to be worked upon in the operations, there are required hollow ſhells, horns, tin plates, bruſhes, hares feet, ſpoons, and ſpatulas. Rounds are alſo required to ſet certain glaſſes on; and for emptying their contents, and thoſe of other veſſels, hooked tongs, cones, ingots, baſons, funnels, and ſtore-glaſſes, furniſhed, according to the nature of the things to be kept in them, with common cocks, wax ſtopples, and glaſs ſtopples; and for the tying down of theſe, bladders, leather, and the like. In the laſt place come the inſtruments for making certain utenſils, as moulds for muffles, teſts, crucibles and melting-pots, and iron rings for cutting glaſſes and the necks of retorts.

The more immediate apparatus, or that employed in the operations themſelves, are veſſels containing the ſubjects to be wrought upon; particularly glaſs eggs, and bodies for digeſtion; retorts and receivers for diſtillation; blind heads for bodies in ſublimation; ſtone pans and cut glaſſes for evaporation; peculiar ſpout-receivers, and glaſſes for ſeparation; ſtrainers for percolation; paper for filtration; muffles and teſts for cupellation; crucibles for melting; pots for cementing; and lutings to cloſe the junctures of the veſſels whenever neceſſary. *Shaw*'s Chemiſtry, p. 384.

See Tab. of Chemical Furnaces, Veſſels, and Utenſils.

VESTIBLE (*Cycl.*)—VESTIBLE is alſo uſed for a kind of little antichamber before the entrance of an ordinary apartment.

VETCH (*Suppl.*)—*Ax*-VETCH, in botany, the Engliſh name of a genus of plants, called by authors *ſecuridaca*. See the article SECURIDACA, *Suppl.*

Bitter-VETCH, the Engliſh name of a genus of plants, known among botanical writers by that of *orobus*. See the article OROBUS, *Suppl.*

Bindweed-leaved-VETCH, a name ſometimes given to the *vetchling*. See the article VETCHLING, infra.

Chickling-VETCH, the Engliſh name of the *lathyrus*, a diſtinct genus of plants. See the article LATHYRUS, *Suppl.*

Crimſon-graſs-VETCH, a name ſometimes uſed for the *niſſolia*, a diſtinct genus of plants. See the article NISSOLIA, *Suppl.*

Hatchet-VETCH, the name by which ſome call the *ſecuridaca* of botanical writers. See the article SECURIDACA, *Suppl.*

Kidney-VETCH, the name by which ſome call a ſpecies of *vulneraria*. See the article VULNERARIA, *Suppl.*

Liquorice-VETCH, the Engliſh name of a genus of plants, known among botaniſts by that of *glycine*. See the article GLYCINE, *Suppl.*

Medic-VETCH, the name by which many call the *onobrychis*, a diſtinct genus of plants. See the article ONOBRYCHIS, *Suppl.*

Milk-VETCH, the Engliſh name of a genus of plants, called by botanical writers *aſtragalus*. See the article ASTRAGALUS, *Suppl.*

VETCH-*graſs*, in botany. See the article GRASS, *Append.*

VETCHLING, the Engliſh name of a diſtinct genus of plants, known among botaniſts by that of *aphaca*. See the article APHACA, *Suppl.*

VIGILIA, *watch*, in antient chronology. See the article WATCH, *Append.*

VINE (*Suppl.*)—*Black*-VINE, a name by which the *tamnus*, or black briony is ſometimes called. See the article TAMNUS, *Suppl.*

Spaniſh-arbor-VINE, a name by which ſeveral ſpecies of *convolvulus* are ſometimes called. See the article CONVOLVULUS, *Suppl.*

White-VINE, or *Wild*-VINE, a name ſometimes given to the *bryonia alba*. See the article BRYONIA *alba*, *Suppl.*

VINEGAR (*Suppl.*) is ſaid to be a good remedy for the ſting of waſps. Perhaps it might alſo be ſucceſsfully applied to the ſting of bees, gnats, &c. A late author pretends, that taken internally, eſpecially if mixed with the powder of cantharides, *vinegar* is a remedy againſt the hydrophobia. *Vinegar* and honey, or oxymel, of the conſiſtence of a ſyrup, ſwallowed warm, is very good in many caſes of ſore throats ariſing from colds.

VIOLET (*Suppl.*)—*Dame*'s, or *Queen*'s VIOLET, the Engliſh name of a diſtinct genus of plants, called by botaniſts *heſperis*. See the article HESPERIS, *Suppl.*

Bulbous-VIOLET, a name ſometimes given to the ſnow-drop, a plant which Linnæus makes a diſtinct genus under the name *galanthus*; but which Tournefort comprehends among the *narciſſo-leucoiums*. See the article NARCISSO-*leucoium*, *Suppl.*

Corn-VIOLET, a name ſometimes given to the *campanula*, or bell-flower. See the article CAMPANULA, *Suppl.*

Dog's tooth VIOLET, the name by which ſome call the *dens canis* of botanical writers. See the article DENS *canis*, *Suppl.*

VIPER's *bugloſs*. See the article BUGLOSS, ſupra.

VIPER's *graſs*, the Engliſh name of a diſtinct genus of plants, called by botanical writers *ſcorzonera*. See the article SCORZONERA, *Suppl.*

VIS *viva*, in mechanics, a term uſed by Leibnitz and his diſciples for *force*, which they diſtinguiſh into two kinds, *vis mortua*, and *vis viva*; underſtanding by the former any kind of preſſure, and by the latter that force or power of acting, which reſides in a body in motion. See FORCE.

VISNAGA, in botany, a genus of plants, according to Ray, but comprehended by Linnæus nnder the article *daucus*. See the article DAUCUS, *Suppl.*

VISNAGA is alſo uſed by J. Bauhine as the name of a ſpecies of *foeniculum*. See the article FOENICULUM, *Append.*

VITRUM *Archimedeum*, *Archimedes's glaſs*, a name given by Swedenborg to an inſtrument which he invented for the examination of mixt metals, and by means of which he could diſcover the quantities, without the trouble of the apparatus, and calculation commonly uſed for this purpoſe.

VIXEN, or FIXEN, among ſportſmen, denotes a fox's cub. Ruſt. Dict. in voc.

UMBER (*Cycl.* and *Suppl.*)—This earth when burnt makes a good ſhade for gold. It need only be put into the naked fire in large lumps, which ſhould not be taken out till they be thoroughly red hot. Build. Dict. in voc.

UNACCENTED *part of a bar*. See ACCENT, *Cycl.*

UNILOCULAR, in botany, is applied to a capſule having but one cell. See CAPSULE, *Cycl.*

UNRECLAIMED *hawk*, in falconry, one that is wild and untamed. Ruſt. Dict. in voc.

UNSUMMED, a term uſed by falconers for a hawk's feathers before they have arrived at their full length. Ruſt. Dict. in voc.

VOLUBILIS, in botany, the name of a genus of plants, according to Dillenius; but comprehended by others under *convolvulus*, or bind-weed. See the article CONVOLVULUS, *Suppl.*

VOMIT (*Suppl.*)—*Black*-VOMIT, a diſtemper frequent in the Weſt-Indies, particularly at Carthagena. The following account of this diſtemper has been communicated to us by a friend.

The city of Carthagena is ſituate 10 degrees 25 minutes 48½ ſeconds of north latitude. The weather there is always ſultry hot. A thermometer conſtructed by Monſieur de Reaumur gave on the 19th of November, 1735, one of their winter months, the degree of the warmth of the air 1025

diviſions and a half; and this with little variation both night and day. The greateſt height to which the ſpirit aſcended at Paris the ſame year by a thermometer, graduated in the ſame manner, was 1025½ diviſions; ſo that the heat of the cool nights at Carthagena was nearly equal to that of the hotteſt days at Paris.

As the heats in this climate are ſo great without receiving any mitigation from the night, it is no wonder that the perſpiration of the inhabitants is very great. From this it comes about, that all thoſe who make their abode there any time appear pale and weakly, as though newly recovering from a fit of illneſs. You remark in all their actions, even ſo far as in their ſpeaking, a certain idleneſs, and, as our author expreſſes himſelf, a disjointedneſs: notwithſtanding this they are in good health, though their aſpect indicates the contrary. The people who arrive there from Europe, hold their appearance of ſtrength and colour in their countenances during three or four months; but after that time they loſe both one and the other from the quantity of ſweat, until they become like the former inhabitants. Theſe effects are moſt obſervable in younger people: on the contrary, thoſe who are further advanced in life when they go thither, preſerve their former appearance better, and enjoy ſo good a ſtate of health, that they live commonly to more than eighty years of age.

As the temperament of this country is particular, ſo are ſome of its diſtempers. Theſe may be conſidered of two kinds, *viz.* thoſe diſtempers to which the Europeans newly arrived there are liable, and they only; and thoſe which are common to all perſons there, as well Criollos as Chapetones.

The diſtempers of the firſt claſs are many, as the reſort of the Europeans there is very great. They are very dangerous, and often mortal. They frequently deſtroy a great part of the people, both ſailors and others, who arrive there from Europe. The continuance of theſe diſtempers is very ſhort: they laſt but three or four days, in which time the ſick either die, or are out of danger. The particular diſtemper, to which they are moſt liable, is very little known, though it takes its riſe in ſome from taking cold, in others from indigeſtion; but from whichſoever of theſe, or what other cauſe it takes its riſe, it becomes in the ſhort time before mentioned the *vomito prieto*, or *black vomit*, which is what kills them; it being very rare that thoſe who have it eſcape. It is obſerved in ſome that their delirium is ſo violent, that they are obliged to be tied down in their beds, that they may not tear themſelves to pieces, and they often die raving with the greateſt degree of agony.

It is to be remarked, that thoſe only are ſubject to this diſtemper who are lately arrived from Europe, the inhabitants of the country, as well as thoſe who have lived there any time, are by no means liable to it, and enjoy perfect health during its greateſt violence. As the crews of ſhips are very liable to this diſtemper, and more ſo than the officers and paſſengers, who have greater variety of food and liquor; it has been conceived that the great exerciſe and labour of theſe people, and their feeding upon ſalt proviſions, prepares their conſtitutions to be liable in this climate to corruption of the blood and humours, from whence is ſuppoſed to proceed the *vomito prieto*. What muſt be obſerved, is, that although the crews of ſhips ſuffer the greateſt mortality, nevertheleſs paſſengers and others, who go the voyage under the greateſt advantages with regard to the conveniences of life, are not free from being expoſed to it. It muſt be remarked alſo, that thoſe perſons, who after having been uſed to this climate, go from thence, and are abſent even three or four years, are not liable to it at their return, but retain their health like the other inhabitants, although in their way of living they have not obſerved the moſt exact regimen.

The deſire of knowing the cauſe of this terrible calamity has occupied from time to time the minds of the ſurgeons who make this voyage in the galleons, as well as thoſe of the phyſicians of the country; and their opinion has been, that it chiefly takes its riſe from the labour, to which the ſhips crews are conſtantly expoſed, and their manner of living. There is no doubt but theſe may greatly contribute thereto; but then it will be difficult to conceive why perſons, who are better circumſtanced, are likewiſe liable to it: and it is ſomewhat extraordinary, that notwithſtanding many endeavours have been made towards finding out remedies equal to this diſeaſe, none have been diſcovered either as ſpecifics or preſervatives; for the inconſtancy of the ſymptoms is ſo great, that they are not in the beginning to be diſtinguiſhed from thoſe, which are in common to this with ſlighter diſtempers; but the principal complaints at firſt are a wearineſs and great diſorder in the head.

This diſtemper does not always attack the ſhips of Europe at their arrival in the bay of Carthagena, nor is it very antient in that country; for what they heretofore called *chapetonada*, ſo denominated, as thoſe from Europe were only liable to it, were indigeſtions; and though they were in that climate always attended with danger, the women of the country, as they do now, cured them with eaſe, eſpecially when they were taken in time. The ſhips afterwards going from Carthagena to Porto Bello, it was there ſucceeded the great mortality, which was always attributed to the unſeaſonableneſs of the climate, and to the fatigue of the ſhip's crew in unloading their ſhips, and in the buſineſs of the fair there.

The *black vomit* was not known at Carthagena, nor in its neighbourhood, until the years 1729 and 30; when firſt it carried off a great part of the crews of the ſhips of war, which Don Domingo Juſtiniani then commanded, and were then there as guarda coſtas. Theſe ſhips were firſt attacked at Santa Martha, where the ſeverity of this diſtemper, and its great ſlaughter, had caſt a great terror upon their crews. The ſecond attack of this diſtemper was on board the galleons commanded by Don Manuel Lopez Pintado, when its mortality was highly formidable; and death followed the attack ſo quick, that perſons who were one day ſeen walking at large, were next day met carrying to their graves.

Our author is of opinion that this, as well as ſome other diſtempers, to which Europeans are liable to at, or ſoon after their arrival at Carthagena, and other places under the ſame circumſtances, ſhould be conſidered as ariſing from the great alteration that happens in their conſtitutions there: and this change, which from the climate is ſoon brought about, makes them ſuffer this and other diſtempers, which either deſtroy them, or generate in them a diſpoſition to bear the heats; after which, being as it were naturaliſed, they enjoy the ſame ſhare of health with the natives.

Our author remarks, that at Carthagena, when the ſhips from Spain fail in their arrival, the European productions, which at all times are dear and much valued there, are ſometimes quite expended. Theſe more particularly are wine, oil and raiſins. When this is the caſe with regard to wine, the people there ſuffer much in their health; as every body, except the negroes and thoſe who uſe brandy, accuſtom themſelves to drink it with their food. From the want of this their ſtomachs fail, they grow ſick, and this ſickneſs becomes general. This want of wine happened when our author arrived at Carthagena, and the ſickneſs in conſequence was ſo general in that city, that maſs was celebrated only in one of their churches.

URSUS, the *bear*, in zoology. See the article BEAR, *Suppl.*

URUBU, in ornithology, the name by which Marcgrave calls a ſpecies of *vultur*. See the article VULTUR, infra.

VULTUR, in ornithology, the name of a genus of birds of the falcon, or hawk-kind. See the article FALCO, *Suppl.*

The neck of the *vultur* is long, and almoſt bare of feathers; the legs are covered with feathers down to the feet, or nearly ſo; under the throat there is a ſpace covered with hair, inſtead of feathers; the head alſo, in many ſpecies, is naked, or has, at the utmoſt, only a downy matter on it.

Of this genus of birds we have the following ſpecies. 1. The greyiſh black *vultur*, with a ſhort tail. This is of the ſize of a full grown turkey. 2. The cheſnut-coloured *vultur*, called alſo the *Bæctic vultur*, with a ſhort tail. This is equal in ſize to a full grown hen. 3. The yellow-legged, creſted *vultur*, called *leporarius*, or the hare-catcher. This is of the bigneſs of a gooſe. 4. The golden-breaſted, blue-legged *vultur*, with a blackiſh back. Its ſize is equal to that of a turkey-cock. 5. The tawney brown *vultur*, with yellow legs. This is of the bigneſs of a large capon. 6. The Braſilian, white-legged *vultur*, called by ſome authors *urubu* and *aura*. In ſize it is equal to the common kite.

W.

WAAL, in the ſea language, the ſame with *wale*. See the article WALE, *Suppl.*

WAG-*tail*, in ornithology, the Engliſh name of the *motacilla* with a black breaſt. See the article MOTACILLA, *Suppl.*

WAIL, in the ſea language, the ſame with *wale*. See the article WALE, *Suppl.*

WALL-*wort*, a name ſometimes given to the *ſambucus*, or dwarf-elder. See the article SAMBUCUS, *Suppl.*

WARDS *of hoſpitals*. See HOSPITAL, *Append.*

WARREN (*Suppl.*)—WARREN is alſo uſed for a contrivance to preſerve fiſh in the midſt of a river, to be taken at pleaſure. Ruſt. Dict. in voc.

WART-*wort*, the name ſometimes given to two very different genuſes of plants, the *tithymalus* and *lampſana*. See the articles TITHYMALUS and LAMPSANA, *Suppl.*

WASHING (*Cycl.* and *Suppl.*)—The *waſhing* or cleanſing of ſome colours may be thus performed: take the colours to be *waſhed*, and put them into a veſſel of fair water; ſtir it about till the water be all coloured therewith, and if any filth ſwim on the top of the water, ſcum it clean off; and when you think the groſſeſt part of the colour is ſettled at the bottom, then pour off that water into another earthen veſſel, that is able to contain the firſt veſſel full of water four or five times; then pour more water into the firſt veſſel, and ſtir the remaining colour till the water be thick; and after it is a little ſettled, pour that water alſo into the ſecond veſſel. Let this be repeated till all the fineſt of the colour is drawn off, and nothing but courſe gritty ſtuff remains behind. Then letting the water in the ſecond veſſel ſtand to ſettle, till it is perfectly clear, pour it off, and reſerve the *waſhed* colour in the bottom of the veſſel for uſe.

The colours to be thus *waſhed* are red lead, blue and green bice, verditer, blue and green ſmalt, Spaniſh brown, yellow ochre, *&c.* Build. Dict. in voc.

WASP. The application of vinegar is ſaid to be good againſt the ſting of theſe creatures.

WATCH (*Cycl.*)—WATCH, *vigilia*, in Roman antiquities, a diviſion of their night; being the fourth part of the ſpace of time between ſun-ſet and ſun-riſing, and conſequently varying according to the ſeaſon of the year. See the articles DAY, HOUR, *&c. Cycl.*

Death-WATCH. See the article DEATH, ſupra.

WATER (*Cycl.*)—It has been proved by many inſtances, that *water* alone is capable of ſuſtaining human life a long time. Phyſical writers give us many accounts of people's living four or five days on it, but the Philoſophical Tranſactions furniſh us with a much more memorable inſtance.

Some people at work in a deep coal-pit near Liege, had the misfortune to pierce into a ſubterranean current of *water*, of ſuch force that it inſtantly filled a great part of the works. The perſon who ſtruck the blow into it was drowned, and ſome that were near the mouth of the pit eſcaped very narrowly by being drawn up; but twenty-four days after, when the mine was cleared of the *water*, and people came down to work in it again, four of the perſons, who had been ſuppoſed drowned, were found alive: they had ſaved themſelves by climbing into a place above the reach of the *water*; they had not the leaſt morſel of bread with them, but had lived all this time on the *water* of a little ſpring which broke out by them. This *water* was examined, and found to have no peculiar matter contained in it, but only the common ſparry ſubſtance found in all *water*, and that not in any abundance. Phil. Tranſ. N° 159.

We have alſo an account in the Philoſophical Tranſactions of a man who lived for eighteen years on no other aliment than *water*, and now and then, though ſeldom, clarified whey. The man was pretty healthy. See N° 466. ſect. 7.

The Italian phyſicians have talked much of cures performed by means of cold *water*, which they eſteem almoſt an univerſal remedy; giving in a day fifteen, twenty, or twenty-five pounds of *water*, made cold by ice, and applying at the ſame time cold *water*, or ſnow, to ſeveral parts of the body. By this method they treat fevers, ſmall-pox, dropſy, *&c.* See Commerc. Norimb. 1736. hebd. 8. ſect. 2.

Water, when applied to animal bodies, and when nearly of the ſame heat with theſe, relaxes their ſolids, and dilutes their fluids.

Water putrifying by ſtagnation is extremely dangerous to health. Thus in the holds of ſhips, the bilge *water*, if the ſhip is tight, and the *water* not pumped out often, ſoon becomes ſo extremely poiſonous, as frequently to ſuffocate thoſe ſeamen, who, as the pumps are ſubject to be clogged with filth, venture down to cleanſe them; and alſo to affect perſons at a diſtance with violent head-achs, cold ſweats, and frequent vomitings, which continue more or leſs, in proportion to the diſtance from the well of the ſhip when the injury was received, and the degree of putrefaction in the *water* and air. Phil. Tranſ. N° 463. p. 63.

To prevent the above mentioned inconveniences many ſchemes have been thought of, particularly the machines of Dr. Hales [a], and Dr. Deſaguliers [b]; the firſt by an inſtrument, which he calls the ventilator, and may not improperly be called the ſhip's lungs; ſee VENTILATOR; and the latter by a machine, which is an improvement of the Heſſian bellows.—[a In his Treat. of Ventilators. b Phil. Tranſ. N° 437.]

Putrified *water* being thus noxious, a method of preventing its putrefaction would be very deſirable, and this ſeems now to be found in the uſe of lime. See LIME-*water*, *Append.*

Rough *waters*, that will not bear ſoap, may often be corrected by letting them ſtand a few days. See *Boyle*'s Works abr. Vol. I. p. 141.

It has been ſaid that Thames *water* has a peculiar property of recovering after putrefaction; but others have the ſame. See *Boyle*'s Works abr. Vol. I. p. 141.

Mr. Boyle tells us, he prepared a ſalt of the ſame nature with Glauber's ſal mirabile, which ſeemed to have a power of coagulating common *water*; for being diſſolved in a proper quantity of it, the whole mixture ſhot together into fine cryſtals, apparently of an uniform ſubſtance, and ſo brittle, as to be reducible into powder. See *Boyle*'s Works abr. Vol. I. p. 332.

Water may be uſed with good ſucceſs in taking the height of any acceſſible object, as it naturally becomes parallel to the horizon. The manner of performing this operation is exactly the ſame as with a mirror. Tr. Pract. Geom. p. 19. See the article MIRROR, *Cycl.*

Water by its fall may be made to afford wind enough to blow a fire. This is practiſed in the braſs works of Tivoli near Rome. See Phil. Tranſ. N° 2.

Chalybeate, or *Steel*-WATERS. The learned Mr. Monro of Edinburgh has an inquiry into *ſteel*, or *chalybeate waters*, where he conſiders them with regard to their medical uſe, in order to diſcover what their real or comparative ſtrength is, how they bear carriage, and how long they retain their virtues; that phyſicians may judge which of them is moſt proper in the various diſeaſes and circumſtances of patients, which muſt be drank at the fountain-head, and which might be conveniently drank at a diſtance from it. See Medical Eſſays, Vol. III. art. 7. Abr. Vol. I. p. 126.

Chalybeate waters ſtrike a red, purple, violet, or black colour with galls; and it is ſaid by ſeveral writers, that this change of colour is a certain mark of a *chalybeate water*, and that the deepeſt colour ſhews the greateſt proportion of ſteel. Mr. Monro, to ſatisfy himſelf of the truth of this, made a weak ſolution of ſal martis in *water*, and found that, with a tincture of galls, he could form all the different colours, the larger quantity of the ſolution always requiring the greater number of drops of the tincture to bring it to all the colour it would take; and that it was deeper, in proportion to the quantity and ſtrength of the ſolution and tincture employed. If words could expreſs the various ſhades of colours betwixt the pale red and the black, the ſimple experiment of bringing *ſteel-waters* to the deepeſt colour they could ſtrike with galls, might determine the proportions of ſteel in each. But as this is impracticable, and as it is neceſſary to know the quantity of ſteel contained in any given quantity of *water*, ſome general ſtandard muſt be appointed, to which all may be brought. To obtain this, he made ſeveral experiments to find out the quantity of ſteel in its artificial ſalt, and found it to be a little more than a third part. He diſſolved ſome of the ſalt in *water*. Twenty ounces of the ſolution contained an ounce, except a ſcruple, which was precipitated; one hundred and forty-two drops of this ſolution weighed two drachms; every drop therefore contained one twenty-fifth of a grain of ſalt, or one ſeventy-fifth of a grain of ſteel. To compare a *chalybeate water* with this ſolution, into a known quantity of ſuch *water* drop a ſtrong clear tincture of galls, allowing a ſufficient time between each drop for its full effect, till the addition of more tincture makes no change. This experiment ſhould be repeated, to come at the exact number of drops requiſite. Then mix the ſame number of drops of tincture with as much common

water, as there was mineral *water*, in a glaſs, exactly like that made uſe of in the preceding trial. Drop in the ſolution of ſteel cautiouſly, till the colour is the ſame with that of the mineral water. By this means, the due proportion of the ſolution to imitate any *ſteel-water* may be known. He has thus made ſpring *water* ſo like to ſeveral *chalybeate waters*, that none could diſtinguiſh them. Med. Eſſ. Edin. Vol. I. p. 126.

Galls in tincture are more convenient than in ſubſtance for making theſe experiments, for it acts much ſooner, and more equally, and can be added in leſs quantities, which deſerves to be regarded; for too large a proportion of galls poured at once into *ſteel-waters*, will be ſo far from ſtriking the colour ſtronger or ſooner, that no change will happen for ſeveral hours after, and at laſt the *water* gradually becomes of a deep ſea-green colour, inſtead of a purple or violet. Good *chalybeate waters* may have been condemned as containing no iron, or as being impregnated with copper, from an addition of too much galls. Freſh tincture of galls is preferable to that which has been long kept; but even ſuch as was grown mouldy, and had a thick ſediment, anſwered the common trials. Frequent trials ſhould be made, at different times, with *water* bottled at different ſeaſons, in order to aſcertain the proper ſeaſons for bottling mineral *waters*, and to find out the time each will keep. It is alſo requiſite to obſerve what time it is before the galls ſtrike the full colour, and how long it remains in an open glaſs; for Mr. Geoffroy's ſuppoſition appears reaſonable, that both theſe effects will be moſt ſlowly produced, when the ſteel is moſt intimately blended with the other principles of the *water*. Med. Eſſ. Edinb. Vol. I. p. 127.

There is a ſtrong reſemblance between our *ſteel-waters* and common *water*, in which ſal martis is diſſolved, but the natural ſpaw expoſed to the air ſoon loſes its chalybeate taſte, and will not ſtrike a purple colour with galls; expoſed to heat its virtues are ſooner loſt, and it becomes vapid in no long time in the cloſeſt veſſels; but a ſolution of ſal martis bears heat, and being expoſed to the air, without alteration; it may be ſuſpected that this difference depends upon the ſmall proportion of the vitriolic principles, and ſome change they may thereby undergo in the *water*; and therefore Mr. Monro having added as much ſal martis to ſome bottles of *water*, as had been found to make it of the ſame taſte, and to ſtrike the ſame colour with *chalybeate waters*, he corked ſome carefully, others leſs carefully, and a third ſort he left open. The *water* in theſe laſt loſt its taſte and virtues in a fortnight, became muddy, and had a ſaffron-coloured powder at the bottom. The ſecond kind kept longer, but had a ſtinking ſmell before it became vapid. The *water* which was carefully corked and roſined kept well, but acquired a ſtrong ſmell of rotten eggs, like to what ſeveral ſpaws have when kept; when the bottle was left open, the ſtinking ſmell went off; ſoon after, the chalybeate virtues were not to be obſerved, and the bottom of the bottle was covered with the ſaffron-coloured powder, which is generally to be ſeen in bottles where *chalybeate waters* have been kept. The difference therefore between the natural and artificial *ſteel-waters* conſiſts in the greater volatility of the former. Med. Eſſ. Edinb. Vol. I. p. 128.

Spaw and Pyrmont, and ſome of our own *chalybeate waters*, ſeem an exception to the reſemblance between the diluted ſolution of ſalt of ſteel and the natural *ſteel-waters*; for the colours they ſtrike with the galls is faint, while their taſte and other effects are ſtrong. This produced another experiment to imitate them, by mixing filings of iron, oil of vitriol, and *water*, in a Florence flaſk, which being laid on its ſide, and another, in which was ſome fountain *water*, immediately fitted to it. The fumes which aroſe upon the effervescence of the oil of vitriol with the ſteel, came over into this. After the effervescence was over, on taking away the glaſs with the *water*, it was found limpid, but with a ſtrong empyreumatic ſmell; its taſte at firſt was pungent, and then the acidulous taſte prevailed. When tincture of galls was mixed with it, it became of a purple, but faint colour, which held many days without precipitation. Next morning the empyreuma was gone, and the *water* had an agreeable ſpaw taſte. In leſs than a day this went off, a ſmall quantity of ſaffron-coloured powder fell to the bottom, and the galls had no effect on the *water*. Med. Eſſ. Edinb. Vol. I. p. 129.

This *water* gives no ſign of acidity, as might be ſuſpected, when mixed with ſyrup of violets and clove-july-flowers, in the colour of which it makes no alteration; neither do the more ſpirituous ſpaws; whereas the ſolution of ſalt of ſteel, and ſome ſpaws, appear alkaline, from changing the colour of both the ſyrups green.

The ſucceſs of this experiment produced ſome others, to diſcover what it was that evaporated, and what precipitated in theſe *waters*. Oil of vitriol poured on the ſaffron-coloured reſiduum made no effervescence; upon the addition of a little *water*, ſome of the powder ſeemed to be diſſolved. Tincture of galls did not change the colour, but upon adding ſpirit of hartſhorn, a great effervescence aroſe, and a deep purple coagulum was made. The ſame experiments ſucceed with ruſt of iron, which reſembles this powder. Neither ruſt, nor the powder, when ſuſpended in *water*, ſtrike any colour with galls, although crocus martis does. What evaporates is the menſtruum, which carries away ſome of the principles of the iron with it. From ſeeing the effects of acid, and of the air upon iron, and finding vitriol naturally formed, it may reaſonably be ſuppoſed, that the menſtruum of the irony particles in theſe *waters* is an acid. From conſidering how much ſulphur is in iron, what a ſtinking ſmell mineral *waters* have before they turn vapid, and how much the ſulphur of iron is deſtroyed before the iron turns into ruſt, which again reſembles the powder precipitated in theſe *waters*, we may fairly ſuppoſe that the menſtruum carries the ſulphur along with it, and leaves only the earthy parts with a ſmall proportion of ſulphur. Med. Eſſ. Edinb. Vol. I. p. 130.

It may hence be ſuſpected, that *ſteel-waters* are impregnated with common groſs vitriol, or with the more ſubtile fumes of iron diſſolved in the natural menſtruum; or with both in different proportions. The quicker precipitation, and leſs volatility of *chalybeate waters*, ſeems to ſhew that the ſulphur is not ſo much freed from the earthy particles, as in others which precipitate more ſlowly, and are more volatile. The common obſervation of air generated in all effervescences, fermentations, putrefactions, and wherever a conſiderable change is produced in the compoſition of bodies, ſeems to account for the quantity of elaſtic air, obſerved in *chalybeate waters*, in the more ſpirituous when recent, and in others, when the putrid ſmell ſhews the ſulphur to be more diſengaged.

It ſeems alſo, that the different kinds of *ſteel-waters* ſhould be preſcribed, according as there is occaſion for a ſubtile, penetrating ſulphureous ſpirit, to pervade the ſmalleſt veſſels, or according to the quantity of an abſorbent aſtringent earth, which is required to be joined with this ſpirit.

Where different ſpaws are not to be had, the ſame *water* perhaps may be made to anſwer each of theſe intentions, according to its being more or leſs kept, or expoſed to the air or heat. Med. Eſſ. Abr. Vol. I. p. 131.

The ingenious author, from whom theſe obſervations and conjectures have been taken, ſeems to think that the menſtruum really flies off from mineral *waters*; but this, as is obſerved in a note added by his learned abridger [a], has not yet been made appear by any ſatisfactory experiments. It is certain, that ſome mineral *waters*, when carefully bottled at the well-head, and oiled at top, after the manner of Florence wine, and then well corked and cemented, have been found to continue many months poſſeſſed of their properties of ſtriking black or purple with galls; and hence it appears that the irony particles, or mineral ſpirit of the *water*, cannot eaſily eſcape through the pores of glaſs; at leaſt not while the *water* remains in a ſound ſtate. When the *water* begins to corrupt, as in time it will, though thus ſecured, it tinges leſs and leſs with galls, and at length affords no red, purple, or duſky colour therewith. Whence we are led to conclude, that the irony particles make their eſcape through the pores of the glaſs, or of the oil, the cork and cement; or elſe are ſo changed, as no longer to retain their irony nature, and ſtrike with galls. But that the latter ſeems rather to be the truth of the caſe, is ſupported by this, that during the diminution of the tinging faculty, there appears to be a manifeſt change in the natural texture of the *water*; for a viſible ſeparation of parts enſues, the whole grows fetid, a groſs matter falls to the bottom, the oil that was liquid before, now becomes almoſt as hard as tallow, and appears tinged black to a conſiderable height: but what is remarkable, the *water* now affords manifeſt ſigns of its containing actual brimſtone, not the leaſt indication whereof appeared before. It ſeems therefore that the *water*, as taken from the well, is a compound liquor, gradually tending to an alteration in its parts, as if there was a ſlow fermentation among them, whereby the natural texture of the whole is broke in time, even though the external air be kept from communicating therewith; but if external air be admitted, remarkable changes muſt ſooner begin, and finiſh their period [b].—[a] Ibid. p. 130. [b] *Shaw*'s Enq. into Scarb. *Wat.* p. 160, ſeq.]

There is commonly ſuppoſed to be ſomething ſo very volatile in many *ſteel-waters*, as well as of thoſe of Liege and Pyrmont, that it diſappears upon the leaſt acceſs of air, after they are taken up from the well, eſpecially in hot weather; yet it does not ſeem clear from experiments, that the alterations which ſpaw *waters* undergo, by being expoſed to the air, is owing to the diſſipation of any volatile part. Ibid. p. 109, and note *.

Though *chalybeate waters* are commonly ſuppoſed to contain vitriol, and to be of a ferruginous nature, and have from thence obtained their name, yet it is not eaſy to determine what ſalts they contain, or whether they be all impregnated with the ſame kind of ſalts. Mr. Du Clos could neither find alum nor vitriol in any of the French wells, only in one he found ſome reſemblance of the latter. All the other wells gave a ſalt, anſwering to a compoſition of nitre and ſea ſalt mixed in various proportions, which probably is the natural ſalt of the earth diſcovered by Tournefort [c], reſembling,

bling, in moſt trials, the nitrum of the Levant, which is neither acid nor alcali, but approaching moſt to the latter [d]. —[c Pref. to Hiſt. of Plants near Paris. [d] Medic. Eſſ. Abr. Vol. I. p. 108.]

Chalybeate waters often break the bottles into which they are put, and many of them ſoon loſe their chalybeate properties when bottled. To prevent the former inconvenience, Dr. Hales put a ſmall glaſs tube through the cork of the bottles, filling them ſo, as to leave no air bubbles between the cork and the *water*. In other bottles he put very ſoft compreſſible corks. By both theſe means the *water* was allowed to rarify, without burſting the bottles. By mixing very few drops of an acid, ſuch as oil of ſulphur, with the *ſteel-waters*, they long retain their chalybeat properties. See *Hales*, Philoſoph. Experiments.

Mineral-WATERS. The method of analyſing *mineral-waters*, according to Dr. Shaw, ſhould be this. Firſt, let it be tried what changes they will ſuffer by mere ſtanding; let ſome of the *water* be put into open glaſſes, and ſome into ſuch as are ſtopt, and after ſome hours keeping, examine by the taſte whether it be any way different from that freſh drawn from the ſpring; after this let it ſtand ſome days or weeks, and finally compare it with freſh *water* of the ſame ſpring, and obſerve whether it have any ſcum at top, or ſediment at bottom, or ſides of the glaſſes.

2. Let ſome of the *water* be kept in open cylindrical glaſſes in a warm place till it is wholly evaporated, the dry ſubſtance left behind muſt be carefully preſerved, to be compared with the reſiduum to be afterwards made by fire.

3. Put a quantity of the *water* at the ſpring-head into a glaſs retort, and a receiver being luted on, let the whole be carefully diſtilled over, and both the *water* and the dry reſiduum weighed, and carefully preſerved. If during this operation a vapour is ſeen to force its way out at the joints, it ſhews there is a ſpirit, or light ſubtile matter. In the *water* too fine to be ſeparated this way, the *water* ſeparated by diſtillation is to be tried ſeveral ways, to ſee whether it differs from common diſtilled *water* or not, and whether it have the ſame mineral particles that the *water* itſelf had before diſtillation. If it contains any ſea ſalt, it will turn white with a ſolution of ſilver; if any vitriol of iron, it will turn black with powdered galls; and if any ſulphur united with an alkaline ſalt, it will turn black in time with any of the metallic ſolutions. The dry matter left in the retort is to be boiled in ſix times its own weight of pure diſtilled *water*, this being afterwards filtered and ſet to cryſtallize, will give, after a proper evaporation, its own peculiar ſalt in cryſtals; and if more ſorts of ſalt than one ſhould be contained in the *water*, they will be all thus ſeparated by repeated evaporations and cryſtallizations.

Whether theſe ſalts be acids or alkalis, is eaſily found by the common experiments, the acid turning ſyrup of violets red, and the alkali turning a ſolution of corroſive ſublimate yellow. The neutral ſalts, waſhed out of the earth by *waters*, are chiefly ſea ſalt, and ſuch as conſiſt of a vitriolic ſalt, and a ſalt or earth of an alkaline nature. Sea ſalt is diſcovered by its taſte, by the white fume it yields on being mixed with oil of vitriol, and by its figure in cryſtallization: and the other neutral ſalts are diſcovered by their property of producing, or regenerating ſulphur, upon being mixed and melted with ſalt of tartar and powdered charcoal. Thus, if two ounces of ſuch ſalt be mixed with one ounce of ſalt of tartar, and an ounce of powdered charcoal, and the whole put into a crucible, there will be produced a reddiſh-coloured maſs of a ſulphureous alkaline taſte, and giving a high yellow colour to ſpirit of wine, which will turn ſilver black; and being precipitated by an acid affords a true lac ſulphuris, which may be ſublimed, and melted into brimſtone like the common.

What remains of the reſiduum, after *water* has ſeparated the ſalt, is properly earth: this is often of more kinds than one, and may be ſeparated by repeated waſhings into bole, ochre, ſand, and whatever elſe it conſiſts of; and theſe may afterwards be tried, as to their nature, by fire in the common ways, the firſt and readieſt of which is the ſeeing whether they will calcine or vitrify; and the next, with proper additions, to try whether they contain any metalline or mineral particles, which may be ſeparable by the ſeveral fluxes: and if the quantity of metalline matter be too ſmall to be collected into a regulus, or ſhew itſelf in the common way, it may be melted with chryſtalline glaſs, and from the colour it gives that glaſs, the metal it contains may be known.

It is generally ſuppoſed, that the *mineral-waters* receive their virtue from the ſalts they contain. Dr. Liſter is of opinion that theſe are principally two, the one common ſea ſalt, and the other the nitrum calcarium; and found, on experiment, that from thoſe very *waters*, which others had boldly affirmed contained nitre of the common kind, vitriol, alum, and the reſt, he only could ſeparate theſe two ſalts.

Theſe ſalts mixed with ochres make the various kinds of our *mineral-waters*, as they happen to be mixed in various proportions.

Monſieur Du Clos obſerves of the examining the virtues of *mineral-water*, that moſt of them are liable to great errors. The French Academy, after long deliberation, propoſed to themſelves a method of examining the *waters* of their own country, by which they arrived at a more thorough knowledge of their virtues than was had before, and which may ſerve as a leſſon to all other experimenters in the ſame way. They have found by all their enquiries, that the principal things giving virtues to *waters* are ſalts and earths, and theſe give very different qualities to them, as they differ in quantity or in quality in the ſeveral ſprings. The ſalts, which they procured by a ſlow evaporation or diſtillation, proved to be of two kinds: the one the nitre of the antients, a ſulphureous mineral ſalt, much reſembling the alkali of plants; the other the common culinary ſalt. This conſiſts of two parts, an alkaline baſis and an acid. Theſe two principles are ſometimes combined in the *waters*, and then it is abſolute ſalt that they contain, and eaſily ſeparated and known: but it ſometimes alſo happens, that theſe principles are ſeparated, and only the one or the other contained in a *water*; theſe therefore, when procured in the analyſis, are not eaſily known, and when they are, as it very often happens, blended with the diſunited principles of other ſalts, they form together a ſort of concretes, yet more hard to be known than the other. It is generally ſuppoſed, that in almoſt all medicinal *waters* there is either alum or vitriol; but this is an opinion taken up too much at random, and it appeared, on the examination of all the mineral ſprings of France, that no one of them contained either the one or the other of theſe ſalts, except that of Vahls in Dauphiné, which contained a ſalt ſomewhat reſembling white vitriol. The taſte and the mixture with acids, alkalis, and tinctures of vegetables, are the great means of knowing theſe ſalts; for as to their figures they vary greatly, even in the ſame portion of ſalt, according to the different degree of the evaporation of the *water* they were diſſolved in. *Du Clos*, Exam. des Eaux Min.

Earths are found in different quantities in the different *waters*, and ſo confuſed by being blended with one another, and with other foſſils, that it is much more difficult to aſcertain their ſpecies, than thoſe of earths in any other form, or than thoſe of the ſalts in the ſame *waters*. The colours of the earths are very various, but this is the leaſt variety; for ſome of them form themſelves into ſhapes and appearances ſo different from the others, that it is hard to ſay what they are like, or to what ſuch ſingularities in their concretions ſhould be attributed. Some float about in the almoſt evaporated *water* in form of films and clouds, ſome like flocks, ſome appear in the form of mucilages, others like little flaccid clods of clay, and others like grains of ſand; ſome are ſoluble in acids, ſome only in part ſoluble, and ſome not at all ſo; ſome will give a tincture to diſtilled vinegar, others not; and in the fire ſome run to glaſs, and others calcine to lime.

The great quantity of the *mineral-waters*, which phyſicians uſually preſcribe to be taken by thoſe they recommend them to, ſeems to prove that they expect the principal benefit from them by their cleanſing the viſcera by this internal ablution; and this effect is indeed no trifling one, ſince moſt of thoſe ſtubborn diſeaſes, which they recommend theſe *waters* in, are owing to obſtructions of the viſcera, which the large quantities of theſe *waters* may eaſily remove: but it were well, if the phyſicians would be more accurate in diſtinguiſhing the different properties of them, and not give them at random, as is too often done, to the no ſmall detriment of the patient.

The vinous ſharp taſte of ſome of theſe *waters* which evaporate with the leaſt heat, or on being expoſed to the air, ſeems to be owing to that matter which is the firſt ſtate or being of ſulphur, and of all the concretions thence reſulting; ſuch as the various vitriols, and the like. There are found earths impregnated with this acid volatile ſulphureous matter, of the concretions of which are ſometimes made ſulphureous and vitriolic minerals. This vaporous and indigeſted matter may very well be the baſis of vitriol; but in this its firſt ſtate it cannot be a vitriolic concretion, if it be found in earths where there is yet no vitriol. It is more eaſy to obſerve it in its products, when it has received ſome mineral concretion, than in its natural ſtate; though in this latter ſtate it is as likely to impregnate *waters* as in any other. The moſt probable opinion, as to the heat of theſe *waters*, is, that there are in certain deep receſſes of the earth hot vapours, which continue at all times ſo, becauſe there is no acceſs of the external air to cool them; and where thoſe rarified matters have not room to become more rarified, and ſo to become leſs hot, or more diſſipated; and that ſuch collections of hot vapours are what give heat to the warm baths, and hot *medicinal-waters*. *Du Clos*, Exam. de les Eaux Min.

Many *mineral-waters* evidently contain a large quantity of ſpar, which though ſuſpended in them in an abſolutely pellucid ſtate, may yet be regularly ſeparated from them by evaporation in its own figure. The *waters* of the fountain de Salut, and thoſe of the ſpring du Pied, and ſeveral other in Gaſcony, have been tried, and are found, if gradually evaporated to a certain degree, to yield a ſcum, which, when examined

examined by the microſcope, is found to conſiſt of oblique parallellopiped parts; and if they are evaporated wholly to dryneſs, there is found at the bottom a ſhining duſt, which, when examined in the ſame manner, is found to contain many particles of the ſame kind, all bright as fragments of the pureſt ſpars.

As to the uſe of *mineral-waters* the learned Heiſter [a] obſerves, that in general they are found to agree much better with perſons in the middle ſtages of life, than with the very old or very young. If any general rule can be given in this caſe, it is, that people ſhould not take them when younger than eighteen, or when older than ſixty. Young people, eſpecially ſuch as are under ten years old, ſhould by no means be allowed to drink the chalybeate *waters*, becauſe of the tender ſtate of their viſcera; and older people than thoſe of ſixty are never found to receive any benefit from them, unleſs they are of very robuſt conſtitutions, or have been long accuſtomed to the drinking them: in ſome caſes however, particularly in hectics, young people may be allowed to drink the milder kinds mixed with an equal quantity of milk, and often find great benefit from them.—[a Compend. Medic. Pract. cap. 20.]

In confirmed conſumptions and ulcers of the lungs, the ſtronger chalybeate *waters* are found to do no ſort of ſervice, but rather hurt; but in caſes where the ulcers are but beginning, the drinking the weaker ones with milk has been known to do great good. In ſpittings of blood ariſing from ulcerations of the lungs, the ſtronger cold chalybeate *waters* do nothing but harm; but in the ſame caſes, where the milder kinds are taken warm, and mixed with an equal quantity of milk, they are found to be very beneficial. They muſt never be taken in caſes of dyſenteries in confirmed dropſies, nor where there is a ſtone in the bladder or kidneys; but in œdematous ſwellings of the legs and feet, they are often found highly uſeful. In venereal caſes, whether recent, or of long ſtanding, they do not cure, but they diſpoſe the body the more readily to be cured: but in a ſimple gonorrhœa, where there is no venereal taint, they have been often known to cure, when all other methods have failed.

Method of taking them. All people who are of a plethoric habit ought to be blooded before they begin to take them, for by this means there is a freer acceſs given them into the veſſels, and they become much more able to correct the whole maſs. Perſons who are not of a plethoric habit have no occaſion to bleed before they take them, but all ought to take a gentle purge to clear the primæ viæ; and to this purpoſe nothing is more proper than the common purging ſalts of Epſom, or Glauber's: but all the draſtic purges are carefully to be avoided on this occaſion, ſuch as ſcammony, reſin of jalap, and the like. If there be indications for vomiting in the patient, ſuch as pains, and a ſenſation of weight at the ſtomach, with bitterneſs in the mouth, naufeas, and reachings to vomit, then it is extremely proper to give, a day or two before the beginning the courſes of the *waters*, a gentle doſe of ipecacoanha.

Time moſt proper. The beſt hour of drinking them is early in the morning; ſix or ſeven o'clock is very proper, becauſe they then have time to finiſh their operation before dinner, but earlier than this is not ſo proper; and thoſe who go to the wells or ſprings at three or four in a morning, are expoſed to all the injuries of a cold and damp air, which prevents perſpiration, and often brings on coughs and other diſorders of the breaſt and head. It was formerly a cuſtom to drink them in an afternoon, but this is at preſent left off, as found to produce many diſorders of the ſtomach; and ſuch as are deſirous of having the utmoſt effects of the *waters*, content themſelves at this time of the day with drinking them at home in ſmall quantities, and mixed with wine.

Seaſon moſt proper. The ſummer is the ſeaſon in which the *mineral-waters* are to be drank with the greateſt advantage. The months of June, July and Auguſt, are more proper for the taking them than any other time of the year; but upon urgent occaſions, the courſe of them may be begun in May, and continued till September; and in ſome extraordinary caſes, the uſe of them may be allowed even in winter.

Method of drinking them. It is always proper to begin the uſe of them by ſmall quantities, and gradually increaſe them to larger. Thus the firſt day it may be proper to drink about a pint and half at four draughts, the ſecond day a quart may be drank, and on the third or fourth three pints: after this the quantity may be increaſed to two quarts a day, and more than this it is not proper to take, unleſs the perſon be of a very robuſt habit; for many people have injured themſelves by taking too large quantities. The quantity that is taken as the moſt the ſtrength will bear, whether it be two, three or four pints, is to be continued every day for a fortnight or three weeks, or longer, if the nature of the diſeaſe requires it; and when the courſe is to be finiſhed, it muſt be done in the ſame manner in which it was begun, by taking leſs and leſs every day, till the uſe is gradually worn off, and no purge or other medicine is neceſſary afterwards.

The *mineral-waters* in general operate in ſome conſtitutions by ſtool, and in others by urine ſingly; but in moſt they operate both ways together. Theſe are both very proper ways of excretion, and whichever nature chooſes the *waters* ſhould paſs off by, it is to be judged proper and ſalutary, and by no means to be checked. If the diſcharge by urine be plentiful, and the bowels are moved but once a day, it is very well in many conſtitutions; but where, as in ſome conſtitutions, it happens that the *waters* actually act as aſtringents in the bowels, this is to be prevented, and a ſmall doſe of the common purging ſalts is to be taken in the firſt draught of the *waters* every morning.

In the taking them it is to be obſerved, that they are not to be poured down as it were all at once, for the ſtomach is often loaded and injured by this, but the firſt glaſs ſhould be ſuffered to paſs off, and then, after walking about for ten minutes or longer, a ſecond is to be taken, and ſo on; and no draught ſhould exceed half a pint in quantity; ſo that the taking the whole quantity in this manner ſhould be the buſineſs of an hour and half, or two hours. After this it is proper to uſe moderate exerciſe by walking, or otherwiſe, till dinner time; and in the mean time, if the *waters* would paſs off by urine or ſtool, this muſt be by no means repreſſed. People who have very weak and tender ſtomachs, or who have diſorders of the breaſt, and drink the *waters* in a rainy ſeaſon, ſhould have them gently warmed before they take them: this is beſt done by ſetting a glaſs of them in a veſſel of hot *water*, and they are only to be ſuffered to ſtand thus till moderately hot, and then immediately drank off; for if heated to too high a degree, they eaſily loſe their virtues by evaporation.

All perſons are to regulate the quantity of the *waters* they drink to the ſtrength of their own conſtitution; however ſmall a quantity they perceive to be enough, and to operate in the manner they expect, they are to be contented with that, and never to teize nature to make her bear more.

It is a certain rule, in regard to all *mineral-waters*, that they are much the beſt when drank at the place, though ſome of them bear carriage much better than others. It is a neceſſary caution, that the motion of the body be never violent in the time of taking the *waters*, for if it produce ſweat it always obſtructs, in ſome degree, their operation by urine or ſtool; and if flatulences are troubleſome at the time, it will be proper to take candied orange-peel, or ſome other carminative at the time. In order to have all the good effects of the *waters*, a regulation of diet is extremely neceſſary; it is proper to dine and ſup early, and the dinner ſhould not be too heavy. It is a good rule indeed, under ſuch a courſe as this, never to eat or drink ſo much as one can, but always to riſe with an appetite. The foods principally to be avoided, during ſuch a courſe, are ſuch as are dried in the ſmoak, or have been long kept in ſalt, and the fleſh of young animals is in general to be greatly preferred to that of old ones; and in general, a too great quantity of vegetables, eſpecially of the flatulent ones, is to be avoided. Lamb, chickens, veal, and the like, are moſt proper for the diet at this time; and to theſe are to be added the tender river fiſh, as trout and pike: broths alſo of all kinds are good; and peas, kidney-beans, ſpinach, and aſparagus, are all very proper. The bread that is eaten under the courſe ſhould never be ſtale; the moſt proper drink at the time is good wine, and if the perſon is not over thirſty, it is beſt to drink this pure, not mixed with *water:* but in this caſe it is only to be allowed within the bounds of moderation; half a pint, at the utmoſt, at a meal to thoſe who have not been habituated to it; and to thoſe who have, ſomewhat leſs than their cuſtomary quantity. The liquor next proper after wine, is ſound and well-bodied ale; but ſuch as is either new and fermenting, or ſo old as to be ſtale, is by no means to be uſed.

Violent exerciſe is wrong, but different conſtitutions will bear different degrees of it, and thoſe of cold and pituitous habits ſhould uſe conſiderably more than others. The ſeaſon of the year is alſo to be regarded, for the ſame degree of exerciſe that is good in a cooler, is too much in a hotter air. The greateſt caution, in the courſe of the taking theſe *waters*, is to avoid too much ſitting ſtill, either after the taking them, or after meals; for the *waters* remaining in the body, or the food remaining undigeſted, from theſe cauſes the conſequence is, that the patient is ſubject to flatulencies, colics, diarrhœas, and pains of the ſtomach. Sleeping immediately after meals is alſo improper, as it occaſions at this time diſorders of the head, and many other complaints.

There are ſome caſes, however, in which the *mineral-waters* may be drank with great advantages by perſons confined to their bed: thus gouty, paralytic, and other extremely emaciated, or weak perſons, have often found great benefit by this method. Slare even goes ſo far, as to adviſe this as the beſt method of taking them in all caſes; but the more judicious writers all judge him in an error in this, becauſe there are very many reaſons why motion and bodily exerciſe, after the drinking them, muſt be beneficial. It is proper to abſtain, as much as poſſible, from all ſorts of paſſi-

paſſions, during the courſe of taking theſe *waters*. Violent anger, grief, or terrors and frights, have been known to occaſion more miſchief at ſuch a time than they would otherwiſe have done; and all people are to abſtain as much as may be from venery during the time, leſt it too much debilitate the body, already weakened by the diſcharges occaſioned by the *waters* by ſtool and urine. Suppers ſhould be moderate during the courſe, and the wine drank at that meal ſhould be diluted with *water:* it is always very adviſeable in this caſe alſo to walk for ſome time after ſupper, that the ſleep may be more quiet, ſound, and refreſhing. And the cold air of the night, eſpecially if it be a damp ſeaſon, is cautiouſly to be avoided, leſt it occaſion catarrhs and other diſorders; for this reaſon, it is proper to ſup early all the while.

Symptoms attending the taking theſe waters. Theſe are of many kinds, and differ greatly from the ſame *waters* drank at the ſame ſeaſon, in perſons of different habits and conſtitutions. One of the moſt common, is a binding of the bowels; and from this there often ariſe pains in the bowels, colics and vomitings, with other the like diſorders. People of melancholy, hypocondriac, and hyſteric habits, are more ſubject than any others to this complaint from them: this is a ſymptom eaſily removed by any of the mild cathartics, and nothing in particular is more proper for that purpoſe than a decoction of ſena, tamarinds, and rhubarb, to be taken a few ſpoonfuls at a time, as occaſion ſhall require. A ſmall doſe of the cooling ſalts may alſo be taken, but all the hot and reſinous purges are apt to occaſion hypercatharſes. On the other hand, ſome are thrown into a diarrhœa by them, and this is often a ſalutary ſymptom; and while the patient's ſtrength is unhurt, and he is not found to ſuffer any great inconvenience from it, this is by no means to be checked, for very often the patient is greatly relieved by a copious diſcharge of the noxious humors this way, and by a continuance in the ſame courſe, becomes abſolutely cured by this means: but when the perſon is perceived to be greatly weakened by this ſymptom, and it is attended with nauſeas, vomitings, and pains in the bowels, it muſt be carefully checked or reſtrained. This is often done by drinking the ſame *waters* in a ſmaller quantity, and warm inſtead of cold; but if this do not prove ſufficient, ſmall draughts of cinnamon-*water* are to be allowed, and, if neceſſary, ſmall doſes of diaſcordium every night. In caſes where the *waters* take this turn violently, it is proper to abſtain from them for ſome days, and then to take to them again with great caution, and in ſmall quantities.

Some perſons, at their firſt entering on a courſe of the *mineral-waters*, are thrown into vomitings by them; and theſe are ſometimes ſalutary, ſometimes merely ſymptomatic. If it be ſalutary, the perſon is always the better for it, and the noxious humors are very happily attenuated and diſcharged this way by the *waters:* in this caſe, all the cautions neceſſary is not to drink too much of them at a time, and ſometimes, between whiles, to take a little of ſome bitter tincture. But if, on the contrary, the patient is greatly weakened by this vomiting, the method is to drink ſmaller quantities, and to eat and drink more ſparingly at meals. Sometimes this ſymptom ariſes from a redundance of bile, or of pituitous humors from the ſtomach and bowels, not having been emptied by a purge before the entering on the courſe: in this caſe a gentle purge is to be given, and after that the common ſtrengthening and bitter ſtomachics, and the *waters* are afterwards to be cautiouſly taken in ſmall quantities.

When the patient is attacked with violent colic pains, and the common method of eating candied orange-peel, and the carminative ſeeds, does not take effect, a gentle purge is to be given to evacuate the humors which occaſion them, and after this, tincture of cardamum ſeeds, or ſome other ſuch carminative, uſually takes effect. In caſes where the pains are more violent and obſtinate, a glyſter of camomile flowers boiled in milk, with a little ſugar, may be given at times, and the *waters* afterwards muſt be drank in ſmall quantities, and always warmed.

If an immoderate flux of the menſes or hæmorrhoids ſhould happen during the time of taking the *waters*, it will be proper to abſtain from the uſe of them on that occaſion for a few days; but if theſe evacuations are in a moderate degree, the *waters* may be continued, only taking them in ſmaller quantity, and not quite cold. Sometimes intermittent fevers come on while perſons are drinking the *waters*; but theſe are not to be regarded as any very bad caſe; for if the uſe of the *waters* be continued, and the carminatives and bitters of the common kind taken at times with them, they are uſually ſoon cured. Pains of the gout, rheumatiſm, ſciatica, and teeth, alſo ſometimes return upon people accuſtomed to them, while they are in a courſe of the *waters*; but theſe are not to be greatly regarded, for they uſually go off again very eaſily, only by continuing the uſe of the *waters*, and require no peculiar cure: only, during the time the pains laſt, ſome comforting cordial may be taken at times; and if they are violent, a few drops of laudanum may be taken every night going to reſt, or a few grains of the ſtorax pill. See *Heiſter*, loc. cit.

Bath and *Briſtol*-WATER. Dr. Guidot pretends that the *Bath* and *Briſtol-waters* are of the ſame virtues, but in a different degree; that both are impregnated with the ſame principles, but the *Bath-waters* containing a much greater ſhare of them, and therefore capable of doing that in a little time which thoſe of *Briſtol* could only do in a much longer. But this ſeems to be far from a true ſtate of the caſe.

The due ſecretions of the blood, and their proper diſtributions, are as neceſſary to the preſervation of life, as the circulation itſelf; and the greateſt part of diſeaſes take their origin from the glandular ſecretions being either too much increaſed or diminiſhed. The blood is ſometimes too thin, and then a too great quantity of its ſerous part is ſeparated either by the glands of the ſkin, guts, or kidneys, as in colliquative ſweats, fluxes of the belly, and diabetes. Some times the blood is too thick and viſcous, and by this means occaſions obſtructions, not only in its own canals, but in the glands; and then the ſecretions are as much leſs than they ſhould be, as in the former inſtance they were greater, and hence ariſe as long a train of diſeaſes. In ſome caſes there is alſo a too great fullneſs of blood, and in others a deficiency, both which hinder the proper ſecretions.

In theſe different caſes the *Bath* and *Briſtol-waters* have their ſeveral uſes: the *Bath-waters* are beneficial when the ſecretions are diminiſhed, the *Briſtol-waters* when they are too much increaſed: the *Bath-waters* powerfully attenuate, the *Briſtol* not leſs powerfully incraſſate: the *Bath-waters* are ſpirituous, and help in deficiences of the blood; the *Briſtol-waters* are cooling, and ſuppreſs plenitude with its ſeveral conſequences, ſuch as inflammations, hæmorrhages, *&c.*

The *Briſtol-waters* are ſuppoſed by many a modern diſcovery, and their uſe but of late date, but this is a very erroneous opinion. Dr. Venner, near eighty years ago, has written profeſſedly of them, and given them their true character, and proper commendations in all the diſeaſes in which they are at this time found effectual, the diabetes only excepted, in which their uſe has not been known ſo long. They were not indeed much frequented at that time, nor of ſome years afterwards; but that was merely from the want of the neceſſary accommodations at the place. Dr. Maplet, in the year 1639, writes largely of their virtues, particularly in diſorders of the urinary bladder and kidneys, and adds great praiſes of their external efficacy in curing cancerous ulcers; but with all this praiſe, they never came into an univerſal repute, till their character was eſtabliſhed by Dr. Mead and Dr. Lane.

The diſeaſes in which the *Briſtol-waters* are found moſt ſucceſsful, are internal hæmorrhages and inflammations, ſpitting of blood, dyſenteries, and immoderate fluxes of the menſes, and purulent ulcers of the viſcera. Hence they are given in conſumptions, ſcurvies, rheumatiſms, diabetes, ſlow fevers, atrophy, gleets, and even in ſcrophulous caſes, with very happy effects: and in all theſe caſes the *Bath-waters* are not only improper, but hurtful; for they rouſe and quicken the circulation, whereas theſe allay the heat, and reſtrain the too rapid motion of the blood. *Bath-waters* ſeem to be adapted to the diſorders of the ſtomach, guts, and nerves; *Briſtol* to thoſe of the lungs, kidneys, and bladder. *Bath-waters* are at variance with a milk courſe, and the *Briſtol-waters* can never be judiciouſly directed, but where milk may be joined with ſucceſs. This is ſo great a truth, that it holds good even in caſes of the diabetes, in which milk is of great ſervice, and has been preſcribed almoſt from the earlieſt times.

The *Briſtol* and *Bath-waters* are both preſcribed by different phyſicians in dropſies. No one can doubt, but that diuretic and drying medicines are of ſervice in this diſeaſe, and as the *Briſtol-waters* poſſeſs theſe virtues in a much greater degree than the *Bath*, they are certainly the moſt adviſeable, unleſs in caſes where a jaundice is joined with the dropſy; in which caſe the *Bath-waters* claim the preference, from their great efficacy in opening obſtructions of the viſcera, where there is no formidable inflammation.

The efficacy of the *Briſtol-water* in the diabetes, has procured it the name of a ſpecific in that diſeaſe; and it certainly much better deſerves that title than moſt of the medicines which have, at one time or other, been honoured with it, for it cures this terrible diſeaſe almoſt infallibly, and that in a very ſhort time, and without any ſenſible evacuation. The patient in this caſe may drink it in as large quantities as he pleaſes. The time for drinking the *Briſtol-waters* medicinally, is from April to September. The *Bath-waters* may be drank the whole year, but the colder months are much the beſt for them, or at leaſt the very heat of ſummer is leſs eligible than any other ſeaſon; and perhaps the beſt months for them are April, May, September, and October.

Buxton-WATERS, the *waters* of medicinal ſprings near Buxton in the Peak of Derbyſhire.

Theſe *waters* are the hotteſt of any in England, except thoſe of

of Bath. The *Buxton-waters* break out in ſeveral places thereabouts; what is called Buxton-bath takes in ſeveral warm ſprings. Thirty-two yards north eaſt of this is St. Anne's well, which is chiefly ſupplied from a ſpring on its north ſide. Twenty yards ſouth eaſt of St. Anne's, in another cloſe, is a place where a hot ſpring and a cold one riſe in the ſame receptacle. About ſixty-three yards ſouth eaſt of this is that called Bingham's well, called alſo Leigh's *water*, from the great benefit a neighbouring gentleman of that name received from it. A little way eaſt of this is another; and in the ſtreams of the level that carries the *water* from the bath, there riſes another very plentiful one; and about four yards farther eaſt there ariſe three or four other ſmall ones. From this account, it may eaſily be conceived that there can be no great difference between the *waters* of theſe ſeveral ſprings, though on trials they ſeem to yield different portions of ſalts and ſediments; at the utmoſt, their difference can be only in degree.

The diſtempers they are recommended in, are the rheumatiſm, gout, ſcurvy, wandering pains, cramps, convulſions, dry aſthmas, want of apetite, indigeſtions, contractions, ſtiffneſs and lameneſs of the limbs, ſuppreſſion of the menſes, and all ſtoppages and beginning obſtructions.

As to the difference of age and ſex in patients, there is little caution required in the drinking them, except that they ſhould be taken more ſparingly by young people, between the ages of twenty-three and thirty, if very full of blood and juices, and by women with child in their firſt and laſt months.

As to the method of uſing them, except the body be coſtive, and the firſt paſſages furred up with groſs humors, it is not only unneceſſary, but hurtful, to prepare the body for them, as it is called, by purging; or at leaſt by any ſtronger purges than manna, cream of tartar, and the like.

The heat of *Buxton-waters*, in froſty weather, is equal to that of common river *water* with which two fifths of boiling *water* has been immediately mixed. See *Short*'s Hiſt. of Min. *Wat.*

Sea-WATER. Authors, who write with accuracy of *ſea-water*, diſtinguiſh it as to its degrees of ſaltneſs and virtues, according to the nature of the ſeas where it is taken, and the depths from which it is drawn up. Count Marſigli always divides the *waters* of a deep ſea into three portions, the upper, the middle, and the deep: each of theſe, according to him, reach to one third of the depth of the bed of *water* from the ſuperficies to the bottom. The upper *water* he finds greatly to differ from the lower or deep *water* in its qualities and ſtrength, but the middle portion to be always more nearly allied to one of the others; he therefore never takes any notice of the middle portion, but makes all his obſervations of the differences of *ſea-water* from the upper and lower portions.

The *ſea-water* is brighter and clearer than that of any river or pond, but this is not ſeen, as the whole body of it is viewed together, becauſe then many various colours are reflected from its ſurface; but on taking up a large glaſs of it, and ſetting it in a ſtill place, it is ſeen to have none of all the whole ſeries of its colours when viewed at ſea, being intirely owing to its motion, and the different reflections its waves have in different angles and directions.

The *ſea-water* appears indeed coloured in its ſuperficial part in ſome places, particularly about the mouths of large rivers; but this is not of its own nature, but is merely owing to the foul *water* of theſe rivers mixing itſelf with it, they being frequently yellowiſh or bluiſh, ſometimes blackiſh, from the quantity of dirt they contain, or the various earthy particles which they waſh off from their banks and bottoms in their paſſage.

As theſe freſh *waters* principally mix themſelves with the ſuperficial part of the *ſea-water*, they extend themſelves a great way, and give a foulneſs to the upper part of a vaſt quantity of *ſea-water*, whoſe bottom part is all the while perfectly clear. Theſe foul *waters* of rivers extend themſelves alſo farther, or a leſs way into the ſea, according to the way the wind ſits; for if the wind blows directly into the mouth of the river, the ſurface is diſturbed in ſuch a direction, that the freſh *water* is beaten under, and blends itſelf below as well as above, and therefore tinges the ſurface for a much leſs extent: but if, on the contrary, the wind ſits directly from the river, all its *waters* are blown on, without ſinking ſo deep as they otherwiſe would, and the foulneſs is extended over a large ſurface, though it is not ſo conſiderable in degree.

The *water* of the ſea taken up at great depths, is generally clear and bright, as has been obſerved; but this is not always the caſe, for in ſome places a quantity of it taken up in very deep *water*, and that near the bottom, is found fouled in the ſame manner as the ſuperficial part is near the mouths of large rivers; and this, when ſtrictly inquired into, is found to proceed from the ſame cauſe, the mixing of a foul river *water* loaded with particles of earth, which it has waſhed off from the ſubſtances it paſſed through, and containing large quantities of blue, black, or yellow earth, all which it would ſuffer to ſubſide, if ſet by for a time in a ſtill place. Count Marſigli has proved, that as rivers burſt up in many places out of the ſurface of the dry ground, ſo they do alſo in ſeveral parts of the bottom of the ſea: in theſe places they pour in their whole body of freſh *water*, which is fouler than that of our common rivers, becauſe, in its ſubterranean paſſage, it has been ſurrounded on all parts with earth, and confined to a much fouler channel. The foul *waters* theſe mouths of rivers diſcharge from the bottom upwards into the *ſea-water*, cannot but act upon that clear liquor, in the ſame manner as the ſuperficial *waters* do on the ſurface, and both muſt be fouled alike. This author has particularly deſcribed one of theſe ſubterranean rivers opening into the ſea from his own obſervations. This foulneſs in ſhallow *water* is ſometimes ſeen through the clearer ſuperficial part by the naked eye, and often, beſide this, an obſerver thinks he ſees many other colours in mid-*water*; but theſe are, for the moſt part, not inherent in the *water*, but are formed by the reflections of the clouds, *&c.* The *ſea-water* being naturally clear, in deep places where it is not diſturbed it appears blue, but in ſhallower *water* it often has different colours, which are owing to the reflections of the coloured matter at the bottom, which will give a tinge to the *water* in places, where not ſo near the eye as to be diſtinctly ſeen themſelves. The clouds alſo give a ſort of coloured appearance to the ſurface of the *ſea-water*, in regard to our eye, though the *water* itſelf be really colourleſs as that of the pureſt ſpring. We have a familiar inſtance of this in the white look of the *ſea-water* in the ſouth ſeas at certain times: and, on the contrary, when any thing fouls the *ſea-water*, and gives it a duſky colour, the clouds above add greatly to that appearance. This we ſee in the Euxine, which being very deep would naturally appear blue if the *water* were clear, but as it is often fouled with duſky matter, and clouds are frequent over it, it appears for a great part of the year abſolutely black, and has thence obtained the name of the Black ſea.

Count Marſigli commemorates alſo another ſingular inſtance of this effect of the clouds on the colour of the *ſea-water*, which fell within his own obſervation. Being at the port of Caſſis on the ſeventeenth of December, in the year 1706, at about an hour before ſun-ſet, there aroſe a large cloud of a blood-red colour, of the nature of thoſe uſual in ſome evenings about ſun-ſet, but accidentally very large, and ſtrongly coloured: as this extended itſelf above, the *ſea-water* under it appeared of the ſame colour, and looked as red as blood for a great extent, ſtill ſpreading the ſame blood colour farther as the cloud extended. This remarkable phænomenon laſted till the darkneſs hid it; and the people of the place, who ſaw the ſea blood coloured, paid no attention to the cloud above that cauſed this colour, but looked on it as a miraculous preſage of war and bloodſhed.

As the clouds in many caſes thus evidently give colour to the *ſea-water*, in regard to our eye, ſo the ſun does the ſame thing in many others: but in all theſe caſes it is to be obſerved, that the colours are ſo far from being real, that the *water* is all the time clear, pellucid, and colourleſs; only its different reflections, from theſe different occaſions, preſent our eyes with colours, as the colourleſs glaſs priſm, or the cut ſide or edge of a common looking-glaſs does.

The ſun, as it ſhines with different force at different times, gives different tinges to the *water*, by ſhewing more or leſs plainly the ſubſtances which are at its bottom. This is evident from a familiar experiment of this author's, who fiſhing on the coaſts with a live bait, which was a ſmall red fiſh, and with a red line, obſerved, that when he let down his bait into the *water*, in places where the rocks kept off the ſun's rays, he could only ſee his fiſh at the depth of ſeven yards; but that even there the fiſh and the line both appeared white, having loſt to the eye their natural red colour: and that, on the contrary, when he let down the bait on the other ſide of the rock where the ſun ſhone, he could ſee it perfectly plain at the depth of eleven yards; and at that greater depth, both the fiſh and the line appeared of their natural red colour. It is evident from this, in how great a degree the ſun's rays affect the *water* in the ſhewing its contents; and it is very evident alſo, that upon this principle alone the ſame ſea, with a coloured bottom, at ſome moderate depth, muſt appear coloured by that bottom in ſunſhiny weather, and not at all ſo in cloudy.

Beſide the clouds, the ſun, the foulneſs of rivers, and the different bottoms, it is certain that the winds alſo contribute greatly to give the colours we obſerve in *ſea-water*. A tempeſt in the winter ſeaſon, an hour or two before ſun-ſet, will ſhew all the colours that *ſea-water* is capable of giving, and that without any other accident whatever to aſſiſt in it. The waves in this caſe ſtriking violently againſt one another, beat off from each other a great number of globules of *water*, and theſe are thrown up to different heights and diſtances; then as the ſun, now low and near the horizon, darts its rays obliquely upon them, they form ſeveral little rainbows, which are of greater and leſs extent, and of more or leſs duration, according to the circumſtances of their aſcent. The freſh *water* of ſome large rivers is alſo found to have, in particular places, the ſame effect where the

the ſtones lie high, and the waves break upon them; the globules of *water* are in the ſame manner raiſed from their ſurface, and little rainbows of ſhort duration are formed. Near the ſhores the *ſea-water*, inſtead of appearing of all this variety of colours, generally looks white: this is owing to the violent motion of the waves, in which they beat one againſt another, as alſo againſt the rocks and ſands, and by the mere agitation of their parts put on this colour. The *water* at theſe times ſeems, in theſe places, really of a milky nature, but as ſoon as it ſettles again into a calm, the clearneſs of the *water* returns, and no ſettlement happens in the whole body of it; which ſhews that it was not made white by the addition of any other matter to it, but only by the diſturbing of its own particles.

Theſe are all the various colours and appearances that the *ſea-water* puts on in different places, and on various occaſions; and we ſee, in the whole, that theſe differences are in general owing not to the alteration in its nature, but only in its change of parts in their directions to the eye, and in their breaking one againſt another, or receiving more or leſs light, or that from a clear or from a cloudy ſky. *Marſigli*, Hiſt. Phyſ. de la Mer.

Count Marſigli has gone through a long courſe of experiments upon *ſea-water*, and after a thouſand tedious proceſſes has obſerved, that three liquors alone are of power to ſhew the different nature of the *ſea-water* in various places, and that very readily: theſe only need, therefore, be carried abroad by thoſe who intend to make experiments of this kind. Theſe are an infuſion of mallow-flowers in *water*, made ſo ſtrong, as to be of a violet colour, ſpirit of ſal armoniac, and oil of tartar. The two laſt of theſe will always keep as long as there is occaſion; the other may be preſerved from decay by ſugar diſſolved in it in different quantities, according to the time it is to be kept, and the climate it is to be carried to; for this ingredient, if added in ſo large a quantity as twice the weight of the liquor, ſo as to make it a true ſyrup, does not prevent it from performing its office in theſe experiments; and in this ſtate it will keep every where, and ever ſo long. When intended for leſs ſevere trials, it may have a ſmaller proportion of the ſugar, and its effects will be then more ſudden and more manifeſt. This infuſion of mallow-flowers mixed with *ſea-water*, turns it to a greeniſh yellow colour, like that of the chryſolite. The ſpirit of ſal armoniac mixed with *ſea-water*, renders it turbid and muddy, and after a time a white ſediment is formed, and ſubſides by ſmall pieces at a time to the bottom of the glaſs. Oil of tartar occaſions the ſame change, but it does it with much more violence.

By mixing theſe liquors with *ſea-water*, taken up in different places, and at various depths, we ſee the different quantity of ſalt it contains manifeſted, by the more or leſs ſudden productions of theſe changes, and by the deepneſs or paleneſs of the colour, and the quantity of matter precipitated.

The common attempts of ſweetning *ſea-water* are alſo eaſily proved by this means, for the more ſalt it contains, after theſe pretended ſweetnings, the more colour or precipitation it will occaſion in theſe mixtures; and the mixing them with it, if perfectly freed from its ſalt, will produce no change at all, as is evident by mixing them ſeverally with *ſea-water* carefully diſtilled; for as this proceſs intirely robs it of its ſalt, there is no ſort of alteration made in it by the mixing theſe liquids. Id. ibid.

The ſudden and ſurpriſing clearneſs of *ſea-water*, on certain occaſions, is a thing not yet accounted for: we have many inſtances given of the fact by the writers of voyages and travels, but one of the moſt remarkable is recorded in the Philoſophical Tranſactions, as having happened on the ſhores of Iceland. On the 13th of May, in the year 1642, all the ſea that beats upon the promontories of that coaſt, and which is uſually very thick and turbid, was for two days together ſo perfectly pellucid and ſhining, that the ſmalleſt ſtones and plants, and the ſea ſhells, where the *water* was forty fathom deep, were ſeen in ſo diſtinct a manner, that they appeared not more than four feet from the ſurface. The fiſhermen who were out in their boats, were ſo terrified at the unuſual appearance, that they left their buſineſs, and the whole country looked on it as a prodigy. Philoſ. Tranſ. N° 110.

In the making of common ſalt from *ſea-water*, it appears that there are other ſubſtances beſide ſalt contained in it, as there is a ſtony cruſt formed on the ſides of the pans, and a powder precipitated to the bottom at the corners; beſide theſe, there are ſome ſubſtances ſeparated from the *water* before it is let into the pan, during its ſubſidence in the ciſtern, and there alſo remain ſome afterwards mixed in the bittern, after all the ſalt is extracted from it. Vid. *Brownrig* of Salt, p. 74.

The *ſea-water* in its motion gathers up mud, ſand, and many other impurities, which ſoon ſubſide in the ciſtern; others, ſomewhat more intimately mixed, are ſeparated with the ſcum raiſed by the whites of eggs in clarifying the brine. But beſide theſe groſs ſubſtances, *ſea-water* contains a glutinous matter of a much finer texture, which is more intimately mixed in it: this Count Marſigli ſays is ſo light, as to riſe with the *water* when diſtilled in a ſand-heat, and therefore may eaſily be raiſed in vapour by the ſun, and falling may fecundate the fields, and promote the growth and nouriſhment of plants. This viſcous matter ſeems earthy, ſaline, and oleaginous; and this is the ſubſtance which, in ſtormy weather, forms a thick ſcum upon the ſurface of the waves; and to this viſcous part is chiefly owing the putrefaction of *ſea-water*, when ſuffered to ſtagnate: for it is evident that the whole ſea in any place will become fetid, when it has been calm for ſome time together, ſo that in ſhips becalmed people have often been threatened with ſickneſſes from the ſtench. Mr. Boyle records two inſtances of this, one in the African ſeas, the other near the Azores iſlands. In the putrefaction of *ſea-water* this ſlimy matter is attenuated, and its texture deſtroyed, and part of it flies off in fetid exhalations, while part ſubſides to the bottom. *Marſigli*, Hiſt. Phyſ. de la Mer. *Boyle* on the Saltneſs of the Sea.

Beſide this viſcous matter, *ſea-water* probably alſo holds an earthy ſubſtance, ſo very bright and ſubtile, that it is elevated in the foregoing proceſs along with the *watery* vapours, as well as the ſlimy matter. The walls of the houſes where ſalt is boiled are covered with this earth, and it ſeems of the nature of that earth contained in clear lime-*water*, which is known to ſubſide from it by proper methods, even after it has been raiſed in diſtillation.

Beſide this light earth, *ſea-water* contains another very coarſe one; this the ſalt-workers call *ſcratch*, and find it on the ſides and at the bottom of the corners of their pans. And it is very probable that this would be ſeparated from *ſea-water* by congelation, for if Briſtol-*water* be frozen, and thawed again, there is always an earth of this kind ſeparated from it; and the petrifying *water* at Knareſborough being frozen in the ſame manner, depoſits its ſtony or calcarious ſediment. Theſe earthy particles are not ſeparated from the *water* in the ſame ſtate in which they were ſuſpended in it, for when the *watery* particles are evaporated, then ſtony ones get together, and concrete in cluſters; and in this ſtate they can no more be diſſolved in *water*, unleſs they are again ſeparated into the ſame minute maſſes which they were in before. It is evident that this powder can riſe in vapour from the experiments of diſtillation, and accident has proved this yet clearer; for in the boiler of a fire-engine, if *water* be uſed which is highly impregnated with this ſtony matter, as is uſually the caſe with that which ariſes from among ſtrata of freeſtone, and the like, the cylinder into which the vapours riſe will be ſo filled with ſtony matter, that the piſton cannot riſe in it.

This powder is properly a ſparry matter, and is in general the ſame ſubſtance which forms incruſtations on the vegetables, *&c.* in ſprings. It has been found, and deſcribed by all authors who have analyſed *waters* of any kind. Dr. Collins, in his Diſcourſe on Salt and Fiſheries, calls it ſtone-powder; Dr. Liſter calls it *arena alba*, and *lapis albus* [a], white ſand and white ſtone; and Dr. Hoffman *pulvis candidus*, and in ſome other parts of his works *ſuccus maris ſalino-terreus calciformis* [b]. [a] *Liſter*, de Font. Med. Angl. [b] *Hoffman*, Oper. Tom. III.

Theſe particles are extremely ſmall and minute while ſuſtained in the *water*, as appears by their paſſing through paper with it in filtration, as has been proved by Dr. Plot in his experiments on it; and hence it is able to enter the veſſels of plants and animals, particularly the teſtaceous fiſhes, the ſhells of which it has great affinity to. It alſo forms the ſtalactitæ in caverns, and many other of the cruſtaceous foſſils. *Plot*, Hiſt. Staffordſhire, cap. 2. p. 109.

This earth is capable of being diſſolved in *water* in very conſiderable quantities, ſome of our ſalt ſprings affording a *water* which contains it in the proportion of one thirty-ſixth part of its own weight, which is nearly the ſame proportion in which common ſalt is found diſſolved in *ſea-water* in general. *Liſter*, de Font. Med. Angl. lib. 1. cap. 6.

The great ſolubility of this earth in *water*, ſhews that it very nearly approaches to the nature of ſalts; and it is even found to enter into the compoſition of perfect ſalts, for being long expoſed to the open air, it imbibes the aerial vitriolic acid, and with it is converted into a neutral ſalt, which Liſter ranks among his calcarious nitres. This ſalt nearly reſembles the bitter purging ſalt of the Epſom-*waters*. It is of a highly alkaline quality, and turns a mixture of ſyrup of violets and *water* green.

The next ingredient of *ſea-water*, that offers itſelf in an analyſis of it, is ſalt: this is the moſt obvious of all others, and is contained in it in very different quantities at different times, and in different places. The Baltic ſea is very weakly impregnated with ſalt; the Engliſh and German ſeas are much more ſtrongly ſo, and the Mediterranean much more ſo than any other; and finally, the *water* on the coaſt of Moſambique is ſuppoſed much ſalter even than this. Mem. Acad. Par. 1711.

Father Feuillee, in paſſing through the Straits of Gibraltar towards America, obſerved the *ſea-water* to diminiſh in gravity as he approached the line. Dr. Hales found the *water* of the ſea, taken up near the buoy of the Nore, to contain $\frac{1}{29.2}$ of its whole weight in ſalt, and that of the Mediterranean contained $\frac{1}{27.5}$; and Count Marſigli found the

the *water*, taken from the ſurface of the Gulf at Lyons, to contain only $\frac{1}{32}$ of ſalt, while that of the ſame place, taken at a greater depth, contained $\frac{1}{29}$. From this that author argues for the ſeas being ſalter at greater depths than near the ſurface, but this might be owing to the falling in of the freſh-*water* rivers near that place; for Mr. Boyle found the *ſea-water* of our own ſeas to be of the ſame ſaltneſs at all depths: and indeed there is great reaſon for ſuppoſing, that in many places, where there falls in little freſh *water*, and where the ſun daily raiſes a great deal of *water* in vapour, it may remain much more ſalt near the ſurface than at great depths, juſt contrary to the foregoing ſuppoſition. *Hales*, Exper. on diſtilled *Sea-water*.

From late experiments it appears, that *ſea-water* is heavieſt and ſalteſt at great depths, and that it is of a temperate heat there; that is, 53 degrees of Fahrenheit's thermometer. See Phil. Tranſ. Vol. 47. p. 213, 214.

It is to be obſerved, that all the authors who have made experiments of this kind have evaporated *ſea-water*, and given the weight of the dry remainder as the quantity of ſalt contained in it; but this is not the true ſtate of the caſe, for this dry reſiduum always contains a quantity of the calcarious earth, or ſcratch, and of the ſalts of the bittern: beſide this, a certain quantity, more or leſs, of aqueous moiſture will remain in the ſalt, and this will alter its weight, as it will be in a greater or leſs proportion, according to the degree of fire uſed; and Mr. Boyle found that his reſiduum of the *water* of the Nore, which, when in the form of what he called a dry ſalt, was $\frac{1}{10}$ part of the *water*, when it had been well dried in a crucible, was but $\frac{1}{37}$ of the *water* uſed. *Boyle* of the Saltneſs of the Sea.

Beſide common ſalt, the *ſea-water* contains other ſalts, which are found in the bittern, or bitter brine remaining after the ſea ſalt is extracted. Firſt it contains a bitter purging ſalt, known in the ſhops under the name of *Epſom-ſalt*. This was firſt extracted from the Epſom, Dullwich, and other purging *waters*, but is now made only from the bittern at Newcaſtle, and other places; and it is chiefly to this bitter ſalt that the *ſea-water* owes its bitter taſte, though that has been ſuppoſed to proceed from bituminous matter contained in it, and often found on its ſurface, or lodged upon the rocks by its motion. Philoſ. Tranſ. N° 377, 378.

Another ſalt is alſo found in bittern, which is called a muriatic calcarious ſalt, its acid principle being ſpirit of ſea ſalt, and its baſis an earth nearly allied to quickſilver. This ſalt remains in the bittern after the purging ſalt has been extracted from it, and though it is a neutral ſalt, it cannot be made to ſhoot in cryſtals, but may be procured in a dry form by fire; but it is very difficultly kept in this form, being, of all other ſalts, the moſt ready to imbibe the *watery* particles of the air, and run *per deliquium*. *Hoffman*, Obſ. Chym. de Lixiv. a Sale relict.

Beſide theſe ſalts, the bittern contains a conſiderable portion of a fixed mineral alkali. Theſe principles are all found in boiling the *ſea-water* into ſalt. But beſide theſe there muſt be many other ſubſtances, which eſcape our ſearch in this manner, ſuch as the ſeeds and excrements of innumerable plants and animals, and the tinctures which thoſe plants and animals impart to it in their decay. Theſe, together with divers ſaline and ſulphureous particles, will naturally fall under the obſervation of thoſe who ſhall attempt a perfect analyſis of *ſea-water* by the nicer methods of chemiſtry; a thing yet much wanted in the learned world. *Brownrig* of Salt, p. 92.

Many ways have been attempted to arrive at the art of making *ſea-water* freſh and potable; the advantages of ſuch a thing are evident enough, but the difficulties very great. Liſter propoſes the doing it by means of ſea plants; theſe vegetables, like other plants, continually exhaling a large quantity of *water* in form of vapour, and that being all freſh, he propoſes on this baſis a diſtillation, without fire, in this manner. The body of a large ſtill, or alembic, is to be filled three parts with *ſea-water*, ſeveral freſh and growing ſea plants are to be put into this in their growing poſture, and the head being then fitted on, and a receiver adapted to the noſe, there will be a continual aſcent of vapours from the plant, which will condenſe into *water* in the head, and this will be thence conveyed into the receiver ſweet, clear, and every way fit for drinking. The quantity thus procured, however, though conſiderable in regard to the manner of its being obtained, can be but ſmall in proportion to the wants of a ſhip's company.

Mr. Kanton therefore attempted a more general method of doing it in quantities; to this purpoſe a large quantity of *ſea-water* is to be taken up in a proper veſſel, and as much oil of tartar *per deliquium* is to be added to this, as will render it turbid, and cauſe a large precipitation. After this the *water* is to be diſtilled, the furnace of the ſtill being ſo contrived as to take up very little room, and conſume but a ſmall quantity of fuel; the ſea itſelf may ſerve for a worm-tub, the worm paſſing out of the ſhip, and in again at another place. When the *water* is thus diſtilled, it is to be mixed with an alkaline earth, and after ſtirring thoroughly about, the earth is to be ſuffered to ſubſide to the bottom, and the *water* poured off clear; it is then ſaid by the inventor of this ſcheme to be perfectly ſweet, and no way diſtinguiſhable from the very pureſt river *water*. Phil. Tranſ. N° 67.

Another method of ſeparating ſalt from *ſea-water* without fire is propoſed in the Philoſophical Tranſactions: take a veſſel of wax, hollow within and every where tight, plunge it into the ſea, or other ſalt *water*, and there will be made ſuch a ſeparation, that the veſſel ſhall be full of ſweet *water*, the ſalt ſtaying behind. But though this *water* have no ſaltiſh taſte, yet a ſalt will be found in the eſſay. Philoſ. Tranſ. N° 7. p. 128.

To obtain freſh wholeſome *water* from *ſea-water*, Dr. Hales's method is to keep the *ſea-water* cloſe ſhut up till it has putrefied, and has again become ſweet, then to diſtill, three fourths of the *ſea-water* will be free both of the bittern and acid. Mr. Hales enters into a particular detail of the circumſtances which may make the practice of this ſupply of freſh *water* eaſy. Philoſ. Experim.

Drinking *ſea-water* with ſome wine, is ſaid to prevent people from being ſick at ſea. Act. Phyſ. Medic. Acad. Nat. Curioſ. Vol. V. Obſ. 84.

Sea-water, drank to the quantity of a pint, is a moderate purgative to moſt people. It has been of late much in faſhion, and is ſaid to be very beneficial in many caſes, particularly in glandular diſorders.

Simple-WATERS. In the diſtillation of *ſimple-waters*, a good general rule is this: take as much of the dried herb, as when cut ſmall will fill two thirds of the ſtill to be uſed; pour upon this as much rain *water* as will make the plant float commodiouſly, leaving however a fourth of the ſtill empty; digeſt this a while in a gentle heat, and then give fire enough to work the ſtill, and draw off ſo long as the *water* appears thick or milky, and taſtes of the herb. *Shaw*'s Lect. p. 198.

It is a principal caution in this operation to remove the receiver before the more pellucid, acid, faint, and dead *water* comes over, as it will at length do, and by mixing with the reſt will ſpoil the whole, by giving it a vapid or faint taſte, and ſometimes a degree of acidity or vitriolic ſtypticity, or emetic quality; for part of the eſſential ſalt of the plant now riſing, corrodes the head of the ſtill, and carries over with it ſome particles of the metal: for which reaſon, ſuch *waters* ſhould be either diſtilled with a glaſs head, or a pewter one, or elſe the laſt running carefully watched, and not ſuffered to come over and mix with the firſt; for want of this caution, children, and perſons of tender habits, have been often vomited, purged, &c. contrary to the intention of the preſcriber, by a *ſimple-water*.

The *ſimple-waters* diſtilled by this method may often be too ſtrong to give alone, but then it is eaſy to let them down to a proper ſtrength with common *water*; which is beyond all compariſon better than to mix them with their own faints, or the liquor of their ſecond running.

There are yet however two methods of improving the common *ſimple-waters*, which might eaſily be put in practice: the firſt is the cohobating, and carefully digeſting the plant; the ſecond the fermenting it. With regard to the firſt, if the liquor remaining in the ſtill be expreſſed from the herb, and returned, along with all the *water* that came over, upon a freſh quantity of the ſame ſubject, and they be digeſted together in a gentle heat for two days, and then diſtilled as before, the *water* thus obtained will be much richer, and more efficacious than before; and if the ſame operation be repeated two or three times, thoſe who have not tried it cannot eaſily conceive how very rich a *ſimple-water* may by that means be made: and this is moſt neceſſary in diſtilling the *ſimple-waters* of roſes, elder-flowers, balm, and the like ſubjects, which afford but little oil, and otherwiſe make but weak *waters*.

The other method recommended, *viz.* by fermentation, is performed by adding to the plant and *water*, put together as for diſtillation, a tenth or twelfth part of ſugar or honey, or elſe a fortieth part of yeaſt; then ſetting the whole in a warm place to ferment for three or four days only, ſo that the herb may not fall to the bottom, nor the fermentation be above half finiſhed; then the whole being committed to the ſtill, a *water* may be procured at one operation, extremely rich, or impregnated with the whole virtue of the plant; and thus may *ſimple-waters* be made fit for long keeping without ſpoiling, the ſmall quantity of inflammable ſpirit generated in the fermentation ſerving excellently to preſerve them. *Shaw*'s Lectures, p. 199.

Diſtilled-WATERS. To procure the *diſtilled-waters* of vegetables, or other ſubjects, pure and free from all mixture of the other principles of the body it was extracted from, let the *water*, as diſtilled, be put into a funnel lined with paper to be filtred, and the funnel being kept continually filled up, that the lighter oil may not come in contact with the paper, the *water* will be tranſmitted through, in a great meaſure, without the oil; but there ſtill remains ſome proportion of oily, and commonly of ſaline matter alſo in it. If the ſaline matter be acid, the way to deſtroy it is by mixing chalk, or any alkaline ſalt with the *water*, which being afterwards diſtilled again, will then riſe pure. If the plant were alkaline, and an alkaline ſalt be ſuſpended in the *water*, let it

be

be made a neutral one, by mixing ſome acid, and then the *water* filtred and diſtilled again. By theſe methods the *water* of vegetables is procured pure; and this is the way of proving, that the chemical principle *water* is lodged in, and may be ſeparated from all ſuch ſubſtances. *Shaw*'s Lectures, p. 150.

Cordial-WATERS. In the making of all compound ſpirituous liquors, or, as they are called by the apothecaries, *cordial-waters*, the great care is to uſe a pure and well-rectified ſpirit, as nearly inſipid as poſſible, that the flavour of it may not mix among the flavours of the other ingredients. It is the general cuſtom to uſe the proof-ſpirit, but it would be infinitely better to uſe the alcohol, or totally inflammable; partly, as the ſtrength of the *water* would be much better aſcertained that way, the proof ſtrength determined by the crown of bubbles being very vague and uncertain, and that of the alcohol or totally inflammable ſpirit perfectly fixed and certain; and becauſe this ſpirit is always more free from the oil of the ingredient it is made from, and on that account not only approaches more to that ſo much deſired thing, a pure and taſteleſs ſpirit, but being free from oil of its own is the more hungry, the more ready to imbibe that of the ingredients added to it, and has no overpowering taſte to give of its own.

If the method of uſing alcohol be not choſen, let a fine, clear, and pure melaſſes ſpirit of the proof ſtrength be uſed, without any farther addition of *water* in the ſtill, an additional quantity of *water* only taking up room to very bad purpoſe, and prolonging and prejudicing the operation; and when alcohol is employed, it ſhould only be mixed with an equal quantity of pure *water*, to reduce it to the proof ſtrength. When the choice of a ſpirit is thus ſettled, the next thing to be had regard to is the matter of digeſtion, for without this many ingredients will not part with their flavour and virtues at all, and many others but very imperfectly. Cinnamon in particular, if not macerated in the ſpirit a long while before diſtillation, will not part with its heavy oil, which will therefore be left in the ſtill, and thrown away, while the ſlightly impregnated ſpirit is ſaved.

When the ingredients have ſtood a due time in digeſtion, according to their ſeveral natures, the ſpirit is to be drawn from them in the manner that beſt tends to bring over their virtues, whereon the character and expectation of the *water* is founded; ſo if the ingredients naturally abound in a heavy viſcous oil, the operation ſhould be performed with a briſker fire, than when the oil is thin, light, and etherial. Thus ſtrong cinnamon-*water*, after a ſufficient digeſtion to looſen the oil, may be drawn over ſmarter, or with a briſker fire, than citron-*water*, the ſpirit of mint, or the like, in which the oil of the ingredient is thin, and will eaſier aſcend with the ſpirit.

The capital thing in this compound diſtilling reſts here, that a ſufficient quantity of the fine eſſential oil of the ingredients be received into, and mixed with the ſpirit, while the groſſer, leſs ſubtile, and leſs agreeable oil is thrown out. To effect this to any degree of perfection, requires that the operation be well conducted from the beginning, that the receiver be changed in due time, and that the ſpirit be prudently made up.

When no regard is had to theſe three particulars, as is uſually the caſe among the apothecaries, the conſequence is, that the *cordial-water* becomes a thick, turbid, and milky liquor, and taſtes more like what the diſtillers call faints, than like a *cordial-water*, and is fitted to give ſickneſs rather than to cure it. At leaſt, before it can be uſed, it muſt either ſtand a long time to fine itſelf, if ever it will fine, or have its groſs and terreſtrial parts precipitated by art. On the contrary, when theſe rules are prudently obſerved, the *water* proves, without farther trouble, clean taſted, clear, briſk, pleaſant, and refreſhing.

The diſtillers in general make their compound *waters* in a much neater manner than the apothecaries; and what has led them into the way of doing ſo, is their ſtrict obſervance of the bubble proof, a thing which the apothecaries ſeem either not to underſtand, or to pay very little regard to.

The diſtillers, in the making of their compound *waters*, find, that if they let the faints run in among the clear ſpirit, it kills the proof, as they call it, before the time; hence they are inſtructed to leave the faints out, and to make up the ſpirit with pure *water*, reſerving the faints to other uſes, to which they are better adapted, as containing a copious oil; or they let the ſtill work longer than the proceſs for making the *water* would require, and by this means obtain a larger quantity of oil than is commonly imagined: this they preſerve ſeparate, if the oil of only ſome one ingredient; and they ſell large quantities of the oils of juniper, aniſe and caraway, and the like, to the druggiſts, chemiſts, and apothecaries. But this is a very ſcandalous cheat on the buyer, for there is a very great difference between a pure and clear eſſential oil, that is perfect and intire, and ſuch a one as has, in this manner, been robbed of its lighter and finer parts by diſtillation with a ſpirituous menſtruum.

It is a general rule in this buſineſs to change the receiver as ſoon as the ſpirit runs proof, and make up the quantity with *water*: in this caſe, the whole is certain to be clean and fine; but there are ſome caſes, as in particular in the diſtilling of cinnamon-*water*, where a ſmall quantity of the faints ought to be ſuffered to come into the ſpirit: but this is to be obſerved by way of ſtint, that ſo much is never to be allowed of the faints as will make the *water* milky; for the *water* ſhould always be kept in the ſtate of full proof, as it mellows and ripens, as they expreſs it, much ſooner in this than in any other ſtate. But if the cuſtom could be univerſally introduced, it would be better that all the *waters*, kept by the apothecaries, ſhould be juſt in the ſtate in which they came over, that is, three fifths of the quantity of the proof ſpirit put into the ſtill: if this were generally brought about, it would be eaſy for the phyſicians to regulate the doſes in their preſcriptions accordingly; every draught and julep that they entered into would be the better for it. *Shaw*'s Eſſay on Diſtillery.

Dr. Shaw in another treatiſe, after obſerving that the apothecaries uſually ſucceed but ill in diſtilling *cordial-waters*, lays down the four following rules, by the obſervance of which the art of making theſe *waters* might be brought to great perfection.

The firſt is, to uſe a well-cleanſed ſpirit that is freed from its own eſſential oil, for as the deſign of compound diſtillation is to impregnate a ſpirit with the eſſential oil of the ingredients, it ought firſt to be deprived of its own.

The ſecond rule is, to ſuit the time of the digeſtion of the ingredients to their tenacity, or the ponderoſity of their oil: thus rhodium wood and cinnamon require to be longer digeſted, before they are diſtilled, than calamus aromaticus, or lemon-peel. Sometimes alſo cohobation, or the pouring of the ſpirit already diſtilled back upon the ingredients, proves neceſſary, as particularly in making the ſtrong cinnamon-*water*, where the eſſential oil is extremely ponderous, and difficultly riſes along with the ſpirit without this cohobation.

The third rule is, to ſuit the degree of fire, or ſtrength of the diſtillation, to the ponderoſity of the oil intended to be raiſed with the ſpirit: thus ſtrong cinnamon-*water* ſhould be diſtilled off briſker than the ſpirit of mint or balm.

The fourth rule is, that a due proportion of only the finer eſſential oil of the ingredients be thoroughly united, or incorporated with the ſpirit, ſo as to keep out the groſſer and leſs fragrant oil. This may chiefly be effected by leaving out the faints, and making up to ſtrong proof with fine ſoft *water* in their ſtead.

The addition of ſugar to *cordial waters* is a thing of little moment, and may therefore be omitted. If the four rules before laid down be duly obſerved, there is no occaſion for diſtilling in balneo mariæ, nor for fining down *waters* with alum, whites of eggs, iſinglaſs, or the like, for they will be preſently bright, ſweet, and pleaſant taſted, without any farther trouble. *Shaw*'s Lectures, p. 127.

Motion of WATER, in hydraulics. The theory of the motion of running *water* is one of the principal objects of hydraulics, and many eminent mathematicians have applied themſelves to this ſubject. But it were to be wiſhed that their theories were more conſiſtent with each other, and with experience. The curious may conſult Sir *Iſaac Newton*'s Principles, lib. 2. prop. 36. with the comment. *Dan. Bernoulli*'s Hydrodynamica. *Jo. Bernoulli*, Hydraulica, Oper. Tom. IV. p. 389, ſeq. Dr. *Jurin*, in the Philoſ. Tranſactions, N° 452, and in Dr. *Martyn*'s Abridg. Vol. VIII. p. 282, ſeq. 'sGraveſande, Phyſic. Elem. Mathemat. lib. 3. pars 2. *Polenus*, de Caſtellis, and others. Mr. Mac Laurin, in his Fluxions, art. 537, ſeq. has illuſtrated Sir Iſaac Newton's doctrine on this intricate ſubject, which ſtill, notwithſtanding the labours of all theſe eminent authors, remains in a great meaſure obſcure and uncertain. Even the ſimpleſt caſe of the motion of running *water*, which is when it iſſues from a hole in the bottom of a veſſel kept conſtantly full, has never yet been determined, ſo as to give univerſal ſatisfaction to the learned. We ſhall here mention ſome of the phænomena of this motion, as ſtated by Dr. Jurin from Polenus.

1. The depth of the *water* in the veſſel, and the time of flowing out being given, the meaſure of the effluent *water* is nearly in proportion to the hole.

2. The depth of the *water*, and the hole being given, the meaſure of the effluent *water* is in proportion to the time.

3. The time of flowing out, and the hole being given, the meaſure of the effluent *water* is nearly in a ſubduplicate proportion to the height of the *water*.

4. The meaſure of the effluent *water* is nearly in a ratio compounded of the proportion of the hole, the proportion of the time, and a ſubduplicate proportion of the depth of the *water*.

5. The meaſure of the *water* flowing out in a given time, is much leſs than that which is commonly aſſigned by mathematical theorems. For the velocity of effluent *water* is commonly ſuppoſed to be that which a heavy body would acquire in vacuo in falling from the whole height of the *water* above the hole; and this being ſuppoſed, if we call the area of the hole F, the height of the *water* above the hole A, the velocity which a heavy body acquires in falling

in vacuo from that height V, and the time of falling T; and if the *water* flows out with this conſtant velocity V, in the time T, then the length of the column of *water*, which flows out in that time will be 2 A, and the meaſure of it will be 2 AF. But if we calculate from Poleni's [a] accurate experiments, we ſhall find the quantity of *water* which flows out in that time to be no more than about $\frac{571}{1000}$ of this meaſure 2AF.—[[a] *Poleni.* de Caſtellis, art. 35, 38, 39, 42, 43.]

Poleni alſo found, that the quantity of *water* flowing out of a veſſel through a cylindrical tube far exceeded that, which flowed through a circular hole made in a thin lamina, the tube and hole being of equal diameter, and the height of the *water* above both being alſo equal; and he found it to be ſo when the tube was inſerted, not into the bottom, which others had obſerved before, but into the ſide of the veſſel.

6. Since the meaſure of the *water* running out in the time T, is $2AF \times \frac{571}{1000}$, the length of the column of *water* which runs out in that time, is $2A \times \frac{571}{1000}$. Therefore if each of the particles of *water*, which are in the hole in the ſame ſpace of time, paſſes with equal velocity, it is plain that the common velocity of them all is that with which the ſpace $2A \times \frac{571}{1000}$ would be gone over in the time T, or the velocity $V \times \frac{571}{1000}$. But this is the velocity with which *water* could ſpring in vacuo to near $\frac{1}{3}$ of the height of the *water* above the hole.

7. But when the motion of *water* is turned upwards, as in fountains, theſe are ſeen to riſe almoſt to the entire height of the *water* in the ciſtern. Therefore the *water*, or at leaſt ſome portion of the *water*, ſpouts from the hole with almoſt the whole velocity V, and certainly with a much greater velocity than $V \times \frac{571}{1000}$.

8. Hence it is evident, that the particles of *water*, which are in the hole in the ſame point of time, do not all burſt out with the ſame velocity, or have no common velocity; though ſome mathematicians have hitherto taken the contrary to be certain.

9. At a ſmall diſtance from the hole, the diameter of the vein of *water* is much leſs than that of the hole. For inſtance, if the diameter of the hole be 1, the diameter of the vein of *water* will be $\frac{21}{25}$, or 0.84, according to Sir Iſaac Newton's meaſure, who firſt obſerved this phænomenon; and according to Poleni's meaſure $\frac{20}{26}$, or $\frac{20\frac{1}{2}}{26}$, that is, taking the mean diameter 0.78, nearly.

As to the manner of accounting for theſe phænomena we have already obſerved that authors are not agreed; and it would be far beyond our deſign to ſtate their different theories, we muſt therefore refer to the originals above quoted.

Neither are authors agreed as to the force with which a vein of *water*, ſpouting from a round hole in the ſide of a veſſel, preſſes upon a plane directly oppoſed to the motion of the vein. Moſt authors agree that the preſſure of this vein, flowing uniformly, is equal to the weight of a cylinder of *water*, the baſis of which is the hole through which the *water* flows, and the height of which is equal to the height of the *water* in the veſſel above the hole. The experiments made by Mariotte and others ſeems to countenance this opinion. But Mr. Daniel Bernoulli rejects it, and eſtimates this preſſure [b] by the weight of a cylinder, the diameter of which is equal to the contracted vein, (according to Sir Iſaac Newton's obſervation above mentioned) and the height of which is equal to twice the height of the *water* above the hole, or, more accurately, to twice the altitude correſponding to the real velocity of the ſpouting *water:* and this preſſure is alſo equal to the force of repulſion [c], ariſing from the reaction of the ſpouting *water* upon the veſſel. For he ſays that he can demonſtrate, that this force of repulſion is equal to a preſſure exerted by a vein of ſpouting *water* upon a plane directly oppoſed to its motion, if the whole vein of *water* ſtrikes perpendicularly againſt the plane. From whence it would follow, that the preſſure or force of the vein will be greater in proportion, as its contraction is leſs; and this contraction vaniſhing, as it does when the *water* ſpouts thro' a ſhort tube, and the vein being at the ſame time ſuppoſed to have the whole velocity it can acquire by theory, the ſpouting *water* will then exert a preſſure double to what is commonly ſuppoſed. But the actual velocity of the *water* being always ſomething leſs than it ought to be by theory, and the vein of *water* being not uncommonly contracted to almoſt one half, experiments have led authors to think that the preſſure, exerted by ſpouting *water*, was equal to the weight of a cylinder of the ſame diameter with the vein, and of the height of the *water* above the hole. The ingenious author remarks, that he ſpeaks only of ſingle veins of *water*, the whole of which are received by the planes upon which they preſs: for as to the preſſures exerted by fluids ſurrounding the bodies they preſs upon, as the wind, or a river, the caſe is different, though confounded with the former by writers on this ſubject.—[[b] Hydrodynamica, ſect. 13. p. 289. [c] Ib. p. 279.]

Mr. Bernoulli endeavours to confirm his theory by a diſſertation in the eighth volume of the Acta Petropolitana [d]; where he obſerves, that the experiments formerly [e] made before the Academy of Sciences at Paris, to eſtabliſh the quantity of the preſſure exerted by a vein of ſpouting *water*, are very far from proving the truth of the rule they are brought to eſtabliſh. For inſtance, in one of thoſe experiments, the height of the *water* in the veſſel above the hole from whence the vein ſpouted was two feet Paris meaſure, the diameter of the circular hole which was cut in the horizontal bottom of the veſſel was four lines, and the force of the vein of *water* was obſerved to be one ounce and three quarters. But the weight of a cylinder of *water* of the diameter of the hole, and of the height of the *water* in the veſſel, is ſcarce equal to one ounce and three eighths. The difference therefore is at leaſt $\frac{3}{8}$ of an ounce, which is about $\frac{3}{11}$ of the whole weight of the beforementioned cylinder of *water*. So that it is ſurpriſing, that this difference ſhould have been aſcribed to the removal of the plane, receiving the impulſe, to ſome diſtance from the hole; for this cauſe, ſuppoſing the plane removed to the diſtance of two inches, could not produce an increaſe of $\frac{1}{16}$ of an ounce. It appears therefore, that the common opinion is rather overturned, than confirmed by experience.—[[d] P. 114. [e] *Du Hamel*, Hiſt. Acad. Paris, An. 1679. ſect. 3. cap. 5.]

Mr. Bernoulli, on the other hand, thinks his own theory ſufficiently eſtabliſhed by the experiments he relates; for the particulars of which, we refer to the Acta Petropolitana, Vol. cit. p. 122, ſeq.

This ingenious author thinks, that his theory of the quantity of the force of repulſion, exerted by a vein of ſpouting *water*, might be uſefully applied to move ſhips by pumping; and he thinks the motion produced by this repulſive force would fall little, if at all, ſhort of that produced by rowing. He has given his reaſons and computations at length in his Hydrodynamica, p. 293 to 302.

The ſcience of the preſſures exerted by *water*, or other fluids in motion, is what Mr. Bernoulli calls *hydraulico-ſtatica*. This ſcience differs from hydroſtatics, which conſiders only the preſſure of *water* and other fluids at reſt; but hydraulico-ſtatics conſiders the preſſure of *water* in motion. Thus the preſſure exerted by *water* moving through pipes, upon the ſides of thoſe pipes is an hydraulico-ſtatical conſideration, and has been erroneouſly determined by many, who have given no other rules in theſe caſes, but ſuch as are applicable only to the preſſure of fluids at reſt. See Hydrodynam. ſect. 12. p. 256, ſeq.

Raiſing of WATER, in hydraulics. The great uſe of raiſing *water* by engines for the various purpoſes of life are well known. Machines have in all ages been contrived with this view, a detail of the beſt of which, with the reaſons of their conſtructions, would be very curious and inſtructive. Monſieur Balidor has executed this in part in his Architecture Hydraulique, and it is to be hoped that he will ſoon finiſh that uſeful undertaking. Dr. Deſaguliers has alſo given us a deſcription of ſeveral engines to raiſe *water*, in his Courſe of Experimental Philoſophy, Vol. II. not to mention the compilers of treatiſes under the title of Theatres of Machines, *&c.*

Dr. Deſaguliers [f] has ſettled the maximum of engines for raiſing *water* thus: a man with the beſt *water*-engine cannot raiſe above one hogſhead of *water* in a minute, ten feet high, to hold it all day; but he can do almoſt twice as much for a minute or two. [[f] Experim. Philoſ. Vol. II. p. 498.]

Dr. Deſaguliers obſerves [g], that when we come to examine the beſt engines, and thoſe that are moſt cried up, if we look narrowly into them, and meaſure the *water* they deliver, and at what height they deliver it; or bring to calculation the beſt atteſted relations concerning them, we ſhall find that they do not exceed this maximum, though they may far outdo ſome very bad engine that they are compared with. —[[g] Ibid.]

The famous machine at Marli, though it has many ingenious contrivances, muſt yet be reckoned a bad one, if we conſider the vaſt loſs of force in it. This loſs, according to Mr. Daniel Bernoulli's [h] computation, is not leſs than $\frac{5}{6}$ of the abſolute force of the machine.—[[h] Hydrodynam. p. 182.]

Mr. Daniel Bernoulli [i] thinks that a man may, with the moſt perfect machine, raiſe one cubic foot of *water*, in one ſecond of time, to the height of one foot. But by an experiment he made at Geneva with a good pump, he found that a man could not raiſe above four fifths of that quantity. —[[i] Hydrodyn. p. 199.]

Yet the greateſt quantity, mentioned by Mr. Bernoulli, falls ſhort of Dr. Deſaguliers's maximum: for according to the Doctor's rule, one hogſhead being equivalent to eight cubic feet, and the raiſing one hogſhead of *water* to the height of 10 feet being equivalent to the raiſing 10 hogſheads of *water*, or 80 cubic feet, to the height of one foot, it follows, that a man may raiſe 80 cubic feet of *water*, in one minute, to the height of a foot. But by Mr. Bernoulli's rule, he can only raiſe 60 cubic feet of *water* to that height in the ſame time.

Engines for raiſing *water* are either ſuch as throw it up with a great velocity, as in jets; or ſuch as raiſe it from one place

to another by a gentle motion. For the general theory of theſe engines, ſee *Daniel Bernoulli*'s Hydrodynamica, ſect. 9.

WATERS, among farriers, the name given to a diſtemperature of horſes. The hinder legs of theſe creatures are very ſubject to a defluxion of certain white, ſharp and corrupt humours, or *waters*, as they call them, which happen very rarely to the fore legs.

This diſeaſe is diſcovered by ſearching the paſterns, where, if a moiſtneſs is felt beneath the hair, and is extremely ſtinking, there is danger of its growing to the utmoſt height of this diſeaſe, in which it will grow all round the paſtern and paſtern joint, and ſometimes almoſt up to the very ham. Theſe *waters* frequently cauſe the paſterns to ſwell, keeping the legs ſtiff, and making the horſe lean; finally, they often ſeparate the fleſh from the coronet near the heel. This diſeaſe is very obſtinate and ſtubborn when once rooted in the horſe. It may eaſily be ſtopt in the beginning, but when of any continuance, it is an error to attempt to ſtop it, for if dried up ever ſo often, it will always return again. It is in vain to attempt a cure of this diſeaſe in the winter, unleſs it be but juſt begun; but in the ſummer ſeaſon all attempts ſucceed better, and what the farriers call the white honey charge has ſurpriſing effects, often performing a cure alone.

Some farriers diſtinguiſh between the *waters* and what they call *watery ſores*, though others call them only degrees of the ſame diſtemper. Thoſe who diſtinguiſh them, deſcribe the *watery* ſore as a white, corroſive, and malignant matter, iſſuing out of the pores of a horſe's leg, uſually on the lower part only, but ſometimes all over it; and beginning from a ſtinking matter, deadening the ſkin of the paſtern and fetlock, and by degrees looſening the hoof from the coronet at the heel. The breaking out of this matter is always uſhered by a ſwelling of the lower part of the leg, and attended with pain; and the humour at length acquiring a ſharp and venomous quality, it is attended with warts, clefts, and nodes, which in proceſs of time over-run the whole part, and render the cure very difficult.

This diſeaſe generally appears firſt on the outſide of the paſtern, and by degrees riſes up to the middle of the leg, peeling off ſome part of the hair all the way. The method of cure ſhould be this: as ſoon as a horſe is ſeized with the diſtemper, he ſhould be blooded ſparingly, at the utmoſt not exceeding two pounds; after this he ſhould take large doſes of a decoction of guaiacum, or of box-wood, twice every day for eight days; after this he is to take three or four briſk purges, and then to have recourſe to the decoction again. In the interim, the hair muſt be all clean ſhaved off from the diſtempered part of the leg, and it muſt be rubbed with a wiſp of hay very often, and the *watery* ſores in it anointed with the following ointment. Take a pound of black ſoap, three ounces of ſpirit of wine, two ounces of common ſalt, and three ounces of burnt alum; there is to be as much meal or flower added to theſe, as will make the whole into a proper conſiſtence: this is to be laid on all the ſores without any covering or bandage, and the next morning it is to be waſhed off with a lee of aſhes freſh made. This anointing and waſhing is to be repeated every day, and between the effect of this, and of the internal remedies, the diſeaſe ſeldom fails of a cure, if it be not very obſtinate, or of very long ſtanding.

Bird-lime-WATER. See LIME-*twigs*, *Suppl.*

Citron-WATER. See the article CITRON-*water*, *Append.*

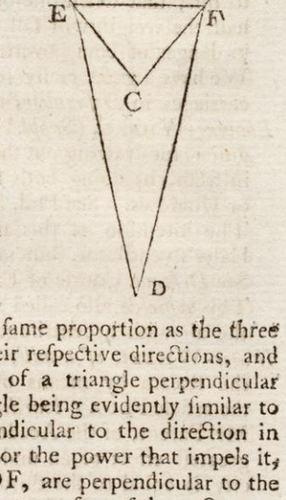
WATER-*parſnep*. See the article PARSNEP, ſupra.

WATER-*pepper*. See the article PEPPER, ſupra.

WAX (*Suppl.*)—*Thorough*-WAX, in botany, the name by which ſome call the *bupleurum*, or hare's ears. See the article HARE'S *ears*, *Suppl.*

WAY, (*Suppl.*) the ſame with *weigh*. See WEIGH, *Cycl.*



WAYFARING-*tree*, a name ſometimes given to the *viburnum*. See the article VIBURNUM, *Suppl.*

WEATHER (*Cycl.* and *Suppl.*)—WEATHER-*boarding*, among carpenters, *&c.* denotes the nailing up of boards againſt a wall, and ſometimes the boards themſelves when thus nailed up. Build. Dict. in voc.

WEATHER-*tiling*, among workmen, the covering the upright ſides of houſes with tiles. Id. ibid.

WEB-*caſe*, in natural hiſtory, the Engliſh name for what zoologiſts more uſually call *aurelia*, or *chryſalis*. See the article CHRYSALIS, *Append.*

WEDGE (*Cycl.*)—The effect of the *wedge* may be thus explained: Let ABC repreſent a *wedge* driven into the cleft EDF, of which DE and DF are the ſides; and if we ſuppoſe thoſe ſides DE and DF to react upon the *wedge* with directions perpendicular to DE and DF, let the horizontal line EF meet DF in F: then when the force impelling the *wedge*, ſuppoſed perpendicular to the horizon, is in equilibrio with the reſiſtances of the ſides of the cleft DE and DF, theſe three powers are in the ſame proportion as the three right lines EF, DE, and DF. But it follows from the compoſition of motion, that when three powers are in equilibrio with each other, they are in the ſame proportion as the three ſides of a triangle parallel to their reſpective directions, and conſequently, as the three ſides of a triangle perpendicular to their directions; ſuch a triangle being evidently ſimilar to the former. But EF is perpendicular to the direction in which the weight of the *wedge*, or the power that impels it, is ſuppoſed to act; and DE, DF, are perpendicular to the directions in which their reſiſtances are ſuppoſed to act, conſequently the power that impels the *wedge*, and thoſe reſiſtances, are in the ſame proportion as EF, DE, and DF.

If other ſuppoſitions are made, concerning the reſiſtances of the ſides of the cleft DE and DF, the proportions of the powers may be determined from the ſame principles. See *Mac Laurin*'s Account of Sir Iſaac Newton's Philoſophical Diſcoveries, p. 168, ſeq.

Mechanical writers have differed very much in determining the properties of the *wedge*, or the proportion between the moving force, and the reſiſtance the *wedge* meets with. In ſplitting of timber, the proportion here mentioned ſeems to take place, and that mentioned in the Cyclopædia wrong. In other caſes, different proportions might obtain; for a detail of which *Varignon*'s Nouvelle Mechanique, ſection 8. Vol. II. p. 149, ſeq. may be conſulted. See alſo 's*Graveſande*, Phyſ. Elem. Mathem. lib. 1. cap. 14. ſchol. 1.

WEED (*Suppl.*)—*Dyer*'s WEED, the Engliſh name of a genus of plants, known among botaniſts by that of *luteola*. See the article LUTEOLA, *Suppl.*

Silver-WEED, *pentaphylloides*, in botany, a diſtinct genus of plants. See the article PENTAPHYLLOIDES, *Suppl.*

WELL (*Suppl.*)—WELL, in ſhip-building, a ſquare place parted off and planked round the main-maſt, from the gun-deck down to the foot-waaling, to keep the ballaſt, *&c.* from the pumps placed therein. *Blanckley*'s Naval Expoſitor, in voc.

WHEAT, in botany, the Engliſh name of a diſtinct genus of plants, called by authors *triticum*. See the article TRITICUM, *Suppl.*

Cow-WHEAT, the Engliſh name of a diſtinct genus of plants, called *melampyrum* by botanical writers. See the article MELAMPYRUM, *Suppl.*

French-WHEAT, or *Buck*-WHEAT, in botany, a genus of plants, called by botaniſts *fagopyrum*. See the article FAGOPYRUM, *Suppl.*

Indian-WHEAT, a name ſometimes given to the *maiz* or *yucca*. See the articles MAIZ and YUCCA, *Suppl.*

WHEE, or WHEY, a word uſed in the northern parts of the kingdom for a heifer, or young cow. Ruſt. Dict. in voc.

WHEELS (*Cycl.*)—The *wheels* of all carriages ought to be exactly round, and the fellies ſhould be at right angles to the naves, according to the inclination of the ſpokes; that is, the plane of the curvature of the *wheel* ſhould cut the nave at right angles, though it need not paſs through the place where the ſpokes are inſerted into the nave.

The reaſon why the ſpokes ought to be inclined to the nave, ſo as the *wheels* may be diſhing, or concave, is this: in paſſing over unequal ground, that *wheel* which is in the rut bears

bears a greater part of the weight than the other, as being lower; now, in ſuch a caſe, the ſpokes of a diſhing *wheel* become perpendicular, and therefore have the greateſt ſtrength; whilſt the oppoſite *wheel*, being upon higher ground, bears a leſs part of the weight, and conſequently the ſpokes need not be at their full ſtrength. Indeed, if *wheels* always turned upon ſmooth and level ground, the ſpokes ought to be ſtrait upon the naves, or at right angles to their axes.

As to the axel-trees of *wheels*, they ought to be ſtrait in all reſpects, and at right angles to the ſhafts, or to the pole. It would alſo be much more advantageous to make the four *wheels* of a coach or waggon large, and nearly of a height, than to make the fore-*wheels* of only half the diameter of the hind-*wheels*, as is uſual in many places. Carriages too with four *wheels* have greatly the advantage of thoſe with two: for in applying horſes to a cart, or chaiſe with two *wheels*, it is plain that the tiller carries part of the weight, in what manner ſoever it be kept in equilibrio upon the axel-tree. In going down a hill, the weight bears upon the horſe; and in going up hill, the weight falls the other way and lifts the horſe, by which means part of his force is loſt. Beſides, as the *wheels* ſink into the holes in the road, ſometimes on one ſide, ſometimes on the other, the ſhafts ſtrike againſt the tiller's flanks, which is the deſtruction of many horſes. Add to this, that when one of the *wheels* ſinks into a hole or rut, half the weight will fall that way, whereby the cart will be in danger of being overturned.

We have a great many more obſervations concerning *wheel*-carriages in *Deſaguliers*'s Experim. Philoſoph. p. 201, ſeq.

Blowing-WHEEL, (*Suppl.*) a machine contrived by Dr. Deſaguliers for drawing out the foul air of any place, or for forcing in freſh, or doing both ſucceſſively without opening doors or windows. See Phil. Tranſ. N° 437.

The intention of this machine is the ſame as that of Dr. Hales's ventilator, but not ſo effectual, nor ſo convenient. See *Deſagul.* Courſe of Exper. Philoſ. Vol. II. p. 563—568. This *wheel* is alſo called a *centrifugal-wheel*, becauſe it drives the air with a centrifugal force.

Water-WHEEL *of a mill*, that which receives the impulſe of the ſtream by means of ladle-boards or float-boards. See the article FLOAT-*boards*, *Append.*

Mr. Parent, of the Academy of Sciences, has determined the greateſt effect of an under-ſhot *wheel* to be, when its velocity is equal to the third part of the velocity of the water that drives it. See MACHINE, *Append.*

In fixing an under-ſhot *wheel*, the workmen ought to conſider whether the water can run clear off, ſo as to occaſion no back-water to ſtop its motion. For a farther account of *water-wheels*, ſee *Deſaguliers*, Experim. Philoſ. Vol. II. p. 422, ſeq.

WHICKEN, a name ſometimes uſed for the *ſorbus*, or quick-beam. See the article SORBUS, *Suppl.*

WHIN, or GORSE, a name uſed in ſeveral parts of the kingdom for the *ulex* or *geniſta ſpartium* of botaniſts. See the article GENISTA *ſpartium*, *Suppl.*

WHIST, or WHISK, a well known game at cards. Several caſes of this game have been the objects of mathematical computations. Thus Mr. de Moivre has ſolved this problem: To find the odds that any two of the partners, that are pitched upon, have not the four honours? Mr. de Moivre concludes from his ſolution,

1°. That it is 27 to 2, nearly, that the dealers have not the four honours.

2°. That it is 23 to 1, nearly, that the eldeſt have not the four honours.

3°. That it is 8 to 1, nearly, that neither one ſide nor the other have the four honours.

4°. That it is 13 to 7, nearly, that the two dealers do not reckon honours.

5°. That it is 25 to 16, nearly, that either one ſide or the other do reckon honours, or that the honours are not equally divided.

The ſame learned author alſo determines, that the odds for the partners who are eight of the game, if dealers, againſt thoſe who are nine, is nearly as 17 to 11. But if thoſe who have eight of the game are eldeſt, the odds will be 34 to 29. And that without conſidering whether thoſe who are eight are dealers, or eldeſt, there is one time with another 7 to 5, nearly. But thoſe who have furniſhed the author with the data for the ſolution, not having ſtated them ſufficiently, the concluſion is deemed erroneous; but we know no body that has endeavoured to rectify it.

We ſhall here inſert another problem.

To find the chance of the dealer's having four trumps. One trump being certain, the problem is reduced to this, to find what probability there is that in taking at random 12 cards out of 51, whereof 12 are trumps, and 39 not trumps, 3 of the 12 ſhall be trumps.

By Mr. de Moivre's rules it will be found, that the total of the chances for the dealer = 92770723800; and that the total of the chances for taking any 12 cards out of 51 = 158753389900. The difference of theſe two numbers = 65982666100. The odds therefore will be 9277 *&c.* to 6598 *&c.*

Or we may compute the chance of three players having 10, 11, or 12 trumps among 39 cards. Then we ſhall find that the total of chances for taking 10, 11, or 12 trumps among 39 cards = 65982666100; and that all the chances out of 51 = 158753389900. The difference = 92770723800 = all the chances for the dealer, and the odds will be 9277 *&c.* to 6598 *&c.* as before.

The approximating ratios to the ratio of 9277 *&c.* to 6598 *&c.* by Mr. Cotes's method, (ſee RATIO, *Suppl.*) are,

Ratios greater than true 2:1, 3:2, 10:7, 17:12, 24:17, *&c.*
leſs than true 1:1, 4:3, 7:5, 52:37, 97:69, *&c.*

But it is to be obſerved that the ratio 24:17, though expreſſed in much greater terms than 7 to 5, is extremely little nearer the truth; and the ratio 17 to 12 is not ſo near as 7 to 5; which ſhews that in practice we ſhould only retain the primary approximations of Cotes's method, for the ſecondary may lead us into error.

The bets for the dealer in this caſe, among the members of a great club, were formerly laid equal. But the vaſt odds of above 40 *per cent.* may ſhew how cautious gentlemen ought to be in laying bets without previous computation. The odds in money in this caſe, is,

	l.	*s.*	*d.*	
more than	140	11	11 1/2	to 100 *l.*
leſs than	140	11	11 3/4	

WHORTLE, or WHORTLE-*berry*, the Engliſh name of a genus of plants, called by botaniſts *vaccinium*, or *vitis idæa*. See the article VITIS *idæa*, *Suppl.*

WIDGEON, in ornithology, the Engliſh name of a bird of the duck kind, with a brown head, a white front, and a tail black underneath. See the article DUCK, *Suppl.*

WIDOW-*wail*, a name by which ſome call the *cneorum* of botanical writers. See the article CNEORUM, *Suppl.*

WILLIAM, or *Sweet*-WILLIAM. See SWEET-*William*, ſupra.

Sweet-WILLIAM *of Barbadoes*. See SWEET, ſupra.

WILLOW (*Suppl.*)—*Dutch* or *Sweet*-WILLOW, the name by which the *myrica* of botaniſts is ſometimes called. See the article MYRICA, *Suppl.* and *Append.*

French-WILLOW, or *Podded* WILLOW-*herb*, names given to the *epilobium* or *chamænerium* of botanical writers. See the article CHAMÆNERIUM, *Suppl.*

WILLOW-*herb*, the Engliſh name of a genus of plants, called by botaniſts *ſalicaria*. See the article SALICARIA, *Suppl.*

WINCH, a popular term for a windlaſs. See the article WINDLASS, *Cycl.*

WINCH alſo denotes the crooked handle for turning round wheels, grind-ſtones, *&c.* *Blanckley*'s Naval Expoſitor.

WINCHING, in the manege, is ſaid of a horſe when he kicks, ſpurns, or throws out his hind feet. Ruſt. Dict. in voc.

WIND-*flower*, the Engliſh name of a genus of plants, called by writers on botany *anemone*. See the article ANEMONE, *Suppl.*

WIND-*ſeed*, the name by which ſome call the *arctotis* of botanical authors. See the article ARCTOTIS, *Suppl.*

WINDING *of ſilk*. We have an excellent machine for this purpoſe at Derby, contrived by Meſſieurs Thomas and John Lombe; but as the proprietors are not willing that a deſcription of it ſhould be made public, the following general account of it muſt ſuffice.

It conſiſts of no leſs than 26586 wheels, and 97746 movements. One water-wheel communicates motion to all the reſt of the wheels and movements, of which any one may be ſtopped ſeparately and independently of the reſt. One fire-engine conveys air to every part of the machine; and one regulator governs the whole work. 73728 yards of ſilk are *wound* every time the water-wheel goes round, which is three times every minute; ſo that 318,504,960 yards of ſilk may be *wound* every day and night, and conſequently 99,373,547,550 yards of ſilk in one year. See *Deſaguliers*, Experim. Philoſoph. Vol. I. p. 70.

WINTER-*cherry*. See the article CHERRY, ſupra.

WINTER-*creſs*. See the article CRESS, ſupra.

WINTER-*green*. See the article GREEN, ſupra.

WITCH-*hazel*. See the article HAZEL, ſupra.

WITHERING *of a cow*, is when, after calving, ſhe does not caſt her cleanſing, which if not timely remedied will kill her. Ruſt. Dict. in voc.

WITHY, a large ſpecies of willow, fit to be planted upon high banks and the ſides of ditches, within reach of the water, or on the weeping ſides of hills. Ruſt. Dict. in voc.

WOLF (*Suppl.*)—WOLF-*fiſh*, the Engliſh name of the *lupus marinus* of authors. See the article LUPUS *marinus*, *Suppl.*

WOOD (*Suppl.*)—*Almiggim*-WOOD. See the article ALMIGGIM, *Suppl.*

WOOD-*bine*, or WOOD-*bind*, the Engliſh name of a genus of plants, called by Tournefort *periclymenum*, but comprehended by Linnæus among the *loniceras*. See the articles PERICLYMENUM, *Suppl.* and LONICERA, *Append.*

WOOD-*men*, certain foreſt-officers appointed to take care of the king's *woods*. Ruſt. Dict. in voc.

WOOD-*roof*, or WOOD-*ruffe*, the Engliſh name of a genus of plants, called by botaniſts *aſperula*. See the article ASPERULA, *Suppl.*

WOOD-*ſage*. See the article SAGE, ſupra.
WOOD-*ſorrel*. See the article SORREL, ſupra.
WOODMEIL, a coarſe, hairy kind of ſtuff, made of Iceland-wool, with which the ſhip-carpenters, in ſome of his majeſty's yards, line the ports of ſhips of war. *Blanckley*'s Naval Expoſitor, in voc.
WOODY-*nightſhade*. See the article NIGHTSHADE, ſupra.
WOOLDING, in the ſea language, denotes the winding of ropes, at certain diſtances, about a maſt, in order to ſtrengthen it. *Blanckley*'s Naval Expoſitor, in voc.
WORM (*Suppl.*)—*Earth*-WORM. See the articles LUMBRICUS, *Append.* and WORMS, *Suppl.*
Golden-WORM, *vermis aureus*, a name ſometimes given to the *aphrodita*, a genus of ſea inſects. See the article APHRODITA, *Append.*
Guinea-WORM, or *Hair*-WORM, names uſed for the *chætia* of naturaliſts. See the article CHÆTIA, *Append.*
Sea-WORM. See the article LUMBRICUS, *Append.*
Tape-WORM. See the article TAPE-*worm*, *Suppl.*
WORMING *of a dog*, is the cutting out a nerve from under his tongue; by which means, it is ſaid, that if ever he runs mad, he will be rendered incapable of biting. Query the fact.
WOULD, a name uſed ſometimes by the farmers for the *luteola*, or dyer's weed. See the article LUTEOLA, *Suppl.*
WOUND-*wort*, the name of a genus of plants, called by botaniſts *vulneraria*. See the article VULNERARIA, *Suppl.*
WOUND-*wort* is alſo the name of the *ſolidago*, another genus of plants, called by Tournefort *virga aurea*, or golden rod. See the article VIRGA, *Suppl.*
WOUND-*wort of Achilles*, a name ſometimes given to the *millefolium*, or yarrow. See the article MILLEFOLIUM, *Suppl.*
WREN. See JENNY-*wren*, *Suppl.*
WYTHERS, the ſame with *withers*. See WITHERS, *Cycl.*

YEOMAN *of the ſalt ſtores*. See ACATERY, *Cycl.*

ARTICLES omitted.

ELECTRICITY *(Cycl.)*—A body in which *electricity* may be excited by ſome action upon that body, as rubbing, patting, or warming it, and ſometimes only expoſing it to cold and dry air, after it has been covered, is called an *electric per ſe:* ſuch are glaſs, cryſtals, and pretious ſtones; reſins, gums, ſulphur, ſealing wax, and moſt dry parts of animals, as ſilk, hair, and the like.

Electrics per ſe are alſo called original *electrics*.

A *non-electric per ſe* or ſimply a *non-electric*, is a body in which *electricity* cannot be excited by any action upon the body itſelf; or at leaſt one in which that property, if at all, is very ſlightly perceptible. Of this kind are wood, animals, living or dead, vegetable ſubſtances, water and metals.

But *non-electrics* receive *electricity*, when brought near to *electrics per ſe*, in which *electricity* has been excited.

In order to know that *non-electrics* have received the communicated *electricity*, they muſt be inſulated; that is, they muſt not be ſuſpended from, or ſupported by any bodies, but what are *electrics per ſe:* for if one *non-electric* be touched by another, and this by a third, *&c.* all the *electricity* received by the firſt will go to the ſecond, and from this to the third *&c.* till at laſt it be loſt upon the ground. But if ſeveral *non-electrics* touching one another, are at laſt terminated by *electric* bodies, in that reſpect they make but one body, and receive and retain *electricity* for ſome time. However it muſt be obſerved, that bodies ſlightly *non-electric*, ſuch as dry wood, may ſerve for ſupporters to thoſe bodies which are very highly *non-electric*, as metals.

Electricity may be communicated to *non-electrics* by applying a glaſs tube or globe, excited by friction, to one end of thoſe bodies; and there are ſeveral ways of finding when the *non-electrics* have received the *electricity*. Thus, if an iron bar be ſuſpended horizontally by two ſilken ſtrings that are very dry, and the rubbed tube be applied, or brought near to one of the ends of the bar, and then ſome leaf-gold, or leaf-braſs, or any other light bodies, placed upon a ſmall ſtand, or a plate, be brought near the other end, they will be alternately attracted and repelled by the bar. Likewiſe, if the finger be brought near the end, or other part, of the bar, the *electrical* effluvia will give a very ſenſible and ſometimes painful ſtroke, with a ſnapping noiſe, and produce a flaſh of light. If the communicated *electricity* ſhould prove too faint to be tried this way, a ſmall flaxen thread, ſuſpended by a ſtick, may be brought near the body that has been *electrified*; and if the *electricity* has been communicated, even in a ſmall degree, the thread will be attracted without deſtroying the *electricity* received by the body till after ſome time. This thread Doctor Deſaguliers calls the *thread of trial.*

It is to be obſerved, that an *electric per ſe* does not receive this virtue from another *electric per ſe*, though excited, till it is become a *non-electric*; which happens when it is made wet or moiſt; and then it will be made *electric* only by communication. *Electric* bodies, in which it is difficult to excite *electricity*, may be looked upon as *non-electrics*, when their *electricity* is not excited; and then they will be in the ſame condition as *non-electrics per ſe*, and be liable to receive *electricity* by communication in the ſame manner.

From what has been ſaid, it appears that *non-electrics* are conductors of *electricity*. Water conducts it very well, but metals are the moſt convenient conductors.

Theſe things being premiſed, we ſhall here add ſome of the principal phænomena of *electricity*; that is, ſuch as ſeem to give ſome light towards a theory of this wonderful property of bodies.

1. When the *electricity* of a glaſs tube has been excited by rubbing, if you move your fingers long-wiſe from one end of the tube to the other, but without touching it, you will hear a continued ſnapping, like a diſtant noiſe of thorns burning; and if the room be darkened, you will ſee ſparks of light wherever the tube ſnaps; and likewiſe a light following the hand that rubs the tube.

2. A down feather being tied to the top of a wooden broach or ſkewer, of about ſix or ſeven inches in height, and fixed upright upon a foot, if you bring the excited tube near it, all the fibres of the feather ſtretch out towards the tube; but as ſoon as you remove the tube, the fibres of the feather turn back, and ſtick ſtrongly to the ſkewer. If you bring your finger near to the feather, while its fibres are tending towards the tube, the finger will repel them; but as ſoon as you remove the tube, they are attracted by the finger. If you cover the feather with a very dry glaſs recipient, ſuch as is uſed on the air-pump, the tube will attract the feather in the ſame manner through the glaſs: and this happens, even when the recipient has been exhauſted of its air by the pump. When the tube is rubbed near the recipient, whether it be full of air or empty, the fibres of the feather follow the motion of the hand along the tube, ariſing upon the broach or ſkewer.

3. Without making uſe of the tube, if you rub the recipient that covers the feather with both hands, the fibres of the feather will ſtretch themſelves out towards the glaſs, like the rays of a ſphere. If you rub but with one hand, the fibres will ſtretch themſelves towards that part of the glaſs which is rubbed; and when you blow againſt the glaſs, thoſe fibres will be repelled, notwithſtanding the interpoſition of the glaſs: which happens alſo, when you ſtrike the air with the hand towards the feather, without touching the recipient.

4. After the tube has been rubbed, if any aſſiſtant lets go a down feather in the air, at the diſtance of a foot or two from the tube, the feather will jump towards the tube with an accelerated motion, and adhere to it for ſome time; and then of a ſudden it will be repelled from the tube, and will fly about the air in ſuch manner, that the nearer you bring the tube to it, the more it will be repelled, till it has touched ſome other body; and then it will be drawn again by the tube; which after ſome time will drive it away again. Sometimes, when the finger is held at eight or ten inches from the tube, the feather will jump from the tube to the finger, and from the finger to the tube, thirty or forty times together.

5. If a ſtring of any kind be ſtretched horizontally, and from the ſtring you hang a thread of ſilk about three foot long, and very dry, and to the lower end of that thread you faſten a down feather; then, at the diſtance of about two or three feet, you hang up another feather, but by a flaxen thread; the rubbed tube being brought near will attract the firſt feather, which, when it has adhered to it a little while, will fly from the tube, and then be repelled by it every time the tube is brought near, till it has touched ſome other body, as in the preceding experiment, and then it will be attracted anew. But the feather, which is ſuſpended by the flaxen thread, will always be attracted at the approach of the tube, and never repelled. And if you wet the ſilken thread, the feather hanging at it will be repelled no more, but always attracted by the tube.

6. If you make uſe of a tube which is hermetically ſealed at one end, and has at the other end a braſs ferril with a ſcrew, by which means the air may be pumped out of it; if you rub the tube, after the air is exhauſted, it does not attract any more, as has already been taken notice of in the Cyclopædia, N° 7; nor does the tube give the light before mentioned, N° 2, but it gives much more light within. Then if, by opening the cock a little way which is faſtened to the tube, the air be let in ſlowly, while the tube is rubbed, the light diminiſhes; and being interrupted by the air, as it comes in, looks like lightning at a diſtance, till all the air is come in, and then there is no more light within; but the light goes all to the outſide, and the attraction returns.

7. If two ſmall boards, or two ſmall octavo books, be ſet edge wiſe, parallel to each other, and about the diſtance of ten inches aſunder, upon a ſtand of ſeven or eight inches diameter; little pieces of leaf gold, or braſs, laid upon the ſtand between thoſe boards, will not be attracted by the rubbed tube held near them, till it be brought quite between the ſaid boards, as near to the ſtand as half the diſtance of the boards from each other: that is, when the tube is ſo held, that a circle deſcribed round the axis of the tube, with the diſtance that is between that axis and the ſtand, paſſes between the boards or books without touching them. But when the rubbed tube being held horizontally, at the diſtance of a foot from the ſtand, ſeems to have no virtue, becauſe the leaf-gold has no motion, if an aſſiſtant ſnatches away the boards, all on a ſudden the pieces of gold will be attracted and repelled ſeveral times, without giving any new friction to the tube.

8. When the air is very dry, and the rubbed tube can attract the leaf-gold laid on a ſmall ſtand, to the diſtance of three foot or beyond; if the ſame leaf-gold be laid upon a table, or any large ſurface, the excited tube muſt be brought very near before it can produce its effect.

9. When the air is moiſt, the experiment, N° 4, does not ſucceed well: for after the feather in the air has been ſome time driven about by the tube, it comes back of itſelf to the tube, without having touched any other body; and ſometimes after having adhered to the tube, towards the middle of it, it flies off from it, and comes again immediately to the tube, ſticking to that part of it which is fartheſt from the hand. It happens alſo, when the air is very dry, and the tube repels the feather, after having attracted it, to the diſtance of two or three feet, that if you wet the top of the tube at the end, for the length of ſix or ſeven inches, the feather will come and ſtick to that end of the tube, without having touched any other body.

10. Having filled with water a ſmall drinking glaſs, of about an inch diameter, when you bring the rubbed tube near it, the water riſes in a little hill, accumulated at the edge of the glaſs; ſometimes jumping towards the tube in a little jet, ſo ſmall that you can hardly ſee it, though you may find the tube wholly wet with it. One may alſo obſerve, that this accumulated water riſes in the ſhape of a ſmall cone, whoſe axis is ſometimes ſtretched out horizontally towards the tube, then ſnaps and falls down again flat upon the reſt of the water. If this experiment be made in the dark, a flaſh of light accompanies the ſnapping.

11. If by means of an artificial fountain, in which air is condenſed upon the water to make it ſpout, you play a ſmall jet, of about the fortieth part of an inch diameter, upwards or downwards; the rubbed tube being brought near, the jet will bend towards the tube at the diſtance of a foot; and if the tube be brought nearer, the jet being wholly drawn away by the tube, is changed into a dew upon the tube, ſo that it adheres to the tube in little drops, provided the jet be not made to ſpout with too much force.

12. If a packthread or hempen ſtring be ſtretched horizontally to the length of about twelve hundred feet, at the end of which is ſuſpended an ivory ball of about an inch and an half in diameter; this ball will draw and repel leaf-braſs, or leaf-gold, when the rubbed tube is brought near the other end of the ſtring, and the thread of trial being brought near to the ball, is attracted by it.

In this experiment the ſupporters of the ſtring muſt be *electrics per ſe*, whether they be hair-ropes, fiddle-ſtrings, or cat-guts, ribbons, ſtrings of ſilk, glaſs tubes, long bodies of ſulphur or of reſin, *&c.* and all theſe bodies muſt be very dry. If the ſtring be wet, the experiment will ſucceed the better.

This experiment was, we believe, firſt made by the late Mr. Stephen Gray; and it might be improved, by employing an iron wire inſtead of a packthread or hempen ſtring. When an iron wire is uſed, its ſupporters might be wooden ſticks, being *non-electrics* in a ſlighter degree, as before obſerved; but *electrics* are beſt.

The conductor of *electricity*, in theſe and the like caſes, need not be ſtretched at length, but may be carried backwards and forwards in parallel or other lines, provided they be not placed too near to each other, but at a proper diſtance, as, for inſtance, three feet.

13. If two or three iron bars be ſuſpended in the ſame horizontal line, at the diſtance of ſix inches from one another, the *electricity* communicated by the rubbed tube to the end of one of the bars will go on from the one to the other quite to the end of the laſt bar, where a pricking will be felt, a noiſe heard, and a flaſh of fire ſeen. If the air is dry, the *electricity* will jump from one bar to another at a greater diſtance; but in moiſt weather, the bars muſt not hang at above an inch diſtance from each other.

Theſe experiments may be made with a glaſs tube, about three foot and an half long, an inch and an half in diameter, and about $\frac{1}{12}$ of an inch thick, open at both ends, but ſometimes hermetically ſealed at the end fartheſt from the hand. Theſe proportions are not neceſſary, but only convenient for the hand; and the glaſs of the tube ought not to be leſs than $\frac{1}{12}$ of an inch in thickneſs; for when thinner, the *electricity* is indeed ſooner excited by friction, but it does not laſt ſo long as when the tube is thicker. See *Deſaguliers*'s Diſſertation concerning *Electricity*, in his Experim. Philoſ. Vol. II. p. 316. ſeq.

The Doctor obſerves with Monſieur du Fay, that there are two ſorts of *electricity*, a reſinous, and a vitreous kind. One of the experiments, upon which this difference is eſtabliſhed, is as follows.

14. If a down feather be ſuſpended by a ſilken thread, as in the experiment N° 5, ſealing-wax, well rubbed, will produce the ſame effect as the tube, but more weakly, drawing the feather; and when once it is ſeparated from the wax, the wax repels it continually, till the feather has touched ſome other body. But the difference here is, that when the feather is in a ſtate of repulſion, in reſpect of the wax, the rubbed tube attracts it; and when the tube has given the feather its repulſive ſtate, then the rubbed wax attracts it: which ſhews, according to theſe gentlemen, that the *electricity* of glaſs is different from the *electricity* of ſealing-wax; and the like may be obſerved of other reſinous ſubſtances.

But, perhaps, this phænomenon may be accounted for, by ſuppoſing, as the truth is, that the *electrical* power of excited glaſs is ſtronger than that of ſealing-wax, and then from Mr. Ellicott's hypotheſis, hereafter mentioned, the phænomenon follows.

Doctor Deſaguliers has deduced from his experiments, that bodies which are *electric per ſe*, being excited to *electricity*, repel all other bodies that have *electricity*, but attract them as ſoon as they have loſt their *electricity*; and ſo *vice verſa*. Theſe deductions agree very well with Mr. Ellicott's mentioned below.

The Doctor conjectures alſo, that the particles of pure air are *electric* bodies, always in a ſtate of *electricity*; and that vitreous *electricity*, and from this *electricity* of the air, he conjectures, ingeniouſly, that the riſe of vapours may depend upon *electricity*. See the Diſſertation before cited.

To theſe experiments related, among others, by Dr. Deſaguliers, we muſt add from Mr. Ellicott [a], that when the tube, N° 1, is ſtrongly excited, ſparks will not only iſſue from it in ſtreams while it is rubbing, but will continue to dart out from it for a conſiderable time after the rubbing has ceaſed, and a very ſtrong offenſive ſmell will be perceived.—[a Several Eſſays towards diſcovering the Laws of *Electricity*, Lond. 1748.]

15. The ſame gentleman obſerves, that if a ball (of cork ſuppoſe, for lightneſs) be hung by a ſilk line, and the excited tube is applied to it, it will not only be attracted, but will have an attractive quality communicated to it from the tube; and if any light bodies are brought near the ball, they will be attracted by it.

16. As the tube, when ſtrongly excited, will not only attract, but afterwards repel any light bodies brought near it, in like manner the cork-ball will be endued with the ſame property; ſo that a ſmaller ball will firſt be attracted towards it, and then repelled from it, in the ſame manner as the leaf-gold in the beforementioned experiments; and on touching any other body, it will be again attracted; and this may be repeated ſeveral times, provided the ſmaller ball is much leſs than the larger one. But the effect will conſtantly grow weaker and weaker; becauſe every time the leſſer ball is attracted, it carries off with it ſome of the *electric* virtue, and is likewiſe endued with the ſame properties as the larger ball.

Mr. Gray, Monſieur du Fay, and others have obſerved, that this *electrical* quality is not only to be excited in glaſs, but in moſt ſolid bodies capable of friction, metals excepted; though in ſome it will ſcarce be ſenſible. And this *electrical* power is found to be ſtrongeſt in wax, reſins, gums and glaſs. And as glaſs is the eaſieſt procured of a proper form, it has generally been uſed in making theſe experiments. It has been further obſerved, that thoſe bodies, in which the *electrical* quality is capable of being excited the ſtrongeſt by friction, will receive the leaſt quantity of it from any other excited body, and therefore are properly made uſe of to ſupport any body deſigned to receive the *electrical* virtue. The truth of this will ſufficiently appear from the following experiments.

17. Two lines, one of ſilk, and the other of thread, being hung up, (as in the experiment, N° 5.) that of thread will be attracted by the tube at a much greater diſtance than the ſilk. If a feather, or other light body, be faſtened to each ſtring, and if the tube be brought to the feather faſtened to the ſilk, it will not only be firſt attracted and then repelled, as has been ſaid N° 5, but by the virtue communicated to the feather from the tube, the ſeveral fibres of the feather will ſtrongly repel each other. On the contrary, the feather faſtened to the thread will be ſtrongly attracted by the excited tube, and not repelled, the virtue paſſing off by the thread it is hung to. If a glaſs ball is hung to the ſilk line, it will be but weakly attracted by the tube; but one of cork or metal will be ſo much more ſtrongly.

18. Let a rod of iron be ſuſtained by ſilk lines, and by means of a glaſs ſphere (which can be more regularly and conſtantly excited than a tube) be made *electrical*, it will be found to have all the properties of the excited tube firſt mentioned. A ſtream of light will come from the end of it, if it is pointed. It will attract, repel, and communicate this virtue to any other *non-electric* body. On the approach of a *non-electric*, a ſpark of fire, with a ſnap attending it, will come from it; which ſpark will be greater or leſs, as the bodies approaching it have more or leſs of the *electrical* quality reſiding in them; and there will likewiſe be the ſame offenſive ſmell as was obſerved of the glaſs tube.

19. Let a rod of iron, pointed at one end, be ſuſpended on ſilk lines, as in the laſt experiment, and by the ſphere be made *electrical*. When the rod is ſtrongly *electrified*, a ſtream of light in diverging rays will be ſeen to iſſue from its point; and if any *non-electric* body is held a few inches from the point, the light will become viſible to a greater diſtance; and if the *non-electric* body is likewiſe pointed, a light will ſeem to iſſue from that in diverging rays, in the ſame manner as from the *electrified* rod. But if the *non-electrical* body is flat, and held at the ſame diſtance from the rod as the pointed one was, no light will be ſeen to come from it. It is alſo to be obſerved, that the effluvia from the end of the *electrified* rod ſtrike againſt the hand or face, brought near to that end, like a blaſt of wind.

20. If the *non-electric* body, whether flat or pointed, be brought nearer to the end of the rod than in the laſt experiment, there will be a ſmall ſtream of light produced, reaching quite from the *electric* to the *non-electric* body; and if brought ſtill nearer, there will iſſue a ſpark, attended with a ſmall ſnapping noiſe, which will be ſucceeded by others at equal intervals; and if the *non-electric* is held at ſome diſtance from the ſide of the rod, the point of it will frequently appear luminous, but no part of the *electrified* rod will be ſo. If it is brought nearer, there will likewiſe be

ſparks produced, at nearly equal intervals from each other, which will ſometimes appear as iſſuing from the ſide of the *electrified* rod, at others, as coming from the *non-electric*.

21. Take two plates of metal, very clean and dry, whoſe ſurfaces are nearly equal; hang one of them horizontally to the *electrified* rod, and bring under it, upon the other, any thin, light body, as leaf-ſilver, *&c.* when the upper plate is made *electrical*, the ſilver will be attracted by it; and if the under plate is held at a proper diſtance, will be perfectly ſuſpended at right angles to the plates, without touching either of them; but if they are either brought nearer together, or carried farther aſunder, the leaf-ſilver will ceaſe to be ſuſpended, and will jump up and down between them. The ſame effect will be produced, if you reverſe the experiment, by *electrifying* the bottom plate, and ſuſpending the other over it. See Mr. *Ellicott*'s Eſſays before mentioned.

22. By the experiments made in Germany, and repeated in England by Mr. Watſon, it appears, that ſpirit of wine may be ſet on fire by the power of *electricity*. This will ſucceed not only with the etherial liquor, or phlogiſton of Frobenius, and rectified ſpirit of wine, but even with common proof ſpirit. But all theſe muſt be warmed a little, ſo as to emit an inflammable vapour.

And the experiment ſucceeds equally well, whether an *electrified* perſon, or other *electrified* body, be brought near the not *electrified* ſpirit; or whether the *electrified* ſpirit be brought near a *non-electric* body.

This laſt method of firing the ſpirit is ſaid, by Mr. Watſon, to be done by the repulſive power of *electricity*. And the former, where the not *electrified* ſpirit is fired by its being brought near to a man ſtanding upon a cake of wax, or to a ſword, or bar of metal, ſuſpended by ſilk lines, is ſaid to be performed by the attractive power of *electricity*. Of theſe two kinds, the repulſive power has generally been found the ſtrongeſt.

23. Not only ſpirits of wine, but alſo ſal volatile oleoſum, dulcified ſpirit of nitre, Peony water, Daffy's elixir, Helvetius's ſtyptic, and ſome other mixtures, where the ſpirit has been very conſiderably diluted, may be fired by the power of *electricity*; and ſo may diſtilled vegetable oils, as that of turpentine, lemon, orange peels, juniper, and even thoſe which are ſpecifically heavier than water, as oil of ſaſſafras; alſo reſinous ſubſtances, ſuch as balſam capivi and turpentine; all which ſend forth, when warmed, an inflammable vapour. The inflammable vapour, produced by putting an ounce of filings of iron, an ounce of oil of vitriol, and four ounces of water into a Florence flaſk, may be fired by the ſame means; as may alſo gunpowder, if ground with a little camphor, or with a few drops of ſome inflammable chemical oil. To increaſe the ſurpriſe, theſe ſubſtances may be fired by ice, or by a drop of water, only thickened a little with the ſeeds of fleawort.

All theſe experiments have ſucceeded, though not always in damp weather, with a glaſs tube rubbed by the hand merely; but if a greater *electrical* force be excited, by means of a globe, theſe experiments will ſucceed in any weather, though not with equal eaſe.

24. If ſome oil of turpentine is ſet on fire in any veſſel, held in the hand of an *electrified* man, the thick ſmoke that ariſes therefrom, received againſt any *non-electric* of a large ſurface, held in the hand of a ſecond man ſtanding upon an *electrical* cake; this ſmoke will, at a foot diſtance from the flame, carry with it a ſufficient quantity of *electricity*, for the ſecond man to fire any inflammable vapour. The *electrical* ſtrokes have been likewiſe perceptible upon the touching the ſecond man, when the *non-electric* held in his hand has been in the ſmoke of the oil of turpentine between ſeven and eight feet above the flame. Here we find the ſmoke of an original *electric*, a conductor of *electricity*.

25. Likewiſe, if burning ſpirit of wine be ſubſtituted in the place of the oil of turpentine, and if the end of an iron rod, in the hand of the ſecond man, be held at the top of the flame, this ſecond man will kindle other warm ſpirits held near his finger. Here we find, that flame conducts the *electricity*, and does not perceptibly diminiſh its force. The like is to be obſerved of red-hot iron; and of the coldeſt mixtures that art can produce.

26. Of all the ſurpriſing phænomena of *electricity*, none ſeems to be more ſo, than the extraordinary accumulation of the *electrical* power in a phial of water, firſt diſcovered by Profeſſor Muſchenbroek of Leyden. The experiment is this: a phial of water is ſuſpended to a gun-barrel by a wire let down a few inches into the water through the cork; and this gun-barrel, ſuſpended in ſilk lines, is applied ſo near an excited glaſs globe, that ſome metallic fringes, inſerted into the gun-barrel, touch the globe in motion. Under theſe circumſtances a man graſps the phial with one hand, and touches the gun-barrel with a finger of the other; upon which he receives a violent ſhock through both his arms, eſpecially at his elbows and wriſts, and acroſs his breaſt. The experiment ſucceeds beſt *cæteris paribus*, 1°. when the air is dry. 2°. When the phial, containing the water, is of the thinneſt glaſs. 3°. When the outſide of the phial is perfectly dry. 4°. In proportion to the number of points of *non-electric* contact. Thus if you hold the phial only with your thumb and finger, the ſnap is ſmall; larger when you apply another finger, and increaſes in proportion to the graſp of your whole hand. 5°. When the water in the phial is heated, which being then warmer than the circumambient air, prevents the condenſation of the floating vapours therein upon the ſurface of the glaſs.

A gun-barrel is not neceſſary in theſe experiments; a ſword, or any other ſolid piece, or tube of metal, is equally uſeful. Mr. Watſon has given us many curious obſerva ions relating to this experiment, and has varied it a great many ways. Among other things he obſerves, that the phial may be *electrified* by applying the wire therein to the globe in motion; after which, if it is graſped in one hand, and the wire touched with a finger of the other, the ſtroke is as great as from the gun-barrel. And if you graſp the phial with your hand, and do not at the ſame time touch the wire, the acquired *electricity* of the water is not diminiſhed. So that, unleſs by accident or otherwiſe the wire is touched, the *electrified* water will retain its force many hours, may be conveyed ſeveral miles, and afterwards exert its force upon touching the wire.

To prove Mr. Watſon's aſſertion that the ſtroke is *cæteris paribus*, as the points of contact of *non-electrics* to the glaſs, Dr. Bevis wrapped up two large round bellied phials in very thin lead ſo cloſe as to touch the glaſſes every where, except their necks. Theſe were filled with water, and corked, with a ſtaple of ſmall wire running through each cork into the water. A piece of ſtrong wire about five inches long, with an eye at each end, was provided, and at each end of this, hung one of the phials of water by the ſmall ſtaple running through the cork. A ſmall wire loop was then faſtened into the lead at the bottom of each phial, and into theſe loops was inſerted a piece of ſtrong wire like the former. If then theſe phials were hung acroſs the gun-barrel and *electrified*, and a perſon ſtanding upon the floor touched the bottom wire with one hand, and the gun-barrel with the other, he received a moſt violent ſhock through both his arms and acroſs his breaſt. The *electrical* exploſion has been ſince vaſtly increaſed. But Mr. Watſon is of opinion, that the violence of the exploſion of the *electric* force accumulated in the glaſs, is not ſo much owing to the quantity of *non-electrical* matters contained in the glaſs, as to the number of points of *non-electrical* contact within the glaſs, and the denſity of the matter conſtituting thoſe points, provided this matter be in its own nature a ready conductor of *electricity*. For a cylindrical glaſs jar blown very thin, of ſixteen inches in height, and eighteen inches in circumference, having been covered both within and without with leaf-ſilver to within an inch of its top, the exploſion from this jar was equal to that from three glaſſes, each about ſeventeen inches in height, and four in diameter, and filled with fifty pounds of leaden ſhot each. The exploſion in theſe caſes is ſo violent as to become dangerous; and has been found mortal not only to ſmall birds, but even to a rat; and Mr. Franklin killed a well-grown turkey with it.

27. A very conſiderable *electrical* exploſion may be made from a plate of glaſs thus: Let a thin plate of glaſs of about a foot ſquare, be covered on both ſides with leaf-ſilver; and make this adhere to the glaſs by a very thin paſte. A margin of an inch muſt be left on both ſides; otherwiſe, upon *electrifying* this plate, the *electricity* would be prevented from being accumulated upon one of its ſurfaces, by being propagated from the ſilver on one ſide to that of the other. When the glaſs plate is thus prepared, if it be placed upon a table in ſuch a manner, that when fully *electrified* by a wire or ſuch like from the prime conductor, a perſon touches the under ſurface with a finger of one of his hands, and brings one of the fingers of the other near the upper ſurface, or near the prime conductor, he will be ſhocked in both his arms and croſs his breaſt. The ſame effect happens, if when this plate is *electrified* as before, a perſon holds it in his hand by the margin, and without touching the ſilver, preſents it, even ſome time after it has been taken from the prime conductor, to another perſon, who touches the under ſurface with his finger, and holds it there till he touches the upper ſurface with a finger of his other hand. This is an experiment contrived by Dr. Bevis, who obſerves, that though the exploſion from the glaſs plate ſilvered was occaſioned by about ſix grains of ſilver, upon which the *electricity* was accumulated, yet the exploſion was equal if not ſuperior to that from half a pint of water contained in a thin glaſs as uſual.

28. The commotion ariſing from the diſcharge of the accumulated *electricity* in the phial, may be felt by a great number of men at once. Monſieur le Monnier, at Paris, is ſaid to have communicated this ſhock through a line of men, and other *non-electrics*, meaſuring nine hundred toiſes, which is more than an Engliſh mile; and the Abbé Nollet [a] made the experiment upon 200 perſons, ranged in two parallel lines.—[a Lettres ſur l'*Electricité*, p. 207.]

29. This *electrical* commotion has been made very ſenſible quite acroſs the river Thames, by the communication of no other medium than the water of that river; and ſpirit of wine has been fired at that diſtance.

30. The commotion has alſo been perceptible to two or more

more obſervers at conſiderable diſtances from each other, even as far as two miles.

In theſe laſt experiments, and in many others of the like nature, Mr. Watſon obſerves, that the *electrical* power, accumulated in any *non-electric* matter contained in a glaſs phial, deſcribes upon its exploſion a circuit through any line of ſubſtances *non-electrical* in a conſiderable degree; if one end thereof is in contact with the external ſurface of this phial, and the other end upon the exploſion touches either the *electrified* gun-barrel, to which the phial in charging is uſually connected, or the iron hook always fitted therein. Thus if a perſon ſtands upon a dry wooden floor with a coated phial ever ſo highly charged in one of his hands, and if another perſon, without touching the firſt, ſtands but ſix inches from him, and touches the iron hook of the phial, neither of them are ſhocked; becauſe the floor between them, though the diſtance is ſo ſhort, will not conduct the *electricity* ſufficiently quick. But if theſe two perſons tread upon a piece of wire laid between them, they each of them feel the *electrical* commotion in that arm which touches the phial and hook, and in that foot which treads upon the wire; the wire here conducting the *electricity* quick enough, which the dry floor would not. The circuit is here formed by the coated phial, its hook, ſo much of the bodies of theſe two perſons as form a curve line between the wire, the phial, and hook, and the wire between theſe perſons. If theſe perſons ſtand upon, or touch with any part of their bodies any *non-electrics*, which readily conduct *electricity*, the circuit is completed, and the effect is the ſame. Hence Mr. Watſon infers, that when the obſervers have been ſhocked at the end of two miles of wire, the *electrical* circuit is four miles; *viz.* two miles of wire, and the ſpace of two miles of the *non-electric* matter between the obſervers, whether it be water, earth, or both. So in the experiments made near Weſtminſter bridge, where the river is above 400 yards over, the circuit muſt have been above 800 yards, *viz.* above 400 yards of conducting wire laid upon the Portland ſtones of the bridge, and ſomething more than 400 yards of water. That the water made part of the circuit, and that the ſhock was not communicated from the Surry ſhore to the other ſide merely by the conducting wire, is evident from this, that if the obſerver on the Weſtminſter ſhore did not communicate with the river, either by dipping his hand, or an iron rod held therein into the river, the ſhock ariſing from the diſcharge of the phial was not at all felt by him, although the obſerver on the Surry ſide felt it as before. This circuit of the *electrical* matter has been farther confirmed by ſeveral other ingenious experiments by the ſame gentleman.

It is to be obſerved, that the commotion is equally ſtrong, whether the *electricity* is conducted by water, or dry ground. And that if the wires, between the *electrifying* machine and the obſervers, are conducted upon dry ſticks, or other ſubſtances *non-electric*, in a ſlight degree only, the effects of the *electrical* power are much greater, than when the wires in their progreſs touch the ground, moiſt vegetables, or other ſubſtances in a great degree *non-electric*.

31. It is remarkable, that if the *electrical* machine, and the man who turns the wheel thereof, be mounted upon *electrical* cakes, the *electrical* power is ſo far from being increaſed hereby, as ſome might expect, that it is, on the contrary, much diminiſhed, and ſometimes is not at all perceptible.

It was this experiment which induced Mr. Watſon to conceive, that the *electrical* power was not inherent in the glaſs, but came from the floor of the room. And, he ſays, he was confirmed in this opinion when he found, that if he touched the frame of the machine with one hand, while he ſtood upon the floor, and with a finger of the other hand touched the gun-barrel, the fire would iſſue, and the ſnapping would continue as long as he held his hand upon the machine, but would ceaſe upon his taking it off. In like manner, if the man, who turned the wheel, put one of his feet upon the floor, the other remaining upon the wax, the *electricity* at the gun-barrel would ſnap, and ceaſe upon his replacing his foot. But of this hypotheſis more hereafter.

32. The accumulation of *electricity* may be meaſured to great exactneſs by the following method, diſcovered by Mr. Canton. When the phial is ſufficiently *electrified*, by applying the wire thereof to the glaſs globe, which is known by the appearance of a bruſh of flame at the end of the wire, hang a ſlender piece of wire to the ſuſpended gun-barrel, detached for this purpoſe from the globes. Upon your applying the wire of the *electrified* phial to that hanging to the gun-barrel, you perceive a ſmall ſnap; this you diſcharge by touching the gun-barrel with your finger, which likewiſe ſnaps: and thus alternately *electrifying* and diſcharging, you proceed until the whole *electricity* of the water is diſſipated, which is, ſometimes, not done under an hundred diſcharges. If you do not diſcharge the *electricity* every time, the ſnaps from the wire of the *electrified* phial to the gun-barrel, are ſcarcely perceptible. The acquired *electricity* of the water is eſtimated in proportion to the number of ſtrokes.

This accumulation of *electricity* may perhaps be thought to deſerve a farther explanation, and may be thus illuſtrated. As we take it for granted, that there is always a determinate quantity of atmoſphere ſurrounding the terraqueous globe, we conceive, when we ſee the mercury in the barometer very low, that there then is a leſs accumulated column of this atmoſphere impending over us, than when we ſee the mercury high. In like manner, when we obſerve that the *electrified* gun-barrel attracts or repels only very light ſubſtances, at a very ſmall diſtance, or that the ſnap and fire therefrom are ſcarce perceptible, we conceive then a much leſs quantity of *electrical* atmoſphere ſurrounding the gun-barrel. This power being more or leſs, is called the greater or leſs degree of the accumulation of *electricity*. And this is only attainable to a certain point, if you *electrify* ever ſo long; after which, unleſs otherwiſe directed, the diſſipation thereof is general. In the phial filled with water, in Muſchenbroek's experiment, or filled with any other *non-electric*, as filings of iron, if the wire be held to the globe in motion, when the accumulation is complete, the ſurcharge runs off from the point of the wire, as a bruſh of blue flame. That by ſtopping the current of *electricity*, *non-electrics* might be excited; and that by accumulating their power, they might be made to exert more force than *electrics per ſe* would at any point of time, is that capital diſcovery of the late Mr. Gray; which is to be regarded as the baſis upon which all the preſent improvements of our knowledge in *electricity* are founded.

33. By comparing the reſpective velocities of *electricity* and ſound, that of *electricity*, in any diſtance yet experienced, appears inſtantaneous.

For the detail of theſe curious experiments, and of ſeveral others, we muſt refer to Mr. Watſon's experiments and obſervations, tending to illuſtrate the nature and properties of *electricity*, Lond. 1745; and the ſequel to the experiments, *&c.* Lond. 1746; as alſo to his account of the experiments made by ſome gentlemen of the Royal Society, Lond. 1748.

34. Mr. Franklin of Philadelphia, in his experiments and obſervations on *electricity*, has obſerved, that granulated lead is better than water for filling the phial or glaſs jar to be *electrified*; and he has been able to excite the *electrical* force to ſuch a degree, as not only to fire gunpowder [a], and to kill a turkey of ten pound weight [b], but to produce a fuſion of metals [c].—[[a] Phil. Tranſ. Vol. XLVII. p. 291. [b] Ibid. p. 209. [c] Ibid. p. 290.]

This ingenious author's method of firing gunpowder by the *electric* flame has ſomething particular, as it does not require any inflammable vapour to be previouſly raiſed. The powder may be fired thus: a ſmall cartridge is filled with dry powder, hard rammed, ſo as to bruiſe ſome of the grains. Two pointed wires are then thruſt in, one at each end, the points approaching each other in the middle of the cartridge, till within the diſtance of half an inch: then the cartridge being placed in the circle, when four *electrified* glaſs jars are diſcharged, the *electric* flame leaping from the point of one wire to the point of the other, within the cartridge among the powder, fires it, and the exploſion of the powder is at the ſame inſtant with the crack of the *electrical* diſcharge.

35. As to metals, this gentleman obſerves, that he has been able by *electricity* frequently to give polarity to needles, and to reverſe it. A ſhock from four large glaſs jars ſent thro' a fine ſewing needle, gives it polarity; and it will traverſe, when laid on water. The polarity is given ſtrongeſt, when the needle is ſtruck lying north and ſouth; and weakeſt, when lying eaſt and weſt. In this caſe, the end entred by the *electric* blaſt points north: but when the needle lies north and ſouth, the end that lies towards the north will continue to point north, whether the fire entred at that end, or the contrary end.

36. In theſe experiments, the ends of the needles are ſometimes finely blued, like a watch-ſpring, by the *electric* flame. This colour, given by the flaſh from two glaſs jars only, will wipe off; but four will fix it, and frequently melt the needles. Sometimes the ſurface on the body of the needles is alſo run, and appears bliſtered, when examined by a magnifying glaſs. The jars Mr. Franklin made uſe of hold ſeven or eight gallons, and are coated and lined with tin-foil. Each of them takes a thouſand turns of a globe of nine inches diameter to charge it. Tin-foil has been melted between glaſs by the force of two jars only. Phil. Tranſ. loc. cit.

37. The effects of lightning and thoſe of *electricity* appear very ſimilar. Lightning has been known to ſtrike people blind, the *electrical* ſhock has had the ſame effect on animals. Animals have been killed by both. The mariners compaſs has ſometimes loſt its virtue by lightning; and by Mr. Franklin's experiments it appears, that polarity may be given and reverſed by *electricity*. The late Mr. Stephen Gray obſerved ſeveral years ago [d], that the *electric* fire ſeemed to be of the ſame nature with that of thunder and lightning. Others have ſince fallen into the ſame opinion. Indeed many experiments ſhew, that the flame of *electricity* has been juſtly called by Mr. Franklin a mimic lightning [e], ſince it blinds and kills animals, and melts metals, *&c.*

like natural lightning.—[d Phil. Tranſ. Vol. cit. p. 536. e Ibid. p. 290.]

38. This analogy is now farther confirmed by the diſcovery made in France, in conſequence of Mr. Franklin's hypotheſis, of being able, by a proper apparatus, to collect the *electricity* from the atmoſphere during a thunder ſtorm. For a pointed bar of iron, 40 feet high, having been placed upon an *electrical* body, and a ſtormy cloud having paſſed over the place where the bar ſtood, thoſe that were appointed to obſerve it drew near, and attracted from it ſparks of fire, perceiving the ſame kind of commotions as in the common *electrical* experiments. The like effect followed, when a bar of iron 99 feet high was placed upon a cake of reſin, two feet ſquare and two inches thick. For a ſtormy cloud having paſſed over the bar, where it remained half an hour, ſparks were drawn from the bar. Theſe were the firſt experiments made in France, and they have been ſufficiently varied and verified ſince; ſo that it ſeems now certain, 1°. that a bar of iron, pointed or not, is *electriſed* during a ſtorm. 2°. That a vertical or horizontal ſituation is equally fitting for theſe experiments. 3°. That even wood is *electriſed*. 4°. That by theſe means a man may be ſufficiently *electriſed* to ſet fire to ſpirit of wine with his finger, and repeat almoſt all the uſual experiments of artificial *electricity*; for ſuch may that which is excited by friction be denominated.

It is, however, to be remarked, that theſe phænomena are attended with irregularities, and do not always ſucceed perfectly. Sometimes ſimple clouds, without thunder or lightning, produce more *electricity*, than when there is loud thunder. Sometimes the *electricity* does not ſhew itſelf but where there is lightning: in other caſes, the *electricity* which ſeemed diſſipated during the rain, began again as ſoon as the rain ceaſed, altho' the thunder was very diſtant. See the Phil. Tranſ. Vol. XLVII. p. 534, ſeq.

39. Mr. Franklin has contrived a very ingenious and eaſy way of trying experiments of this kind by means of an *electrical* kite, made of a large thin ſilk handkerchief, extended and faſtened at the four corners to two ſlight ſtrips of cedar, of ſufficient length for this purpoſe. This kite being accommodated with a tail, loop, and ſtring, will riſe in the air like thoſe of paper. To the top of the upright ſtick of the croſs is to be fixed a very ſharp-pointed wire, riſing a foot or more above the wood. To the end of the twine, next the hand, is to be tied a ſilk ribband; and where the twine and ſilk join, a key may be faſtened. The kite is to be raiſed when a thunder guſt appears to be coming on, and as ſoon as the thunder-clouds come over the kite, the pointed wire will draw the *electric* fire from them, and the kite with all the twine will be *electrified*; and the looſe filaments of the twine will ſtand out every way, and be attracted by an approaching finger. When the rain has wet the kite and twine, ſo that it can conduct the *electric* fire freely, it will ſtream out plentifully from the key, on the approach of a man's knuckle. At this key the phial may be charged; and from *electric* fire thus obtained ſpirits may be kindled, and all the other *electrical* experiments be performed, which are uſually done by the help of a rubbed glaſs globe or tube, and the ſameneſs of the *electric* matter with that of lightning may thereby be completely demonſtrated. Phil. Tranſ. Vol. cit. p. 565, ſeq.

From this identity, ſome have conceived hopes of depriving the clouds of all their thunder, and thereby rendering thunder ſtorms harmleſs. See Philoſ. Tranſ. Vol. cit. p. 289, 535.

40. It has been pretended, that odours would pervade *electrified* globes and tubes of glaſs, and that the medicinal effects of drugs might likewiſe be tranſmitted this way; as alſo, that if perſons were to hold in their hands, or place under their naked feet, odoriferous, or purging ſubſtances, and were then to be *electriſed*, they would be ſenſible of the effects of theſe ſubſtances. But it ſeems now certain, that all theſe pretences have been impoſitions on the credulity of the world, and that when proper experiments have been tried, no ſuch effects have been perceived, nor have the moſt poiſonous ſubſtances manifeſted any influence in this way. See Dr. Bianchini's experiment, mentioned in the Philoſ. Tranſ. Vol. XLVII. p. 399, ſeq.

41. However, though theſe pretended wonders, tranſmitted to the reſt of Europe from Italy and Leipſic [f], have no foundation in fact, yet it does not follow, that medicinal advantages are not to be gained from *electricity* itſelf. So ſubtle and ſo elaſtic a fluid admitted in a large quantity into our bodies, as, from undoubted experience, it greatly heats the fleſh, and quickens the pulſe, may, more eſpecially when aſſiſted with the expectation of ſucceſs in the patient, in particular caſes be attended with very great advantages [g]. —[f Phil. Tranſ. Vol. cit. p. 231, ſeq. g Mr. Watſon in Phil. Tranſ. Vol. cit. p. 406.]

In effect, we meet with ſome cures performed in paralytic caſes by the force of *electricity*. See Hiſtoire generale et particuliere de l'*Electrité*, Paris, 1752, part. 3. p. 36, ſeq. And we meet with accounts of ſeveral other diſorders cured by the ſame means, in that treatiſe; but we fear not all equally well atteſted.

42. The *electrical* virtue having, in ſome caſes, accelerated and facilitated the motion of liquids through capillary tubes, the Abbé Nollet was led to ſuppoſe, that the *electrical* effluvia might alſo contribute to accelerate the growth of vegetables, and to increaſe the perſpiration of animals, and the experiments made by that gentleman ſeem to ſupport his opinion; though objections have ariſen, as to what he has advanced with reſpect to the acceleration of the motion of fluids through capillary tubes or ſyphons: for Mr. Ellicott ſeems to have proved, that this acceleration is not barely owing to the fluids being *electrified*, but that other circumſtances are neceſſary, in order to produce this effect. Mr. Ellicott obſerves, that if a veſſel of water is hung to the prime conductor, having a ſyphon in it of ſo ſmall a bore that the water will be diſcharged from it only in drops, on the water's becoming *electrical* by means of the machine, it will immediately run in a ſtream, and continue to do ſo, till the water is all diſcharged, provided the ſphere is continued in motion. And the true reaſon of the water's running in a ſtream in this caſe ſeems to be, that ſo long as the machine is in motion, there is a conſtant ſucceſſion of the *electric* effluvia excited, which viſibly run off from the end of the prime conductor in a ſtream; and as they are in like manner carried off from all bodies hung to it, thoſe effluvia which run off from the end of the ſyphon, being ſtrongly attracted by the water, carry ſo much of it along with them, as to make it run in a conſtant ſtream. See Mr. *Ellicott*'s Eſſays before mentioned, p. 11, 12, *&c.*

The ſame author obſerves farther, that if the veſſel of water, with the ſyphon in it, is ſuſpended by any *non-electric* body over another ſtrongly *electrified*, the water will immediately run from the ſyphon in a ſtream; but if ſupported by a piece of ſilk, or any other *electrical* body, the water will immediately ceaſe running, and only be diſcharged in drops. And he accounts for this phænomenon from the principles of attraction between *non-electrics* and *electrical* effluvia, and of non-attraction between the ſame effluvia and original *electrics*. See page 15 of the Eſſays before cited.

43. Mr. Watſon has given us a particular account of ſeveral curious phænomena of *electricity* in vacuo in the Philoſophical Tranſactions, Vol. XLVII. p. 362, ſeq. The *electrical* effluvia, in their paſſage through an exhauſted glaſs tube, of almoſt three inches in diameter, afford a moſt agreeable ſpectacle in a darkened room. We may obſerve, not as in the open air, bruſhes or pencils of rays an inch or two in length, but coruſcations extending the whole length of the tube, that is, in his experiment, thirty-two inches, and of a bright ſilver hue. Theſe did not immediately diverge, as in the open air, but frequently, from a baſe apparently flat, divided themſelves into leſs and leſs ramifications, and reſembled very much the moſt lively coruſcations of the aurora borealis. At other times, when the tube has been exhauſted in the moſt perfect manner, the *electricity* has been ſeen to paſs between two braſs plates, contrived ſo, that they might be placed at different diſtances from each other, in one continued ſtream, of the ſame dimenſions throughout its whole length.

If the exhauſted tube be made part of the circuit before mentioned in Muſchenbroek's experiment, at the inſtant of exploſion, a maſs of very bright embodied fire may be ſeen jumping from one of the braſs plates in the tube to the other. But this is obſerved not to take place, when one of the plates is farther diſtant from the other than ten inches. If the diſtance be greater, the fire begins to diverge, and loſe part of its force; and this force diminiſhes in proportion to its divergency, which is nearly as the diſtance of the two plates.

But though the vacuum here employed greatly exceeded that which is uſually made by common air-pumps, yet it was far from being perfect. Theſe experiments were therefore tried with a torricellian vacuum, very ingeniouſly contrived by Lord Charles Cavendiſh. The apparatus conſiſted of a cylindrical glaſs tube of about three-tenths of an inch in diameter, and of ſeven feet and an half in length, bent in ſuch a manner, that thirty inches of each of its extremities were nearly ſtraight, and parallel to each other, from which an arch ſprung, which was likewiſe of thirty inches. This tube was carefully filled with mercury; and each of its extremities being put into its baſon of mercury, ſo much of the mercury ran out, until, as in the common barometrical tubes, it was in equilibrio with the atmoſphere. Each of the baſons containing the mercury was of wood, and was ſupported by a cylindrical glaſs of about four inches in diameter, and ſix inches in length; and theſe glaſſes were faſtened to the bottom of a ſquare wooden frame, ſo contrived, as that to its top was ſuſpended, by ſilk lines, the tube filled with mercury before mentioned; ſo that the whole of this apparatus, without inconvenience, might be moved together. The torricellian vacuum then occupied a ſpace of about thirty inches. In making the experiment, when the room was darkened, a wire from the prime conductor of the common *electrical* machine, communicated with one of the baſons of mercury, and any *non-electric* touching the other baſon, while the machine was in motion,

the *electricity* pervaded the vacuum in a continued arch of lambent flame, and as far as the eye could follow it, without the leaſt divergency.

It is to be obſerved, that upon admitting a very ſmall quantity of air into the exhauſted tube, the phænomena diſappear; not ſo much from the ſmall quantity of air admitted, as from the vapours which inſinuated themſelves therewith. For theſe phænomena have been viſible, though in a leſs perfect degree, when a much larger quantity of air was left in the receiver, by omitting to exhauſt it as much as poſſible.

If the *electrifying* machine, and the man who turns the wheel thereof, are ſupported by *electrics per ſe*; and if a piece of wire be connected with the braſs cap covering the upper extremity of the exhauſted tube, or to the end of the long braſs rod, by the ſliding of which through a box of oiled leather, the upper braſs plate may be moved in the tube; and if the other end of the wire be faſtened to any part of the frame of the *electrifying* machine, when this is put in motion, the *electrical* coruſcations may be ſeen to paſs, as before, from one of the braſs plates contained in the tube to the other, and to continue, unleſs the air inſinuates itſelf, as long as the machine is in motion. If, under theſe circumſtances, the hand of a perſon ſtanding on the floor is brought near the ſides of the glaſs, the coruſcations will direct themſelves that way in a great variety of curious forms.

This experiment, in which the *electricity* is ſeen puſhing itſelf on through the vacuum by its own elaſticity, is conſidered by Mr. Watſon as an *experimentum crucis* of the truth of his doctrine hereafter mentioned.

It may be obſerved in all theſe experiments, that a vacuum does not conduct *electricity* ſo perfectly as metals or water. For, in the laſt experiment, a perſon ſtanding upon the floor, and applying his finger to the upper braſs cap of the tube, receives a ſmart ſtroke; and in the former, ſnaps of fire may be drawn from the prime conductor. Theſe are arguments of ſome degree of accumulation, while the *electricity* is paſſing through the vacuum; ſince nothing of this kind happens when metals, ſtanding upon the ground, touch the prime conductor.

Such are the principal phænomena of *electricity* hitherto diſcovered; but the chief queſtion remains: What are the general laws of theſe phænomena, and what are their cauſes?

Mr. Ellicott thinks that the following concluſions, or general laws, may be juſtly deduced from the phænomena.

1°. That theſe remarkable phænomena are produced by means of effluvia; which, in exciting the *electrical* body, are put into motion, and ſeparated from it.

2°. That the particles compoſing theſe effluvia ſtrongly repel each other.

3°. That there is a mutual attraction between theſe particles and all other bodies whatſoever.

That there are effluvia emitted from the tube when rubbed, and which ſurround it as an atmoſphere, is evident from that offenſive ſmell ariſing from them, from that ſenſation on the hands or face, when the tube is brought near either of them, and from thoſe ſparks of light, on a ſtill nearer approach of the finger to it.

That the particles of theſe effluvia repel each other, is proved by the cork balls, and the fibres of the feather repelling each other, when impregnated with them; and by the leaf-gold being repelled by the tube, and not returning to it again, until by coming near, or touching ſome *non-electric* body, the effluvia are drawn off from it. From this property it is, that theſe effluvia expand themſelves with ſo great a velocity whenever they are ſeparated from the *electric* body; and as they are likewiſe capable of being greatly condenſed, may we not from hence juſtly conclude they are *elaſtic*?

That there is a mutual attraction between theſe effluvia and moſt other bodies, appears from their collecting from the tube ſuch quantities thereof, as to endue them with the ſame properties with the tube itſelf, as is proved from ſeveral of the experiments above mentioned.

Theſe principles being admitted, it will follow, that the greater difference there is in the quantity of *electrical* effluvia in any two bodies, the ſtronger will be their attraction. For, if the effluvia in each are equal, inſtead of attracting, they will repel each other; and in proportion as the quantity of *electric* matter is drawn from one of the bodies, will the attraction between them increaſe, and conſequently be ſtrongeſt, when any one of them has all the *electrical* matter drawn from it.

The particles of theſe effluvia are ſo exceeding ſmall, as eaſily to pervade the pores of glaſs, as is evident, in that a feather, or any light bodies incloſed in a glaſs ball hermetically ſealed, will be put in motion on the excited tube being brought near the outſide of it: and it has been generally thought that they paſs thro' the pores of the denſeſt bodies, and ſeveral experiments render this ſuppoſition not improbable, tho' none of them are quite concluſive.

Mr. Ellicott then proceeds to ſhew, in a very ingenious manner, how, from theſe principles, the phænomena of ſome of the more remarkable experiments of *electricity* may be accounted for. But as what he ſays cannot, with juſtice to his reaſonings, be abridged, we muſt refer the curious to his eſſays before quoted; only adding, that we have ſeen a manuſcript of his, where he endeavours to account for the experiment of Muſchenbroek on theſe principles, in a manner that makes us wiſh to ſee the reſt of his experiments, obſervations, and reaſonings on this ſubject publiſhed.

Mr. Watſon has endeavoured to prove, that *electricity* is not furniſhed from the glaſſes employed in the experiments, nor from the circumambient air. He thinks that *electricity* is the effect of a very ſubtile and elaſtic fluid, occupying all bodies in contact with the terraqueous globe, and that every where in its natural ſtate it is of the ſame degree of denſity; and that glaſs, and other bodies, which are called *electrics per ſe*, have the power of taking this fluid from one body, and conveying it to another, in a quantity ſufficient to be obvious to all our ſenſes; and that under certain circumſtances, it is poſſible to render the *electricity* in ſome bodies more rare than it naturally is, and, by communicating this to other bodies, to give them an additional quantity, and make their *electricity* more denſe; and that theſe bodies will thus continue until their natural quantity is reſtored to each; that is, by thoſe which have loſt part of theirs, acquiring what they have loſt, and by thoſe, to which more has been communicated, parting with their additional quantity. Both one and the other of theſe is, from the elaſticity of the *electric* matter, attempted to be done from the neareſt *non-electric*; and when the air is moiſt, this is ſoon accompliſhed by the circumambient vapours, which here may be conſidered as preventing, in a very great degree, our attempts to inſulate *non-electric* bodies.

This ſhort ſketch of Mr. Watſon's ſyſtem is taken from his own words in the Philoſophical Tranſactions, Vol. XLVII. p. 371, 372. For the detail of his illuſtrations and proofs, his treatiſe before quoted, or the Phil. Tranſact. Vol. XLIV and XLV, muſt be conſulted, and particularly Vol. XLVII, p. 372, & ſeq. where, after giving the *experimentum crucis* before mentioned, he endeavours to ſhew that it amounts to a full proof of the truth of his doctrine, that *electricity* is furniſhed by thoſe bodies, hitherto called *non-electrics*, and not by the *electrics per ſe*; and that we are able to add to, or take from, that quantity of *electricity* naturally adherent to bodies.

Mr. Watſon's ſyſtem naturally leads him to aſk, by what denomination ſhall we call this extraordinary power? From its effects in theſe operations ſhall we call it *electricity*? From its being a principle neither generated nor deſtroyed; from its being every where and always preſent, and in readineſs to ſhew itſelf in its effects, tho' latent and unobſerved, till by ſome proceſs it is produced into action, and rendered viſible; from its penetrating the denſeſt and hardeſt bodies, and its uniting itſelf to them; and from its immenſe velocity; ſhall we, with Theophraſtus, Boerhaave, Niewentiit, 'sGraveſande, and other philoſophers, call it elementary fire? Or ſhall we, from its containing the ſubſtance of light and fire, and from the extreme ſmallneſs of its parts, as paſſing thro' moſt bodies we are acquainted with, denominate it, with Homberg and the chemiſts, the chemical ſulphureous principle, which, according to the doctrines of theſe gentlemen, is univerſally diſſeminated? Whatever we call it, it ſeems certain, that this power has many ſurpriſing properties, and cannot but be of great moment in the ſyſtem of the univerſe.

To conclude, we muſt obſerve that the ingenious Mr. Wilſon has, in a treatiſe expreſs, endeavoured to account for the phænomena of *electricity*, from Sir Iſaac Newton's æther.

As to other hypotheſes, we refer to the *Hiſtoire generale et particuliere de l'Electricité* before mentioned.

SOUND (*Suppl.*)—The ſpace through which *ſound* is propagated in a given time, has been very differently eſtimated by authors who have written concerning this ſubject. Roberval gives it at the rate of 560 feet in a ſecond; Gaſſendus, at 1473; Merſenne, at 1474; Du Hamel, in the Hiſtory of the Academy of Sciences at Paris, at 1172; the Academy del Cimento, at 1185; Boyle, at 1200; Roberts, at 1300; Walker, at 1338; Sir Iſaac Newton, at 968; Dr. Derham, in whoſe meaſure Mr. Flamſteed and Dr. Halley acquieſced, at 1142. But by the accounts ſince publiſhed by M. Caſſini de Thury, in the Memoirs of the Royal Academy of Sciences at Paris for the year 1738, where cannon were fired at various, as well as great diſtances, under great variety of weather, wind, and other circumſtances, and where the meaſures of the different places had been ſettled with the utmoſt exactneſs, *ſound* was propagated at a medium at the rate only of 1038 French feet in a ſecond. The French foot exceeds the Engliſh by nearly ſeven lines and a half, or is as 107 to 114: And conſequently, 1038 French feet are equal to 1106 Engliſh feet. The difference therefore

of

of the meaſures of Mr. Derham and M. Caſſini is 34 French, or 36 Engliſh feet in a ſecond. According to this laſt meaſure, the velocity of *ſound*, when the wind is ſtill, is ſettled at the rate of a mile, or 5280 Engliſh feet, in $4\frac{77}{100}''$.

UNDULATION, or BEAT, in muſic, is uſed for that rattling, or jarring of ſounds, which is obſerved, chiefly, when diſcordant notes are ſounded together.

The phænomenon is more fully deſcribed thus, by Dr. Smith[a]: In tuning muſical inſtruments, eſpecially organs, it is a known thing, that while a conſonance is imperfect, it is not ſmooth and uniform, as when perfect, but interrupted with very ſenſible *undulations* or *beats*; which, while the two ſounds continue at the ſame pitch, ſucceed one another in equal times, and in longer and longer times, while either of the ſounds approaches gradually to a perfect conſonance with the other, till at laſt the *undulations* vaniſh, and leave a ſmooth, uniform conſonance.—[a Harmonics, p. 107.]

This learned author obſerves farther, that quicker *undulations* are *beats*, and are remarkably diſagreeable in a concert of ſtrong, treble voices, when ſome of them are out of tune; or in a ring of bells ill tuned, the hearer being near the ſteeple; or in a full organ badly tuned. Nor can the beſt tuning wholly prevent that diſagreeable battering of the ears with a conſtant rattling noiſe of *beats*, quite different from all muſical ſounds, and deſtructive of them, and chiefly cauſed by the compound ſtops called the cornet and ſeſquialter, and by all other loud ſtops of a high pitch, when mixed with the reſt. But if we be content with compoſitions of uniſons and octaves to the diapaſon, whatever be the quality of their ſounds, the beſt manner of tuning will render the noiſe of their *beats* inoffenſive, if not imperceptible.

The Doctor has with great ingenuity deduced the theory of theſe *undulations* from his principles, and has applied his doctrine to the tuning of inſtruments; by which he has ſhewn, that a perſon of no ear at all for muſic may ſoon learn to tune an organ, according to any propoſed temperament of the ſcale, and to any deſired degree of exactneſs, far beyond what the fineſt ear, unaſſiſted by theory, can poſſibly attain to. This may be done by counting the number of *undulations* in a certain time, ſuch as 15 ſeconds. See the treatiſe before cited, Prop. xx. p. 215. and the table, p. 244. Plate 20.

From this ingenious theory the learned author has demonſtrated ſeveral errors in what Monſieur Sauveur has delivered concerning theſe *undulations* or *beats*. See Harmonics, Scholium 2. p. 115.

In the ſame treatiſe we find ſome curious obſervations relating to the analogy of audible and viſible *undulations*. See p. 128, 273.

FINIS.

A General Table of Fossils.

Clafs. 1. *Native Fossils*

Talcs

Specularis — Hyalina — Bracteatum

Fibrariæ

Elasmis — Tricheria — Lachnis — Asbestus — Amianthus

Clafs. 2. *Selenitæ*

Leptodecarhombis — Pachodecarhombis — Tetradecarhombis — Tschnambluris — Isambluris — Sanidium — Symplexium — Oxeucia — Inoxucia — Cathetolipes — Trichestrum — Lepastrum

Clafs. 3. *Crystals*

Macroteloscylum — Pauradrastylum — Brachyteloscylum — Polyedra-stylum — Elipsoma-crosty-lum — Elipopa-chystylum — Oligadrum — Pangonium — Arthrodia — Siderion — Cassiterion — Molybdion

Clafs. 4. *Siderochitæ*

Empherepyra — Heteropyra — Heteropyra — Geodes — Geodes — Enhydros

Clafs. 5. *Pyritæ*

Pyriplacis — Gymnopyris — Pyrituchum — Pyritrichiphyllum — Pyritrichiphyllum — Pyriculum — Pyroctogonia — Pyripolyzonium

Clafs. 6. *Extraneous Fossils*

Plants in Stone

American Fern in Stone — Horsetail in Stone — Stellate Plant on Stone — Stellate Plant on Stone — Ear of Corn in Stone — Leaves of Trees in Stone — Mosses in Stone

Clafs. 7. *Corals*

Porpitæ — Mycetitæ — Porus in Marble — Columna Trabius Petrifactus — Tubularia — Astroites — Astroites — Astroites — Astroites — Junci Lapidei — Corallium Album fossile — Lithostrotion

3 Subbuteo, The Hobby.

4 The Caracara.

5 Lanius cinereus major, The greater Butcher Bird.

6 Magnocodiata, The bird of paradise.

7 The Horn Owl.

8 Coracias, The Cornish Chough.

9 Corvus Aquaticus, The Cormorant.

10 Garrulus Argentoratensis, The Roller.

11 Pica Brasiliensis, The Toucan.

12 Picus varius major, The great spotted Woodpecker.

13 Jynx Sive Torquilla, The Wryneck.

14 The Aracari.

15 Certhia, The Oxeye. Creeper.

16 Ficedula, Cannabina.

17 Merops, The Bee-Eater.

18 Ispida, The Kingfisher.

19 Struthiocamelus, The Ostrich.

20 Emeu, The Cassowary.

21 The Pintado.

22 The Dodo.

23 The Rothbeinlin.

24 Mituporanga.

25 Urogallus Sive Tetrao major, The great Cock of the Mountain.

26 Urogallus Minor, The Grous.

27 Palumbes torquatus, The Ring-Dove.

28 Otis, The Bustard.

29 Passer Solitarius, The Solitary Sparrow.

30 Merula Torquata The Ring-Ouzell.

31 Atinga.

32 Hortulanus.

33 Ananthe, The White-tail.

34 Guainumbi, The Humming Bird.

35 Luscinia, The Nightingale.

36 Loxia, The Crossbill.

37 Serinus.

38 Passer Indicus, The long-tailed Indian Sparrow.

39 Jaberu-Guacu.

40 The Demoiselle, or dancing Bird.

41 Grus Balearica.

42 Platea, The Spoonbill.

43 Himantopus.

44 The Tamatia.

45 Charadrius, The Sea-Lark.

46 Phœnicopterus, The Flamingo.

47 Columbus cristatus, The great Diver.

48 The Penguin.

49 Brenta, The Brent-Goose.

50 Clangula, The Golden-Eye.

51 Anas niger major, The great Black Duck.

52 Tropicorum Avis, The Tropick-Bird.

J. Mynde sc.

THE MOST SCARCE and REMARKABLE FISHES

1 The Narwal, or Sea-Unicorn.

2 Zygæna, The hammer-headed-Shark.

3 Canis Carcharias, The Shark.

4 Galeus glaucus, The Blue Shark.

5 Pristis sive Serra Clusij, The Saw-Fish.

6 Pastinaca Marina.

7 Squatina, The Monk-fish.

8 Rana Piscatrix, The Frog-Fish.

9 Guaperva, The Toad-Fish.

10 Rhombus aculeatus.

11 Conger, The Sea-Eel.

12 Serpens marinus, The Sea-Snake.

13 Lampetra.

14 Remora, The Sucking-Fish.

15 The Sand-Creeper, or Dwarf.

16 Blennus, The Butterfly-Fish.

17 The Dracunculus, or Exocætus of Bellonius.

18 Orbis, The Moon-Fish.

19 Aper, The Strival, or Riondo.

20 Histrix Piscis, The Porcupine-fish.

21 Guamajacu-Atinga.

22 The Capriscus, or Pesce-Balester.

23 Guaperva longa.

24 Xiphias, The Sword-fish.

25 Acus, The Tobacco-Pipe-Fish.

26 Hippocampus, or Sea-Horse.

27 Mola Salvij, The Sun-Fish.

28 The Ling, or Asellus longus.

29 Thynnus, The Tunny-Fish.

30 The Pogge, or Cataphractus.

31 Thymallus, The Grayling.

32 Lumpus, The Lump-Fish.

33 Gobius Marinus, The Sea-Gudgeon.

34 Tamoata, or The Soldado.

35 The Guaracapema.

36 Monoceros piscis, The Perch-Unicorn-fish.

37 The Sea-Bat.

38 Sphyræna.

39 Clupea, A Shad.

40 Petimbuaba.

41 Milvus Piscis, The flying-Fish.

42 Huso Danubij.

43 Orfus.

44 Studis.

45 Lyra, The Piper.

46 Cuculus, The Rochet, or Red-Gurnard.

47 Lucerna.

48 Uranoscopus, The Star-gazer.

49 Nigui, The Pieterman.

50 Faber, The Doree-fish.

51 Abacatuaia, or The Picxe-Gallo.

52 Pesce Corvo.

53 Auguiuguacu, or Jacob Evertsen.

54 Sargus, The Sargoe.

55 Salpa, The Sarpoe.

56 Boops, The Boga.

57 Corcovada.

58 Brama marina cauda Forcipata, The Sea-Bream.

59 Pavo The Peacock-fish.

60 The Parrot-Beck, or Pudiano Verde.

61 Scorpius, The Sea-Scorpion.

62 Xanthurus.

63 Orbis muricatus, The Prickly Orb-fish.

64 The Bont-Fish.

65 Diabolus marinus, The Sea-Devil.

66 Piscis cornutus, The Horn'd-Fish.

67 Aquila marina, The Sea-Eagle.

68 Piscis Triangularis, The Triangular Fish.
